Technical and Bibliographic Notes/Notes techniques et bibliographiques

The Institute has attempted to obtain the best original copy available for filming. Features of this copy which may be bibliographically unique, which may alter any of the images in the reproduction, or which may significantly change the usual method of filming, are checked below.

L'Institut a microfilmé le meilleur exemplaire qu'il lui a été possible de se procurer. Les détails de cet exemplaire qui sont peut-être uniques du point de vue bibliographique, qui peuvent modifier une image reproduite, ou qui peuvent exiger une modification dans la méthode normale de filmage sont indiqués ci-dessous.

- [ ] Coloured covers/ Couverture de couleur
- [ ] Covers damaged/ Couverture endommagée
- [ ] Covers restored and/or laminated/ Couverture restaurée et/ou pelliculée
- [ ] Cover title missing/ Le titre de couverture manque
- [ ] Coloured maps/ Cartes géographiques en couleur
- [ ] Coloured ink (i.e. other than blue or black)/ Encre de couleur (i.e. autre que bleue ou noire)
- [ ] Coloured plates and/or illustrations/ Planches et/ou illustrations en couleur
- [ ] Bound with other material/ Relié avec d'autres documents
- [ ] Tight binding may cause shadows or distortion along interior margin/ La reliure serrée peut causer de l'ombre ou de la distortion le long de la marge intérieure
- [ ] Blank leaves added during restoration may appear within the text. Whenever possible, these have been omitted from filming/ Il se peut que certaines pages blanches ajoutées lors d'une restauration apparaissent dans le texte, mais, lorsque cela était possible, ces pages n'ont pas été filmées.
- [ ] Additional comments:/ Commentaires supplémentaires:

- [ ] Coloured pages/ Pages de couleur
- [ ] Pages damaged/ Pages endommagées
- [ ] Pages restored and/or laminated/ Pages restaurées et/ou pelliculées
- [x] Pages discoloured, stained or foxed/ Pages décolorées, tachetées ou piquées
- [ ] Pages detached/ Pages détachées
- [x] Showthrough/ Transparence
- [ ] Quality of print varies/ Qualité inégale de l'impression
- [ ] Includes supplementary material/ Comprend du matériel supplémentaire
- [ ] Only edition available/ Seule édition disponible
- [ ] Pages wholly or partially obscured by errata slips, tissues, etc., have been refilmed to ensure the best possible image/ Les pages totalement ou partiellement obscurcies par un feuillet d'errata, une pelure, etc., ont été filmées à nouveau de façon à obtenir la meilleure image possible.

This item is filmed at the reduction ratio checked below/
Ce document est filmé au taux de réduction indiqué ci-dessous.

10X 12X 14X 16X 18X 20X 22X 24X 26X 28X 30X ✓ 32X

The copy filmed here has been reproduced thanks to the generosity of:

University of British Columbia Library

The images appearing here are the best quality possible considering the condition and legibility of the original copy and in keeping with the filming contract specifications.

Original copies in printed paper covers are filmed beginning with the front cover and ending on the last page with a printed or illustrated impression, or the back cover when appropriate. All other original copies are filmed beginning on the first page with a printed or illustrated impression, and ending on the last page with a printed or illustrated impression.

The last recorded frame on each microfiche shall contain the symbol —► (meaning "CONTINUED"), or the symbol ▼ (meaning "END"), whichever applies.

Maps, plates, charts, etc., may be filmed at different reduction ratios. Those too large to be entirely included in one exposure are filmed beginning in the upper left hand corner, left to right and top to bottom, as many frames as required. The following diagrams illustrate the method:

L'exemplaire filmé fut reproduit grâce à la générosité de:

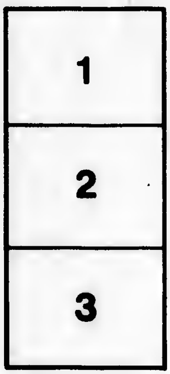
University of British Columbia Library

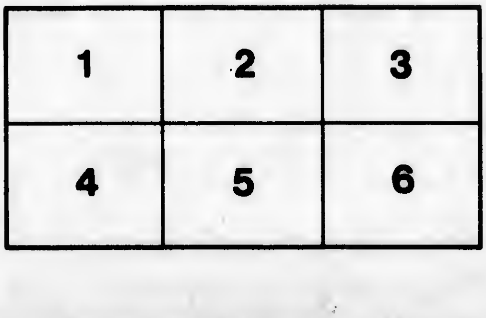
Les images suivantes ont été reproduites avec le plus grand soin, compte tenu de la condition et de la netteté de l'exemplaire filmé, et en conformité avec les conditions du contrat de filmage.

Les exemplaires originaux dont la couverture en papier est imprimée sont filmés en commençant par le premier plat et en terminant soit par la dernière page qui comporte une empreinte d'impression ou d'illustration, soit par le second plat, selon le cas. Tous les autres exemplaires originaux sont filmés en commençant par la première page qui comporte une empreinte d'impression ou d'illustration et en terminant par la dernière page qui comporte une telle empreinte.

Un des symboles suivants apparaîtra sur la dernière image de chaque microfiche, selon le cas: le symbole —► signifie "A SUIVRE", le symbole ▼ signifie "FIN".

Les cartes, planches, tableaux, etc., peuvent être filmés à des taux de réduction différents. Lorsque le document est trop grand pour être reproduit en un seul cliché, il est filmé à partir de l'angle supérieur gauche, de gauche à droite, et de haut en bas, en prenant le nombre d'images nécessaire. Les diagrammes suivants illustrent la méthode.





CHAMBERS'S

INFORMATION FOR THE PEOPLE.

CONDUCTED BY WILLIAM AND ROBERT CHAMBERS, EDITORS OF "CHAMBERS'S JOURNAL" AND "HISTORICAL NEWSPAPER."

INTRODUCTORY ARTICLE.

AN ACCOUNT OF THE EARTH—PHYSICAL AND POLITICAL.

No species of information can form so appropriate an introduction to general knowledge as that which describes the earth we inhabit: its dimensions and physical character, its relation to other planetary bodies, and its political divisions into states, empires, and kingdoms.* Until comparatively recent times, the earth was generally believed to be a large flat body floating upon or fixed in the ocean, on the remote boundaries of which the firmament rested, or was unaccountably lost in the waters. The sun, which gives us light, was at the same time considered to be a body which moved round the earth, rising every morning and setting every evening; but where it went to during the night, or how it got back from west to east, could not be explained. While these opinions prevailed, the earth was believed to remain always at rest; and it was a general opinion that no navigator dared or would be able to sail to any great distance on the ocean, for that he would either soon be enveloped in darkness, or, with his vessel, fall over the uttermost bounds of the waters, and be for ever lost.

The Egyptians studied the starry heavens, and the Grecian sages reasoned on the nature and figure of the earth; but none of them propounded a theory which has been found on investigation to be correct. The idea of the earth being a globe, bearing an affinity in character to the moon and the other planets; of being only one among perhaps millions of worlds floating in space, all under the guidance of certain laws organised by one universal Creator, was in a certain degree entertained by Ptolemy, the ancient geographer; but it is to modern science alone that we are indebted for this splendid discovery of the true planetary system. The proper theory of the earth was first made known by Copernicus and Galileo, betwixt the years 1500 and 1600, and afterwards improved and determined by Sir Isaac Newton.

According to the discoveries of these and other eminent men, as well as the experimental voyages round the globe performed by Cook and other navigators, it has been clearly proved that the earth is a sphere, or nearly round ball, in its figure. The cause of this sphericity is very evident, if we consider the earth to have been originally a yielding mass, capable of assuming any form; then, by the force of gravity, every particle contained in it tending towards the common centre, by which the globular form is produced as a necessary consequence. It has been imagined by superficial thinkers, that, if the earth were a sphere, and inhabited on all sides, those who were *undermost* in its diurnal revolution would fall from its surface. But this idea, which is quite natural, is completely answered by an explanation of the tendency which all bodies have to its centre. Properly speaking, there is neither *down* nor *up*, neither *under* nor *above*. The earth is not, however, an exact sphere, but is flattened at the northern and southern extremities, or poles. Philosophers were first led to observe this by the variation in the vibrations of the pendulum at the equator, or middle of the earth, and near the poles. It was found that the pendulum performed its vibrations slower the nearer it approached the equator, and hence was inferred the reasonableness of the force of gravity. This was easily explained in the theory just mentioned, because, the circle of daily revolution being greatest at the equator, all bodies revolve proportionally faster there than at the poles, so that the centrifugal force is greater, and the force of gravity less, than at other parts of the earth's surface; and because, at the equator, the centrifugal force is exactly opposed to that of gravity, but towards the poles, being oblique to it, produces less effect. From these observations it was justly inferred that the earth is a sphere flattened at the poles, or a spheroid; and this form was satisfactorily accounted for by the fact that the particles of a yielding mass, which revolves on its own axis, depart from the poles and tend to the centre, by which the poles are of course flattened, and the middle elevated. Various measurements have put this beyond all doubt.

Another important desideratum for a more intimate acquaintance with the earth, was to fix its magnitude. The labours of the ancients, in this respect, were all fruitless, owing to their want of suitable instruments. Accurate results were first obtained in the year 1615. Willibrord Snellius, a Dutchman, first struck into the only true way, and measured an arc of a meridian from Alcmaar to Leyden and Bergen-op-Zoom, by means of triangles. After him, the measurements of Picard, and the later ones of Maupertuis, approximated nearer the truth. These made the circumference of a great circle of the earth 25,000 miles. But it is to be remarked, that in this calculation the earth is regarded as a perfect sphere. Further measurements of all parts of the surface of the earth will be necessary to find, rigidly and accurately, the true magnitude of it.

If we take a view of our earth in its relation to the solar system, astronomy teaches us, that, contrary to appearances, which make the sun revolve about the earth, the earth and ten other primary planets revolve about the sun, and, being themselves opaque bodies, receive from the sun light and heat. The earth completes its revolution round the sun in about three hundred and sixty-five days and six hours, which forms our common year. The orbit of the earth is an ellipse, with the sun in one of its foci. Hence the earth is not equally distant from the sun in all parts of the year: its least distance is estimated at 93,336,000 miles, and its greatest at 95,484,572, making a difference of more than 2,000,000 of miles. In winter, we are nearest the sun, and in summer, farthest from it; for the difference in the seasons is not occasioned by the greater or less distance of the earth from the sun, but by the more or less oblique direction of the sun's rays. Besides the annual motion about the sun, the earth has also a daily motion about its own axis (according to mean time, in twenty-three hours, fifty-six minutes, and four seconds). This diurnal revolution is the occasion of the alternation of day and night. But as the axis on which the earth performs its diurnal rotation forms, with its path about the sun, an angle of twenty-three and a half degrees, the sun ascends, from March 21 to June 21, about twenty-three and a half degrees above the equator towards the north pole, and descends again towards the equator from June 21 to September 23; it then sinks till December 21, about twenty-three and a half degrees below the equator towards the south pole, and returns again to the equator by March 21. This arrangement is the cause of the seasons, and the inequality of day and night attending them, which, for all countries lying beyond the equator, are equal only twice in the year, when the ecliptic coincides with the equator. The moon, again, revolves about the earth, in a similar elliptical path, in twenty-eight days and fourteen hours. For a complete theory of the earth and heavenly bodies, we refer to the article ASTRONOMY.

MATHEMATICAL DIVISIONS OF THE EARTH

In order to facilitate the operations of the navigator and traveller, and with the view to mark the relative situation of every spot on the earth's surface, for a better understanding of geography, the globe has been made the object of divers measurements, by means of ideal lines drawn from north to south and east to west. The principal line which has thus been drawn, as will be perceived by an examination of maps of the earth, is the equator. It forms a circle round the earth, equally distant from the poles, and divides the globe into two equal parts, called the northern and southern hemispheres. From the equator to the north pole the earth is divided into ninety parts, by lines indicating degrees of latitude. From the equator to the north pole the same kind of division takes place into ninety degrees. Any place north of the equator is said to be situated in such a degree north latitude; and any part south of the equator is in the same way described as lying in such a degree south latitude. These degrees are composed of sections of sixty-nine and a half English miles each. When written, they are indicated by a small ° after the figures, as 22°, which means twenty-two degrees; and when odd miles over a degree have to be signified, it is done also by a small mark ′, as 12′, which means twelve miles or minutes. So much for the measurement of the earth north and south. In order to indicate spots eastward or westward on the surface of the earth, a similar division takes place. The globe is reckoned to contain one hundred and eighty parts, called degrees of longitude, measuring from one given spot to another. Most nations reckon from the capital city of their own country. The English reckon from the observatory at Greenwich. By a navigator or traveller ascertaining the degree of latitude and the degree of longitude of the spot on which he is placed, he can tell his relative situation on the earth's surface, and is enabled to proceed in the exact direction which will lead him to the place which he may desire to reach.

Besides being divided into degrees of latitude and longitude, the earth is sectioned into five zones or belts. A zone is a broad space included between certain degrees of latitude, and it takes its name from the peculiar heat or cold which prevails within its compass. The torrid zone, called so from its excessive heat, lies within twenty-three and a half degrees on each side of the equator. It is bounded on the north by an ideal line called the tropic of Cancer, and on the south by an equally ideal line called the tropic of Capricorn. That portion of the earth's surface between these distant circling lines is often familiarly said to be "within the tropics." Next to the north and south lie the two temperate zones, which similarly encompass the earth. It is within the northern temperate zone that Great Britain is situated. Next these, still farther north and south, lie the frigid zones—the cold regions—which extend round the poles to the distance of about twenty-three and a half degrees. The northern frigid zone is separated from the adjacent temperate zone by a line called the arctic polar circle; and the southern frigid zone in the southern hemisphere, is similarly bounded by the antarctic polar circle. The torrid zone is computed to contain 10,500,375 square miles; the two temperate zones 103,114,775; and the two frigid zones 79,328,600—altogether 196,943,750 square miles.

SURFACE OF THE EARTH AND OCEAN.

To the physical knowledge of the earth belongs especially the consideration of its surface and interior.

* This introductory article is chiefly confined to notices of those countries which are not treated separately in the body of the work, and is written more with the view of giving a familiar general illustration than a precise statistical account. It also comprehends many particulars which were not of sufficient volume or importance to form distinct treatises. The Editors embrace this opportunity of stating, that they have spared neither pains nor expense to make the present work complete and accurate in its details, so as to fit it for very general use among all classes of the community, particularly those who cannot encounter the expense of an encyclopædia. They have much pleasure in mentioning, that, in the course of its publication, they have derived very valuable assistance from Mr John Francis Smith, one of the individuals permanently engaged upon the new edition of the Encyclopædia Britannica. The articles furnished by this able young gentleman are "Astronomy," "Geological Account of the Globe," "Natural Philosophy," "Hydrostatics," "Pneumatics," "Optics," "Electricity," "Chemistry," "Chemistry applied to the Arts," &c.

The earth's surface contains, as is said, 196,943,750 square miles, of which scarcely a third part is dry land; the remaining two-thirds are water. The land is composed principally of two large masses or tracts, one of which comprehends the continents of Europe, Asia, and Africa; the other comprehends the continent of America. Australia, which lies in the ocean in a southerly direction from Asia, is so extensive as to be entitled to the name and character of a fifth division. All the detached and smaller masses of land, called islands, when taken together, are computed to contain as much land as the continent of Europe. In reference to maps of the earth, Europe, Asia, Africa, and Australia, with their islands, are distinguished as lying in the eastern hemisphere; while America, with the West Indian and other islands, are comprehended in the western hemisphere. The seas which encompass these extensive tracts of land have locally various names; but the two principal expanses of water are the Atlantic and Pacific Oceans—the former separating Europe, Asia, and Africa, from America on the west, and the latter lying betwixt the western shores of America and the eastern shores of Asia. The extensive oceans surrounding the north and south poles are called the Polar Seas, which have not been explored sufficiently for us to be able to say whether any large tracts of land lie in these remote quarters of the globe. Great diversity of opinion prevails with respect to the depth of the ocean. By numerous investigations, it does not appear that the depth is any where much more than two or three miles, generally it is a great deal less; and it might be argued, that, notwithstanding the large surface of the ocean, the body of its waters can only be considered as lying like lakes in the hollows of the land; for the earth is eight thousand miles in diameter, and to that huge mass of dense matter the sea bears no proportion in its depth. While the surface of the land exhibits a variety of mountain ranges, hills, vales, and plains, so also is the bottom of the sea varied in its configuration, abounding in sandbanks, hills, rocks, and reefs, dangerous to the mariner; and the islands which rear their heads above the surface are only the tops of the highest hills and mountains in the sea. The waters of the ocean, as every one knows, are salt, to a greater or less degree—a quality which is considered necessary to preserve them from putridity; but how this saltness is produced, no one is yet able to tell correctly, although, as is generally conjectured, it must arise from the abundance of saline substances at the bottom of some parts of the ocean. The cause of springs on the land, from which rivers draw their sources, is also acknowledged to be still very doubtful. Some consider they originate from the rains which the earth has imbibed; some allege that they rise from subterranean lakes by means of capillary attraction; and others say that they are outlets for the water accumulated in higher parts of the country, which water has found its way through seams of rock, as if carried by pipes: but to all these suppositions there appear different objections. The most enlightened men are likewise unable to give any rational account of the existence of volcanoes or burning mountains. Whether they derive their action from a depth of only a few miles, or from the centre of the globe, or what it is that feeds their combustion, are questions which have never yet been satisfactorily solved. It is, however, known that they are connected with earthquakes, and in that respect of extensive subterranean influence. The most interesting of all the phenomena connected with our globe, are the tides of the ocean, which have been the subject of much scientific disputation, and are generally attributed to the influence of the moon. We believe they will be found to be elucidated agreeably to the best received ideas, in the article ASTRONOMY.

THE ATMOSPHERE.

The earth—the surface of which is so beautifully diversified by water and dry land, mountains and vallies, extensive forests and tracts of open country—is on all sides surrounded with air, without the presence of which, not even the humblest being in the scale of organisation could support its own existence. The ancients were not unacquainted with the vast importance of this agent in the great economy of nature; but they possessed no just idea of its properties, and it remained for Galileo and his pupil Toricellius to make us acquainted with the nature of atmospheric pressure. The air is generally described as a fluid, because all bodies move through it with facility; and in a state of rest, it does not oppose the passage of the minutest winged insect, or the transmission of the most delicate odour. Its whole mass, surrounding the earth, may be regarded as a great aërial ocean, at the bottom of which, man, and a vast variety of animals, live; while winged tribes alone rise into its higher regions. How high it extends, has not been yet satisfactorily determined; but from the length of time during which the sun's rays continue to be reflected from its upper regions back to the earth, after its orb has sunk below the horizon, there is reason to infer that it extends, in a state of extreme tenuity, to a very considerable height; nay, it has been conjectured that, in this attenuated condition, it may pervade all space, accumulating round the sun, moon, and stars, and forming an atmosphere round each of them, of greater or lesser density, according to their respective powers of attraction. By the experiments of Toricellius, it is ascertained that the pressure of the atmosphere on the earth and bodies upon it, is equal to a pressure of mercury to the depth of thirty inches, or of water to the depth of thirty-four feet. It has since been calculated that the pressure of air amounts on an average to fourteen pounds and a half on every square inch of the earth's surface, so that the human body is held down under a weight of from fifteen to twenty tons. This burden, which is serviceable in preventing bodies from flying off from the surface of the earth, is, however, unfelt, because our persons and the bodies of all living things are permeated or saturated with air to such an extent as to neutralise the incumbent influence of the atmosphere. The pressure of the atmosphere, or its density, diminishes as we ascend high mountains, and it is only in these extremes that we are sensible of its character by the difficulty experienced in breathing.

The atmosphere requires a certain quantity of moisture for the support of the vegetable creation, and this end is attained by a constant evaporation of the watery particles of the seas, rivers, lakes, &c. which, when carried into mid-air under a particular temperature, assume the appearance of masses of vapour or clouds. More vapour rises in maritime countries, and those interspersed with lakes, than in inland situations; more rises during hot than cold weather, and during a brisk wind than during a calm. As long as the air holds this moisture in solution or suspension, so as not to exceed its capacity of saturation, it remains invisible; but if the temperature diminishes, the quantity of vapour which surpassed the degree of saturation condenses, and, according to its degree of condensation, resumes the liquid state, descending in the shape of fogs and rain. In certain conditions, the atmosphere becomes charged with electric matter, by the agency of which, thunder and lightning are produced.—See articles ELECTRICITY and AERONAUTICS.

INTERIOR OF THE EARTH.

The interior of the earth, beyond the depth of a few hundred feet, is entirely unknown to us. We can only judge of it by an examination of its exterior, and by penetrating below its surface to a certain depth. From these examinations, it appears that the upper coating of the globe consists of a variety of layers of different descriptions of rock or stone, with a covering of beds of sand, clay, and other kinds of soil. The nature of these encrustations, and the order in which they lie, are sufficiently explained in the article GEOLOGY; and we need here only advert to the remarkable fact of all these various layers or strata of rock, with only one exception, abounding in the petrified remains of vegetables and animals, and which usually receive the name of fossils, or organic remains. By these remarkable indications we learn that the earth has undergone several extraordinary revolutions since its origin. But what is still more curious, we learn, by the absence, on all occasions and in all places, of the remains of human beings as well as the monkey tribes, that these are of a much later creation than other animals. It would seem that there have been several great eras, each distinguished by a peculiar class of vegetables and animals, rising successively up and up in excellence of configuration, to that which we now discover in the present day. On this subject, Bakewell, in his "Introduction to Geology," observes—"The fossil remains of animals not now in existence, entombed and preserved in solid rocks, present us with durable monuments of the great revolutions which our planet has undergone in former ages. We are carried back to a period when the waters of the ocean have covered the summits of our highest mountains, and are irresistibly compelled to admit one of two conclusions—either that the sea has retired and sunk far below its former level, or that some power operating from beneath has lifted up the islands and continents, with their hills and mountains, from the watery abyss, to their present elevation above its surface.

These organic remains present also undeniable proofs of another fact equally interesting. Every regular stratum in which they are disseminated was once the uppermost rock, however deep it may be below the present surface, or with whatever rocks it may now be covered. This inference is not the less conclusive, whether we suppose that the animals lived and died where their remains occur, or whether they were aggregated and carried by marine currents into their present situation. Hence we learn that the secondary strata were formed in succession over each other, and thus these fossil remains preserve the records of the ancient condition of our planet, and the natural history of its earliest inhabitants. The unknown causes by which zoophytes and different genera and species of testaceous animals, of reptiles, vegetables, and mammiferous quadrupeds, were buried in different strata, have operated in succession at distant intervals of time; for we do not find the remains of different classes confusedly intermixed together, except in beds of clay or gravel, near the surface, or in fragments of various rocks which have been broken down and subsequently united. Bones of vertebrated animals, or such as had a brain and spinal marrow, have never been found in the lower strata, except of a few species of fish; nor have the bones of large mammiferous quadrupeds ever been discovered below the chalk. Hence we acquire a perfect certainty that the different beds which form the crust of our planet were deposited in distant epochs, and under different conditions of the globe. The animal remains in some of the strata are so delicate, and so regularly deposited, that we can have but little doubt that the animals lived and died tranquilly where their remains are now found: in other strata the remains are dispersed and broken, and the animals appear to have perished by some sudden convulsion.

The absence of human bones in stratified rocks or in undisturbed beds of gravel or clay, indicate that man, the most perfect of terrestrial beings, was not created till after those great revolutions which buried many different orders and entire genera of animals deep under the present surface of the earth. That man is the latest tenant of the globe, is confirmed by the oldest records or traditions that exist of the origin of the human race. The great convulsions which here at distant periods changed the ancient surface of the globe, and reduced it from a chaotic to its present habitable state, were not, it is reasonable to believe, effected by the blind fury of tumultuous and conflicting elements, but were the result of determined laws, directed by the same wisdom which regulates every part of the external universe. Compared with the ephemeral existence of man on the earth, the epochs of these changes may appear of almost inconceivable duration; but we are expressly told, 'that with the Creator a thousand years are as one day, and one day as a thousand years.'"

Having given an account of the various races of men now found on the earth, in the article HISTORY OF MANKIND, in the present work, we proceed to notice those territories and nations which have not elsewhere engaged our attention.

EUROPE.

Europe is the smallest of the great divisions of our globe, but distinguished above the rest by the character of its population, the superior cultivation of the soil, and the flourishing condition of arts, sciences, industry, and commerce, the multitude of large and well-built cities, and its power and influence over the other parts of the world. Of the origin of its name and its inhabitants, history furnishes no certain account. It is most probable that the first inhabitants emigrated from Asia, the cradle of the human race. Greece was first peopled by the emigrants. In that country, about 1400 years before our era, grew up the Hellenes, who soon outstripped the civilisation of Asia. The most flourishing period of that nation, commonly called the Greeks, was about 300 B. C. Equally distinguished in action and speculation, adorned by the arts and sciences, rich in the noblest productions of cultivated minds, it will be, as long as civilisation endures, an object of admiration, and its remains the foundation of our knowledge and taste. But with the dissolution of Alexander's empire, which had been raised on the ruins of Grecian freedom, Greece sunk into insignificance.

At the same time, another nation was rising in Italy, the Romans, who appeared, indeed, at an earlier period, but made no figure in history till they had become masters of Italy, and had proved victorious in their struggle with the Carthaginians. From that period their power began to extend over all Europe. They subdued the divided Greeks, and transplanted their arts and refinement to the Italian soil. By the progress of the Roman arms, Spain, Portugal, France, the coast of England, Belgium, Helvetia, the part of Germany between the Danube and the Alps, the Hungarian provinces (then called *Pannonia*, *Illyra*, and *Dacia*), became known, and received the Roman manners, language, and refinement. Agriculture was introduced, and flourishing cities rose among the wandering tribes. The Christian religion, which spread throughout the wide Roman empire, was also a powerful instrument in the civilisation of most of the European nations. Germany alone resisted the overwhelming power of Rome, and thereby prevented the spreading of Roman civilisation in the north of Europe, which still remained unknown in history. With the fall of the Roman empire, occasioned chiefly by its separation into the Eastern and Western empires, a great change in the political constitution of Europe was produced, by the universal emigration of the northern nations. These nations poured down upon the beautiful and cultivated countries of the Roman empire, now in the weakness of decline, and Roman art and science were obliged to give place to the barbarity, the deep ignorance and superstition, of the middle ages.

The Ostrogoths and Lombards settled in Italy, the Franks in France, the Visigoths in Spain, and the Anglo-Saxons in South Britain, reducing the inhabitants to subjection, or becoming incorporated with them. The empire of the Franks was enlarged, under Charlemagne, to such an extent that the kingdoms of France, Germany, Italy, Burgundy, Lorraine, and Navarre, were afterwards formed out of it. About this time, the northern and eastern nations of Europe began to exert an influence in the affairs of the world. The Slavi, or Sclavonians, founded kingdoms in Bohemia, Poland, Russia, and the north of Germany; the Magyarians appeared in Hungary, and the Normans agitated all Europe. The establishment of a hierarchy was now undertaken by the Popes, and finally carried to its completion by Gregory VII. and Innocent III. The power of the Popes was increased by the crusades. Nevertheless, this struggle between Asia and Europe had the effect of forming a middle class, of leading the peasant gradually to throw off the chains of bondage, and of introducing the arts and sciences through the Arabs and Greeks into Europe. The revival of letters, by the Greeks fleeing from Constantinople, gave an entirely new impulse to Europe. The establishment of universities, the invention of printing, and the Reformation, served to cherish and develope these seeds of improvement. The feudal contests, the struggle of privileges, led eventually to the acknowledgment and establishment of the rights of the individual.

Out of the chaos of the middle ages, arose the states of Germany, France, Spain, Portugal, England, Scotland, Switzerland, the Italian powers, Hungary, Bohemia, Poland, Denmark, Sweden, Norway, and Russia. By the capture of Constantinople (1453), the Turks, with their fanatical military despotism, became an European power. Austria, Holland, Prussia, and Sardinia, were also added to the number of European states; and Russia, from the time of Peter I., was changed from an Asiatic into an European empire. The attempts of Charles V. and Louis XIV. to become masters of Europe, failed; but in our own times, Napoleon conceived the project of forming, from the European states, an universal monarchy, and pursued it for ten years. Since the formation of the states of Europe, the following have disappeared from the list of independent powers: Hungary, Poland, the German empire, Scotland, Bohemia, Venice, Genoa, and Milan. The following have been added: the states of the German confederacy, the Italian states, the republic of the Ionian Islands, and that of Cracow. A natural consequence of the general diffusion of intellectual cultivation, and the decay of the feudal system, has been the gradual developement of the ideas of equal right and individual liberty; bloody struggles have naturally ensued between the adherents of the new and old opinions, and Europe is still convulsed by them.

Europe is washed on three sides by the sea, which is called by different names, and belongs either to the Northern Arctic or the Atlantic Ocean. A narrow strait of the Mediterranean separates it from Africa. On the east alone it joins the main land, being there separated from Asia by an imaginary line. Europe is situated in the northern frozen and the northern temperate zones, between 10° and 63° east longitude, and 36° and 71° north latitude. Including the islands, which contain about 317,000 square miles, the whole extent of Europe amounts to about 3,250,000 square miles, of which Russia comprises nearly one-half. The greatest length, from Cape St Vincent, in Portugal, to the northern extremity of the eastern boundary, at Waygatt's, is about 3500 miles. The greatest breadth, from Cape Matapan, in the Morea, to the North Cape, in Norway, is about 2500 miles. Europe is remarkably well watered, although its rivers have not so long a course nor such large cataracts as those in other parts of the globe, particularly in America. The principal rivers are the Ebro, the Rhone, and the Po, running into the Mediterranean; the Danube, the Dnieper, and the Dniester, into the Black Sea; the Don, into the Sea of Asoph; the Wolga, into the Caspian; the Dwina, into the Arctic Ocean; another Dwina or Duna, the Vistula, and the Oder, into the Baltic; the Elbe, Weser, and Rhine, into the North Sea; the Seine, into the English Channel; the Thames into the German Ocean; the Loire and Garonne, the Duoro and Tagus, the Gaudiana and Gaudalquiver, into the Atlantic. The Wolga and Danube are the longest. Of its numerous lakes, the largest, which, however, bear no comparison with the North American, are in the north of Europe; viz. in Russia, Lakes Ladoga (the largest in Europe), Onega, and Tchudskoe, or Peipus; in Sweden, Lakes Maler, Wener, and Wetter. On the borders of Germany and Switzerland is Lake Constance; on the borders of Italy and Switzerland is the Lake of Geneva (Lake Leman); in Hungary are Lakes Platten and Neusiedler.

A great part of Europe is mountainous; the southern more so than the northern. The most elevated region is Switzerland, from which there is a descent, which terminates, on the side of the North Sea and the Baltic, in low plains. The lowest and most level parts are Holland and Northern Germany, Denmark, Russia, and Prussia. The highest mountains are the Alps, in Switzerland and Italy, which spread from those countries in various directions, extend westwardly into France, and are connected by the Cevennes with the Pyrenees, which separate France from Spain. One chain of the Alps stretches south towards the Mediterranean; then, taking an easterly course, runs through Italy, under the name of the Appenines. Several branches run eastward from the Alps, through the south of Germany, as far as the Turkish provinces. Another chain, the Jura, runs to the north, and separates Switzerland from France. In the east of Europe are the Carpathian mountains, which on one side meet the Sudetic range, and on the other the mountains of Turkey in Europe. The highest mountain in Europe is Mont Blanc, in Savoy, one of the Alps, which is said to be 15,766 feet above the level of the sea.

Several of the European mountains are volcanoes; as Ætna, Vesuvius, and Hecla. It is a fact worthy of notice, that none of the volcanoes of Europe are to be found in any of the great chains of mountains which have just been enumerated. The only one on the continent is Vesuvius, and this is too much detached to be considered as properly forming one of the Appenines. Ætna, in the island of Sicily, rising to the height of ten or eleven thousand feet above the level of the sea, is the largest European volcano. The Lipari Islands, anciently called the *Æolian*, a few miles to the north of Sicily, bear evident marks of a volcanic origin; and in several of them, subterranean fires are still in operation. The volcano of Stromboli is in almost incessant activity, and differs in this respect from any other with which we are acquainted. The Azores, in the Atlantic Ocean, are doubtless indebted for their formation to the same circumstance as the Lipari Islands; and indeed new rocks have risen from the sea in their vicinity, within a recent period. An eruption took place at St George, during the present century. Iceland, too, though lying under 65° of north latitude, presents the most abundant tokens of the presence of volcanic fire, and has often suffered under its devastations. Mount Hecla is the most noted, though not the only source of the eruptions on this island. To the possession of many inland seas, and, consequently, of a line of coast very extensive in proportion to its area, Europe is greatly indebted for the great advancement of its inhabitants in civilisation; these circumstances being favourable to that intercourse without which nations never make great advances. The peninsulas are six: Scandinavia, Jutland, Crimea, Italy, Spain, and Greece. The soil of Europe, though not equal in luxuriance to that of the tropics, is almost throughout fit for cultivation. The tracts in the northern zone are almost the only exception.

With respect to climate, Europe may be divided into three parts—the warm region, where the lemon-trees grow wild, as far as 48° north lat., having a pleasant spring, a hot summer, and short winter; the temperate, as far as 65° N., in which grain ripens; and the cold region, to the extreme north, where nothing will grow but reindeer moss, and no domestic animal can live except the reindeer. The products are not so various as in other parts of the world, and many of them were originally brought from foreign countries and naturalised; but, on the other hand, Europe can boast of a more perfect cultivation. Among the animals are horses, some of which are of the noblest breeds, horned cattle, sheep in Spain, Saxony, and England, of the finest wool, asses, goats, swine, dogs, reindeer, wild beasts of different kinds, valuable for their flesh or fur, whales, sea-cows, sea-dogs, abundance of wild and tame fowl, large quantities of fish in the seas, lakes, and rivers, among which the herring, in particular, affords sustenance to many of the inhabitants: useful insects, such as bees, silkworms, kermes, gall-flies, and Spanish flies. Oysters and pearl mussels also abound. It produces all kinds of grain, and sufficient for its consumption; beautiful garden plants; abundance of fruits, including those of southern climates, such as figs, almonds, chestnuts, lemons, oranges, olives, pomegranates, dates; also flax, hemp, cotton, madder, tobacco, the best kinds of wine, and a great variety of wood for fuel, and for house and ship building. The birch and the willow best endure the cold of the northern polar circle. Europe produces all the varieties of metals and minerals in great excellence and abundance. In gold and silver, Hungary and Transylvania are the richest; in iron, the northern countries, Sweden, Norway, and Russia. Salt of all kinds, rock, sea, and spring salt, is also abundant in Europe.

The inhabitants, estimated by Malte-Brun at 200 millions at least, are unequally distributed; in Russia and Sweden there are from fifteen to eighteen to a square mile; in the Netherlands, where the population is most dense, Italy, France, Great Britain, and Germany, the same extent supports from one hundred and fifty to two hundred and fifty persons. The inhabitants consist of several different races, speaking distinct languages. The stocks to which the principal languages belong, are—the Teutonic, which is the mother of the German, Dutch, English, Swedish, and Danish; the Latin, or Roman, now spoken only by the learned, but the mother of the Italian, French, Spanish, Portuguese, and Wallachian; the Sclavonic, to which belong the Russian, Polish, Bohemian, Bulgarian, Vandal, and the Servian, or Illyrian. Besides these, there are the modern Greek; the Turco-Tartaric; the Finnish and Hungarian; the Celtic in Wales and the north-west part of France (Bretagne); the Highlands of Scotland and Ireland; the Basque, among the Pyrenees. The most widely spoken is the German, with its kindred languages, formed by a union of the Roman with the Sclavonic.

The prevailing religion is the Christian, which includes several churches, viz., the Roman Catholic, which is the most numerous; the Protestant (Lutheran, Calvinistic, and Anglican), consisting of numerous sects—Anabaptists, Mennonites, Quakers, Unitarians, Methodists, Moravians, and the Greek church. A part of the inhabitants profess the Jewish, a part the Mahommedan religion. Among the Laplanders and Samoeides, there are also some heathens, but their number is small.

Agriculture has made great advances in Europe, and is daily improving. In this respect, those countries are particularly distinguished where the Teutonic languages are spoken, as also are France and a part of Italy. In no part of the world are manufactures carried to such perfection as in several of the European countries, especially in Great Britain, France, the Netherlands, and Germany. The inhabitants work up not only native European, but also foreign products, and supply all the wants and luxuries of life. Commerce is not less active, and is promoted by well-constructed roads and canals, by well-organised posts, banks, insurance companies, commercial companies, and fairs. The commerce of Europe extends to all quarters of the world, and every sea is filled with European ships. In this respect, Great Britain is most distinguished. Europe is the seat of art and science; to her belongs the honour of discovering the most important truths, of giving birth to the most useful inventions, the finest productions of genius, the improvement of all the sciences. In intellectual progress, the Teutonic races, and those who speak the languages derived from the Latin, have surpassed the Sclavonic nations. The Turks have remained strangers, in many respects, to the literary and scientific improvement which has marked the other European nations. Eighty-five universities provide for the higher branches of education; numerous gymnasia and academies for the preparatory studies, and a great number of lower schools, particularly in Germany, are employed in educating the common people. In many places there are academies of science, and societies of all kinds, for the cultivation of the arts and sciences.

By its physical situation, Europe is divided into East and West Europe. West Europe comprises the Pyrenean peninsula (Spain and Portugal), the country west of the Alps (France), the countries north of the Alps (Switzerland, Germany, and the Netherlands), the country south of the Alps (Italy), the islands of the North Sea (Great Britain, Ireland, and Iceland), and the countries on the Baltic (Denmark, Norway, Sweden, and Prussia). East Europe contains the countries north of the Carpathian mountains (Russia and Galicia), and the countries south of the Carpathian mountains (Hungary, in its more comprehensive sense, and Turkey). The following are the political states of Europe: the three empires of Austria, Russia, and Turkey; seventeen kingdoms, viz. Portugal, Spain, France, Great Britain, Holland, Belgium, Denmark, Sweden, Norway, Sardinia, the Two Sicilies, Greece, Prussia, Bavaria, Saxony, Hanover, and Würtemberg; one ecclesiastical state, the papal dominions; seven republics, namely, Switzerland, the Ionian Islands, San Marino, Hamburg, Lubeck, Bremen, and Frankfort; one electorate, Hesse; six grand-duchies, Baden, Hesse-Darmstadt, Saxe-Weimar, Mecklenburg-Schwerin, Mecklenburg-Strelitz, and Tuscany; twelve duchies, viz. Oldenburg, Gotha, Meiningen, Altenburg, Brunswick, Nassau, Dessau, Bernburg, Cöthen, Modena, Parma, and Lucca; one landgraviate, viz. Hesse-Homburg; one grand principality, Finland, and twelve principalities, viz. Hohenzollern-Hechingen, Hohenzollern-Sigmaringen, Schwarzburg-Rudolstadt, Schwarzburg-Sondershausen, Waldeck, Lippe-Detmold, Schaumburg-Lippe, Lichtenstein, Reuss-Greiz, Reuss-Schleiz, Reuss-Lobenstein, and Reuss-Ebersdorf.

CONSTITUTIONAL GOVERNMENTS.

We consider that it will be advantageous in a work of this popular nature, to present a short notice of those European states which have in the course of time obtained constitutions, with the dates when they came under this improved mode of government. Nevertheless, such are the changes constantly effecting in this respect, that all we can hope to ascertain is an approximation to correctness. It will also be difficult to point out distinctly what is sometimes the nature of the constitutions we allude to, for, however free in appearance, they are occasionally under the immediate influence of armed intervention, and the apparent restraints on the rulers, as well as the security of the subjects, are in many instances little else than a mockery.

The first kind of constitutions to be noticed are those founded on the feudal estates of the middle ages, and on the system of corporations: for instance those in the Austrian monarchy, as follows:—In the archduchy of Lower Austria, in Stiria, and Carinthia, in Bohemia, Moravia, and, since 1810, also in Galicia and Lodomeria with Bukowine, the estates are still kept up, comprising the four orders—the clergy, nobility, gentry, and citizens; the latter being represented by the magistrates of the royal cities. In the Tyrol, we find again, since March 24, 1816, the estates of peasants, citizens, nobility, gentry, and clergy. But notwithstanding their gallant struggle against the French and Bavarians, they have not even received from Austria the right of a voice in the imposition of their own taxes, which formerly belonged to them; but the constitution allows them the right of making representations, in the name of the country, to the emperor! In the imperial part of Silesia, the estates are composed only of the dukes and princes, with the lords and gentry, who are immediately under the emperor. In the Lombardo-Venetian kingdom, the estates are founded, according to the constitution of April 24, 1815, on the system of corporations. Two central congregations exist at Milan and Venice: the different provincial congregations in the Lombardic part of the kingdom consist of deputies appointed by the king; in the Venetian part, of deputies elected by the central congregation and the *gubernium* (the Austrian designation of the government). All these deputies are from among the noble and not noble landed proprietors, and from the royal cities, under the sway of the imperial governors or delegates. The privileges of these estates consist almost solely in the right of granting the royal *postulates*, and in the distribution and collection of the taxes. Some have also the right of advising the government, and that of petitioning. In Hungary the four orders of the estates

—the high clergy, the barons and *magnates*, the gentry, and royal free cities—have important privileges. The nobility or gentry and the cities elect their deputies, and give them instructions. In Transylvania, the grand-prince exercises certain rights of sovereignty, assisted by the representatives of the three nations (the Hungarians, Szeklers, and Saxons) whom he convokes. These representatives consist partly of royal officers, partly of deputies appointed by the regent or elected by the corporations.

2. Sardinian monarchy.—On the island of Sardinia, the clergy, nobility, and deputies of the cities and boroughs, exercise, together with the king, the right of legislating and taxing. 3. In the kingdom of Sweden, there exist, according to the latest constitution of June 7, 1809, the old estates, comprising four orders—the nobility, clergy, citizens, and crown-peasants. The diet has the right of legislation and taxation, and the superintendence of the finances, bank, and mint. The king has an unconditional veto.

4. In the kingdom of Saxony, the estates are composed of three orders. The first order consists of the higher clergy, or prelates, princes, counts, and lords, with the deputies of the university of Leipsic. The second order embraces the gentry, to which, since 1820, twenty-nine deputies also have been joined from the possessors of noble estates. The third order consists of deputies from the magistrates of the cities. The business of granting and fixing the taxes, and of receiving the accounts connected therewith, belongs to the diet; important laws of a general character must also be laid before them for consideration. 5. A similar constitution exists in the duchy of Saxe-Gotha, in which the legislative body consists of the estates of the counts, the gentry, and the citizens. Each of these estates has only one vote. The principality of Altenburg has two estates—the gentry and the citizens.

6. In the kingdom of Hanover, the estates were, according to a decree of December 7, 1819, divided into two chambers. The old system of corporations was retained. 7. In the principality of Liechtenstein, a constitution a. .r the Austrian fashion was introduced, Nov. 9, 1818. The estates consist of the clergy and the deputies from the communities, appointed by the magistrates. Their power is simply to make propositions. 8. In the two grand-duchies of Mecklenburg-Schwerin and Mecklenburg-Strelitz, the estates consist of the *Ritterschaft* and deputies of the corporations. They have very great privileges, which the former particularly maintains with great strictness. 9. In the principalities of Reuss, the old estates also exist, as, likewise, 10. in the Danish duchy of Saxe-Lauenburg.

11. The republic of the seven Ionian Islands was erected March 21, 1800, and governed according to the aristocratic constitution, established under Russian influence, Dec. 6, 1803. When the republic was placed under the protection of Great Britain, the lord-commissioner, Maitland, dissolved the senate, which had existed at Corfu since 1803, and established a new constitution Jan. 1, 1818, according to which the legislative body consists of deputies of the nobility, and the senate is chosen from among the legislative body.

The second description of constitution is that of Great Britain, which is founded jointly upon hereditary monarchy, estates of nobility, and that of a general national representation. The British constitution, which has been greatly modified by a strong democratic infusion consequent on the reform acts of Parliament, being well known to our readers, needs no illustration here.

The third kind of constitution consists of a government composed entirely through the medium of national representation. The first government erected of this kind was that of the United States of America, which began in 1787. Constitutions in which the aristocratic element was excluded were soon after established in France. Several other states then shook off the fetters of the feudal system, and introduced more or less of the democratic element into the constitutions which they adopted. During the last half century, there have been one hundred and fourteen new written constitutions established in Europe and America: thirty-one of them have been abolished, but the remainder still exist, and about one hundred millions of people are ruled by them.

France has seen, since the revolution, nine different constitutions:—1. The monarchical-representative constitution of 1791. 2. The republican-democratic constitution of June 24, 1793. This never went wholly into operation, much power being given, for the time, to dictatorial bodies. 3. The constitution of September 23, 1795, which established the directorial government, and divided the legislative body of the national convention into the council of the ancients and the council of the five hundred. It vested the right of electing the representatives immediately in the primary assemblies. 4. The constitution of December 13, 1799, established a first consul for ten yea[rs] with the right of proposing laws, and two other consuls. The first consul (Bonaparte) was surrounded by a council of state and ministers. A triple election was at the same time established. The citizens of each commune chose one-tenth of their number as persons qualified for public office; the aggregate of the persons thus named in all the communes of a department chose also one-tenth of their number; and from the whole body of persons thus nominated by all the departments, forming the national list of persons eligible to official situations, the conservative senate chose the legislators, tribunes, consuls, the members of the court of cassation, and the commissioners of accounts. In this instrument the principles of the liberty of the press, and others of a similar kind, which had been guaranteed in the former constitution, were omitted. 5. Many essential changes were soon after made in this constitution by the various *senatus-consultes organiques*, so called. These decrees of the senate, of August 2 and 4, 1802, gave the first consul, Napoleon Bonaparte, his dignity for life, and invested him with several monarchical prerogatives. 6. At last, the *senatus-consulte* of May 18, 1804, elevated the first consul to the dignity of emperor of the French, and the succession was made hereditary in his family.

France had now a monarchical constitution with some democratic forms; one of these—the tribunate—was abolished by the *senatus-consulte organique* of August 19, 1807. The equality of all citizens, in the eye of the law, was a principle preserved in all the French constitutions, and even the Bourbons were obliged to make it a prominent feature in the *Charte Constitutionnelle*. 7. After the downfall of Napoleon, the senate drew up a new constitution, of April 6, 1814, in which an aristocracy, hereditary in the families of the senators, was established. It guaranteed, however, in several respects, the liberties of the people. But Louis XVIII., as it is well known, adopted, at St Ouen, May 2, 1814, only certain principles of this constitution, relating to the representative system in two bodies, the responsibility of the ministers, the judges' tenure of office during good behaviour, the irrevocability of the sale of the national property, the capacity of every Frenchman for all civil and military appointments, and, as before mentioned, the equality of all citizens in the eye of the law. 8. After this, the king promulgated, June 4, 1814, the present constitution, the *Charte Constitutionnelle*, which had been drawn up by a committee appointed by him. It established a chamber of peers, to be elected by the king, and a chamber of deputies, to be chosen by electoral colleges. These two bodies, together with the king, were to form the legislature. But this instrument left many points unsettled, which allowed full play to machinations of all kinds. 9. After the return of Napoleon from Elba, the emperor promulgated a new constitutional instrument, as an addition to the imperial constitution, April 22, 1815. This was adopted by the people, in June, on the occasion of the celebrated *Champ de Mai*.

When Louis XVIII. returned to Paris, the *Charte* went again into operation. By the electoral law of June 28, 1820, the democratic element of this fundamental law, as respects the representation of the people, has been essentially weakened, or rather thrown out; as, in a population of 35,000,000, there are only 70,000 electors, and only five or six thousand who can be elected. The law of June 9, 1824, established septennial elections of the chamber of deputies, though the *Charte* had limited their term of office to five years. The constitution of France was subsequently improved at the installation of Louis Philip in 1830.—See FRANCE, under.

The kingdom of the Netherlands was established under a constitutional form of government in 1815, but this conjoined nation has recently been dismembered by civil war, and now Holland, under King William I., and Belgium, under King Leopold, have been erected into independent states, each with constitutions of a peculiar nature. It is not less difficult to speak of those nations than of Spain and Portugal, both of which are at present undergoing important changes in their forms of government. It is sufficient to say, that both in Spain and Portugal the powers of the sovereigns are now, at least nominally, restrained by the influence of the cortes or estates and people. Of late, also, considerable modifications are understood to have taken place in the constitution of Norway, by which the ancient aristocratic body is divested of authority.

We now pass to a notice of the constitutions of those various states composing the empire of Germany. The constitution of the former German empire was founded entirely on the principles of the feudal system and the old corporations. The states were independent to a considerable extent of each other; but for purposes of war or other aggregate movements, they submitted to one head, an emperor, who was at the same time ruler of a special district. Napoleon abolished the empire, and established the confederation of the Rhine in 1806. This confederation was practically of no avail, yet it led to the introduction of constitutional governments into some of the states between 1806 and 1815. 1. The kingdom of Westphalia, which lasted from 1807 to 1814, received a constitution modelled after the French representative system. This served as a model for the constitutions of several other states belonging to the confederation of the Rhine. It expired with the kingdom. 2. The grand-duchy of Frankfort had a similar constitution, from August 16, 1810, to 1813, which met with a like fate. 3. In the kingdom of Bavaria, which belonged also to the confederation of the Rhine, a national representation was established in May 1808, by a formal constitution and six constituent edicts; but by the decree of December 2, 1811, the owners of *majorates* (entailed estates) and the possessors of noble fiefs, were declared representatives of the Bavarian nation by right of birth. At last, the king, Maximilian, granted the constitution of May 26, 1818, accompanied by ten edicts. May 17, 1818, a regulation for the communities had been already promulgated. The constitution establishes two houses—one of peers, the other of commons—the former to hold their places by right of birth, or by appointment of the king, the latter by election. This election, however, is not made by the people collectively, but by the different estates—nobility, clergy, and scholars, citizens and peasants. This constitution nominally provides for the chief points of civil liberty, freedom of conscience and of the press, equality of all the citizens in the eye of the law, the equal capacity of all citizens for all appointments in the service of the state, also the equal distribution of taxes, the responsibility of public officers, &c. 4. Würtemberg.—King Frederic abolished, in 1806, the old constitution, founded on a compact concluded between the estates and the sovereign, and governed absolutely, according to the decree of organisation of March 18, 1806. January 11, 1815, he issued a proclamation, by which he intended to prepare the way for the establishment of such a constitution as he wished; but the assembly convoked by him in March 1815 refused the proposed constitution, asking for the re-establishment of the old one. At last the constitution of September 25, 1819, was established by way of compact. It provides for two houses of legislature.

5. The grand-duchy of Baden, after several preliminary decrees, received a constitution, August 22, 1818, which provides for two houses of legislature. The first is composed of peers, of the deputies of the gentry and the universities, a Catholic bishop, a Protestant prelate, and eight members nominated by the monarch, without reference to their birth or station. The lower house consists of deputies, chosen with reference to the population. 6. The grand-duchy of Hesse-Darmstadt received a constitution, providing for two houses, May 18, 1820. 7. The principality of Waldeck and Pyrmont received a constitution January 28, 1814. This was changed, however, April 19, 1816, when a constitution was established, by which only the landowners and corporations of the cities are represented. 8. The duchy of Nassau received a constitution by the ordinance of September 2, 1814, which establishes two houses, one of hereditary peers, the other of representatives, chosen for a limited time. July 1, 1816, a new organisation of the government was proclaimed. It is founded, for the most part, on the division of estates. 9. Saxe-Weimar received a constitution September 20, 1809, while she belonged to the confederation of the Rhine. Another constitution was adopted May 5, 1816, founded on the estates of the nobility, citizens, and peasants, each of which sends ten deputies, while the university of Jena sends one. There is only one house of legislature. The elections are free, and the liberty of the press is guaranteed. The diet, opened December 17, 1820, exhibited the remarkable instance of a representative body refusing publicity to its deliberations, and allowing only the publication of portions of its proceedings. The liberty of the press has been long since suspended. It is hardly necessary to mention how utterly insufficient a basis of representation the ancient estates are in our times, since the important classes of the learned (who were formerly represented in the clergy), artists, mechanics, merchants, and manufacturers, remain, on this system, unrepresented.

10. Saxe-Coburg received a constitution from its sovereign, August 21, 1817, founded on the estates. When the diet is not sitting, a permanent committee watches over the maintenance of the constitution, and the execution of the laws. A further constitutional regulation was given December 15, 1820, and the diet first assembled in 1821. 11. Saxe-Hildburghausen received a constitution, January 7, 1818, founded on the estates. A permanent committee of the nobility, the cities, and clergy, represents the diet when it is not sitting. 12. The principality of Schwarzburg-Rudolstadt received a constitution, April 21, 1821, founded on the estates. 13. The principality of Lippe-Schaumburg received a constitution by a decree of January 15, 1815. It is founded on the estates. 14. Lippe-Detmold received a constitution, June 8, 1819, from the princess regent Paulina, drawn up by herself; but this instrument was too liberal for the old estates of the nobility and the cities, which protested against it, as did also the prince of Schaumburg as agnate. 15. The duchy of Brunswick-Wolfenbüttel received a constitution, January 19, 1820, founded on the estates and corporations. It provides only one house of legislature. In respect to the granting of taxes, the old constitution was retained.

16. The free city of Frankfort, during the reign of Napoleon, received a liberal organisation, October 10, 1806. July 18, 1816, an act was passed by the senate, supplementary to the old constitution of the city, when it was an imperial free city, which was accepted by the citizens. The former privileges of the patrician families do not exist any longer. 17, 18, 19. The three Hanseatic cities have re-established, since 1814, their old constitutions, founded on the ancient corporations, and, like several others, little in unison with the demands of the age. 20. The duke of Saxe-Meiningen established a constitution, September 4, 1824, founded on the estates. The Swiss confederacy was transformed, by the French directory, in 1799, into the Helvetic republic, with a democratic form of government. This gave rise to bloo[d]y contests. Bonaparte, by the act of mediation, Fe[b]ru[ar]y 19, 1803, gave a new federative constitution to th[is] country, combining ancient and modern elem[ents]

September 8, 1814, the cantons convened again, and received into the confederacy of the nineteen cantons three new ones—Valais, Geneva, and Neufchatel. Each canton has its own representative constitution, founded on the elements of the old system, together with the principles of the act of mediation. In some, the aristocratic principle prevails; in others, the democratic. Some cantons are purely democratic, as Valais, Coire, Zug, &c. Neufchatel has a constitution in which aristocratic, democratic, and monarchical principles, are combined. The king of Prussia, the sovereign of this canton, established this constitution, June 18, and December 28, 1814.

Having thus enumerated the European states which have received constitutions, it may not be uninteresting to take a survey of those European states which are governed by sovereigns entirely absolute. Austria was mentioned among those countries in which constitutions founded on the old feudal estates exist; but although this may be the case in point of form, yet the Austrian monarchy is virtually one of the most absolute governments that can exist, and has systematically pursued, for a long series of years, so arbitrary a course in many respects (including the administration of the finances and the intellectual cultivation of the people), that we can hardly find any thing parallel in governments which claim to be purely absolute; as, for instance, in Prussia. The following governments are without constitutions:—1. Piedmont, Savoy, and Nice. 2. Tuscany, Parma, and Modena. 3. The Two Sicilies. 4. The States of the Church. 5. Prussia, with the exception of Neufchatel. 6. The electorate of Hesse-Cassel. In 1815, the elector, having resumed possession of the electorate, after the abolition of the kingdom of Westphalia, convened not only the old estates, those of the nobility, clergy, and citizens, but also that of the peasants, which gave rise to animadversion; and on the assembly's disagreeing to the new constitution which he presented to them, the elector dissolved the body; since which time the government has been entirely absolute. 7. The landgraviate of Hesse-Homburg. 8. The duchy of Anhalt. December 28, 1810, this little country received from the reigning duke a constitution, modelled entirely on that of the French empire; but the guardian of his successor suspended the constitution, October 24, 1812. 9. The principalities of Hohenzollern-Hechingen, and Sigmaringen. 10. The principality of Schwarzburg-Sondershausen. 11. The duchy of Oldenburg. 12. The duchy of Holstein. Both the latter, however, are about to receive, according to public report, constitutions founded on the estates. 13. The kingdom of Denmark, in which the ancient constitution was abolished in 1660. The people co-operated with the government in the overthrow of the old system, as it was favourable only to the nobility and the privileged corporations, the former of whom greatly abused their powers. Lastly, Russia, which is under the rule of an emperor, and exhibits a perfect specimen of a despotic government.

THE BRITISH ISLANDS.

These islands, the most important belonging to Europe, lie at a short distance from the north-west coast of France, betwixt the Atlantic Ocean on the west, and the German Ocean on the east. From their southernmost boundary upon the British Channel to the most northerly of the Shetland group, is a distance of very nearly eleven degrees, measuring from the 50th to the 61st degree of north latitude. The main island, which since the Union has been called Great Britain, is composed of two portions, with considerably distinctive features, under the names of England and Scotland. England forms the larger, the most southerly, and much the finest portion of the island, and lies betwixt the 50th and 55th degree. Scotland lies on the north of this division, and reaches the 58th degree. Ireland is a large and beautiful island lying to the west of England, from which it is separated only by a channel half a day's sail in breadth, and extends in length from 51° 10′ to 55° 20′ north latitude. Its greatest length, measuring from N. E. to S. W. is about 300 miles; the greatest breadth about 60 miles. The chief of the minor islands are the Isle of Man, lying in the Irish Channel; Anglesea, on the coast of Wales; the Hebrides, a series of large and small isles on the west coast of Scotland; the Orkney Islands, separated from the north point of Scotland by the Pentland Firth; and the Shetland Islands, lying considerably north of the Orkneys. Besides these, there are some islands in the British Channel, near the coast of France, called Guernsey, Jersey, Alderney, &c. Reckoning large and small, the British islands amount to at least five hundred in number, but many of the smallest are not inhabited.

England, or South Britain, is triangular in form, and measures from north to south 400 miles; and in some places it is 300 miles broad. Towards the north, at its junction with Scotland, it is greatly contracted. Within its western verge lies Wales, once an independent kingdom, but now politically, and in every other respect, associated with England. By the best surveys, it appears that England and Wales contain 57,960 square miles, or 37,094,400 imperial acres. England is divided into 40 counties and 9860 parishes; Wales into 12 counties and 833 parishes. The general aspect of England is varied and delightful. In some parts verdant plains extend as far as the eye can reach, watered by copious streams, and covered by innumerable cattle. In others, the pleasing vicissitudes of gently rising hills and bending vales, fertile in vegetable products, waving with green woods, and interspersed with meadows, offer the most delightful landscapes of opulence and beauty. Over the whole of these level regions there wind innumerable artificial canals and roads, every where giving token of the commercial character of the country. The chief elevations in England are in the southerly counties of Westmoreland and Cumberland, where the hills rise to upwards of 3000 feet in height. The general aspect of Wales is bold, romantic, and mountainous. It consists of continued ranges of lofty mountains and impending crags, intersected by numerous and deep ravines, with extensive vallies, and affording endless views of wild mountain scenery. The Welsh hills are also often green and pastoral, and feed an immense number of sheep and black cattle.

The most considerable rivers of England and Wales are the Thames, Severn, Medway, Trent and Ouse forming the Humber, Tyne, Tees, Wear, Mersey, Dee, Avon, Eden, and Derwent, which, aided by the extensive system of canal navigation, afford an easy access into the interior of the country, and enable the most inland districts to communicate readily with the sea, as well as with one another. Among the mountains of Westmoreland and Cumberland there are a number of beautiful lakes, of which Windermere is the chief, and is the most extensive piece of water in England, being upwards of ten miles in length, and from one to two miles in breadth. The coasts of England are among the finest in the world for maritime traffic. Generally speaking, the western coast of the island is rugged and precipitous, while the eastern coast is almost wholly level. The main channels for the shipping trade of Great Britain are the Thames, the Humber, the Tyne, the Forth, and the Tay, on the east coast, and the Severn, the Mersey, and the Clyde, on the west. The climate of England and Scotland is variable, inclining to moisture and cold; in the northerly part of the island especially, the east winds are occasionally piercingly cold and most destructive to health. The mean average heat of England is about 52°; in summer, the heats rise to upwards of 80°, though only for a few days; the common winter cold is a little above the freezing point, or varying from 30° to 40° of the thermometer. During some winters, no snow is ever seen on the low hills or vallies. The worst feature in the British climate is its variableness, which baffles all calculation.

By the latest census, it appears that there are in England and Wales about 170 cities and towns, each with a population above 5000 in number; 60 having above 10,000; 25 with above 20,000; 7 with above 50,000; and three with above 100,000; that is, including the dependencies of each. London, the capital, along with Westminster, the borough of Southwark, and parishes both within and without the bills of mortality, according to the returns of 1831, comprised a population of 1,470,000; that is, nearly a million and a half of inhabitants. At present, this huge city is daily increasing, and it is impossible to say to what extent it will soon reach. After London, the most flourishing cities in England are Manchester and Liverpool, both the seat of trade and commerce, and of comparatively modern date as places of importance. Manchester, with Salford and environs, has now a population upwards of 270,000 in number; Liverpool reckons 165,000 inhabitants. For an account of the trade and commerce of these great marts, as well as for England generally, we beg to refer to the article upon the British Empire and its Resources, and that upon the Cotton, Silk, and Woollen Manufactures, as well as that upon the Trade and Commerce of the World, in this work.

Scotland, or North Britain, is separated from England by a line formed by the Tweed, the Cheviot mountains, and some streamlets falling from them into the Solway. From this boundary to the most northerly point, the country extends 280 miles in length; its greatest breadth is 160; but its form is very irregular, and the coast is so deeply indented by large arms of the sea, that it is difficult to describe its dimensions. Nearly all that portion that has figured in history lies betwixt the borders of England and the Firth of Tay, or perhaps within the narrower limits of the Firths of Forth and Clyde. It is within this section that Edinburgh, the capital, is situated; also Glasgow, now the most populous city in Scotland. The entire extent of the country is estimated at 29,600 square miles, or upwards of 18,000,000 acres, of which only five millions are cultivated, and the remainder consisting of uncultivated lands, woods, and plantations.

Scotland consists of two districts, quite distinct in character—the Highlands and Lowlands. Those unacquainted with the country personally, very frequently misapprehend this division, and somehow consider that the whole of Scotland partakes of Highland character. The Highlands compose a rugged mountainous district in the north and north-west part of the kingdom, including the counties of Sutherland, Ross, Inverness, Perth, Argyle, and Dumbarton, upon the mainland, together with Bute, and other islands, besides a considerable portion of the counties of Nairn, Elgin, Banff, Aberdeen, Forfar, and Caithness. In this district, which includes fully a half of Scotland, Gaelic was or is the vernacular tongue, and the manners and dress were or continue to be Celtic. The Lowlands consist of the southern shires, and a broad stripe of land on the east coast of the Highland counties. In this district the English tongue has been spoken for nearly eight hundred years, and every species of civilised usage and institution prevails, as well as the usual English garb. Indeed, to the Lowlanders, the genuine Celt of the mountains is as much a curiosity as he would be in the centre of England. The Hebrides, or Western Isles, belong to the Highland division; but the northerly islands of Orkney and Shetland are essentially Lowland in manners, language, and institutions of the inhabitants, all of whom are of Gothic origin.

While the Highlands are nearly altogether mountainous and pastoral in character, the Lowlands are by no means flat, but are distinguished by a great variety of hill and dale. There is indeed little perfectly flat ground in any part of Scotland. In general the land has an inclination to the beds of rivers or streamlets, or to the sea; the uplands being mostly pastoral, and the low grounds chiefly under culture for grain or green crops. The most fertile and level counties are Berwickshire, in its lower division, and East Lothian, which is adjacent. What are called the carse grounds, that is, large tracts of alluvial soil on the borders of the Tay and upper Forth, are, however, more of a dead level, and are exceedingly beautiful and productive. Scotland abounds in rivers of various extent, but they are generally so rapid in their descent as to be of no use in navigation. The Clyde in its lower parts is the only navigable stream. The Forth and the Tay are only navigable in their firths or estuaries. The firths of these rivers, and the Moray Firth on the north-east coast, are of great consequence to the shipping trade, and also for fishing. The Tay is the largest river in Scotland, and after the Clyde and the Forth are ranked the Spey, Findhorn, Dee, Tweed, Ness, Nith, and Lochy. The Earn is a fine river, falling into the lower part of the Tay. Almost all these rivers have their origin in obscure rivulets among clusters of inland mountains. The northern rivers, Spey, Findhorn, Dee, &c. draw their sources from the groups of Highland hills, chiefly in Aberdeenshire and Inverness-shire. In this latter county rises the lofty Ben-Nevis to the height of 4370 feet above the level of the sea, and forms the tallest of the Scottish mountains. In the bosom of the Highland country there lie many beautiful and extensive lakes, the most noted of which, Loch Catrine and Loch Lomond, are found in Dumbarton and Stirling shires.

Within the last sixty or seventy years, Scotland has undergone an almost entire change of character, both physically and morally. It is now extensively and well cultivated and enclosed, intersected by excellent roads and two or three canals, and as nearly as may be resembles England in appearance. From having almost no trade or commerce, it is now deeply engaged in trade, in manufactures of divers kinds, and possesses a large amount of shipping. But perhaps the greatest improvement is observable in its chief towns, which have all been modernised, and greatly extended in size and population. Its principal cities and towns are as follow:—Edinburgh, the capital, with Leith and suburbs, with a population of 162,156 (without Leith, 136,294); Glasgow and suburbs, 202,426—(this being the third town in the empire); Aberdeen, new and old, 58,019; Paisley, burgh and abbey parish, 57,466; Dundee, 45,355; Greenock, 27,571; Perth, 20,016; Inverness, 14,324; Montrose, 12,055; Dumfries, 11,606; Arbroath, 6660; Kirkaldy, 5034. Scotland is divided into 33 counties, which are or were lately subdivided into 910 parishes; the population of the whole, by the census of 1831, amounted to 2,365,807, which was more than double what it was thirty years before. Politically, Scotland is now thoroughly incorporated with England; nevertheless, it still possesses its own peculiar usages and legal code, it being only some of the acts of the Imperial Parliament which affect its laws. The system of administration of justice also differs a good deal from that of England, and its supreme courts are settled at Edinburgh. Ecclesiastically, it is likewise peculiar in its institutions, as has been elsewhere described in this work.

Ireland, which now forms a portion of the United Kingdom, and is under the same kind of institutions as England, though naturally a fine country, has hitherto been the least prosperous of the British islands. It is computed that it contains more than 30,000 square miles, or nearly 30,000,000 acres. Politically, it is divided into the four provinces of Leinster, Ulster, Munster, and Connaught, which compose 32 counties. Dublin, the capital, by the returns of 1831, had a population of 204,155; Belfast, in the northern part of the island, is a flourishing town and seaport, with a population of 53,000; Cork, on the south-east coast, has a population of 107,016. Ireland contains about sixty towns, each with above 2000 of a population. The total population of the country in 1831 was 7,767,401.

FRANCE.

After Great Britain, France is usually reckoned the most powerful and influential country in Europe. In point of territorial extent and amount of population, it stands much higher than Great Britain, which is but a small country, and it likewise possesses a finer climate; nevertheless, such have been its unfortunate political and religious dissensions and misarrangements, that it has permitted itself to be outstripped in the race of improvement by England. Yet under all its backwardness, in many points France forms a great nation, well deserving of the sympathy and respect of its neighbours; and it is greatly to be desired that in future a good understanding should subsist betwixt it and Great Britain.

France is situated between latitude 42° 20′ and 51° 5′ N., and longitude 3° 51′ E. and 9° 27′ W., comprising an extent of 213,800 square miles, with a population, according to official returns, in 1827, of 31,851,545. It is bordered on the north-east by the Low Countries, the Prussian province of the Lower Rhine, and Rhenish Bavaria; on the east, it is separated from Baden by the Rhine, and touches Switzerland and Sardinia; on the south, its boundaries are the Mediterranean, the Pyrenees, and the Bidassoa; the ocean bounds the rest. The island of Corsica, and the Hières, in the Mediterranean, and the Isles of Oleron, Ré, Noirmoutier, Belle-Isle, Dieu, and Ouessant (Ushant), in the Atlantic, belong to France. The foreign possessions are of little value. They are, in Asia, Pondicherry and Karical on the Coromandel coast, Yanaon in the Northern Circars, Chandernagore in Bengal, Mahe on the Malabar coast, a factory at Surat, and some factories in Arabia, in all 179,000 inhabitants; in Africa, Senegal, Goree, the Isle of Bourbon, and some factories, containing 90,000 inhabitants; in America, Martinique, and Gandaloupe with its dependencies, Guiane, and the small islands of St Pierre and Miquelon, near Newfoundland, containing 275,000 inhabitants. The territory is divided into 86 departments, which generally derive their names from the rivers. They are subdivided into 363 arrondissements, 2844 cantons, and 38,339 communes. Each department is governed by a prefect, and each arrondissement by a subprefect. The cantons have no administrative powers. The communes are under a mayor. All these officers, with the counsellors of departments, arrondissements, and communes, were, before the recent changes, appointed by the king. The empire under Napoleon comprized about 300,000 square miles, with 42,500,000 inhabitants, of which 28,000,000 were French, 6,500,000 Italians, 4,500,000 Flemish and Dutch, and 4,000,000 German.

The principal mountains of France are, 1. The Vosges on the north-east. They are of a rounded outline, with gentle slopes, and afford much open pasturage. The highest summit is not more than 4500 feet high. 2. The Jura mountains lie to the south of these, and their summits rise to the height of 6000 feet. 3. Many Alpine branches intersect Dauphiny and Provence. In the centre of the kingdom are, 4. The mountains of Auvergne, of volcanic origin, of which the Puy de Dome, the Monts d'Or, and the Cantal, are the principal groups. 5. The Cevennes lie to the south-east of the range last mentioned. Their highest summit is Mont Lozère (about 6510 feet). 6. The Pyrenees form the principal part of the boundary between France and Spain. These mountains divide the country into four great basins, the form and exposure of which necessarily have a great influence on their climate and productions. The narrow valley of the Rhine runs from north to south, while the open basins of the Seine, the Loire, and the Garonne, stretch in a north-western direction. The Adour rises in the Pyrenees, and washes the walls of Bayonne. The other rivers are principally tributaries. The Marne and the Oise fall into the Seine; the Allier, the Loire, the Sarthe, and the Mayenne, into the Loire; the Rhone receives the Saône, the Isère, the Durence, the Ain, and the Sorgue; the Tarn and the Dordogne join the Garonne. The numerous branches of these rivers are joined by canals, which form an extensive internal water communication.

In respect to soil, the richest part of France is the north-west division, comprehending the provinces of Flanders, Artois, Picardy, Normandy, and the Isle of France, where there is a deep rich loam; about 18,179,590 acres in extent. The valley of the Garonne is composed of a friable sandy loam, with a calcareous mixture, and moisture sufficient for every purpose. This district contains 7,654,561 acres. The great valley of Languedoc is extremely prolific, though the soil is not so fine as that of the preceding districts. The Limagne, a valley of Auvergne, is considered to have one of the finest soils in the world. It consists of beds of earth, said to be twenty feet deep, formed from the decomposition of soft basalt. The calcareous and chalk formations are extensive. The chalk provinces are unfruitful in grain, but the genial influence of the sun allows them other riches. The calcareous loam on the borders of the chalk formation is more productive. In Bretagne, Anjou, and Maine, are immense heaths. The *landes* are extensive tracts of sandy deserts, producing nothing but broom, heath, and junipers. The most extensive are the landes of Bordeaux, twenty leagues in length by twelve in breadth. In the remaining provinces, gravel, or a gravelly sand, is the predominating soil. The woods and forests are estimated to cover a space of 18,795,000 acres. The principal are those of Ardennes, Orleans, and Fontainebleau. The northern and western coasts are formed in a great proportion by immense downs or sandbanks, and where the shores are formed by cliffs, they are seldom bold enough to be approached with safety. The harbours are therefore few. On the Mediterranean, the coast of Languedoc is very dangerous, but Provence abounds in good harbours. The culture, throughout the northern half of the kingdom, consists of wheat, barley, oats, pulse, and of late, much more than formerly, of potatoes; in the southern half, corn (particularly maize), vines, mulberries, and olives. The eastern parts, being more elevated than the western, have more rigorous winters and more ardent summers. Coal and iron are found in abundance. The most common fuel is wood.

The superficial extent of France has been recently estimated by Baron Dupin at 53,533,428 hectares, or 132,694,000 English acres. The value of capital vested in agricultural pursuits is estimated at 37,522,001,476 francs; the gross annual produce at 4,678,708,885 francs; the expenses of cultivation at 3,334,005,515; leaving a profit of 3½ per cent. on the capital. The produce of wheat in the best cultivated districts, and on the best soil, hardly exceeds eighteen bushels per acre: an English farmer expects twenty-five on the same extent. In 1812, the number of horses in France was 2,176,000; but in 1819, the horses and mules together amounted only to 1,657,671; at present the number is estimated at 2,500,000. The number of horned cattle is 6,973,000; of sheep, about 45,000,000. The total number of all kinds of poultry is about 51,600,000. The French are the best wine-makers in the world. The Champagne, Burgundy, Claret, Hermitage, are drunk all over the world. For a long time, the choicest growths were in the hands of the church; and in the frequent changes of property which have taken place since the revolution, many vineyards have deteriorated in consequence of bad management. The brandies of France are the best in the world. The value of the whole produce of wine and brandy is about 800,000,000 of francs. The culture of the vine is supposed to have increased nearly one-fourth since the revolution, owing principally to the small proprietors, each of whom endeavours to supply his own consumption by a little patch of vineyard. M. Dupin says that many hectares of French territory are yet uncultivated, merely for want of cattle to stock and manure them; that two-thirds of the inhabitants are without animal food; that more than one-third subsist entirely on oats, buckwheat, rye, chestnuts, or potatoes, and that the agricultural population is too great for the prosperity of France. Two-thirds of the population is agricultural.

France possesses a soil and climate capable of furnishing her with all the raw materials of manufacture except cotton. The manufacture of fine woollen cloths at Sedan was introduced under the auspices of Colbert. The machinery used was very defective until M. Chaptal engaged an English machinist to instruct the French artizans. Steam-engines are rare; the spinning mills being worked chiefly by water or by horses. The quantity of native wool manufactured in 1819 was 38,000,000 kilogrammes (of about 2⅕lbs. each), and, in 1826, 42,000,000, with 8,000,000 of imported wool: the value of the manufactured articles was 265,000,000 francs; of the raw wool, 105,000,000: the quantity exported was about one-thirteenth of the whole quantity manufactured. By the exertions of Henry IV., the mulberry-tree was cultivated in all the southern provinces. At Tours, silk stuffs for furniture are chiefly manufactured; at Ganges, and other places in the Cevennes, silk stockings. Lyons is the principal place for silk manufactures of all kinds. Paris ranks next after Lyons. In 1812, the value of the raw material amounted to 45,560,000 francs, of which 22,000,000 were the price of imported silk. The value of manufactured goods, at the same period, was 107,500,000 francs, of which less than one-third was exported. Forty years ago, the spinning of cotton by machinery was hardly practised in France. Cotton mills have been established within that period, and the manufactures of Alsace are now superior to those of England in the brilliancy of their colours. In 1812, 10,362,000 kilogrammes of cotton were spun by machinery, and, in 1825, 28,000,000 of greater fineness. The cambrics, gauze, and lawn of St Quentin, Valenciennes, and Cambray, are among the most valuable products of French industry. Lace is made in great quantities.

The whole produce of the linen and hemp manufactures is estimated at 200,000,000 francs. In 1814, 100,000,000 kilogrammes of cast-iron were produced; in 1825, 160,000,000. Gilding and watch-making are carried on, chiefly in Paris, to the annual value of about 38,000,000 francs each. Printing also employs a great number of persons at Paris. In 1814, the number of printed sheets was 45,675,039; in 1820, 80,921,302; and in 1826, 144,561,094. Notwithstanding the low price of labour in France, the industry of that country cannot enter into competition with that of England. One of the circumstances which depress it is the want of internal communication by roads and canals. The practicable roads of France are not more than one-third of the extent of those of England. The cross-roads are few, and the great roads are seldom kept in good order. The length of the canals in France is not more than one-eleventh of those of England. Another point in which France is inferior is in the use of steam-engines, attributable in part to the deficiency of coal, or the difficulty of transporting it. The total force of steam-engines in France, according to Dupin, is equal to that of 480,800 men; that of England is equal to a power of 6,400,000 men. All the power derived from machinery of every sort, or from constructive ingenuity, and applied to purposes of industry in France, is only one-fourth of the similar power employed in England.

The commerce of France has been very much diminished by the loss of her colonies. The value of the colonial imports, in 1788, was 227,000,000 francs; in 1824, it was only 50,000,000. The exports for 1788 amounted to 119,000,000; in 1824, to 44,000,000. The total value of exports from France, in 1824, was 440,542,000 francs; of which 163,056,000 were productions of the country, and 277,486,000 manufactured articles. The amount exported to the United States was 55,000,000, being more than that to any other country. The imports for the same year were of the value of 454,861,000 francs; of which 272,873,000 francs were raw materials for manufacture, 121,957,000 natural productions for consumption, and 60,030,000 manufactured articles. In 1824, the number of sailors in French ships was 328,489; of whom 26,649 were engaged in foreign commerce, 47,283 in the fisheries, and the remainder in the coasting trade. The navy, according to the budget of 1828, consisted of 36 ships of the line, 35 frigates, 8 steam-boats, and 186 other vessels, and 14,963 officers and sailors. The army in 1828 amounted to 233,770 men, and was recruited by voluntary enlistment and annual levies, every Frenchman of twenty years of age being bound to serve for a term of eight years. The receipts of 1828 were 1,037,104,491 francs; the expenditure, 1,035,415,552 francs.

As we have given the history of the French Revolution of 1789 in another portion of the present work (No. 8), nothing need here be said of that event. It is sufficient to state that the military character which was engrafted upon the nation by subsequent events still predominates, and may be described as one of the main causes for the deficiency of France in manufactures, commerce, wealth, and many comforts of social life. The character of the French, however, is fast undergoing an improvement under the constitution which the country has enjoyed since 1830, when Louis Philip was placed on the throne, by the events of what are termed the "three days," or the revolution which deposed the elder line of the Bourbons. The present reigning family, or house of Orleans, is a collateral line of the former branch, being derived from the only brother of Louis XIV., Philip Duke of Orleans. The following are the eras of the reigning princes of France:—1. *Capet Dynasty:* Hugh Capet (987), died 996; Robert, died 1031; Henry I., died 1060; Philip I., died 1108; Louis IV., died 1137; Louis VII., died 1180; Philip II. (Augustus), died 1223; Louis VIII., died 1226; Louis IX. (the Saint), died 1270; Philip III. (the Bold), died 1285; Philip IV. (the Fair), died 1314; Louis X. (Hutin), died 1316; Philip V. (the Long), died 1321; Charles IV. (the Fair), died 1328.—2. *Branch of Valois:* Philip VI., died 1350; John (the Good), died 1364; Charles V. (the Wise), died 1380; Charles VI., died 1422; Charles VII., died 1461; Louis XI., died 1483; Charles VIII., died 1497.—3. *Branch of Orleans:* Louis XII., died 1515; Francis I., died 1547; Henry II., died 1559; Francis II., died 1560; Charles IX., died 1574; Henry III., died 1589.—4. *Branch of Bourbon:* Henry IV., died 1610; Louis XIII., died 1643; Louis XIV., died 1715; Louis XV., died 1774; Louis XVI., died 1793; Louis XVII., died 1795. [French republic, from 1792 to 1804; Napoleon (Bonaparte), Emperor of the French, from 1804 to 1814.]—Bourbons restored by foreign arms: Louis XVIII., from 1814, died 1824; Charles, to 1830, when he was dethroned.—5. *New House of Orleans:* Louis Philip I., with the title of King of the French (*roi-citoyen*). Of the dethroned Bourbon family, there are living the ex-king, Charles X.; his son, Louis Antoine, Duke of Angoulême (late dauphin), born August 6, 1775; married his cousin, Marie Therese, daughter of Louis XVI. The second son of Charles X., Duke of Berry, born Jan. 24, 1778; married to Caroline, Princess of Naples (born Nov. 5, 1798); was assassinated by Louvain, Feb. 14, 1820. His children are Marie Louise (Mlle. d'Artois, born Sept. 21, 1819), and Henry (Charles Ferdinand Marie Dieudonné), Duke of Bordeaux, born Sept. 29, 1820, after the death of his father, late heir-presumptive. Charles and the dauphin abdicated in his favour, calling him King Henry V. Louis Philip has a family of five sons and three daughters; the eldest son, Ferdinand Philip Louis Charles Henry, now Duke of Orleans, was born in 1810.

France is a limited monarchy, hereditary in the eldest male line. If the late changes become permanent parts of the system, it will be the most limited monarchy in Europe. The charter has undergone several important alterations. The principal are, that the Roman Catholic religion has ceased to be the religion of the state; the 14th article, which the Polignac ministry cited in their late attempt to overthrow the constitution, has been changed, so as to stand as follows:—"The king is the supreme head of the state; he commands the land and sea forces, declares war, makes treaties of peace, alliance, and commerce; appoints to all offices of the public administration, and makes all the regulations and ordinances necessary for the execution of the laws, under the responsible advice of his ministers;" any of the three branches of the legislature can propose laws; the Chamber of Peers may sit without that of the Deputies only as a court of justice; peers may speak in the house at the age of twenty-five years; princes of the blood may sit in the House of Peers without a special summons from the king; the deliberations of the peers are public; the renewal of one-fifth of the deputies every year is abolished; persons are eligible as deputies at the age of twenty-five years; the deputies elect their president without the concurrence of the king; and the electors choose the officers of the electoral colleges without the interference of the king; articles 46 and 47 of the old charter, respecting amendments, and the adoption of the tax acts by the deputies, previously to being sent to the peers, are repealed; as is also article 56, exempting the ministers from impeachment, except for treason or extortion; the *prevôtal* courts are abolished; the king takes the constitutional oath, not at the time of the coronation, but on his accession, as in England. Besides this, provision is to be made, by separate laws, for, 1. The trial of offences of the press by a jury; 2. The responsibility of ministers and other agents of power; 3. For the re-election of deputies promoted to offices with salaries; 4. The annual vote of supplies for the army; 5. The organisation of the national guard; 6. The settling the rank of all naval and military officers; 7. Departmental and municipal governments founded on the elective system; 8. Public instruction provided for; liberty of teaching allowed to all; 9. The abolition of the double vote, and of the electoral candidates and their eligibility. The charter is entrusted to the protection of the national guard and the patriotism of the nation. The charter, with the "changes and modifications expressed in the declaration of the Chamber of Deputies," was presented to Louis Philip, who, on the 9th of August 1830, took the constitutional oath; and thus the *constitution octroyée* was changed into a real contract between the ruler and the people.

France possesses a considerable number of towns, with populations of from five to thirty thousand, and more particularly about twelve thousand, but not many of any consequence with a larger amount of inhabitants. Paris, the capital, in 1827, had a population of 890,531, which is about half the amount of the population of London. The other chief towns are Lisle, with a population of 69,860; Rouen, 90,000; Strasburg, 49,708; Nantes, 71,739; Boulogne, 19,314; Havre, 21,049; Rheims, 34,862; Brest, 26,655; Cambral, 17,031; Lyons, with suburbs, 170,875; Marseilles, 115,943; Toulon, 30,171; Aix, 23,132; Grenoble, 22,149; Clermont, 30,010; Besançon, 28,795; St Etienne, 30,615; Dunkirk, 24,517; Amiens, 42,032; and Orleans, 40,340. The chief port in the north of France is Havre, on the English Channel, and Marseilles and Toulon are the principal outlets on the south. In point of capability for maritime trade, France is far inferior to Great Britain, from its want of good harbours, though perhaps that circumstance is of less consequence than the peculiar genius of the people, which is adverse to naval adventure.

SPAIN AND PORTUGAL.

Spain, or the Peninsula, as it is frequently called, is an extensive country, occupying the south-western extremity of Europe, between latitude 36° and 44° N. and is surrounded by the Atlantic Ocean and the Mediterranean Sea, except on the north-east, where part of the Pyrenean chain of mountains form its boundary with France. In its dimensions, this country extends 700 miles in length by 500 in breadth, forming an area of 45,000 square miles. Portugal, afterwards to be mentioned, lies like a patch on the side of the Peninsula, facing the Atlantic. Spain, proper, is divided naturally into two unequal compartments, one of which includes the central region, and the other that of the coast. Spain is essentially mountainous. It consists chiefly of extensive plains traversed by lofty ridges, towering to a height of from eighteen hundred to two thousand feet. There are comparatively few trees in the country, and the air being dry, the number of rivers is not great. The principal are the Ebro, Duoro, Tagus, Guadiana, and Guadalquivir; but from the bad system of things, they are not put to their full uses for navigation and trade. In the lower parts of Spain, particularly on the coast, the climate is delightful, but in the high central plains the heat is as intense in summer as the cold is piercing in winter. The productions of Spain are rich and various. Iron, tin, copper, quicksilver, and indeed every valuable mineral, abound in the Peninsula. There are also a number of coal and salt mines. Wheat of the finest quality is produced in most of the provinces. The other principal productions of the soil are oats, barley, maize, rice, oil, honey, sugar, hemp, flax, cork, cotton, silk, and barilla; the wool, as is well known, is of a very superior quality. There are many fine fruits grown, as figs, oranges, pomegranates, lemons, &c. Among the animal productions, the horse of Andalusia, a province on the Mediterranean, opposite Africa, is esteemed among the finest in the world. The sheep are millions in number. The sea-coasts supply abundance of fish. In a word, nature seems to have exhausted her bounty on this favoured land; and had not ungrateful man laboured but with too successful perversity to counteract her beneficence, Spain, instead of being the poorest and most degraded, would now be the richest, happiest, and most prosperous country in Europe.

About the beginning of the present century, the population of Spain amounted to 10,409,879 individuals, among whom were the following classes:—Beginning with the religious bodies, there were 140,242 clergy and monks, and 32,000 nuns, exclusive of about a fourth of the population living on their property without doing any thing; there were 100,000 individuals existing as smugglers, robbers, pirates, and assassins, escaped from prisons and garrisons; about 40,000 officials appointed to capture these, and having an understanding with them; nearly 300,000 servants, of whom more than 100,000 were unemployed and left to their shifts; 60,000 students, most of whom begged, or rather extorted charity at night; and if to this melancholy list we add 100,000 beggars, fed at the doors of monasteries and convents, we shall find that there existed in Spain nearly 860,000 persons who were of no use in agriculture or the mechanical arts, and who were only calculated to prove dangerous to society. Having made these, we find there then remained 964,571 day-labourers, 917,197 peasants, 310,739 artizans and manufacturers, and 34,339 merchants, to sustain by their exertions upwards of ten millions of inhabitants. These results, which are as applicable at the present day, when the population has increased to about 14,000,000, as at the time when they were deduced, exhibit a state of society so radically corrupt and debased, as to render all hopes of its regeneration very nearly desperate. Lately, on the death of Ferdinand, the reigning monarch, the queen, in the capacity of regent, made a powerful attempt to establish constitutional government, which is the first step towards practical reform of abuses; but as yet little has been done by the Cortes, or estates, to put the affairs of the kingdom on a steady and prosperous footing.

Portugal, which lies on the western frontier of Spain, facing the Atlantic, and measures 41,500 square miles in extent, is an ancient small kingdom, intimately resembling Spain in almost every particular, and at present in much the same unsettled condition. The country possesses two fine rivers, the Duoro, which forms the great maritime emporium of Oporto, and the Tagus, which is that of Lisbon. Portugal is rich in natural productions, but wants the cultivation of industrious hands. The rich mines of precious metals are now neglected on account of want of hands and fuel. The chief source of profit is in the fruits, which are exported in abundance, particularly the orange and grape. Wines of several sorts, both dry and sweet, are produced; the red port wine is exported, but in less quantities than formerly, and chiefly to England. Agriculture, commerce, the arts, every thing, in short, is neglected in Portugal, which in the present day is a miserable poverty-struck country. Like Spain, it is eaten up by clergy, secular and regular, and these classes have moreover rendered at least a third part of the year holidays, greatly to the loss of the nation. The late Don Pedro, father of the present queen Maria, had the address to abolish the monastic institutions, and to sequestrate the property to the state, which was an important measure of national regeneration. The population of Portugal was stated in 1826 at 3,214,000.

ITALY.

Italy, once the seat of universal empire, but which, since the overthrow of the Roman power, has never formed an independent whole, the pride of its inhabitants and the admiration of foreigners, on account of its delicious climate and former renown, is a narrow peninsula, extending from the Alps (46° to 38° N. lat.) into the Mediterranean Sea, which, on the east side of Italy, is called the Adriatic, on the west, the Tuscan Sea. The Appenines, rising near the maritime Alps, are the principal chain of mountains, and stretch through the country, dividing Lombardy from the Genoese territories and Tuscany, and Tuscany from Romagna, intersecting the States of the Church, and running through the kingdom of Naples to the Strait of Messina. Upper Italy (Lombardy) is remarkably well watered. The Po, which receives a great number of rivers from the large lakes at the foot of the Alps (Lago Maggiore, di Lugano, di Como, d'Iseo, and di Garda), and the Adige, are the principal rivers. They both rise in the Alps, and flow into the Adriatic sea. In Middle Italy (Tuscany and the States of the Church) are the Arno and the Tiber, which rise in the Appenines, and flow into the Tuscan Sea. In Lower Italy (Naples) there are no large rivers, on account of the shortness of the course of the streams from the mountains to the sea; the Garigliano is the principal. The climate is warm, without excessive heat, and generally salubrious. The winter, even in Upper Italy, is very mild; in Naples it hardly ever snows. The abundance and excellence of the productions of the soil correspond with the beauty of the climate. In many places both of the north and south, there are two and even three crops a-year. The volcanic character of the coasts of Lower Italy is particularly remarkable in a geological point of view, especially in the region of Puzzuoli and Vesuvius. The neighbouring islands of the Mediterranean are distinguished by the same character. The present number of inhabitants is much inferior to the former population of this delightful country, the total amount being 21,397,600.

The national character of the Italians, naturally cheerful, but always marked by strong passions, has been rendered, by continued oppression, dissembling and selfish. The Italian, moreover, possesses a certain acuteness and versatility, as well as a love of money, which stamp him for a merchant. In the middle ages, Venice, Genoa, Florence, and Pisa, were the chief marts of the European commerce with the East Indies; and Italians (then called Lombards, without distinction, in Germany, France, and England) were scattered all over Europe for the purposes of trade. The discovery of a passage by sea deprived them of the India trade, and the prosperity of those republics declined. The Italian, restricted almost solely to traffic in the productions of his own country, has nevertheless always remained an able and active merchant. Before Rome had (2100 years ago) absorbed all the vital power of Italy, this country was thickly inhabited, and for the most part by civilised nations. In the north of Italy alone, which offered the longest resistance to the Romans, dwelt a barbarous people, the Gauls. Farther south, on the Arno and the Tiber, a number of small tribes, such as the Etrusci, the Samnites, and Latins, endeavoured to find safety by forming confederacies. Less closely united, and often hostile to each other, were the Greek colonies of Lower Italy, called Magna Grecia. The story of the subjection of these nations to the Roman ambition, belongs to the history of Rome. Italy, in the middle ages, was divided into Upper, Middle, and Lower Italy. The first division comprehended all the states situated in the basin of the Po; the second extended between the former and the kingdom of Naples, which formed the third.

Italy is in modern times cut up into a number of distinct states, partly independent with native princes, partly under the rule of Austria, and a portion under the civil sway of the head of the Romish church. Throughout the greater part of this fine country the system of police is wretched, and robbery is exceedingly common; commerce, agriculture, and the useful arts, are in a low condition; bigotry prevails, and the national character is reduced to the lowest moral standard. The most civilised and best governed part of Italy is Tuscany, which differs very materially from the adjacent states. In the present day, Italy is only celebrated for its music, and its collections of works in the fine arts. The following sketch gives a view of the amount of population in the five great divisions into which Italy is partitioned:—

The population of the States of the Church is about 2,000,000. The capital is Rome, the seat of empire of the ancient Romans, but now greatly altered in figure and appearance, and completely changed in character; this venerable city possesses a population of 150,000. The other chief towns are Bologna, with a population of 65,000; Ancona, 30,000; Perugia, 30,000; Ferrara, 24,000; and Ravenna, 24,000. There are other eight towns with a population of from 7000 to 14,000.

The duchy of Tuscany, in 1826, had a population of 1,275,000 inhabitants. The capital of this state is Florence, the population of which amounts to 80,000. The other chief towns are, Leghorn, 66,000; Pisa, 20,000; Sienna, 18,000; Prato, 10,000; Pistira, 9000; Avesso, 7000; and Costona, 5000.

Austrian Italy, or the Lombardo-Venetian kingdom, which consists of the great plain of the Po, is subdivided into the governments of Milan, Venice, Parma, and Modena. The chief towns of the state of Milan are, Milan, 151,000; Brescia, 31,000; Cremona, 26,000; Mantua, 25,000; Pavia, 21,000; Lodi, 18,000; and Como, 7600. The chief towns in the state of Venice are, Venice, 101,000; Verona, 48,000; Padua, 35,000; Vicenza, 19,000; Udina, 18,000; Treviso, 15,000; Bellinno, 8000; and Rovigo, 7000. The state of Parma has the town of Parma, 30,000; Placentia, 28,000; and Guastalla, 5000. The state of Modena possesses the town of Modena, 27,000; Reggio, 18,000; and Mirandola, 6000.

The Sardinian states are composed of Piedmont, Genoa, Savoy, and the island of Sardinia, the whole of these divisions having a population of 3,831,350. The principal town and sea-port in this district is Genoa, which possesses a population of 80,000 inhabitants.

The fifth division of Italy is composed of the states of the kingdom of Naples, or, as it is sometimes called, the Two Sicilies. This forms the southern, and perhaps the finest portion of the Italian peninsula, and branches out into the two smaller peninsulas of Otranto and Calabria. Naples is the chief town, with a population of 354,000 inhabitants, being thus the largest city in Italy. Naples is famed for the beauty of its environs, particularly the bay on which it is situated, and for the exceeding fineness of its climate. Sicily, an island belonging to the kingdom of Naples, measures 180 miles long by 150 in breadth, and is one of the most beautiful islands of Europe. It is chiefly distinguished for its celebrated volcano, Mount Etna. Malta, an islet in the Mediterranean, about fifty-four miles to the south of Sicily, now belongs to the British government.

RUSSIA.

The Russian empire stretches over the half of Europe, and the whole of Northern Asia, from the Baltic to the Pacific, and includes vast territories on the north-western coast of North America. It lies between lat. 38° and 78° N. It is bounded on the north by the northern or Icy Ocean, west by Norway, Sweden, the Baltic Sea, Austria, and Prussia, and south by Turkey, the Black Sea, Persia, the Caspian Sea, Independent Tartary, and China. The total superficial area is estimated at 8,000,000 square miles, of which about 1,500,000 are situated in Europe, and 5,500,000 in Asia. The Russian dominions compose about one-seventh of the habitable globe. The surface of Russia is generally level, and some tracts of land of this flat nature, frequently bleak and barren, are called steppes. The country also possesses chains of lofty mountains in different quarters. Russia raises vast quantities of corn, which it exports; and it produces fruits and wine in abundance. The forest also yields important articles of export. Cattle of all kinds, horses, and sheep, are likewise bred in immense numbers, chiefly for the exportation of their skins. The mines of the country are productive of platina, silver, copper, quicksilver, alum, and salt, all which are continual sources of revenue. Russia possesses various rivers of the first magnitude, and canals are in the course of establishment on a considerable scale.

The population of Russia, including Poland and Finland, is 57,000,000, of nine different races:—1. Sclavonians 44,000,000, including the Russians (42,000,000, among whom are the Cossacks, about 600,000 capable of bearing arms) and the Poles; 2. Finns, who are scattered over the country, from Tornea and the Niemen to the Obi (3,000,000); 3. Tartars, from the Dniester to the Caucasus (2,000,000), mostly under their own government, without agriculture or firearms; 4. Georgians and Circassians (2,000,000); 5. Samoiedes; 6. Mantchoos; 7. Mongols, to whom belong the Calmucks; 8. eastern tribes (including Tchutsches, Kuriles, and Aleutians); 9. Jews, particularly in the Polish provinces. Besides these races, there are natives of almost all countries of Europe and Asia, as Greeks, Arabs, Hindoos, Gypsies, French, English, and Danes. There are among these Russian subjects eighty tribes, differing in language, religion, and manners, from the rudest state of barbarism to the highest degree of European civilisation. The population is divided into four classes, the nobility, clergy, common people or freemen, and peasants or serfs. In 1811, the number of persons subject to do military duty was as follows: 643,135 persons engaged in trade; 6,389,269 crown peasants; 10,113,177 peasants belonging to individuals; 1,077,636, appanage peasants; 112,453 freemen; in all, 18,335,730 men. We find manufactures of leather, tallow, candles, soap, felt, coarse linen, mats of the bark of the linden tree, hardware and the art of dyeing, among the Russians before the time of Peter the Great; but since his reign these have been carried to much greater perfection, and many new manufactures have been introduced. In 1815, Russia contained 3253 manufacturing establishments; twenty-three of these deliver to the government annually cloth of 700,000 roubles in value, and there are, besides, one hundred and eighty-one private establishments. Drugs are prepared in forty-five laboratories; and there are distilleries of brandy, of which 120,000,000 gallons are consumed in the country. Ship-building is carried on in the large villages on the Wolga and in the sea-ports.

The government is an unlimited monarchy; the emperor is autocrat of all the Russias; the state is indivisible; the ruler cannot be, at the same time, ruler of any other country (since 1815, however, he has been king of Poland), and must be of the Greek religion. In 1797, the succession was settled in the male line, by the rules of primogeniture, and, in failure of males, in the female line. All the princes of the blood are called grand-princes. By the ukase of March 20, 1820, it was declared that only the children of a marriage acknowledged by the emperor are capable of succeeding to the throne. The highest councils are, 1. the imperial council, under the presidency of the emperor, erected Jan. 1, 1810, with four departments—that of legislation (the supreme tribunal in civil and ecclesiastical suits), that of war, that of civil and ecclesiastical affairs, and that of finance; 2. the senate, for home affairs (a deliberative body, consisting of eight departments, three of which have their seat in Moscow); 3. the holy synod; 4. the ministry of state. The ministers have a seat and voice in the imperial council and in the senate. The ministry is divided into three sections—that of foreign affairs, war, the marine, the home department, ecclesiastical affairs, education, and finance; that of the imperial treasury; and that of the public accounts, roads and canals, and justice. The whole state is divided into fifty-one governments and several provinces; of these, forty are in Europe, exclusive of the Cossacks of the Don, the Cossacks of the Black Sea, and the kingdom of Poland. The military force of Russia is exceedingly great, yet nothing to excite any dread. By some accounts it is stated as having totally amounted to 670,000 men; but a vast proportion of this force is composed of irregular militia, or armed slaves. It is considered by recent writers on the subject that the utmost amount of regular force which Russia can bring into the field is 150,000 men, infantry, cavalry, and artillery. It is indisputable that Russia has no pecuniary resources to support a large army long in the field, and therefore any fear expressed by European powers on this score is ridiculous. The principal dependence of Russia is upon England, and a quarrel with the British government would most likely lead to a serious commotion in the state. The prevailing religion is that of the Greek church, with a full toleration of all religions. The state of society is a strange mixture of refinement and barbarism. The population is composed of four different classes, as has already been mentioned. The boors or peasants are the property of the crown or of individuals; they amount to about 35,000,000, and are in a state of great poverty. They are sometimes emancipated by their owners, and are sometimes permitted to purchase their freedom. The noble families are about 150,000, comprising 750,000 individuals, and enjoy some privileges and exemptions. The freemen, not nobles nor clergymen, are divided into six classes—the inhabitants of cities, the three guilds (capitalists, according to their income tax), the trades, foreigners or strangers, the notable citizens (savans, artists, bankers), and the colonists. In regard to rank, these classes form fourteen gradations; and all who can claim either of the eight highest are considered as noble. Distinction of any kind, however, is only gained by the possession of a superior military rank.

Debased as Russia is, it has recently made great advances in civilised usages. Science, literature, and the arts, are highly cultivated and liberally endowed. The Russians, it seems, have not much original genius, but they are the best imitators in the world, and quickly adopt foreign manners, language, and improvements. The wretched system of territorial slavery is gradually disappearing, and the peasants are now more protected by the laws than formerly. The punishment of criminals is also becoming more lenient. Russia possesses a number of towns of from 10,000 to 30,000 inhabitants. Petersburg, the capital, has a population of 425,000, and Moscow 240,000. Petersburg, which is built upon the flat banks of the Neva, is considered to be in appearance the most splendid city in the world.

GERMANY.

Germany is a term of wide and not very definite meaning. It is familiarly applied to a large territory extending from the Baltic Sea on the north, to the Gulf of Venice on the south, having Hungary and Russia on the east, and France and the Netherlands on the west. At its south-west corner it is touched by Switzerland. This immensely large territory occupies the bulk of the centre of Europe, and consists of an area of 250,000 square miles. The most remarkable circumstance about Germany is its being composed of a considerable number of states, each less or more independent within its own bounds, but externally dependent on the other states of the confederation, as is mentioned already under the head Constitutional Governments. Altogether there are thirty-four monarchical states, and five free cities, which enter into a confederation as equal sovereigns. For mutual safety they compose a diet or congress, at which each state has a certain number of votes. The principal states of Germany are Prussia and Austria; Saxony, Bohemia, and Hanover, are of lesser dimensions and importance. The others do not require any notice.

In the days of Roman greatness, Germany, or Germania, as it was then called, was inhabited by a barbarous but powerful people, reckless of control, and ambitious of securing the spoils of richer nations. They broke loose at different periods, overrunning Italy and other fair portions of Europe, and, under the general appellation of Goths, finally prostrated the empire of Rome. The term Goth is now used in a contemptuous sense, but it has to be remarked that modern Europe stands indebted for its liberties to the Goths. The free institutions of Germany were carried into England and other countries, where they have since grown and flourished; and in later times the world has received various useful arts from the same source, in particular the art of printing, which transcends all other inventions. In the tenth century, Otho the Great united the Roman imperial crown (a thing merely so in name) with the German empire, and the great territory we are speaking of was thenceforward called the Holy Roman empire of Germany. This empire lasted till its dissolution in 1806; but long before that era Germany had been broken up into states, by the enterprise of its native dukes and princes, and the name empire was little else than nominal. In 1815, the states entered into the confederation which now binds them.

This large confederated country is watered by 500 rivers, of which the principal are the Rhine, the Danube, the Weser, the Elbe, and the Oder. The most southern chain of German mountains is formed by the Tyrolese Alps, the Alps of Algau, the Camic and Julian Alps, running from east to west. To the south-west are the Carpathian mountains, to the north-west the Bohemian forest. There are also alpine regions on the Upper Rhine. In Northern Germany there are sandy heaths and moors, and many districts contain fertile strips only along the large rivers. On the whole, the soil is fertile, and the climate in general is temperate and healthy. The number of inhabitants is estimated at 34,343,900 in 2390 towns, of which 100 have over 8000 inhabitants; 2340 market villages; 104,000 villages, and numerous small settlements. Of the inhabitants, there were, in 1825, Germans, 27,705,855; persons of Slavonic origin, 5,325,000; Walloons and French, 309,000; Jews, 292,500; Italians, 188,000; Gipsies, 900; and Armenians and Greeks, 900. In the same year, the number of persons of different religious persuasions was as follows:—Roman Catholics, 18,370,300; Protestants, 15,150,500; Jews, 292,500; Greeks and Armenians, 900. It should, however, be stated, that in this enumeration there are in all likelihood many religionists who are altogether unsettled in belief, although ostensibly belonging to some communion; for in no country in the world is there such latitude in thinking upon points of faith. Germany contains 24 universities, which are attended by about 30,000 students—a class of wild young men, having habits and an appearance very different from what usually characterise attendants at colleges in Great Britain. The reading and publishing of books is carried to a great height in Germany, which is essentially literary in its tastes. There are public libraries in 150 places, with about six millions of volumes. Ten thousand authors produce annually from about 3300 to 5000 new books. There are about 100 political journals, 220 other journals, and at least 150 periodical publications. Most of the best English productions are regularly translated and printed in Germany. It is curious that, with all this abundance of literature, and the prevalence of education, with also freedom of religious opinion, Germany is far from being a free country. It is despotically ruled by great or petty sovereigns, has only here and there the mockery of representative government, and the people in the mass are destitute of the power to better their condition. Germany, from which all our freedom sprung, is itself ranked among the least free of the nations of Christendom.

One of the chief of the small German kingdoms is Saxony, lying at the centre of Europe, and consisting principally of the plain of the river Elbe, in its upper part, with a population of 1,400,000 inhabitants. It is rich in agricultural produce, and feeds about a million and a half of sheep, the wool of which is remarkably fine and valuable. Saxony has various flourishing manufactures, linen and woollen goods being the staple. It also carries on a brisk trade with various parts of the world. The grand centre of its commerce, and indeed that of all Germany, is at Leipsic, one of its chief towns. Here annually a great fair is held, which is attended by merchants from all parts of Europe, and at which, in particular, the sale of books is very great. The most elegant town in Saxony is Dresden, situated upon the banks of the Elbe.

Germany possesses four free cities, acting as independent states within their own bounds, and individually entitled to vote in the Germanic diet; namely, Hamburg, Lubeck, Bremen, and Frankfort on the Mayn. The independence of these towns is a remnant of a confederacy of cities which took place in the thirteenth century, and was called the Hanseatic league. Besides these four free cities in Germany, Cracow was likewise declared a free city by the general act of the congress of Vienna, and is under the protection of Russia, Austria, and Prussia. Hamburg, situated upon the Elbe, which flows into the North Sea, is one of the chief commercial and maritime cities of Europe. It possesses a population within its territory of 150,000 inhabitants.

AUSTRIA.

Austria is a monarchy now forming one of the leading powers of Europe, and is usually esteemed the principal of the German states. Only a portion of the territory, however, belongs to Germany. In a general sense, Austria is composed of a large tract of country in the southern part of Europe, immediately north of Italy and European Turkey. Properly speaking, Austria is composed of a number of states conquered and joined together by a series of unprincipled sovereigns, and now, as a whole, ruled by a despotic prince with the title of emperor, as being the head of the Germanic body. The various states which have in this way been added together are what are called Upper and Lower Austria, Bohemia, Moravia, with the alpine regions of Styria, Carinthia, and the Tyrol; several of the Polish provinces, now called Gallicia; the kingdom of Hungary, and the Lombardo-Venetian kingdom in Italy. The whole Austrian monarchy contains more than 256,309 square miles, and upwards of thirty-two millions of inhabitants. Of these it is reckoned that there are twenty-two millions of Roman Catholics, three millions of the Greek church, two millions of Protestants, and half a million of Jews. The military force of the monarchy in 1819 amounted to 270,000 men, independent of militia. Austria numbers 777 cities, 2224 market towns, and 69,105 villages. The most populous cities are Vienna, Milan, Venice, Lemberg, and Padua. The principal sea-ports are Trieste, Venice, and Fiume; other places of trade are Vienna, Prague, Pest, Lemberg, Brody, and Gratz. The bank of Vienna affords the most important support to the commercial interests of the state.

PRUSSIA.

Prussia is one of the most remarkable kingdoms in Europe. It has risen from nothing at the beginning of last century to be one of the principal continental nations. The increase of its size from its original dimensions, as the duchy of Brandenburg, to the condition of a first-rate kingdom, has been effected by the intrepidity of its people and the military character of its sovereigns, particularly of Frederick II., or the Great. Prussia, as now constituted, lies in the northern quarter of Europe, with the Baltic Sea on the north, and Russia on the east. It comprises the districts or provinces of East and West Prussia, Posen, Pomerania, Brandenburg, Silesia, Westphalia, and the Rhenish provinces; which divisions include the portion of Poland which was taken by Prussia at the partition of that unfortunate kingdom. In 1827, the aggregate extent of these territories amounted to 106,852 square miles, with a population of 12,605,078, upwards of ten millions of which inhabitants were Germans. Prussia is considered to be greatly weakened as a power by its large scattered extent of territory. The kingdom has three vulnerable parts, towards Russia, Austria, and France; hence its situation is dependent. It is compelled to keep up a large military force, which in 1829 amounted to 165,000 regular troops. The king of Prussia is an absolute monarch, yet he is surrounded by a spirit of freedom, which necessarily influences his actions. One of the most striking features of this monarchy is the care which it bestows on science and education. The sciences are nowhere fostered with more care, and there are few countries in which common schools are more widely diffused.—See our article History and Present State of Education. Prussia carries on some maritime trade by means of the Baltic, and its inland trade is promoted by the rivers Oder, Vistula, Elbe, and Saale, the Rhine, Memel, Pregel, Warta, Netze, Hanel, Spree, Weser, Moselle, &c., which either flow through Prussia or belong to it. See article COMMERCE AND MANUFACTURES. Most of the inhabitants of Prussia are of the reformed churches.

SWITZERLAND.

Switzerland is a mountainous territory, occupying the alpine regions betwixt France and Germany, and having Italy on the south. This beautiful and romantic country has, from time immemorial, been inhabited by a hardy and independent race of inhabitants, mostly attached to republican forms of government, and always ready to defend their rights and their country from the aggression of the great powers in the neighbourhood. Switzerland measures about 300 miles in length by 140 in breadth, and is supposed to contain 19,000 square miles. Politically, the country is divided into twenty-two small states or cantons, generally independent of each other, but confederated for purposes of mutual protection. Some states are more free in their forms of government than others. The total population amounted, in 1827, to 2,037,030 persons, of which upwards of one-half were Protestants, and the remainder chiefly Roman Catholics and Jews. The German language is most commonly used. Geneva is the smallest but most populous state in proportion to its size, and in this canton is situated the town of Geneva, upon a beautiful lake of about fifty miles in length and eight or ten in breadth. The highest mountains of Switzerland are found in the cantons of Uri, Berne, Underwalden, and Grisons. Of about sixty Swiss mountains which have been measured, the highest is Monte Rosa, 15,535 feet high; the lowest, Chalet, is 3000 feet high. Mont Blanc, within the limits of Savoy, is the highest mountain in Europe, being 15,668 feet high. The mountains of Switzerland are pastoral in their lower parts, and often covered with snow at their summits. The glaciers, more than 400 in number, are either the barren parts of the mountains, or heights which consist only of snow and ice. The continual alternation of hill and dale affords the most striking natural scenes in every part of Switzerland. In some places, within a short distance, one may see at the same time all the seasons of the year; and it is often possible to stand between spring and summer, so as to collect snow with one hand, and to pluck flowers from the soil with the other. Every mountain has its waterfalls; and as their sources are sometimes lost in the clouds, the cataracts seem to descend from the skies. Switzerland abounds in lakes and rivers, the fisheries of which are valuable, and which serve to embellish the landscape; but none of the rivers are navigable. Small steam-vessels now ply on the lake of Geneva, and are a great convenience to travellers. The chief rivers are the Rhine, the Reuss, the Rhone, and the Tesino. The cultivation of the vine is carried on to a considerable extent in Switzerland; the breeding of cattle is, however, the chief employment of the inhabitants. Swiss cheeses are imported in great numbers into Germany, France, and Italy. Manufactures of silk, cotton, and linen, have of late years greatly increased in Switzerland, which is rivalling England in some kinds of goods, particularly printed calicos. Recently great improvements have been made upon the roads through this attractive territory, and travellers are now well accommodated on all the main routes.

NORWAY, SWEDEN, AND DENMARK.

These, with the province of Finland, form the north-western frontier of Europe facing the North Sea or German Ocean, and reaching to the shore of the Baltic on the south. Norway lies on the shore of the North Sea, Sweden is behind it with its southern extremity to the Baltic, and Denmark is formed by the peninsula of Jutland projected northwards from the Netherlands and kingdom of Hanover into the mouth of the Baltic. Norway and Sweden are now erected into a kingdom, under one sovereign, much in the same manner as England and Scotland are united. Bernadotte, one of Bonaparte's commanders, has for a number of years been the reigning monarch. The united kingdom measures 1550 miles in length by about 350 in breadth. The country is mostly mountainous and pastoral, and covered with dense forests, producing the finest timber in the world. The climate is dry and cold, but that of Sweden is warmer than that of Norway. The mineral kingdom is rich, particularly those of iron, copper, and silver. The inhabitants of these countries are of the ancient Scandinavian races; hardy, honest, industrious, and kind-hearted. In the sciences, the Swedes have shown a sound and penetrating mind. The two kingdoms, Norway and Sweden, had, in 1825, a population of nearly four millions of inhabitants. Stockholm, the capital, had a population of nearly 80,000; Gottenburg, the principal commercial city, had 24,000; Christiana, the capital of the Norwegian division, had 20,000; and Bergen, the chief commercial city in Norway, 20,800. Few towns, however, number more than 4000 inhabitants, and many have scarcely 500.

The Danish monarchy is composed of the peninsula already mentioned, with some islands and detached portions. The principal of the attached territories are the duchies of Holstein and Lauenburg; likewise the Feroe Islands, in the North Sea; Iceland; the western coast of Greenland; some places in Guinea; and the city and territory of Tranquebar, in the East Indies. The exact measurement of so scattered a territory is of little moment; and it is sufficient to state, that Denmark proper and the duchy of Sleswick contain 17,375 square miles. Denmark proper is estimated to contain 1,230,000 inhabitants; Holstein and Lauenburg, 370,000; and the total population under the monarchy amounts to something under two millions. The people are partly Danes and partly Germans. Denmark is a level country. The coasts are low, and protected from the sea by dykes. The soil consists partly of marshes and heaths, and is on the whole but moderately fruitful. By the improvident extirpation of the woods, which protected the north and north-western coasts of Jutland against the sea, vast extents of fruitful territory have become barren and sandy deserts. The staple productions are grain, rapeseed, and tobacco; and the breeding of cattle forms a principal source of profit. Denmark now contains, without including Iceland and the Feroe Islands, 100 cities, 73 boroughs, 2305 parishes, and 5500 villages. The government is an absolute monarchy. Copenhagen, situated on the east coast of the island of Zealand, is the capital, and contains a population of 105,000 inhabitants.

HOLLAND AND BELGIUM.

These countries, under the general appellation of Netherlands, occupy a large flat territory stretching southward from the confines of Denmark on the north, to France on the south; having Prussia and the small kingdom of Hanover on the east, and the North Sea or German Ocean on the west. They therefore form that part of the continent of Europe which lies opposite the east coasts of Scotland and England. The entire extent of the Netherlands amounts to 24,870 square miles. Through the centre, from east to west, flows the Rhine, one of the finest rivers in Europe, and which parts into a number of channels before pouring its waters into the ocean. On the lower part of one of these channels stands Rotterdam, a large and flourishing commercial city. The surface of the Netherlands is flat, and rich in the luxuriance of vegetation. So low is the land that it has to be protected from the sea by dykes or embankments. The country is every where intersected with canals, which are of prodigious use for commercial and general intercourse. Locally, the Netherlands are divided into a number of districts, among which the old Flemish or Flanders provinces find a place. The whole territory is nearly equally divided into the two distinct states of Holland and Belgium. Except in respect of geographical resemblance, these states, till lately united, are totally dissimilar in character. Holland is inhabited by the Dutch, who are an exceedingly industrious, quiet, honest, and painstaking people. Belgium is peopled by a race who, except in particular districts, are neither industrious, honest, nor orderly. The Dutch are Protestants; the Belgians are Roman Catholics, and deplorably sunk in bigotry. Never was there so preposterous an attempt made as that which was intended to cement these opposite races of inhabitants. As elsewhere mentioned, the Netherlands were disjoined by the revolution of 1830, and now form independent kingdoms. In 1810, the total population of the Netherlands amounted to 5,401,945, being 2,476,159 for the northern provinces, or Holland; 3,249,841 for Belgium; and 225,045 for the duchy of Luxembourg. Some of the largest towns on the Continent are situated in these low countries; the principal in Holland are Rotterdam, with a population of 63,033; Amsterdam, 201,000; Hague, 45,144; Middleburg, 20,800; Utrecht, 34,087; Leyden, 29,045; besides a number of towns with from six to twenty thousand inhabitants. In Belgium the chief cities are Brussels, the capital, population 72,800; Antwerp, 65,000; Ghent, 81,941; Bruges, 36,000; Mons, 18,400; Liege, 45,300; besides several with from three to ten thousand inhabitants.

TURKEY.

Turkey is a territory partly in Europe and partly in Asia, and is inhabited by an Asiatic-Tartar race called Turks, who in the year 1453 conquered that portion lying within the confines of Europe, formerly the metropolitan part of the western empire of the Romans, and have there ever since, at Constantinople, held a barbarous sway of this beautiful district of Europe. Turkey in Europe is separated on the south-west from Asia only by a long range of straits called the Dardanelles, and by the Black Sea, and is bounded on the northern side by the dominions of Austria and Russia. On the west it has the Adriatic Sea, which in part separates it from Greece, till lately a portion of itself. The Turkish monarchy nominally possesses Egypt and some other possessions in Africa; but, not computing these distant territories, it may be estimated that Turkey in the present day measures in Europe 176,928 square miles (but including the insecure provinces of Moldavia, Wallachia, and Servia), with a population of upwards of nine millions of inhabitants; and in Asia 425,000 square miles, with a population of above ten millions. The bulk of the population in both regions is Mahommedan, and uncivilised. The climate of Turkey is among the most delicious in the world; its soil is generally productive, and its natural appearance is beautiful. Constantinople, situated on the Dardanelles, is a large and populous, though crowded and inconvenient city, excellently situated for trade, communications being carried on with it by the Mediterranean on the west, and the Black Sea on the east. Every region in Turkey yields its productions in abundance. The staple articles of export are wheat, rice, cotton, tobacco, silk, figs, and other fruits; hair, wool, and opium. Mining is totally neglected; and there is in general little manufacturing industry in the country. The inhabitants are at once extremely ignorant, proud, and slothful, and the commerce carried on is chiefly in the hands of Jews and Christians. The spread of knowledge is sedulously prevented; printing, till lately, was carried on only by Armenians, Jews, or Greeks; and transcribing books with the pen is pursued as a common employment. Painting and sculpture are neglected, because the Koran, or Bible of the Mahommedans, forbids the imitation of the human form. A great effort has lately been made by the sultan or reigning monarch to introduce some civilised usages, and among other improvements he has established a newspaper at Constantinople, in French and Turkish. The sultan padishah, as caliph, or successor of Mahommed, enjoys the character of Pope to the Mahommedan world, and unites the highest spiritual dignity with the supreme secular power. He has unlimited control over the property and lives of his subjects, especially of the highest officers of state, whom he can remove or put to death at will. They kiss the bowstring which he sends them, and it is what they may all look forward to. The sultan makes laws without being himself subject to them. The Koran and the fear of public opinion, when it speaks by the voice of rebellion, alone restrain his will. All his subjects are equal in his eyes, for they are all slaves. The people have no rights. Merit, or favour, or intrigue, can raise the lowest to the highest stations. There is no hereditary nobility. The succession to the throne is hereditary in the family of Osman; the will of the people and of the janissaries has often decided upon the individual. On the extinction of the male posterity of Osman, the right to the throne passes into the family of the former Tartar khan. Women are excluded from the succession. The padishah is not crowned; he is merely girded with the sword of Osman, after he has sworn to uphold the religion of Mahommed. The women of his harem are for the most part Circassians or Georgians. Since Ibrahim, the sultans have been accustomed to choose from among them seven wives. She who first bears a son is called *chakessi sultana*; the other mothers of the princes have the name of *sultona chassecki*. The mother of the reigning sultan enjoys great privileges. She is not confined in the apartments of the Eski seraglio, and has a yearly pension of 600,000 piasters. The princes are usually brought up in confinement among the eunuchs and women. Each learns a mechanic art or handicraft, but they never acquire the knowledge which would fit them to rule. They have no prospect but the throne or death in prison. The daughters of the sultan have the title of *sultana*, and, while yet in the cradle, are married to viziers, pachas, and other great officers; but their male posterity, by a law of the empire, are condemned to death from their birth.

The court establishment, with all the eunuchs, women, guards, &c., includes 10,000 persons. The external court consists of the attendants of the grand master of the seraglio, seven chamberlains, the court officers, a body-guard of about 2000 men, the confidants or titular dignitaries, to which class belong the mutes, the dwarfs, the musicians, the masters of audience, the masters of the stirrup, and the viziers of the shoulder. The inner court establishment consists of the harem, with its women, white and black eunuchs (whose chiefs, the kislar and capi aga, possess great influence), the grand vizier, and the sublime porte, which form the two cabinets of the Kiaga Beg, or Minister of the Interior, and of the Reis Effendi, or Minister of Foreign Affairs. The title of the present padishah is "Sultan, son of a sultan, Chakan, son of a chakan, sultan Mahmoud II., khan, son of the victorious Abd-ul-Hamid, by the infinite grace of the Creator of the world and the eternal Being, and through the mediation and great miracles of Mahommed Mustepha, the greatest of prophets, upon whom rest the blessing of God, servant and master of the cities of Mecca, Medina, and Kods (Jerusalem), towards which all men turn their faces when they pray, padishah of the three great cities of Istambul, Edreneh (Adrianople), and Bursa, which all princes regard with envy," &c. The arms assumed by Mahmoud II., after the conquest of Constantinople, are a silver crescent in a green shield. Selim III., in 1790, after Nelson's victory of the Nile, founded the order of the crescent, in three classes, for Franks, which has been conferred on Nelson, Sebastiani, and other foreigners. The administration of government is also Oriental. The grand vizier rules in the name of the sultan, or in his absence, the caimachan. The intrigues of the women and the eunuchs in the seraglio have also much influence. The supreme council of state, the divan, is held in the second hall of the seraglio, under the presidency of the grand vizier.

The source of all civil, political, and criminal law, is the Koran. In addition to the code of laws, the interpretations of the ulema have great weight in the tribunals. The mufti is not only the chief of the priests, but the highest interpreter of the laws. His decisions (fetvas) are collected. The highest tribunal, the divan chaneh, is held four times a-week by the grand vizier in his palace, or in his absence by the tchaush-baschi. In the lower tribunals of the large cities, the mollas sit; in those of small towns, the cadis. The moslems are, under them, the executors of the sentences. The administration of justice is as simple as it is prompt and energetic. The common punishments are the bastinado, hanging, drowning, strangling, and impaling. Bearing false witness is the greatest crime. At the head of the church stands the sultan, as caliph, and in his name the mufti, who is appointed and deposed by the grand seignior. In the larger cities, the mufti appoints under muftis.

The land forces were until recently organised on a miserable Asiatic system, and amounted, according to Marsigli, to 220,000 men; of whom 74,000 were mercenaries, 59,000 infantry, topshis, or artillery, and others, and 15,000 cavalry. There were, besides, in time of war, the bands of feudal vassals, amounting to 126,000 men; the contingent of the Tartars, 12,000; and that of the Moldavians and Wallachians, 8000. The grand vizier is commander-in-chief; the separate corps are commanded by agas, the provincial troops by pachas and sangiacs. The present sultan, with more success than Selim III., has begun, since 1814, to form an army on the European plan; and, in the year 1826, dissolved the body of janissaries throughout the kingdom. Selim III. formed a mathematical school for the officers of the navy, which consists of ten ships of the line, twenty frigates, and thirty smaller ships, commanded by the capudan pacha.

GREECE.

The north-eastern part of the Mediterranean is divided into two large bays or gulfs, which run far up into the European continent; that towards the west being called the Adriatic, and the other the Egean Sea. The peninsula, or tongue of land which lies between the two, is the original country of the Greeks; colonies of the same nation have, from time beyond the reach of history, occupied the whole coasts and islands of both these gulfs, from Sicily almost to Cyprus; but the parent states of the middle peninsula are those to which the Grecian name is indebted for all its splendour; and it is this country only which is properly called Greece. From the situation of the Greeks in a region whose bays, headlands, and islands, present a great extent of sea-coast, habits of adventure and mutual intercourse were produced among them in the earliest times, which had the greatest influence in cherishing a national activity of character, and making each community eager to rival the prosperity of the others. The people were early accustomed to make voyages, sometimes for traffic, sometimes for war, betwixt the opposite coast of their gulfs, guiding themselves by the stars from island to island. The early period of Grecian history, it is presumed, is already in some measure known to the reader. The country with its already much debased inhabitants was latterly conquered by the Turks, from whom it was in part only recently wrested by a skilful rebellion or revolution. In the present day, Greece comprises in its northern parts the districts of Albania and Macedonia; next, in a southerly direction, Epirus and Thessaly; the Morea (anciently Peloponnesus) is an island-like peninsula, almost cut off from the latter divisions by a strait called the Gulf of Lepanto. Altogether, modern Greece measures about 400 miles in length, and little more than 100 in general breadth. Greece is a mountainous and romantic region, with several beautiful rivers. Its agriculture is in a very rude condition, but its commerce is increasing; and the long-exhausted nation is gradually assuming a settled powerful character. A constitutional monarchy, not very well organised, has been imposed on the newly erected nation by the European powers. The population of the continental part of Greece is stated at three millions, and nearly half a million for the islands adjacent.

ASIA.

Asia—the cradle of the human race, of nations, religions, and states; of languages, arts, and sciences; rich in natural gifts and historical remembrances; the theatre of human activity in ancient times, and still exhibiting, in many places, the characteristic traits which distinguished it many centuries since—forms the eastern and northern part of the old world, and is separated from Australia by the Indian and the Pacific Oceans, including the Gulfs of Bengal, Siam, and Tonquin; from America, on the north-east, by Behring's Straits, and on the east by the great Eastern or Pacific Ocean, including the Gulf of Corea, the Seas of Japan, Tongou (Yellow Sea), and Okotsk; from Africa by the Arabian Sea (with which is connected the Persian Gulf) and by the Arabian Gulf, or Red Sea, with the Straits of Babelmandel; from Europe by the Sea of Azoph, with the Straits of Caffa, by the Black Sea with the Bosphorus, by the Sea of Marmora and the Dardanelles, and by the Grecian Archipelago. On the other hand, it is united with Africa by the desert Isthmus of Suez, and with Europe by the waters of the Wolga, which rises near the Baltic, and falls with the Ural into the Caspian Sea.

The area of Asia is about 16,175,000 square miles. It extends from 26° to 190° E. lon., and from 2° to 78° N. lat. Its greatest breadth, from north to south, is 4140 miles, and its greatest length about 8000. It is four times larger than Europe. It is divided into 1, Southern Asia, comprehending Natolia, Armenia, Curdistan, Syria, Arabia, Persia, Hindostan, Farther India, Siam, Malacca, Annam, Tonquin, Cochin China, Laos, Cambodia, China, Japan; 2, Middle or Upper Asia, containing Caucasus, Tartary, Bucharia, Mongolia, Tungusia; 3, Northern or Russian Asia, from 44° N. lat., containing Kasan, Astrachan, Orenburgh, Kuban, Kabarda, Georgia, Imireta, Siberia, with the Alpine regions of Dauria and Kamschatka. The centre of this continent, probably the oldest ridge of land on the earth, is called Upper Asia. Here the Bogdo (the majestic summit of the Altai) forms the central point of all the mountains of Asia. Upper Asia comprises perhaps the most elevated plain on the surface of the earth—the desert of Kobi, or Shamo, on the northern frontiers of China, 400 leagues long, and 100 leagues broad; barren, dry, and waste; visited alternately by scorching winds and chilling storms, even in summer, and affording, besides its deserts, only rivers and lakes; as the Caspian, the Lakes Aral and Baikal, and several situated among the mountains. From the northern and southern declivities of this region, the first tribes of man set out in all directions, following the course of the rivers in four chief lines of descent (north, east, south, and west). Nature has spread over Asia all the treasures of the earth, most abundantly in India; her bounties are distributed, by imperceptible gradations, through all its three zones. In the torrid zone, whose genial warmth converts the juices of plants to spices, balsams, sugar, and coffee, with which Asia has enriched the West Indies, the palms (sago, cocoa, date, and umbrella-palms) reach a height of 200 feet, and the white elephant attains a size surpassing that of all other quadrupeds. From hence the silk-worm was brought to Europe. This region conceals in its bosom the most beautiful diamonds, the finest gold, the best tin, &c., whilst the waves flow over the purest pearls and corals. The temperate zone has given to Europe the melon, the vine, the orange, and many of its most agreeable garden fruits, as well as the most productive farinaceous grasses, and the most charming flowers; and unites, in its productions, symmetry with richness, particularly in the western regions. Here the oldest traditions place Paradise; here lie the enchanting Cashmere and the Garden of Damascus; here blossoms the rose of Jericho, near the cedars of Lebanon. The eastern countries in the same latitude possess the tea-shrub and the genuine rhubarb. The camel, the Angora goat, the Thibetan sheep, the pheasant, and the horse, are natives of this zone. In the north blossoms the Alpine *flora* of Dauria, and from the icy soil grows the dwarf-like Siberian cedar, till, at 70°, vegetation mostly ceases. Here lives the smallest of quadrupeds—the shrew-mouse of the Yenisey. Sables, ermines, foxes, otters, &c. afford the finest fur. The mineral kingdom furnishes rich ores, rare precious stones, and remarkable fossil remains of the mammoth, in high northern latitudes.

The inhabitants (amounting to 300,000,000; according to some, to 580,000,000) are divided into three great branches:—The Tartar-Caucasian, in Western Asia, exhibits the finest features of our race in the Circassian form; the Mongolian race is spread through Eastern Asia; the Malay in Southern Asia and the islands. The north is inhabited by the Samoiedes, Tchooktches, and others. Twenty-four tribes, of different language and origin, may be distinguished, some of which are the relics of scattered tribes of Nomades: Kamtschadales, Ostiacs, Samoiedes, Koriacks, Kurilians, Aleutians, Coreans, Mongols, and Kalmucks, Mantchoos (Tungoos, Daurians, and Mantchoos Proper), Finns, Circassians, Georgians, Greeks, Syrians and Armenians, Tartars and Turks, Persians and Afghans, Thibetans, Hindoos, Siamese, Malays, Annamites (in Cochin China and Tonquin), Birmese, Chinese and Japanese, besides the indigenous inhabitants of the East Indian islands, Jews and Europeans. The principal languages are the Arabian, Persian, Armenian, Turkish, Tartar, Hindoo, Malayan, Moogol, Mantchoo, Chinese, and Sanscrit. All the forms of society are displayed in the existing Asiatic nations, from the savage state of the wandering hordes to the most effeminate luxury; but liberty founded on law and the moral and intellectual education of man, is wanting. Priests and conquerors have long decided the political character of the East, amidst frequent revolutions and changes of dynasties, ever maintaining the principles of blind obedience. Asia has been subject, at different times, to the Assyrians, Medes, Chaldeans, Persians, Greeks, Syrians, Parthians, Arabians, Mongols, Tartars, Seljooks, Turks, Afghans, &c. Ancient forms are preserved most rigidly, and the intellect is least progressive in China and Japan. Slavery still prevails in this continent. Woman yet remains degraded to a slave of man.

The prevailing government in Asia is despotism. Hence those artificial forms of a rigid etiquette which are kept up in all the public relations, and that apathy of the people, in regard to fate, connected with cruelty, and produced partly by opium, partly by superstition, which is almost an universal characteristic of the Asiatics, notwithstanding the violence of their passions. There are, however, some tribes with a republican form of government; and relics of the patriarchal authority of the heads of families still are found. Near the colonies of the Europeans in Southern and Northern Asia, the civilisation of the Christian world has been introduced. The astronomy and astrology, poetry, morals, theology, laws, and the rude empirical medicine of the Asiatics, are mostly confined to the priests, and united with deeply-rooted superstition, which leads even to child-murder and self-sacrifice in the flames. The Mahommedan religion, the central point for instruction in which is at Samarcand, prevails in Western Asia. Over all Central and the Eastern part of Northern Asia, prevails the religion of the Lama. The religion of Brama, the head-quarters of which is Benares, is confined chiefly to Hindostan, and Shamanism, to the tribes in Northern Asia, and to the Russian Archipelago. The ancient doctrine of Zoroaster is confined to single families in India and Persia; whilst the Mosaic has numerous adherents through all Asia, except the Russian part. Physical and mechanical cultivation is carried to a higher degree of perfection than intellectual and moral; namely, by the Indian jugglers and Chinese mechanics. Remarkable skill has been acquired by certain classes of Hindoos in the weaving of silk and cotton. The shawls of Cashmere, the leather of Persia and Syria (morocco, cordovan, shagreen), the porcelain of China and Japan, the steel of Turkish Asia, the lackered wares of China and Japan, &c. are well known. The internal commerce is still carried on by caravans, as in the most ancient times, before Abraham and Moses, when merchandise was transported from India, through Bactria, to Colchis, as at present to Makariev, Moscow, and Constantinople.

The religious, civil, and social condition of the Asiatics, proves, that, where the free developement of the higher powers of man is subject to the restraints of castes, and to the tyranny of priests and despots, and where the adherence to established forms has become a matter of faith, law, and habit, the character of society must degenerate, and the energies of man become palsied. Hence the Asiatic, notwithstanding the richness of his imagination, never attained the conception of ideal beauty, like the free Greek; and, for the same reason, the European, whose mental improvement and social activity have been unimpeded, has shaken off the control which the East formerly exercised over the West, and has obtained dominion over the coasts and territories of his old lord and master. Greece led the way, and, after having transformed the obscure symbols of the East to shapes of ideal beauty, shook off the spiritual fetters of priests and oracles, and, at the same time, the temporal yoke which the Persian Darius had prepared for Athens and Sparta. After a struggle of fifty years, the triumphs of Cimon (in 449 B. C.) first enabled Europe to prescribe laws to the East. Grecian civilisation then spread over the whole of Western Asia, to India, and even the military despotism which succeeded has not been able to extinguish the light entirely. In later times, the Romans and Parthians fought for the possession of the Euphrates, and the Persians, under the Sassanides, attempted to tear the dominion of the world from the hands of Rome. Since that period, Asia has four times taken up arms against Europe. The nations of Upper Asia, driven from the frontiers of China to the Irtish, crowded upon the West. Huns, Avari, Bulgarians, and Magyars, successively issued from the Caucasian gates, and from the wildernesses of the Ural, to subdue Europe; besides those later hordes, which were mingled and confounded with each other in Southern Russia and on the Danube. But the rude power of Attila and of the grandsons of Arpat was broken in conflict with the Germans.

Next, the Arabians attacked Constantinople, Italy, and France, but their fanatical impetuosity was checked by Charles Martel, in 732, and the chivalrous valour of the Gothic Christians rescued the peninsula within the Pyrenees. The West then armed itself against the East, to recover the holy sepulchre from the sultan of the Seljooks, and Christian Europe became better acquainted with Asia; but the sword alone cannot conquer a continent. Finally, the Tartars and Ottoman Turks invaded Europe. In 1453, they took the Bosphorus and Greece from the feeble hands of the eastern Romans. In succeeding times, Europe has been defended against Asia, on this side, by Germany. The intellectual progress of the European, since that period, has raised him above the most ancient nations of the East—Persians, Arabians, Indians, and Chinese. Gunpowder, the mariner's compass, and the art of printing (which the last-mentioned nation possessed, but could not apply to much use), have become powerful in his hands. Hence Russia has gained the Wolga, explored Siberia, kept watch over the seat of the ancient and modern Scythians, the mountains of the Altai, and finally conquered the tribes of the Caucasus; whilst (since Vasco da Gama discovered the way by sea to the East Indies, in 1498) the Portuguese, Dutch, and French, and particularly the English, by their universal commerce, have made the rich countries of Southern Asia acquainted with European laws, and Europe with the condition and luxury of those countries. Persia is already entangled in the European international policy, which is principally owing to the efforts of Sir Harford Jones, Sir Gore Ouseley, Mr James Morier, and the Russian general Yermaloff. The diplomacy of the court of China, now more than ten centuries old, still resists European encroachments. Japan alone yet denies all approach to Europeans; and her jealousy is as effective as the polar ice which blocks up the passages of the frozen seas. The most interesting country of Asia, PALESTINE, or the Holy Land, as it is termed by Christians, is described at length in the present work; and here also will be found accounts of CHINA and the EAST INDIES.

AFRICA.

Africa, one of the five divisions of the globe, mentioned in history thousands of years ago, is still to us what it was to the ancients—the land of mystery. Only a small extent of sea, namely, the Mediterranean, separates Africa from Europe; its coasts lie in sight of the most civilised countries, and yet we know nothing more than its outlines; into the interior the foot of a European has lately, for the first time, penetrated. Whether the Africans are descended from a negro Adam, or whether a descendant of Noah conducted thither from Asia its first inhabitants, who received their black complexion from the fierce heat of the African sun, is a problem which can never be solved. Under the same name which it now bears, the valley of the Nile was, in the earliest ages of history, the cradle of commerce, the arts, and sciences. But even in the period of Egypt's greatest prosperity, deep night seems to have enveloped the surrounding countries, which were called Negroland. Subsequently, the Greeks and Romans became better acquainted with the Mediterranean coast of Africa, and penetrated into the interior perhaps as far as the river Joliba; but their knowledge never reached beyond the confines of Numidia, and they were totally ignorant of the southern part of Africa. How vague was the conception which Ptolemy himself formed of this portion of the earth, though it appeared to him a large peninsula! Its outlines were not determined till the fifteenth century. Henry, the navigator, sailed round the formidable Cape Non (*non plus ultra*), Dias and Vasco de Gama discovered the Cape of Good Hope, and both the western and eastern coasts were examined by European navigators.

Africa is a vast peninsula, forming a triangle, with its vertex towards the south, containing 12,256,000 square miles; situated between 18° W. and 51° E. lon., and from 34° S. to 37° 30′ N. lat.; bounded on the north by the Mediterranean, on the east by Asia, the Red Sea, and Indian Ocean, and on the south and west by the Southern and Atlantic Oceans. It has a great breadth from east to west. The northern portion is much larger than the southern; the greatest breadth, from west to east, from Cape Negro to Cape Guardafui, is 69°. Under the equator, the breadth is 4500 geographical miles. The internal structure of Africa is marked by many peculiarities. It possesses immense chains of mountains, extending, perhaps, from the Cape of Good Hope to the Mediterranean, in many parallel ranges. Such are the Atlas mountains, the mountains of the Moon, of Kong, and Lupata; those of the Cape, 5000 feet high, and covered with continual snows; but, on the whole, it is more level than any other quarter of the globe. In none other do we find such boundless deserts; and the Cobi, in the centre of Asia, is not to be compared with the Sahara. These deserts appear like oceans of sand, by no means destitute of fertile islands. These islands are the Oases, peculiar to Africa.

Among the mighty streams of Africa, we can now follow the Egyptian Nile to its sources. The courses of the other great rivers have not yet been satisfactorily explored. We know, indeed, where the Congo or Zaire, Coanza, and Cuama or Zambeze, terminate, but not where they rise. The Joliba (the Niger of Herodotus), Mungo Park has informed us, flows from west to east. The Senegal, the Gambia, and the Orange, are also important rivers. Africa contains several large lakes, such as the Dembea, Wangara, Maravi, Tschad, and Aquilunda. The climate is various, but in general extremely hot. In the lifeless atmosphere of the tropics, which have but two seasons, the wet and the dry, the heat of the sun is terrible; and Adanson tells of eggs being roasted in the sands of Guinea, and the naked feet of the negroes blistered. On the coasts, the heat is mitigated by the breezes from the sea and the mountains, and by incessant rains; but the atmosphere is not so healthy and pure as in the interior, which has a higher elevation. The whole tract of Barbary is warmer than the more southerly regions, and all Africa, compared with Europe, is a hot country. Of its winds, the dry parching harmattan is peculiar to Africa; it has the simoom in common with Asia, and the sirocco with Europe.

To the naturalist, this wonderful country seems the first favourite of nature, as far as it respects the riches of the organic world, and the number of giant forms of animals and plants. It can enumerate five times as many species of quadrupeds as Asia, and three times as many as all America. It excels Asia in the size of its colossal river-horse (hippopotamus), gigantic giraffe, and large antelopes and apes. That giant of birds, the ostrich, is exclusively indigenous to Africa. But the most beneficent gift of nature to the African is the camel, the constitution of which is in every respect adapted to the country and climate. Among the other animals are the elephant and rhinoceros, the lion, panther, leopard, ounce, jackal, hyæna, wolf, fox, dog, cat, mongus, bat, rat, marmot (*cavia capensis*), hare, rabbit, jerboa, porcupine, hedgehog, mole, civet-cat, ichneumon, bear, horse, ass, zebra, sheep (some with hair and large fat tails), argalis (*capra ammon*), goat, innumerable varieties of the gazelle, the buffalo, fallow-deer. In Guinea are found the roe, swine, engalos, babyroussa, and other quadrupeds, whose natural history has been as yet by no means sufficiently investigated; even the problematical unicorn is still said to exist in the interior.

The varieties of birds are equally numerous; among which is the crown-bird, the most beautiful of the feathered tribes; the flamingo, kingfisher, pelican, and many kinds of parrots; the peacock, partridge, pheasant, widow and cardinal-bird; the cuckoo, the cuculus indicator, turtle-doves, pigeons, ducks, geese, &c. The class of reptiles comprises the crocodile and boa-constrictor, with many other serpents, some innoxious, some highly poisonous. The bays and rivers abound in fish, but the variety of the species is not so great as in the northern seas, and many of the most useful are entirely wanting. The shrubs and earth swarm with termites, ants, scolopendras, spiders, and caterpillars, while passing armies of locusts obscure the sun like clouds. The most beautiful insects abound. Still more extraordinary is the force of vegetation. The earth renders back the seed to the cultivator increased a hundred-fold, and produces those immense trees, among which the baobab, or monkey bread-tree, whose crown of branches sometimes forms a circle one hundred and thirty feet in diameter, holds the first rank; the splendid white trunk of the ceiba grows almost perpendicularly from the root to the branches sixty feet, and, with its fine round crown, rises to a height of one hundred and twenty feet.

Our information respecting the mineral kingdom is the most limited. Of gold, Africa has more than any other portion of the globe; and iron is found in most parts of this continent, but it wants the other metals. Of other minerals, it has only saltpetre, sal ammoniac, some fullers' earth, and emery in abundance; ambergris is found on the coasts. The want of salt, except in a few regions, is most severely felt.

The African races of men offer many points of interest to the inquirer. The majority of them are distinguished from the rest of the human family, not only by their black complexion and curly hair, but also by peculiarities in the construction of the bones of the head and even of the nerves. This seems to imply that the negro is originally a distinct race. It is thought that traces of this primitive race may still be detected here and there; for example, of the original Egyptians in the Copts, and of the Guanches (the original inhabitants of the Canaries) in the natives of Barbary. The population is probably between a hundred and a hundred and ten millions. The interior of the country must be very populous, since, within two centuries and a half, it has contributed forty millions of vigorous men to the slave trade, and, notwithstanding, is any thing but depopulated. Even the countries along the coast are thickly peopled. Jackson computed the population of Morocco alone at seventeen millions, and the Barbary states, with Egypt, which constitute but an eighth part of the continent, contain twenty millions. The torrid Guinea has, on the whole, a numerous population; and large cities are situated on the Joliba, of which we hardly know the names. The inhabitants belong to two branches of the human family; to the black or Ethiopian race, which extends from the Joliba to the southern extremity, comprising, notwithstanding their tawny complexions, the Hottentots; and to the Caucasian race, which includes the natives of Barbary, Copts, the Arabs or Moors, the Agaziones or Abyssinians, and the nations of Nubia. The Arabs are not to be regarded as aborigines of Africa, but they have scattered themselves, and become occupants of the greater part of the north and west.

On the islands and some points of the sea-board, we find Portuguese, Spaniards, French, Dutch, British, and even Jews, in particular spots; but the Falasches in Tigre, though they profess the religion of Moses, seem not to be of Hebrew descent. The Arabic is the leading language throughout all the north, and as far as the Joliba, where it is understood, in some degree at least, by those nations who revere the Koran. The Berberd and Shelluh tongues are spoken in the Barbary states, and along the Atlas mountains. The Mandingo language is used from the Senegal to the Joliba. On the western coast, a corrupt Portuguese is heard; in the regions of Abyssinia, the Tigre and Amhara tongues prevail. The languages of the blacks are as multifarious as the nations. In Sahara alone, forty-three dialects are said to be spoken. But of all the hundred and fifty languages (this conjectural number was adopted by Seetzen) of the African nations, we are hardly acquainted with seventy. Equally manifold are the modes of worship. Mahommedanism has diffused itself over the north to the Joliba, and most of the eastern coast; the Christian religion is professed by the inhabitants of Tigre and Amhara, by the Copts, the Nubians, and European strangers, though with great diversity of forms. The most disgusting Fetichism prevails among most of the negro nations, demanding, from many of its votaries, human sacrifices.

We must not look to Africa for the triumphs of science, not even to the country which was its cradle in the infancy of men. All that the Pharaohs and Ptolemies had ever effected, was swept away by the storms which broke upon this unhappy region in the middle ages. Schools, however, are still maintained by the Mahommedans in the cities of Barbary, by the Maraboots, in the countries where they have settled, and here and there by the Copts and Monophysites in Tigre and Amhara. The arts are exercised only on the northern coasts, where the Moors manufacture much silk, cotton, leather, and linen; an active commerce is carried on by them with the maritime nations of Europe, and, by means of caravans, a traffic, full as important, with the interior, to which they convey their own products and those of Europe.

The blacks stand on the verge of absolute barbarism, even where they are united into states. Their wants are exceedingly simple, and every article used by them is prepared by themselves; the cloth which surrounds their loins, the hut which protects them from the weather, the bow and arrow necessary for the hunt and self-defence, as well as all their household furniture, are manufactured by themselves; the gold which they collect from the surface of the earth is wrought by them into ornaments, and iron into arms. Commerce, however, with Europeans has taught them many wants, and increased their list of necessaries; among which may now be reckoned fire-arms, powder, brandy, tobacco, different kinds of cloth, glass beads, coral, &c.; for which they barter slaves, ivory, gold, and gums, the staples of Africa. The slave-trade is yet of such importance, that, although most of the European and American nations have agreed to prohibit it, nearly 50,000 negroes are yearly torn from the interior by the Mussulman, Portuguese, French, American, and even British dealers. Formerly, 105,000 slaves were annually introduced into the West Indies, besides those who were transported into Asia by the Kermanians, and by the North Americans into the southern states of the Union. The exports of ivory, gold dust, and gums, are also important; those of ostrich feathers, tiger skins, hides, and other natural productions, are of less consequence. Of all the states of Africa, Barbary alone uses coin; in the rest not frequented by Europeans, money rarely serves as the medium of exchange; in some, on the western coast, cowries are made to answer the purpose of coin; in others, pieces of salt.

The tropic of Cancer and the equator divide Africa into three principal parts:—1. Northern Africa, comprising Egypt, the piratical states of Tripoli (including the coast of Barca), Tunis, and Algiers, the empire of Morocco, Fezzan, and the northern part of Soodan or the Sahara, with the Azores, Canary and Madeira islands. 2. Central Africa, comprising, on the eastern coast, Nubia, Tigre, Ambara, Efat, Adel, Ajan, the southern part of Soodan, with Darfur and the countries of the Gallas; and, on the western coasts, Benin, Owhere, Senegambia, and Guinea, besides the Cape Verd islands, those near Guinea, the sixteen Bissao islands, Socotora, &c. 3. Southern Africa, with all the south-east and south-western coasts and interior, the Cape of Good Hope, and the island of Madagascar, the Comoro islands, with those of Mascarenhas, Amirante, Tristan d'Acunha, St Helena, and Ascension.

The following description, from the Edinburgh Cabinet Library, conveys a luminous view of the character of the African continent:—

"Vegetable life, in consequence of the absence of moisture, is scantily diffused over a great extent of the continent. In the heart of the mountains, however, and in the kingdoms along their border, the soil is most profusely watered, and, under the influence of a tropical sun, produces, perhaps, beyond any other part of the world, that luxuriant growth, and those gigantic vegetable forms, which distinguish the equatorial regions. The baobab, or great calabash, appears to be the most enormous tree on the face of the earth. Adanson assures us that the circumference, in some cases, is equal to thirteen fathoms, as measured by his arms clasped round the trunk, that is, varying from seventy-four to seventy-seven feet. Branches extending horizontally from the trunk, each equal to a large tree, make the baobab a forest, as it were, in itself. The mangrove, too, which rises on the borders of rivers or inundated spots, diffuses itself in a manner truly remarkable. The branches, dropping down upon the watery bank, strike root and grow; hence the original plant, spreading farther and farther, forms over the stream a species of natural arcade. These mighty trees do not stand alone, but have their interstices filled up by numberless shrubs, canes, creeping and parasitical plants, which intersect and entwine with each other till they form a thick and impenetrable mass of underwood. As we approach the confines of the desert, these giants of the wood disappear, and vegetation presents a different and more pleasing aspect. It exhibits now the light and gay form of the acacia, whole forests of which rise amid the sand, distilling those rich gums that afford an important material of African commerce. The lotus, a celebrated and classical shrub, the tamarisk, and other small and elegant trees, afford agreeable and nutritive berries, which constitute the food of several nations. Various flowering shrubs, of the most delicate tints, rising into wild and spontaneous beauty, embellish the precincts of the waste. Thus the desert, in its first approaches, and before vegetable life begins to expire, does not assume its sternest character, but wears even a peculiarly pleasing and smiling aspect.

The animal world in Africa changes equally its nature as it passes from one to another of its opposite regions. In those plains which are inundated by the great rivers, it multiplies at an extraordinary rate, and often assumes huge and repulsive forms. Throughout all this continent, the wild tribes exist in large and formidable numbers, and there is scarcely a tract which they do not either hold in full possession, or fiercely dispute with man. Even the most densely peopled countries border on wide forests and wastes, whose savage tenants find their prey occasionally in men himself, as well as in the domestic animals which surround him; and when the scent of human slaughter is wafted on the breeze, bands of hungry monsters hasten from every side to the feast of blood. These ferocious creatures hold indeed so commanding a position, that the colonist scarcely makes any attempt to extirpate them, or even to keep down their numbers. He wages against them only a defensive war, and employs his courage and skill chiefly in hunting the elephant, the antelope, and other peaceful species, by whose spoil he may be enriched. The lion, that king of the desert, that mightiest among the tribes which have the wilderness for their abode, abounds in Africa, and causes all her forests to re-echo his midnight roar. Yet both his courage and his fierceness have, it is said, been overrated; and the man who can undauntedly face him, or evade his first dreadful spring, rarely falls his victim. Wider ravages are committed by the hyena, not the strongest, but the most ferocious and untameable of all the beasts of prey. These creatures, by moving in numerous bands, achieve what is beyond the single strength of the greater animals: they burst with mighty inroad into the cities, and have even carried by storm fortified enclosures. The elephant roams in vast herds through the densely-wooded tracts of the interior, disputing with the lion the rank of king of the lower creation; matchless in bulk and strength, yet tranquil, majestic, peaceful, led in troops under the guidance of the most ancient of the number, having a social and almost moral existence. He attacks neither man nor beast. The human being is more frequently the aggressor, not only with the view of protecting the fruits of the earth, but also in order to obtain the bony substance composing his tusks, which, under the name of ivory, forms one of the most valued articles of African trade. The prodigious strength of the elephant, his almost impenetrable hide, his rapid though unwieldy movements, render him a most perilous object of attack even to the boldest hunters; so that pits and snares of various kinds are the usual modes by which his capture is effected. Instead of the tiger, Africa has the leopard and the panther, belonging, however, only to certain of its districts. In the large and broad rivers of Africa, and through the immense forests which overshadow them, a race of amphibious animals of monstrous form and size display their unwieldy figures. The rhinoceros, although not strictly amphibious, slowly traverses marshes and swampy grounds, and almost equals the elephant in strength and defensive powers, but wants his stature, his dignity, and his wisdom. The single or double horn with which he defends himself is an article of commerce in the East, though not valued in Europe. A still huger shape is that of the hippopotamus, or river-horse, fitted alike to stalk on land, to march along the bottom of the waters, or to swim on their surface. He is slow, ponderous, gentle: yet when annoyed, either by design or accident, his wrath is terrible; he rushes up from his watery retreat, and, by merely striking with his enormous tusks, can overset or sink a loaded canoe. But the most dreaded of all the inhabitants of the African rivers is the crocodile, the largest and fiercest of the lizard tribe. He lies like a log upon the waters, watching for his prey, attacking men and even the strongest animals, which, however, engage with him in obstinate and deadly encounters.

We have not yet done with all the monstrous and prodigious forms which Africa generates. She swarms with the serpent brood, which spread great terror, some by their deadly poison, others by their mere bulk and strength. In this last respect, the African serpents have struck the world with amazement; ancient history records that whole provinces were overrun by them, and that one, after disputing the passage of a river with a Roman army, was destroyed only by the use of a battering-engine. Emerging from these dank regions, where the earth, under the united influence of heat and moisture, teems with such a noxious superabundance of life, we approach the desert. Here a change takes place, equally singular and pleasing as in the vegetable world. Only light, airy, and fantastic forms trip along the sandy border; creatures innocent, gentle, and beautiful—the antelope of twenty different species, all swift, with bright eyes, erect and usually elegant figures—preying neither on men nor animals, but pursued by all on account of the delicate food which they afford. Here, too, roams the zebra, with its finely-striped skin wrapped round it like a robe of rich cloth; and the camelopard, the tallest and most remarkable of animal forms, with its long fore-legs and high-stretching neck, of singular and fantastic beauty, crops the leaves of the African forest. Though a rare species, he is seen occasionally straying over a great proportion of that continent. The insect race, which in our climate is generally harmless, presents here many singular, and even formidable characteristics. The flying tribes in particular, through the action of the sun on the swampy forests, rise up in terrible and destructive numbers. They fill the air, and darken the sky; they annihilate the labour of nations; they drive even armies before them. The locust, when its bands issue in close and dark array from the depths of the desert, commits ravages surpassing those of the most ferocious wild beasts, or even the more desolating career of human warfare. In vain do the despairing inhabitants seek, with fire and other means, to arrest their progress; the dense and irresistible mass continues to move onward, and soon baffles every attempt to check its course. Whole provinces, which at their entrance are covered with rich harvests and brilliant verdure, are left without a leaf or a blade. Africa, from the earliest ages, has been the most conspicuous theatre of crime and of wrong; where social life has lost the traces of primitive simplicity, without rising to order, principle, or refinement; where fraud and violence are formed into national systems, and man trembles at the sight of his fellow-men. For centuries this continent has seen thousands of her unfortunate children dragged in chains over its deserts and across the ocean, to spend their lives in foreign and distant bondage."

TABLE OF THE HEIGHT OF THE PRINCIPAL MOUNTAINS ON THE GLOBE.

EUROPE.

	English Feet.
Mont Blanc, Alps, Savoy	15,668
Monte Rosa, Alps, Switz.	15,527
Finster Aarhorn, Alps	14,325
Jungfrau, Alps	13,730
Schreckhorn, Alps	13,310
Oertler Spitze, Alps	13,065
Gross Glockner, Alps	12,900
Simplon, Alps	11,730

Missouri	North America	Mississippi	2310
Ohio	North America	Mississippi	1190

AUSTRALASIA,

Which now ranks as one of the great divisions of the earth, consists of a number of large and small islands in the Indian or South Pacific Ocean, between the 1st and 30th degrees of south latitude, in a south-easterly direction from China, which is the nearest part of the Asiatic continent. These islands also lie in a fair south-easterly direction from India, or Hindostan. The chief island in the group is Australia or New Holland, the principal settlement upon which is termed New South Wales, which, with Van Diemen's Land, a smaller island and British settlement, are described in separate articles in the present work. The other islands, which are still inhabited by only savage races, are New Zealand, New Guinea, Solomon's Islands, New Britain, New Ireland, New Hebrides, and New Caledonia. The whole islands are understood to comprise fully three millions of square miles, of which the British government claims the dominion.

POLYNESIA.

Polynesia—a word signifying "many isles"—is the name now given to the numerous groups of small islands scattered over the Pacific Ocean, but principally lying in an easterly and north-easterly direction from the above-mentioned territory of Australia, within about thirty degrees on both sides of the equator. They are perhaps better known under their specific titles of Sandwich Islands, Friendly Islands, Society Islands, Queen Charlotte's Islands, &c. They are many thousands in number, and are inhabited by savage races, who have generally been found much more tractable than the barbarous tribes of the other parts of the world. Most of the islands are fruitful and beautiful; some are exceedingly high and romantic, and their climate is reckoned the most delicious on the globe. Otaheite is one of the principal of the Society Islands. Owhyhee, or Hawai, is the largest of the Sandwich Islands, and measures eighty-four miles in length by seventy in breadth. Here Captain Cook, in 1779, fell a victim to a sudden resentment of the natives, with whom his party unfortunately had a dispute.

AMERICA.

The continent of America lies in the western hemisphere, in a situation altogether aloof from the continents of the Old World—as Europe, Asia, and Africa are termed. America, or the New World, was first discovered by Columbus in the year 1492, but its coasts were not fully known to Europeans for nearly a century after that period. Although Columbus is entitled to be considered the first discoverer of America, it happened that he was robbed of the honour of giving it his name by the superior address of Americus Vespucius, one of his adventurous successors. America consists of two large portions, very nearly separated by the intervening Gulf of Mexico, and only connected by a neck of land called the Isthmus of Darien. The northern portion is named North America, that in the south, South America. From its northern boundaries to the Gulf of Mexico, North America extends about 4376 miles in length, and 3000 miles wide at the broadest part. South America commences at the 9th degree of north latitude, reaching to the 56th degree south latitude, being a length of 4550 miles, by a breadth at widest of nearly 3000 miles. On this vast double continent the works of nature are found on a large scale, calculated to excite our wonder. Mountain ranges, plains, and rivers, are all larger and more magnificent in their proportions and appearance than those in the eastern hemisphere. The soil is also very generally fertile, and covered with the most lofty timber and luxuriant vegetation. At the period of the discovery of America, it was found to be thinly inhabited by a number of tribes of aboriginal people, generally of a copper colour, and more or less savage in character and habits. The subsequent settlement of colonists from Spain, Portugal, Holland, England, France, and other European nations, had the effect of either extirpating these races, or of driving them westward towards the shores of the Pacific Ocean. They are now comparatively few in number. While they have decreased, the colonists have vastly increased in number by emigration, and the natural increase of population. In a general sense, North America has fallen to the share of British colonists, while South America has become the portion of the Spanish and other bigoted and bad-managing Europeans. In the course of time, the colonists in nearly all parts have emancipated themselves from the dominion of the mother countries, and set up as independent nations. In doing so, they have embraced the opportunity of trying to establish democratic institutions, with an absence of aristocratic distinction. The greatest of the republics thus established has been that of the United States of North America. A third race, the descendants of negroes imported as slaves, is rising into a large amount of population over the whole continent, partly emancipated and still partly as slaves; and being most unfortunately or inhumanely kept as a despised caste, their increasing numbers and condition are at present exciting the attention of the civilised world. It has been computed that the whites and their descendants in all parts of America amount in number to nearly fourteen millions; the Indians to eight millions; the negroes to about seven millions; and the mixed races to at least six millions—making a total of thirty-five millions: but there is yet space and fertile soil for more than five hundred millions. Besides the United States, North America comprises the British settlements of Upper and Lower Canada, on the north; a district claimed by Russia, on the north-west; and the state of Mexico, in the south-western quarter. Having in various numbers of the present work given an ample description both of the North and South American states and settlements, we do not here require to enlarge on the subject, but refer the reader to the separate articles, beginning with that which immediately follows this sheet; namely, a description of our possessions in Upper Canada.

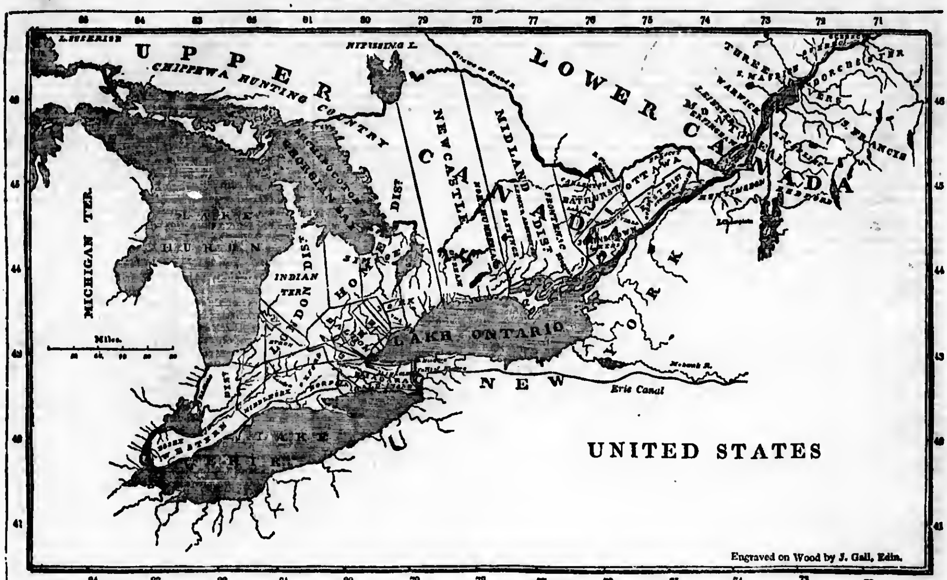
EMIGRATION TO CANADA.



PRELIMINARY.

It naturally occurs, when the condition and prospects of the working classes in one country sink beneath what they are in another, that all who can remove from the worse to the better, wish to do so. Now, Great Britain is at present in the condition of a country where, though the wealthy are *very* wealthy, and the middle orders at once larger in number and better in condition than in any other quarter of the world, yet the poor are very poor—greatly overwrought, in general, where work is to be had—poorly fed and clothed—and totally without hope, if they marry, of withholding their offspring from the same misery. The population of the country is yearly increasing; but it may be said, in the deeply touching language of Scripture, the nation is multiplied, but the joy is not increased. (*Isaiah*, ix. 3.) The only remedy, as pointed out elsewhere by the present writers, is in flight. At this moment, there are several countries at no great distance, to which the depressed workman may transport himself, with a reasonable prospect of bettering his condition; and of these it is the purpose of the present and some other sheets to give an account.

In this task we cannot pretend to much originality; the most of our materials are and will be derived from the books of late travellers in those countries, and we will only give new information, when we think it decidedly better than what is to be found in books. In condensing our materials, we have been, and will continue to be, inspired by a most conscientious sense of responsibility regarding the interests of those who may act upon our information alone. Nothing is flattered or exaggerated: we have no reason to wish that men may emigrate, if they think themselves better in Great Britain; nor have we any reason for describing one country as better for emigrants than another, unless a regard for truth shall induce us to do so. The whole will be, in fact, a plain and unvarnished report of what the most clear-headed and trustworthy men have said about the countries in question—a report which we compile with no other governing wish than that our suffering fellow-countrymen may be cheaply and faithfully instructed in what it concerns them to know for their guidance in, perhaps, the most important step of their lives.

There are three regions of the earth to which the attention of emigrants is chiefly directed, namely, Canada and the other British possessions in North America; the United States, which many prefer, and which hold out similar advantages; and the British colonies in New South Wales and Van Diemen's Land. At present, our attention will be confined entirely to Canada.*

GENERAL DESCRIPTION.

North America, of which Canada is a part, lies at the distance of 3000 miles west from Great Britain, on the opposite side of the Atlantic Ocean. This vast continent is much larger than Europe, measuring 4376 miles in length from north to south, and 3000 miles across from east to west. In a general sense, civilization has penetrated no more than from 1000 to 1200 miles westward, and that only in straggling lines: the remainder of the territory is still inhabited by wild Indians. The more southerly civilized portion of North America consists of the United States, governed as an independent republic; the more northerly part, with some islands, is in the possession of Great Britain, and comprehends the provinces of Upper and Lower Canada, New Brunswick, Nova Scotia, Newfoundland, Cape Breton, St John's or Prince Edward's Island, &c. The population of these extensive colonies amounts to nearly a million and a half of souls, or what Scotland alone contained some years ago. The line of division betwixt the British possessions and the United States, is either the River St Lawrence and the lakes from whence it proceeds, or an ideal and partly contested boundary. Canada extends chiefly from 61 to 81 degrees of west longitude, and from about 42 to 52 degrees of north latitude, and measuring about 1300 miles in length from east to west. The population is estimated at 700,000. Canada is politically divided into the two provinces of Upper and Lower Canada. A legislative council and an assembly are appointed for each, having power to make laws, with consent of the governor. These local governments resemble in miniature that of the mother country, to whose supreme rule the whole are subject. In Lower Canada, or that portion next the sea-coast, the greater part of the population is of French descent (this having originally been a French colony): the laws resemble those of France; and the Roman Catholic religion is established. Upper Canada, or, more properly, *Inner* Canada, lies to the west and south-west of the lower province. Its inhabitants are of British descent, and a very great number of them are from Scotland, both lowlands and highlands.* The

---

* That the purchaser of the present sheet may know where to obtain more detailed information on Canada, with reference to emigration, we subjoin a list of the books used in our compilation:—"The British Dominions in North America," by Joseph Bouchette, Esq., 2 vols. quarto, with plates and drawings. Colburn, London. This work possesses a very complete body of information, chiefly of a statistical and political nature; and it is particularly recommended to the perusal of those who wish a good account of the whole British possessions in North America.—"British America," by John Macgregor, 2 vols. octavo. Blackwood, Edinburgh. This work relates principally to the British possessions on the sea coast, including Lower Canada.—"Five Years' Residence in Canada," by E. A. Talbot, 2 vols. octavo, Longman, London.—"Sketches of Upper Canada," by John Howison, Esq. octavo. Oliver and Boyd, Edinburgh. This is one of the most delightful works ever published on the subject of Canadian emigration; its details are highly entertaining and instructive, and the author's views are solid and philanthropic: it should be read, if possible, by intending emigrants.—"Practical Notes made during a Tour in Canada," by Adam Fergusson of Woodhill. Mr Fergusson's Notes were originally published in the Quarterly Journal of Agriculture; they are of a valuable practical nature, but being already widely circulated and well known, they here require no recommendation. We have had recourse also to numerous volumes of travels in North America, and to some smaller works of merit; among others, to "Hints to Emigrants," by the Rev. William Bell, 12mo. Waugh and Innes, Edinburgh; and to a pamphlet entitled "Information published by his Majesty's Commissioners for Emigration, respecting the British Colonies in North America. Knight, London.

* The stream of emigration from Britain and Ireland has for some years been flowing steadily towards the province of Upper Canada, which is greatly preferable to the Lower Province, and whose resources are annually increasing to a very great extent. From 1831 till 1832, the population increased twenty-five per cent.; and every expectation is in favour of an equally rapid increase during the current year. As a proof of the respectability of the emigrants, the fact is stated in the colonial newspapers, that during the summer of 1832, the enormous sum of 300,000 sovereigns was deposited in the Bank of Upper Canada.

English law and church are here established; but there is no tax for the clergy; and there is the most perfect liberty of conscience, and as great a security of life and property as in Scotland or England. Upper Canada is divided into districts, counties, ridings, townships, special tracts, and allotments; together with blocks of land, reserved for the clergy and the crown, and lands appropriated to the Indians. A district contains two or three counties, and each county contains from four to thirty townships. There are 11 districts, 26 counties, and 6 ridings, comprising together 273 townships. The line of division betwixt Upper and Lower Canada is in one part the Ottawa or Grand River; nearly all the other lines of division in the provinces are straight, without regard to physical distinction, such as hills and rivers; and this peculiarity is common over the whole of North America. The average territory of each township may be estimated at 61,000 acres, making an aggregate quantity of 16,816,800 acres. About 7,000,000 of acres have been granted to different classes of settlers; 4,805,400 acres are reserved for the crown and clergy (part of which has already been granted by the crown to the Canada Company); and 5,011,400 acres remain to be granted within the townships. This extent of country, chiefly bordering the north shore of the River St Lawrence to Lake Ontario, the northern side of that lake and of Lake Erie up to Lake St Clair, and of the communication between it and Lake Huron, a distance little short of five hundred and seventy miles, and stretching northward from the water to a depth varying from fifty to eighty miles, is composed of a soil, which, for productive richness, variety, and applicability to the highest purposes of agriculture, may challenge competition with the choicest tracts of land in the New World.

Upper Canada is chiefly a flat country, and is for the greater part covered with timber, but possesses a number of chains or ridges of high lands running in different directions, and separating the sources and channels of innumerable rivers and brooks. The higher and level districts are called Table Lands. The grand feature of the country is its water-courses. By looking at the map, it will be perceived that there is a series of large lakes, communicating with each other; these are unequalled by any inland sheets of water in the world, and are entitled to the appellation of fresh water seas, for they are not only of great extent, but are liable to be affected by storms like the ocean itself. The uppermost, called Lake Superior, is 381 miles long, and 161 broad; Huron, 218 miles long, and from 60 to 180 broad; Erie, 231 miles long, and about 70 in breadth; Ontario, 171 miles in length, and 60 in breadth. The accumulated waters of these lakes form the River St Lawrence, which is one of the largest streams in the world, and which, after a course of 2000 miles, falls into the Atlantic. This majestic river is 90 miles wide at its mouth, and is navigable for ships of the line for 400 miles from the ocean. In its upper parts, its navigation is impeded by *rapids*, or the rushing of the stream down an inclined plane; but some of these impediments are obviated by means of canals, recently cut; wherefore there is now a continued water communication for vessels from the Atlantic into the interior, or innermost lakes. Lake Erie is also connected by a canal with the Hudson, a river of the United States, which also falls into the Atlantic. The Ottawa, or Grand River, is next to the St Lawrence in point of size, and is tributary to it. It falls into the north side of the St Lawrence at Montreal. The Welland, or Chippewa, is also a remarkably fine river, wholly unobstructed by falls. The St Lawrence has a tendency northward in its course, and, therefore, the farther up its banks the more mild does the climate become.

CANADIAN TOWNS.

The chief towns in Canada are Quebec, Montreal, Three Rivers, Prescot, Kingston, and York. The city of Quebec is the capital of Lower Canada, and stands in the extremity of a precipitous cape, on the north bank of the St Lawrence, opposite the island of Orleans. The appearance of the town, on coming into view, is particularly striking. The city is divided into an upper and lower town; the former being of ancient date, and adopted as the seat of commerce, and the latter being the residence of the higher and more respectable classes. There are a number of fine public edifices; among the rest, the castle of St Louis, a prominent object on the summit of the rock; the Roman Catholic and Protestant cathedrals; the barracks; hospitals; the Quebec bank; and a handsome monument to Wolfe and Montcalm. The institutions are, in many instances, of French character, and the language of the inhabitants is French and English. In 1825, the population of the city and suburbs amounted to 22,021; at present it may amount to 30,000.

Montreal is a city of an entirely different appearance. It is agreeably situated on a beautiful island of the same name in the St Lawrence, which measures 32 miles long, by 10½ broad, and lies at the confluence of the Ottawa River and the St Lawrence. The island of Montreal is nearly level, and is scarcely excelled in fertility. The city stands on the south side of the island, and is reckoned the first in the province, in respect of situation, local advantages, and superiority of climate. The houses are well built, and the streets commodious. There are also some handsome public buildings. The literary

and scholastic institutions in Montreal are numerous, and are of great benefit to the province. There are no wharfs, and the ships and steam-boats sail close to the bank of the river, where there is deep water. Mr M'Gregor mentions, in his work on British America, that there is much activity observable among all classes connected with trade. "The position of Montreal (says he), at the head of the ship navigation, and near the confluence of the St Lawrence with the Ottawa, and its subsequent communication with Upper Canada, the Gennessee country, and other parts of the United States, will always constitute it one of the greatest commercial emporiums in America, which must increase in magnitude and importance along with the rapid improvement and increasing population of the upper and surrounding countries. In winter, the trade of Montreal is not suspended like that of Quebec. Thousands of sledges may be seen coming in from all directions with agricultural produce, and frozen carcases of beef and pork, firewood, and other articles. Manufactured goods of all kinds are continually selling off in packages by the merchants or the auctioneers, to the shopkeepers and country dealers, who again retail them to the townsfolk, or country people; and flour, wheat, potatoes, &c., are continually coming in, and filling the stores or warehouses. The markets of Montreal are abundantly supplied at all seasons of the year."

The population of Montreal and suburbs, in 1825, amounted to 22,357. Upwards of three-fourths are French, and the rest English, Scotch, Irish, and Americans. York, the capital of Upper Canada, and the other towns, are much inferior in size, and will be noticed in passing.

PERSONS WHO OUGHT TO EMIGRATE.

The question of most importance as regards emigration, seems to be that referring to the description of persons who ought preferably to take the great step of leaving their native country. This is a point of great moment, and should be well weighed by intending emigrants, for it is obvious that success will in a great measure depend upon previous habits and occupations. "The persons who may be inclined to emigrate to Upper Canada (says Howison), are of three different descriptions, viz. the poor peasant or day-labourer; the man of small income and increasing family; the man possessing some capital, and wishing to employ it to advantage.

Persons of the first class never would repent if they emigrated to Upper Canada, for they could hardly fail to improve their circumstances and condition. The poorest individual, if he acts prudently and is industrious, and has a common share of good fortune, will be able to acquire an independence in the space of four or five years. He will then have plenty to eat and drink, a warm house to reside in, and no taxes to pay; and this state of things surely forms a delightful contrast with those hardships and privations which are at present the lot of the labouring population of Great Britain.

It is evident that some descriptions of emigrants will succeed better in Upper Canada than others. Those who have been accustomed to a country life and to country labour, are of course more fitted to cultivate land, and endure the hardships at first attendant upon a residence in the woods, than artizans or manufacturers, whose constitutions and habits of life are somewhat unfavourable to the successful pursuit of agriculture. But every individual, who to youth and health joins perseverance and industry, will eventually prosper. Mechanics cannot fail to do well in Upper Canada; for, when not employed in clearing lands, they will find it easy to gain a little money by working at their professions; and they likewise have the advantage of being able to improve their dwelling-houses, and repair their farming utensils, at no expense. Weavers, being ignorant of country affairs, and unaccustomed to bodily exertion, make but indifferent settlers at first, and their trade is of no use to them whatever in the woods. Married persons are always more comfortable, and succeed sooner, in Canada, than single men; for a wife and family, so far from being a burden there, always prove sources of wealth. The wife of a new settler has many domestic duties to perform; and children, if at all grown up, are useful in various ways."

Every candid traveller in Canada concurs in these views. "Of this, I think (says Fergusson) there can be no doubt, that either the moderate capitalist, or the frugal, sober, and industrious labourer or artizan, cannot fail of success. *Fortunes* will not be rapidly or even readily acquired; but it must be the settler's own fault if he does not enjoy, in large abundance, every solid comfort and enjoyment of life, and rear around his table even a *forest* of 'olive plants,' without one anxious thought regarding their future destination or provision."

PASSAGE.

It seems doubtful whether the passage to Upper Canada should be effected by way of the St Lawrence, or New York and the Erie Canal. Both ways are recommended, and it is more than likely that most emigrants will have to be governed in their decision by convenience of shipping and other circumstances. Having wound up his affairs in this country, and otherwise prepared himself and family for proceeding to the land of their adoption, it is recommended that the emigrant should take with him a box of tools, whether he be learned to use them or not. The tools should consist of a common axe, handsaw, three augers of different sizes, pick-axe, spade, two gimlets, a hammer, iron wedge, three hoes; a kettle, frying pan, an iron pot, nails, and a small portable handmill for grinding corn; a gun and fishing nets will be of great service, if he has means to purchase them. He should also have good warm frieze coats and jackets, and worsted stockings and mittens for the winter; also strong hide leather shoes, without iron heels, as iron is not required in soft roads, and is apt to attract the frost, and make the feet colder; linen trousers and jacket for the summer, as many cotton shirts as he can afford to take out (linen being dear in Canada, and more apt to rot with perspiration in summer), and a short flannel shirt, to be worn next the skin, both in summer and winter. Without caution as to clothing, the settler has a chance of being attacked with ague, which is the only complaint to be dreaded. He should also provide himself with a small stock of simple medicines, to preserve the bowels in regularity. Every one ought to take a dose of medicine on landing. No bulky articles or furniture of any kind should be taken, but an emigrant should take all his mattresses and bedding, and as many good blankets as possible; also a warm fur cap. Straw hats for summer can be had at a cheap rate in Canada. Every thing should be packed in substantial handy trunks. Plain furniture can be bought at a cheap rate in the colony, or the emigrant can perhaps manage to make some articles for his new household. The bark of the bass tree, woven or laced across his bedstead, will support a mattrass, and that mattrass need consist of nothing more expensive than the boughs of the spruce fir, or dry beech leaves; a buffalo skin will answer for quilt and blankets.

"Passages to Quebec (says the official pamphlet of the Commissioners) may either be engaged inclusive of provisions, or exclusive of provisions, in which case the shipowner finds nothing but water, fuel, and bed-places, without bedding. Children under fourteen years of age are charged one half, and under seven years of age, one third, of the full price; and for children under twelve months of age, no charge is made. Upon these conditions the price of passage from London, or from places on the east coast of Great Britain, has generally been L.6, with provisions, or L.3 without. From Liverpool, Greenock, and the principal ports of Ireland, as the chances of delay are fewer, the charge is somewhat lower [we would here strongly advise emigrants to sail, if possible, from a port on the west coast, as being a great saving of time, trouble, and expense]; this year the charge will probably be from L.2 to L.2, 10s. without provisions, or from L.4 to L.5 including provisions. In ships sailing from Scotland or Ireland, it has mostly been the custom for passengers to find their own provisions; but this practice has not been so general in London, and some shipowners, sensible of the dangerous mistakes which may be made in this matter through ignorance, are very averse to receive passengers who will not agree to be victualled by the ship. Those who do resolve to supply their own provisions, should at least be careful not to lay in an insufficient stock; fifty days is the shortest period for which it is safe to provide, and, from London, the passage is sometimes prolonged to seventy-five days.*

The best months for leaving England are certainly March and April. The names of the vessels to sail are generally advertised in the public newspapers. The conveyance of passengers to the British possessions in North America is regulated by an act of Parliament (9 Geo. IV. cap. 21), of which the following are the principal provisions:—Ships are not allowed to carry passengers to these colonies unless they be of the height of five feet and a half between decks, and they must not carry more than three passengers for every four tons of the registered burthen; there must be on board at least fifty gallons of pure water, and fifty pounds of bread, biscuit, oatmeal, or bread-stuff, for each passenger. Masters of vessels who land passengers, unless with their own consent, at a place different from that originally agreed upon, are subject to a penalty of L.20, recoverable by summary process before two justices of the peace in any of the North American colonies. The enforcement of this law rests chiefly with the officers of his Majesty's customs; and persons having complaints to make of its infraction, should address themselves to the nearest custom-house."†

Taking it for granted that the emigrant and his family find their way across the Atlantic by the means just specified, we have next to direct him how to proceed on his landing. On this important particular we cannot do better than lay before him the following two exceedingly valuable official documents, issued for the express benefit of emigrants, by his Majesty's agent at Quebec, entitled

ADVICE TO EMIGRANTS.

Quebec, 1st May 1832.

There is nothing of more importance to emigrants

* Scotch families usually, and very judiciously, provide themselves with a sufficient quantity of oatmeal, eggs well packed, and some tea and sugar, besides other provisions. A tea-kettle, and one or two pans for cooking victuals, are indispensable. Milk boiled with loaf sugar, in the proportion of one pound of sugar to a quart of milk, and bottled when quite cool, will keep sweet all the voyage.

† We here recommend that emigrants should stipulate for the use of the water-closet, and not to be *forced* ashore for at least 24 hours after their arrival at Quebec; and all bargains ought to be by *written* agreement with the captain.

on arrival at Quebec, than correct information on the leading points connected with their future pursuits. Many have suffered much by a want of caution, and by listening to the opinions of interested designing characters, who frequently offer their advice unsolicited, and who are met generally about wharfs, and landing places frequented by strangers. To guard emigrants from falling into such errors, they should, immediately on arrival at Quebec, proceed to the office of the Chief Agent for Emigrants, in Sault-au-Matelot Street, Lower Town, where every information requisite for their future guidance, in either getting settlement on lands, or obtaining employment in Upper or Lower Canada, will be obtained *(gratis)*.

Previous to disembarkation, arrange your baggage in a small compass, the fewer packages the better, but have them well secured—old dirty clothing, large boxes, and other useless articles, are not worth the carriage. If you have any provisions left, such as oatmeal, potatoes, &c., you can sell them at Quebec at a profit, and avoid the expense of transport, and you can purchase baker's bread, butter, tea, sugar, and other necessaries more suited for your journey. All sorts of provisions may be bought cheaper, and generally of a better quality, in Montreal and Upper Canada, than at Quebec. Dress yourself in light clean clothing. Females frequently bring on sickness by being too warmly clothed. Cut your hair short, and wash daily and thoroughly. Avoid drinking ardent spirits of any kind, and, when heated, do not drink cold water. Eat moderately of light food. Avoid night dews. By attending to the preceding directions, sickness will be prevented, with other serious inconveniences. When every thing is ready for disembarkation, and if the ship is lying at anchor in the river, take care in passing from the ship to the boat; avoid all haste, and see that your baggage is in the same conveyance with yourself, or left under the charge of some friend, with your name on it. If the ship hauls to the wharf to disembark, do not be in a hurry, but await the proper time of tide, when the ship's deck will be on a line with the quay or wharf. Passengers are entitled by law to the privilege of remaining on board ship 48 hours after arrival; and it is unlawful for the captain to deprive his passengers of any of their usual accommodations for cooking or otherwise; you may, therefore avoid the expense of lodgings, and make all your arrangements for prosecuting your journey. Previous to disembarkation, should sickness overtake you, proceed immediately, or be removed to the Emigrant Hospital, in St John's Suburbs, where you will be taken care of, and provided with every thing needful until restored to health. Medicine and medical advice can also be had at the Dispensary attached to the Quebec Charitable Emigrant Society. This society will grant relief to all destitute emigrants. In Montreal there is a similar institution for the relief of emigrants. It is particularly recommended to emigrants not to loiter their valuable time at the port of landing, but to proceed to obtain settlement or employment. Many have regretted, when too late, that they did not pursue this course, and take advantage of the frequent opportunities that presented themselves for settlement in convenient situations in Upper or Lower Canada, instead of squandering their means and valuable time in looking after an imaginary paradise in the aguish swamps of Illinois and Missouri, or other distant regions of the Western States. There is no portion of the American continent more congenial to the constitution or habits of emigrants from the United Kingdom, or that offer a wider field or surer reward for industry and good conduct, than the fertile districts of Upper Canada or Lower Canada. Many emigrants will find employment in the city of Quebec and its vicinity, as also in and about Montreal. Single men in particular are advised to embrace the offer; but emigrants with large families had better proceed without delay to Upper Canada, as hereafter directed, or to situations in Lower Canada, particularly the Eastern Townships; and if they have sons and daughters grown up, they will find a sure demand for their services. Artificers and mechanics of all denominations, and farming labourers, if sober and industrious, may be sure of doing well. Blacksmiths, particularly those acquainted with steam-engine work, also good millwrights and sawyers by machinery, are much wanted in the Canadas.

The following are the current rates of wages paid in Upper and Lower Canada to persons acquainted with the country;—strangers ought not to expect so much:—

	Upper Canada.	*Lower Canada.*
Ship Carpenters and Joiners, per day - - - - -	4s 0d to 7s 6d	3s 6d to 6s 0d
Bricklayers and Masons, do.	6s 6d to 7s 6d	4s 0d to 9s 6d
Blacksmiths, Millwrights, &c. do.	5s 0d to 8s 6d	3s 6d to 7s 6d
Farm and Common Labourers, &c. do. - - -	2s 6d to 4s 0d	2s 0d to 3s 0d
Ditto ditto, per month, and found - - -	30s 0d to 60s 0d	20s 0d to 50s 0d
House Servants (Men) do. do.	30s 0d to 50s 0d	20s 0d to 40s 0d
Ditto do. (Females) do. do.	20s 0d to 35s 0d	10s 0d to 30s 0d

A great number of labourers are employed on board ships, and about timber-yards, at Quebec and Montreal, who get from 3s. to 4s. 6d. a-day, and generally found. The extravagant habits engendered in such occupations are decidedly in favour of the labouring emigrant proceeding immediately to the country. Emigrants with families, and who are possessed of from L.20 to L.25, are advised to push immediately into the woods, in the vicinity of old settlements, where they can obtain provisions for their spare labour. The difficulties, although great at first, soon subside, and much experience is the result. The cost of clearing wild lands, and making them ready for crop, is from 50s. to 70s. per acre in Upper Canada and the Townships of Lower Canada. To these I should say, select a favourable spot for your log-house, near a spring of water, or running stream, and where a *cellar to keep your potatoes in winter can be dug under the house.** If you proceed to build houses and clear lands on a large scale on first arrival, it rarely succeeds so well; for the price of labour is so high, and the difficulty of getting persons to work, added to the great expense of providing food for increased numbers, until produced from your own land, ought in every instance to induce the strange emigrant and family to proceed cautiously in laying out their money; but a crop of potatoes and fodder for a cow is the first object, and this may be accomplished the first year, if you arrive early. The second you will be enabled to feed your family with the necessaries of life, and the third year you may find yourself possessed of a yoke of oxen, a cow or two, and a year old calf, a couple of pigs, poultry, &c., abundance of provisions for your family, and fodder for your cattle. The Irish and Scotch peasantry know well how to value the economy of a milch cow; every new settler ought to strive to obtain one as soon as possible, taking care to provide a sufficiency of fodder for the long winter. Cattle require a little salt in the Canadas. It is not considered necessary to go farther into the details of the first settlement, as on all these points you will be guided by your own observations on the spot, and the advice you will get from the local agents and superintendants. Great caution is necessary in all your transactions. When you stand in need of advice, apply to the government agents, or other respectable sources. You will find many plans and schemes offered to your consideration on your route from Quebec to your destination in Upper Canada; but turn away from them, unless you are well satisfied of the purity of the statements. Should you require to change your English money, go to the banks or some well known respectable person. The currency in the Canadas is at the rate of 5s. to the dollar, and is called *Halifax currency.* The value of English gold or silver is regulated by the rate of exchange in England, which fluctuates. At present the gold sovereign is worth 23s. 6d. to 24s. currency. In New York, 8s. is calculated for the dollar; hence many are deceived when hearing of the rates of labour, &c.—5s. in Canada is equal to 8s. in New York; thus, 8s. New York currency is equivalent to 5s. Halifax. In Upper Canada, and in the Townships of Lower Canada, the tenure of lands is "Free and Common Soccage," as in England. In the Seigneurial or French parts of Lower Canada, the feudal or French tenure is the custom. In the Canadas you live under the British laws and constitution, and are less encumbered with taxes or local imposts than in any other country on the face of the globe. You ought, previous to leaving Quebec, to apply at the post-office, should you expect any letters; and if you are writing to your friends in the United Kingdom by post, you must pay the postage; so also when writing to the United States. Letters from one part of the Canadas to the other do not require to be post-paid. Emigrants may forward letters to the United Kingdom from Quebec, by taking them to the keeper of the Merchants' Exchange, and paying one penny for each.

Having arranged all your business at Quebec, you will proceed without loss of time to Montreal, by steam-boat, on your route to Upper Canada. Two steam-boats ply daily to Montreal, 180 miles up the St Lawrence, which is performed in 24 to 30 hours. The fare for deck passengers is 7s. 6d. for adults; children under 12 years pay half-price; and under 7 one-third. These steam-boats belong to private individuals. Government is in no manner connected with them. At Montreal you will find a government agent, who will advise you should you require it.

Routes to the principal places in Upper Canada, as follows:—

Quebec to Montreal, by steam-boats, -	7s 6d cost.
Montreal to Prescot, by Durham boats, -	6s 3d
Prescot to Kingston, by steam, - -	5s 0d
Ditto to Coburgh, or Port Hope, - -	7s 6d
Prescot to York, Capital of Upper Canada, Hamilton, and Niagara, - -	10s 0d

From Niagara, you proceed by land to Fort Erie, opposite Buffalo on Lake Erie, where steam-boats, or sailing schooners, will convey those destined to Port Talbot, or other parts of the London district, or vicinity of Lake St Clair. Persons going to settle on the lands of the Canada Company will proceed to York or Burlington Bay, head *of Lake Ontario.*

At most of the preceding towns and landing places you will find government agents. If you are bound to Perth, or New Lanark, or the vicinity, disembark at Prescot; or you may go by By-Town on the Ottawa. If for the thriving settlements in the Newcastle district, disembark at Coburgh or Port Hope, on Lake Ontario. Those going to the townships of Seymour may proceed from Kingston, by the beautiful Bay of Quinté, to the mouth of the Trent River, from whence a road, distance 18 miles, brings you to Seymour. If proceeding to the Home or Western Districts, disembark at York, the capital of Upper Canada. Emigrants going any where beyond York, will in general find it their interest to make it their route. If for the London District, proceed by the Niagara frontier, to Lake Erie and the Talbot Settlement. If for By-Town, Grenville, Hull, Horton, or other situations on the Ottawa River, proceed from Montreal and Lachine by the usual conveyances.

Crown lands, of the most fertile quality, are prepared for the reception of emigrants in many parts of Upper Canada, and will be sold, payable by instalments. The following offices have been opened by the Commissioner of Crown Lands in Upper Canada, for the convenience of emigrants:—

In the Bathurst District, Mr M'Naughton will open his office at By-Town.

Major Campbell, of the Township of Seymour, for the Midland District.

Mr Ritchie for the Home District, and will reside in Sunnidale.

Mr Mount, Deputy-Surveyor for the Western District, between Carradoc and the St Clair.

Emigrants may obtain employment, for two or three months, on the roads, in several townships, in the Western and Home Districts of Upper Canada.

Routes to the principal settlements in Lower Canada are as follows:—

District of Quebec, south side of the River St Lawrence.

Township of Frampton, 36 miles from Quebec by Point Levy, a thriving settlement. Inhabitants, mostly Irish.

Townships lying contiguous to the Kennebec road, beyond Frampton, offer good prospect for settlement. The lands are principally private property. The seignlory of St Giles, 30 miles from Quebec, by St Nicholas and the Craig's road, is favourably situated for emigrants, from its contiguity to the capital, and is increasing rapidly; its population is principally Irish.

New Argyle, in the seignlory of St Croix, 8 miles from Richardson's Tavern, on the Craig's road in St Giles, and 38 miles from Quebec; the new road to the township of Inverness passes through this settlement. Inhabitants, principally Highlanders from the Island of Islay, and Irish. The lands in this part are of good quality.

The settlements of Ulster, Yorkshire, Dublin, and New Hamilton, commence four miles beyond New Argyle, and 42 miles from Quebec, and are situated in the flourishing township of Inverness, through which a new road has been nearly finished to the borders of the township of Halifax. The inhabitants of Inverness are from various parts of the united kingdom. Those from England are principally from Yorkshire; those from Ireland, mostly from the northern counties; and those from Scotland are chiefly Highlanders from the Island of Arran. Beyond Inverness lie the townships of Halifax, Chester, and Tingwick, good lands for settlement; but at present there is no convenient road to them. The township of Athabaska joins Inverness, and is a desirable place for settlement.

The township of Leeds, through which Craig's road passes, lies to the left of Inverness, is 50 miles from Quebec, and is increasing rapidly in population. Inhabitants, Scotch, Irish, and English.

The township of New Ireland, through which Craig's road also passes, lies beyond Leeds, 60 miles from Quebec, and is increasing much in population. The inhabitants are principally Irish, and a number of English of the Wesleyan connexion, also about 25 American families from the United States.

Craig's road leads to Shipton and Dudswell, but is impassable for wheel-carriage transport beyond Ireland.

From the Market-slip, in the Lower Town of Quebec, ferry-boats go daily as the tide suits to St Nicholas, 12 miles up the river on the south side, where Craig's road begins.

Eastern Townships of Lower Canada. The present route is by Three Rivers, 90 miles above Quebec, by steam-boat; here cross the St Lawrence to the south side, and proceed to *Sherbrook*, by Nicolet, La Baie, and Drummondville; or you may proceed to Sorrel, 40 miles above Three Rivers, on the south side of the St Lawrence, and there disembark. The rate of passage from Quebec by the steam-boat will be about the same as to stop at Three Rivers, and you will avoid the ferry. A good road leads from Sorrel to Sherbrook, by Yamaska and Drummondville. The distance from Quebec to Sherbrook, in a straight line by the new road to Inverness, when finished, is 99 miles; and by Three Rivers or Sorrel, the route to be taken for transport is 160 miles, of which 70 is land-carriage.

Sherbrook is the capital of the Eastern Townships, and is surrounded by thriving settlements, particularly Stanstead, where industrious farming labourers or mechanics are much wanted, and are sure (by good conduct) to do well; as also the townships of Stanbridge, Brome, Dunham, Potton, and the seignlory of St Armand, the route to which is by St John's.

Chambly is 40 miles from Sorrel, and 18 from Montreal. Labourers may get employment at the canal now making at Chambly. Chateauguay, Godmanchester, and Sherington, from 25 to 40 miles from Montreal, south side of the St Lawrence, are thriving situations.

* Carefully clear the timber and brush to a distance from your dwelling and out-buildings, or, in the event of fire in the woods, great risk is incurred of their being destroyed.

North side of the River St Lawrence, and in the district and vicinity of Quebec, are the settlements of Beauport, Stoneham, Tewkesbury, Valcartier, and Jacques Cartier, Deschambault, and the settlement of Portneuf. Inhabitants, principally Irish.

Three Rivers and its vicinity, 90 miles from Quebec, give employment to many emigrants. In the rear of Berthier, 130 miles above Quebec, are the Townships of Brandon, Kilkenny, Rawdon, and Kildare.

New Glasgow settlement in the seigniory of Terrebonne, is about 30 miles from Montreal. Persons bound for the Townships bordering on the Ottawa River, particularly Lochaber, Templeton, Hull, &c., will take their route and departure from Montreal. There are many desirable situations for settlement belonging to private individuals in Upper and Lower Canada. The names of the proprietors or the agents may be had on application at this office.

It is particularly recommended to emigrants to be exceedingly cautious in ascertaining the titles to such lands as they may settle on.

Recommendation for lands to the respective Township agents and superintendants of settlements in Upper and Lower Canada, with routes, &c., will be furnished to emigrants (*gratis*).

A. C. Buchanan, *Chief Agent.*

Emigrant Department,
Quebec, 1st May 1832.

Quebec, 1st June 1832.

Emigrants arriving at Quebec from the United Kingdom, and who are desirous of settling in Upper Canada or Lower Canada, or of obtaining employment, are informed that all necessary information for their guidance may be obtained (*gratis*) on application at this office, between the hours of 10 and 3 o'clock daily, Sundays excepted.

The principal situations in Upper Canada, where arrangements are made for locating emigrants, are in the Bathurst, Newcastle, Home, and Western Districts.

Indigent emigrants, on condition of actual settlement, may obtain a location on the following terms, viz.

Fifty acres of land will be allotted to each head of a family, upon condition of paying at the rate of 5s. currency per acre. The first payment to be made at the expiration of three years, and the whole to be paid by annual instalments of L.3, 2s. 6d. each, with interest, to commence from the expiration of three years.

The government will incur the expense of building a small log-house, for the temporary accommodation of settlers on their respective locations, and will afford some assistance towards opening roads to the lands proposed to be settled, but will make no advances in provisions or utensils, and the settlers must depend entirely upon their own resources for bringing their lands into cultivation.

Settlers with means will have opportunities of purchasing Crown lands in several parts of the province at the public sales, due notice of which may be obtained on application at the Commissioner of Crown Lands' Office, York, or to the following government agents :—

Ottawa and Bathurst Districts,	Mr M'Naughton, at	*By-Town.*
Newcastle District,	Mr M'Douall,	*Peterboro.*
Home District,	Mr Ritchie,	*Township of Medonte.*
Western District,	Mr Mount,	*Carradoc and St Clair.*

A. C. Buchanan, *Chief Agent.*

SETTLING ON LANDS.

The difficulties which an emigrant has to encounter in settling upon his lands are most severe at the outset. His first object is to erect a wooden hut, formed of trees laid upon each other in a particular manner; and his neighbours, if he be in a located part of the country, will generally assist him. If quite inexperienced in such kind of labour, he must necessarily hire some one to build his cabin for him. In erecting one of these log-huts he must not consult an elegant outside appearance, all that is wanted being protection from the atmosphere and a fire to cook his victuals. Having selected a dry commodious situation, he will fell some trees, and, having cut them into straight logs, of the length required, and drawn them by oxen to the spot where the dwelling is to be placed, he will next lay them across one another at the corners, notching them half through at the ends, so as to admit them to lie close upon each other. A log-hut so formed is usually eighteen feet by sixteen. The roof is covered with thin shingles or split logs. As for the door and windows, they are sawed out after the house is erected; and the fire-place is formed with stones at one end. A log-hut, if paid for, will cost about L.12 when completed. The emigrant is next advised to bring his family, cattle, provisions, and farming utensils, upon his lot, and, when fully settled, to commence his operations on the forest around his habitation. The brushwood and small timber being cleared off, the trees are next cut down, the axe being applied at about three feet from the ground. Some persons cut a circle of bark from the trees, so that its vegetative principle may die, and the sun and air thereby reach the lands; but this plan is not to be recommended. The trees should be at once cut down and burnt, however toilsome the labour may be. The stumps will continue to disfigure the fields after this process, but these may be eradicated at any future convenient opportunity; and if the settler be active, he will in a few years have his whole lot, or *estate*, as we would term it, altogether clear and in a state of productiveness. The lands, after being cleared, require at first little cultivation; the ground is rudely dug or harrowed and sown, and the first crop in mostly every instance is sufficient to repay all that has been expended.

CANADA COMPANY AND ITS LANDS.

This association was incorporated by royal charter on the 19th of August 1826, and empowered to enter into extensive contracts with his Majesty's government for the purchase of reserves, and other large tracts of crown lands in the province of Upper Canada. By these purchases the Company became possessed of upwards of two millions three hundred thousand acres, one million three hundred thousand of which they hold in dispersed tracts of two hundred, two thousand, and ten thousand acres, and also, in a few cases of blocks, containing from twelve thousand to forty thousand acres. The residue, amounting to one million acres, composes one vast section of territory on the shores of Lake Huron, known by the name of the Huron tract, which was granted in lieu of the moiety of the clergy reserves scattered through the various townships of the province. Since the institution of the Company, it has been paying government from L.15,000 to L.20,000 a-year; and at the end of sixteen years, the stipulated period of credit, it will have paid L.295,000. The Canada Company sells its lands in small or large lots to emigrants, at much the same price as government; the lands it possesses are generally good, especially those in the Huron tract. Many prefer to buy their lands at once from this respectable association, which is considered liberal in its dealings. There are agents in London, Edinburgh, and other places, who will give every explanation to, and enter into arrangements with, intending emigrants. They will also furnish, *gratis*, plans of the lots.* The agents of the Company, on the arrival of the emigrants at Quebec or Montreal, will convey, at the Company's expense, purchasers who pay a first instalment in this country of 2s. an acre upon not less than one hundred acres, to the head of Lake Ontario, which is in the vicinity of their choicest lands; and their agents in all parts of the Upper Province will give emigrants every information and assistance in their power. Should emigrants, on their arrival, not settle on the Company's lands, the money paid them will be returned, deducting the actual expense of conveyance to York. The Canada Company sold upwards of eighty thousand acres of land in 1829, 1830, and 1831, in lots of various extent, at from 10s. to 14s. per acre.

The Huron tract, in the western part of the province, belonging to this Company, is nearly triangular in its general outline, and extends about sixty miles along the south-eastern and eastern shores of Lake Huron. "The general surface of this territory (says Bouchette) is remarkably level, and frequently presents rich natural meadows and excellent pastures. The soil chiefly consists of a deep, rich, black loam, with a subsoil of clay intermixed with sand, which, in point of facility of cultivation and fertility, does not probably yield to any in the province. The forests are composed of the most valuable and useful timber, and are not of that almost impenetrable thickness that in general characterizes a Canadian wilderness. The maple tree, which here predominates, is a source of essential profit to the farmer, from the copious supplies of sugar he derives from it, by the most simple process, and with the least possible labour and expense. The soil is well watered by the river Maitland, a large branch of the Thames and its tributaries, the River Aux Sables, and numerous rivulets and brooks. Fresh springs abound throughout the tract, and salt springs are frequent. The rivers are partially navigable, and are well adapted to the erection of mills.

In the township of Godrich, a town has been laid out on the borders of Lake Huron, in a good situation, with a harbour. The town of Guelph, the capital of another extensive tract belonging to the Company, situated in the county of Halton, district of Gore, is also in a thriving condition. The country around Guelph enjoys most of the advantages of the Huron tract, in respect of climate and fertility; but a nearer proximity to the older settlements of the province gives it probably a superiority of relative local situation.

The Company gives the following information regarding the lands it possesses for sale :—"Lots of land are selling at prices varying from 7s. 6d. to 20s. an acre, one-fifth payable down, and the remainder (which industrious settlers would be able to pay out of the crops) by annual instalments in five years, with interest. Settlers with capital, who prefer establishing themselves on land in which partial clearings have been made, and log-houses erected, will generally find lots with such improvements for sale. This arises from persons going originally in very destitute circumstances, or rather dependant on the Company's assistance, who, having succeeded on their lots, are willing to sell their land, with a reasonable profit, to new comers, at from four to six dollars, with the improvements on the same, houses, barns, &c. These individuals generally remove further westward, having acquired sufficient knowledge of the country, and purchase on the Huron tract, which is equal in quality, at from 7s. 6d. to 10s. per acre."

CHARACTER OF DISTRICTS.

The various writers on Canada each recommend particular districts for the settlement of the emigrant; but it is hardly to be expected that persons in this country can make a perfectly judicious choice, an absolute inspection of the lands, or at least information near the spot, being in almost every case requisite. The most elaborate details are given by Bouchette regarding the different parts of the province; and as what he mentions may be of use in furnishing emigrants with an idea of the nature of the lands, we take the liberty of offering a few of his observations.

"*The Eastern Section*, including Ottawa, Johnstown, Midland and Bathurst districts.—Situated between two broad and navigable rivers, the Ottawa and the St Lawrence, and centrally traversed in a diagonal course by an extensive and splendid sloop canal, connecting the navigation with the waters of Ontario, this section of country evidently enjoys important geographical and local advantages. Its surface presents, almost unexceptionably, a table level of moderate elevation, with a very gentle and scarcely perceptible depression, as it approaches the margin of the magnificent streams by which it is bounded to the northward and south-east. The soil, though sometimes too moist and marshy, is extremely rich and fertile, and chiefly consists of a brown clay and yellow loam. This section is intersected by numerous rivers, remarkable for the multitude of their branches and minor ramifications. There are also a number of good public roads, both along the St Lawrence and Ottawa, and into the interior. Great industry and attention to improvement are displayed upon most of the lands throughout this tract. The town of Kingston, the largest and most populous of the Upper Province, is very advantageously seated on the north side of the St Lawrence, or rather at the eastern extremity of Lake Ontario. The streets are regular and well planned, and the number of houses may be estimated at about 620. The town has now considerable mercantile importance; the harbour is well sheltered and convenient.

The thriving village of Perth is situated in the township of Drummond, on a branch of the Rideau, and occupies a central position between the Grand River and the St Lawrence, communicating by tolerably good roads with Kingston to the south, and By-Town to the northward, at the opposite extremities of the Rideau Canal. The first establishment fostered by government was made in 1815, by British emigrants, chiefly from Scotland, many of whom are now at the head of excellent farms, possess comfortable habitations, and reap the fruits of their perseverance and industry.

Ascending along the shores of Lake Chaudiere, the objects of note first presenting themselves are the rising colonies in front of the townships of March and Tarbolton; they are chiefly composed of families of high respectability, possessed, in general, of adequate means to avail themselves of the advantages that are incident to a newly-opened country. High up, on the bold and abrupt shore of the *Chats*, the Highland chief Macnab has selected a romantic edifice, Kinell Lodge, which he has succeeded, through the most unshaken perseverance, in rendering exceedingly comfortable. His unexampled exertions in forming and fostering the settlements of the township, of which he may be considered the founder and leader, have not been attended with all the success that was desirable, or which he anticipated.

The Central Section of the province (continues the accurate Bouchette) embraces the districts of Home and Newcastle, which occupy a grant of about one hundred and twenty miles upon Lake Ontario, extending from the head of the Bay of Quinté westward, to the line between Toronto and Trafalgar. Although less populous than the tract of country composing the first part of the division which we have adopted, this portion of the province does not yield to it in fertility, and is equally well watered by numerous lakes, broad and beautiful rivers, and innumerable rivers and brooks. The rivers in general abound with excellent fish, and especially salmon, great quantities of which are annually speared in the River Credit for the supply of the western country. In front of Newcastle district, on the borders of Lake Ontario, the soil consists of a rich black earth; but in the district of Home, the shores of the lake are of an inferior quality. The lands upon Yonge-street [roads are frequently called streets in Canada], which connects York with Lake Simcoe, are exceedingly fertile, but so destitute of stores as to create some inconvenience to the settlers. A sandy plain, of some extent, exists some distance north of Ontario, towards Rice Lake:

* The chief office of the Canada Company is at 13, St Helen's Place, Bishopsgate Street, London. The agents are—

For England.—*Bristol*, W. D. W. and W. E. Acraman; *Hull*, Richard Tottie; *Liverpool*, Hugh Mathie; *Oundle*, Thomas Bell; *Plymouth*, Hawker and Sons; *Swansea*, J. C. Morgan.

For Scotland.—*Edinburgh*, James Adam, W. S.; *Leith*, Jas. Duncan and Company; *Aberdeen*, J. Catto, Son, and Company; *Glasgow*, Alexander G. Gilkison; *Greenock*, R. Ewing and Company; *Haddington*, John Haldane.

For Ireland.—*Dublin*, John Astle; *Belfast*, William Gray; *Cork*, Sexton Bayley; *Limerick*, John Carroll; *Londonderry*, George Buchanan; *Ross* and *Waterford*, Watson and Graves.

In *Quebec*, John Davidson; *Montreal*, Hart Logan; and *New York*, J. C. Buchanan.

but, saving this, and probably one or two more comparatively insignificant exceptions, the soil of this tract of country is extremely fertile, highly conducive to agriculture, and yields luxuriant crops of wheat, rye, maize or Indian corn, peas, barley, oats, buckwheat, &c. The fronts of all the townships from Kingston to York are, with few exceptions, well settled; roads lead through them, from which, in many places, others branch off to the interior. At intervals, rather distant indeed from each other, there are a few small villages. On the lands that are occupied great progress has been made in agriculture; the horses, generally speaking, are strong and well built; and the inhabitants appear to be possessed of all the necessaries, as well as most of the comforts, that a life of industry usually bestows." In this division is settled the town of York. Our authority next proceeds to notice

The Western Section, including Gore, Niagara, London, and Western districts; but as part of this division is noticed under the head Canada Company, we need not here enter into long details. "With the aid of a little fancy (says Bouchette), the tract of country we are now describing may be shaped into a vast equilateral triangular peninsula, whose base, extending from Fort Erie to Cape Hurd on Lake Huron, measures 210 miles, and whose perpendicular, striking the Detroit River at Amherstburgh, is about 195 miles. It is bounded to the north and west by Lake Huron, River and Lake St Clair, and Detroit River; south by Lake Erie; and east by Niagara River, Lake Ontario, and the western limits of the district of Home. The surface it exhibits is uniformly level, or slightly undulating, if we except a very few solitary eminences, and those parts of the districts of Gore and Niagara traversed by the ridge of elevated land. The variety of soils, and the diversity of their combinations observable in these four districts, are by no means so great as might be expected in so extended a region. The whole tract is alluvial in its formation, and chiefly consists of a stratum of black, and sometimes yellow loam, above which is deposited, when in a state of nature, a rich and deep vegetable mould, the sub-stratum beneath the bed of loam being generally a tenacious gray or blue clay, which in some parts appears at the surface, and, intermixed with sand, constitutes the super-soil. There are numerous and extensive quarries of limestone to be found in these districts, that supply the farmers with excellent materials for building. Freestone is also found, but in small quantities, and generally along the shores of the lakes. The Thames River, in this section, rises far in the interior, and, after pursuing a serpentine course of about one hundred and fifty miles, in a direction nearly south-west, discharges itself into Lake St Clair." This portion of the province seems to us to be that most worthy of the attention of the emigrant; the climate is pleasant, the land excellent, the rivers numerous and useful; roads are opening up in all directions for the benefit of the inhabitants; and although at a great distance inland, the communication with the ocean is conveniently kept up by means of the lakes and canals. Were we about to emigrate, we would have little hesitation in directing our steps towards this portion of Upper Canada, so tempting from the prodigious vastness of its waters, the exuberant fertility of its extensive plains, its luxuriant orchards, and its busy scenes of rural and thriving industry.

Nearly equal to this tract, and superior as regards exemption from ague, is the Simcoe District, lying betwixt the lake of that name and the eastern part of Lake Huron. This land is about 100 feet above the level of Ontario, and of the richest quality. A steamboat on Lake Simcoe conveys the produce to Holland-landing at the south end of the lake, and a rail-road has been projected from thence to York. A great part of this tract being settled by naval and military half-pay officers, who draw their pay quarterly, there will, consequently, be more ready money circulating here, and more employment for all kinds of tradesmen, than in most other places. The land here is rising rapidly in value.

We may state that all kinds of tradesmen will find abundance of employment at York; but, in consequence of its low situation on Lake Ontario, it is liable to agues, and will be avoided by those who may be so affected.

It may here be remarked, that the general salubrity of the climate improves as you recede from the banks of the lakes and great rivers, although these possess, as a counterpoise, a greater facility of disposing of surplus produce, being nearer to markets.

The general complaints on the shores of the lakes and large rivers are fevers and the ague, which, although a most annoying complaint, is by no means fatal. By great care being given to regularity of the bowels, moderate use of spirituous liquors, keeping the feet dry, and unnecessary exposure to night air, it may generally be avoided. We cannot sufficiently impress on the minds of emigrants the necessity they will be under of adhering to temperate habits. In the Canadas, whisky is much cheaper than in Britain; hence this advice becomes of double importance.

Mr Fergusson, in his "Practical Notes," made during a tour in Canada in 1831, furnishes his readers with a number of valuable illustrations of the state and appearance of the Upper Province, along the routes he pursued: indeed, all who can afford it should purchase his very instructive and entertaining volume. Speaking of that part of the territory adjacent to Lower Canada, he says—"Returning to the St Lawrence, we enter the Upper Province, the Ottawa here forming the boundary line. As we ascend the river, we find numerous settlers, and thousands of acres well adapted for the farmer. One of the first settlements we meet with is the Glengarry district, an extensive tract of good land, enjoying the advantages of water carriage. The language, the customs, the native courage of their Celtic sires, still distinguish the clan, though at the same time, we are afraid, accompanied by some of those less profitable traits which stamp the Highlander as more at home in wielding the claymore, or extracting mountain dew, than in guiding the ploughshare to slow but certain results. The farms are but indifferently improved, considering the advantages they have enjoyed; and much valuable time is expended in the depths of the forest, in a demi-savage life, cutting and preparing timber for the lumber merchant, which, if steadily devoted to the cultivation of the land, would certainly be attended with infinitely greater benefit, both in a physical and moral point of view.

To go minutely into the statistics of even the banks of the river, would far exceed the limits to which I must necessarily restrict myself. Suffice it to say, that a constant succession of eligible situations present themselves for estates and farms. I was much pleased with the Matilda district, and consider it capable of great improvement. The soil is a fine mellow sandy loam, sometimes perhaps rather light, but admirably adapted for turnip husbandry and fine-woolled sheep, with numerous beautiful situations for a residence, the noble St Lawrence ever forming a prominent feature, its surface varied by lovely wooded islands, similar to those we so justly admire on many of our British lakes. In approaching Kingston, or the east end of Lake Ontario, the River Gananogue falls into the St Lawrence, and, at its mouth, is the establishment of Messrs M'Donell, two brothers who came about eight years ago to the colony, and who, by steady enterprise, without original capital, have realized considerable wealth, while, along with it, they have secured the respect and esteem of all who know them. They have here what is called in America a valuable water privilege, or fall, and have erected flour and saw-mills to a large extent. Last season they sent down to Montreal 24,000 barrels of flour; and a friend of mine, who was their agent, informed me that one of the brothers having resolved upon becoming their own agent in Montreal, it would be a loss of some hundreds a-year to his house in commission. They have a very clever cooperage worked by water, similar to the steam cooperage at Glasgow, and the articles turned out are uncommonly reasonable, substantial, and neat. I regretted much not having it in my power to form an acquaintance with these spirited colonists, more especially as they farm likewise to a large extent. The farm at Gananogue extends to 1200 acres, and the mansion-house and barns are commodious and handsome.

Having received very encouraging accounts at Kingston, of the country along the Bay of Quinté, a deep inlet of Lake Ontario, formed by a peninsula called Prince Edward's Island, I made an excursion into that district. The scenery was pleasing, in many places very fine; and settlements are forming on every hand. The soil is partly clay, partly loam and sand, sufficiently rich to yield fifteen crops of good wheat, with impunity, in a period of twenty years. Granite, limestone, and schistus, or clay-slate, are successively met with. Wherever a stream or creek of any importance falls into the lake, there we find a mill-seat and a village growing up, the embryo, in many cases, of considerable towns.

To the patriot or philanthropist, it is highly gratifying to remark, how the wants of the farmer and the interests of the trader or mechanic co-operate in the rapid progress of general improvement and civilization. Holywell, Sophiaburgh, and Belville, are all thriving villages of this description; and many individuals are to be met with in each, who, from the humble situation of merchant's clerks, &c., are rapidly acquiring independence.

York (he says in another place) is a very desirable station for a settler to choose as head-quarters, in looking about for a purchase. He is sure, at this place, to meet with numerous offers of farms, regarding which he will do well to act with caution; and he will be able to inspect the plans of public lands in the government land-office, under the superintendence of Mr P. Robinson, a gentleman able and willing to afford him every facility. The *rich* and *heavy* land of Upper Canada is not to be found, in general, upon the immediate banks of the lakes and rivers. It lies for the most part from twelve to twenty miles back, and thus compensates the enterprising settler for plunging into the forest."

CLIMATE AND PRODUCTIONS.

It will prove both important and interesting to persons who have any intention of emigrating to Upper Canada, to have some knowledge regarding the climate of the country. On this subject, Howison gives the following account:—

"The nature of the climate is a consideration of the greatest consequence to all those who propose to remove to a foreign country, and deservedly so; for a malignant atmosphere exerts an influence over the mind and body, which it is impossible to evade. But he who takes up his residence in Upper Canada runs no risk of suffering in this way. The climate, in the westerly parts of the province particularly, is alike healthful and agreeable. In winter, the thermometer occasionally stands several degrees below *zero*; but this intense cold seldom continues more than three or four days at a time, and is by no means unpleasant. The temperature, during January and February, may, in the generality of seasons, average 15° Fahrenheit. The snow usually lies six or seven weeks; but the time, of course, varies according to the quantity that falls. While it remains upon the ground, the carriage called a *sleigh* or *cariole* (which is too generally known to require description), is exclusively used, and forms a delightful mode of conveyance, one pair of horses being able to draw several persons sixty or seventy miles in the course of a day, without much fatigue. Often, for some weeks in winter, the sky continues bright and cloudless; and though the air is intensely keen, yet its bracing and exhilarating effects enable one to bear the cold without any inconvenience. At these times the public roads are crowded with sleighs; and the farmer conveying his produce to market, the wood-cutter hauling wood, the quack doctor, the merchant driving for pleasure, and the jogging traveller, all meet the eye in varying succession.

When the winter is moderate and steady, with plenty of snow, it is the most agreeable season in the year; however, it is sometimes subject to vicissitudes which render it the most unpleasant. I have seen storms of thunder and lightning in the month of February, the thermometer having stood at *zero* only a few days before; and have also known hail, rain, and snow occur successively in the course of half an hour. The changes of temperature are sometimes inconceivably sudden and extraordinary; but they affect the Canadians very slightly; for they are always prepared for them, and their constitutions are not so *barometrical* as those of English people. The winter season is extremely healthy, sickness of any description being almost unknown either among the natives or foreigners.

Spring commences in March; but the early part of this season is seldom agreeable, being damp, tempestuous, and rainy, and occasionally very cold. The roads likewise become so bad, that it is hardly possible to go out of doors. Towards the end of April the ground becomes dry, vegetation commences, and the fields afford a little pasture to the cattle. In May the earth is covered with verdure; and if the weather is genial and warm, the buds of the trees expand with astonishing rapidity, while the forests exhibit an innumerable variety of hues, all resplendently bright and exquisitely pure.

In June the orchards are in full blow, and a transparent atmosphere and cloudless sky prevail from the rising to the setting of the sun. During July and August, however, the heat becomes so intense, that it is unpleasant to leave the house, or take the least exercise; and musquitoes abound wherever there are woods, which prove a torment to those who are exposed to their attacks. The heat in the course of the summer has several times been found to exceed 100° Fahrenheit in the shade; but it usually averages from 82° to 90°.

The autumns of Upper Canada very much resemble those of Britain. October is usually a delightful dry month, with mild days and clear frosty nights. The early part of November is generally characterized by a peculiar state of the weather, which the Canadians term *Indian summer*. The atmosphere has a haziness and smokiness which makes distant objects appear indistinct and undefined, and a halo often encircles the sun. At the same time, a genial warmth prevails, and there is seldom any wind. The Indian summer is so delightful, that one would almost suppose the country where it takes place to be transported for a season to some celestial clime, where the elements ever existed in harmony and acted in unison. It is extremely difficult to explain the cause of the regular recurrence of this kind of weather; for scarcely a year passes, in the autumn of which there are not some days of Indian summer. It derives its name from the vulgar and prevailing notion, that the haziness of the weather is produced by the smoke which arises from the burning of the long grass that covers the immense prairies bordering on the Missouri and Mississippi. It is true that these prairies are annually set on fire by the Indians; but that the conflagration affects the climate and atmosphere of Canada, is an idea too absurd to require refutation.

The climate of Upper Canada has not yet attained that salubrity and purity which will eventually characterize it. Thick forests cover nine-tenths of the inhabited parts of the province, and these, by preventing the evaporation of water from the surface of the earth, produce marshes, swamps, and collections of water, which in their turn generate mists, chilly winds, and agues. When the woods are cleared away, the air, although perhaps colder, will be even more dry than it is at present. The lakes will then attract the clouds towards their surface, and Upper Canada will seldom be exposed to heavy falls of rain, or violent storms of snow.

I have already mentioned (he continues) that the soil and climate of the province are very favourable to the growth of fruit. The cultivation of orchards, however, has hitherto been almost entirely neglected. The kinds of fruit most common in the country are not well chosen, and they appear to degenerate from want of care and attention. Wild grapes grow abundantly in the forests, and would, I believe, by proper culture, become equal in size and flavour to the garden grape, and also fit for making wine. Hickory nuts, walnuts, butter-nuts, plums, wild strawberries, cranberries, &c. are found in profusion almost every where, and might all, of course, be improved in value and quality by suitable cultivation.

The soil of Upper Canada is in general excellent, and likewise of easy cultivation. Wheat is the grain that is raised in greatest quantity. A bushel and a half of seed is generally allowed for an acre, and the return averages from twenty-five to thirty-five bushels. Buck-wheat is also cultivated to a considerable extent, and an acre yields about fifteen bushels. Rye succeeds well, the crop being generally twenty bushels an acre. Oats are very indifferent, and much inferior to those raised in Europe, being small and light in the grain, and, comparatively, not nutritious. An acre yields on an average from thirty to forty bushels. Barley is but little known in Upper Canada; however, it would appear that the seasons are rather too warm and dry to be favourable to its growth. Indian corn is much cultivated in the western parts of the province, and yields largely, if it is not injured or destroyed by late frosts. Potatoes succeed well in most soils, but are much inferior in quality to those produced in Britain. Turnips also form a profitable crop, and are used to feed live stock during winter; but the vegetable best adapted for this purpose is the squash or gourd, which affords an abundant crop, is much liked by the cattle, and never communicates any unpleasant flavour to the milk of the cows, as turnips invariably do.

But while examining this general estimate of the returns made by different crops, it must be recollected that in Upper Canada the land is scarcely ever made to produce nearly so much as it would do, were it under judicious cultivation. The Canadian farmers have no system in their agricultural operations, or in the management of their lands, and they prepare the soil for the reception of the seed very imperfectly. These circumstances are generally the result of ignorance, but often arise from a want of capital, and a difficulty of procuring labourers to assist them in the business of the farm. Were an enlightened English farmer to subject a portion of the best lands in Upper Canada to the British system of agriculture, making of course those deviations which the climate, soil, and other circumstances might render necessary, he would raise crops infinitely superior, alike in quantity and quality, to those that are generally yielded at present throughout the province."

MAPLE SUGAR.

In Upper Canada, the inhabitants of the woody districts have it in their power not only to supply themselves with sugar for the use of their families, but to make such quantities as may be advantageous in a commercial point of view. This sugar is produced from the sap of the maple tree, one of the most valuable vegetable products of the American forests. An active farmer and his wife may make, it is said, about 700 lbs. of sugar annually, not inferior in quality to that of the West Indies, and worth about 4d. per pound. The manufacture of this native sugar greatly tends to lower the price of West India sugars, which would be otherwise as high as 1s. 6d. a pound. Talbot, in his "Five Years' Residence in the Canadas," writes with enthusiasm of the value and use of this manufacture, which it seems is far from being properly attended to by the settlers. "Maple sugar might be manufactured (says he) by the rudest mountaineer in your country, as well, in the first season after his arrival here, as by the most eminent sugar refiner in Jamaica. The manufacture is generally commenced early in the month of April, when the sap of the tree is first put into motion at the return of spring, and when no other agricultural operation can be carried on to good purpose by the farmer, on account of the unpleasant weather which occurs at that period. A part of the estate is selected which contains the largest quantity of flourishing maple trees nearly contiguous to each other; and a temporary hut is erected for the accommodation of the operators, not more than two or three being required for the management of a hundred trees, from every one of which the sap is oozing out at the same time. In rainy weather, the trees yield their valuable juice rather tardily; and, during the whole month which is sometimes devoted to this employment, it often happens that only eight or nine days are propitious to this part of the settler's labours. The best weather for the purpose is that in which the night is frosty, and the day cheered by the rays of a warm sun. If the process of boiling were not continued both day and night, the sap would accumulate too rapidly in the reservoir, and soon evince symptoms of vinous fermentation, which would change its quality, and render it useless for the manufacture of sugar.

The first thing necessary for commencing the manufacture of this article is a metal boiler, which costs in Upper Canada about L.2, 10s. sterling. This holds nearly thirty gallons, and, with a small cooking-pot, is sufficient, in a prosperous season, to boil down 800 lbs. One hundred and fifty troughs, eight reservoirs, and four hand-buckets, will be necessary for the regular supply of this boiler. The troughs cost about 12s. 3d. per hundred; the reservoirs, which are barrels without heads, about 4s. each; and the buckets, 2s. 6d. each. These are the only utensils which an emigrant will need: The troughs may be made by himself, if he has acquired any skill in the use of his axe during the preceding winter. An expert hand can make 30 or 35 troughs in a day, which, though formed only with the axe, will last for many years, if carefully placed under cover during summer. The trees are tapped either by means of an incision made by an axe, or the perforation of an auger. But the latter mode is considered the less injurious to the growth of the tree, and is therefore the more approved plan. A small spout about nine inches long is made the conductor of the sap from each incision to its respective trough, from which, when nearly full, it is conveyed in buckets to the reservoirs, and there allowed to subside. When the grosser particles of the sediment have been left to sink to the bottom, the sap is drawn off into the boilers, and reduced to molasses by the simple process of evaporation. The liquid in this purer state is then drawn from the boilers, and placed in the reservoirs, or coolers, until it becomes nearly cold, when it is strained through a woollen cloth into a smaller boiler, and, after being clarified with eggs, milk, or bullock's blood, is boiled down to the consistence of sugar, and poured into moulds of the particular shape which it is intended to assume as a sort of candy; but, if to be used as soft sugar, the syrup in its last stage of purification is left in a sugar-cask, which is perforated, to allow the moist particles, in the form of molasses, to ooze through the bottom. Many people neither clear nor strain the molasses, and consequently make very coarse and dirty sugar; but by a strict adherence to the simple directions which I have given, the most ignorant novice in the art might manufacture sugar equal to any that is imported into England. Some of it, indeed, has what is called 'a smack,' or peculiar taste, derived often from the kind of wood of which the troughs are made, and sometimes from being neglected while in the act of boiling, and suffered to burn. Every tree, on an average, will from a single wound yield about twenty gallons of sap, and a proportionate quantity from any number of incisions not exceeding four. Five gallons of sap contain at least one pound of sugar."

POTASHES.

Settlers in the woods have also an excellent opportunity of manufacturing potashes, an article of great use and considerable value. A vast quantity of this substance is annually made in Canada, and exported to Great Britain. Potashes are made from the ashes of burnt trees. In burning timber to clear the land, the ashes are carefully preserved, and put in barrels, or other vessels, with holes in the bottom; and water being poured over them, a liquid or alkali is run off; this ley being boiled in large boilers, the watery particles evaporate, and leave what is called black salts, a sort of residuum, which, when heated to a high degree, becomes fused, and, finally, when cool, assumes the character of potash. By these potashes the Canadians make their own soap: the ley of a barrel of ashes, boiled along with ten pounds of tallow, till it is of a proper consistence, produces about forty pounds of very good soft soap. It is related, that when the land has been covered with heavy timber of a hard nature, there is such a quantity of ashes produced that their value will pay for clearing the land.

ORIGINAL LETTER FROM AN EMIGRANT.

We have much pleasure in now introducing an original letter from Upper Canada, which brings up information regarding the colony to the month of November 1832. The emigrant by whom this letter was written was, till lately, a shopkeeper in Edinburgh, and a person of respectability and substance. Finding that his means as a tradesman were subject to constant diminution, and that, by the most persevering efforts in his business, he could not anticipate a competence, at however distant a date, he resolved on emigrating to Canada; and the result of this important step, it appears, has been such as he had reason to expect. We give his very interesting letter to a friend in Edinburgh, precisely as it was put into our hands, and only suppress the name of the writer; but we vouch for its authenticity and the integrity of its details, and thus leave it to make its own impression on the minds of intending emigrants.

Whitby, Upper Canada, 14th Nov. 1832.

MY DEAR SIR,—I confidently expect that long before you receive this letter you will have heard of our safe arrival in Canada, in good health, and otherwise in comfortable circumstances. We stopped at Quebec for eight or ten days, during which time I never allowed my family to quit the ship, in dread of the cholera, which raged in the town at the time with very great violence. We immediately proceeded on our journey to York with all due speed; this is performed partly by land, and partly by water, the accommodation in both cases perhaps as good as the country can afford; the charges, however, are very high. I paid for my luggage alone, from Montreal to York, nearly L.12, and for my family a great deal more; from Quebec to Montreal my luggage cost nothing, this circumstance arising entirely from great opposition in the latter case, and more in the former. Our journey, however, upon the whole, was comparatively agreeable, and, under the superintending care of Divine Providence, we arrived at York in safety and good health. I had expected, upon our arrival at York, to have stopped there for a month at least, and left my family, while I myself surveyed the country for the purpose of obtaining information, and procuring a permanent place of residence, but I found this to be quite impracticable, owing to the state of the town—as regarded the cholera—and secondly, as regarded the enormous rent of houses. I therefore determined to quit York next day, and proceed to Whitby. I accordingly procured a coach for that purpose, and came to John Williamson's; we stopped there for eight or ten days till once our luggage arrived; I then procured a small house. We lived in this house for four or five weeks, when a hundred acres of land coming to hand, which I considered well worth the money asked for it, I purchased it, and am now lodged in my own house, and at my own fire-side, with my family around me, all in excellent health and spirits. I have thus shortly conducted you from Quebec to York, and from York to my *lairdship* in Whitby, where I shall leave you for a while, and proceed to matters of perhaps greater interest. The scenery upon the banks of the river and lake between Quebec and York is very dull, and altogether uninteresting—at least it appears to be so in my eyes, and, I believe, in the eyes of Scotsmen in general, so much accustomed to hill and dale. Excepting towns such as Montreal, Kingston, a few villages, and farm-houses, nothing is to be seen but an interminable range of wood, stumps of trees, and wooden fences, which are at once calculated to damp the spirits of the emigrant, and to make him wish he had never left his native land. I can assure you, Sir, I then felt that Canada, as it is, was not the Canada I had formed an idea of in my own mind; I was severely disappointed on this score, and I believe thousands have experienced the same kind of disappointment, and have returned home with an evil report of the country, without giving it any thing like a fair trial. I mention this circumstance, in order to warn any person who may be similarly placed not to despair; only let him allow reason to resume its legitimate sway, and those airy castles which had been formed in the imagination will be demolished in a minute—Canada will then be seen as it really is. And what is Canada? Why, I'll try to answer that question. Well, then, Canada is a country where persevering labour and industrious habits will accomplish what the same persevering and industrious habits will not accomplish at home. I frankly confess, however, that this circumstance, coupled with the entirely different manners and customs of the people, so wrought upon me as to damp my spirits very much—so very much, indeed, that I deeply regretted I had ever left Scotland. I then found it no easy matter to bid adieu to my native land—the land where repose the ashes of my father, my mother, and sister, the wife of my youth, and some of my dear children; it was then that the early scenes and associations of my boyhood and youthful years rushed into my mind in all their native force and impetuosity, and, in language of silent eloquence, unuttered and unutterable, consecrated these scenes as sacred, and the places where they happened.

Whitby is universally allowed to be one of the finest townships in the whole of the Upper Province; its local situation, as regards markets and the other conveniences, is very good; there is always a ready market here for all kinds of farm produce; the soil is excellent, and, taking all things to account, generally speaking, well cultivated; the price of land here is rising very fast—land that was selling last season at from 15 to 20 shillings per acre, has advanced to 25 and 30 shillings, and cleared land, which was selling at L.4, 10s. per acre, has advanced this season to L.5 and L.6, and, in all probability, will advance still higher; so that it appears to me quite plain, that those who intend to emigrate, especially those who intend to purchase land, should do so as soon as possible. Whitby, in my opinion, is a very eligible situation for emigrants of almost every description; there is not a baker in the whole township; there is not a flesher; a wright and cabinetmaker would succeed well, provided he kept close to his business; a tavern-keeper to keep lodgings for travellers, and be discreet, would also do well; store-keepers have all made fortunes, and more fortunes may still be made by emigrants judiciously following out the same line of business. But why do I enumerate? Suffice it to say here, that Canada is a rising country, and every class of emigrants must succeed, provided they act with prudence and caution. There are a good number of Scotsmen settled in this part of the country. Upon the one hand, and within ten minutes' walk of my house, is a Mr Armstrong, a justice of the peace for the district; I had the honour and happiness to dine with him the other day, when I found him to be a very agreeable and intelligent gentleman. His case is a singular one, inasmuch as it clearly shows, in a strong point of light, what perseverance and industry will accomplish, under trials and difficulties seemingly altogether insurmountable. This gentleman came to the township in Whitby about twelve years ago, without any original capital; he bought 200 acres of land, and began clearing it with great spirit; he built himself a log-house, and all things seemed to go on and prosper; but in an evil hour his fair prospects were completely blasted, and his fondest hopes dashed from his lips to the ground. His log-house was reduced to a heap of ruins by fire, and his little all perished along with it. He, however, by extraordinary perseverance and industry, soon overcame the whole, and he is now proprietor of as fine land as Canada can boast of. His whole property cannot be valued at less than between L.2000 and L.3000. The next that I shall mention is a Mr Tweedie, from Symington, in the Upper Ward of Lanarkshire. This gentleman came to this country about three years ago, and brought L.500 with him; he has now property worth L.1200. Much about the same distance from me as the two other gentlemen, is a Mr Balmer, from Roxburghshire, who came to this township, and without any original capital has succeeded in getting his land cleared of wood, and mostly cleared of debt. This gentleman is certainly a very remarkable instance of what perseverance and industry will accomplish. Nearer me still are the Messrs Williamson, from Stockbridge. These gentlemen have bought 100 acres of land, at a remarkably low price, and promise to do well. The next is a Mr Hepburn. He has bought 100 acres of land, very fine, and has begun the clearing of it with great spirit. Adjoining to him is a Mr Black, from the neighbourhood of Carnwath, who came out this season. He has bought 300 acres of excellent land, and has begun to improve it with great spirit also.

You will thus see, from what I have enumerated, that I am in no great want of Scottish society, and it only requires a few more to enable them to go on in public matters with greater spirit and complete success. As regards the state of religion in this township, I would say, that the majority of inhabitants are composed of Methodists and Baptists, and the remaining part are Presbyterians and Quakers. These different classes have all of them places of worship, except the Presbyterians, who are not yet supplied.

Schools for the education of youth are very numerous in this township, but a great deal requires to be done in the way of obtaining better teachers; as society advances, however, this will be rectified. The season here has been rather backward, in consequence of which a considerable failure of certain kinds of crop has taken place. Wheat, upon the whole, may be considered an average crop, and so may oats; but hay, Indian corn, buck wheat, and potatoes, have failed to a considerable extent. On that account, markets are looked upon to be very high during the season, and holders of grain are beginning to speculate on the subject. Wheat has been selling during the summer as high as six and seven shillings per bushel, and other kinds of grain in proportion. Potatoes are at this time selling at 10s. per two imperial bolls, and are expected soon to be a great deal higher. Butter brings here 10d. to 1s. per lb.; cheese, 10d. to 15d. per do.; eggs, 7d. to 7½d. a dozen; pork, L.3 to L.3, 5s. a barrel of 200lbs. Cows from L.4 to L.6; a good yoke of oxen from L.17, 10s. to L.20; and horses from L.20 to L.25 each. Farm-servants get from L.25 to L.30 per annum, with victuals. It is impossible for me to say what may be the wages of mechanics, as I have not been able to obtain correct information upon the subject. Harvest wages are a dollar per day, but still you can cut your own crops a great deal cheaper than in Scotland. Cradling wheat and oats is a very common way of cutting these kind of crops, and I can assure you a very excellent way it is. A Canadian can easily cut two acres of wheat per day. There are plenty of labourers who will take it to cut it at 5s. per acre, and upwards, according to the heaviness of the crop. Farming utensils seem well adapted to the present uncultivated state of the country, and work well, where Scotch carts, ploughs, harrows, &c. would be of no use whatever, and the same observations apply to carriages on the roads. Upon land free of stumps, however, the case is different; upon such land Scotch implements of husbandry are decidedly preferable. Oxen are much used in husbandry, and, in so far as my opinion and observation go, they are used wisely. It is truly astonishing to see these cattle drawing the logs of wood together in heaps for burning, and to see them ploughing and harrowing among the stumps. I have often stood upon the road in passing, and admired the docility and tractableness of the animals, and, while viewing such scenes, have thought that Canada could not have been cultivated without them, the fast and fiery disposition of the horse, in general, utterly unfitting them for performing any such work. The same observations also apply to roads in wet weather, as oxen will go through with the same load where horses would turn restive and refuse to work altogether; *both* are best, however; and it so happens that Canada is richly stored with both.

As regards my own situation and prospects, I am truly happy to say that they are cheering. It is allowed on all hands that the purchase I have made is a good one. It is a hundred acres of very fine land, fifty of which are cleared, with an excellent new barn upon it, built this season, which cost L.70, with a frame-house and other offices. The soil is a deep rich loam, and adapted to every kind of crop. Its local situation is also excellent, being within one mile of the main road between York and Kingston, where coaches pass daily; and about three miles from Windsor Bay, where there is plenty of shipping to all parts. A fine stream of water runs through a part of it, upon which is erected a saw-mill, and presents one of the finest situations for a grist-mill, which is very much wanted in this part of the country. The price I paid for my land was 256 sovereigns; but, after deducting the improvements on it, it costs only 22s. 6d. per acre—a small price, when it is considered that land in its immediate neighbourhood is selling at from L.2 to L.2, 10s. per acre.

My prospects of a crop next season are not of the most flattering description, owing entirely to the extreme indolence of the person I purchased from. I shall, however, have five acres of wheat in pretty good condition, and other crops in proportion. I intend to keep 10 milch cows next summer, which will pay me well, as dairy produce sells very high. By next fall of the year, if spared so long, I shall have 50 acres ready for wheat, which, calculating the produce per acre so low as from 25 to 30 bushels, will bring me from 350 to 400 bolls of wheat, which, at 5s. per bushel, will be as many pounds; this, along with the produce of the cows, and other crops, will bring me a sum nearly equal to pay all expenses, and bring me back the whole of the money I paid for the land. I do not mean to say that I shall have 50 acres of wheat annually; but I do mean to say, that, by prudent management and persevering industry, I shall be fully enabled to realise between L.300 and L.400 a-year, for the payment of expenses and the maintenance of myself and family. This circumstance, coupled with the fact that I have no rent to pay, and almost no taxes, certainly presents, in a worldly point of view, a cheering and animating prospect indeed. This, I believe, is no exaggerated statement; but as I have had no opportunity of realising it in my own experience, I only offer it as my opinion. Being upon the spot, however, and judging from the state of the markets, and other circumstances, I not only offer it simply as my own opinion, but as my *decided* opinion. If the above statement be at all correct—and I believe I am rather below the mark as otherwise—then it must appear perfectly plain to every unprejudiced mind, that, in so far at least as worldly circumstances are concerned, the ends of emigration are completely answered. It is perfectly true, that, if a person is judicious in laying out his money upon land, and be at all industrious, he must be independent; and let it be understood, that the same observation applies to every branch of trade.

It is no uncommon occurrence, however, to find persons possessing from 100 to 300 acres of land, of the finest quality, not at all able to support their own family, proceeding entirely from their own indolence; but this circumstance, melancholy as it is, is one of the reasons, among many others, why an industrious man makes himself the sooner independent, inasmuch, at least, that in so far as the individuals alluded to are concerned, the market for grain and other farm produce remains almost entirely unoccupied, and naturally throws a greater number of local purchasers into the market. The prospects of the farming interests in this young country are certainly of a very pleasing description, and calculated at once to rouse and animate the mind to redoubled activity and vigilance, in endeavouring, by honest industry, to better the circumstances of yourself and family. All kinds of farm produce have been gradually on the increase for these two or three years past, and still continue so. I believe I am correct when I say, that, speaking generally, both cattle and grain have risen one-third, and in some cases more than one-half, within the time alluded to. A farmer here is at little or no expense whatever as regards his young cattle after they are one year old; they are turned into the woods, and thrive there remarkably well; they will regularly return to the farm, once or twice in the fortnight, for the purpose of getting a little salt—a thing which all cattle must have in this fresh-water country; they then go back to the woods again, and I have not heard of any of them being lost. As regards swine, the case is somewhat similar. Many a farmer keeps from fifty to sixty of these animals, which do not cost one sixpence for keep, except when any are penned up to feed off; they then get a little Indian corn, peas, &c. &c., and, as I am informed, pay well. Under these circumstances, it must appear quite evident that the land that would thus be required for the maintenance of the above species of stock, the farmer has it in his power either to put a crop upon it, or milch cows; and this presents another source whereon he may calculate with safety the sooner to raise himself, and, of course, to independence.

Such being the facts of the case, and when all things are considered, I have not the slightest hesitation in declaring, that it appears to me as plain as the sun at noonday, that a farmer in Scotland, occupying a farm that does not pay him, distressed as he must be, perplexed and degraded, toiling from morning till night, with a degree of mental anguish pressing upon him, calculated at once to unnerve all his energies, and to bring him to a premature grave, and yet, after all, unable to support his family or better their circumstances in any shape—I say, a farmer, in such circumstances, ought to rouse himself from his lethargy, and, by one grand and mighty effort, shake himself free of the fetters by which he is enclosed, and, along with his family, cross the mighty Atlantic, and set himself down in Canada, where his talents and industry as a farmer will be far better paid, and both his character and standing in society, in a moral and political point of view, more duly appreciated.

These observations apply with equal force to every other class of persons placed in similar circumstances, and to all such the call to bestir themselves is equally loud. If I were asked the question, whether (all things considered) I would purchase land, or betake myself to some other trade, I would instantly answer, *Buy land.* I do not mean to say, however, that purchasing land is the quickest way of realising a fortune. I believe the reverse to be the fact. I am persuaded, however, it is the safest plan. As regards people in the mercantile way, I am credibly informed there are several in this line, and even in this township, who have realised fortunes, within these ten or twelve years past, of upwards of L.1500. This fact speaks volumes to persons in that line, and requires no comment from me.

I shall now state a few things that may be of use to such of my readers for whom this letter is intended, and who may have emigration in view. I here wish it distinctly to be understood, that I mean to offer no advice, but simply to state my own opinion, leaving those who read to judge and determine for themselves. What I have just now stated applies to every other part of this letter.

The price of land varies in this township according to circumstances; for instance, land upon the front of the township, say cleared land, and free of stumps, is selling at from L.5 to L.6 per acre, upon a farm of 100 acres in extent, and 75 acres cleared. Again, a farm of the same extent of land and clearance, but the stumps upon it, and similarly situated, sells at from L.4 to L.4, 10s. In proportion, however, as you go back into the township, the price falls. A farm of 200 acres, seven or eight miles back, with 70 acres cleared, but the stumps upon it, sells at from L.2 to L.2, 10s. per acre—houses upon the farms in both cases, to less or more extent; uncleared land in the former situation, at L.2 to L.2, 10s., and in the latter case, at L.1, 5s. to L.1, 10s. per acre. Lodgings are very ill to be got here, and present very serious difficulties to emigrants with large families. I myself was exceedingly put about in this respect; but these difficulties were soon overcome. A room with firewood included, costs 5s. per month. Persons with small capital, say from L.50 to L.100, must lay their account with hard work. In my opinion, they ought to buy land, if they intend to do so, whenever they arrive, and pay the first instalment; then work at some trade or other for a year or two, and in the interim pay the instalments as they fall due: they may depend on it they will find this plan very much to their advantage, as it will assuredly better their circumstances very much, and enable them to go on their land with every prospect of complete success. For want of such caution, I am credibly informed that many a one, in the course of a year or two, get so entangled as to be obliged to quit their farms, and so render their situations incomparably worse than at first.

Upon the whole, from what I know personally, and from others, I am decidedly of opinion, that, in almost all cases of the above description, the plan I have just now recommended ought invariably to be adopted. There are very few lots of land in this township which are not already occupied, but there are plenty of farms to purchase from private individuals; there are still, however, a few lots, and I shall give you a description of one of them. This lot is situated on the front of the third Concession, about one mile distant from me, on the main road from York to Kingston, and about three miles from the lake. It consists of 600 acres of excellent land, with a large stream of water running through it, and includes by far the best waterfall and situation for a grist-mill that is to be found in the whole township. The price put on it is 30s. per acre, and is certainly well worth the attention of persons of capital and enterprise. Keeping in view the case of the M'Donalds, I do not think it at all presumptuous to look forward to similar results.

In my opinion, all articles of household furniture, husbandry utensils, &c., ought to be brought out, at least so far as the circumstances of the individual will permit. I hazard this opinion from my own experience, because, had I known what I now know, I certainly would have brought out more than I did. The price of conveyance from Quebec to York is 4s. 7d. per cwt. All articles ought to be put up in as small packages as possible. China, crystal, earthenware, &c., ought to be carefully packed. I unfortunately had the most part of what I brought with me of that kind broken to atoms.

With regard to how emigrants should bring out any capital they may have, I dare scarcely venture an opinion. I myself brought out the most part of the capital I had in *gold*: I got 24s. for every sovereign, which certainly paid well. In other circumstances, however, prudence may dictate otherwise.

Upon the voyage out, your provision store should consist mostly of oatmeal, plenty of potatoes, eggs, hams; plenty of porter and ale, which you will find to be very useful. Tea will not be much used; coffee will. Bring along with you some rice, with every other article to make a rice pudding; and particularly bring plenty of red herrings; you will find these very useful indeed; a few dried fruits; &c. Be sure to bring provisions for three months at least; and if you do not use them all on the voyage, you will find them of great use to you afterwards.

I would strongly recommend all emigrants to come out by the way of New York; the expenses are much the same in both cases, and the passage shorter, and by far the safest. You will then get intelligence which way to proceed, to go to York, or any other part in Upper Canada.

I had written thus far, when I have now to state that I have purchased 50 more acres of land immediately adjoining the 100 acres I formerly purchased. I paid rather a high price for it as otherwise, viz. L.3, 10s. per acre. It, however, makes my farm a complete one, and is not surpassed for quality of soil and local situation by any farm in the township of Whitby. There are about 20 acres of cleared land upon the 50—so that upon the farm there are in whole 70 acres cleared, 50 acres with stumps upon it, and 20 acres free of stumps. I have let about 30 acres of woodland, to be chopt, logged, burnt, and fenced, and ready for receiving the seed by the first of September next, at L.3 per acre. If the land is sown down with grass-seed immediately after the first crop of wheat, and remains so, it will require 10 or 12 years in that state to rot out the stumps; but if continued under the operation of the plough, the stumps will come out in six or eight years, and in some situations a good deal sooner.

The above purchase will materially increase my yearly income, without adding much to the item of expenses. In the meantime, however, my expenses are high, but not near so high as the same extent of land would require in Scotland for stocking it only, *and a heavy rent to boot*, and the returns not much less. The weather here at this time, 10th November, is uncommonly fine, with a slight frost in the mornings, and clear sunshine through the day. I will have the most part of my land ploughed before the winter sets in, which is calculated to take place about six weeks hence. I have hired a man of the name of John Cairns, a Scotsman, from Symington, in the Upper Ward of Lanarkshire, who came out this season. He seems a very quiet and steady lad, and ploughs uncommonly well; with his help I intend to chop ten acres of wood during winter. The wood upon the land here, in general, is not very heavy; the trees are very tall, but not of great girth—of course they are more easily managed to cut into proper lengths for drawing into proper heaps to burn. I have thus endeavoured to give you all the information at present in my power. The facts I have stated may with safety be depended upon, and, as regards my own opinion, you can either adopt or reject it as you choose. I must say, however, that I have given it candidly and honestly; and whatever difference of opinion there may be on the subject, I can say, from the bottom of my heart, these hands are clean. Emigration, however, is a serious matter, and I would advise every person to be fully persuaded in his own mind before he resolves upon the step. You can easily perceive, by the tenor of this letter, what my mind is upon the subject, but, as I said before, so say I now again, let every who reads, judge and determine for himself. I shall now conclude, by observing that Canada may, with propriety, be emphatically styled the poor man's country—to such persons the prospects in this country are certainly cheering. Language cannot describe the thrill of pleasing and delightful sensation which must take possession of the breast of every one, who, from a state bordering on absolute destitution, is thus suddenly raised to a state of comparative plenty and independence. In such distressing circumstances, how often must such a man, while looking with trembling emotion upon the wife of his bosom, and the dear innocent and prattling pledges of their mutual affection and love to each other—how often, I say, must such a one, with tears in his eyes, have perceived such coming misery with horror and dismay, the contemplation of which is calculated at once to palsy every nerve within him, and freeze the blood within his veins! Things, however, are changed for the better. The mind that was once the constant prey of fearful forebodings of coming wretchedness, is now peaceful and serene. The cloud that was dark and lowering, and threatened a coming storm, has now passed away, and the sun, which was thus for a time obscured, suddenly breaks forth in all his noonday brightness and brilliancy. Well may such persons (at least in so far as worldly circumstances are concerned) lay their heads down upon their dying pillow, and with their weeping family around their beds, commit their souls to God, and close their eyes in death, without a corroding thought of what is to become of their surviving relations, after they have gone the way from whence they shall never return.—I am, my dear Sir, yours sincerely,

J. F. S———

Since the preceding was written, the price of rural produce has risen considerably in Upper Canada, a circumstance advantageous to those already in possession of cleared productive lands, and which will act as an incentive to the emigration of agriculturists.

EMIGRANTS ON HALF-PAY.

Upper Canada seems to be a country excellently adapted for the comfortable settlement of officers on half-pay, and others who happen to be possessed of a small annuity. The sums of money they from time to time receive enable them to purchase many of the conveniences and luxuries of life; the style of living suits their previous habits, and they have it always in their power to provide for their children, which is not often the case with those upon small fixed incomes in this country. It will also be remembered that government gives a certain quantity of land gratis to those who have been in the army. Captain Hall, in his "Travels in North America," presents his readers with a letter which he had received from a half-pay officer, who had emigrated to Upper Canada, an extract from which we here take the liberty of offering, as illustrative of the condition of emigrants of that class:—

"Having made my mind up, in the winter of 1818 I began to make preparations, by disposing of my household furniture, reserving for myself beds, bedding, carpets, and such other things as were portable, and likely to be useful. I also made arrangements for borrowing the sum of L.200. Arrived at Bristol, I procured a variety of tools, implements of husbandry, clothing, &c., to the amount of L.100, and laid in a good stock of provisions, and every thing likely to make the voyage comfortable across the Atlantic.

We sailed on the 3d of May 1819, and after a tedious voyage to Quebec, and some detention afterwards in getting up the country, we arrived at the village of Cobourg, in the district of Newcastle, on the 19th of July. The whole of my expenses for voyage, provisions, and all other travelling charges, amounted to L.100, 8s., so that, on my arrival, I had a very small sum left. However, my quarter's pay came round; I was in a cheap country; and, moreover, found a most warm and hospitable reception in the house of an old and esteemed friend. As a new township on the Rice Lake was about being surveyed, and I had not means to purchase a cleared farm near my friend, I determined to wait till the survey was finished, and try the Bush—as the woods here are called. This was in the month of December of the same year. I then obtained the grant of land my rank in the naval service entitled me to. In February 1820, I contracted with two men to put me up a log-house, 28 feet by 20; and thirteen logs, or as many feet, high; to roof it with shingles, and to board up the gable ends; and to clear off one acre about the house, to prevent the trees from falling on it, for all which I paid them 100 dollars. This shell of a building had merely a doorway cut out of the middle; and when my friend and the clergyman of Hamilton drove out in a single sleigh with me, to see it, and we took our dinner at one end and our horse at the other, on a miserably cold day in the month of March, it looked wretched enough; but as it was the first but one, so it was the last in the township. Whilst the snow and ice were good, I moved all my effects, got boards sufficient to finish my house, and a six months' stock of provisions out, and on the 8th of May took my family into their pile of logs in a Canadian forest.

I will own, for a time our situation appalled me, and to my then unformed judgment in Bush matters, it seemed a hopeless struggle; but I was out with my family, and as I did not want for energy, I set to work in earnest. To two Americans I let a job to chop four acres and a half, at six dollars an acre; and at the same time, a man whom I had occasionally employed at home, followed me out, and came to hire. During the course of the summer, he felled and chopped up three acres more; my cleared acre I planted with potatoes, a little corn, and turnips; my stock consisted of a cow and yoke of steers three years old, with the management of which I was totally unacquainted when I bought them; but if a man will give his mind to any common thing of the kind, and not think it a hardship, it is surprising what he may do, as in this case after a few days I found no difficulty.

I was now anxious to get my house made habitable as soon as possible, and a carpenter being employed not far off, I endeavoured to engage him to put in the windows and door; but finding that he wished to take advantage of my situation, I determined to do it myself, and thus was forced to learn the business of a carpenter. This I considered no hardship, as I had always been fond of the use of tools, and had, previous to my leaving England, taken several lessons in turning. During the summer, I got my house chinked, or filled the interstices between the logs with pieces of wood to make the inside flush or smooth, and to prevent the mud used as plaster on the outside from coming through. I then put in the windows and door, laid the floors, and partitioned off the lower part of the house into two good rooms, on wet days employing my men to dig a cellar under the house; in short, before the winter, I had made the log-house comfortable within, and, with the addition of some white-wash, smart without.

In August, we cut some coarse grass in a beaver-meadow close by, sprinkling salt through the little stack as we made it; after this we logged up and cleared three acres of the land I had chopped, and by the latter end of September had it sown with wheat; the logging, though heavy, I did with my hired man and steers, and before the winter had it fenced with rails. Here, it may be remarked, I did not get much land cleared, but by doing little, and that partly with my own hands, I gained experience; and I would strongly advise gentlemen settling in Canada with small means, to commence clearing slowly, and with as little expense as possible.

In the fall, or autumn, I put up a log-kitchen, and a shed for my cattle; during the winter, I employed my man in chopping three acres more, in which I now and then assisted him, and soon became very expert in the use of the axe, felling the trees to the most advantage to assist their burning, and to save trouble in logging. With my beaver-meadow hay, and the fir tops of the fallen trees, my cattle were kept fat all the winter. In the spring, three acres more were cleared, fenced, and cropped with corn, potatoes, and turnips; and where log heaps had been burnt, the ashes were hoed off, and planted with melons and cucumbers; a small patch was fenced off for a nursery, and apple seeds sown, trees which are now ten and twelve feet high. I also put out several of the wild plum-trees of the country, which now bear abundance of fine fruit. From this time, about five acres yearly have been added to my farm, taking great care, in clearing off my land, never to destroy a log that would make rails, by which means the fence always came off the field cleared; and although they are small—from four to six acres—the fences are all six feet, or nine rails high. Here I will remark, it is a great fault to split rails small, an error that most new settlers persist in. In the spring of 1822, my attention was turned to making a flower and kitchen garden. Round the latter I made a straight fence with cedar posts, and thirteen rails high, which is at this day stocked with every kind of fruit tree to be had in the neighbourhood, which flourish beyond my expectation. My stock of animals has been gradually increasing, and to my other stock I have added horses and sheep, with poultry of all kinds.

In the year 1825, I had repaid the money I borrowed, by leaving back a small part of my half-pay every quarter, and had received a deed for 600 acres of my land, on which I had performed the settlement duty, which cost me L.30. My farm is now increased to 36 acres. I have the deed for the remaining 200 acres of my land; also deeds for town and park lots in the rapidly settling town of Peterborough; and, as my family have increased to six, and are growing up, I am just now about building a frame-house, 36 feet by 20 in the clear, two stories high, with a commodious kitchen behind, the timber and shingles for which I have bought by disposing of a mare, after using her for five years, and breeding a pair of horses from her. With my own exertions—being able to do most of the carpenter's work inside—and about L.100, I expect to get it finished.

Some of my first chopped land is now nearly clear of stumps. I am planting out an orchard of apple-trees, raised from the seed sown by myself; have a good barn and stable, with various other offices;—in short, feel that I have surmounted every difficulty. A town is growing up near me, roads are improving, bridges are built; one of the best mills in the province is just finished at Peterborough, another within three miles of me. Boards, and all descriptions of lumber, are cheap—about five dollars 1000 feet, four saw-mills being in operation. Stores, a tannery, distillery, and many other useful businesses, are established, or on the eve of being so, at Peterborough; on the road to which, through Otanabee, the Land Company, the clergy, and some private individuals, have some of the best land in the province for sale, at from 7s. 6d. to 10s. per acre. The price of land generally, except on the roads, is about 5s. per acre. I was the first settler in the township, and almost before a tree was cut down; now there are nearly two thousand acres cleared, and 125 families, consisting of 600 souls."

CONCLUSION.

Very little remains now to be told regarding Canada. In our opinion, the question of emigration is one of a very simple nature, and may easily be solved by every thinking human being. We have proved beyond the possibility of doubt, that Upper Canada is a country placed in infinitely better circumstances at the present moment, than any part of Great Britain and Ireland. We have shown that, in most places, the climate is delightful, and the lands fertile. It is not denied that in many portions of the colony agues and other local diseases prevail, but it admits of demonstration, that Canada, on the whole, is as healthy as these islands. If the inhabitants of the low uncleared lands in North America be liable to ague and fevers, those of this country are, on the other hand, continually liable to colds and consumptions to a degree fully as dangerous; indeed, the *colds* of the island of Great Britain seem to rank as the most destructive of the diseases which affect mankind. Besides, every year, the continent of America, as it becomes cleared, is becoming more salubrious, and it certainly possesses extensive tracts of land already fully as healthful and pleasant as any part of England. If it be established that Upper Canada is that fertile and promising territory which it is represented to be, the whole of the question of emigration resolves itself into this: are men who are in difficulties in this country willing to undergo the trouble of removing thither, and of exerting themselves for a few years after they arrive? As for the notion which obtains as to the pain of parting with early friends, and the place of our birth, that we take to be entirely fallacious. It is the duty of every man to go where his mental and physical properties can be most advantageously exercised. It is a fundamental law of human nature, that mankind must disperse themselves over the whole earth to seek out the best means of subsistence, and the most agreeable spot for their residence. Had intending emigrants to proceed to a land of barbarians, where neither human nor divine laws were understood or acted upon, and where they had to settle on sterile deserts, or burning wildernesses, we might excuse their hesitation to depart from their native country; but the case is quite different. To emigrate to Canada, or any other British colony, is simply to remove, as it were, to another part of Great Britain. Distance is nothing; for the removal of a family from the north of Scotland to the south of England would be attended with nearly the same trouble and expense; and, in each case, the family would find itself surrounded with neighbours equally strange. But to emigrate to Upper Canada with the means of purchasing a tract of land, holds out a much better prospect than to remove from one part of Great Britain to another. In this country, it now requires a very great mental and physical effort to obtain a comfortable subsistence. Nearly the whole of the lands and manufactures in the United Kingdom are passing into the hands of capitalists. The rich are becoming very rich, and the poor are sinking deeper and deeper into poverty and wretchedness. The small farmers and tradesmen of England, Scotland, and Ireland, are now placed in that peculiar condition, when emigration to a country less occupied and overdone than their own is almost imperative; for, looking around on all sides, they see little chance of rising into better circumstances, or of rearing their families in that comfortable and reputable manner which their feelings dictate. To such, therefore, Upper Canada offers a fair field for removal and settlement. In that country lands can be had in full possession, at an expense of from fifteen to twenty times less than what is paid here by way of annual rent; and it is seen that in a space of from three to five years, the whole cost may be realized by the amount of the produce. In Upper Canada, moreover, there are no taxes; at least they are so very trifling—a penny an acre, we believe, for cultivated land—that they are not worthy of being classed as taxes. There are also no poor-rates, and no tithes, both of which imposts are severely felt in England. The emigrant thither will likewise have nothing to annoy him in a political sense. In the United States, to which he can always proceed from Canada, if it suit his pleasure, he becomes a free citizen after a certain period; but it is alleged that he will most likely have his feelings hurt occasionally, if he has any sentiment of attachment to Great Britain and its form of government. In the Canadas, he continues to be a British subject, and can claim all the prerogatives of such a distinction. In short, if we consider how quickly local and other attachments can be formed, and how invariably the objects pressing most immediately around us become in our eyes the most important and interesting—if we further consider the almost instant improvement of circumstances which must take place after the first difficulties are got over, and the great value of what is in this country only a source of anxiety and vexation, a family of children, we see such advantages in emigration, that we are convinced nothing but a want of knowledge of those advantages, sufficient to create confidence in their reality, prevents many thousands from annually leaving this exhausted and monopolised country, and betaking themselves to a place where there is literally "a world for the winning."

EDINBURGH: Printed and Published by W. and R. CHAMBERS, 19, Waterloo Place; also by W. ORR, Paternoster Row, London; and W. CURRY, Jun. and Co. Sackville Street, Dublin. Sold by all the Booksellers in Scotland, England, and Ireland.
"CHAMBERS'S INFORMATION FOR THE PEOPLE" will be continued once a fortnight (every alternate Wednesday). Each number will consist of a distinct and different work of a popular and instructive nature, at three-halfpence in price.
Stereotyped by ALEXANDER KIRKWOOD, St Andrew Street, Edinburgh.

HISTORY OF THE ISLAND OF GREAT BRITAIN,

From its Conquest by the Romans, till the Civil War.

INTRODUCTION.

THE United Kingdom of Great Britain and Ireland forms, at the present time, one of the most important parts of the face of the whole earth; and there is hardly any human being who enjoys such advantages in respect of society, personal liberty, and education, as the subject of that kingdom. But, as may be easily supposed, this has not always been the case. The time has been when the people of these countries had somewhat inferior advantages; the time has been when they were no better off than the inhabitants of neighbouring countries; nay, there has been a time when they were far less enlightened and comfortable in their circumstances than some other people—in short, savages, like the Indians of America.

Now, the purpose of this history is to show how the people who lived before ourselves in Great Britain and Ireland contrived to be always improving their circumstances from the worse to the better state, till in the end the generation which now lives has become what we all know it to be. Knowledge of this kind is called history, and its use is to teach the living by the experience of the dead what is for their advantage. If the men who now live did not know any thing of those who lived before, they would be in a condition little better in that respect than the animals which have no knowledge whatsoever; but by knowing the events of past times, and what sort of people their ancestors were, they assert their superiority, in one material point, to animals, and have the advantage of not only all their own experience in the world, but that of many generations now in the dust.

History is only to be rendered intelligible by dates and periods. By dates is meant the years in which events happened; by periods is meant the dates of the most remarkable events. Some people say they cannot remember and do not care for dates; but this is only because they cannot remember and do not care for events. If a person has a general idea of history, dates become ideas—it may be said, leading ideas—serving to arrange the whole in his mind. In fact, dates form the perspective of history, and, without them, the whole would be a confused mass, like a picture in which sheep at a distance are made as big as churches in the front.

The present year, every body knows, is 1833; that is, the eighteen hundred and thirty-third year since the birth of Jesus Christ, the founder of the Christian religion. Go back three years, and we have 1830, when the present king acceded to the throne. Go back thirteen years, and we have 1820, when George the Fourth became king. Go back thirty-three years, and we have 1800, when the kingdoms of Great Britain and Ireland were united under one legislature. If we go back to 1714, which is a hundred and nineteen years ago, we have the date of the accession of the present royal family to the throne, in the person of King George the First, who was his present Majesty's grandfather's grandfather. All these are *periods*, particularly the last, because the sway of the Stuarts (another family) then came to an end. The next great period is the Revolution of 1688, when the people expelled one king (James the Second), because he was a tyrant and a Catholic, and set another (William the Third) on the throne, because he was a Protestant, and willing to rule with a more moderate exercise of power. We may next mention the period 1603 (two hundred and thirty years since), when the two kingdoms of England and Scotland were united under one monarch, by the accession of James the Sixth of Scotland to the throne of England. Previous to that period, the political history of these two countries was quite distinct, to the great discomfort and injury of both. Go back sixty-six years farther—namely, to the year 1537—and we have the date of the Reformation of religion in England, perhaps the most important event in its history. Fifty-two years earlier we have 1485, when the line of the Plantagenet race of sovereigns ceased in the person of Richard the Third, and a period was at the same time put to a contest and civil war, which had raged on account of two rival branches of that family for many years. All before this period is rude and warlike, as if men were different in nature from what they are now; all after, though occasionally rude enough, is something like the mildness and intelligence and neighbourly peacefulness of the present day. History, therefore, before the year 1485, is of much less use than what follows; the experience which it teaches does not bear so strongly on the circumstances of the present age. As we go back farther and farther, we find always a more and more imperfect government and system of laws, till, about the beginning of the Christian era, we reach the ages of absolute barbarism.

CONQUEST OF BRITAIN BY THE ROMANS.

At the time when the British islands were inhabited by barbarians, the Romans had extended their sway over nearly the whole of the known world, being a people almost as enlightened, or at least the ruling classes among them were so, as the people now living in Great Britain. Our islands being situated at the extremity of the earth, as then known, came late under the attention of the Romans. It was not till the year 55 before Christ, that their great captain, Julius Cæsar, having subdued Gaul (now France), thought of extending his conquests to the opposite island, of which he was so ignorant, that he had to gather some Gaulish merchants to tell him about it. He disembarked near Deal, and soon overawed the savage natives, though they were naturally warlike, and averse from a foreign yoke. He did not, however gain a proper footing in the country till the succeeding year (54 before Christ), when he employed no fewer than eight hundred vessels to convey his troops from Gaul. Except on the coasts, where some tillage prevailed, the British tribes lived exactly as the Indians now do, upon animals caught in hunting, and fruits which grew spontaneously. They stained and tattooed their bodies, and had no religion but a bloody idolatry called Druidism.

Little was done on this occasion to establish the Roman power in Britain; but about a century afterwards, namely, in the year of Christ 43, when the Emperor Claudius was reigning at Rome, another large army invaded the island, and reduced a considerable part of it. A British prince, called Caradoc or Caractacus, who had made a noble defence against their arms, was finally taken and sent prisoner to Rome, where he was regarded with the same wonder as we would bestow upon a North American chief who had greatly obstructed the progress of our settlements in that quarter of the world. In the year 61, an officer named Suetonius did much to reduce the Britons, by destroying the numerous Druidical temples in the Isle of Anglesey; religion having, in this case, as in many others since, been a great support to the patriotic cause. Soon after, he overthrew the celebrated British Princess Boadicea, who had raised an almost general insurrection against the Roman power. In the year 79, Agricola, a still greater general, extended the influence of Rome to the Firths of Forth and Clyde (that is to say, over the southern part of the country now called Scotland), which he formed into a frontier, by connecting them with a chain of forts. He was the first to sail round the island. In the year 84, having gone a little beyond the Forth, he gained a decisive victory over the rude inhabitants of the north, who were assembled under a chief named Galgacus.

It is generally allowed that the Romans experienced an unusual degree of difficulty in subduing the Britons; and it is certain that they were entirely baffled in all their attempts upon the northern part of Scotland, which was then called Caledonia. The most they could do with the inhabitants of that country, was to build walls across the island to keep them by themselves. The first wall was built in the year 120, by Hadrian, between Newcastle and the Solway Firth. The second was built by Antoninus, on the line of forts between the Firths of Forth and Clyde. When the conquest was thus so far completed, the country was divided into six provinces, of the following names and boundaries:—*Britannia Prima*, or First Britain, to the south of the Thames and Severn; *Britannia Secunda*, or Second Britain, containing Wales and the adjoining districts along the Severn; *Flavia Cæsariensis*, from the two former provinces to the German Ocean, the Humber, and the Don; *Maxima Cæsariensis*, to the north of the Humber, from its mouth, to the mouths of the Tyne and Eden; *Valentia*, from the Tyne and Eden to the Forth and Clyde; *Vespasiana*, the level country beyond the Forth, over which they had only a temporary dominion. The country was governed in the usual manner of a Roman province; and towns began to rise in the course of time, being generally those whose names are now found to end in *chester*, a word derived from *castra*, the Latin word for a camp. The Christian religion was also introduced.

CONQUEST BY THE SAXONS

A time came, by and bye, when the Romans could no longer defend their own proper country against the nations in the north of Europe. The soldiers were then withdrawn from Britain (about the year 440), and the people left to govern themselves. The Caledonians, who did not like to be so much straitened up in the north, took advantage of their unprotected state to pour in upon them from the other side of the wall, and despoil them of their lives and goods. The British had no resource but to call in another set of protectors, the Saxons, a people who lived in the north of Germany, and were very warlike and enterprising. The remedy was found hardly any better than the disease. Having once acquired a footing in the island, this hardy nation proceeded to make it a subject of conquest, as the Romans had done before—with this material difference, that they drove the British to the western parts of the island, particularly into Wales, and settled themselves, and new hordes of their countrymen, over the better part of the land. So completely was the population changed in this manner, that, excepting in the names of some of the hills and rivers, the British language was extinguished, and even the name of the country itself was changed from what it originally was, to Angle-land, or England, a term taken from the Angles, who were a detachment of the Saxon conquerors. The conquest required about a hundred years, and, like that of the Romans, it extended no farther than the Firths of Forth and Clyde. The great warrior Arthur, of whom every body has heard, was a patriotic prince of the Britons, who in vain tried to defend his country from the Saxons.

England, exclusive of the western regions, was now divided into seven kingdoms, called Kent, Northumberland, East Anglia, Mercia, Essex, Sussex, and Wessex, each of which was governed by a race descended from the leader who had first subdued it; and the whole have since been called by historians the *Saxon Heptarchy*, the latter word being composed of two Greek words signifying *seven kings*. The kingdom of Northumberland included the present Scottish counties of Berwick, Roxburgh, and the Lothians; while Lanarkshire and Dumfriesshire, with part of the present northern counties of England, formed a British kingdom called Strathclyde. To the north of the Firth of Forth, dwelt a nation called the Picts, who had also a king; and in the Highlands there was another nation, known by the name of the Scots, who had come thither from Ireland in the year 503, and established a monarchy, destined in the long-run to absorb all the rest. There were at one period no fewer than fifteen kings, all reigning at once in the island of Britain, and Ireland was in much the same situation. The prosperity of the whole has been found to increase as these small principalities were gradually amassed together: it has only happened, very unfortunately, in Ireland, that a distinction in religion, and some other causes, have prevented that union of national feeling which has elsewhere followed the political union of the different nations.

The Saxon Heptarchy prevailed from about the year 585 to 800, when Egbert, King of Wessex, acquired a paramount power over all the other states, though their kings still continued to reign. Alfred, of whom all must have heard, was the grandson of Egbert, and began to reign in the year 871. At this time, the Danes, who are now a quiet inoffensive people, were a nation of pirates, and, at the same time, heathens. They used to come in large fleets, and work dreadful ravage on the shores of Britain. For some time, they completely overturned the sovereignty of Alfred, and compelled him to live in obscurity in the centre of a marsh. But he at length fell upon them, when they thought themselves in no danger, and regained his kingdom. Alfred spent the rest of his life in literary study, of which he was very fond, and in forming laws and regulations for the good of his people. He was, perhaps, the most able, most virtuous, and most popular prince that ever reigned in Britain; and all this is the more surprising, when we find that his predecessors and successors, for many ages, were extremely cruel and ignorant. About his time, the country of England became divided into counties. He died in the year 901, in the fifty-third year of his age.

The Saxon line of princes continued to reign, with the exception of three Danish reigns, till the year 1066, when the crown was in the possession of a usurper named Harold. The country was then invaded by William Duke of Normandy, a man of illegitimate birth, attended by a large and powerful army. Harold opposed him at Hastings (October 14), and, after a well-contested battle, his army was defeated, and himself slain. William then caused himself to be crowned king at Westminster; and in the course of a few years he succeeded, by means of his warlike Norman followers, in completely subduing the Saxons. His chiefs were settled upon the lands of those who opposed him, and became the ancestors of the present nobility of England.

Previously to this period, the church of Rome, which was the only surviving part of the power of that empire, had established its supremacy over England. The land was also subjected to what is called the feudal system, by which all proprietors of land were supposed to hold it from the king for military service, while their tenants were understood to owe them military service, in turn, for their use of the land. All orders of men were thus kept in a chain of servile obedience, while some of the lower orders were actually slaves to their superiors.

In the year 853, Kenneth, King of the Scots, had added the British kingdom to his own, and his descendant Malcolm the Second, in 1020, extended his dominions over not only the south of Scotland, but a part of the north of England. Thus the whole island, putting aside Wales, was divided into two kingdoms, of unequal magnitude and strength—the kingdom of England and the kingdom of Scotland, under which distinctions they were destined to continue for several hundred years, neither being able to make much impression upon the other.

THE NORMANS.

William the First, surnamed the Conqueror, reigned from 1066 till 1087, being chiefly engaged all that time in completing the subjugation of the Saxons. He was a monarch of much sagacity and power to command, but of a violent and brutal character. His eldest son Robert, happening to be at a greater distance from London than William, who was the second son, that individual seized upon the crown, of which he could not afterwards be dispossessed, till he was shot accidentally by an arrow in the New Forest, in the year 1100. In the latter part of this king's reign, the whole of Christian Europe was agitated by the first crusade—an expedition for the recovery of the Holy Land from the Saracens. Robert of Normandy had a high command in this enterprise, and gained much glory as a warrior; but while he was in Italy, on his return, his youngest brother Henry usurped the throne left vacant by William, so that he was again disappointed of his birthright. Henry the First, surnamed Beauclerk, from his being a fine scholar, was a prince of some ability; but he disgraced himself by putting out the eyes of his eldest brother, and keeping him nearly thirty years in confinement. Such barbarous conduct shows that, in this age, might was the only right, and that men hesitated at no actions which might promise to advance their own interests.

Contemporary with William the Conqueror in England, was Malcolm the Third in Scotland, surnamed *Canmore*, from his having a large head. This prince, after overthrowing the celebrated usurper Macbeth, married Margaret, a fugitive Saxon princess, through whom his posterity became the heirs of that race of English sovereigns. He was a good prince, and, by settling Saxon refugees upon his lowland territory, did much to improve the character of the Scottish nation, who are described as having been, before this time, a nation in which there was no admixture of civilization. At Malcolm's death, in 1093, the crown was contested for a while by an usurper called Donald Bane, and the elder sons of the late monarch, but finally fell to the peaceable possession of his youngest son David the First, who was a prince of much superior character, apparently, to the Norman sovereigns who lived in the same age. It was David who founded so many of the abbeys and monasteries which still overspread the land.

Henry Beauclerk of England, in order to strengthen his claim by a Saxon alliance, married Maud, the daughter of Malcolm Canmore and of the Princess Margaret. By her he had an only daughter of the same name, whom he married first to the Emperor of Germany, and then to Geoffrey Plantagenet, eldest son of the Earl of Anjou, in France. This lady and her children by Plantagenet were properly the heirs of the English crown; but on the death of Henry, in 1135, it was seized by an usurper, named Stephen, a distant branch of the Conqueror's family, who reigned for nineteen years, during which the country was rendered almost desolate by civil wars, in which David of Scotland occasionally joined. At this time, the birthright of princes used to cause immense bloodshed and misery among the people in other quarters of Europe, besides England. A Duchess of Brittany being declared unfaithful by her husband on his death-bed, caused the devastation of that province before the succession was settled.

On the death of Stephen, in 1154, the crown fell peacefully to Henry the Second, who was the eldest son of Maud, and the first of the Plantagenet race of sovereigns. Henry was an acute and politic prince, though not in any respect more amiable than his predecessors. His reign was principally characterised by a series of measures for reducing the power of the Romish clergy, in the course of which, some of his courtiers, in 1171, thought they could not do him a better service than to murder Thomas à Becket, archbishop of Canterbury, who had been the chief obstacle to his views, and was one of the ablest and most ambitious men ever produced in England. For his concern in this affair, Henry had to perform a humiliating penance, which is not wonderful, however, when we consider, that, about this time, the Pope caused two kings to lead his horse.

Henry was the most powerful king that had yet reigned in Britain. Besides the great hereditary domains which he possessed in France, and for which he did homage to the king of that country, he caused William of Scotland, the grandson of David, to acknowledge himself as his vassal for the whole of that kingdom. [William reigned from 1166 to 1214.] Henry also added Ireland to his dominions. This island had previously been divided into five different kingdoms—Munster, Leinster, Meath, Ulster, and Connaught. The people, being quite uncivilized, were perpetually quarrelling among themselves; and this, with their heathen religion, furnished a flimsy pretext for invading them from England. Dermot Macmorrough, King of Leinster, having been dethroned by his subjects, introduced an English warrior, Richard Earl of Strigul, generally called *Strongbow*, for the purpose of regaining his possessions. The discipline of fifty knights, ninety esquires, and four hundred and sixty archers, in all six hundred men, enabled them to overthrow the whole warlike force that could be brought against them; and the conquest was easily completed by Henry in person, who went thither in 1172. The military leaders were left to rule over the country, and they managed their trust so ill, that the Irish never became peaceable subjects of the Norman king, as the English had gradually done.

MAGNA CHARTA.

Henry the Second was much troubled in his latter years by the disobedience of his children. On his dying, at length, in 1189, he was succeeded by his son Richard, styled *Cœur de Lion*, from his headstrong courage, and who was much liked by his subjects on that account, though it does not appear that he possessed any of the other good qualities which usually command affection. At the coronation of Richard, the people were permitted to massacre many thousands of unoffending Jews throughout the kingdom. He was in reality a military savage, only redeemed a little by the profession of religion, and of what is called chivalry. Almost immediately after his accession, he joined the King of France in a second crusade; landed in Palestine, and fought with prodigious valour, but no good result; and then, returning with a small remnant of his gallant army, wandered in disguise into the dominions of his mortal enemy, the Duke of Austria, who, with the Emperor of Germany, detained him till he was redeemed by a ransom, which impoverished nearly the whole of his subjects. This prince spent the rest of his life in unavailing wars with Philip of France, and was killed at the siege of a castle in Limousin, in 1199, after a reign of ten years, of which he had spent only about three months in England.

John, the younger brother of Richard, succeeded, although Arthur Duke of Bretagne, the son of an intermediate brother, was the proper heir. John who was at once vain, cruel, and weak, alienated the affections of his subjects almost at the very first, by the assassination of his nephew, which he is said to have performed with his own hands. It happens, however, that the weakness of kings is often the means of giving increased liberties and privileges to the people. The paltry tyranny and wickedness of John caused his barons to rise against him, and the result was, that, on the 19th June 1215, he was compelled by them to grant what is called the *Magna Charta*, or great charter, for securing the various orders of his subjects in their rights. The clergy and barons, who acted in this noble enterprise, gained for themselves many privileges and exemptions, which suited their own interests; but they fortunately deemed it necessary, in order to procure the support of the people, to stipulate something for them also. The principal point secured to the barons and commoners was, that no tax or supply should be levied from them without their own consent in a Great Council—the first idea of a Parliament. Some excellent provisions were also made regarding courts of law and justice, so as to secure all but the guilty. The Pope was dreadfully wroth at this invasion of the royal privileges; he excommunicated the barons, declaring them to be worse than infidels. The opinion of a modern historian is very different; he says, "To have produced it (namely, the Great Charter), to have preserved it, to have matured it, constitute the immortal claim of England on the esteem of mankind."* And such is now the universal sentiment regarding this first bulwark of English liberty.

FIRST PARLIAMENT.

On the death of John, in 1216, he was succeeded by his son Henry the Third, then a boy in the tenth year of his age, who eventually proved as weak, but not just so wicked, as his father. In his reign was held the first assemblage approaching to the character of a Parliament. It was first called in 1225, in order to give supplies for carrying on a war against France. The money was only granted on condition that the Great Charter should be confirmed; and thus the example was set at the very first, for rendering supplies a check upon the prerogative of the king, and gradually reducing that power to its present comparatively moderate level. Under the earlier Norman kings, and even, it is believed, under the Saxons, an assembly called the Great Council had shared with the sovereign the power of framing laws; but it was only now that the body had any power to balance that of the king, and it was not till 1265 that representatives from the inhabitants of towns were introduced.

EDWARD THE FIRST.

The reign of Henry the Third, extending to fifty-six years, was characterised by frequent civil broils, and was disgraced by the pusillanimity of the king; but it derives a lustre, with which the king has no connection, from its having given birth to the present constitution, or system of legislature and government. Edward, the son of Henry, succeeded (1272), a prince as warlike and sagacious as his father was the reverse. He distinguished himself by his odious attempts to add Wales to his kingdom, an object which he accomplished in 1282, by the overthrow and murder of Llewellen, the last prince of that country. In the meantime, from the death of William the Lion in 1214, Scotland had been ruled by two princes, named Alexander the Second and Alexander the Third, under whom it advanced considerably in wealth, civilization, and comfort. On the death of Alexander the Third, in 1285, the crown fell to his grand-daughter Margaret, a young girl, whose father was Eric, King of Norway. Edward formed a treaty with the Estates of Scotland for a marriage between this princess and his son, whom he styled Prince of Wales. Unfortunately, the young lady died on her voyage to Scotland; and the crown was left to be disputed by a multitude of distant relations, of whom John Baliol and Robert Bruce seemed to have the best right. Edward, being resolved to make Scotland his own at all hazards, interfered in this dispute, and being appointed arbitrator among the competitors, persuaded them to own, in the first place, an ill-defined claim put forward by himself of the right of paramountcy or superior sovereignty over Scotland. When this was done, he appointed Baliol to be his vassal king, an honour which the unfortunate man was not long permitted to enjoy. Having driven Baliol to resistance, he invaded the country, overthrew his army, and, stripping him of his sovereignty, assumed to himself the dominion of Scotland, as a right forfeited to him by the rebellion of his vassal. After he had retired, a brave Scottish gentleman, named William Wallace, raised an insurrection against his officers, and, defeating his army at Stirling in 1297, cleared the whole country of its southern invaders. But in the succeeding year, this noble patriot was defeated by Edward in person at Falkirk, and the English yoke was again imposed. It is to be remarked, that this could have hardly taken place if the common people, who rose with Wallace, and who were exclusively of Celtic and Saxon race, had been led and encouraged by the nobility. The grandees of Scotland, and even the competitors for the crown, being recent Norman settlers, paid more reverence to Edward than to the national

* Mackintosh's History of England, Cabinet Cyclopædia.

spirit of Scotland, and thus were disposed to betray the independency of that kingdom into the hands of the usurper. At length, as Edward became engrossed with his French wars, ROBERT BRUCE, Earl of Carrick, grandson of him who had competed with Baliol, conceived the idea of putting himself at the head of the Scots, and endeavouring, by their means, at once to gain the crown, and to recover the independence of the kingdom. After a series of adventures, among which was the unpremeditated murder of a rival named Comyn, Bruce caused himself, in 1306, to be crowned at Scone. For some time after, he had to skulk as a fugitive, being completely unable to maintain his ground against the English officers; but at length he became so formidable, that Edward found it necessary (1307) to lead a large army against him. The English monarch, worn out with fatigue and age, died on the coast of the Solway Firth, when just within sight of Scotland, leaving his sceptre to his son EDWARD THE SECOND. That weak and foolish prince immediately returned to London, leaving Bruce to contest with his inferior officers. After several years of perpetual skirmishing, Bruce was at last met on the open field by King Edward, who had a hundred thousand men to oppose to thirty thousand Scots. The result of the battle of Bannockburn, fought on the 24th of June 1314, was the complete rout of the English army, and the flight of the king, who never again molested Bruce in his hard-won sovereignty. Thus, at the time when Ireland was sinking under English rule, through its unfortunate internal dissensions, the national spirit of the Scots, united under one beloved leader, saved their comparatively poor country from that disaster, and enabled it, at the proper time, to accede to a union, instead of submitting to a conquest.

The weakness of Edward the Second chiefly took the direction of a fondness for favourites, into whose hands he committed the whole interests of his people. In private life, extravagant friendships, or a custom of depending much upon the company and countenance of others, is always a strong general mark of an inferior character; but in sovereigns, the infirmity becomes a crime. Edward's first favourite, a low Frenchman, named Piers Gaveston, fell a victim to the indignation of the barons. His second, Hugh Spencer, misgoverned the country for several years, till at length the Queen and Prince of Wales raised an insurrection against the King, and caused him to be deposed, as quite unfit to reign. The prince was then crowned as EDWARD THE THIRD (1327), being as yet only about fourteen years of age; and, in the course of a few months, the degraded monarch was cruelly murdered in Berkeley Castle.

During the minority of the young king, the reins of government were held by his mother and the Earl of March. Under their administration, a peace was concluded with King Robert of Scotland, of which one of the conditions was a full acknowledgment of the independency of the Scottish monarchy. The English historians have since laboured to prove, that, in earlier times, the King of Scots really did hold his kingdom from the sovereign of England. Even if this had been the case, it would have been the greater honour to Scotland to have retrieved its independence. The holding of one king from another, in an early age, was a comparatively slight matter, according to the feudal ideas; but it was a noble matter for a small nation to have thoroughly shaken off a greater, at a time when others were sinking in *actual bondage* under England.

EDWARD THE THIRD.

Edward the Third, who soon after assumed full power, was destined to make good the remark prevalent at this time, that the kings of England were alternately able and imbecile. He was a warlike and sagacious monarch, and inspired by all his grandfather's desire of conquest. In 1329, Robert Bruce died, and was succeeded by his infant son David the Second, to whom a young sister of the English king was married, in terms of the late treaty. Notwithstanding this connection, Edward aided a son of John Baliol in an attempt to gain the Scottish crown. Edward Baliol overthrew the Regent of Scotland, at Dupplin, September 1332, and for two months reigned as King of Scots, while David and his wife took refuge in France. The usurper afterwards returned, and for many years the country was harassed by unceasing wars, in which the English took a leading part. But for his attention being diverted to France, Edward the Third would have made a more formidable effort to subdue Scotland, and might have succeeded. He was led into a long course of warfare in that more wealthy country, in consequence of an absurd pretension which he made to the throne of France. In the victories which he gained at Cressy (August 26, 1346) and Poitiers (September 17, 1356), the national valour, and his own, and that of his celebrated son, the Black Prince, were shown conspicuously; but this lavish expenditure of the resources of his kingdom, in which he was supported by his Parliament, was of no permanent benefit, even to himself, for whom alone it was made. In those days, almost all men fought well, but very few had ever the art to improve their victories. John, King of France, who had been taken at Poitiers, and David, King of Scotland, who had been taken in 1346, while conducting an invasion of England, were at one time the prisoners of Edward the Third; but no permanent advantage

was ever gained over either of the states thus deprived of their sovereigns. In 1361, after about twenty years of active fighting, the English king left France with little more territory than he had previously enjoyed. Edward had invaded Scotland with a powerful army in 1356, but without making any impression. The Scots, under David's nephew, Robert Stewart, effectually protected themselves, not only from his arms, but from a proposal which David himself basely undertook to make, that Lionel, the third son of the English king, should be acknowledged as his successor. Edward died in 1377, a year after the decease of his son the Black Prince; and, notwithstanding all their brilliant exploits, the English territories in France were less than at the beginning of the reign. The truth is, kings at this time acted only like bold and thoughtless children, and their inferiors were held of no use but to be their playthings.

RICHARD THE SECOND.

RICHARD THE SECOND, son of the Black Prince, succeeded—a gay, profligate, and wicked youth. Stung by the severity of a tax imposed upon all grown-up persons, the peasantry of the eastern parts of England rose, in 1381, under a person of their own order, named Wat Tyler, and advanced sixty thousand strong to London, where they put to death the Chancellor and Primate, as evil counsellors of their sovereign. They demanded the abolition of bondage, the liberty of buying and selling in fairs and markets, a general pardon, and the reduction of the rent of land to an equal rate. The king came to confer with them at Smithfield, where, on some slight pretence, Walworth, mayor of London, stabbed Wat Tyler with a dagger—a weapon which has since figured in the armorial bearings of the metropolis. The peasants were dismayed, and submitted, and no less than fifteen hundred of them were hanged. Wat Tyler's insurrection certainly proceeded upon a glimmering sense of those equal rights of mankind which have since been generally acknowledged; and it is remarkable, that at the same time the doctrines of the reformer Wickliffe, who has been called the Morning Star of the Reformation, were first heard of.

HENRY THE FOURTH.

Richard the Second misgoverned his country till 1399, when he was deposed by his subjects under the leading of his cousin, Henry Duke of Lancaster. This person, though some nearer the throne were alive, was crowned as HENRY THE FOURTH, and his predecessor, Richard, was soon after murdered. In the meantime, David of Scotland died in 1371, and was succeeded by Robert Stewart, who was the first monarch of that family. Robert the First dying in 1389, was succeeded by his son Robert the Second, who was a good and gentle prince. He had two sons, David and James: the former was starved to death by his uncle, the Duke of Albany; and the second, when on his way to France for his education, was seized by Henry the Fourth of England, and kept captive in that country for eighteen years. Robert the Second then died of a broken heart (1406), and the kingdom fell into the hands of the Duke of Albany, at whose death, in 1419, it was governed by his son Duke Murdoch, a very imbecile personage.

THE HOUSE OF LANCASTER.

Henry of Lancaster proved a prudent prince, and, comparatively, a good ruler. The settlement of the crown upon him by Parliament was a good precedent, though, perhaps, only dictated under the influence of his successful arms. He was much troubled by insurrections, particularly a formidable one by Percy Earl of Northumberland—and one still more difficult to put down, in Wales, where Owen Glendower, a descendant of the British princes, kept his ground for several years. On the death of Henry in 1413, his son succeeded as HENRY THE FIFTH—a prince, youthful, brave, and victorious, and, therefore, revered by the people of England, although he seems to have been destitute of humanity, like most of the other individuals whom mankind have hitherto agreed to call great. The Lollards, a body of religious reformers of this age, were by him condemned in multitudes to the flames; and the splendid victory which he gained at Agincourt (October 25, 1415), in the course of his French wars, was stained by the deliberate massacre of several thousand prisoners, whom he feared to leave in life. He succeeded, in a great measure, in asserting the claims of his family to the throne of France, and actually, for some time, conducted the government at Paris. But he died in the prime of life, 1422, leaving the crown to an infant nine months old, who was proclaimed as Henry the Sixth, King of France and England.

Under HENRY THE SIXTH, whose power was for some time in the hands of his uncle the Duke of Bedford, the English maintained their footing in France for several years, and, at the battle of Verneuil, in 1424, rivalled the glory of Cressy and Poitiers. At that conflict, a body of Scotch, seven thousand strong, who had proved of material service to the French, were nearly cut off. In 1428, when the nation seemed completely sunk beneath the English rule, the interests of the native prince were suddenly revived by a simple maiden, named Joan of Arc, who pretended to have been commissioned by Heaven to save her country, and, entering into the French army, was the cause of several signal reverses to the English. By her enthusiastic exertions, and the trust every where reposed in her supernatural character, Charles the Seventh was crowned at Rheims, in 1430. Being soon after taken prisoner, the heroic maiden was, by the English, condemned for witchcraft, and burnt. Nevertheless, about the year 1453, the French monarch had retrieved the whole of his dominions from the English, except Calais, and no other attempt was ever made to reduce that country.

Henry the Sixth was remarkable for the extreme weakness of his character. His cousin Richard Duke of York, descended from an elder son of Edward the Third, and, therefore, possessed of a superior title to the throne, conceived that this imbecility of the monarch afforded an excellent opportunity for asserting what he thought his birthright. Thus commenced the famous *Wars of the Roses*, as they were called, from the badges of the families of York and Lancaster, the former of which was a red, while the latter was a white rose. In 1454, the duke gained a decisive victory over the forces of Henry, which were led by his spirited consort, Margaret of Anjou. In some succeeding engagements, the friends of Henry were victorious; and at length, in the battle of Wakefield (December 24, 1460), the forces of the Duke of York were signally defeated, and himself slain. The pretensions of this claimant were then taken up by his eldest son Edward, who, with the assistance of the Earl of Warwick, gained such advantages next year, that he assumed the crown. Before this was accomplished, many thousands had fallen on both sides. Henry, who cared little for the pomp of sovereignty, was confined in the Tower.

Scotland, in the meantime, had (1424) redeemed her king from his captivity in England; and that prince, styled JAMES THE FIRST, had proved a great legislator and reformer, not to speak of his personal accomplishments in music and literature, which surpassed those of every contemporary monarch. James did much to reduce the Highlands to an obedience under the Scottish government, and also to break up the enormous power of the nobles. By these proceedings, however, he excited a deep hatred in the bosoms of some of his subjects; and, in 1437, he fell a victim to assassination at Perth. He was succeeded by his infant son JAMES THE SECOND, the greater part of whose reign was spent in a harassing contention with the powerful house of Douglas, and who was finally killed in the flower of his age, by the bursting of a cannon before Roxburgh Castle. His successor, JAMES THE THIRD, was also a minor, and, on reaching man's estate, proved to be a weak, though not ill-meaning prince. He fell a victim, in 1488, to a conspiracy formed by his subjects, and which was led by his eldest son. The morality of princes in this age seems to have been much upon a par with that ascribed to the Turkish sovereigns of a later age. They never scrupled to destroy life, either within the circle of their own family, or out of it, when it suited their interests to do so.

HOUSE OF YORK.

EDWARD THE FOURTH reigned ten years, perpetually disturbed by renewed attempts of the Lancastrian party, of which he mercilessly sacrificed many thousands who fell into his hands. At length, having offended the Earl of Warwick, who had been chiefly instrumental in placing him upon the throne, that powerful nobleman raised an insurrection against him, and in eleven days was master of the kingdom, while Edward had to take refuge on the Continent. Henry the Sixth was then restored, and Warwick acquired the title of King-maker. Nine months after (1471), Edward landed with a small body of followers, and, having called his partisans around him, overthrew and killed Warwick at St Alban's. Margaret of Anjou, who had fought battles for her husband in almost every province of England, gathered a new army, and opposed Edward at Tewkesbury Park, where she was completely defeated. Her son and husband, being taken, were murdered in cold blood, and she herself spent the remainder of her singular life in France. Edward reigned, a profligate and a tyrant, till 1483, when he died in the forty-second year of his age. He had previously caused his brother, the equally profligate Duke of Clarence, to be drowned in a butt of malmsey wine.

Edward the Fourth was supposed to be succeeded by his son EDWARD THE FIFTH, a mere boy; but his brother, the Duke of Gloucester, a wicked and deformed wretch, in whom all the bad qualities of the family seemed concentrated, caused the young prince, with his still younger brother, to be murdered in the Tower, and soon after mounted the throne under the title of RICHARD THE THIRD. For two years, this disgrace to humanity retained possession of the English throne, though universally abhorred by his people. At length, in 1485, Henry Tudor, Earl of Richmond, a connection rather than a descendant of the Lancaster family, resolved to attempt the dethronement of this monster. Having landed with about two thousand followers at Milford Haven, he advanced into the country, and speedily gained such accessions of force as enabled him to meet and overthrow Richard at Bosworth Field, where the tyrant was slain, and the victorious Richmond was immediately proclaimed king, under the title of HENRY THE SEVENTH. The new monarch soon after sought to strengthen his title by marrying Elizabeth, the daughter and heir of Edward the Fourth, by which it was supposed the families of York and Lancaster were united.

THE TUDORS—HENRY THE SEVENTH.

Under Henry the country revived from a long course of civil wars, in the course of which far more than a hundred thousand men had been slain, the most powerful of the nobility broken down, and the industry and commerce of the land interrupted and laid waste. Even during that dreadful contest, it was remarked that the evils of war fell chiefly on those who made it; that the government, however disturbed by various claimants of the throne, was mild and equitable—at least as compared with that of other countries, and that the people throve under a system in which their own consent, by the voice of the House of Commons, was necessary to the formation of every new law, and the imposition of every tax. It was remarked at this time by Sir John Fortescue, an exiled English judge, that the comparatively despotic monarchy of France produced oppressions and grievances from which the English subject was exempt. According to this lawyer, the sovereign of England held his power from and in behalf of the people, and not from any abstract right, as was pretended by other kings. This idea could never have arisen, but for the repeated breaks in the succession which have already been described. The English kings had in fact undersold each other to the people, and thus, in the course of time, bated down their rights, as they called them, to something very trifling compared with what they were at first. Thus it may be seen that the usurpations which had occasioned so much civil war and bloodshed had also transferred a great deal of power from the hands of the few to the many, and gradually paved the way for the freedom which now prevails.

The reign of Henry the Seventh was much disturbed by insurrections, in consequence of his imperfect title. Some friends of the house of York, rather than want a real claimant on that side, set up a baker's boy, named Lambert Symnel, to personate the son of the late Duke of Clarence; and an army of about eight thousand men was led into the field to assert his pretensions to the crown. This force was defeated at Stoke, in Northamptonshire (June 1487), and Symnel being taken, was contemptuously appointed by the king to be one of his menial servants. A similar pretender, named Perkin Warbeck, but affecting to be Richard Duke of York, the younger brother of Edward the Fifth, set up his claims (1493), and received great encouragement in Ireland, Flanders, and Portugal, by means of which he landed with a considerable force at Deal, but was defeated and obliged to re-embark. This youth, who is said to have been the son of a Jew, next found refuge in Scotland, where James the Fourth, a young and gallant sovereign, was now reigning. James gave to Perkin in marriage a young lady connected with the royal family, and undertook an expedition into the north of England, in favour of his pretensions. This enterprise failed entirely in its object, and the Scottish king soon after deserted the cause of the impostor. Perkin subsequently raised a formidable insurrection in the southern counties of England, but, when about to encounter the royal forces, deserted his army, and took refuge in a monastery, where, according to the ideas of that age, his person was quite secure from all earthly force whatsoever. Here he was literally besieged by the royal army, who, though they could not touch him within the building, were yet able to starve him into a surrender, exactly after the manner of a garrison in an impregnable fortress. Perkin capitulated, and was brought to London, where a pretence was soon found for hanging him (November 23, 1499) at Tyburn. Almost at the same time, Henry procured the judicial assassination of the Earl of Warwick, the real son of the late Duke of Clarence, a poor idiot boy, whom he had kept fifteen years in confinement, and whose title to the crown, being superior to his own, rendered him uneasy. Henry also, in the same manner, killed his own stepfather Sir William Stanley, the individual who had chiefly aided him in obtaining the throne of England. It will be seen with surprise, by the reader, that it was not till a somewhat later period, that the sovereigns of this great country began to have scruples about putting their relations to death.

Henry, though a bloody tyrant, like the rest of his race, was a sagacious and peaceful sovereign. With laudable forethought, he was anxious to seal a peace with Scotland, by marrying his eldest daughter Margaret to James the Fourth; a marriage which, he calculated, might lead to the union of two countries hitherto only productive of war and misery to each other. The marriage took place in August 1503, and Henry's calculation was fulfilled exactly a hundred years after, by the accession of the great-grandson of the royal pair (James the Sixth) to the throne of England.

HENRY THE EIGHTH.

At the death of Henry the Seventh, in 1509, his son HENRY THE EIGHTH succeeded, a prince then in his eighteenth year, and whose character seemed at first that of a gay and jovial young man. Some years before, he had been affianced to Catherine, a Spanish princess, who had previously been the wife of his deceased brother Arthur; he was now married to this lady, the Pope having previously granted a dispensation for that purpose. For many years the reign of Henry was unmarked by any unusual incidents. The chief administration of affairs was committed to a low-born but proud churchman, the celebrated Cardinal Wolsey. The king became much engaged in continental politics; and, during a war which he carried on against France, his brother-in-law James the Fourth, who sided with that state, made an unfortunate irruption into the north of England, and was overthrown and slain, with the greater part of his nobility (September 9, 1513), at Flodden.

Several changes of great importance to European society took place about this time. Ever since the destruction of the Roman empire, the nations which arose out of it had remained in subjection to the papal see, which might be said to have inherited the universal dominion of that government, but altered from an authority over the bodies of men to an empire over their minds. It is said that this authority of the Roman Catholic religion had, in the course of time, become much abused, while the religion itself was corrupted by many superstitious observances. So long as men had continued to be the thoughtless warriors and unlettered peasants which they had been in the middle ages, it is not probable that they would ever have called in question either the authority of the Pope, or the purity of the Catholic faith. With knowledge, however, and the rise of a commercial and manufacturing class, came a disposition to inquire into the authority of this great religious empire. The art of printing, discovered about the middle of the preceding century, and which was now rendering literature accessible to most classes of the community, tended greatly to bring about this revolution in European intellect. The minds of men, indeed, seem at this time as if rising from a long sleep; and it might well have been a question with persons who had reflection, but no experience, whether the change was to turn to evil or to good. When men's minds are in a state of preparation for any great change, a very small matter is required to set them in motion. There was an Augustine monk at Wirtemberg, in Germany, of the name of Martin Luther, who became incensed at the Roman see, in consequence of some injury which he conceived to have been done to his order, by the Pope having granted the privilege of selling indulgences to the Dominican order of friars. Being a man of a bold and inquiring mind, he did not rest satisfied till he had convinced himself, and many others around him, that the indulgences were sinful, and that the Pope had no right to grant them. This happened about the year 1517. Controversy and persecution gradually extended the views of Luther, till he at length openly disavowed the authority of the Pope, and condemned some of the important peculiarities of the Catholic system of worship. In these proceedings Luther was countenanced by some of the states in Germany, and his doctrines were speedily established in the northern countries of Europe.

THE REFORMATION.

Henry the Eighth of England had been originally educated for the church, and still retained a taste for theological learning. He now distinguished himself by writing a book against the Lutheran doctrines; and the Pope was so much pleased with it, as to grant him the title of Defender of the Faith. Henry was not destined, however, to continue long an adherent of the Roman Pontiff. In the year 1527, he became enamoured of a young gentlewoman named Anne Boleyn, who was one of his wife's attendants. He immediately conceived the design of annulling his marriage with Catherine, and marrying this younger and more agreeable person. Finding a pretext for such an act in the previous marriage of Catherine to his brother, he attempted to obtain from the Pope a decree, declaring the marriage unlawful, and that the dispensation upon which it had proceeded was beyond the powers of the former Pope to grant. The Pontiff (Clement the Seventh) was much perplexed by this request of King Henry, because he could not grant it without offending Charles the Fifth, Emperor of Germany, one of his best supporters, and the brother of Queen Catherine, and at the same time humbling the professed powers of the Papacy, which were now trembling under the attacks of Luther. Henry desired to employ the influence of his minister, Cardinal Wolsey, who had now reached a degree of opulence and pride never before attained by a subject of England. But Wolsey, with all his greatness, could not venture to urge a matter disagreeable to the Pope, who was more his master than King Henry. The process went on for several years, and still his passion for Anne Boleyn continued unabated. Wolsey at length fell under the king's displeasure for refusing to serve him in this object, was stript of all his places of power and wealth, and, in November 1530, expired at Leicester Abbey, declaring, that if he had served his God as diligently as his king, he would not thus have given him over in his grey hairs. The uncontrollable desire of the king to possess Anne Boleyn—an object the most contemptible and the most base—was destined to be the immediate cause of one of the most important changes that ever took place in England—no less than a total reformation of the national religion. In order to annul his marriage with Catherine, and enable him to marry Anne Boleyn, he had to shake off the authority of the Pope, and procure himself to be acknowledged in Parliament as the supreme head of the English church. His marriage with Anne took place in 1533, and in the same year was born his celebrated daughter Elizabeth.

In 1536, Henry became as anxious to get quit of Queen Anne as he had ever been to rid himself of Queen Catherine. He had contracted a passion for Jane Seymour, the daughter of Sir John Seymour, a young lady then of the queen's bed-chamber, as Anne herself had been in that of Catharine's. In order to gratify this new passion, he accused Anne of what appears to have been an imaginary frailty, and within a month from the time when she had been an honoured queen, she was beheaded (May 19) in the Tower. On the very next day he married Jane Seymour, who soon after died in giving birth to a son (afterwards Edward the Sixth). His daughters Mary and Elizabeth were declared illegitimate by act of Parliament, and therefore excluded from the succession.

Hitherto, though professing independence of Rome, Henry still maintained, and even enforced, by severe and bloody laws, the most of its doctrines. He now took measures for altering this system of worship to something nearer the Lutheran model, and also for suppressing the numerous monasteries throughout the country. Being possessed of more despotic power, and, what is stranger still, of more popularity than any former sovereign of England, he was able to encounter the dreadful risk of offending, by these means, a vastly powerful corporation, which seems, moreover, to have been regarded with much sincere affection and respect in many parts of England. No fewer than six hundred and forty-five monasteries, two thousand three hundred and seventy-four chaunteries and chapels, ninety colleges, and a hundred and ten hospitals, enjoying altogether a revenue of one hundred and sixty-one thousand pounds, were broken up by this powerful and unscrupulous monarch, who partly seized the revenues for his own use, and partly gave them away to the persons who most actively assisted him, and who seemed most able to protect his government from the effects of such a sweeping reform. By this act, which took place in 1537, the Reformation was completed in England. Yet for many years Henry vacillated so much in his opinions, and enforced these with such severe enactments, that many persons were burnt as heretics on both sides of the question. It was in the southern and eastern parts of England, where the commercial classes at this time resided, that the doctrines of the Reformation chiefly prevailed. In the western and northern parts of the country, Catholicism was still predominant, and in Ireland, which was remotest of all from the Continent, the Protestant faith made little or no impression. After the death of Jane Seymour, Henry married Anne of Cleves, a German princess, with whose person, however, he was not pleased; and he therefore, in the coolest manner possible, divorced her by an act of Parliament. He next married Catherine Howard, niece to the Duke of Norfolk, but had not been long united to her when he discovered that she had committed a serious indiscretion before marriage. This was considered a sufficient reason for beheading the unfortunate queen, and attainting all her relations. Though Henry had thus murdered two wives, and divorced other two, and become, moreover, a monster in form as well as in his passions and mind, he succeeded in obtaining for his sixth wife (1543) Catherine Parr, widow of Lord Latimer, who, it is certain, only contrived to escape destruction by her extraordinary prudence. Almost all who ever served Henry the Eighth as ministers, either to his authority or to his pleasures, were destroyed by him. Wolsey was either driven to suicide, or died of a broken heart. Thomas Cromwell, who succeeded that minister, and chiefly aided the king in bringing about the Reformation—Sir Thomas More, lord chancellor, the most virtuous, most able, and most consistent man of his time—the Earl of Surrey, who was one of the most accomplished knights of the age, and the first poet who wrote the English language with perfect taste—all suffered the same fate with Anne Boleyn and Catherine Howard. It was truly said of Henry, that he never spared man in his rage, or women in his lust.

When James the Fourth died at Flodden, in 1513, the Scottish crown fell to his infant son James the Fifth, who struggled through a turbulent minority, and was now a gay, and, upon the whole, an amiable prince. His uncle Henry the Eighth endeavoured to bring him into his views respecting religion, but James, who was much in the power of the Catholic clergy, appears to have rather wished to become the head of the Popish party in England, in the hope of succeeding, by their means, to the throne of that country. A war latterly broke out between the two monarchs, and the Scottish army having refused to fight, from a dislike to the expedition, James died, December 1542, of a broken heart, leaving an only child, Mary, who was not above a week old. Henry the Eighth immediately conceived the idea of marrying his son Edward to this infant queen, by which he calculated that two hostile nations should be united under one sovereignty, and the Protestant Church in England be supported by a similar establishment in Scotland. This project, however, was resisted by the Scotch, of whom very few as yet were inclined to the Protestant doctrine. Henry, enraged at their hesitation, sent a fleet and army, in 1544, to inflict vengeance upon them. The Scotch endured with great patience the burning of their capital city, but still refused the match. The government of Scotland was now chiefly in the hands of Cardinal Beaton, a man of bold and decisive intellect, who zealously applied himself to suppress the heretical preachers, and regarded the English match as likely to bring about the destruction of his religion.

EDWARD THE SIXTH.

Henry the Eighth died January 28, 1547, leaving the throne to Edward the Sixth, a boy between nine and ten years old. The Duke of Somerset, maternal uncle to the young king, became supreme ruler under the title of Protector, and continued to maintain the Protestant doctrines. Under this reign, the church of England assumed its present form, and the Book of Common Prayer was composed nearly as it now exists. Somerset being resolved to attain, if possible, the match between Edward the Seventh and Mary of Scotland, invaded that country in autumn 1547, and was met at Musselburgh by a large army under the governor, the Earl of Arran. Though the Scotch were animated by bitter animosity against the English, against their religion, and against the object of their expedition, they did not fight with their usual resolution, but were defeated, and pursued with great slaughter. Finding them still obstinate in refusing to give up their queen, Somerset laid waste a great part of the country, and then retired. Previous to this period, Cardinal Beaton had been assassinated by private enemies; but the Scotch were encouraged to persevere by the court of France, to which they now sent the young queen for protection.

In the reign of Edward the Sixth, the government was conducted mildly, until the Protector Somerset was degraded from his authority by the rising influence of Dudley Duke of Northumberland, who caused him soon after to be tried and executed. Northumberland, who was a secret Roman Catholic, was not so mild or popular a ruler. Yet throughout the whole reign of Edward the Sixth, which was terminated by his death, on the 6th of July 1553, at the early age of sixteen, no religious party was persecuted, except those who denied the fundamental doctrines of the Christian religion. It would have been well for the honour of a church which has produced many great men, and to which the modern world is indebted for the very existence of Christianity, if it had not been tempted after this period to commence a very different course of action. The crown now belonged by birthright to Mary, the eldest daughter of Henry the Eighth, who was a zealous Catholic. Northumberland, however, assuming the illegitimacy of that princess, and her sister Elizabeth, set up as queen the Lady Jane Grey, who was descended from a younger sister of King Henry, and who had been married to a son of the Duke of Northumberland. Lady Jane was the most beautiful, most pure, and most amiable of all the females who appear in the history of England. Though only seventeen, she was deeply learned, and yet preserved all the unaffected graces of character proper to her interesting age. Unfortunately, her father-in-law Northumberland was so much disliked, that the Catholics were enabled to displace her from the throne in eight days, and to set up in her stead the Princess Mary. Northumberland, Lady Jane, and her husband, Guildford Lord Dudley, were all beheaded by that savage princess, who soon after took steps for restoring the Catholic religion, and married Philip the Second, King of Spain, in order to strengthen herself against the Protestant interest. Mary experienced some resistance from her Protestant subjects, and being under great suspicion of her sister Elizabeth, who professed the reformed faith, but took no part against her, was almost on the point of ordering her to execution also. As soon as she had replaced the Catholic system, and found herself in possession of sufficient power, she began that career of persecution which has rendered her name so infamous. Five out of fourteen Protestant bishops, including the revered names of Cranmer, Latimer, and Ridley, were committed to the flames as heretics; and during the ensuing part of her reign, which was closed by her death, November 17, 1558, nearly three hundred persons suffered in the same manner. These scenes did not take place without exciting a proper horror in the minds of Englishmen in general, including even many Catholics; but the royal authority was at all times too great under this line of princes to allow of effectual resistance. Such a persecution, however, naturally fixed in the minds of the British Protestants a hereditary horror for the name of Catholic, which has in its turn been productive of many retaliatory persecutions, almost equally to be lamented. In the latter part of her reign, she was drawn by her husband into a war with France, of which the only effect was the loss of Calais, the last of the French possessions of the Kings of England. The natural sourness of Mary's temper was increased by this disgraceful event, as well as by her want of children, and she died in a state of great unhappiness.

ELIZABETH.

A more auspicious scene opened for England in the accession of Elizabeth, a princess of great native vigour of mind, and who had been much improved by adversity, having been kept in prison during the whole reign of her sister. From the peculiar circumstances of Elizabeth's birth, her right of succession was denied by all the Catholics at home and abroad. This party considered Mary Queen of Scots, who was descended from the eldest sister of Henry the Eighth, and had been brought up in the Catholic faith at the court of France, as their legitimate sovereign. Elizabeth had no support in any quarter, except among her Protestant subjects. The Pope issued a bull, which, directly or indirectly, pronounced her an usurper, and gave permission to her subjects to seek her dethronement. The court of France professed to consider the Queen of Scots, who had recently been married to the Dauphin, as the Queen of England; and all the English Catholics befriended the claims of this princess. Under these circumstances, Elizabeth found no chance of safety, except in restoring and maintaining the Protestant religion in her own country, and in seeking to support it in all others where the people were favourable to it. She gained one great point, in the Reformation which now took place in Scotland, by the agency of John Knox, and a part of the nobility, who, with the assistance of a small English army, sent by Elizabeth, overthrew at once the ancient religion and the government of Mary of Guise, who acted as regent for her daughter, the queen. Elizabeth thus established a friendly, though irregular, government in Scotland, and raised an attachment towards herself among the Scotch in general, which eventually proved destructive to their Catholic sovereign.

Mary, the most renowned beauty of her time, and in early life apparently the most fortunate of women, became, in 1559, the Queen-consort of France, by the accession of her husband Francis the Second to the throne of that country. By the death of her husband, however, at the end of the year 1560, when she was only eighteen years of age, she lost in a great measure all interest in France. In August 1561, she returned to her own country, and assumed a nominal sovereignty, where in reality all authority was vested in the Protestant nobles who had lately effected the Reformation.

REFORMATION IN SCOTLAND.

The change of religion in Scotland was of a more decisive kind than it had been in England. The English Reformation was effected by sovereigns, who, while they wished to throw off the supremacy of the Pope, and some of the more odious of the Catholic rites, desired to give as little way as possible to popular principles, and, therefore, not only seized the supremacy of the church to themselves, but, by bishops and other dignitaries, preserved the church as completely in the light of a dominant power over the people, as it had ever been. In Scotland, however, where the reformation was effected by the nobles and the people, and at a time when still bolder principles had sprung up, none of this machinery of power was retained: the clergy were all equal, and all useful; only a small part of the ancient revenues was allowed to them; their general affairs, instead of being entrusted to the hands of bishops, were confided to courts formed by themselves: these courts being partly formed by lay elders, kept up a sympathy and attachment among the community, which has always been greatly wanting in the English church; and, to crown all, while a large part of the ancient revenues was absorbed by the nobles, a very considerable portion was devoted to the maintenance of parish schools, under the express control of the clergy, which at once formed regular nurseries of Protestant Christians, and disseminated instruction more extensively over this small and remote country, than it has ever been over any other part of the world; an advantage which has placed Scotchmen ever since in the most confidential and important offices in all other countries, and given to Scotland itself a lustre superior to that derived from any other source. The English have much to boast of; but in the important matter of public instruction, they are nearly three centuries behind their northern neighbours.

The affairs of England and Scotland are, for some time after this, inextricably mingled. Queen Mary had no power as a Catholic in her own country, and was obliged to govern by means of her natural brother James Stewart, Earl of Moray, who was the leader of the Protestant interest in Scotland. Personally, however, she was intimately connected with the great Catholic powers of the Continent, and became a party, in 1564, to a coalition formed by them for the suppression of Protestantism all over Europe. She had never yet resigned her pretensions to the English throne, but lived in the hope, that, when the Catholics succeeded in every where subduing the Protestants, she would attain that object. Elizabeth, who had only the support of the Protestant part of her own subjects, with a friendly feeling among the Scotch and other unimportant Protestant nations, had the greatest reason to dread the confederacy formed against her, which rendered her situation very similar to that of Great Britain during the war of the French revolution. It was proved, however, at this trying crisis of our history, that the commerce, the insular situation, and, perhaps, the superior intelligence of the British people, fitted them for resisting nearly all the rest of Europe. Elizabeth stood firm upon the Protestant faith, and the principles of a comparatively liberal and popular government—the only safe position, as it has proved oftener than once in our history, for the sovereign of these islands.

A series of unfortunate events threw Mary into the hands of Elizabeth. The former queen, in 1565, married her cousin Lord Darnley, and by that means alienated the affections of her brother and chief minister, the Earl of Moray, as well as of other Protestant lords, who raised a rebellion against her, and were obliged to fly into England. Soon after, the jealousy of Darnley, respecting an Italian musician named Rizzio, who acted as French secretary to the queen, united him in a conspiracy with the banished Protestant noblemen for the murder of that humble foreigner, which was effected under very barbarous circumstances, March 9, 1566. Mary, who was delivered in the succeeding June, of her son James, withdrew her affections entirely from her husband, and began to confide chiefly in the Earl of Bothwell, who some months afterwards caused Darnley to be blown up by gunpowder, while he lay in a state of sickness; in which transaction it has always been suspected, but never proved, that the queen had a considerable share. Bothwell soon after forced her, in appearance, into a marriage, which excited so much indignation among her subjects, that the same Protestant lords who had effected the Reformation, and were the friends of Elizabeth, easily obtained the possession of her person, and, having deposed her, crowned her infant son as king, under the title of James the Sixth, while the regency was vested in the Earl of Moray. In May 1568, Mary escaped from her prison in Lochleven, and put herself at the head of a body of her partisans, who were overthrown, however, by the regent at the battle of Langside, and Mary was then compelled to seek refuge in England. By placing her rival under strict confinement, and extending an effectual protection to the regents Moray, Lennox, Mar, and Morton, who successively governed Scotland, Elizabeth fortified herself in a great degree against the Catholic confederacy.

GOVERNMENT OF ELIZABETH.

It has already been seen that the liberties of the people were much favoured by the frequent interruptions in the succession to the crown. Whenever one branch of the Plantagenet family displaced another, the new king felt himself weak, and endeavoured to strengthen his title, by procuring a Parliamentary enactment in support of it. It thus became established as a regular principle in the English government, that the people, who were represented by Parliament, had a say in the appointment of their king. A considerable change, however, had taken place since the accession of Henry the Seventh. The great power acquired by that king through his worldly wisdom, and the destruction of the nobility during the civil wars, had been handed down through four successive princes, who inherited the crown by birthright, and did not require to cringe to the people for a confirmation of their title. The Parliaments, therefore, were now a great deal more under the control of the sovereign than they had ever been before. Henry the Eighth never permitted his Parliament to oppose his will in the least; it was also seen that to the various changes of religion under successive sovereigns, the Parliaments presented no obstacle. An idea was now beginning to arise, very much through the supremacy the sovereigns had acquired over the church, that the right of the crown was one derived from God, and that the people had nothing to do with it, except to obey what it dictated to them. Of this notion, no one took so much advantage, or was at so much pains to impress it, as Elizabeth. The vigorous talent and fortitude of this woman have always been a subject of admiration and pride among Englishmen, but they have failed to see that the very greatness of her character at once prompted and enabled her to be a tyrant. No doubt the arbitrary measures of Elizabeth were generally of a popular nature; yet this does not excuse them in principle; and their ultimate mischief is seen in the attempts of future sovereigns to pursue worse ends upon the same means. Elizabeth's government consisted entirely of herself and her ministers, who were, from the beginning to the end of her reign, the very choice of the enlightened men of England. Her prime minister was the celebrated Lord Burleigh, by far the most sagacious man who ever acted as a minister in Britain. All her emissaries to foreign courts were of one complexion—circumspect and penetrating men, devoted to their country, their mistress, and to the Protestant religion; indeed, the wisdom of Elizabeth's government might almost be said to have reached an unamiable extreme, as we often find, in individuals, that their perfect propriety and worldly knowledge keep the feelings too much in the background. Elizabeth appeared so much as the champion of the reformed faith against Catholic Europe, that the people do not seem to have ever wished to control her actions. It will hardly be believed that she was at one time permitted to assume a power of making and dispensing with laws by her own proclamation. It is perfectly natural, however, that the people should allow of a more arbitrary line of conduct in sovereigns and ministers, who are in a manner on their own side, than in others who attempt to rule over them more expressly in the light of rulers.

WAR IN THE NETHERLANDS.

The great business of this century was religion. In the Netherlands, which formed part of the dominions of Philip the Second of Spain, the reformed faith had made considerable advances. Philip, like other Catholic princes, entertained the idea that this new religion, besides being condemnable as a heresy and an offence against the Deity, tended to make men independent of their rulers. Finding the people obstinate in their professions, he commenced a war with the Netherlanders, for the purpose of enforcing his authority over their consciences. This war lasted about twenty years. The Netherlanders fought like desperate men, and endured the most awful slaughters and hardships rather than submit to the tyrant, whom some claim of what is called birthright had given a title to oppress them. Elizabeth could not help wishing well to the Netherlanders, though, for a long time, her dread of Spain, then one of the greatest powers in Europe, prevented her from openly assisting them.

The chief leader in this war of liberty was William Prince of Orange, ancestor of the present King of the Netherlands, and one of the purest and most courageous patriots that ever breathed. At the same time, about two millions of the people of France were Protestants, or, as they were then called, Hugonots, who acted also for the general Protestant cause with as much energy as the great strength of the French government would permit. It was the general sentiment of the Catholics of that age, that heresy was an evil the extirpation of which could not be too dearly purchased. They therefore persecuted it at the expense of almost all the best human feelings, trusting to the importance of the end for a justification of every species of means. We do not say this for the purpose of exciting the hostility of Protestants against Catholics. The latter class of persons have, for many years, been far less inclined to persecution than the Protestants, so that the mutual account of injury is now pretty nearly balanced. But, in the sixteenth century, Protestantism seemed a new and dangerous experiment, which all good Catholics felt bound, so far as lay in their power, to prevent from going any farther. Under this feeling, Charles the Ninth of France caused the massacre of from ten to twenty thousand Protestants at Paris, on St Bartholomew's day (August 24), 1572, a barbarity which is said to have given satisfaction to all professors of the Romish faith throughout Europe, and to have been celebrated with public thanksgivings at Rome. Many other cruelties of the same nature were perpetrated by Catholics upon Protestants. Elizabeth at length, in 1578, extended an open protection to the Netherlanders, excusing herself to Philip by stating her fear that they would otherwise throw themselves into the arms of France. The northern provinces were thus enabled to assert their independence, and to form the country which has since been called Holland. It is curious to reflect, that, in modern times, this country has stood conspicuously in opposition to the liberal interest throughout Europe, under the government of a king descended from the patriotic Prince of Orange; while Lord Burleigh, the great English statesman who counselled that England should protect it in its resistance, is the ancestor of two noblemen* distinguished in their own country for their zeal against innovatory principles.

DEATH OF MARY OF SCOTLAND.

It may be easily imagined that the severities and threats of the Catholics provoked some retaliation on the part of the Protestants. It was at this time that the English government began to enact those penal laws against the adherents of the ancient faith, which have only of late been altogether abolished. Elizabeth hanged many men for no other crime than that they were Romish priests; being solely provoked to do so, however, by the plots which were perpetually forming by men of this class for assassinating her. Her principal victim was the unfortunate Queen of Scots, who had been kept in captivity for nineteen years. The liberation of this princess was generally a part of the schemes of all the enthusiasts who plotted the murder of Elizabeth. A law was at length passed, intended for the destruction of Mary, by which it was declared, that any person, by or *for* whom any plot should be made against the life of the Queen of England, should be guilty of treason. In 1586, a gentleman of the name of Babington, with some others, contrived a plan for assassinating Elizabeth, and placing Queen Mary on the throne. The plot was discovered by spies—a class of persons of whom great numbers were employed in this reign. The conspirators were seized and executed; and out of the confessions extracted from them by torture, was woven a tissue of pretended evidence, for proving that the Queen of Scots was concerned in the conspiracy. In reality, Mary might have some vague knowledge that such a plot was in agitation; but, as a prisoner, detained in defiance of all law, she was neither called upon to divulge any secret involving the life of Elizabeth, nor was it in her power to prevent any man from entering upon an enterprise in her favour.

Thirty-six commissioners, appointed by Elizabeth, arrived at Fotheringay Castle, in Northamptonshire, where Queen Mary was confined, in order to subject one independent princess to a trial for high treason against another; a proceeding quite unparalleled in history, and which, indeed, was only giving to murder the form of law. Mary protested, both against the law upon which she was arraigned, and against the competency of the court, but was at length induced to appear upon trial, lest it should have been supposed that she refused, from a consciousness of guilt. "It is impossible," says an English historian, "to read, without admiration, in the minute records of the trial, the self-possessed, prompt, clear, and sagacious replies and remarks by which this forlorn [illegible] defended herself against the most expert lawyers and politicians of the age, who, instead of examining her as judges, pressed her with the unscrupulous ingenuity of enemies." Upon a mere shadow of evidence, which any lawyer would now pronounce to be not only imperfect, but illegal, she was condemned to death, October 25, 1586. Elizabeth had not only public reasons for taking the life of this queen, but was also animated by a deadly hatred against her on account of the personal superiority of Mary; yet with detestable hypocrisy she pretended to all around her that she could never be induced to grant the warrant for execution, unless it was seen to be imperatively necessary for the welfare of her country. Accordingly, the kingdom was now filled with rumours of plots, treasons, and insurrections; and the queen seemed to be continually kept in alarm with fictitious dangers. She appeared to be in great terror and perplexity; sat much alone, and muttered to herself half sentences, importing the difficulty and distress to which she was reduced. In this situation, she one day called her secretary, Davidson, whom she ordered to draw out secretly the warrant for Mary's execution, informing him that she intended to keep it by her, in case any attempt should be made for the delivery of that princess. She signed the warrant, and then commanded it to be carried to the chancellor, to have the seal affixed to it. Next morning, however, she sent two gentlemen successively to desire that Davidson would not go to the chancellor until she should see him; and, upon being informed that the warrant had been already sealed, she seemed displeased at his precipitation. But Davidson, who was not ignorant that his mistress wished to have the sentence executed, laid the affair before the council, who unanimously resolved that the warrant should be immediately carried into effect, and promised to justify him to the queen. Accordingly, the fatal instrument was delivered to Beale, the clerk of the council, who summoned the noblemen to whom it was directed, viz., the Earls of Shrewsbury, Kent, Derby, and Cumberland; all of whom set out immediately to Fotheringay Castle, accompanied by two executioners, to dispatch their bloody commission.

On the 6th of February 1587, Mary was informed of the arrival of these functionaries, who ordered her to prepare for death by eight o'clock the following day. Early on the fatal morning, she dressed herself in a rich habit of silk and velvet, the only one which she had reserved for this solemn occasion. Thomas Andrew, the under-sheriff of the county, then entering the room, informed her that the hour was come, and that he must attend her to the place of execution. She replied that she was ready; and, bidding her servants farewell, she advanced, supported by two of her guards, and followed the sheriff with a serene aspect, having a long veil of linen on her head, and in her hand a crucifix of ivory. She then passed into another hall, the noblemen and the sheriff going before, and Melvil, her master of the household, bearing up her train. In this hall into which they had entered, a scaffold was erected, covered with black. As soon as Mary was seated, Beale began to read the warrant for her execution; and Fletcher, dean of Peterborough, standing without the rails, repeated a long exhortation, which she desired him to forbear, as she was firmly resolved to die in the Catholic religion. The room was crowded with spectators, who beheld her with pity and distress; while her beauty, though dimmed by age and affliction, gleamed through her sufferings, and was still remarkable in this fatal moment. The two executioners kneeling and asking her pardon, she said she forgave them, and all the authors of her death, as freely as she hoped for forgiveness from her Maker, after which she once more made a solemn protestation of her innocence. Her eyes were then covered with a linen handkerchief, and she laid herself down upon the block without any fear or trepidation. After reciting a psalm, and repeating a pious ejaculation, her head was severed from her body, at two strokes, by the executioner.

Thus died Mary, in the forty-fifth year of her age and nineteenth of her captivity, the last victim of that spirit in the royal family of England, which prompted them to embrue their hands in each other's blood. Her son was in the meantime grown to manhood, and, under the title of JAMES THE SIXTH, had assumed the supreme direction of affairs in Scotland, in which, however, he was much controlled by the clergy, who, though they had less apparent power than their brethren in England, were in reality possessed of an influence over the people which set the sovereign at defiance. James made many attempts to assert a control over the church like that enjoyed by the English monarch, and also to introduce an Episcopal hierarchy, but never could attain more than a mere shadow of his object. He had been educated by the regents in the Protestant faith, and was now regarded as heir-presumptive to the English crown.

SPANISH ARMADA.

The year 1588 was remarkable in England for the famous enterprise called the Spanish Armada. It was resolved by the King of Spain to hurl one decisive blow at the Protestant interest, by invading England with an immense fleet, the preparation of which had employed all the resources of his kingdom. The ports of Spain, Portugal, and other maritime dominions belonging to him, had long resounded with the noise of his preparations, and the most eminent Catholic soldiers from all parts of Europe flocked to take a share in the expedition.

The Marquis of Santa-Croce,* a sea-officer of great reputation and experience, was destined to command the fleet, which consisted of a hundred and thirty vessels, of greater size than any that had been hitherto seen in Europe. The Duke of Parma was to conduct the land forces, twenty thousand of whom were on board the ships of war, and thirty-four thousand more were assembled in the Netherlands, ready to be transported into England; so that, as no doubt was entertained of success, the fleet was ostentatiously styled the Invincible Armada.

Nothing could exceed the terror and consternation which seized all ranks of people in England, upon the news of this terrible armada being under sail to invade them. A squadron of not more than thirty ships of the line, and those very small in comparison, was all that Elizabeth had to oppose it by sea; and it was considered impossible to make any effectual resistance by land, as the Spanish army was composed of men well disciplined and long inured to danger. But although the English fleet was much inferior in number and size of shipping to that of the enemy, it was much more manageable, while the dexterity and courage of the mariners were greatly superior. Lord Howard of Effingham, a man of great valour and capacity, took upon him, as lord high admiral, the command of the navy. Drake, Hawkins, and Frobisher, the most renowned seamen in Europe, served under him; while another squadron, consisting of forty vessels, English and Flemish, commanded by Lord Seymour, lay off Dunkirk, in order to intercept the Duke of Parma. Such was the preparation made by the English; while all the Protestant powers of Europe regarded this enterprise as the critical event which was to decide for ever the fate of their religion.

In the mean time, while the Spanish armada was preparing to sail, the admiral, Santa-Croce, died, as likewise the vice-admiral, Paliano; and the command of the expedition was given to the Duke de Medina Sidonia, a person utterly inexperienced in sea affairs; so that these unexpected circumstances served, in some measure, to frustrate the design. Some other accidents also contributed to its failure. Upon leaving the port of Lisbon, the armada next day met with a violent tempest, which sunk some of the smallest of the ships, and obliged the rest to put back into the harbour. After some time spent in refitting, the Spaniards again put to sea, where they took a fisherman, who gave them intelligence that the English fleet, hearing of the dispersion of the armada in a storm, had returned to Plymouth, and that most of the mariners were discharged. From this false intelligence, the Spanish admiral, instead of going to the coast of Flanders, to take in the troops stationed there, resolved to sail directly to Plymouth, and destroy the shipping laid up in the harbour. But Effingham was very well prepared to receive him, and was just got out of port, when he saw the Spanish armada coming full sail towards him, disposed in the form of a half-moon, and stretching seven miles from the one extremity to the other. The English admiral, seconded by Drake, Hawkins, and Frobisher, attacked the Spaniards at a distance, pouring in their broadsides with admirable dexterity. They did not choose to engage the enemy more closely, because they were greatly inferior in number of ships and guns, as well as in weight of metal; nor could they pretend to board such lofty vessels without manifest disadvantage. In this action, however, two Spanish galleons were disabled and taken.

As the armada advanced up the Channel, the English still followed and infested its rear; and as their ships continually increased from different ports, they soon found themselves in a capacity to attack the Spanish fleet more nearly, and, accordingly, fell upon them while they were taking shelter in the port of Calais. To increase their confusion, Howard selected eight of his smaller vessels, which, after filling them with combustible materials, he sent one after another, as if they had been fire-ships, into the midst of the enemy. The Spaniards, taking them for what they seemed to be, immediately bore off in great disorder; while the English, profiting by their panic, captured or destroyed about twelve ships. The Duke of Medina Sidonia being thus driven to the coast of Zealand, held a council of war, in which it was resolved, that, as their ammunition began to fail, as their fleet had received great damage, and as the Duke of Parma had refused to venture his army under their protection, they should return to Spain by sailing round the Orkneys, as the winds were contrary to their passage directly back. Accordingly, they proceeded northward, and were followed by the English fleet as far as Flamborough-head, where they were terribly shattered by a storm. Seventeen of the ships, having five thousand men on board, were afterwards cast away on the Western Isles and the coast of Ireland. Of the whole armada, three-and-fifty ships only returned to Spain in a wretched condition; and the seamen, as well as the soldiers who remained, were so overcome with hardships and fatigue, and so dispirited by their discomfiture, that they filled all Spain with accounts of the desperate valour of the English, and of the tempestuous violence of that ocean by which they are surrounded.

The reign of Elizabeth saw the commencement of the naval glory of England. Up to the reign of Henry the Seventh, there was no such thing as a navy belonging to the public, and the military genius of the people was devoted exclusively to enterprises by land. The rise, however, of a commercial spirit in Europe, which in 1492 had caused the discovery of America, and was again acted upon by the scope for adventure which that discovery opened up, had latterly

* The Marquises of Exeter and Salisbury.

* We here pursue the account of the Spanish armada given by Goldsmith in his Abridgement of the History of England.

caused great attention to be paid to naval affairs in England. Englishmen of all ranks supported and entered into enterprises for discovering unknown territories, and under Drake, Cavendish, Hawkins, and Frobisher, various expeditions of less or more magnitude were sent out. Drake was the first English seaman who sailed round the world. When hostilities with Spain became more open, these commanders made many successful attacks upon the colonies of that country in the West Indies, and also upon the fleets of merchant vessels which were employed to carry home the gold, and other almost equally valuable products of the New World, to the Spanish harbours. These attacks were now made in a more systematic manner, and with a more overpowering effect, as a revenge for the affair of the Armada. It may almost be said, that the dominion of Britain over the seas was perfected in one reign; a power which has been of such advantage to the country, both in protecting its commerce, and keeping it secure from foreign invasion, that it would have conferred everlasting lustre on this period of our history, even although it had not been characterised by any other glorious event.

It is remarkable, that while Elizabeth increased in power and resources, she became more noted for female weaknesses. In her early years she had shown a stoicism, and superiority to natural affections, not usually observed in womankind. But when she became old and infirm—not to mention another word, which politeness will not permit us to use respecting any individual of the sex—she also became volatile and susceptible to an extraordinary degree; so that the hand which she had withheld, in her younger days, from the noblest princes of Europe, seemed likely to be bestowed, in her old age, upon some mere court butterfly. Her favourite, in middle life, was Robert Earl of Leicester, a profligate and a trifler. In her latter days she listened to the addresses of the Earl of Essex, a young man of greater courage and better principle, but also headstrong and weak. Essex, who had acquired popularity by several brilliant military enterprises, began at length to assume an insolent superiority over the queen, who was, on one occasion, so much provoked by his rudeness as to give him a hearty box on the ear. Notwithstanding all his caprices and insults, the queen still doatingly forgave him, until he at length attempted to raise an insurrection against her in the streets of London, when he was seized, condemned, and, after much hesitation, executed (February 25, 1601).

It is always alleged that the life of Essex would have been saved, if the queen had received from him a ring which she had given him in his happier years as a pledge of her affection, and which she told him would at any time recal her tenderness towards him, however deeply he might have offended her. It is said that Essex gave this ring to the Countess of Nottingham, to be carried to Elizabeth, but that the Countess was prevailed upon by her husband, who was an enemy of Essex, to suppress it. Elizabeth, in at last ordering the execution of Essex, had acted upon her usual principle of sacrificing her feelings to what was necessary for the public cause, but in this effort, made in the sixty-eighth year of her age, she had miscalculated the real strength of her nature. She was seen from that time to decline gradually in health and spirits, till a settled melancholy overtook her. Her distress was increased to a great degree by a death-bed confession of the Countess of Nottingham, respecting the ring. The dying woman asked the queen's forgiveness for her treachery, but Elizabeth turned from her in a transport of grief and indignation, saying, that God might forgive her, but that she never could. After this, she declined still more rapidly, and at length became so much absorbed by her sorrow as to refuse sustenance, and to sit for days and nights on the floor, supported by a few cushions brought to her by her attendants. On the 24th of March 1603, she expired, after a reign of nearly forty-five years, during which England advanced from the condition of a second-rate to that of a first-rate power, and the Protestant religion was established on a basis from which it could not be shaken, though it has since made hardly any progress.

THE STUARTS—JAMES THE FIRST.

The successor of Elizabeth, by birthright, was James of Scotland, who was now in the thirty-sixth year of his age, and had been married for some years to the Princess Anne of Denmark, by whom he had two sons, Henry and Charles, and one daughter named Elizabeth. Robert Carey, cousin of the late queen, rode from London to Edinburgh in three days and two nights (which nearly equals the speed of the fastest of the present conveyances), in order to inform the King of Scots that Elizabeth was no more. James immediately removed to London, and assumed the government of England, while his native kingdom, though thus united under the same sovereignty, still retained its own superior institutions. James had all Elizabeth's ideas respecting the power, or, as it is called, the *prerogative* of the crown, and was equally anxious to manage all affairs after his own free will. But though he was not deficient in talent, he entirely wanted the vigorous personal character, and the imperious, and, at the same time, popular manner, which had enabled Elizabeth so effectually to subdue her Parliaments. It must also be owned, that he had not the same straight-forward anxiety for the public welfare and greatness, which always formed such a specious excuse for the despotic proceedings of his predecessor.

PROGRESS OF RELIGIOUS LIBERTY.

It may be easily conceived that James was not so successful a ruler as Elizabeth. The truth is, the popular spirit had been gaining such force in the latter years of that princess, that it would have required a stronger instead of a weaker sovereign, to keep it in check. During the whole reign of Elizabeth, there had been rising in England a party called the Puritans, who wished still greater reforms to be effected in the church, and carried on their devotions in the same manner as our modern dissenters. Elizabeth looked upon the Puritans as her greatest enemies, and enacted many severe laws against them; by one of which it was declared, that any person found guilty for the third time of merely not attending the regular church of the parish, should be punished with death. Perhaps no one ever suffered to the full extent under this bloody law, but it may give an idea of the general severity with which the Puritans were treated in this reign. A dissent from the church, indeed, was looked upon at this time by the higher powers as a kind of rebellion, and there can be no doubt that the Puritans, in struggling with these powers for a mere toleration of their simple system of worship, contracted ideas of natural rights and civil freedom, in the highest degree threatening to the arbitrary sovereigns of this age. It may even be said, that if men had not had the desire of a freedom in religious matters, and been thereby animated by a zeal which despised all worldly dangers, there would not have been so early or so powerful a spirit of civil freedom; for men could never have contested for that object with the same eagerness or constancy, seeing that it rested upon less intelligible principles, and had not such a sacred end in view. Elizabeth had been able to keep the Puritans in some measure in check; yet, as they were constantly increasing in numbers and confidence, the succeeding monarch found it far more difficult to evade their demands. James, in fact, while he inherited all the apparent powers and prerogatives of the Tudor princes, inherited, it may be said, a people always becoming less disposed to obey arbitrary rule, so that this well-meaning monarch has been more blamed for the simplest exertions of what he thought his rightful authority, than Queen Elizabeth has been for the most violent; among which may be reckoned her open contempt for the House of Commons, and her occasional imprisoning its members when they attempted to express their independent opinions.

THE GUNPOWDER PLOT.

One circumstance which greatly tended to favour the opening views of the people respecting their liberties, was, that the Protestant faith was not now threatened by those Catholic powers, in opposing which Elizabeth had been enabled to carry matters with so high a hand. The Protestant faith being itself secure, the people were now bent upon putting it on an improved footing; and hence the spirit of the people was now chiefly turned against the high power of the church and the king. His Majesty, at the same time, was much troubled by the Catholics, of whom a respectable minority still remained among his subjects, and who were grievously oppressed by the penal laws enacted against them. Under the intolerable pressure of a persecution, which transported men beyond the bounds of reason, a few Catholic gentlemen contrived a plot for sweeping off the King and his Parliament, by an explosion of gunpowder from under the House of Lords, and which was to take place on the 5th of November 1605. The gunpowder had all been properly stored in a cellar, and a man named Guy Fawkes was ready to light the train, when one of the conspirators, named Henry Percy, caused the discovery of the plot, by an attempt which he made, through the means of an anonymous letter, to withhold his friend, Lord Mounteagle, from attending the fatal house. Fawkes was seized, and confessed his intentions; and the rest of the conspirators fled to the country, where most of them were cut to pieces in endeavouring to defend themselves. This plot is generally alluded to as a stigma upon the Catholics, and it is still barbarously kept in remembrance by an annual celebration of the day on which it was to have taken effect. In reality, it is a disgrace to the Protestants, or, at least, to the Protestant government of that time, since nothing but the severest persecution could have induced men to contrive any thing so repugnant to all the dictates of humanity. James himself never could be induced to take advantage of it, as most of his subjects desired, for the purpose of increasing the persecution of the Catholics. If men had then been as enlightened as they are now, and not smarting so much under the recent dread of the Catholic confederacies against Protestantism, they would have treated the gunpowder plot as only an awful lesson of toleration.

THE SPANISH MATCH.

The reign of James the First is not marked by any of what are called great events. In 1612, he lost his eldest son Henry, a youth of nineteen, who was considered as one of the most promising and accomplished men of the age. The second son Charles then became the heir-apparent, and James was busied for several years in seeking him out a proper match.

The princess selected by his Majesty was the second daughter of Philip the Third of Spain—a match not very popular, on account of the young lady being a Catholic, but which James thought advantageous, as tending to conciliate the people of that religion, and also because the princess belonged to one of the most powerful houses in Europe. Some delay occurring in the negotiations, the prince set out in 1622, with his young friend the Duke of Buckingham, to visit the court of Spain in disguise, and, if possible, make personal application to the lady herself. The prince and duke travelled under the name of John and Thomas Smith, probably for the very good reason that these were then, as well as now, the most common and undistinguishing names in England. In passing through Paris, the prince saw Henrietta Maria, a sister of the French king, whom he was in reality destined to marry. At Madrid, he was received with great distinction under his proper character; but he was kept at such a distance from his proposed bride, that the Duke of Buckingham proposed to send home for a telescope, in order that he might obtain a peep at her as she walked in her garden. Some disgust finally broke off this match.

CHARLES THE FIRST.

James died in March 1625, in the 59th year of his age, and his son succeeded, under the title of CHARLES THE FIRST. Elizabeth, the only remaining child of the late king, had been married to Frederick Prince Palatine of the Rhine, who was so unfortunate as to lose his dominions, in consequence of his having placed himself at the head of the Bohemians, in what was considered as a rebellion against his superior the Emperor of Germany. This discrowned pair, however, by their daughter Sophia, who married the Duke of Brunswick, were the ancestors of the family which now reigns in Britain. James was greatly blamed by his subjects for not entering into a war with the emperor for the purpose of replacing his son-in-law—a contest which would have been very popular, in so far as it had a Protestant object, but was otherwise unadvisable. James was also blamed, in the course of his reign, for successively giving himself up to the company of trifling young men, who became his favourites, though they had no other recommendation than that of an agreeable aspect; indeed, his fondness for these favourites—the most remarkable of whom were Robert Carr, created Earl of Somerset, and George Villiers, who became Duke of Buckingham—can only be accounted for by supposing him to have prematurely fallen into a state of dotage. Though a man of much natural talent, and still more learning, he has left the general character of a timid, weak, and undignified prince; he was so good-natured, however, that, notwithstanding the frequent contests he had with his Parliament, he never became decidedly unpopular.

One of the first proceedings of Charles the First was to marry Henrietta Maria of France, a Catholic princess, who is supposed to have exercised a great control over her husband at every period of his life. After breaking off the proposed match with the Princess Mary of Spain, Britain eagerly threw itself into a war with that country, which was still continued. To supply the expenses of that contest, and of a still more unnecessary one into which he was driven with France, he applied to Parliament, but was met there with so many complaints as to his government, and such a keen spirit of popular liberty, that he was obliged to revive a practice followed up by other kings, and particularly Elizabeth, of compelling his subjects to grant him gifts, or, as they were called, *benevolences*; and also to furnish ships at their own charge, for carrying on the war. Such expedients, barely tolerated under the happy reign of Elizabeth, could not be at all endured in this age, when the people and the Parliament were so much more alive to their rights. There was, therefore, a great deal of discontent over the nation. The Commons, seeing that if the king could support the state by self-raised taxes, he would soon become independent of all control from his Parliaments, resolved to take every measure in their power to check his proceedings. They also assailed him respecting a right which he assumed to imprison his subjects upon his own warrant, and to detain them captive as long as he pleased. Having made an inquiry into the ancient powers of the crown, before these powers had been vitiated by the tyrannical Tudors, they embodied the result in what was called a PETITION OF RIGHT, which they presented to him as an ordinary bill, or rather as a second Magna Charta, for replacing the privileges of the people, and particularly their exemption from arbitrary taxes and imprisonment, upon a fixed basis. With great difficulty Charles was prevailed upon to give his sanction to this bill (1628); but his disputes with Parliament soon after ran to such a height, that he dissolved it in a fit of indignation, resolving never more to call it together. About the same time, his favourite minister, the Duke of Buckingham, was assassinated at Portsmouth, and Charles resolved thenceforward to be in a great measure his own minister, and to trust chiefly for the support of his government to the English hierarchy, to whose faith he was a devoted adherent, and who were, in turn, the most loyal of his subjects. His chief counsellor was Laud, Archbishop of Canterbury, a man of narrow and bigotted spirit, and who made it his duty rather to increase than to diminish the ceremonies of the English church, although the tendency of the age was decidedly favourable to their diminution. For some years Charles governed the country entirely as an irresponsible despot, levying taxes by his own orders, and imprisoning such persons as were obnoxious to him, in utter defiance of the Petition of Right. The Puritans, or church reformers, suffered most severely under this system of things. They were dragged in great numbers before an arbitrary court called the Star-Chamber, which professed to take cognisance of offences against the king's prerogative, and against religion; and sometimes men venerable for piety, learning, and worth, were scourged through the streets of London, and their ears cut off, and their noses slit, for merely differing in opinion on the most speculative of all subjects with the king and his clergy. The great body of the people beheld these proceedings with horror, and only some opportunity was wanted for giving expression to the public feeling.

It is to be observed, that none of the taxes imposed by Charles were in themselves burdensome; the country was then in a most prosperous condition, and the taxes far less in proportion to every man's means than they have ever since been. It was only to the principle of their being raised without Parliamentary sanction, which had formerly been so necessary a control on the royal power, that the people were disposed to resist them. It may easily be supposed, that, though there might be a general disposition to resistance, the most of individuals would not like to be the first to come forward for that purpose, as, in such an event, they would have been sure to experience the severest persecution from the court. One man, however, was at length found—and let it never be forgotten that his name was John Hampden—who was determined to undergo any personal inconvenience rather than pay his twenty shillings of ship-money. The case was tried in the Exchequer (1637); and as the judges were then dismissable at the royal pleasure, and of course the humble servants of the king in every thing, Hampden lost the day. He roused, however, more effectually than ever, the attention of the people to this question, and means were not long wanting to check the king in his unfortunate career.

TROUBLES IN SCOTLAND.

An attempt had been made by King James to introduce the Episcopal church into Scotland, because it was thought dangerous to the English church that a form of worship, resembling that of the Puritans, should be permitted to exist in any part of the king's dominions. The same object was prosecuted with greater zeal by King Charles, and although the people were universally adverse to it, he had succeeded, after a visit which he paid to the country in 1633, in settling thirteen bishops over the church, by whom he hoped to govern the clergy as he did those of England. But when he attempted, in 1637, to introduce a Book of Common Prayer into the Scotch churches, as a substitute for extemporary prayers, the spirit of the people could no longer be kept within bounds. On the Liturgy being opened in the principal church at Edinburgh, by a dignitary styled the Dean, the congregation rose in a violent tumult, and threw their clasped bibles, and the very stools they sat on, at the minister's head, and it was not till the whole were expelled by force that the worship was permitted to proceed. It was found necessary by the Scottish state officers to withdraw the obnoxious Liturgy, till they should consult the king, who, not dreading any mischief, gave orders that it should be used as he had formerly directed, and that the civil force should be employed in protecting the clergymen. It was found quite impossible to obey such an order in the face of a united people, who, by committees assembled at Edinburgh, representing the nobles, ministers, gentry, and burghers, endeavoured to awe the king into an abandonment of all the late innovations. Charles endeavoured, by every means in his power, to avoid such a humiliation, which he calculated would give immense force to the innovators in England. But the Scotch, when they found him hesitating, bound themselves, March 1638, under a bond called the National Covenant, which was signed by nineteen-twentieths of the whole population, to resist their sovereign in every attempt he might make to bring in upon them the impurities of Popery—for such they held to be the forms of worship and ecclesiastical government which Charles had lately imposed upon their church. The king sent his favourite Scotch counsellor, the Marquis of Hamilton, to treat with his northern subjects; but nothing would satisfy this devout, and, at the same time, spirited people, but the calling of a General Assembly (a form long disused), for the purpose of settling all disputes. Charles, though he saw that this was only an appeal to the Scottish church itself, consented to the proposal, for the purpose of gaining time, in order that he might make warlike preparations against his refractory people.

The assembly met at Glasgow in November, and, as might have been expected, formally purified the church from all the late innovations, excommunicating the bishops, and declaring the government of the clergy to rest, as formerly, in the General Assembly, which consisted of a selection of two clergymen from each presbytery, with a mixture of lay elders, and no one to control its proceedings but the divine founder of the Christian religion. Early in the succeeding year, the king had, with great difficulty, collected an army of twenty thousand men, whom he led to the border of Scotland, for the purpose of reducing these despisers of his authority. The Scotch, however, strengthened by devotional feeling, and a certainty that the English, in general, were favourable to their cause, formed an army equal in number, which was placed under the command of General Alexander Leslie, an officer who had served with distinction in the long Protestant war carried on against the Emperor of Germany. The Scottish army was encamped on the top of Dunse Law, a hill overlooking the border, where the duties of military parade were mingled with prayers and preachings, such as were never before witnessed in a camp. The king, seeing the wavering of his own men, and the steadfastness of the Scotch, was obliged to open a negociation, in virtue of which it was agreed to disband both armies, and to refer the disputes once more to a General Assembly and a Scottish Parliament.

The king now adopted a new policy with the turbulent people of Scotland. It is consistent with the self-love of a king, who, by mismanagement, has brought his people into a state of resistance, to suppose that it is not so much the discontent of the mass, as the ambition of the leaders, that causes the insurrection. In reality, the leaders, with all their ambition, are but the creation of the mass; beings called into existence, or at least into action, by the general sentiment. Charles, overlooking the radical evils altogether, thought that he should overcome all opposition, if he only could gain over the nobles who had hitherto taken the lead. He accordingly called a number of them to his court at Berwick, and, by blandishments and promises, endeavoured to make them his own partisans. He was successful only with the Earl of Montrose, an ambitious and unscrupulous person, though of great abilities, who was already dissatisfied on account of the ascendancy of the Earl of Argyle. Montrose is henceforth found at the head of a royalist party, which gradually began to gain strength.

In the new General Assembly and Parliament, the votes were equally decisive against Episcopacy; and though Charles prorogued the latter body before it had completed its proceedings, it nevertheless sat still, and voted every measure which it thought necessary. The king collected a second army, and, in order to raise money for a second attack upon the Scots, was reduced to the necessity of calling an English Parliament, the first that had met for eleven years; but finding it bent upon the redress of grievances, he thought fit to dissolve it, and trust for supplies to the clergy, and other friends of arbitrary power. The Scots did not wait for his attack, but, in August 1640, marched into the north of England, in the expectation of being supported in their claims by the English people in general. Throughout all these proceedings, the Scotch professed, and were no doubt sincere in professing, a rational loyalty towards the king, and only avowed a hostility to Archbishop Laud, the Earl of Strafford, and other royal counsellors, whom they professed to consider as alone blameable for the differences between the king and his people. On the 28th of August, the Scotch were opposed by an advanced party of the royal army at a ford on the Tyne, near Newburn; but they forced their way through all impediments, and, driving the English before them, took possession of Newcastle. Charles and his minister Strafford tried every means of exciting the old hostile feeling of the English against the Scots; but common objects in civil and religious liberty had now rendered them friends, and both nations conceived themselves to have no enemy but the king's tyrannical counsellors. Animated by such feelings, the English army showed a strong disinclination to meet the Scots on the field, insomuch that the king found it necessary to abandon all hope of reducing the latter people to obedience by arms. He once more opened a negotiation for peace; and it was soon after agreed at a council of peers, that all the present dissensions should be referred to the Parliaments of the two countries, the Scottish army being in the mean time kept up on English pay, till such time as they were satisfied with the state of their affairs.

SITTING OF THE LONG PARLIAMENT.

The English Parliament met in November, and immediately commenced a series of measures for effectually and permanently abridging the royal authority. There was even a large party, who, provoked by the late tyranny, contemplated the total abolition of the monarchy, and the establishment of a republic. Religion was to appearance the moving-spring of the revolution. The destruction of the Episcopal system was anxiously desired by an immense party, who conceived that large benefices, and a connexion with the state, were incompatible with pure religion. All were alike furious against the Catholics, but evidently not so much from a sincere fear of that body of Christians, as the conveniency of setting them up for the objects of popular alarm, and making all revolutionary acts appear as only so many necessary safeguards against their machinations. The first acts of the Parliament had little or no immediate reference to Scotland. The Earl of Strafford was accused of treason against the liberties of the people, and executed. William Laud, the Archbishop of Canterbury, another zealous counsellor, was impeached and imprisoned, but reserved for future vengeance. The remaining ministers of the king only saved themselves by flight. Some of the judges were imprisoned and fined. The abolition of Episcopacy was taken into consideration. The Catholics fell under a severe persecution; and even the person of the queen, who belonged to this faith, was not considered safe. It was not till August 1641, when the English Parliament had gained many of its objects, that they permitted the treaty of peace with Scotland to be fully ratified. They then gratified the troops, not only with their full pay at the rate of L.850 a-day, but with a vote of no less a sum than L.300,000 besides, of which L.80,000 was paid down, as an indirect way of furnishing their party with the means of future resistance. The king, on his part, also took measures for gaining the attachment of this formidable body of soldiery, and of the Scottish nation in general. He had agreed to be present at the meeting of their Parliament, in the autumn of this year. In his journey to the north, he passed through the army at Newcastle, and accepted an invitation to dine with General Leslie. On his arrival at Edinburgh, August 14, he squared his conduct most carefully with the rigour of Presbyterian manners. In the Parliament he was exceedingly complaisant: he at once ratified all the acts of the preceding irregular session; he yielded up the right of appointing the state officers of Scotland; and he ordained that the Scottish Parliament should meet once every three years without regard to his will—an immense point in the claims of freedom. The men who had acted most conspicuously against him in the late insurrections, now became his chief counsellors, and he seemed to bestow favours upon them exactly in proportion to their enmity. He created General Leslie Earl of Leven, putting on his coronet with his own hand. Argyle was made a marquis. Many others received promotions in the peerage. The offices of state were distributed amongst them. Thus, it will be observed, the affections of the Scots were in a manner set up to auction between the king and his English Parliament, and from both did they receive considerable gratifications.

But while thus intriguing with the covenanting leaders, Charles also kept up a correspondence with that royalist party which had been embodied by the Earl of Montrose. This nobleman was now suffering confinement in Edinburgh Castle, for his exertions in favour of the king. In the anguish of disappointed ambition, he concocted an enterprise in the old Scottish style against the lives of his political opponents. The king having refused his sanction to the scheme, he seems to have resolved upon executing one of a less ferocious character, without his Majesty's knowledge. The Marquis of Argyle had all along been the prime object of Montrose's antipathy, and the odium was now shared by the Marquis of Hamilton, who at this time held a nearly equal place in the Scottish councils, and by the Earl of Lanark, his younger brother. These three noblemen Montrose intended to be suddenly seized, and taken on board a vessel in the Firth of Forth. On the same night, his friends were to surprise Edinburgh Castle, and endeavour to bring about a complete revolution in favour of the royal cause. The plot was detected, and the three noblemen retired precipitately to the country. Charles himself was the only person who suffered: the scheme, though probably unknown to him, was universally laid to his charge, and it introduced suspicions of his sincerity, that tended to neutralise the effects of his late favours, and also to afford matter of reproach to the English Parliament, who had of course viewed his journey to Scotland with great jealousy. After spending about three months in Scotland, the king was suddenly called away, in consequence of intelligence which reached him from Ireland. The Catholics of that country, who formed the great majority of the population, and had for many years groaned under the oppression of the English, became infected by the example of the Scottish Covenanters, and resolved that they would also endeavour to obtain toleration and equal rights. Their proceedings led to an intestine war, during which the greatest cruelties were perpetrated on both sides. Though the poor Irish were struggling for both national and religious freedom, they gained no sympathy from the patriots of Britain, who, on the contrary, urged the king to suppress the Irish rebellion, being afraid that a religious toleration in that country would be inconsistent with the same privileges in their own. The Scottish Covenanters immediately sent over a large body of troops to assist in rivetting those bonds upon the Irish from which they themselves were just emancipated. It is by such traits of exclusive feeling that the religious sects of this age diminish their title to the sympathy of an enlightened posterity: for it is invariably found that the persecuted became the persecutor, whenever it obtained an ascendancy.

How this dispute with the king grew wider and wider, till it ended in open and general war, and how at length the liberties of the British nations were secured against the power of the crown, will form the subject of a future sheet.

Edinburgh: Printed and Published by W. and R. Chambers, 19, Waterloo Place; also by W. Orr, Paternoster Row, London; and W. Curry, Jun. and Co. Sackville Street, Dublin. Sold by John Macleod, Glasgow, and all other Booksellers in Scotland, England, and Ireland.

"Chambers's Information for the People" will be continued once a fortnight (every alternate Wednesday). Each number will consist of a distinct and different work of a popular and instructive nature. Price *three-halfpence*.

Stereotyped by A. Kirkwood, St Andrew Street, Edinburgh.

HISTORY OF MANKIND.

INTRODUCTION.

If the history of one man, whose life has been diversified by adventures, be interesting to his fellow man, how much more interesting must be the history of the whole human race, viewed as the collective members of one family, the branches of which have extended through all regions of the globe! By ancient records, by monuments that have been preserved through the revolutions of ages, and by numerous other kinds of evidence, we are enabled to look back through the mist of time to that remote period, when this world was in its infancy, and when man had only just gone forth, like a labourer at day-break, to commence his arduous pilgrimage. At first we behold him, an isolated being, standing alone on the yet unpeopled earth; then we find him increase and multiply his species, build cities, invent arts, and disperse into different and far distant countries, where both his body and mind become assimilated to the most opposite extremes of climate. At every step of his progress, we observe his character modified or changed, by the effects of external circumstances operating upon the peculiar pliability of his nature. In one position, we find him degraded into the condition of a savage; he lives naked in the forests; his food consists only of the roots and herbs which grow wild in the fields; his time is passed in the repose of sloth-like indolence; or his actions are wild, fierce, and brutal, prompted by the darkest and the most unhallowed passions that can rend the human heart. In another, we observe him surrounded by all the glowing luxuries of civilisation; his person is swathed in gorgeous silks and golden tissues; his steps rest only on the softest carpets; his bed is swelled with luxuriant down; his table loaded with all the delicacies which the animal or vegetable creation can provide; he is attended by a retinue of his fellow-creatures, habited as beings of an inferior order; he has been born to fortune, and is, perhaps, the envied scion of royalty! But, instead of taking either of these extremes, let us look into the origin and history of nations; let us view man as he existed in ages far remote, and as he still exists in all regions of the world. Surely it will afford us no ordinary interest and pleasure thus to trace the stream of our existence, through all its deviations, down from its fountain head. If we could read the history of our own race aright, how much would it contribute to our own happiness! for every condition in which man may be found must suggest its own moral. Here do we see how energy, activity, and industry, have delivered him from the miseries of savage life, and surrounded him by all the comforts that are required to redress his wants and satisfy his desires; there do we observe how misgovernment may enthral the most civilized society with slavery, and how excessive luxury may undermine the stability of the proudest empire. In the one instance, we read the lesson which should urge us to subdue and govern our own individual passions; in the other, we observe the elucidation of those political principles which can alone link nation to nation in the bonds of peace and friendship.

ORIGIN OF MAN.

That man did not exist from all eternity, but was created, is obvious; for we see that nations increase according to a certain rate of progression; so that the further we recede in our calculations, the more we must reduce the existing number of inhabitants, until we reach a period when only a single family could have existed. But this is not all; a more conclusive proof remains, which is, as it were, lettered in the structure of the globe itself. We find that this earth is constructed of numerous rocks and soils, laid in regular succession, one above the other—the lowest being the most simple, and the oldest; the highest the most complex, and the most recent. We observe, in like manner, that there are various gradations of living beings—plants constituting the lowest, man the highest link in the chain; between which extremes, we find fishes, reptiles, birds, and quadrupeds. Now, when the structure of the globe is examined, it appears to have undergone prodigious revolutions, all of which have been more or less destructive to the beings which were then in existence. We first find rocks, wherein no remains of plants or animals are found. We next find another series, where the remains of plants and the simplest kind of animals abound; then we excavate the bones of reptiles, birds, and numerous quadrupeds, each in successive strata; yet the remains of man we do not discover. At the present time caves are continually opened, which appear to have been the abodes of wild and savage beasts, proving that when they prowled abroad, mankind were too few in number to subdue them. Animals multiply quicker (generally speaking) than the human species; and before the flood which imbedded their remains, they had wandered far into the woods, extending their dominion over the greater part of the uninhabited world, while the human race, few in number, was confined to a single region. Since, then, amidst the vestiges of those great revolutions which have occurred in the globe itself, we do not find the bones of man, but only the remains of inferior animals, it is evident that only few of the human species could have existed when these catastrophes took place; therefore, the multiplication of mankind must be (comparatively speaking) very recent; but let not this be misunderstood, for all we mean by recent, is, that, in the sight of eternity, three or four thousand years are but as a day, or as a wave in the bosom of a passing stream.

Accordingly, there was a time when man first began to exist: that he did not create himself, is obvious; therefore he must have been created. The tales of the gravest philosophers on this subject rival in extravagance the most ludicrous nursery stories that ever beguiled the ear of childhood. But it is unnecessary to enter into these absurdities: it only remains for us to ask ourselves—by what kind of evidence are we to explain the origin of man?

When we examine the human body, we find it composed of many parts, all of which harmonize together for the production of a certain system, exactly as the stars we see in heaven, by their mutual relations, compose the system of the universe. But no examination of the human body can elucidate its origin. The anatomist may unravel its most intricate machinery, and lay bare, with his dissecting-knife, the course of the minutest nerves—the physiologist may explain how the structure of the eye may be adapted to the sense of sight, and how every organ has a structure appropriate to its particular use—the chemist, when death has sealed down the eyelids, and the vital spirit has departed, may, in his turn, analyse and explain the principles which composed the decaying frame—but not all their combined sagacity can approach even to the remotest explanation of how these elements could so arrange themselves as to produce an organization so complete and so perfect, that its contemplation alone cannot fail to humble the pride of the most daring philosophy. Since, then, no effort of ingenuity can solve this mystery, nor any examination of the body itself afford us the slightest assistance, there is only one other kind of evidence to which we can have recourse—it is the evidence of History.

The most ancient history in existence was discovered about the fifteenth or sixteenth century before the birth of Christ, and is thus described by Sir William Jones, whose knowledge of eastern languages, and extensive erudition, are of the highest character:—"The oldest composition," says he, "perhaps in the world, is a work in the Hebrew, which we may suppose at first, for the sake of argument, to have no higher authority than any other work of equal antiquity that the researches of the curious had accidentally brought to light; it is ascribed to MUSAH, for so he writes his own name, which, after the Greeks and Romans, we have changed into MOSES. After describing, with awful solemnity, the creation of the universe, he asserts that one pair of every animal species was called from nothing into existence; that the human pair were strong enough to be happy, but free to be miserable; that, from delusion and temerity, they disobeyed the Supreme Benefactor, whose goodness could not pardon them, consistently with his justice; and that they received a punishment adequate to their disobedience, but softened by a mysterious promise, to be accomplished in their descendants."*

Trusting, then, to this historical testimony—which can only guide us through this and other perplexing mysteries—we must come to the conclusion that man was formed by a Creator; and although it is not necessary for us to advance any further proofs in support of this belief, we may observe, that, notwithstanding this account is handed down by tradition, yet the events which took place before the deluge have been transmitted to us almost as directly as any of those which took place after that epoch. This was occasioned by the very great longevity of the Patriarchs. Noah lived some hundred years with thousands of persons who had conversed with Adam; and Abraham lived with Shem, the son of Noah; so that from the time of Adam to that of Abraham was comparatively no greater a length, even for tradition, than from our father's grandfather to ourselves.

The birth-place of man—or that region of the world in which he was created—has attracted much notice; and, independently of all higher authority, natural historians have come to the conclusion that both men and animals originally migrated from Asia. The illustrious naturalist Linnæus says, that the "hill of creation" exists in nature, not only as a single acclivity, but as an extensive amphitheatre—a constellation of mountains, the arms of which stretch out into various climates. In the early history of the world, while other parts of the earth were covered with water, or presented only a dreary surface of bogs and morasses, the high land of Asia was already crowned with forests, and abounded with multitudes of animals, which have since dispersed themselves into every latitude of the globe. Here roamed in freedom the wild ox or buffalo, the musimon (whence is derived our common sheep), the camel, the wild cat (from which our domestic cat is sprung), the jackall, which (by intermixture with the wolf, and even, as some suppose, with the hyæna) originated our domestic dog; the rein-deer, the sagacious elephant, the cunning ape. Here, too, the grape, olive, pomegranate, orange, and all the most luxuriant fruits, grew wild. In many places even corn grew spontaneously. In this delightful region was man created; here did our first parents enjoy the brief sunshine of primeval innocence; here all was happiness, until their disobedience to Heaven's high decree "brought death into the world, and all our woe;" then were they driven forth, under the Divine pleasure, to till the land whence they had derived their own existence; then commenced the sorrowful and perilous wanderings of the human race.

The world was all before them, where to choose
Their place of rest, and Providence their guide.

* Asiatic Researches, Vol. III. p. 424.

THE MULTIPLICATION AND DISPERSION OF MAN.

When mankind had existed 1656 years,* an event took place, so awful in its nature and so terrible in its consequences, that its vestiges may yet be traced on the summits of the highest mountains and in the bosoms of the lowliest vallies. The human race, like all other animals, in the beginning, was created both male and female, for the obvious purpose of reproduction; and between the period of the fall and that of the flood, we find that mankind had increased to a prodigious amount, owing partly to the very great longevity to which many of the antediluvians attained, and partly to the numerous intermarriages which then took place. All nations, even the most unlettered, have some tradition of this disastrous event, which destroyed the whole human race then existing, with the exception of Noah and his three sons, with their wives, who, escaping in the ark, and taking along with them such animals as were necessary for the repopulation of the earth, remained in safety until the ark rested on Mount Ararat, which signifies the "Mountain of Descent," and is one of the highest mountains in Armenia.

When the waters had subsided, and the face of the earth became again uncovered, Noah and his family took up their abode in the plains of Shinar, where it appears they dwelt in tents, which were the kind of dwellings first adopted, and used until some of their descendants began to build houses. Here Noah pursued the art of husbandry; here his family increased in numbers, and remained for about 150 years, when the confusion of tongues took place, and they were dispersed into different and distant regions of the earth. The confusion of tongues did not affect the issue of Shem or Japhet, but that only of the impious Ham. To describe the routes which the different groups took, is not necessary; but it must appear obvious, that, as the descendants of Shem and Japhet yet understood each other, they would unite into small societies, and continue to practise those arts which had already been acquired; while the descendants of Ham, not understanding each other, would separate, and degenerate into a state of barbarism. The descent of mankind, originally from a single pair, and the multiplication of the families of Noah, may be proved, by arithmetical calculation, to have been sufficient to supply the earth with its present number of inhabitants; nay, had not wars, plagues, and famines reduced the population, their descendants alone would have over-peopled the world.† Here, therefore, we shall simply explain how the multiplication and dispersion of the families of Noah gave rise to numerous nations.

SHEM, THE SON OF NOAH.—His sons were: Elam, Ashur, Arphaxad, Lud, and Aram.

The region to which they migrated.—The south part of Asia.

The nations to which they gave rise.—The Assyrians and Persians.

HAM, THE SON OF NOAH.—His sons were: Cush, Mizraim, Phut, and Canaan.

The regions to which they migrated.—Africa and the West of Asia.

The nations to which they gave rise.—Cush gave rise to the Ethiopians, and American tribes; Mizraim, to the Egyptians, Cyrenians, and Lybians.

JAPHET, THE SON OF NOAH.—His sons were: Gomer, Magog, Madia, Javan, Tubal, Meshech, and Tiras.

The regions to which they migrated.—North of Asia and North of Europe.

The nations to which they gave rise.—Gomer gave rise to the Gauls, Germans, and Celts; Madia, to the Medes; Javan, to the Ionians and Greeks; Tubal, to the Spaniards; Meshech, to the Muscovites; Tiras, to the Thracians.

Besides the direct dispersion of mankind through the regions of the globe specified, they were occasionally dispersed to detached islands by accidental causes. Cook, Forster, and other celebrated travellers, have remarked, that parties of savages in their canoes must often have lost their way, and been driven on distant shores, where they were forced to remain, deprived both of the means and of the requisite intelligence for returning to their country. Thus, Captain Cook found on the island Wateoo three inhabitants of Otaheite, who had been drifted hither in a canoe, although the distance between the two islands is five hundred and fifty miles. In 1696, two canoes, containing thirty persons, who had left Ancorso, were thrown by contrary winds and storms on the island of Samar, one of the Philippines, at a distance of eight hundred miles. Captain Beechey, in his late voyage to the Pacific, fell in with some natives of the Coral Islands, who had been in a similar manner carried to a great distance from their native country. They had embarked, to the number of a hundred and fifty souls, in three double canoes, from Aran or Chain Island, situated about three hundred miles to the eastward of Otaheite. They were overtaken by the monsoon, which dispersed the canoes; and, after driving them about the ocean, they were left becalmed, so that a great number of persons perished. Two of the canoes were never heard of, but the other was drifted from one uninhabited island to another, at each of which the voyagers obtained a few provisions; and at length, after having wandered for a distance of six hundred miles, they were found, and carried to their home in the Blossom. Kotzebue, when investigating the coral isles of Radack, at the eastern extremity of the Caroline Isles, became acquainted with a person of the name of Kadu, who was a native of Ulea, an isle fifteen hundred miles distant, from which he had been drifted with a party. Kadu and three of his countrymen one day left Ulea in a sailing boat, when a violent storm arose, and drove them out of their course; they drifted about the open sea for eight months, according to their reckoning by the moon, making a knot on a cord at every new moon. Being expert fishermen, they subsisted entirely on the produce of the sea, and, when the rain fell, laid in as much water as they had vessels to contain it. Kadu, the best diver, frequently went down deep into the sea, where it is known that the water is not so salt. Thus, with a cocoa-nut shell, with only a small opening, he occasionally relieved their want. When they reached the isles of Radack, every hope, and almost feeling, had died within them; their sail had long been destroyed; their canoe had long been the sport of winds and waves; and they were picked up by the inhabitants of Aur, in a state of insensibility; but by the hospitable care of those islanders, they soon recovered, and were restored to perfect health. "Accidents similar to these (says Professor Lyell) might suffice to transport canoes from various parts of Africa to the shores of South America, or from Spain to the Azores, and thence to North America; so that man, even in a rude state of society, is liable to be scattered involuntarily by the winds and waves over the globe, in a manner singularly analogous to that in which many plants and animals are diffused." There is yet another fact connected with the dispersion of man worthy of our notice, because it explains how he may have emigrated into countries which appear now far separated from each other. There is no doubt that the whole aspect of the globe has, in the course of ages, undergone the most remarkable changes, owing to the action of the water breaking down the land, against which its waves constantly heave; and owing, also, to the action of volcanoes, which, it is well known, have uplifted hills, and even vast ranges of mountains; and islands, and groups and clusters of islands. Hence there is every reason to believe that the continent of America was once united with that of Asia; for while the destructive action of the waters is impressed visibly on the American coast, Asia, from the earliest periods, has been subjected to the most violent earthquakes. Voltaire has triumphantly asked how man could have emigrated into North America; but, independent of the explanation just given, navigators have discovered that the north-east part of America is very nearly connected with the north-west part of Asia, the distance between the coasts being so trifling, that both men and animals may even yet pass across without much difficulty. Thus does the progress of knowledge triumph over the doubts and errors which our ignorance and credulity too often upraise; nor do we despair of a time when truth will establish her dominion, and one faith prevail throughout the world.

* Hebrew calculation.

† "Various are the ways," says Stackhouse, in his History of the Bible, "which have been attempted by learned men to show the probable increase of mankind. For our present purpose, it will be sufficient to suppose, that the first three couples, *i.e.* Noah's three sons and their wives, in twenty years after the flood, might have thirty pair; and, by the gradual increase of ten pair for each couple, in forty years' time, there would, in three hundred and forty years after the flood, have arisen a sufficient number to spread colonies over the face of the whole earth."

In some parts of North America the population is supposed to double itself every twenty-five years. In the year 1717, the Russian subject were computed at not more than 10,000,000; in the year 1763, a space of forty-six years, the numbers were 20,000,000. This is doubling, in no favourable climate, and during even the devastation of many bloody wars. With the rapid increase of the population of Great Britain, every person is well acquainted; but how much faster must men have multiplied at the period we are considering, when the climate was more favourable, the habits of men less sophisticated, and fewer checks to population existed!

THE EXTERNAL FORM OF MAN—HIS STATURE.

All the productions of nature—no matter whether we contemplate the curiously constructed fabric of animal bodies, the structure of plants, or the regularly arranged particles of minerals—are in themselves perfect; and, as if it were intended that the eye of every observant being should be gratified, all we behold seems to have been moulded in a cast of beauty such as must in every instance excite admiration. In the vegetable kingdom—from the oak of the forest to the gracefully drooping willow of the valley, from the rarest flower of foreign climes to the most common weed—we behold the most agreeable variety; so, too, in the animal kingdom—from the lions and tigers which prowl wild through the woods, down to the lizards and serpents that creep along the grass or desert sands—from the eagle that builds its eyrie on the loftiest cliff, down to the little humming-bird which flits about like a mote in a sunbeam—all we see excites wonder and admiration. Yet, amidst all that has been created, the human form, by universal consent, has been esteemed the most admirable; so just are all its proportions; so exquisitely do they harmonize together; and so obviously is the whole stamped with the expression of superior intelligence. Let us, then, proceed to examine the various peculiarities by which the human frame is distinguished in different regions of the world.

The variable stature of man first claims our attention. In this country, the average height of men is five feet eight inches;* the average height of women five feet five inches; and all who exceed or are beneath either of these measurements, may be considered above or below the ordinary standard. In the temperate climate of Europe, the stature of the human race may be said to vary from five feet and a half to six feet; but in the high northern latitudes, where the growth of animals and vegetables is checked by the intensity of the cold, the stature of man is low. The Laplanders, Greenlanders, and Esquimaux, are all very short, measuring only from four to a little above five feet; but there is no uniformity between any particular climate and variety of human stature. It is true that the Laplander is short, but the Norwegian, living nearly in the same latitude, is tall; so, also, while the Hottentots, living in the south of Africa, are very short, the Caffres, a neighbouring tribe, are tall, robust, and muscular. In Asia, the Chinese and Japanese are nearly of the same stature as ourselves; but the Mongols, and some other tribes, are remarkably short. The inhabitants of America present us with very striking differences. In the regions north of Canada, the tribes are very tall; among the Cherokees many exceed the height of six feet, and few are below five feet eight or ten inches. The western Americans of Nootka Sound, near the Columbia, are of low stature; so also are many tribes in South America. The Patagonians, however, who occupy the north-eastern part of this country, are of prodigious stature; most of them are six feet five or six inches, and many eight feet high.

Individuals of very remarkable height have frequently existed, and among them the following examples, which we believe to be well authenticated, may be adduced:—

	Ft.	In.
Duke John Frederic, of Brunswick, Hanover, measured	8	6
One of the King of Prussia's guards - -	8	6
Gilly, a Swede (exhibited as a show) - -	8	8
Reichardt of Friedberg, near Frankfort - -	8	3
Martin Salmeron, a Mexican - - -	7	8½
An Irishman (skeleton in the London College) -	8	4
A Danish female, named La Pierre - - -	7	0

But while we call to recollection these and other gigantic personages, we may also remember, that a remarkable diminution of stature is likewise frequently observable.

Beke, King of Poland, measured only -	33 inches (French)
Boruolaski, a Polish nobleman (skilled in many languages) - - - -	28 do. do.
Stoberin, a female in Nuremberg -	3 feet.

In some instances, these varieties of stature appear to have been hereditary; thus, the father and sister of the gigantic Reichardt, above mentioned, were gigantic; the parents, brothers, and sisters of Stoberin, dwarfs. It is well known that the King of Prussia had a body of gigantic guards, consisting of the tallest men who could be collected from all the neighbouring countries. A regiment of these men was stationed, during fifty years, at Potsdam. "And now," says Forster, "a great number of the present inhabitants of that place are gigantic, which is more especially striking in the numerous gigantic figures of women, and is certainly owing to the connections and intermarriages of these tall men with the females of that town."

All such cases, showing an excess or a diminution of the developement of the human body, may be regarded as irregularities of nature, or as species of monstrosities. Accordingly, those men who have much exceeded the ordinary standard, are generally ill proportioned, and have not possessed strength corresponding to their size. In general, in such cases, the nervous system seems as if insufficient to supply with muscular vigour, or intellectual energy, the demands of the preternaturally sized body. It may indeed be remarked, that a sort of healthy balance should exist between mind and matter; and if, therefore, from the original formation of the body, or from habits of luxury, the human frame make too great a demand on the nervous influence by which all its parts are animated, the mind itself must be enfeebled and impaired. Dwarfs are, for the most part, the victims of disease; they are in general ill-made; their heads are very large, and their powers, physical and mental, very feeble. It may be concluded, then, that few healthy well-made men, having all the attributes of their race, will be found to exist who are much above or much below the average height of their fellow-countrymen. The causes which produce these varieties of stature are not well understood; but, doubtless, a simple mode of life, nutritious sustenance, and a salubrious atmosphere, will be found to favour the full, healthy, and natural developement of the human body. The influence, indeed, of these causes, may be well illustrated by the following observations of the traveller Barrow:—"There is perhaps no nation on earth," says he, "that can produce so fine a race of men as the Caffres; they are tall, stout, muscular, well-made, excellent figures; they are exempt, indeed, from many of those causes which in more civilized societies contribute to impede the growth of the body; their diet is simple, their exercise of a salutary nature; their body is neither cramped nor covered by clothing; the air they breathe is pure; their rest is not disturbed by violent love, nor their minds ruffled by jealousy; they are free from those licentious appetites which proceed frequently more from a depraved imagination, than a real natural want; their frame is neither shaken nor enervated by the use of intoxicating liquors, which they are not acquainted with; they eat when hungry, and sleep when nature demands it. With such a kind of life, languor and melancholy can have little to do. The countenance of a Caffre is always cheerful, and the

* The late Dr John Gordon of this city observes, that this measurement is rather above the average.

whole of his demeanour bespeaks content and peace of mind."

The causes producing such varieties of stature are not confined to man alone, but extend through inferior races of animals; as may be observed by comparing the small Welsh cattle with the large Herefordshire cattle, or the Shetland pony with the tail-backed mares of Flanders. In the interior of Ceylon, according to Mr Pennant, there is a small variety of the horse, not exceeding thirty inches in height; so, too, in the Island of Celebes, a race of buffaloes is found, not exceeding the size of our common sheep. The Padnan fowl, likewise, is double the size of the common fowl; and we are all aware how the Bantam breed is prized for its superior size and strength.

The human race has been supposed to have degenerated in stature; many persons, indeed, believe that men are now much shorter than they were at a former period in the history of the world. The Scriptural statement, that "there were giants in those days," has, indeed, given rise to much useless discussion; for while some have maintained that all men before the deluge were giants, others have argued, more correctly, that no giants ever existed, but that the term simply refers to men noted for their crimes, and the violence they committed. There is certainly no reason to suppose that the general stature of man differed before the flood from that which we at present observe; yet, that some few very gigantic men did exist, is recorded on authentic testimony; nor, from the instances above mentioned of men of extraordinary stature, could such occurrences be regarded as marvellous, or out of the ordinary course of experience.

The remains of Egyptian mummies preserved from the earliest antiquity prove satisfactorily that the stature of the Egyptians did not exceed the ordinary height of the human race; many of these being five feet six inches, five feet eight inches, &c. Besides which, from the helmets and breast-plates preserved, from the buildings designed for their accommodation, and from monuments and works of art that have escaped the vicissitudes of ages, we may be satisfied that men were not formerly any taller than they are at present. Immense bones have often been dug up, and exhibited as the bones of men, which, on inspection, have proved to be those of animals. In 1613, the bones of the great giant Teutobachus were shown through Europe; but these, on inspection, turned out to be the bones of an elephant. It is remarkable, that even the great natural historian Buffon fell into a similar blunder, which has been corrected by Blumenbach.

It is a fashion with all poets, and with early historians, who often encroach on the land of fable, to describe giants as originally composing the nations whose praises they sing, or whose history they record; but such narratives are, for the most part, founded only on popular traditions, which have been sometimes suggested by superstition, and not unfrequently by the premeditated craft of interested and better informed persons. To excite the energies of the people, and to goad them on to war, their leaders often represented their enemies to them as gigantic beings, who would destroy them, unless they prepared themselves for the most enterprising and daring feats. Every poetic hero or heroine is yet expected to undertake some marvellous achievement—to encounter some appalling danger—to surmount some tremendous obstacle: hence, in Fletcher's introduction to the *Worthy Citizen and his Wife*, the Knight of the Burning Pestle is made to ask what the principal person of the drama shall do?—to which the following pithy desire is responded:—"Marry! let him come forth and kill a giant!"

THE COMPLEXION OF MAN.

As the inferior animals over which man claims dominion, present us with diversities of colour, corresponding to the climates in which they live, so does the human race present us with certain varieties of complexion, in all the different latitudes of the globe. Beneath the burning rays of a tropical sun, the complexion of man is of a deep jet black, as may be observed in the numerous tribes of African negroes; but as we proceed from the equator into more temperate climates, the complexion loses its darkened hue, and passes through all varieties of shade, until it becomes delicately fair. If, passing from the extreme of heat to the extreme of cold, we extend our observations to the highest northern latitudes, we shall there find that the human body becomes of a brownish or dusky hue, such as may be observed in the Laplander, Greenlander, and Esquimaux. We may, indeed, establish the following classification of complexions:—1. The white. 2. The yellow, or olive-coloured. 3. The red, or copper coloured. 4. The brown, or tawny coloured. 5. The deep ebony jet black. The original complexion of man has afforded matter for much speculation; but the general opinion of those who have examined the subject is, that he was not, as we flatter ourselves, of a white or fair, but of a dark complexion. When we consider that man was created in Asia, there is no extravagance in conjecturing that his complexion may have been of such a character.

Many persons have argued that such varieties and contrasts of complexion as are observed among different races of men, could not have arisen from external circumstances; wherefore they conclude, that more than one species of man must have been originally created. But the truth is, that the influence of light, heat, dry or moist air, food, soil, artificial habits, and very many other causes, which it is difficult even to enumerate, may, through a long succession of ages, have effected these changes. We have a proof of this in the Jews, who are undoubtedly derived from one parent stock; yet the English Jew has a fair complexion, the Portuguese Jew is swarthy, the American Jew is olive, the Arabian Jew is copper-coloured, and the African Jew is black. Here, then, we distinctly see the influence of climate on a people, who seldom or never intermarry with others of a different sect, and who have preserved their peculiar character, as a distinct nation, entire, amidst all the other inhabitants of the world.

Even in this country, the influence of climate on the complexion is very obvious, as may be noticed by comparing the countenance of the rustic who toils in the open fields, or the seaman who traverses the "boundless plains of ocean," with that of the literary man in his retirement, or the mechanic, who, from sunrise to sunset, toils in a manufactory. Compare, too, the daughter of a rich noble, who has had the misfortune to have been born an heiress, and is educated for the display of her beauty in the fashionable world, with the daughter of the cottager, who has, from her childhood, been accustomed to exercise in all weathers; in the one, the skin is exquisitely soft and smooth, and emulates in whiteness the purity of the winter snow; in the other, the skin is less smooth and fair, and the tinge of the life-blood is seen mantling below it; the one is a complexion indicative of a delicate or perhaps sickly constitution, which cannot withstand a winter blast or a summer shower; the other indicates a being continually cheered by the conscious and animating glow of health. In a foreign country, where the sun's rays fall more directly, and, therefore, with greater force, on the earth, exposure to their influence undoubtedly tans and darkens the complexion, as may be observed in all those who have returned from a long residence in India. Even among the natives in Africa, the women of the higher classes, who live much under shelter, and seldom expose themselves to the sun's rays, are of a lighter complexion than those who move about in the open air. It may be observed, too, that negro children, when born, are as fair as Europeans, and gradually afterwards become black. Besides this, the palms of the hands, the soles of the feet, and other parts of the body which are concealed from light, are not so dark in the adult African as those that are more exposed.

Here, too, as in many other instances, a striking analogy may be traced between the causes influencing the complexion of man, and those influencing the colour of animals; for as plants and flowers spread forth richer hues in the cheerful light of the sun, than they do when drooping beneath continued clouds, so do the birds and animals of a tropical climate wear a gaudier plumage and a gayer covering than those which are destined to live in the snowy and gloomy regions of the north. Within the tropics, trees and plants generally attain the most luxuriant growth, and the air is often loaded with delicious perfumes. Here the peacock, the parrot, and the bird of paradise, sport their beautiful plumage; and the tiger with his bright stripes, the leopard with his spots, and the lion with his noble mane, seek the solitude of the forests; where, too, serpents, with the most glowing and dazzling hues of skin, may be seen either reposing beneath the boughs of trees, or not unfrequently turning round their trunks. Even in Britain, birds that fly by day have a brighter and more varied plumage than those that only venture out by night; as may be seen by comparing the feathers of the goldfinch with those of the owl. Animals, too, such as hares, rabbits, moles, &c., which burrow in the earth, and conceal themselves from light, generally assimilate in colour to the soil they frequent. Nor does climate limit its influence only to the colour of animals; it affects the texture and nature of their coverings. Hence the dogs of New Guinea are nearly naked; those in the northern latitudes are covered with coarse woolly hair. In Africa, the wool of the sheep degenerates into coarse hair. The colour of the plumage of birds, when domesticated, undergoes many changes. Some singing birds—principally those of the lark and finch kind—are known to become black when fed upon hempseed. Owing to the varied influence of such causes, wheresoever we rest our eye on the surface of the globe, there do we behold a character peculiar to that region, not dependent alone upon the relations of its mountains or its vallies, its lakes or its rivers, but on all animate nature—the trees of the forest, the birds of the air, the animals both wild and tame, and man himself, who, like the rest, in the succession of ages, has localized himself, and found an appropriate habitation in every climate.

EFFECTS OF ART IN CHANGING THE FORM AND FEATURES OF THE HUMAN BODY.

All nations, even in their infancy, have recourse to such customs and fashions as gratify that feeling of vanity which appears natural to man. It is not alone in civilized society that fashion exercises her tyranny; she extends her influence over even the most uninformed of the human race. Savages almost universally delight in painting their bodies, in hanging rings through their noses and lips; and the natives of almost all countries, at an early period of their history, have undertaken to fashion particular parts and features of their bodies into a happier mould. In infancy, especially just after birth, all the bones of our frame are soft and pliable, and admit of being compressed into shapes such as were never designed by the provident wisdom of nature. The head, the face, the breasts, the feet, and other parts of the human body, have been subjected to the most capricious interference, the inquiry into which is not so much a matter of curiosity, as of importance, because we may hereby discover the origin of certain peculiar appearances, which are now characteristic of particular races of men. The head, the configuration of which, in early infancy, is changed with great facility, has been submitted to many alterations in figure. The Scythians, as a sign of their nobility, chose to have it shaped like a sugar-loaf, which was effected by the midwives binding the infant's head with cloth bands. Anciently, the women of Peru had recourse to this absurd fashion; so also had many Indians; and, that this form was occasionally transmitted to their children, is evident, from the birth of several infants, with this congenital monstrosity, having been recorded. A remarkable length of head, by other nations, was conceived a beauty. This the ancient Portuguese produced in the same artificial manner. The Germans esteemed a short head as the most preferable, wherefore we are informed that the German mothers took especial care to lay their children in their cradles in such a manner that the back part of the head should be compressed. Other nations preferred round heads, a fashion which was affected by the Greeks, and also by the Turks, who considered it the most commodious form for the turbans they wear; and the Turkish skull, at this day, is observed to be remarkably round. In the province of Old Port, in the West Indies, the men, admiring the square head, gave it that form by compressing the infant head between boards, which enclosed it on all sides like a square wooden box. The forehead has, in like manner, been made the subject of many capricious fashions. The Mexicans judged those to be most beautiful who had little foreheads. The Spaniards, on the contrary, accounted a high forehead a happy distinction; wherefore the ladies drew back their hair, to extend its height beyond its natural dimensions. The Russians admired broad foreheads, to acquire which, they compressed the head from above, so as to increase its breadth. The Italians, on the other hand, endeavoured, by artificial means, to render the forehead more prominent than natural. If possible, a more singular fancy prevailed with some nations, who were accustomed to burn letters on their foreheads. The Siamese, Thracians, and the people of Malabar, adopted this fashion; among whom, both men and women cut into the flesh of their brows, crosses, letters, and numerous fanciful characters. A very receding, or sloping forehead, has been and is still considered a beauty by many of the African tribes, and this they give their children, by making them wear a flat compressing instrument, which has been often exhibited in this country.

Not only has the head been subjected to these capricious changes, but the nose and the ears have likewise been submitted to the ingenious contortions of fashion. "The Indians," says an old author, "have their noses slit like broken-winded horses." The truth seems to be, that they made an incision in the centre, down the length of the nose, and used to keep the aperture gaping by pieces of bone or wood stuck in as ornaments. The Chinese consider a short nose a beauty; but some tribes in Africa, and also the Peruvians, reverted this decree of taste, and esteem a large nose the most desirable. The inhabitants of the Island of Zanzibar turned the nose from its point upwards, and thus gave it a curved upward direction. The Tartars, and Caffres, and many tribes both in North and South America, took particular pains to flatten the nose in infancy; and this still is a feature desired, and prevailing among most of the natives of Africa. In consequence of their king, Cyrus, having had a hawk-like nose, the Persians considered this shape a mark of nobility, and adopted every artifice to produce it. This fashion, we find, was also highly esteemed among the Romans, wherefore it has been termed the "Roman nose." Another very preposterous custom adopted has been that of lengthening, by artificial means, the lobes of the ears, and the length to which they have been dragged is indeed almost incredible. We are informed that some Indians, having extended them to half the length of their body, used to lie upon them, making them, as it were, a couch to rest on. In the West Indies, among some tribes the same fashion prevailed, and the elongation was effected by hanging weights to them, which they gradually increased. The Hollanders adopted the custom, and decorated them with heavy jewels. The travellers Condamine and Ulloa saw the lobe of the ear, in many instances, hanging down to the shoulder. Very large ears having likewise been deemed less asinine than at present, were considered beautiful, and diligently cultivated by being continually dragged beyond their natural size. This the Caribs took great pains to effect, as also did the inhabitants of Zanzibar, as well as the Peruvians. Not only were the ears subjected to this species of torture, but many nations esteemed it a very great beauty to have the lobe pierced with a large hole, the great dimensions of which constituted its principal charm. This was effected by means of pegs of wood, the diameter of which they gradually enlarged; this custom was adopted by the people of Malagar. "The gentlewomen of Indostan," says an amusing old author, "have the flaps or nether part of the ears bored when they are young, which they daily stretch and make wider, by things kept in for that purpose, until it at last becomes large enough to hold a ring as big as a little saucer, made for its sides to rest in the flesh; besides which, round about their ears they make other holes for pendants, that when they please they might wear rings in them also. The Brasilians, on the authority of Mr Southey, insert gourds in the slits of their ears, and increase them in size, until the fist can be put through, and the ears reach the shoulders. The practice of wearing many rings in the ear was common among the natives of Virginia, among the Brasilians, and many nations. The custom of perforating the lobe of the ear, and wearing ear-rings, is extremely ancient, and was condemned by many older moralists, who affirmed that it would have been nothing to wear vain ornaments about the neck and hair, but that it was most absurd and monstrous to "let them into their bodies." We cannot pursue this subject further; but may observe, that we do not think that the beauty of the human form, such as we behold it in the most lovely of the female sex, can be enhanced by the dangling of any jewel from the ear; but, as our learned authority quaintly observes, "the conceit worked very strong in their head who first introduced this fashion."* Almost every person has heard of the practice of the women of many countries, who draw out and enlarge the bosom of their children as soon as they become developed; a custom which prevailed among the Mexican women, and is still practised by the Hindoos, who, while they carry their children on their back, afford them milk by throwing their bosom over the shoulder. It appears, too, that this was once a custom among the Irish; for Meubsel observes, that "the Irish-women at this day (1653) would give suck to their babes behind their backs, without taking them in their arms;" and adds, "that their breasts were fit to be made money-bags for East or West Indian merchants, being more than half a yard long." The Portuguese of the present day are said to be remarkable for the large size of their bosoms; while the Spanish women, on the contrary, take pains to compress them, and prevent their luxuriant growth. The hands have been, in like manner, made notoriously the subjects of similar fantastic interferences. The ladies of Portugal were formerly ambitious to display long and narrow hands; wherefore the hands of children were, in early years, tightly bandaged, to prevent their increase in breadth. The Hindoos, Chinese, and Esquimaux, are remarkable for their small hands; the sabres of the Hindoos brought into England have the handles too small for the European hand. Among the ancient Spanish women, large hips were deemed desirable; to procure which, they compressed, with cloth bands, the neighbouring superior and inferior parts of the body. In China, from the very earliest period, small feet have been considered so essential to the beauty of personal appearance, that the custom of bandaging the feet of infants to retard their growth prevails among all classes. If a mother, says a traveller, were to break this custom, she would incur the note of infamy, and be punished. But while we are gratifying our curiosity, and smile at these fantastical customs adopted by other nations, we must not forget that we have ourselves, even in these enlightened times, given way to customs as absurd, and as injurious to the healthy condition of the human body. It is not more than ten or fifteen years since the London dandy, then known as the "Bond Street lounger," assumed invariably a fashionable stoop, lifting up the shoulders, and turning down the neck, till the chin nearly met the chest; and, as if to convey a satire on her own subjects, this despotic genius of fashion immediately afterwards reversed the order of her decrees; and then the same loungers were seen with their bodies erect as ramrods, and their chests stuffed prominently out, as if they were desirous of emulating the breasts of women. We are all too well acquainted with the false notion adopted by ladies, who fancy that a preternaturally small waist contributes to the beauty and gracefulness of their figure; to acquire which, the pernicious habit of tight lacing was introduced, which has given rise to curvatures of the backbone, and deformities of the chest, which are too hideous to contemplate any where, excepting in the cases of a surgical museum. Another abominable practice is, or very recently has been general in this country, that of binding tightly the tender limbs and delicate body of the child just born; another most obvious means of producing deformity in after life. How far the changes of form and feature which we have now enumerated, by transmission from parent to child, may have become permanent, remains to be considered; but, in the meantime, it may be laid down as an axiom, that if we wish to give the body a graceful form, we should encourage its natural and healthy developement, and allow all its muscles full freedom of action.

VARIETIES OF MANKIND.

Notwithstanding the differences of stature, complexion, and general habits exhibited by different nations, the whole human race, multiplied and dispersed as it is through all parts of the world, constitute but one species; the apparent varieties of which, occasioned by the influence of climate and other external circumstances, pass so insensibly, and by so many shades, into one another, that it is impossible to separate them by any definite boundary. But, notwithstanding this, philosophers have attempted to establish certain varieties of mankind, as if, indeed, there had been original and specific differences between those races of men which appear somewhat different in appearance from one another. It generally happens in science, that if one man start into a new path, and announce the discovery of facts before unknown, the majority of those who succeed him content themselves with reiterating his statements, and founding on them the inferences they wish to establish. Hence the learned Malte Brun, the ingenious Lawrence, and all who have written on the history of man, follow, with little or no variation, the classification proposed by the celebrated Blumenbach, who reduces the human race to five varieties; the Caucasian, the Mongolian, the Ethiopian, the American, and the Malay. But the truth is, that this and all other divisions are perfectly arbitrary, and we doubt much whether they should be received. The differences so established depend principally on the various configurations of the skull; but the truth is, that there is almost as much difference between the skull of an Irishman and that of a Scotchman, as there is between the skull of a Circassian and that of Mongolian; nay, not only in the same country, and among the same inhabitants, but even in the same families, the most remarkable differences, in the form of the head and the features of the face, are observable; yet we do not dream of classifying them into any definite order of varieties. Indeed it is very questionable, notwithstanding the greatness of his authority, how far the accounts given by Blumenbach, of the different skulls of nations, should be admitted; his observations were, for the most part, founded on individual skulls, which can never be relied on as representing correctly those of the bulk of any nation. We hold, therefore, that excepting as a matter of fancy, it is not right to speak of the varieties of mankind at all; for, instead of reducing them to five, we may make fifty or a hundred, in fact as many as our ingenuity or pleasure may choose to suggest.* The method most agreeable to nature, perhaps, would be to describe the organisation of man only in reference to the latitude or climate in which he lives, proceeding from the equator to the poles; but owing to the free communication between nations, and the continual intermarriages that occur, every step we proceed is beset with difficulty. If we wished a specimen of the form of a Scotchman, we should not rest contented with taking an individual who happened to have been born in Scotland, even from Scotch parents; but we should inquire how far his lineage had been exposed to corruption, or gradation of form, by intermarriage with the natives of other countries; yet it is sufficient for many, esteeming themselves observers of nature, to place as specimens on the shelves of museums, skulls labelled Chinese, German, Hindoo, simply because these skulls happened to be picked up in those countries, or belonged, perhaps, to individuals whose genealogy could never be ascertained. We know well, that, owing to the effects of climate, and many causes, some of which have been already referred to, the inhabitants of different parts of the globe present us with varieties of stature, feature, shape of head, proportion of limbs, &c.; but it would be indeed highly absurd for any person to pretend to establish distinctions of permanent varieties, by referring only to the differences observable in the form of the head, which is a part only of the human system, the *whole* of which should be brought into evidence. Here, therefore, we shall deviate from the arrangement usually adopted, and notice only some of those nations or tribes of people whose *general* physiognomy and habits seem to establish for them a prominent position in the History of Man.

ALBINOS.

In Asia, Africa, America, and even in Europe, we occasionally meet with a very remarkable variety of complexion, which is exhibited by those persons denominated white people, or Albinos. The skin of these individuals is remarkably white; the hair, which in the European Albino is flowing, is of a soft silky texture, and likewise of a yellowish white, or cream colour; their eyes appear at first of a rose colour, but, on examining the pupil in the light, are discovered to be decidedly red; the iris, too, or that delicate fringe which surrounds the pupil of the eye, has a constant tremulous motion. During our stay in Otaheite (says Captain Cook), we saw about five or six persons, whose skins were of a dead white, like the nose of a white horse, with white hair, beard, eyebrows, and eyelashes, red tender eyes, a short sight, and scurfy skins, covered with a kind of white down." Mr Bankes and Dr Solander thus describe an individual seen on the same island:—"His skin was of a dead white, without the least appearance of what is called complexion, though some parts of his body were, in a small degree, less white than others; his hair, eyebrows, and beard, were as white as his skin; his eyes appeared as if they were bloodshot, and he appeared to be very short sighted." Here we may observe, that nature, ever provident in her designs, has, in constructing the eye, placed, on a particular coat within it, a dark colouring matter, for the purpose of absorbing those rays of light, the intensity of which would otherwise injure the nerve of vision. It is, we may add, this matter which gives the eye its peculiar colour; in some instances it is black, in others brown, and, according to its different shades, gives rise to blue, grey, hazel, dark, or black eyes. Furthermore, we may observe, that there is generally a sympathy between the nature of this colouring matter and the hair, whence people with light hair have often blue or greyish eyes, while those with black hair have generally dark or black eyes. The same principle is also observable in animals, among whom variety in the colour of the skin and hair is accompanied by variety in the colour of the eyes; which may be observed in dogs, cats, rabbits, and other variously spotted or coloured animals. Accordingly, it is the want of this colouring matter in the eye of the Albino which gives it the rose or red colour, and, at the same time, renders it painfully sensible to light. Hence a traveller, describing them, informs us that "they see not well in the sun, poring in the clearest day, their eyes being weak, and running with water if the sun shines towards them; so that, in the day time, they care not to go abroad, unless it be a cloudy dark day. Besides, they are a weak people in comparison to the other, and not very fit for hunting and other laborious exercises, nor do they delight in any such; but, notwithstanding their being thus sluggish and dull in the day time, yet, when moonshiny nights come, they are all life and activity, running about in the woods, and skipping about like wild bucks, running as fast by moonlight, even in the gloom and shade of the woods, as the other Indians do by day." Another traveller says, "They have this distinguishing peculiarity, that they cannot endure the light of the broad day. While the sun is up, they cannot look steadily at any object, and, during all that time, they contract their eyelids so, as apparently to exclude vision. But, in return, they are gifted with the faculty of seeing every object in the dark. By the Hindoos they are looked upon with horror, and their bodies, like those of persons labouring under skin diseases, are cast upon a dunghill, or left to be eaten by wild beasts."

In Africa, among the black races, Albino negroes are frequently born; they are looked upon as great curiosities, and are often collected by the black kings, and kept as objects of wonder and ornament. One of the kings of Ashantee is said to have collected nearly a hundred white negroes. Buffon has given a minute description of a white negress, born in the island of Dominica, of parents who were natives of Africa. She was not quite five feet high, but well proportioned. Another is described by Dr Winterbottom, who informs us, "that she had all the negro features, with woolly hair of a dirty white colour, and a skin equalling in whiteness that of a European, without any thing disagreeable in its appearance or texture. Her eyes were between a red and white hazel, and not much affected by light."

Albinos have been said to appear most frequently among dark people, and in hot countries; but they may occur among all races of men, and in every latitude of the globe. This peculiarity is not, we may add, restricted to mankind, but often found among the inferior animals, especially in the horse, cow, cat, mice, rats, and moles.

PYEBALD OR PARTY-COLOURED BLACK AND WHITE PEOPLE.

Nature presents us with so many varieties of production, both in the vegetable and animal world, that our incredulity is often excited, merely because the related fact happens not to be in accordance with our own individual experience. This disposition to scepticism should not be encouraged; the duty which in such cases devolves upon us being simply to weigh well the evidence on which the narration has been founded. It is certain that instances have occurred of people having been born pyebald; that is, the surface of the body has been found marked by blotches distinctly defined, and not running into one another—exactly as is observed in pyebald horses, which are very common in this country. In these instances, the prevailing contrast is between black and white. Thus, in the Zoological Magazine, we read that a girl was born in Somersetshire, with the hair of her head of two remarkable distinct colours; after she had grown up, the hair on the left side was that of a jet black—that on the right side of a carroty red. In Southwark, a few years ago, a person was born with the right side of the body white, and the left side black; another was born with the lower half of the body white, and the upper black. Instances have certainly occurred of negro women, who have been married to Europeans, giving birth to twins, the one completely white, the other completely black. It is impossible for any effort of human ingenuity to explain these irregularities; but certainly they are not more wonderful than numerous other monstrosities that have been recorded, and still occasionally appear.

THE PROPORTIONS OF THE HUMAN BODY AND STRENGTH OF MAN.

The beauty of the human form depends very much on the proportions which the head, trunk, and limbs

* See Bulwer, whose amusing book on this subject has the following droll title:—"Anthropometamorphosis—Man Transformed—or the Artificial Changeling Historically Presented in the mad and cruell Gallantry, foolish Bravery, ridiculous Beauty, filthy Fineries, and loathsome Loveliness, of most Nations fashioning and altering their Bodies from the Mould intended by Nature." A. D. 1653.

* M. Virey divides the human race into two species; Desmoulins into *seven*; Bory St Vincent into *fifteen*. Such divisions, and other subdivisions, are very amusing; but little better than a romance.

bear to each other; and artists therefore, have taken great pains to determine these, which they have in general done by measuring those celebrated ancient statues that have been esteemed the wonders of their art. But as many of these statues are colossal or diminutive in size, and, more especially, as every variety is observable in the height and proportions of men, no standard so taken can be universally applicable; indeed, no definite rule of beauty can be established, for it must depend entirely on the model we may choose to prefer. Hence our varieties of taste are interminable. The Greek statues are considered very beautiful, and are those generally chosen by artists; but if we go into nature, and behold man as he actually exists in all climates, what infinite varieties of form and proportion shall we find, and these, too, compatible with remarkable bodily vigour! It is probable that all these differences were originally owing to the influence of external circumstances, more especially to artificial habit, which more or less prevail among all nations.

The ancient Germans were remarkably tall and well-proportioned. The ancient Britons were likewise strong well-proportioned men, capable of undergoing great fatigue and exertion. The Romans were notoriously a fine race of people, until their intermingling with the inferior Asiatic races, and their habits of luxury and effeminacy, vitiated their forms and reduced their strength. Many of the American, and also African tribes, that have not yielded to those sophisticated habits which are engendered by a high degree of civilisation, present us with admirable models of symmetry; they have been poetically, but not less truly, described as the "naked Apollos of the woods." The healthy developement of the human body must depend much on the nature of the food by which it is nourished; wherefore those tribes that subsist on a scanty and inferior diet have their growth checked, and become ill proportioned and enfeebled. The natives of New Holland are small in stature, with long and slender limbs, which may be attributed entirely to this cause, for we are informed that their food is always of the least nutritious kind, and very scarce; indeed, the scarcity is often aggravated to all the horrors of actual famine, under which they are reduced to the appearance of spectres, and not unfrequently perish. The stature and proportions of the negro have often been compared with those of the European, by which it has been shown, that the trunk of the negro is more slender, particularly about the loins, the arm and forearm longer in proportion to the height of the body, and the calf higher up on the leg. While the savages of New Holland have their legs so extremely long, the Mongolians and Americans have their legs and thighs too short in proportion to the rest of the body. Such differences in the stature and proportions of the body necessarily occasion considerable differences in strength; for, as we have observed, it is not on the height of the body, but on the just proportions of all its parts, that physical power is dependent. The art of training men to run races, fight, lift heavy weights, &c., is founded entirely on the principle of supplying the body with just sufficient solid and nutritious aliment to support it, and to enable it to undergo additional exertion.

It has been often supposed that man in a savage state possesses a superior degree of bodily strength; but this does not appear to be the fact. A French philosopher, M. Peron, made numerous experiments on this subject, which he communicated to the French Institute; and these have been regarded as perfectly satisfactory. He took twelve natives of Van Dieman's Land, seventeen of New Holland, fifty-six of the Island of Timor, seventeen Frenchmen, and fourteen Englishmen, and, by the aid of an instrument, which indicated by a dial-plate the force of the individuals who experimented, he determined the strength of the arms and loins. The Englishmen proved the strongest; then came the Frenchmen; after them the natives of Timor; then those of New Holland; and, lastly, those of Van Dieman's Land: hence it was fairly concluded that civilization, always excepting its abuse in the luxuries to which it often gives rise, does not impair bodily strength. Desanguilier states, that, by means of a certain harness which he has contrived, and by which every part of the body was proportionally loaded, a person was enabled to support, in the erect posture, a weight of not less than 2000lbs. Besides the nature of the climate and the quality of the food, habits of exertion have a great influence on the developement of muscular power; hence gymnastic schools were instituted by the ancients, who encouraged their children to persevere in using athletic exercises. The South Sea Islanders, by practice, are enabled to swim about in the strongest surf, which would instantly destroy a boat or vessel. Men accustomed to running will outstrip the speed of horses. The royal messengers of Ispahan, who are trained to running, go thirty-six leagues in fourteen hours. And we are assured by travellers, that Hottentots outstrip lions in the chase, and that those savages who live by hunting outrun and catch deer and other fleet animals. In some efforts of muscular exertion there is a peculiar knack; thus in the Highland games it is observed, that the man who will throw the bar farthest often fails with the hammer, or with instruments of equal weight, but of a different shape. So, too, a porter will carry a greater weight than a sailor; but the sailor will haul a rope or drag a weight with much more ease than the porter. Both in ancient and modern times, individuals have exhibited themselves who displayed the most extraordinary feats of strength. The power of an individual named Echeberg, a German, and the strength of another named Topham, attracted the attention of many men of science, who bear testimony to the very wonderful actions they achieved. Erkeberg, by the strength of his hand, doubled a thick piece of iron, and, taking another bar of the same hard metal, he twisted it into a corkscrew shape. Topham rolled up in his hand a pewter plate, and lifted the enormous weight of eight hundred pounds. The French philosopher to whom we have referred, Desanguilier, has, from his observations, concluded the strength of very weak men to be equal to 125lbs., that of very strong men 400lbs. The effects of exertion in increasing the size and the power of muscles may be observed by noticing the arm of the blacksmith, and also the arms and chests of prize-fighters. We observe, too, that dancers have the calves of the legs fully and well developed, while waggoners, who are accustomed to walk without duly raising the arch of the foot, have those muscles very small and weak. Athletic exercises are at present very fashionable in this country, and the use of poles or clubs is now common in almost all schools; but it is not to be forgotten, that all inordinate muscular exercise is prejudicial to health, and tends to shorten the duration of life. When great exertion is made, the action of the heart and blood-vessels becomes increased; and when this is often repeated, they become impaired. Hence blacksmiths are particularly liable to diseases of the heart: besides, when, from very great and repeated exertion, the muscles are drawn out into the highest possible state of tension, the fibres that compose them are brought into the condition of overdrawn wires, which will give way on the slightest occasion. When one [illegible] tic men, who has devoted his whole [illegible] ance of feats of strength, is thrown upon a sick-bed, his whole frame becomes speedily unstrung, and reduced to a state of the most miserable debility. Prize-fighters wrestlers, men who practise violent gymnastic [illegible]ses continually, seldom or never arrive at old age; they concentrate, and, as it were, bring into a focus the whole vigour of their constitution; they are, for a time, all-powerful and triumphant, but their victory is short-lived, their pre-eminence not enviable; they too soon find that they have exhausted the fountains of their strength, and must sink to rise no more. Exercise, moderate and healthy, and also gymnastic amusements, are not only proper, but essential to good health; but let them not be carried to excess—let not the bow be too far bent, lest it become irrecoverably broken.

THE INHABITANTS OF ASIA.

When we consider that Asia was the cradle of the human race, it is natural, in taking a general survey of the globe, to fix our attention on this region, which, although no longer illumined by the arts which once shed over it a glory, still retains, even amidst its ruins, sufficient vestiges of the past to excite our interest and animate our contemplations. Owing to the peculiar aspect of this country, we here find every variety of climate; spring, summer, autumn, winter, seem here to have chosen regions for their perpetual abode, and may be found co-existing beneath the same sky in the same territory. It is no wonder, then, that such varieties of character should here be impressed on the yielding and susceptible frame of man; that he in one district exhibits all the energies of the hardy, bold, and fearless mountaineer or warrior; and that he in another betrays all the effeminacy and weakness incident to excess of languor and luxury.

CIRCASSIANS AND GEORGIANS.

Proceeding on the principle of selection, we may perhaps with impunity begin with describing those people who are considered to exhibit the finest models of the human form, and whose surpassing beauty has become proverbial throughout Europe; we allude to those particular races living on the great chain and at the foot of the Caucasus—the former the Circassians, the latter the Georgians. Blumenbach is inclined to believe they represent what was the primitive form of man; but this, of course, is a mere fancy, founded only on the fact, that the human race was created in this region, and that here the human form seems to exist in its highest state of perfection. The Circassian men, especially in the higher classes, are mostly of a tall stature; their form is thin, but Herculean in structure; they are slender about the loins, have small feet, and uncommon strength in their arms. The women are distinguished by a white skin, regular features, and dark brown or black hair, which some travellers describe to be intermixed with red, constituting, perhaps, what we term an auburn colour. It is the fashion among them to compress the waist by means of straps in early infancy, considering, like the Turks, that a very small waist adds to the grace or elegance of the form. Painting the face is considered to denote a want of chastity, therefore never practised; but the girls are allowed to dye their nails. At the foot of the Caucasus live the Georgians, who, like the Circassians, are considered to be the most beautiful women in the world; indeed, one traveller assures us that they are more beautiful than the Circassians, but the complexion is not so fair. Chardin, describing them in the French language, says—"The Georgian race is the most beautiful in the East, I may say, in the world. I have not observed an ugly face in the country, neither among the one nor the other sex; they are all angelic. Nature has spread graces over the most part of the women we find no where else. I hold it impossible to see without loving them; we can neither paint more charming countenances, nor more beautiful forms, than they possess." But while nature has thus gifted them with pre-eminence of personal beauty, she has left them, like the Turkish women, in a state of intellectual and moral degradation, inasmuch as they are deplorably ignorant, and possess no mental activity; they have no idea of commerce, but indulge in that species of traffic from which human nature recoils, viz. the sale of their own children—sometimes sold to gratify the animal passions of the purchaser, and sometimes to be converted into slaves.

THE TARTARS.

The Tartars, who occupy immense regions in Asia, present considerable variety in their persons, as well as in their manners and customs. They are distinguished by large and wrinkled foreheads, very short noses, and eyes deep sunk in the head. Their cheek-bones are high, and the lower part of their face very narrow; their chin is long and prominent, and their upper jaw falls in; their teeth are long, and distinct from each other; their eyebrows thick, and cover a part of their eyes; their skin tawny; their hair black; and their bodies of middle stature, neither strong nor robust. We have mentioned the length of the teeth, a part of physiognomy seldom noticed, yet in some nations possessing characteristic differences: thus the teeth of the Egyptians are found very thick, and the crowns of them obtusely cone-shaped; the incisors or front cutting teeth of the Greenlanders are short and flat, more resembling grinders than cutting teeth; the same, too, has been observed in the teeth of the Esquimaux. Among the Tartar race, the Calmucks are notorious for their remarkable ugliness. Their faces are so flat, that their eyes, which are very small, are situated five or six inches asunder; their noses are so low, that, instead of nostrils, two holes are often only to be seen; their knees bend outwards, and their legs inward. The little Tartars, or those of Norway, are not so ugly as these Calmucks; they, however, have small eyes, and large flat faces, with a short and sunk nose, and tawny complexion. The Tartars are a wandering people, very fierce and warlike, and renowned for their invincible courage and striking conquests.

THE INHABITANTS OF EUROPE.

Europe, when compared with Asia, Africa, or America, appears to occupy only a small space on the surface of the globe, and all the features which it presents are as it were softened down into a gentler or milder character. Its mountains, even the loftiest of them, are diminutive when compared with the Andes, or the Himalaya; its lakes, even the most extensive, are insignificant when contrasted with those we meet with in America; its vallies, if lovely, are only of small extent; and all its productions, inanimate as well as animate, appear less endowed with rich and valuable qualities. Its mines do not abound with precious minerals; its trees, such as are indigenous, do not put forth luxuriant blossoms, nor droop beneath loads of fragrant and delicious fruits; its animals, too, such as exclusively belong to it, do not amount to more than a very few species, which are not of the most useful kind: yet, notwithstanding all this, the enterprise and the diligence of man has rendered it perhaps the richest and most enviable region of the world. All the grasses, herbs, and trees that we most prize, have been transplanted from foreign climes—the peach from Persia; the orange from China; the potato from America. The most esteemed animals, too, the useful horse, the tractable ox, the faithful dog, have been transported from abroad. Industry and care have toiled, and not in vain; for now the once poor and barren fields afford rich and abundant harvests; cities, adorned with palaces, and boasting of all the conveniences and luxuries that can contribute to the wants and happiness of man, now flourish. Their inhabitants have explored the burning deserts of Africa, and the forests of America; they have gone forth as settlers to people the most distant continents, carrying along with them the knowledge to rescue the slave from the chains of his oppressor, and the poor savage from the superstitions and ignorance by which he was enthralled. Such is the omnipotence of the human mind, that it has thus raised a comparatively small and ungifted territory into the most important region of the world.

Europe fell, there can be no doubt, to the lot of JAPHET and his posterity; and it is clearly proved that his son GOMER gave birth and name to the GOMERIANS: whence were derived numerous European nations. The Gomerians were also called the GOMÆREI and GOMERITÆ; after which they obtained the name of CIMMERIANS, which was contracted into CIMBRI—a name which prevailed not only through Germany, but through Gaul. Nor is this all; for not only did the Gauls derive their name from GOMERITÆ, but it is said that the Celts also were originally called Cimbri: and this, too, explains to us their origin. These descendants of Japhet peopled Europe gradually, spreading themselves by degrees through the adjoining or the nearest countries. Thus they peopled Italy before France, and France before England. Malte Brun remarks, that there are still ten distinct races of men observable in Europe; but we apprehend that these races run so much into each other, that it is impossible to recognise any real distinction between them. Thus the Goths avowedly resemble the Swedes; the Swedes the Germans; and, in like manner, we may trace a gradation, as it were, passing insensibly through the Goths, Swedes, Germans, Swiss, French, Irish, Scotch, English; indeed, through all the nations of Europe, the deviations from the original family likeness having been occasioned by the difference of climate, and other external causes, which exert an analogous influence on the human frame in every latitude of the globe. Compare the stinted form of the Laplander with the hardy frame of the German or the Scotch Highlander. The difference is very striking; but we should no more doubt their being descendants from the same stock, than we should doubt the identity of the same plants, which, transported into a barren soil and cold climate, refuse to put forth the same luxuriance as they exhibited in a more congenial region.

THE GREENLANDER.

The Greenlander, Laplander, and Esquimaux, may either of them be instanced as examples of the character presented by the human form in those dreary and desolate regions, where winter, arrayed in all her sternest horrors, seems to hold an eternal reign. There, in those snowy solitudes which appear fit only to be disturbed by the prowling of the arctic bear, does man exist, shrunk and withered in aspect, like the lichens that cling to the barren rocks by which he is surrounded. Here his frame, as we have elsewere observed, appears of diminished size; his stature seldom exceeds the height of five feet, and has an appearance of imbecility; his face is broad and flat; his eyes, nose, and mouth very small, and the under lip somewhat thicker than the upper. It has been observed, that the expression of the countenance is somewhat similar to what we observe in this country, when the features have been drawn in, and, as it were, shrivelled by intense cold. Their bodies are dark grey, but their face appears more of an olive colour; their skin is unctuous, and unpleasantly cold to the touch; and their hair long, straight, and jet black. The female countenance, without pretension to regular beauty, is said to be often agreeable, having a frank and good-humoured expression. They are extremely nimble with their feet, and dexterous with their hands; they manage their canoes with much skill, and carry burthens which we could not lift. Such is the appearance of man in these cold and forbidding regions. Happier, indeed, is the lot of those born in more temperate climates, which alone are favourable to the full developement of those attributes which alone give man that moral and intellectual importance which raises him so high in the scale of created beings.

SCOTCHMEN AND ENGLISHMEN.

We have observed, that the human race, having migrated from the east, always proceeded to colonize the adjoining or neighbouring countries; thus Cyprus was peopled from the neighbouring country of Asia, Crete and Sicily from Greece, Zeland from Germany, Iceland from Norway. Britain, in like manner, derived its inhabitants from Gaul, the people of which, having crossed the Channel, landed on its southern coast. These Gauls were descended from Gomer, the son of Japhet, and they derived their name from the Gomeritæ. Much dispute has existed concerning the origin of the word BRITAIN. The learned Camden is of opinion that it was derived from the practice which the ancient Britons had of painting their bodies; it having been with them the custom to call whatever was painted or coloured, BRITH: whence was derived the word BRITHA, used by the Saxons, which was then turned into BRITHON, and afterwards into BRITAIN.

The ancient Briton is thus described by an old historian:—"The Britons are taller than the Gauls; their hair is not so yellow, and their bodies are looser built. In proof of their tallness, I must observe, that I saw at Rome some of their young men half a foot taller than the tallest men; their legs are weak, and the rest of their bodies far from well made." These ancient Britons adopted the superstitious rites of the Gauls, from whom they sprung; they lived in tents, they went uncovered, and were habituated to many barbarous customs. The method of staining their bodies which they adopted, was that of burning into their flesh certain marks, and then infusing into the burned part as deep a dye as they could procure. This was done in very early infancy; the colour chosen was obtained from *woad*, which gives a deep blue; and the figures impressed were generally those of various animals. Living in this unprotected state, their island was invaded by the Romans; after which, they were so much harassed by the incursions of the Picts and Scots from the north, that, unable to defend themselves against the fierce and rapacious attacks of their enemies, they invited over the Anglo-Saxons from Germany, to assist them in their emergency. But this turned out to have been very wretched policy; for no sooner had the Picts and Scots been driven back, than the Saxons turned their arms against the miserable Britons, put most of them to the sword, or compelled them to slavery, and then took possession of their country. In the midst of these calamities, many of the unhappy ancient Britons sought refuge in the western parts of the island, now called CORNWALL and WALES, where nature, by mountains and friths, seemed to open for them the path of protection. As every thing foreign was at that time called *Walsh*, those people soon derived the name of the Welsh, which they still retain. Thus did Britain become inhabited by the Anglo-Saxons; but the numerous nations which afterwards broke in upon them, and destroyed their constitution, together with the subsequent division of the kingdom, peopled and governed by so many clans, have been the sources of confusion which perplex the most learned historian and antiquarian. While England thus became peopled, the Scots or Celtic tribe made their appearance in Ireland,* whence they migrated into this country, and the first territory of which they took possession is supposed to have been Argyleshire.

Having thus given a general account of the origin of the inhabitants of this country—a digression which we thought would not be unacceptable to our readers—we may revert to the appearance of the external form and features of man in this climate; and yet this is scarcely necessary, as with these all of us cannot fail to be familiar. Yet are there some essential differences in the physiognomy, which amount almost to national peculiarities; insomuch, indeed, that he who leaves Scotland to make a tour through Ireland or England, will soon recognise the very marked differences observable in the persons of the people by whom he becomes surrounded. The frame of the Scotchman is, generally speaking, hardier, more robust, and stronger than that of the Englishman; we might almost assert that the bony skeleton of the one is made on a larger or stronger scale than that of the other—not that the difference may be appreciable in height, but in the compactness and strength of its construction. The people of Scotland have generally high cheek bones, and their features are strongly marked. The formation of their heads approaches much to what we observe among the Germans; that is, the skull is broad, and somewhat flattened at the back. The features of both the English and Irish herein present a marked difference, not only in the character of the face, but also in that of the head. Their features are less strongly brought out; their cheek bones smaller; the head, too, has a different contour. Among the English, in particular, the head is more flattened at the sides, and less so in its posterior region; however, with them the upper part is commonly well developed. With the Irish the whole frame and countenance has a more active character; their features are more variable—we should rather say, breathe a greater variety of expression—and their head presents a different configuration, having the upper region just above the forehead (especially among the lower classes) much depressed, and being narrower in breadth than either the English or Scotch. While the whole skeleton of the English seems more slender than that of the Scotch, the difference as in other nations is the most perceptible about the hands and feet. It is certainly the custom in Scotland to put children to walk at a much earlier period than they do in England, which, we have no doubt, brings out into a stronger developement the muscles of the ancle and foot. Among the lower classes, the practice of going barefooted also gives a coarse character to the feet; for it may be observed, that all those nations which pride themselves on having small and delicate feet, are careful to protect them from exposure. The Chinese, and especially the Circassians, always have their feet covered; the former wear, when going out, boots of silk, satin, or cotton, and, when at home, loose shoes or slippers made of silk stuff; the latter are especially careful in using a covering for their feet, to which is generally added, when they go abroad, wooden clogs.

THE INHABITANTS OF AFRICA.

Africa, unhappily by its very name, suggests to our mind many very painful associations, such as are inseparably connected with the recollection of those abominable atrocities which have been systematically committed for the purpose of enslaving and oppressing many of its defenceless natives, and such as are also necessarily excited by the memory of those enterprising and amiable men who sacrificed their lives in vainly endeavouring to explore its sandy deserts, for the purpose of carrying the light of Christian truth into the habitations of those uninstructed and unfortunate beings who live amidst the gloom of its impenetrable forests.

Africa, ranking next in respect to its size to Asia and America, was undoubtedly peopled originally by the descendants of the impious Ham; and while these constitute what may be called the native inhabitants, there are, besides, numerous races met with, which migrated from Arabia, and other Asiatic countries. Here we find Moors, Turks, Arabs, Jews, and various tribes, existing in a state of society that is involved in all the darkness which must ever attend on the want of Christian civilization. We have not space to enter into a consideration of the condition of ancient Africa; here we shall speak only of the African negro, the slavery to which he has been subjected, and the improvement of which his moral and intellectual nature is susceptible.

THE AFRICAN NEGRO—NEGRO SLAVERY.

Not only have the African negroes been forced to submit to all the cruelties and degradations of political oppression, but even men of science, whose minds no prejudices should darken, have endeavoured to represent them as beings of an inferior order—a connecting link between man and the lower class of animals. But, indeed, no idea can be more false, certainly no prejudice more abominable, than this; for although his skin may be black, the heart that beats within his bosom still heaves and groans and bleeds under affliction, and is sensibly alive to every act of kindness and humanity. With the external form and appearance of the African negro, with his dark complexion, depressed forehead, woolly hair, flat nose, thick lips, we are all acquainted, but we must not thence conclude that his soul cannot be illumined by one ray of Christian charity, and that he is a being proscribed beyond the limits of all possible civilization. Such a conclusion would not only be uncharitable, but false; for all travellers have agreed, that, notwithstanding the disadvantages under which they have laboured, notwithstanding the cruel despotism under which they have writhed, they often manifest some of the kindliest feelings which can do honour to humanity. If, indeed, we for a moment ask ourselves wherefore they cannot be put on an equality with other civilized nations, we shall be sorely puzzled; for surely we do not recognise inherent disability in their depressed foreheads; for if so, how many of our own fellow countrymen would be disqualified for freedom, and fit only to wear the chains of slavery! Again: we surely cannot discover any cause for their perpetual degradation in the circumstance of their forearms being a little longer in proportion to the height of their bodies than our own, or in that of the calves of their legs being half an inch higher up; such reasons as these we should never dream of entertaining; therefore we are driven to the inevitable conclusion, that, although, like the inhabitants of other countries, they may always retain certain characteristic peculiarities, yet they must be as capable of being civilized as the barbarous Anglo-Saxons from whom we ourselves derived our origin. African negroes, under all the disparaging circumstances by which their progress has been retarded, have been known to make considerable intellectual advancement; thus they have been known in America to make sufficient money by their musical exertions to purchase their freedom. A negro named Hannibal, a colonel in the Russian artillery, and another named Lislet, on account of their meteorological observations, were elected corresponding members of the French Academy. A negress at Yverdun is celebrated by Blumenbach for having made considerable progress and acquired great dexterity in a particular practical department of medicine. A. W. Arno, an African from the coast of Guinea, in the year 1734, took his degree as a doctor of medicine at the Wurtemberg university. John Capitein, who was bought by a slave-dealer when only eight years old, studied theology, and published several sermons and poems. Lastly, Ignatius Sancho and Gustavus Vasa distinguished themselves as literary characters in this country. Accordingly, the physical organization of the African negro by no means offers any insurmountable obstacles to his intellectual improvement—not that we would pretend to define the exact height to which he might attain, for we know that the intellectual qualities of all nations of Europe differ extremely, and that there is even among them a scale of gradation which it might seem invidious to describe. In the whole History of Man, there is no chapter so humiliating, none, certainly, more appalling, than that which records the infamous and blood-stained atrocities that have arisen from the slave-trade, which inhuman traffic appears to have been first adopted by the Portuguese, then by the Dutch, then, in the reign of Queen Elizabeth, by the English. Happily we live in an age in which the cause of humanity at length begins to triumph over the tyranny of political interest, for all parties of the state have now agreed that reason, justice, and religion, alike imperiously demand the abolition of negro slavery; and the only doubt or difficulty that remains, respects the mode in which the emancipation of the present slaves should be effected most judiciously for their happiness, and for the peace and security of those who have been their proprietors. Into this perplexing subject of discussion it would not become us to enter; but we despair not of a time when the interior of the vast continent of Africa will be fully explored, and when the poor African will be able to sit down by his domestic fireside, surrounded by as many comforts as those that cheer the hearth of the Scottish cottager.

THE INHABITANTS OF AMERICA.

America, which is perhaps one of the finest countries of the world, when first discovered was found to be only thinly inhabited by a few scattered tribes, who dwelt by the sides of the majestic rivers or magnificent lakes, or, like other uncivilized people, led a solitary and savage life amidst the intricate paths of its extensive forests. We are all aware how its different regions became populated by emigration from other countries; but with these settlers we shall not interfere, as it is the original natives of America alone who here claim our attention and interest. It is presumed, as we already explained, that this continent was peopled by migrations from the north-east part of Asia—a fact borne out by the circumstance, that when America was discovered, no natives were found to be acquainted by tradition with the most remarkable events narrated in the Mosaic history; in addition to which, the American language appears to have been founded on the Asiatic.

* Ritson's Annals of the Caledonians, Picts, and Scots

The natives of America possess a large and robust frame, and a well-proportioned figure; their complexion is of a bronze, or reddish copper hue, as if it were rusty coloured, not unlike cinnamon or tannin; their hair is black, long, coarse, and shining, but not thick set on the head; their beard is thin, and grows in tufts; their forehead low, and their eyes lengthened out, and their outer angles turned up towards the temples; their eyebrows are high; their cheekbones prominent; the nose a little flattened, but well marked; the lips extended; and their teeth closely set and pointed. In their mouth there is an expression of sweetness, which forms a striking contrast with the gloomy, harsh, and even stern character of their countenance. Their head is of a square shape, and their face is broad, without being flat, and tapers towards the chin. They have a high chest, massy thighs, and arched legs; their foot is large, and their whole body squat and thick set. The stature and complexion of the native Americans vary considerably in different parts of this continent; but, on the whole, they bear, in their physical and moral character, so strong a resemblance to each other, that there can be little doubt that they derived their origin from the same stock.

JEWS.

Notwithstanding that the Jews have suffered the most ruthless persecution, and that their blood has stained almost every altar in Christendom, they yet remain, though scattered far and wide amidst all nations, a distinct race, and afford, perhaps, the best example that can be adduced of the transmission of a very singular physiognomy through successive ages, from one generation to another. The head of the Jew is considered to be extremely well formed; indeed, the Jewish skull is observed to approach very nearly to the Caucasian model, which, as we have it explained, is the most perfect yet known. Although the Jews existing in every climate present us with varieties of complexion, they are naturally fair; and, though born beneath the glare of an African sun, their children possess the same fairness. According to West, the late celebrated painter, and President of the Royal Academy of London, the peculiarity of their physiognomy consists principally in the nose, the bridge of which is curved, or crooked, giving them much the resemblance of Lascars; but, besides this, there is obviously a peculiar expression breathing over the whole countenance, which does not admit of being easily described. The Jewish women have always been considered beautiful; hence poets and novelists frequently introduce into their fictions the Jewess, arrayed in all the most glowing charms of female loveliness.

GIPSIES.

Very analogous to the Jews are the Gipsies, a vagrant, though distinct, race of people, who, deriving their origin either from Egypt or Wallachia,* overspread most of the countries of Europe. They led an Arab-like, wandering, desultory life; carrying with them tents, and such utensils as they required, they secluded themselves in the recesses of forests, until, having exhausted their ill-gotten booty, they again went forth on their errands of depredation. It is a curious fact, that the inhabitants of many of the towns in Italy and Spain, subdued by their own ignorant fears, regarded them with superstitious wonder, and seldom or never ventured to recover their stolen property. Among the gipsies, both women and men were generally tall; their complexion was swarthy; their features prominent and sharp; but the expression of the whole face can only be conveyed by the pencil or brush of the painter. It had a character of its own, which was, and still remains, characteristic of a distinct race; and this (as in the instance of the Jews) has been occasioned by their keeping themselves, as much as possible, apart from the rest of mankind, marrying only individuals belonging to their own tribes, and preserving in every country the customs and the habits peculiar to themselves.

We have now shown, on distinct evidence, that the transmission of particular forms and likenesses, however they may have orginated, may take place in such a degree, and to such an extent, as to impress, with specific differences, families, and whole races of men; and applying these and the preceding facts to the inhabitants of the many nations to whom we have referred, we may legitimately conclude, that the differences we have described arose gradually from the operation of external circumstances, and were rendered permanent by transmission from one generation to another.

THE TRANSMISSION OF NATIONAL VARIETIES OF THE HUMAN FORM.

Having now considered the very remarkable differences which the human form presents in various regions of the globe, having alluded, in a general manner, to the effects of climate, and other external causes, and having explained, too, the methods which have been adopted for the purpose of altering the original shape or character of many of its features, let us proceed to consider how far peculiarities so induced may be transmitted from generation to generation. How happens it that the Circassian mothers give birth to forms as fair and lovely as their own? that the negro woman gives birth to a child with a low brow, flat nose, thick lips, and all the other negro characteristics? Assuredly it would appear that the stream of human blood, through whatever channel it may flow, carries along with it qualities derived from its original source; so that hereby nation is preserved distinct from nation, and one race of men from another We are all aware that certain temperaments of constitution, certain dispositions, and certain diseases, are hereditary in particular families; and such evils no education or efforts of art can eradicate. Occasionally, too, we remark, that a certain character of physical frame, such as the height of stature, the form of the head and chest, the resemblance of features, &c., prevails through all the members of one family, derived either from father or mother.

* Muratori insists that they come from Wallachia, and denies the popular notion that they were originally natives of Egypt, deprived of their settlements by one of the kings of Hungary.

The life of man does not extend long enough for him to observe the progress of these changes which can only be effected in the course of successive generations; therefore, on this subject we can only reason from analogy, or from what may be observed to take place among inferior animals. If we instance the dog, it may be observed that we do not find greyhounds, terriers, spaniels, pointers, existing in a state of nature; these which we may term different races of dogs, result from the artificial intermixture of particular breeds; they are all descended originally from the same stock, but, in the course of successive generations, have severally acquired forms, habits, and dispositions of the most opposite description. Again, in almost every county we observe similar deviations among cattle; thus the red oxen of Devonshire appear of a very different race to the white-faced oxen of Herefordshire; the hornless breed naturalized from Poland presents an equally striking contrast with the brown oxen of Yorkshire; then, let any one or all of these be compared with the straight black heifer which browses on our Scottish hills, and we shall at once perceive what varieties may, by artificial causes, be permanently established among animals of the same species. Horses vary no less remarkably, which cannot fail to be observed when we compare the breed of the racer with that of the clumsy and bony draught-horse of Lincolnshire, and when we contrast these in their turn with the Scotch Galloway or Shetland pony. It is perfectly evident that the differences here exhibited between individual animals belonging to the same species are by no means greater than the differences exhibited by the human race in different parts of the world; and we may, therefore, reasoning from analogy, conclude, that, if such differences as these could in these animals be induced by external causes acting upon them, so likewise might differences as remarkable in the human frame arise from analogous causes, operating, doubtless, with not less power upon it.*

The hereditary transmission of certain peculiarities of structure has been attested on indisputable authority, and many singular facts, in illustration, have been recorded. But the truth is, that although certain variations of existing features and limbs may be presented, such as the nose of one race being more flattened than that of another, or the legs of one more elongated than that of another, no change can ever take place which can transform one species of animals into another. The barrier seems to be this—the impossibility, through all changes, of adding any additional faculty or organ of sense to the animal. The sense of smell may be improved in the dog, as it is in the American Indian; the sense of hearing may be also brought, in an animal already possessing that sense, to a higher state of perfection, as it is likewise in many savages; but all the art of man cannot develope either a new sense or a new function in any class of animals. It is this which separates, by an everlasting and insurmountable barrier, the highest class of apes from the lowest and most miserable class of savages. The former may be taught every kind of trick but never can they acquire the gift of speech, because the organisation in their windpipes exhibits a defect which must prevent their ever attaining this faculty. It appears that the greatest variety, or the most remarkable deviation from any original animal organization that has yet been propagated, amounts to a supernumerary toe on the hind and forefeet; but it is observed, that there is a continual effort on the part of nature to recur, after any such digression, to the original type. On this principle may perhaps be explained the very curious fact, that in picture galleries the likeness of the members of the same family may be seen to pass through various gradations, receding from, then returning to, a very exact resemblance of the original; so that it is presumed, that, in the course of generations, individuals arise who are the exact facsimiles of one or more of their very remote ancestors.

DURATION AND END OF HUMAN LIFE.

The life of man has been likened to a dream—a falling star—a taper-flame—a leaf—a dew-drop—and, most assuredly, that object which is the most fragile in creation, be what it may, it will most resemble; for frail, though mysteriously subtile, is the power which confines the soul within its earthly tabernacle. We have viewed man as the inhabitant of all regions of the world; yet, whatever variety his external form has

* Blumenbach affirms that there is less difference between the skulls of the most dissimilar of mankind than there is between the elongated head of the Neapolitan horse and that of the Hungarian horse. He also states, that the difference which exists between the skull of a negro and that of an European is not more striking than that which may be observed between that of the wild boar and the domesticated swine.

presented to us, the blood is of the same nature which throbs within his heart, the mind is of the same essence which animates his frame. We may now, therefore, narrow our view, and look into our own breasts, for man is complete in every individual man; one regarded as an isolated being is the type of the whole human species. It has been beautifully said by Wordsworth—

> "Our birth is but a sleep and a forgetting;
> The soul that rises with us, our life's star,
> Hath had elsewhere its setting;
> And cometh from afar.
> Not in entire forgetfulness,
> And not in utter nakedness,
> But trailing clouds of glory do we come
> From God, who is our home—
> Heaven lies about us in our infancy."

But the joyous smiles of infancy, and the reckless pastimes of boyhood, must soon be exchanged for the gravity and sedate habits which are summoned into existence by the anxieties and cares of advancing life. That the path we have to tread is beset with thorns, and overgrown with weeds, there is no doubt; but still even the most wretched consider that life is preferable to death—existence to non-existence. It has, therefore, been a matter of care to ascertain those causes which are most conducive to human longevity; and these are reducible to a narrow compass, comprising their dependence almost entirely on the climate in which we live, and on the habits to which we have recourse. In the savage state, life is shorter than it is in the civilized state. The savages in Africa and America seldom live beyond forty years; but, during that period, they are not subject to so many diseases as man is afflicted with in civilized society. Those who attain the greatest longevity are generally the inhabitants of temperate climates, and amongst them very notable instances have occurred. Lewis Cornaro, a Venetian nobleman, having recovered from a severe illness in his thirty-sixth year, enjoyed good health, living on twelve ounces of solid food and thirteen of liquid, until he reached the hundredth year of his age. Thomas Parre, a peasant of Shropshire, died in 1635, at the great age of 152 years and 9 months; and it appeared, from the inspection of his body after death, that he might have lived several years longer, had not a plethoric state of his lungs been induced by his exchanging the coarse fare and pure air of his country for the luxurious diet and dense atmosphere of the palace in London. The Countess of Desmond, in Ireland, lived to her 145th year; and numerous instances of longevity, equally surprising, might be adduced. It is observed, that such cases are principally supplied by the country; indeed, living in towns is so unfavourable to life, that the expectation of its duration is there greatly reduced; thus the greatest expectation of life at six years of age for London is only thirty-six years; but it is forty-one for Northampton, and forty-five and a half for Sweden. Some few curious, but well-attested particulars, concerning the duration of life, may be here enumerated:—1. Dr Fothergill states, that he has not found a single instance of a person who has lived to be eighty, who had not descended from long-lived ancestors. Dr Franklin, who died in his eighty-fourth year, was descended from long-lived parents—his father died at eighty-nine, and his mother at eighty-seven. 2. More persons who have married live to be very old than persons who have remained single. "I have only," says the same author, "met with one person beyond eighty years of age who was never married." 3. More women live to be old than men; but more men live to be *very* old than women. Indeed, there appears to be a provision in nature for the mutual accommodation of the sexes; for, at those periods of life when women are the weakest and most subjected to disease, men are stronger than at any other period of their lives; then, when men, by old age, become weakened, women again have the superiority of strength. 4. It is observed that the number of births exceeds, in town and country, the number of deaths, but the proportion varies in different districts, according to a variation of political and moral causes. 5. A numerical proportion of births always exists between the sexes; but more males are born than females, which appears to be a provision of nature for maintaining a due equality between the number of the sexes; for the life of man, independent of destructive wars, is more exposed to accidental causes inducing death, than that of women. Sadler has pointed out a curious fact, which seems established by the tables he has published, viz. that if a man marry a woman younger than himself, the number of boys in their family will exceed the number of girls; but if the man be younger than his wife, then, according to the disparity between their respective ages, the number of girls will equal or predominate over the number of boys. 6. Of all newborn infants, one out of four dies the first year; two-fifths only attain the sixth year; and, before the twenty-second year, nearly one-half the generation is consigned to the grave. Attained, however, to the age of maturity, one out of every thirty or forty individuals dies annually. Such are the general facts which appear to have been established concerning the duration of human life; but it is not to be forgotten that its extension and accompanying happiness must be materially modified by the habits which each individual in his own sphere is led to adopt. An ingenious medical author, Mr Thackrah, has explained the influence which particular trades have on the health of the persons engaged in them; but we are not aware that any attempt has been hitherto made to ascertain the influence which the pursuit of the several professions must have on the lives of those by whom they are pursued. This deficiency we have endeavoured to supply, by classifying together the ages which have been attained by the most celebrated men engaged in different professions, and deducing the average period to which the life of each has been found to extend. By this it appears, that statesmen have attained the longest duration of life; then come physicians; then divines and theologians; next to them musical composers; next, philosophers and mathematicians; then artists and literary men; and last, poets—those men whose vivid sensibilities and susceptible feelings render them too often little fit to encounter the common-place annoyances and difficulties of the world.

Statesmen and Lawyers.		*Physicians.*		*Divines and Theologians.*		*Musical Composers.*		*Philosophers and Mathematicians.*		*Artists.*		*Miscellaneous Literary Men.*		*Poets.*

FALL OF NATIONS—EXTINCTION OF RACES OF MEN.

History teaches us that all nations, after attaining the meridian of their glory, and after being crowned with laurels of triumph and victory, sink down into decay, even as the oak of the forest has it leaves scattered by the wind, and its trunk uptorn and laid prostrate upon the spot on which it flourished. It is a melancholy fact, and one that cannot fail to teach a stern lesson, "where Athens, Rome, and Sparta stood, there is a moral desert now;" nay, the very site on which mighty cities have flourished are no longer to be discovered. Hence, a noble poet has said—

"I've stood upon Achilles' tomb,
And heard Troy doubted—time will doubt of Rome."

The causes of this decline and fall of nations are sometimes not easily unravelled; but there are at least two which stand forth more prominently than the rest, viz. moral degradation, and the extermination effected by the sword of tyranny. When nations are in their infancy, the struggle to advance forward leaves them no time to indulge in luxury and licentiousness; but when they have attained the summit of their imperial ambition, then their energies relax, their habits become vitiated, and their blood tainted by intermixture with other races that have already succumbed to similar degradation. When the emperors, whose robes of royalty were most of them dyed with blood, reigned over Rome, once "the mistress of the world," these causes were in full operation. "In reality, the citizens of Rome (says a very accomplished author) were a new race, brought together from every quarter of the world, but especially from Asia. So vast a proportion of the ancient citizens had been cut off by the sword, and partly to conceal this waste of population, but much more by way of cheaply requiting services, or of showing favour, or of acquiring influence, slaves had been emancipated in such great multitudes, and invested with all the rights of citizens, that, in a single generation, Rome became almost transmuted into a baser metal, the progeny of those whom the last generation had purchased from the slave merchants. * * * Scarcely a family has come down to our knowledge that could not enumerate a long catalogue of divorces within its own contracted circle. Every man had married a series of wives, every woman a series of husbands. * * * Thus, the very fountain of all the 'household charities' and virtues was polluted; and, after that, we need little wonder at the assassinations, poisonings, and forging of wills, which then laid waste the domestic life of the Romans."[a] We apprehend, that, with all other nations that have been gradually swept from the face of the earth, a similar train of causes have been in operation. Mutato nomine de te fabula narratur—moral depravity, political misrule, and unjust and exterminating wars, are the steps by which all nations descend into their grave. The extinction of particular races of men has no doubt often occurred; thus Malte Brun observes—and the fact is well known, and independent of any authority—that "the Indian tribes, continually forced back by the advancing tide of white population, are fast disappearing from the eastern section of America. It is to be lamented that the cruelty of Europeans completely exterminated that unhappy race of people, the Red Indians of Newfoundland. In 1828, a journey was undertaken by Mr Cormack, for the purpose of making inquiries into the customs and habits, and tracing, if possible, the remnants that might remain, of this race of people; but although they reached the spot which had been their settlement, and discovered the various implements they had used in their domestic life, they could not discover one of the unfortunate Indians left to recount the afflictions which his tribe had endured. One particularly affecting incident is related. The local government, having, among other of its sanguinary decrees, offered a reward for those who would "bring a Red Indian to them," its emissaries carried away by force a Red Indian female, whom they named, from the month in which it happened, "Mary March." Her husband, in defiance of the fire-arms and fixed bayonets of her captors, made a noble attempt to rescue her, and in so doing was cruelly shot. His tribe built a cemetery for him, in which they placed his body. Shortly afterwards, the same government, influenced by interested motives, adopted a different line of policy, and ordered Captain Buchan to repair to the lake by which she was captured, and restore her to her tribe, for the purpose of opening a friendly intercourse with them. Unfortunately, she died in Captain Buchan's vessel at the mouth of the river; but they took her body to the lake, and, not meeting with any of her people, left it exposed on the bank, for them to meet with it. It appears that the Red Indians were at this time encamped on the banks of the river Exploit, and observed Captain Buchan's party passing up the river. They retired from their encampment in consequence; and, some weeks afterwards, by a circuitous route, went to the lake, where, finding her body, they removed it from the place on which it was left, and laid it in the cemetery by the side of her husband. Captain Cormack, finding all their villages untenanted, at length determined to repair to the Red Indian Lake, which was known to be their favourite rendezvous. "After much fatigue," says he, "we approached the lake with hope and caution, but found, to our mortification, that the Red Indians had deserted it for some years past. My party had been so excited, and so sanguine, and so determined to obtain an interview with these people, that, on discovering, from the appearances around us, that the Red Indians—the terror of the Europeans, as well as the other inhabitants of Newfoundland—no longer existed, the spirits of one and all of us were deeply affected. The old mountaineer (who accompanied us) was particularly overcome. There were every where indications that this had long been the central and undisturbed rendesvous of the tribe when they had enjoyed peace and security; but these primitive people had abandoned it, after having been tormented by parties of Europeans during the last eighteen years. We spent several melancholy days wandering on the borders of the east end of the lake, surveying the various remains of what we now contemplated to have been an unoffending and cruelly extirpated people."[a] There is little or no doubt that many other tribes or races of men have in like manner become extinct. Indeed, says Professor Lyell, "few future events are more certain than the extermination of the Indians of North America and the savages of New Holland, in the course of a few centuries, when these tribes will be remembered only in poetry and tradition." But it is not among small tribes or races of men alone that these exterminating causes are in gradual operation; for if we examine the peerage of every European state, we shall discover that families of the highest celebrity and the proudest distinction have died out, and become extinct. The Medicean family, once the glory of Europe—the ancient nobility of France—the Tudors and Plantagenets of England—have all passed away; their names live only recorded in their epitaphs. Yet, in the extinction of particular tribes and classes, we find no evidence that the world is in its dotage, or that the human race is in its decay. Mankind are yet, after the lapse of thousands of years, in the infancy of their moral and intellectual strength; and ages will yet pass away before they exhibit, on a great and universal scale, the latent virtues and possibilities of excellence with which they have been endowed by a beneficent Creator.

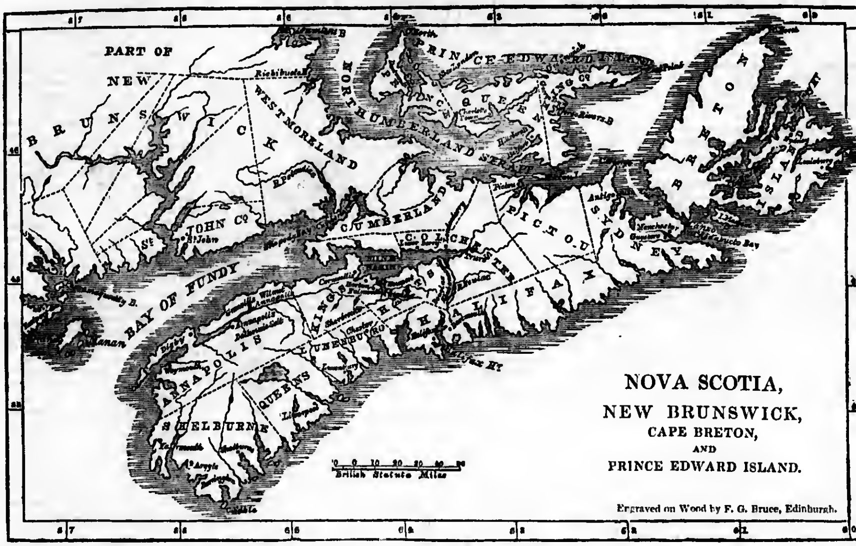
No. 4. PRICE 1½d.

EMIGRATION TO NOVA SCOTIA, NEW BRUNSWICK, PRINCE EDWARD ISLAND, AND THE CANADAS.



NOVA SCOTIA,
NEW BRUNSWICK,
CAPE BRETON,
AND
PRINCE EDWARD ISLAND.

Engraved on Wood by F. G. Bruce, Edinburgh.

WHILE the flood of British emigration has been poured chiefly into Upper Canada, whose unoccupied lands offer a boundless scope for the efforts of a large and industrious population, the American colonial possessions lying nearer home, and situated chiefly about the mouth of the great river St Lawrence, have also received a considerable body of settlers; but the territories for the reception of emigrants in this quarter have never yet been sufficiently made known to the people, and it is now our design to do so in as [illegible] and popular a manner as possible.*

The British possessions on the sea-coast of America (exclusive of Lower Canada and Newfoundland) are Nova Scotia, New Brunswick, Prince Edward Island, and Cape Breton. The first two form part of the mainland; the other two are islands, and, as may be seen on the map, they are all near to each other—Nova Scotia lying furthest to the south, while New Brunswick bounds with the United States. The whole lie within the 43d and 47th degree of north latitude, and from about the 60th to the 68th degree of west longitude. These countries are not so warm or genial as Upper Canada; they are what Scotland is to England, more rugged and mountainous, and more unpromising in their outlines; but they are not less healthful and pleasant, and they possess, what many will esteem a great advantage, the property of being the nearest colonial possessions of Great Britain, with the likelihood of remaining longest under its paternal government.

NOVA SCOTIA.

Nova Scotia is a peninsula of the mainland, with which it is connected by a narrow isthmus. It measures about three hundred miles in length, but is of unequal breadth; altogether, it contains 15,617 square miles, or nearly ten millions of acres. One-third of this superficies is occupied by lakes of various shapes and sizes, spread in all directions on the face of the peninsula. There is no part of the land thirty miles distant from navigable water, and in all parts there are fine streams and rivers. The southern margin of Nova Scotia is broken and rugged, with very prominent features, deep indents, and craggy islands. The features of the northern coast are soft, and free from rocks. It is bounded on the north by part of the Gulf of St Lawrence, which separates it from Prince Edward Island; on the north-east by the Gut of Canso, which separates it from the island of Cape Breton; on the west by the Bay of Fundy, which separates it from New Brunswick; and on the south and south-east by the Atlantic Ocean. Including Cape Breton, which is now a part of the same government, it is divided into ten counties, namely, Halifax, Lunenburg, Cumberland, King's County, Hants, Annapolis, Shelburne, Sydney, Queen's County, and Cape Breton. The chief towns are Halifax, Truro, Londonderry, Onslow, Lunenburg, Amherst, Horton, Cornwallis, Windsor, Newport, Falmouth, Annapolis, Digby, Granville, Shelburne, Barrington, Yarmouth, and Liverpool. Halifax is the capital.

No part of the British American settlements has occasioned so many contests, or has been so often granted and purchased, conquered and ceded, as Nova Scotia. It became known to the French, who called it Acadia, about the year 1603; and, till 1712, it was alternately possessed by the French and English, when the latter became its permanent possessors. It is placed under the management of a governor, legislative council, and assembly of representatives, similar to the other colonies. At an early period of its history, it became distinguished by the name of *Nova Scotia*, which signifies *New Scotland*, an appellation not inappropriate, considering the number of its inhabitants from North Britain. The population of the province, including Cape Breton, amounted, in 1827, to nearly 143,000. About a twentieth part are the descendants of the French colonists; there are about 600 native Indians remaining; about 1500 free negroes; and the remainder of the inhabitants are the descendants of British settlers and refugee loyalists from the United States. The public revenue is raised from imposts on imported goods, and is at present rapidly increasing. Direct taxation is practically unknown.

TOWNS.

Halifax, we have said, is the capital of this flourishing colony. It is a town pleasantly situated on the slope of a rising ground, facing a fine spacious bay or natural harbour in front, on the east, or more accessible side of the peninsula. It resembles some English county towns in appearance, and is gradually improving, there being now a number of good houses of stone and brick. There are churches of the Episcopal or established religion, and chapels for different bodies of dissenters. The town possesses barracks for military, and government buildings. It has likewise several schools, a banking-house, and various institutions of a useful nature; also several newspapers. A description of the place is thus given by Macgregor:—

"Halifax is in length rather more than two miles, and about half a mile in breadth. The streets are wide, and cross each other generally at right angles, but that only next the water is paved; most of the others, however, are macadamised, and, from the ascent and nature of the ground, usually dry; but in summer, the dust, which is often whirled furiously along by the winds, is exceedingly disagreeable. The appearance of Halifax from the water, or from the opposite shore, is prepossessing and peculiar. The front of the town is lined with wharves, alongside of which, vessels of all sizes, and variously rigged, are incessantly discharging or loading their cargoes

* Our chief authority is a Description of Nova Scotia, &c., printed at Halifax, and of which there are probably few copies in this country. We have likewise had recourse to the works of Bouchette and Macgregor, and the letters of Captain Moorsom, besides official documents and pamphlets.

Warehouses rise over the wharves, as well as in different parts of the town; and dwelling-houses and public buildings rear their heads over each other as they stretch along, and up the sides of the hill. The spires of different churches; the building above the town, in which the town clock is fixed; a rotunda-built church; the signal posts on Citadel Hill; the different batteries; the variety of style in which the houses are built, some of which are painted white, some blue, some red, and some built of brick and stone, intermixed with those built of wood; rows of trees showing themselves in different parts of the town; his Majesty's ships moored opposite the dock-yard; the establishments, and tall sheers of the latter; the merchant ships under sail, at anchor, or alongside the wharves; the wooded and rocky scenery of the back ground, with the islands and the small pretty town of Dartmouth on the eastern shore; are all objects which strike most forcibly on the view of a stranger when sailing up the harbour. The number of dwelling-houses is estimated at about 1700, the public buildings 62, and the population, exclusive of the army and navy, about 16,000. The houses are very irregularly built, some being one, some two, some three, and a few four stories high. Handsome stone and brick buildings are built and furnished in the English style; and many of the houses built of wood are really more imposing in their appearance, being large, neatly finished, and painted white, than the best stone houses."

Halifax has the advantage of being the principal naval station of British North America, and this distinction it will, in all likelihood, enjoy as long as our government possesses an acre of land on the western shores of the Atlantic. It is the seat of government, and the principal commercial mart in the province. Its manufactures are still in an imperfect state: they consist of a sugar refinery, distilleries of rum, gin, and whisky, breweries of porter and ale, and factories of soap, candles, leather, flour, and cordage, and a few minor articles. It is now a free warehousing port. According to Bouchette, "In 1828, the exports, exclusive of the coasting trade, amounted to L.246,852, in 553 vessels, containing 61,511 tons, and navigated by 3323 men; and the imports L.733,392, in 544 vessels, containing 62,829 tons, and navigated by 3340 men. There were owned at Halifax, in 1828, seventy-three square-rigged vessels, and seventy-seven schooners; of which, seventy were employed in the West India trade, four between Halifax and Great Britain, six in the trade with foreign Europe, and Brazil, and the remainder in the fishery. The Falmouth, or English packet, regularly arrives with the mails once a month."

The fashions of Halifax are imported from Great Britain, towards which there is a strong feeling of attachment; and, in respect of dress and manners of the inhabitants in general, the place resembles a provincial town in England. The gayest season is winter. The first fall of snow is hailed as the signal for commencing amusements. Sleighs built, decorated, and trimmed in all the different shapes and forms that the fancy of the owner can desire, immediately make their appearance, some driven with four horses, and some with two. So long as the snow continues on the ground, the amusement is prosecuted with great eagerness and spirit. In the winter, also, there are public assemblies for dancing got up by subscription among the inhabitants, or by the officers of the different regiments. Besides these, balls are occasionally given by the governor. From the character of the society, cheapness of living, &c., Halifax is a place well fitted for the settlement of persons on limited but fixed incomes from this country, and is much preferable to the dull and dear country or sea-side towns in the United Kingdom.

Windsor, the county town of Hants, is situated nearly in the centre of the province, on the banks of the river Avon. The town, or village, as we would call it, is small, but well built, and one of the prettiest in America. The scenery in the neighbourhood is remarkably fine, and the undulation of the land such as to present a variety of landscape. The scene is diversified by the serpentine windings of the Avon and St Croix rivers, which are bordered on either side by rich and fertile meadows. The neighbourhood is not devoid of trees and groves. After leaving Windsor, and proceeding on the western road, the traveller is very much struck by the extent and beauty of a view which bursts upon him very unexpectedly on descending the Horton mountains. A sudden turn of the road displays at once the townships of Horton and Cornwallis, with the Basin of Mines, and the Gasperaux and Horton rivers. The great breadth and extent of this view, the still retired verdant vale at the foot of the mountain, the extended townships of Horton, interspersed with groves of wood and cultivated fields, form an assemblage of pleasing and interesting objects in this juvenile country. The post road, after passing through parts of Horton, Cornwallis, Aylesford, and Granville townships, brings the traveller to Annapolis, a place of little importance, but remarkably salubrious and agreeable in summer, by a cool sea breeze. Annapolis is situated near the shore of the Bay of Fundy, and a packet plies weekly to St John's, in New Brunswick, on the opposite coast. Liverpool is a town of some importance on the coast of the Atlantic, and carries on a considerable trade in the fisheries, West India produce, and timber.

Pictou is one of the principal towns in Nova Scotia, and has, perhaps, more connexion with Scotland than any other sea-port. It is situated on a harbour of the same name on the north coast, opposite Prince Edward Island. "Although (says Bouchette) not very regularly laid out, the houses are generally better than in any of the other provincial towns; many of them are built of stone. It contains four places of worship—an Episcopal, a Roman Catholic, and two Presbyterian chapels. There are also the Pictou academy, a grammar school, court-house, and public library. The population cannot now be less than 2500 or 3000 souls. Pictou is a free warehousing port, and its trade is very considerable in lumber (wood in a rough state), coal, and the fishery. Coasters from all parts of the Gulf of St Lawrence resort to Pictou, and its exports have amounted to L.100,000 in a single year. One hundred vessels have been loaded here with timber for Great Britain, and its exports to the West Indies were not less extensive and important. There are still in this district some considerable portions of ungranted land in the interior, on the borders of Sydney county; the aggregate may be about 70,000 acres, upon the whole tolerably good land; and although not immediately adjacent to the sea, yet in no place above twelve or fifteen miles from it, and, in all instances, intersected by rivers." Captain Moorsom describes Pictou as a place agitated by the violence of sectarian strife and feudal prejudice, brought from this country, but he anticipates a great change for the better, in the manners and comforts of the people, in the course of a few years. "The Highland bonnet (says he), which slouches like a nightcap over the eyes of the present generation of settlers, will be worn out, and replaced by the best of native straw, plaited by the hands of their children. A soil generally rich, and a climate available for the modes of Scottish husbandry, are facts less presumptive of its future prosperity, than t[illegible] [illegible]ndance of mineral, which, from the limited ex[illegible] [illegible] has hitherto undergone, we are warran[illegible] [illegible] its substrata contain."

[illegible]TE AND PRODUCTIONS.

It has [illegible] peculiar misfortune of this portion of the North American continent to be represented by almost every writer as a gloomy sterile region, constantly enveloped in fogs which obscure the sun and impede vegetation; whereas nothing can be more distant from the truth. This strange representation can only be accounted for, by supposing that the travellers who have visited it did not extend their investigations farther than the vicinity of Halifax, where the land has a bleak, and by no means agreeable aspect; but this is only a local characteristic, and the interior possesses much fine land, with a pleasant climate. The ground is generally covered with snow from the 25th of December till the 5th of March, which is, we believe, nearly the case with Upper Canada; and during this period of winter, the farmers draw upon sleds their wood and poles from the forest, and carry their produce to market. It is difficult to say when spring commences, as it is rather late and irregular in its approaches. When vegetation commences, it is very rapid, and two or three days make a perceptible change in the verdure of the foliage. The summer heat is moderate and regular, and by no means intense, there seldom being more than a week of very warm weather. The autumns are peculiarly delightful: the temperature in the middle of the day is similar to that of May, moderated by a fine, clear, elastic, healthy air, which gives a great cheerfulness to the spirits. This weather continues sometimes until the 1st of December, the evenings and mornings being, however, a little colder. Altogether, the climate of Nova Scotia is as good as that of Scotland, if not much superior. The air is healthy and pleasant, and never visited by any of those local or epidemical disorders with which other countries are frequently afflicted. Although the winters are intensely cold, they are not so disagreeable as the raw changeable winters of this country, nor nearly so fatal to human life. Besides, if the settlers work during three quarters of the year, they will have ample provision for the remaining quarter, and they therefore look forward to winter as their season of holiday enjoyment and relaxation.

Few parts of the world are so well watered as Nova Scotia. The rivers, brooks, springs, and streams of different kinds, are very numerous. Some of the lakes are extremely beautiful, containing, in general, one or more small islands, which are covered with a luxuriant growth of wood, and vary in every imaginable shape. The land in the neighbourhood of them is often undulated in the most romantic manner. These lakes will, in time, be of great service to the province; in several instances they nearly intersect the peninsula, offering scope for inland navigation. Already, by the efforts of art in connecting a chain of lakes or rivers (like our Caledonian Canal), there is a water communication across the country from Halifax, which will be of immense benefit to commerce and agriculture.

The fruits of this country form a good criterion of the climate. Besides a great variety of wild fruits, gooseberries, strawberries, cherries, and raspberries, there are pears of various kinds, all the varieties of English plums, apples of a very superior quality, quinces, peaches, apricots, and grapes, if assisted by the shelter of wooden fences. The other vegetable products are cucumbers, potatoes, artichokes, cauliflowers, cabbages, beans and peas. Hops are an invariable and sure crop, and may be raised in great abundance. Pumpkins and Indian corn are cultivated to a great extent. Carrots, onions, parsnips, beet, celery, and most other kitchen herbs, are produced with ease. The grains cultivated by the farmers, are summer and winter wheat, rye, buckwheat, barley, and oats. The natural forests are elm; cherry; white, black, yellow, and grey birch; red oak; beech; white and yellow pine; white, red, and black spruce; maples, &c. Some of these woods produce bark for tanning leather; and the sugar maple, as in Canada, affords sap for the manufacture of sugar. Potashes may also be made from the burnt ashes in eradicating the timber. It is mentioned that there are a variety of herbs and roots which are used by the inhabitants instead of tea, but the cheapness of that article of luxury hardly renders it worth while to resort to such expedients.

The mineral products of this part of America are valuable, but none is so much worthy of consideration as coal, which is found at Sydney, in Cape Breton, to a great extent, and of better quality than in any part of America: it is as highly valued as that from Newcastle in England, and will bring as good a price in the market. In the district of Pictou, coal is discovered in many places. There can be no doubt, therefore, that the possession of this fossil will constitute one of the chief superiorities of these provinces over every other. Limestone, freestone, and slate, abound, of the best qualities, and there is plenty fine clay for bricks. Iron ore has also been discovered in several places. The province has no animals of a troublesome nature. There are foxes, mice, squirrels, and rats. Among the feathered tribe there are a number of birds of the same kind as in Britain, including those called game in this country, all of which may be shot and used as food without any restriction. The only troublesome insects are the musquitoes and black flies, which are the torment of America, but they disappear in a great measure as the land becomes cleared and drained. It may be added, that the rivers abound in the finest fish, among which are salmon and trout; and the shores yield large supplies of white and shell fish of different kinds.

CHARACTER OF DISTRICTS.

The soil of a country of such an extent as Nova Scotia must necessarily be various in different parts. If an imaginary line be drawn, dividing the province in the exact centre, from east to west, the north-western half will be found to contain by far the greatest portion of good land. On the side towards the Bay of Fundy, the soil is very rich and free from stone, and contains many thousand acres of dyked marsh land. This is alluvial land, and is made by the deposit of the tides, a sediment composed of the finer particles of soil, brought away by the rivers and torrents in their course to the Bay of Fundy, of putrescent matter, salt, &c. This land called marsh, after it has attained a suitable height, is dyked, and the waters of the rivers excluded. Nothing can exceed its fertility. In many places, particularly about Windsor and Truro, it yields three tons of hay per acre, and has continued to do so without manure for fifty years past. There is a difference in its quality. Where the tide which overflows it is not much enriched, by a long course through the country, it is thin, and of an inferior quality; and on the other hand, that which is partly marsh and partly intervale, that is, composed as well by the sediment of salt water as that of fresh water, it exceeds in luxuriance any land in the province. The quantity of these dykes is very great. At the head of the Bay of Fundy, there are seventy thousand acres in one connected body. There is one marsh in Cumberland containing nearly as much land as Romney marsh in Kent, and of a quality vastly superior. There is something peculiarly agreeable to cattle in the grass growing upon these marshes, which has a wonderful tendency to fatten them. This land is found in great quantities in Cumberland, Macan, Napan, Londonderry, Truro, Onslow, Shubenacadie, Noel, Kennetcook, Newport, Windsor, Falmouth, Horton, Cornwallis, Granville, Annapolis, &c. The next best quality of land is called by a term peculiar to America, *intervale*, an alluvial soil made by the overflowing of large fresh-water brooks and rivers in the spring and autumn. The quantity of intervale is incalculable. It is to be met with in every part of the province, and is frequently found covered with a long natural grass, several feet in length, and is sometimes called wild meadow, and sometimes intervale. The quality varies according to the size of the brook or river by which it is made, but in general it is very fertile and rich. The upland varies so much that it is difficult to give a general description of it, but one tract deserves notice, from its extent and quality. It commences at Cape Blomidon in Cornwallis, and runs in one continuous ridge of high land for upwards of one hundred miles in the direction of Digby, and varies from three to seven miles in breadth. This is a very strong soil, and, with little exception, of a most excellent quality throughout, producing wheat and other grains in abundance. In Horton and Cornwallis the upland has something of a uniform character, and consists of a light sandy loam, which possesses the double advantage of being early and easily worked; and the crops raised upon it are as great as from any land in the country. But almost every other township contains a great variety of soil, varying from the heavy clay land to the lightest gravelly loam, and from the richest to very indifferent. The south-western part of Halifax county is in general stony, and requires a great deal of labour to fit it for cultivation, but the eastern part, about the three rivers that empty into Pictou Basin, the Gulf Shore, Mount Thom, and the whole district of Colchester, contains a large portion of excellent land, consisting of dyke, intervale, and upland. Sydney county consists more of upland and intervale, having but few marshes, and is in general an excellent tract of country. The best proof of the opinion usually entertained of a place, is the state of its population, and this county has greatly increased of late years.

Cumberland, including all its different townships, possesses more valuable land than any county of its size in North America. It is an immense prairie, extending in places as far as the eye can reach, and, being principally under grass, presents in the autumn of the year, with its numerous hay-stacks and extensive herds of cattle, an interesting scene.

Hants and King's counties rank high in value in point of soil, containing larger portions of intervales and marshes of superior quality than either of the remaining four counties. The upland of these two counties also is more invariably good land.

Annapolis county is very extensive, being one hundred miles in length, and containing seven large townships, and exhibiting every variety of soil. The upper half, or the part between the borders of King's county and Digby, may be considered as much the best land. The valley of the Annapolis river is one of the most picturesque and fertile parts of the Province, and retains this character for a distance of nearly forty miles. The land upon both sides is, at some distance from the river, high, and gradually slopes with various undulations, until it descends to the meadows, which, on either side, border the river.

Shelburne, Queen's, and Lunenburg, contain a large portion of stony land, and being principally inhabited by a commercial population, less attention is paid to the improvement of their interior than that of the other counties. In each of these three districts the quantity of inferior land preponderates. The counties which have been thus cursorily alluded to, contain the whole of Nova Scotia Proper.

Of the fertility of the forest land of America, where the soil is naturally good, a stranger can form but little conception. Nature has been enriching it for centuries, and has fitted it to yield the settler good crops for successive years, without the additional aid of manure. Dr Robertson, speaking of America, says, "If allowance be made for the diversity in the degree of heat, the soil of America is naturally as rich and fertile as in any part of the earth. As the country was thinly inhabited, and by a people of little industry, who had none of the domestic animals, which civilized nations rear in such vast numbers, the earth was not exhausted by their consumption. The vegetable productions to which the fertility of the soil gave birth, often remained untouched, and being suffered to corrupt on its surface, returned with increase into its bosom. As trees and plants derive a great part of their nourishment from air and water, if they were not destroyed by man and other animals, they would render to the earth more, perhaps, than they take from it, and feed rather than impoverish it. Thus the unoccupied soil of America may have gone on enriching for many ages. The vast number and enormous size of the trees in America indicate the extraordinary vigour of the soil in its native state. When the Europeans first began to cultivate the New World, they were astonished at the luxuriant power of vegetation in its virgin mould, and in several places the ingenuity of the planter is still employed in diminishing and wasting its superfluous fertility, in order to bring it down to a state fit for profitable culture."

The growth of the wood is generally an index to ascertain the quality of the soil. When it produces black and yellow birch, and rock maple, or either of those trees, intermixed with hemlock and oak, or elm, ash, and beech, the land is in general of superior quality. Its strength is also manifested by the height and bulk of the wood, and the distance between the root and the first limb of the tree; but spruce and fir, or white birch and poplar, are in general marks of an inferior quality. Land bearing beech of a good growth, and pines of large dimensions, forms a medium between the two, and is of an ordinary description. Although the first mentioned wood is a sure proof of good land, the latter is not an infallible mark of its inferiority.

Large fires have at different times raged in the wilderness, either by the neglected embers in the Indian camps, or by other accidents; and where these fires consumed the original growth, a new set of saplings arose, frequently of a different description from the first. This is not peculiar to Nova Scotia, but has been noted in England and Canada. Evelyn, a writer of the seventeenth century, who paid great attention to the rearing of forest trees, mentions, "That when his grandmother's woods were cut down, which consisted entirely of oak, there sprung up again not oaks, but beeches, and when they in their turn felt the axe, there arose spontaneously a third plantation, not of oak or beech, but of birch," which he does not set down as a thing singular, but merely because it happened under his own eye. M'Kenzie, in his North American Tour, speaking of the country bordering on Slave Lake, says, "It is covered with large trees of spruce pine and white birch; when these are destroyed, poplars succeed, though none were before to be seen." It is owing to this circumstance that the settler has been frequently agreeably surprised to find that land, which he supposed to be of an ordinary nature, has turned out upon cultivation to be of a very good quality. The growth, however, of the wood, as first observed, is most commonly a pretty good criterion by which to estimate the soil. The first kind never proves bad, the latter sometimes better than is expected.

Bouchette mentions, that the quantity of land appropriated in Nova Scotia amounts to 3,073,277 acres, and the quantity at the disposal of the crown about 5,000,000. "The first settlers (he continues) naturally selected the best land, both as to quality and situation; the ungranted, or crown lands, therefore, lie in the rear of the townships, and in the interior, and consist of almost all the inferior tracts, with a very considerable quantity of good land. There are extensive tracts of crown lands in the county of Cumberland, extending from one end of it to the other, a great part of which is of very excellent quality. The whole of the county of Shelburne is still undisposed of; some of it is well wooded, and the soil in many places of good quality. There are also considerable tracts of good crown land in the interior of the county of Annapolis, Queen's, and Sydney. In short, considerable tracts of superior and good land are to be found among the crown lands in all parts of the province. The value of land necessarily depends on the fertility of the soil, local situation, and state of improvement. It is impossible, therefore, to form any general estimate of the value of improved land. Wilderness or unimproved land varies from L.5 to L.40 per hundred acres. About L.10 per hundred acres is the full average value of improvable wilderness land.

"The process of bringing the wild land into a state of cultivation, and the operations of agriculture, are much the same in this province as in all other newly-settled countries. The first thing to be done is to clear off the wood. The trees are cut down at about three feet from the ground, lopped and sawn into convenient lengths, and then burnt; where this is not performed by the settler himself, the cost of the whole is about L.4, 10s. per acre, exceeding the rate at which the same service may be procured in the Canadas by about L.1, 10s. per acre. The wood, although green, burns freely, and the whole clearing may be, and generally is, performed in one season, from March to September. The land is then prepared, by manual labour, with the hoe, for the seed, and wheat, rye, maize, sown, or potatoes planted; grass seeds are always sown with the grain crops, and after they are taken off, the land remains in grass, producing hay for the food of the cattle in winter, until the stumps of the trees decay, and the plough can be used. The settler is enabled to keep a stock of cattle as soon as he can raise hay off his land, which is generally the third year. The settler carries on the same process on a portion of new land every year, either until his whole farm is cleared, or until, by the decay of the stumps, he is enabled to cultivate again the already-cleared land with the plough, which can generally be done in five or six years. New land yields the most abundant crops, and a farm, consisting of both new and cleared land, is considered more profitable than one entirely cleared. Farms of the former description are called "half-improved farms." Wheat is raised with some difficulty in Nova Scotia; if the seed be well selected, and sown early on good land, properly tilled, it will ripen in all ordinary seasons; it requires great care in its culture, and if that be neglected, it is probable it will not succeed. The average crop on good upland is from sixteen to twenty-five bushels; on intervale and marsh, much more: it has been known to yield forty bushels per acre. The quantity grown in the province is not nearly sufficient for its own consumption, and flour is consequently imported to a considerable extent. The climate is very congenial to rye, oats, and barley; they are raised without difficulty, and yield abundantly. The average crop on good land is oats, 25; barley, 20; and rye, 16 bushels per acre. Maize, or Indian corn, is indigenous in America; it is extensively cultivated in the western districts of this province, and is a most valuable vegetable. It is easily cultivated: the leaves and stalk afford good food for cattle; the grain is the very best that horses and swine can eat; and the meal the best for bread, next to wheat-flour. Indian corn bread, though very little used in this province, is in common use in the New England provinces and New York, indeed all through the United States; the average crop is about twenty-five to thirty bushels per acre.

"Potatoes thrive better in Nova Scotia than in any part of America, and are very much cultivated; the produce is about 200 bushels per acre. Turnips, beans, and buckwheat, are also cultivated very generally, and with success. Few places are regularly divided into fields, but a rotation of crops is generally adopted. On the virgin land, wheat, rye, potatoes, maize, and sometimes turnips, compose the first crop; then grass for a few years. On the breaking up of the grass land, generally oats, then potatoes, then wheat, succeeded by potatoes and wheat, and laid down with clover or timothy grass. Hay is indispensable for the subsistence of cattle in the winter in this province, and the culture of grasses is therefore a primary object with the Nova Scotian farmer, insomuch that the land laid down in grass is scarcely ever broken up until the failure of the grass crop indicates the necessity of renewal and change. New land requires no manure in the first instance, and some soils, marsh, and intervale, have been under crop for several successive years without the aid of manure. Dung is the most common manure used, particularly on upland; lime has come but partially and lately into use. Gypsum, of which such quantities are exported to the United States for manure, is not at all used for that purpose in this province; the alluvial deposit of the tide and rivers is, where it can be had, considered the best manure, and used as such."

FARMING OCCUPATIONS.

It is related by our authorities, that, until recent times, the operations of the husbandman were conducted in a rude style, little resembling the fine system of culture prevailing in the mother country. Great improvements in this respect have been effected, partly through the attention of the late governor, the Earl of Dalhousie, and by the establishment of boards of agriculture. The change produced by these societies is more visible in the improved breeds of cattle, in the variety and quality of seeds, and in the attention paid to manure, than in the different branches of work performed upon a farm. Ploughing is still (or was very lately) badly executed, and there is great room for conducting the cultivation of the fields in a better style. The rotation of crops is very simple. Potatoes, grain, and clover, constitute the usual routine; sometimes commencing with grain, but oftener with potatoes, of which two hundred bushels will be produced on an acre of good land. Turnips have not entered largely into the agriculture of the country, and they are not easily preserved during winter. Great quantities of oats, wheat, buckwheat, barley, and rye, are produced. Flax is seldom raised for sale, but the country is favourable to its production, and its culture is rapidly increasing.

The hay of the country consists of a variety of grasses. The intervales, when in their natural state, produce a grass vulgarly called blue joint, which is very luxuriant, but affords a coarse and inferior food. The dykes produce clover, or timothy mixed with clover. Sometimes they bear flat grass, which is a plant strongly partaking of a saline nature. A proportion of this flat grass land is very valuable to a farmer, as the crop may be gathered after all his other hay is secured, and receives but little injury from the rain. Working oxen sometimes prefer the hay made of it to clover, and it is always an agreeable change of diet for them. The undyked marshes produce a coarse salt grass, which is covered at high tides by the sea water without injury. Young cattle are fed upon this in winter, and continue in very good condition. This grass is also valuable for the manure made of it, which is of a much superior quality to that produced by cattle fed upon clover. White and red clover, timothy and brown top, are the grasses usually raised upon upland. The farms in the old townships consist generally of dyke and upland. The former is set apart for hay, with a small portion for grain. The latter is divided into two parts, one of which contains a small piece of ground for tillage, and the rest is a large pasture, in which the whole of the stock, cows, horses, sheep, pigs, and young cattle, feed at large during the summer. In the autumn, so soon as the hay is gathered, the stock is removed to the dykes to depasture upon the after-grass. The properties of this grass are so peculiar, that horses or horned cattle, however low in condition, become completely fattened in the course of six weeks.

This system among others is now undergoing an alteration. The proportion of tillage land is becoming greater, and the pastures consequently somewhat improved. The farmer is hereby enabled to raise potatoes or other vegetable products sufficient for stall feeding, and the markets are not so much glutted by grass-fed beef in the autumn as heretofore, but regularly supplied at different periods according to the demand. The quantity of manure is also proportionally increased, and the soil thereby rendered more rich and productive. The period of sowing differs according to the season and soil; but in general, oats and wheat are sown in April; Indian corn is planted according to local circumstances, at any time between the 10th of May and the 10th or 12th of June. Barley and buckwheat are sown about the 1st of June, and turnips about the 10th of July. Mowing commences about the 25th of July. Reaping begins in August, and is finished in September.

Dung is the only manure which has been used in Nova Scotia until within these two or three years. But since the establishment of agricultural societies, lime has been applied with much success, and composting has become a general practice. In most districts bordering on the Bay of Fundy, marsh mud (of which the dykes are composed) is applied as a superficial dressing for grass lands, and as a manure for grain crops. The effects of this application are very great, often producing two or three courses of wheat in succession, and afterwards a strong growth of grass for several years. In Hants, King's, and Annapolis counties, there are very extensive orchards of excellent fruit trees, and a very great quantity of apples of superior quality, and cider is annually exported to New Brunswick, Newfoundland, and the West Indies. Cumberland and Annapolis counties are remarkable for the great amount of butter and cheese which they export every season.

The routine of farming operations is thus pleasingly described by Captain Moorsom:—"As soon as the ground is clear from snow, the farmer is busily employed in piling his summer fuel, securing his sleds and other winter apparatus about the house, clearing his drains, and setting up his fences. These fences are either walls of loose stones, or rough trunks, or poles placed in a variety of ways; in winter they are frequently thrown down in order to allow a free track for the passage of sleds over the snow, and always require to be fixed afresh in spring. Much labour and expense is thus annually incurred beyond that which is called for in clipping an English hedge; but the readiness with which poles are procured from the woods, the facility offered of shifting the pole-fence in any desired direction, and, still more, the expense and trouble attendant upon first rearing a hedge where no such thing has been ever planted before, are the reasons which induce the employment of timber fences, even where a farm is at some distance from the forest; hedges, however, are slowly creeping up in the best cultivated districts. Ploughing, sheep-shearing, and seed-time, occupy every moment from the middle of April to the middle of June; and attending to the garden and field crops, and removing the accumulated refuse of winter, bring the farmer to the mowing season before he is nearly ready for it. The scythe comes into play in the middle of July; and in some seasons I have seen the hay left rotting on the ground, for want of time to secure it before the speedy ripening of the grain obliged the husbandman to employ the sickle. The sheaves are commonly brought into the barn or stacked by the middle of September. Digging potatoes, gathering Indian corn, and fall-ploughing, both for winter grain, and as a preparative for the soil against the following spring, occupy the farmer till frost and snow compel him to put on mitts and woollens, and labour with his axe in the woods, in order to provide fuel and fencing-poles, which he brings home as soon as the snow renders 'hauling' easy. Amid such a variety of work there is but little time left for attention to neatness; much, however, might be done which is now neglected. The large quantity of land under cultivation, in proportion to the number of hands employed upon it, is another cause not only of slovenly farming, but of the general inferiority of produce, both in quantity and quality, below the real capabilities of the soil. The lower class of farmers seldom employ additional labour, other than the voluntary aid of his neighbour, for which he gives his own in return. About the Windsor country, the common practice is to hire labour on a farm for a period of six months, for which from fifteen to eighteen pounds currency, besides the man's 'keep,' are given; this is considered less expensive than giving twenty pounds per annum, as the keep of a man during winter is of more value than the labour he would then be required to perform. Part of this payment is generally made in produce. Farms are sometimes rented by the proprietor to the farmer for the half of the returns he raises; but labourers are seldom hired in this way. Upon any press of work, such as hay-making or harvest, a labourer will sometimes, though rarely, get as much as a dollar per day, and his keep. Mowers will sometimes engage for a dollar per acre, but they then find their own provisions; a good mower will get through his acre in the course of the day, by working after sunset. The wages of labourers, compared with the state of the market for agricultural produce, are the greatest drawback that the Nova Scotian farmer experiences; in this way he finds the greater part of his profits absorbed; and hence it is that a large family, instead of being a clog, is a direct source of wealth, so long as its members will combine in operating for the common benefit."

It appears by statistical returns that there are in the province about 10,000 acres under wheat, 22,500 acres under other grain, 22,500 acres under potatoes, and about 164,000 acres under hay; in all about 200,000 acres under crop. In 1828, the province owned 12,952 horses, 110,776 horned cattle, 174,053 sheep, and 71,904 swine. The country is intersected by excellent roads, which are every year improving and extending at the expense of the local government.

The inhabitants of Nova Scotia enjoy the advantage of having articles of foreign luxury, especially tea, at a very low expense. The East India Company annually sends one or two vessels direct from China, which arrive about June; and the cargo is sold to merchants or others free of the heavy duty payable in this country. "Tea (says Captain Moorsom) is more extensively consumed throughout Nova Scotia than any other article of luxury, except spirits. It is used in the poorer cottages at every meal, particularly among those settlers who originally came from New England. In the third year from the first experiment of the China vessels, the sale of the East India Company trebled its original extent. The Company's agent disposes of the consignment by wholesale, with a very moderate charge to meet contingent expenses; and tea, of the best quality, next to gunpowder, may be procured at Halifax, at an average, when mixed, of three shillings sterling per pound."

PURCHASING AND SETTLING ON LANDS.

Lands are now disposed of by government on a uniform plan in all our North American possessions—that is, by public auction or sale, an upset price being specified. The regulations for the disposal of lands are thus given in substance by Bouchette:—"That the Land Commissioner, having notified to the governor the quantity of land proposed to be sold the ensuing year, with the upset prices, the same to be published in the Gazette: that no lot contain more than 1200 acres: that the purchase-money be paid by four instalments, the 1st at the time of sale, and the 2d, 3d, and 4th at intervals of a year: that if instalments be not regularly paid, the deposit-money will be forfeited, and the land again referred to sale: that purchasers under 200 acres, unable to pay the purchase-money by instalments, may be put in possession under a quit-rent, equal to five per cent. upon the whole amount of the purchase money, to be paid annually in advance; upon failure, the lands to be again referred to auction: that the quit-rent be subject to redemption: that the party who shall have paid an instalment towards redeeming his quit-rent, and shall afterwards neglect to pay the accruing quit-rent, be liable to have his land resold so soon as the arrears of quit-rent shall have covered the amount of the instalment: that the names of purchasers failing in the regular payment of their purchases or quit-rents, be made public, and their lands the first to be put up to auction the following year: that no lands be granted but at the current sales in each district, except to poor settlers who may not have been in the colony more than six months preceding the last annual sale, in which case such poor settlers are entitled to purchase the lands at the upset prices fixed for the same at the previous year's sale: that settlers may, at any period within seven years from the date of those regulations, obtain lots of 200 acres, but no more, in unsurveyed districts upon a quit-rent, equal to five per cent. on the estimated value of the land at the time of occupancy, and that such quit-rent may be redeemed before the expiration of that term, upon 'payment of twenty years' purchase of the amount, and afterwards upon payment of any arrear of quit-rent which may be then due, and twenty years' purchase of the annual amount of the rent." No patent or transfer to be granted until the purchase money, or arrears of instalments or quit-rent, shall have been paid: that the purchase money and quit-rents be paid to the commissioner, or his delegate, at the time and place named in the condition of sale."

If settlers possess nothing but their industry, they will be under the necessity of acting for a time as the servants of others. To be enabled to go at once upon a farm, it will be necessary to possess a small stock of money, not only to pay the price of the land, whatever that may be, but to lay in some useful articles of furniture and provisions for a family. The provisions to be taken by an emigrant to his lot, if his family consists of five persons, are as follows:—

Fifty bushels of potatoes -	L.2	10	0
Two barrels flour - -	3	10	0
One barrel rye, Indian, or oatmeal	1	0	0
One barrel mackarel and one barrel herrings - - - -	2	0	0
Half barrel beef - - -	1	15	0
Five gallons molasses - - -	0	12	6
Three gallons rum - -	0	12	0
Three pounds of tea - -	0	15	0
Twelve pounds sugar - -	0	8	0
One milch cow - - -	5	0	0
	L.18	8	8

He will then expend L.10 on the following articles: Two axes (the axes got in this country do not answer for cutting down trees), four hoes, one saw, one or two planes, one adze, twenty or thirty pounds nails, two pots, one kettle, some tea mugs, gridiron, frying-pan, and some earthenware; all which he can advantageously purchase in the colonies.

LOCATIONS.

In a small pamphlet, entitled "The Emigrant's Friend," published at Glasgow, in which are many useful hints, we find the following good advices. "In choosing a property, *location* is generally the first thing looked to. 1st, Its vicinity to a good market town, or a principal road or canal, on both of which latter there are generally stores where you can dispose of your produce. 2d, The state of the bye-roads in its vicinity. Proprietors are assessed to work upon these a certain number of days every year, proportioned to the value of their property, and the better these are, or the more of them completed (for according to the district plans they are generally very numerous, although only one at a time is opened), the less are proprietors assessed, and the more valuable are their properties. I was amused, although sorrowfully so, some years ago, by a letter which was shown to me, from an emigrant to his friend here. He had been lured into the Canadian woods, by having land given to him *for nothing*. Along with his family, he had gone through six years of privations and hardships, which no earthly reward would induce him to go through again. One year they were well nigh starved, owing to the deers having eaten up the little crop of grain which they had sown in their partially cleared field, and to the bears paying a similar compliment to their Indian corn; for except during three months in the winter, they were cut off from all intercourse with their kind: a swamp 'like the Greenock harbour at low water' lying between them and the nearest settlement. Yet he thanked God that their difficulties were fewer now, for they were getting used to the fever and ague, and expected soon to have a wooden causeway completed through the swamp; and they were also able (after six years of toil) to get enough of produce off their farm to feed themselves, and to procure a few of the *luxuries* (knives and forks and spoons, I suppose) which they had been used to in Britain. Mind they were very poor people whilst here; from this you will perceive the importance of the word *luxuries*. The roads, however, he considered a great hardship; his son and he had to work two or three weeks in the year upon them; and he saw no end to this, for though the causeway through the swamp was nearly ready for going upon, 'yet there were twelve roads in the township, *and all these roads to be made*.' Here then is the price, or rather rent, paid by this poor man for his property—six weeks labour annually, which, considering that he kept himself, was equal to L.8, or 52 dollars; the generous bestower for nothing, be it observed, having his adjacent lands increased in value, to the amount of the roads made through them, independent of the advantage of having a neighbourhood commenced in them, and having probably purchased them himself at the rate of one or two shillings for each acre. 3d, The state and vicinity of schools to the intended purchase; as also of places of worship."

SQUATTERS AND BACKWOODSMEN.

"There are three grades of settlers (continues this amusing author), from one of which you will have to choose your neighbours, according to the age of the settlement which you fix upon. 1st, the *squatters*: these men are generally found upon the frontiers, a few miles in advance of other white settlers, and occasionally in all of the large unsettled tracts throughout the populated part of the country. They are usually either disaffected to society, or outcasts from it. They refuse to submit to the law of civilized governments, affect to consider that one man has as good a right to unoccupied lands as another, and *squat* down accordingly, wheresoever they choose, generally choosing, however, to keep a good distance from the more conformable settlers. They are tolerated because they are not very numerous; because they are serviceable, in as far as the first pathways for white men into the woods are made by them; and because they are rather dangerous people to pick a quarrel with. They seldom cut down more wood than what they need for their log-house and fires. A small patch of potatoes, and another of Indian corn, some poultry, and a litter of pigs, which feed and fatten upon the roots and acorns of the surrounding forest, are all that they have to depend upon, except what they obtain through the aid of the rifle; with this, the bears and the deers, which so annoyed our Scotsman, become valuable prizes to them, and it generally enables them to provide themselves with a few of the commodities of the settlements. 2d, The *backwoodsmen*: these are a restless, adventurous class of men; they always are, and require to be, able to do a little of every thing—to build log-huts, hunt and trap game, make sledges, mend shoes, &c., &c.; these are done rudely enough to be sure, but they are always first-rate wood choppers. They use an axe of a shape peculiar to America, which they swing round their heads dexterously, and even gracefully; and which few learn to handle well, unless they commence practising it in boyhood. They generally purchase a lot of wild land, and *improve* it; that is, *clear* from a quarter to a half of it, build a log-house, barn, &c., fence it, and open up one or two of the bye-roads in the vicinity. By this time the country is ready for the third grade, to whom they generally sell out, and again go into the woods. They know little or nothing of the art of farming, as known to good agriculturists; nor could they practise this art to good account if they did know it; very little tillage being necessary for the first crops from wild lands, which, by reason of stumps, &c., require to be cultivated after a manner of their own. The third grade of settlers I call the *capitalists*. They are made up of those who come with money and purchase the fruits of the backwoodsman's labour, and of others who were backwoodsmen, but who now choose to 'settle down,' and enjoy the advantages of their accumulated industry themselves. As the settlement thus increases in population and wealth, mechanics become in demand, and a blacksmith, shoemaker, and house-carpenter, are not long of finding their way to it, and are heartily welcomed; a "jack-of-all-trades" is never wanted. Some favoured spot begins to thicken into a village; which character it becomes fully entitled to on the arrival of a doctor, lawyer, tavern-keeper, and store-keeper, who soon follow the other more important, though less exalted members of society. In a year or two more, a pretty white-painted church, with a tall, light spire, completes the picture, of which you will see many counterparts in the country to which you are going.

"It is in or near one of these that I advise you to abide, if you can so rule it; and even in these you will have to put up with many inconveniences which you did not know in this country, owing to the more perfect division of labour here not requiring you to turn your hand to more than one employment, and enabling you to get other men's handiworks readily and cheaply."

NEW BRUNSWICK.

The province of New Brunswick, lying on the mainland of North America, contiguous to the United States and Lower Canada, consists of an extensive tract comprising nearly 28,000 square miles, the greater part of which is still covered with dense forests; the land, however, is generally fertile, and excellently adapted for the settlement of emigrants. Besides being recommended by a fertility of soil, it possesses innumerable rivers and streams, in all directions, suitable for purposes of trade or manufacture. The climate is salubrious; the natural products numerous and valuable; wild animals are plentiful; and the rivers and lakes abound in fish, while along the coasts, cod, haddock, salmon, and other fish, are yielded in plenty to the enterprising fisherman. The resources of the province are thus inexhaustible, and, according to Macgregor, suitable to the maintenance of at least three millions of inhabitants. As yet, New Brunswick has a small population, and the principal settlements are along the river St John and its lakes. On the northern side of the entrance to this large river from the Bay of Fundy, stands the town of St John, the largest in the province, though not the capital. Fredericton, the metropolis, and seat of goverment of the colony, is situated nearly ninety miles above St John's, on the same river; it is still a village in appearance. The chief buildings are the government house and a college.

The province of New Brunswick presents an extensive line of coast to the Gulf of St Lawrence on the east, while on the north it has part of Lower Canada, which separates it from the River St Lawrence upwards. Its latent capabilities for carrying on trade with the interior are thus very considerable. Miramichi is the chief river after the St John. It falls into the Gulf of St Lawrence, and is navigable for large vessels for about forty miles. Along its banks, here and there are seen the huts and houses of settlers, who have not made great advances in cultivation. The cutting and export of timber form the main trade of the district. About twenty miles up, on the south bank, is seen the village of Chatham, where many of the ships load, and where several of the merchants are settled, who have erected stores and wharves. Four miles farther up is seen the village of Newcastle. The Miramichi river divides into two great branches. "On coming down the south-west branch (says Mr Macgregor) in the autumn of 1820, from where the road from the river St John joins the Miramichi, about eighty miles above Chatham, I was astonished at the unexpected progress made during so short a period in the cultivation of the soil. Near where the road parts off for Fredericton, an American, possessing a full share of the adventurous activity of the citizens of the United States, has established himself. He told me that when he planted himself there, seven years before, he was not worth a shilling. He has now (1829) more than three hundred acres under cultivation, an immense flock of sheep, horses, several yokes of oxen, milch cows, swine, and poultry. He has a large dwelling-house, conveniently furnished, in which he lives with his family and a numerous train of labourers, one or two other houses, a forge, with a powerful trip-hammer worked by water power, fulling-mill, grist-mill, and two saw-mills—all turned by water. Near these, he showed me a building, which he said he erected for the double purpose of a school and chapel, the floor of which was laid, and on which benches were arranged so as to resemble the pit of one of our theatres. He said that all preachers who came in the way were welcome to the use of it. An English parson, a Catholic priest, a Presbyterian minister, or a Methodist preacher, should each, he said, get something to eat at his house, and have the use of the chapel, with equal satisfaction to him. He then showed me his barn, and in one place a heap, containing about ninety bushels of Indian corn, that grew on a spot scarcely an acre, which he pointed out to me. This man could do little more than read and write. His manners were quite unpolished, but not rude; yet he had wonderful readiness of address, and, as far as related to his own pursuits, quick powers of invention and application. He raised large crops, ground his own corn, manufactured the flax he cultivated and the wool of his sheep into coarse cloths; sold the provisions which his farm produced, and rum and British goods to the lumberers; kept a tavern; employed lumberers in the woods, and received also timber in payment for whatever he sold. He made the axes and other tools required by the lumberers at his forge; he ate, gambled, and associated with his own labourers, and with the lumberers, and all others, who made his house a kind of rallying point; he appeared, however, to be a sober man, and a person who had in view an object of gain in every thing he engaged in; he talked much in praise of the rich interior country, and how rapidly it would be settled and cultivated, if possessed by the Americans."

The following is a list of prices compiled from documents sent in to the Commissioners for Emigration from various parts of New Brunswick:—

	£	s.	d.		£	s.	d.
Wheat, per bushel	0	5	0	to	0	10	0*
Maize, per ditto	0	4	6	...	0	5	0
Oats, per ditto	0	1	6	...	0	2	6
Barley, per ditto	0	4	0	...	0	5	0
Potatoes, per cwt.	0	1	3	...	0	3	6
Butter (fresh), per lb.	0	0	9	...	0	1	0
Ditto (salt), per ditto	0	0	8	...	0	0	10
Cheese, per ditto	0	0	4	...	0	0	7
Eggs, per dozen	0	0	7½	...	0	1	0
Ducks, per pair	0	2	0	...	0	3	6
Fowls, per ditto	0	1	6	...	0	2	6
Geese, per ditto	0	3	0	...	0	5	0
Turkeys, per ditto	0	7	6	...	0	10	0
Hay, per ton	1	10	0	...	2	10	0
Straw, per ditto	1	0	0	...	1	5	0
Bread, per 4lb. loaf	0	0	10	...	0	1	0
Beef, per stone	0	3	3	...	0	4	0
Mutton, per ditto	0	2	4	...	0	4	0
Pork, per ditto	0	2	0½	...	0	4	0
Veal, per ditto	0	2	4	...	0	4	8
Flour, per 100 lbs.	0	16	0	...	0	17	0
Salt pork, per barrel	4	15	0	...	5	5	0
Ditto beef, per ditto	3	0	0	...	3	10	0
Malt, per bushel	0	6	2	...	0	6	4
Rye flour, per barrel	1	2	6	...	0	0	0
Indian flour, per ditto	1	2	6	...	0	0	0
Oatmeal, per cwt.	0	16	0	..	0	18	0
Salt cod, per 112 lbs.	0	10	0	...	0	12	0
Ditto mackarel, per barrel	0	17	0	...	1	0	0
Ditto alewives, per ditto	0	10	0	...	0	12	0

* Although some wheat fetched this price in the course of 1831, the price very rarely rises higher than 7s. 6d.

Coals are sold at 30s. per chaldron. House-rent at St John's is from L.5 to L.6 per annum for families occupying one room; and for families occupying two rooms, from L.6 to L.10. Common labourers receive from 3s. to 4s. a-day, finding their own subsistence; but, when employed at the ports in loading vessels, their subsistence is found for them. Mechanics receive from 5s. to 7s. 6d. per day, and superior workmen from 7s. 6d. to 10s.

Upon the foregoing statements it must be observed, that emigrants, especially such of them as are agricultural labourers, should not expect the highest wages named until they have become accustomed to the work of the colony. The mechanics most in demand are those connected with the business of house-building. Shoemakers, tailors, and ship-builders, also find abundant employment.

By order of the Commissioners for Emigration,

T. FREDERICK ELLIOT.

PRINCE EDWARD ISLAND.

This rich and productive island is situated in the Gulf of St Lawrence, betwixt Cape Breton on the east, and New Brunswick on the west, and is separated from Nova Scotia on the south, by a strait of about nine miles in breadth. It measures 140 miles in length, and is 34 at its greatest breadth. The account given by Mr Macgregor of this province is one of the best we have, and as the author, we believe, was a considerable period in the island, his details may be relied on. The following are a few of his observations:—"In coming within view of Prince Edward Island, its aspect is that of a level country, covered to the water's edge with trees, and the outline of its surface scarcely curved with the appearance of hills. On approaching nearer, and sailing round its shores (especially on the north side), the prospect becomes interesting, and presents small villages, cleared farms, red head-lands, bogs, and rivers, which pierce the country; sand-hills covered with grass; a gentle diversity of hill and dale, which the cleared spots open to view, and the undulation of surface occasioned by small lakes or ponds, which from the sea appear like so many vallies.

"On landing, and travelling through the country, its varied, though not highly romantic scenery, and its agricultural and other improvements, attract the attention of all who possess a taste for rural beauties. Owing to the manner in which it is intersected by various branches of the sea, there is no part at a greater distance from the ebbing and flowing of the tide than eight miles. It abounds with streams and springs of the purest water. There are no mountains in the island; a chain of hills intersects the country; and in different parts the lands rise to moderate heights, but in general the surface of the island may be considered as deviating no more than could be wished for the purpose of agriculture. Almost every part affords agreeable prospects and beautiful situations. In summer and autumn, the forests exhibit a rich and splendid foliage, varying from the deep green of the fir, to the lively tints of the birch and maple, and the character of the scenery at these seasons displays a smiling loveliness and teeming fertility. The island is divided into three counties, these again into parishes, and the whole subdivided into sixty-seven townships, containing about 20,000 acres each. The plot of a town, containing about 400 building lots, is reserved in each county. Charlotte Town, the seat of government, is situated on the north bank of Hillsborough river (east side of the island), and its harbour is considered one of the best in the Gulf of St Lawrence. The town stands on ground which rises in gentle heights from the banks of the river, and contains about 350 dwelling-houses, and about 3400 inhabitants.

"The climate of Prince Edward Island, owing to its lying within the Gulf of St Lawrence, partakes, in some measure, of the climate of the neighbouring countries; but the difference is greater than any one who has not lived in the colony would imagine. In Lower Canada, the winter is nearly two months longer, the frosts more severe, and the snows deeper, while the temperature during summer is equally hot. In Nova Scotia, New Brunswick, and Cape Breton, the frosts are equally severe, the transitions from one extreme of temperature to another more sudden, and fogs frequent along those parts that border on the Atlantic and Bay of Fundy. The atmosphere of this island is noted for being free of fogs. A day foggy throughout seldom occurs during a year, and in general not more than four or five that are partially so. As regards the salubrity of the island, it is agreed by all who have lived any time on it, and have compared its climate with that of other countries, that there are few places where health is enjoyed with less interruption.

"Large tracts of the original pine forests have been destroyed by fires, which have raged over the island at different periods. In these places, white birches, spruce-firs, poplars, and wild cherry trees, have sprung up. Poplars of great dimensions are plentiful. Many other trees are met with. Among the wild fruits, raspberries, strawberries, cranberries, (which are very large), blueberries, and whortleberries, are astonishingly abundant. Foxes and hares are numerous. Mosquitoes and sandflies are only annoying during the heat of summer in the neighbourhood of the marshes, and in the woods; where the lands are cleared to any extent, they are seldom troublesome. The varieties of fish that swarm in the harbours and rivers, or around the shores, and that abound on the different fishing banks in the vicinage of the island, are numerous, each abounding in great plenty.

"The excellence of its soil, its climate, and the configuration of the surface, adapt the lands of Prince Edward Island more particularly for agriculture than for any other purpose. All kinds of grain and vegetables raised in England ripen in perfection. Wheat is raised in abundance for the consumption of the inhabitants, and a surplus is exported to Nova Scotia. Both summer and winter rye, and buckwheat, produce weighty crops; but the culture of these grains is scarcely attended to. Barley and oats thrive well, and are, in weight and quality, equal to any met with in the English markets, and superior to what are produced in the United States. Beans of all kinds yield plentiful returns. Peas, when not injured by worms, which is often the case, thrive well; and turnips are sometimes liable to flies and worms. In no country do parsnips, carrots, beets, mangel-wursel, or potatoes, yield more beautiful crops. Cucumbers, salads, cabbages, cauliflowers, asparagus, and, indeed, all culinary vegetables common in England, arrive at perfection. Cherries, plums, damsons, black, red, and white currants, ripen perfectly, and are large and delicious. Flax is raised, of excellent quality, and manufactured by the farmers' wives into linen for domestic use. Hemp will grow, but not to the same perfection as in Upper Canada, or some parts of Nova Scotia and New Brunswick. The principal grasses are timothy, red and white clover, and a kind of soft indigenous upland grass, of which sheep are very fond; also marsh grasses, on which young and dry cattle are fed during the winter months. As a few cold days and wet weather frequently occur in the latter end of April or the first week of May, wheat or oats are seldom sown until the first of the latter month. Barley will ripen if sown before the 20th of June, although it is generally more early. Potatoes are planted about the last of May, or before the middle of June, and often later. Turnip-seed is sown about the middle of July; some prefer sowing it in the first week in August, in which case the leaves are not so liable to injury from worms. Gardening commences early in May, and generally combines the different departments of fruits, flowers, and vegetables. Hay-making begins in the latter end of July, and as the weather is commonly very dry at this time, it is attended with little trouble in curing. Potatoes and turnips are left undug until the middle or end of October; the first are generally ploughed up, except on new land, where the hoe alone is used. Parsnips may remain on the ground during winter, and are finer when dug up in spring than at any other period.

"Milch cows, and such horses and cattle as require most care, are housed in November, but December is the usual month for housing cattle regularly. Sheep thrive better by being left out all winter; but they require to be fed, and it is necessary to have a shelter without a roof, to guard against the cold winds and snow-drift. Black cattle are generally smaller than in England; a good ox will weigh from eight to nine hundred pounds, but the common run will not exceed six or seven hundred. The beef is usually very fine and tender. Sheep thrive remarkably well; but until lately, very little care was observed in improving the breed. Swine seem to thrive here as well as in any country, and the pork brought to Charlotte Town by the farmers is probably equal in general to that met with in the Irish market. Little care is, however, taken of swine. The horses are, with few exceptions, small, but capable of performing long journeys, and enduring great fatigue with much spirit. The greater number of farmers, particularly the Highland Scotch, keep by far too many cattle for the quantity of provender they usually have to feed them with during winter. These people think if they can manage to carry their cattle through the winter, they are doing well; but the consequence is, that their cattle, especially milch cows, are in such lean condition in spring, that they are not in tolerable order till July. Various improvements are taking place by means of cattle shows, and exhibitions of agricultural produce, which have been established. It is also pleasing to observe the improvement in the mode of cultivating the land, which has spread over the colony during the last few years, and which may be attributed principally to the force of example set by a few of the old settlers, chiefly the loyalists and Lowland Scotch, and by an acquisition of industrious and frugal settlers from Yorkshire in England, and from Dumfriesshire and Perthshire in Scotland.

"The principal disadvantage connected with this island, and, in fact, the only one of importance, is the length of the winters, which renders it necessary to have a large store of hay for supporting live stock; and which also, from the abrupt opening of spring and summer, abridges the season for sowing and planting. About a ton of straw for each, taking large and small together, is requisite to winter black cattle properly. The winter season has also many advantages—wood and firing poles are easily brought from the forests, over the smooth slippery roads made by the frosts and snows, and distances are shortened by the bays and rivers being frozen over. The ground is also considered to be fertilized by deep snow and frosts, and there are few farmers who consider the winter an impediment to agriculture, otherwise than the spring opening so suddenly upon them, and the astonishing quickness of vegetation, leaving them only five or six weeks for preparing the soil, and sowing and planting.

"When travelling through the settlements of Prince Edward Island (continues Mr Macgregor), we discover the inhabitants to consist of Englishmen, who, though fewer than any others in numbers, are found from almost every county in England; Scotchmen, who form more than one-half of the population, from the Highlands, Hebrides, and the southern counties; American loyalists; and a few Dutch, Germans, and Swedes. The whole population may be estimated at 35,000. The English settlers, although for some time discontented with their condition, are generally found to thrive, particularly those from Yorkshire; and they are much more attentive to in-door comfort and cleanliness than most other settlers.

"The inhabitants of the colony, particularly the old farmers, are hospitable, kind, and obliging, and, generally speaking, a moral people. Litigation, which the timber business and the credit given by the tavern-keepers and small shopkeepers have produced, and the low price of rum, form the sole causes of immorality, and the most baneful evils connected with the island. The farmers are employed during the winter in attending to their cattle, thrashing out their corn, cutting and hauling home fire-wood for winter use, and a stock of fuel for summer; these occupations, with many other little matters connected with his farm, house, and markets, engage the constant attention of a managing industrious man. The farmers' wives and daughters are generally very industrious, decorous, and correct, and strictly domestic and attentive to household duties. They assist in the labours of the farm during seed-time, hay-making, and harvest, and, during winter, prepare their flax and wool for spinning and knitting, and many of them also weave their home-spun cloth. The different denominations of religion that have places of worship are the Church of England, as established by law the Kirk of Scotland, Scottish Dissenters, Roman Catholics, Methodists, and Baptists. All the members of these professions associate together as neighbours, and frequently attend the places of worship of each other with great good feeling. There is in Charlotte Town a very respectable grammar-school, a school on the Madras system, and schools in most of the settlements for elementary instruction. The Legislative Assembly vote money for the partial support of these schools. The island is governed by a lieutenant-governor, a council, and a House of Assembly of eighteen representatives, elected by the people.

"As to the prospects which this colony may present to persons in the United Kingdom who are desirous of emigrating, not more than 20,000 acres, if so much, are held by the crown. Woodlands in convenient situations may, however, be purchased for from 10s. to L.2 per acre; and leases, in perpetuity, or, what amounts to the same thing, for 999 years, can be obtained for the annual rent of from 1s. to 2s. per acre, and in some situations for less. So that, taking into consideration the advantages of residing in the vicinity of well-disposed society, the opportunity that is afforded of having children instructed in the rudiments of education, of roads communicating between all the settlements, of corn-mills and saw-mills, being almost every where in the neighbourhood, and having the convenience and benefit, by living near the shipping ports, of ready markets for the produce of the land or sea, it may be reasonably concluded, that the terms on which lands are now to be had in this island are much more favourable than those on which they can be had in the United States."

CAPE BRETON.

Cape Breton is a romantic and mountainous island, lying close to Nova Scotia on the east, and only divided from it by a narrow strait, called the Gut of Canso. On the western side is the Gulf of St Lawrence. The island measures upwards of a hundred miles in length, by about sixty in breadth, including the numerous bays which indent the land. The natural productions of this island resemble those of Nova Scotia, though wheat is less generally grown, and oats and potatoes are raised to a considerable extent. There are large tracts of good land in the lower parts, and the expense of clearing it of timber is estimated at L.3 an acre. The minerals of the island are valuable. Cape Breton is politically annexed to Nova Scotia, of which it forms a county. The number of inhabitants is about 30,000, who are of French, Scottish, English, and Irish origin. There are some small towns along different parts of the shores.—Farther information respecting the island will be found in the Parliamentary evidence.

NEWFOUNDLAND.

The island of Newfoundland is seldom made the place of settlement by emigrants, and it therefore requires little or no description here. It is situated on the north-eastern side of the entrance into the Gulf of St Lawrence, and measures about 1000 miles in circumference. It is a wild, rugged country, poorly wooded, and of a rocky and barren soil, unfit, it would appear, for agriculture, but celebrated for its extensive fisheries, which are the chief business of the inhabitants. In 1830, 700 vessels were employed in this lucrative trade, and the amount of the imports was L.640,000. The population are thriving and increasing, and may now amount to 75,000. Its government and laws have hitherto been exceedingly defective. St John's is the chief town, and lies on the east side of the island, being almost on the spot of land nearest to Great Britain of any part of the American continent or islands. The distance betwixt Valentia in Ireland and St John's is computed to be 1656 sea miles, or betwixt eighteen and nineteen hundred ordinary miles; and it has been proposed to have a line of steam-packets to sail to and fro from these places. A company was some time ago formed to establish this exceedingly excellent species of communication with America; but, though promising to be one of the most successful schemes of modern times, it is a matter of astonishment that nothing has been done to bring it into practical use. It was calculated that a steam-vessel fit for crossing the Atlantic with emigrants would consume 360 tons of coal per trip, which could be laid in at Valentia and Nova Scotia at L.1 per ton, or less, and that the wages and other charges on the voyage would be about an equal sum—making per voyage L.1440.

HOW TO TRANSFER YOUR MONEY TO AMERICA.

In carrying money to these provinces, the emigrant ought in the first place to turn it into sovereigns, which will pass in the colonies for from 21s. 6d. to nearly 24s., according to the scarcity of cash. But as there is always danger, and at least inconvenience, in carrying specie either about the person or among luggage, a better plan is to take Bank of England notes, which have also a premium. Persons proceeding to Canada have another fully as advisable plan. If in England, they can pay in their money to the bank of Smith, Payne, and Smiths, Lombard Street, London, and for which they will receive an order on the Montreal Bank. If in Scotland, they can pay in their money to the British Linen Company's bank in Edinburgh, or to any of their country agents, and they will receive a similar order on the same Montreal Bank, and perhaps on a bank at Quebec or York. No sum below L.20, however, will be taken in either case. The exchange, as it is called, being to a considerable extent in favour of this country, a person, by paying in this manner L.100, and seeking for a "letter of credit," which is the same as a "bill at sight"—that is, payable on presentation—will receive from the bank in Canada the sum of L.123, 6s. 6d., less or more, according to the fluctuation of exchange, of the currency of the place. In the event of death or disaster on the passage out, the heirs of the deceased here would, of course, receive the money.

PARLIAMENTARY EVIDENCE ON THE ADVANTAGES OF EMIGRATION.

We have now to bring forward some satisfactory information relative to these provinces, selected from the minutes of evidence before a select committee of the House of Commons, which sat on the subject of emigration, in 1826.

Colonel John Ready called in, and examined.

"You are Lieutenant-Governor of Prince Edward Island?—I am.

Have you had any opportunity since you have held the government of Prince Edward Island of becoming acquainted with the state of the waste lands in that colony?—I have.

What is your opinion with respect to an emigration directed to that colony; could it be maintained upon the terms which are involved in the proposed emigration to Upper Canada?—An emigration to Prince Edward Island might be carried on at considerably less expense, because the transport is shorter; emigrants could be sent out for probably L.2 a-head alone, with the advantage of being placed on their land the day after their arrival. When placed on his land, he would in all probability have a water conveyance for his produce, no part of the island being more than from eight to ten miles from water-carriage.

Where would be the market for the produce raised by the emigrant?—Independent of the island markets, the principal markets are Nova Scotia and Newfoundland; to Newfoundland they send their provisions, live stock and corn to Halifax, and to other parts of Nova Scotia their flour, oats, &c.

Is the quality of the land of Prince Edward Island more suitable for pasturage, or the growth of corn?—More suitable for the growth of corn than any other production.

Could you inform the committee as to the average production per acre of bushels of wheat from land of the best quality in Prince Edward Island?—The average production is considered about twenty bushels of wheat an acre; I have heard of more being grown on well cultivated land. My own opinion is, that twenty is a fair average; but there are persons that have asserted, and who have means of knowing, that it is upwards of twenty.

Is that wheat of good quality, so as to compete wi[illegible] other wheat in the market in that part of the wor[illegible]?—I think it is, though it is not the custom to grow the best quality of wheat.

Have you any estimate of the amount that is exported from Prince Edward Island to Newfoundland in a year?—The trade is carried on in small vessels from the numerous outports, so that I am unable to furnish any thing like a correct estimate; it is considerable.

Is the climate of Prince Edward Island healthy?—It is particularly healthy; the country is very dry, and it is well watered, and all wooded.

In what are the returns made [illegible] the corn that is exported?—They are West India [illegible]oduce, teas, British manufactured goods of all descriptions which they require; they have little direct trade with England; rum and money are what they principally bring from Newfoundland.

Richard John Unlacke, Esq. called in, and examined.

You are one of his Majesty's council, and Attorney-General for the province of Nova Scotia?—I am.

Are you of opinion that an emigration might be conducted to Nova Scotia with the same advantage that has taken place with respect to the province of Upper Canada?—I am of opinion that it may, with greater advantage. I have no doubt but what the province in Nova Scotia would absorb, every year at least, from 1200 to 1500 emigrants, taking them as they run, young and old, and provide ample subsistence for them, so that they should not be in want of any kind of necessary when they were landed on shore. A statement of a transaction that took place in the last year, and the year before, may give, perhaps, some insight with respect to the island of Cape Breton. Sir James Kempt made an allotment of land there; he appointed a land committee to allot the land to the settlers: as soon as it was known in Scotland that there was an allotment of land made in the island of Cape Breton, a number of poor people in the north of Scotland, where the custom-house regulations are not so strictly enforced, found the way to embark in three or four vessels; and there have, in the years 1824 and 1825, upon a moderate calculation, at least 300 settlers come from the north of Scotland, whose passage did not cost them more than fifty shillings, or three pounds, for those people provided for themselves. All that the master of the vessel looks to, is to see that they have a pound of oatmeal for every day, and half that quantity for a child, with, perhaps, about half a pint of molasses, a little butter, and a few eggs, and he provides them with water in the passage, they paying about thirty to thirty-five shillings. Those settlers came out here upon their own expense; there was not a mouthful of provisions or any thing given to them by government. They settled themselves upon the land that Sir James Kempt allotted to them, and I doubt whether there is in Scotland so happy a set of people as these. They have got their log-huts erected. The custom of settlers there is, that they cut down the trees that are just round, and put up a log-hut, and the bark of those trees makes the covering; so that, in point of fact, he is under cover and housed in a few hours. He then cuts down as fast as he can till the ensuing year, so that the wood lies all the winter upon the ground, cut up in ten or fifteen pieces. After burning the masses of wood, he does nothing but just cast his corn in, without plough or harrow, or any thing else, except scratching a little with a thing made like a dung-fork; he makes very little more scratching than a fowl in a dung-heap. A man and a woman will cover in an acre or half an acre in the course of a day, and the crop comes up as fine as any in the world; there is no finer crop raised in the world than the first crop that comes in that way; so that, in the first year, a man with any kind of industry will have, at any rate, his potatoes, perhaps not a full allowance of bread, but he would have a greater allowance if he could go to the mill with it; but the mills are at a great distance, and they are obliged to make what are called querns; in that way they grind their little crop of corn; but in the first year these people are all comfortable. I may make another remark, with respect to the great facility of settling upon the Bras D'Or Lake, which is this: the lands upon each side of it are remarkably good; an arm of the sea nearly divides Cape Breton in two islands, except the peninsula at St Peter's; that peninsula may be cut down, so as to make a navigation through at a very small expense, so as to unite the sea on both sides. The isthmus is not more than 150 yards broad.

You said you had no doubt that any number of emigrants, landing upon the shores of Nova Scotia, would be immediately absorbed?—I think any number of emigrants, distributed judiciously, that is, not all thrown on one spot, but scattered round to the different harbours, from 15,000 to 20,000 voluntary emigrants would be absorbed in the province every year.

For how many years do you imagine that that great annual absorption might take place?—When I first knew it, its population was under 11,000; its population is now upwards of 70,000; and when I speak of Nova Scotia, the committee will remember that I am speaking of New Brunswick also, because I consider New Brunswick as part of Nova Scotia; they are so much alike, that whatever applies to one part, applies to all the province of Nova Scotia; therefore, whatever I say applies to the one as much as to the

Cape B

other. I consider that Nova Scotia and New Brunswick would well provide for a population of 4,000,000 or 5,000,000, taking advantage of the fishery, coupled with the agriculture. In stating the population of Nova Scotia, I have set it much lower than it really is; I think it not short of 100,000; that of New Brunswick I think as great, say 100,000; the last census, about two years ago, made it 75,000.

How do you think that they would be immediately absorbed?—The single men would, of course, immediately hire themselves out to day labour; they would get immediate employment either in the fishery or in the farms of the country, so that all the single men and the children would be at once provided for. The demand for children there is beyond conception. If the father and mother are unable to provide for them, they can always be provided for there, because every farmer will take a child, or two or three children, from five to six or seven years of age, apprentice, as fast as you can give them to them. As the army and navy resort to Halifax, we generally have a very large portion of orphan children thrown upon the poor list; and our mode of disposing of these children is, that at four to five years of age we put them out apprentices to farmers, unless they choose a trade: if they choose a trade, of course they are bound to a trade. The stipulation that is made for those children with the person to whom each child is bound, is, that the first year he is to give that child a sheep, the second year a heifer calf; and as long as that child is under indentures to him, he is bound to preserve and keep that sheep and heifer calf, and all the produce of it, till the child comes of age, and then it becomes a portion for that child to settle with; if a female, in marriage; or if a male, as farming stock; he will generally have a stock of five or ten head of grown-up cattle, and eight or ten sheep, by that means. In fact, we never can supply half the number of children that there is a demand for. We take it month and month, acting as commissioners; and the last month I acted as commissioner, I left demands for upwards of fifty children, that we could not supply, upon the books. I am convinced that the country would, without any sort of pressure, receive at least a population of several thousands every year for these fifty years; and perhaps it would be increasing, because every year the ratio will increase. If they can provide for 20,000 this year, in the course of five years they will be able to provide for twice as many.

What is the site of this colony [or district in Nova Scotia]?—It lies between the Great Shubinacade Lake and the Windsor road. Every year brings out a little addition to that colony: the old settlers can now receive their countrymen and relations that come there without any trouble; there are potatoes and provisions for them. The last time I visited that place, I asked them how they were situated—"Tell our old masters at home that we would not exchange situations with them." The way they became possessed of their stock is this:—They go to a farmer and hire the use of a cow for 20s.; that cow they get in the spring of the year in calf; they keep that cow through the summer, and they keep it the next winter, for the sake of the calf that the cow will have, and then they pay the owner of the cow 20s., and return him his cow in the ensuing spring, in calf, as they got it. They begin with that calf which is in the cow, for their stock; that calf in time becomes a cow; and they hire a sheep and an ox in the same way; the produce of the ox is the use that he is of in harrowing in the corn. But now they have got a stock of their own; they have now got sheep, and cows, and oxen, and they have got horses, and they are living in a great degree of comfort. I state this to show from what an extreme degree of poverty those people can get into a tolerable degree of affluence.

Is that 20s. which you say they pay for the use of the cow, paid in labour or in money?—They agree to pay in money, but they generally pay in labour.

For what purpose are children required by the farmers?—A farmer takes an orphan child, and he uses it exactly as his own; it sleeps in the same bed that his own children do, it eats at the same table, and it is clad in the same dress.

For what purposes are they used?—A girl is brought up to spinning, and milking, and making butter; a boy is brought up to ploughing, and all sorts of agricultural work. In fact, the want of labour is so great that they will take any thing; but a boy of five years old is able to do something for his living, and he soon begins to earn his clothes and his maintenance. The boys are bound out till they are twenty-one; they then have the labour of a man, because he is trained up to the habits of labour. When a native of that country comes to a farmer to hire, he will never stipulate for less than from thirty-five to forty pounds a-year wages; he will sit down at the farmer's table to eat, and, besides that, the farmer must keep his horse for him to ride.

What is the average rate of labour in Nova Scotia?—The general rate of labour for a new comer is about 3s. a-day currency; 4s. 9d. would be the dollar in sterling; but a native of the country will not work under 5s. a-day; in harvest time, 7s. It is to me a matter of serious apprehension, the attack that will be made upon me when I go back to Ireland to take these people out, for I expect to be surrounded with thousands who wish to go. I suppose I have received more than L.200 from different persons to pay passages out.

Henry John Boulton, Solicitor-General of Upper Canada, called in, and examined.

Are you prepared to state in detail in what manner an emigrant from any part of this country would acquire property enough to make a payment of L.4 per annum quit-rent for his land, at the expiration of seven years, and how he would obtain the money for it?—In the first place, if he is tolerably industrious (and I will here say, that the Irish make equally good settlers after a short time, and readily acquire the use of the axe), an American will, in the course of a week, chop down the timber upon an acre of land; it is commonly considered a week's work for an able-bodied labourer to chop the timber off an acre of land; I am not prepared to say how long it would take him to burn it; it could not take him that length of time; but I may say generally, that an able-bodied man can, without over-working himself, clear, fence, and put into crop ten acres of land in the course of a twelve-month.

Having done that on that ten acres of land, what will he be able to raise?—That ten acres of land he can put into wheat, which is a profitable crop; but it is not proper for the first year, because he would require a crop that would come more early into use; he would possibly put in half an acre or an acre of potatoes; he would put in some Indian corn, but that would depend upon the season of the year in which he went upon his land; but if he put the land in wheat, the average crop of wheat, on medium land, depending upon the season, would be from fifteen to thirty bushels an acre; if it is a wet season, and badly put in, with bad husbandry, it might not be over fifteen bushels an acre, but it must be very badly done not to produce fifteen Winchester bushels. I have known as much as fifty bushels to an acre, but very rarely. I cannot name above one or two instances of it; but forty bushels an acre is not very uncommon, though it is not usual; but not being a farmer myself, I cannot speak very positively on the subject; but I have often inquired of farmers, and I should say that about twenty-five bushels an acre, or, to speak within bounds, I may certainly say that twenty bushels an acre, is commonly produced.

Do you mean upon an acre where the stumps of the trees are still standing?—Certainly.

With this corn so acquired, will you describe the process by which he is to replace his clothing and his general means of going on; where does he find a market for his produce?—If emigration was going on, he would find a market from the incoming emigrants, and there is frequently the best market in the most out-of-the-way parts of the country from that circumstance; within two years, I have known wheat selling for 6s. a bushel, that is, about 5s. sterling, back in the woods, when you could buy it for half that sum upon the lake shores, because the incoming emigrants required it, and the great difficulty of getting it there gave it its value when it was there.

Did you ever know the wheat which is sold for 5s. paid for in money?—No, very seldom; that is, by new coming emigrants.

Will you explain the process by which the settler would be enabled to pay his rent in money, as he receives the value of his produce chiefly in goods and barter?—When he had made such improvements upon his land as I presume he would have done, from the general proceedings of emigrants in the country who have no assistance, at the end of seven years he would have seven or eight barrels of flour at least more than he would want for his own use, and with those barrels of flour he would be perfectly certain to get L.4 for them at the neighbouring towns, and a great deal more.

There would be the transport to deduct for those barrels of flour; therefore, can you name any settled market to which the settler could take his produce, and get a fair remuneration in money for it?—The very lowest price that I ever knew a barrel of flour sell at was, I think, 12s. 6d. I have occasionally bought it at that price for the use of my own family, but I should say that 20s. is the average price throughout the country. Now, the expense of the farmer as to transport is not very great; the farmer is the producer; he is not selling his flour with a view to a profit over and above the value of his labour in raising it; but if he can afford to sow it, and raise it, and bring it to market at the price he gets for it in the market—namely, four dollars a barrel—and thereby obtain a fair rate of wages for his year's labour, that is all he ought to expect; it is not to be supposed that he is to buy his grain, and bring it to market, and make a profit upon it; and, therefore, if he can get eight barrels of flour, which he must certainly be a very idle person not to get, over and above the maintenance of his family, he can bring those to any of the neighbouring towns, where he will get 12s. 6d. a barrel for it at least, which will amount to L.4, 10s.

Is that currency or sterling money?—Upper Canada currency, which is in the proportion of ten to nine sterling. The value of a barrel of flour in Upper Canada currency is four dollars, and the dollar is worth 4s. 6d. sterling; a pound currency is 18s. sterling. He will, generally speaking, get 18s. sterling for his flour; but supposing he only got half that, which is a thing very unusual, and a thing which I should think hereafter never will occur again, because there is a market for the flour through Montreal and Quebec to the West Indies, and at present to the home market.

What would be the difference between the cost of transport and the value of the flour?—The cost that the farmer is at in transporting it is almost nothing, because he does it with his own team; and he brings his own bread and cheese in the vehicle he brings his produce in, and he is at no expense at all on the road.

What market are you alluding to in Upper Canada?—To the market in the town of York; but the same applies to any other town in Upper Canada. If a man lives forty miles from York, he puts his flour into his sleigh, with a sufficient quantity of provisions for his own use, and oats and hay for his horses, and he comes to York market, and sells his commodity, and whatever he gets is clear gain; and then he returns home again empty.

Is not the York market a very limited market indeed?—No, it is not a very limited market; it would purchase any quantity of produce, and so would the Niagara market, and so would all the principal towns, because the shopkeeper or merchant would buy up this produce, and send to Montreal for exportation what is not required for home consumption; and I never knew the prices so bad as not to admit of the merchants giving 12s. 6d. for it in the town of York, for the purposes of exportation.

When you particularize eight barrels of flour as the probable amount of surplus produce in seven years, is that the result of any accurate calculation?—No; it is an accidental quantity that I have named, as being sufficient, under any circumstances, to insure the payment of the L.4 annuity.

Do you think you could, by attending to the subject, make some more definite calculation as to the quantity which it might be presumed could be produced upon a property of that sort?—I think I could; but it is impossible for any person in my situation to be so acquainted with the detail of the management of a poor man's estate, as to enter into a calculation of that sort very minutely. I have known countless instances of persons who came there without a shilling in their pockets, and have asked me to give them a meal of victuals, whom I have known in a few years afterwards living very comfortably at their own house, and coming to the town and getting credit for five, or six, or ten pounds' worth of tea and sugar, or whatever they wanted, as readily as I could.

Do you mean at all to assume, that eight barrels would be the surplus of produce at the end of seven years on a hundred acres?—No; I think it is the very minimum. I think it is almost impossible a man should have so little as that. I think a man, at the end of seven years, would unquestionably have thirty acres of land under improvement. I apprehend he would undoubtedly have a pair of horses, with either a waggon or a cart, or some vehicle for carrying about his produce. I apprehend he would likewise have two or three cows, a yoke of oxen, a house to live in, and plenty of wholesome food for himself and family. I have no doubt that any person who is moderately industrious would be in that situation. I have known many persons in Upper Canada, who came there without a farthing, who, in the course of fifteen or twenty years, have become men of considerable property, and filling in that country the dignified situation that the gentlemen I address do here. I have known such persons to become members of the Colonial Legislature, and people of considerable importance in the colony, magistrates, and forming a part of the aristocracy of the country."

Two instances are brought forward of the thriving condition of settlers in New Brunswick. "Mr Nicholas Cunliffe, of Woodstock, commenced clearing his farm in May 1824. The work was done by contract, at the rate of from L.3, 10s. to L.4 per acre. He has now 107 acres of land cleared, excepting the stumps of the trees (74 acres were cleared since May last); and the crop raised from this land, last season, was 900 bushels of good clean wheat, weighing 63 pounds to the bushel, 400 bushels of Indian corn, nearly 100 bushels of potatoes, besides a quantity of beans and garden stuff, of which no particular account was kept. This crop alone will leave a profit of about L.100 over and above the expense of clearing the whole of the land.

"Mr Joseph Bedell commenced clearing his farm at Richmond, in the parish of Woodstock, about four miles from the River St John, in May 1821. Without any other assistance than that of three sons (the eldest of whom is now but sixteen, the next twelve years of age, and the other still younger), he had cleared fifty acres of land, from which he raised, last season, two hundred and forty bushels of wheat, two hundred and fifty bushels of oats, fifty bushels of buckwheat, six hundred bushels of potatoes, one hundred and fifty bushels of turnips, and a small quantity of Indian corn. He has paid L.110 since he went on the farm, is now clear of debt, and owns four cows, one pair of horses, eight head of young cattle, twelve sheep, and eight hundred acres of good land."

VARIOUS INFORMATION ON THE CANADAS.

The following scraps of information, selected from the excellent and popular works, entitled "Statistical Sketches of Upper Canada," by a Backwoodsman, and "The Advantages of Emigration to the Canadas," by Mr Cattermole, will be perused with advantage by intending emigrants:—

"Who then are to go to Canada? In the first place, all who cannot comfortably support themselves by their labour at home; because, let a man be ever so poor in this country, his wages as a labourer will more than support his family; and if he be prudent and sober, he may in a short time save money enough to purchase for himself a farm; and if he has a family, so much the better, as children are the best *stock* a farmer can possess, the labour of a child seven years old being considered worth his maintenance and education, and the wages of a boy of twelve or fourteen years of age being higher than those of a stout and skilful ploughman in most parts of Great Britain, generally from three to four dollars a month, with bed, board, and washing besides. At home they talk of "a poor man with a large family;" but such a phrase in Canada would be a contradiction of terms; for a man here who has a large family must, under ordinary circumstances, soon cease to be a poor man. Mechanics and artizans of almost all descriptions—millwrights, blacksmiths, carpenters, masons, bricklayers, tailors, shoemakers, tanners, millers—and all the ordinary trades that are required in an agricultural and partially shipowning and commercial country, will do well to come to Canada. Of these trades, the blacksmith, tailor, shoemaker, and tanner, are the best. If there were in nature (which is doubtful) such a being as a sober blacksmith, he might make a fortune.

Emigrants would find their account in bringing out small quantities of seeds, particularly those of the rarer grasses, as lucern, trefoil, &c.; for if they did not need such articles themselves, they would find plenty who would buy them at a high price. To these may be added some small parcels of potato oats, and of the large black oat of the south of Ireland, for seed, as that grain, if not renewed, degenerates into something little better than chaff in the course of time.

When a bear runs away with one of your pigs, there is no use in going after him, hallooing, without a gun. When once they have killed a pig, if you do not manage to kill the bear, you will never keep one hog; for they will come back till they have taken the last of them; they will even invade the secret precincts of the hog-stye. An Irishman in the Newcastle district once caught a bear *flagrante delicto*, dragging a hog over the walls of the pen. Pat, instead of assailing the bear, thought only of securing his property; so he jumped into the stye, and seized the pig by the tail. Bruin having hold of the ears, they had a dead pull for possession, till the whillilooing of Pat, joined to the plaintive notes of his *protégé*, brought a neighbour to his assistance, who decided the contest in Pat's favour, by knocking the assailant on the head.

The wild turkey takes the lead of our Upper Canadian feathered game. He is found in the London and western districts exclusively; though I have heard that, in New England, he is domiciliated much farther to the north. He is large, weighing from 25 to 35lbs., of a dark colour, which in some individuals is lighter, and in others, approaches to a leaden grey, and is very like the domestic turkey of the country, which, there is little doubt, must in many instances hold the same relation to him as the half Indian (or "*bois brulé*," as the French call them) does to the original proprietor of the soil. You can only distinguish him from his civilized cousin by a quick, firm, light infantry step in his gait, and his independent, watchful look. At certain periods of the year, he is any thing but shy. I have walked along the highway for half a mile at least, with a flock of fourteen of them marching in front of me, all the time within easy shot; some of them marching in the middle of the road, some hopping up on the rail fences and running along them, some jumping over into the neighbouring field, but none showing any unreasonable fear of me.

The stream is no less prolific in sport than the forest and field; and if a man thinks proper, in the words of Izaak Walton, "to be pleasant and eat a trout," he can gratify his taste to any extent in Upper Canada. Trout are only found in the small streams, not in the larger rivers; the large fish probably making the latter unsafe quarters for them. They, generally speaking, are small, like those of the moorland burns at home, but very delicately flavoured. When, however, mill-dams are erected on streams, they increase in size; and in the beautiful clear streams, fed from springs in the Long Point country, they are as large as I have seen them any where in England. The banks being overhung with trees, fly-fishing is rarely to be had, except you station yourself on a bridge or mill-dam; but the bait they take at all seasons, from the middle of winter, when you catch them through a hole in the ice, to summer, when you wash down the middle of the stream, with it floating before you. Not being acquainted with the ways of the world and the deceits of mankind, a piece of beef is as good a bait for a Canadian trout as any that can be found. Of other fish there is no lack; and many of them have no European name, but are very good fish for all that.

There are different kinds of houses in Canada, about which a few words may be useful to the settler. Most of the houses, more particularly those of recent settlers, are built of logs. When a man gets on a little in the world, he builds a frame house, weather-boarded outside, and lathed and plastered within; and, in travelling along the road, you can form a pretty accurate estimate of the time a man has been settled by the house he inhabits; indeed, in some instances you may read the whole history of his settlement in the buildings about his farm-yard.

The original shanty, or log-hovel, which sheltered the family when they first arrived on their wild lot, still remains, but has been degraded into a piggery; the more substantial log-house, which held out the weather during the first years of their sojourn, has, with the increase of their wealth, become a chapel of ease to the stable or cow-house; and the glaring and staring bright-red brick-house is brought forward close upon the road, that the frame dwelling, which at one time the proprietor looked upon as the very acmé of his ambition, may at once serve as a kitchen to, and be concealed by, its more aspiring and aristocratic successor; just like a man who, having acquired wealth from small beginnings, is anxious to conceal from the world the gradations by which he rose, and to exhibit only the result of his successful industry.

If you can afford to build a brick or stone house at first, by all means do so; but if you cannot, take my advice, and, like a good fellow, don't build a frame one. It is the most uncomfortable dwelling ever man lived in."—*Backwoodsman.*

"For the purpose of agriculture, the Upper Province is decidedly preferable, the climate being much milder. However, to go there with any reasonable prospect of success, some capital or a labouring or mechanical employment, connected with the every-day pursuits and necessities of life, is indispensably required.

In January the greatest fall of snow usually happens, when the winter trade with the interior commences; the snow sometimes, but not of late years, allows of two months good sleighing; last winter was mild, and it did not exceed five or six weeks; this is considered, in the present state of the roads, as a calamity, preventing the farmers who live far back in the country from getting to the different markets with their produce. In fact all, both Canadians and emigrants, after the first year, do not wish for mild winters, as they are less favourable to health and business than fine frosty weather, accompanied with plenty of snow.

In general we pay far greater attention to proper clothing than is done at home, wearing stout fearnoughts, &c.; this pervades all ranks; even the Indian observes it, and rarely appears, at least, to suffer from the most severe weather, which, it should be observed, is generally dry, seldom taking cold; if the feet and head are kept warm, all goes on well; fur caps are much worn in winter, being better adapted than hats, and may be had near 100 per cent. cheaper here than in Canada; 10 dollars is the usual price of a good cap. The air, though much colder than in this country, being dry and deprived of its moistness by congelation, has less effect on the human body than moister air, although many degrees warmer.

Deer abound in the woods; all persons capable and willing to hunt them do so, there being no game laws. Bears, wolves, and foxes, are not so numerous as to be troublesome; the flesh and skins of the first of these are valuable, and the reward paid for the scalps of the wolves, on producing them before a magistrate, which was raised last session, I believe from L.1 to L.2 per head, tends to keep them under.

Women servants can hardly be procured, and they generally receive 18s. or 21s. a month."—*Cattermole.*

CONCLUDING REMARKS.

We have now presented what we consider a correct account of the extent, character, and prospects of the British colonial possessions on the coast of North America. Although it is obvious that these territories do not offer the same wide field for the settlement of emigrants, or the same means of advantageous employment, as Upper Canada or the United States, it is a matter of certainty that they possess large and fertile tracts of good land, fit for the support of an abundant population, and that they afford a ready refuge and home for steady and industrious men and their families from this over-burdened country. However much these countries may suffer in comparison with the interior of the North American continent, it is, we think, clear that they are on the whole equal to Europe; and it is remarked by a native authority, "that of all the emigrants who come to the country, none return to their native land, notwithstanding the numerous opportunities from the different ports." In these provinces, as in other places, the description of emigrants who most promote their own interest and that of the colony, are farmers, or persons accustomed to rural occupations, who carry with them from L.200 to L.500; men who, instead of beginning a settlement themselves, can purchase one already commenced. The native is now expert with his axe, more used to the clearing of land, and better fitted for a pioneer in the woods. The European is generally his superior in all kinds of rural occupations: the one is at home with his axe, the other with his plough. The emigrant should therefore purchase a farm, which, besides suitable buildings, &c., should contain three or four hundred acres of land, forty or fifty of which should be cleared, and the native should recede to the woods, to contend again with new roads and new settlements, to which he has been accustomed. To the other class of emigrants who go to these provinces with small means, it may be proper to suggest, that experience has shown the necessity of their not being too eager to obtain lots of land. It is better for them to engage as workmen for a few years, until they become acquainted with the climate, mode of cultivation, habits and manners of the people, markets, relative value of land, and other useful information, after which there is a greater probability of their selection being judicious, and their efforts successful. We have heard it frequently remarked by a person of respectability in Nova Scotia, that, in very many instances, emigrants ruin their prospects at the outset, leaving themselves almost paupers, simply by not attaching themselves at once, on their landing, either to some occupation, or some select spot of land as their location. They go from place to place, seeking for the paradise they had anticipated, and spend all in the vain search. Let us try to impress upon the minds of intending emigrants of every class the absolute necessity of being persevering and steady in their habits. An idle man in any part of America is an anomaly, and one who falls into unsettled or dissipated habits is sure of being visited with ruin and contempt. Every man who departs for these vast western territories must resolve to work with his own hands; and if he use those obvious means which are pointed out, and which it requires no genius to understand, he cannot fail in placing himself and his family in a condition of respectability and permanent comfort. In speaking of the state of the labouring classes in Nova Scotia, Captain Moorsom makes the following striking observation:—"The cheapness of living, and, indeed, of every thing except clothing, is such, that the wages of most operative tradesmen enable them to be idle, if they are so inclined, three days out of the six. Instances are far too numerous in which this is a common practice, and most of the hours thus deducted from labour are passed in the various stages of intoxication." We would earnestly hope that those whom we are now addressing, who design emigrating to these provinces, will sedulously avoid such a pernicious habit of intemperance, which will bring disgrace not only to themselves, but be in some measure a reproach on the land which sent them forth.

There is one form of emigration which we would particularly recommend to intending emigrants, for we believe it will be found the most agreeable, if not the most economical; this is the removal, in a body, of a number of families known to each other, and who may all settle in a cluster, or in the neighbourhood of each other. This plan, if pursued discreetly, will neutralise many of the pains of emigration, and will originate a little society, in which there will be a similarity of sentiment and a sympathy not otherwise to be obtained. Such an advantageous species of removal has already been tried in a number of instances, particularly by Scottish families, and is productive of the most agreeable results. We would, therefore, advise those friendly to emigration, in any particular part of the country, and who intend to employ themselves in farming occupations, to proceed, if possible, in this manner, all going by the same vessel, and, on their arrival in America, selecting a district suitable to their wants.

It may here be appropriately remarked, that emigration, in recent times, has very much changed its character. The poor artizan, and the humble and hardy peasant, are not now the only class of persons who betake themselves to the countries beyond the Atlantic. Every day these extensive and fertile regions are coming more and more under the notice of capitalists, regularly bred farmers, active master tradesmen, in short, our middle class of society; and the wealth from this source alone, which will be speedily poured into North America, is incalculable, both as to its amount and its results on the surface of the country. It may be anticipated, that, in a few years, large tracts of country in these valuable colonial possessions will be as well settled, as well cultivated, as well regulated in their affairs, public and private, and, therefore, as civilized and refined, as many of the rural districts in Great Britain. Even as it is, many portions of North America have outstripped Great Britain in the career of general intelligence. Such being the capabilities and flattering prospects of these territories, it appears a species of infatuation for farmers to continue to peril thousands of pounds on land in this country, with the barest chance of success, enduring innumerable vexations, and at the mercy of landowners and law-agents, while they can obtain, for the matter of a few hundreds of pounds, lands, in the British colonies or the United States, of the most fertile description, and which, in a short time, by active exertion, will repay all that is expended upon them, and remain a permanent and valuable freehold for their family. Luckily, both for the benefit of the mother country and individuals, this kind of delusion is wearing off. A knowledge of the vast resources and general character of North America, such as that presented in this and other sheets, cannot but dispel the ignorance prevailing on the subject, and be useful in directing the views of a large proportion of the people towards a process of emigration highly beneficial to themselves and their descendants.

EDINBURGH: Printed and Published by W. and R. CHAMBERS, 19, Waterloo Place; also by W. ORR, Paternoster Row, London; and W. CURRY, Jun. and Co. Sackville Street, Dublin. Sold by John Macleod, Glasgow, and all other Booksellers in Scotland, England, and Ireland.—Published once a fortnight.—Numbers, containing accounts of the United States, New South Wales, and Van Diemen's Land, with maps, for the use of emigrants and others, are in preparation.

Stereotyped by A. KIRKWOOD, St Andrew Street, Edinburgh.

CHAMBERS'S
INFORMATION FOR THE PEOPLE.

No. 5. PRICE 1½d.

EMIGRATION TO THE UNITED STATES.

The United States now occupy the largest portion of the North American continent, and offer a boundless field for the settlement of emigrants. Originally confined to the territory along the shore of the Atlantic, this great republic has extended its influence and power over nearly the whole of the regions spreading westward to the Pacific. This vast territory, surpassing in internal resources, and nearly in dimensions, any of the empires of the Old World, extends from the 25th to the 49th degree of north latitude, and from the 67th to the 124th degree of west longitude. It measures in extreme length, from the Pacific Ocean to the Atlantic, 2780 miles, and its greatest breadth is estimated at 1300 miles.

The United States consist of three great natural divisions—the slope from the range of the Alleghany mountains to the Atlantic, comprehending the oldest settlements; the valley of the Mississippi, now in the course of settlement; and the slope from the Rocky or Chippewau mountains towards the Pacific, which is still in a wilderness condition, and inhabited by Indians. The greatest wonder of this immense country is the valley of the Mississippi, which is considered the largest division of the globe, of which the waters pass into one estuary. The Atlantic slope contains 390,000 square miles, the Pacific slope about 300,000; but this great central valley contains at least 1,300,000 square miles, or four times as much land as the whole of England. The valley of the Mississippi, into which the flood of emigration to the states is chiefly directed, is divided into two portions, the upper and lower valley, distinguished by particular features, and separated by an imaginary intersecting line at the place where the Ohio pours its waters into the Mississippi. This large river has many tributaries of first-rate proportions besides the Ohio. The chief is the Missouri, which, indeed, is the main stream, for it is not only longer and larger, but drains a greater extent of country. Its length is computed at 1870 miles, and upon a particular course 3000 miles. In its appearance it is turbid, violent, and rapid, while the Mississippi, above its junction with the Missouri, is clear, with a gentle current. At St Charles, 20 miles from its entrance into the Mississippi, the Missouri measures from five to six hundred yards across, though its depth is only a few fathoms.

The Mississippi Proper takes its rise in Cedar Lake, in the 47th degree of north latitude. From this to the Falls of St Anthony, a distance of five hundred miles, it runs in a devious course, first south-east, than south-west, and, finally, south-east again; which last it continues, without much deviation, till it reaches the Missouri, the waters of which strike it at right angles, and throw the current of the Mississippi entirely upon the eastern side. The prominent branch of the Upper Mississippi is the St Peter's, which rises in the great prairies in the north-west, and enters the parent stream a little below the Falls of St Anthony. The Kaskaskia next joins it, after a course of 200 miles. In the 36th degree of north latitude, the Ohio (formed by the junction of the Alleghany and Monongahela) pours in its tribute, after pursuing a course of 750 miles, and draining about 200,000 square miles of country. A little below the 34th degree, the White River enters, after a course of more than 1000 miles. Thirty miles below that, the Arkansas, bringing in its tribute from the confines of Mexico, pours in its waters. Its last great tributary is Red River, a stream taking its rise in the Mexican dominions, and flowing a course of more than 2000 miles.

Hitherto the waters in the wide regions of the west have been congregating to one point. The "Father of Waters" is now upwards of a mile in width, and several fathoms deep. During its annual floods, it overflows its banks below the mouth of the Ohio, and sometimes extends thirty and forty miles into the interior, laying the prairies, bottoms, swamps, and other low grounds, under water for a season. After receiving Red River, this large stream is unable to continue in one channel; it parts into separate courses, and finds its way to the ocean or the Gulf of Mexico, at different and distant points below New Orleans.

The capabilities of the Mississippi for purposes of trade, are almost beyond calculation, and are hardly yet developed. For thousands of years this magnificent American river rolled its placid and undisturbed waters amidst widely-spreading forests, rich green prairies, and swelling mountain scenery, ornamented with the ever-varying tints of nature in its wildest mood, unnoticed save by the wandering savage of the west, or the animals which browse upon its banks. At length it came under the observation of civilized men, and now has begun to contribute to their wants and wishes. Every part of the vast region, irrigated by the main stream and its tributaries, can be penetrated by steam-boats and other water craft; nor is there a spot in all this wide territory, excepting a small district in the plains of Upper Missouri, that is more than one hundred miles from some navigable water. A boat may take in its lading on the banks of the Chetaque Lake, in the state of New York, within a short distance of the eastern shore of Lake Erie—another may receive its cargo in the interior of Virginia—a third may start from the Rice Lakes at the head of the Mississippi—and a fourth may come laden with furs from the Chippewau mountains, 2800 miles up the Missouri—and all meet at the mouth of the Ohio, and proceed in company to the ocean.

Those whom we are now addressing probably inhabit the island of Great Britain, where the traffic of every sea-port, every branch of inland navigation, has been pushed to its utmost limits, where every art is over-done, and where the heart of the ingenious almost sinks within them for want of scope for their enterprise. But here, on this wide-spread ramification of navigable streams, there is an endless, a boundless field for agricultural and mercantile adventure. Within the last twenty-four years, the Mississippi, with the Ohio, and its other large tributaries, have been covered with steam-boats and barges of every kind, and populous cities have sprung up on their banks. There are now *sea*-ports at the centre of the American continent—trading towns, each already doing more business than some half dozen celebrated ports in the Old World, with all the protection which restrictive enactments and traditional importance can confer upon them.

The valley of the Mississippi, one of the greatest natural wonders of the world, will one day possess and comfortably sustain a population nearly as great as that of all Europe. Let its inhabitants become equally dense with England, including Wales, which contains 207 to the square mile, and its numbers will amount to 179,400,000. But let it become equal to the Netherlands, which its fertility would warrant, and its surface will sustain a population of *two hundred millions.*

Such are the great natural divisions of the United States. Usually the country is divided into what are termed the Northern and Southern, or Free and Slave-holding States, in which the climate and habits of the people differ very considerably. It is chiefly, and almost entirely, to the northern or free states that the attention of emigrants should be directed, because such persons will there have at once a temperate climate, more agreeable to their constitutions, and a greater scope for their industry in agricultural and mechanical employments. The Southern or Slave States afford no place for any except those who have capital to purchase both land and slaves; and the soil and temperature, besides, are adapted chiefly to the culture of tobacco, cotton, indigo, rice, and other tropical productions, in raising and preparing which, the people of this country have no experience. We shall, therefore, advert but slightly to these states, in giving directions to emigrants, and make our information as full as possible on those which afford practicable and desirable settlements to people from this country. These latter are bounded on the south pretty nearly by the 40th degree of latitude, so that they lie in a climate corresponding to that of the south of France and the northern part of Spain, though, as yet, on the whole, they are less salubrious than these old cleared countries of Europe. When the climate of the northern states is placed in comparison with that of Great Britain, it may be described as more extreme in summer heats and winter colds; but from all we can learn, it appears that the Americans are exempted from that amount of *disagreeable* weather—that vexatious mixture of rawness, cold winds from the east, rains, sunshine, and frost, which constitutes the greatest drawback on this country, and which annually carries off a large proportion of the inhabitants.

The following is a list of the various States and Territories, with the names of the chief towns, amount of population, and extent in square miles:—

State.	Chief Town.	Population in 1830.	Area in Sq. Miles.
Maine	Portland	399,462	32,191
New Hampshire	Portsmouth	269,533	8,700
Vermont	Montpelier	280,679	9,330
Massachusetts	Boston	610,014	7,335
Rhode Island	Providence	97,210	1,200
Connecticut	Hartford	297,711	5,050
New York	New York	1,913,508	46,000
New Jersey	Trenton	320,779	7,870
Pennsylvania	Philadelphia	1,347,672	47,000
Delaware	Dover	76,739	2,100
Dist. of Columbia	Washington	39,858	100
Maryland	Baltimore	446,913	10,000
Virginia	Richmond	1,211,272	70,000
North Carolina	Raleigh	738,470	50,000
South Carolina	Charleston	581,458	33,000
Georgia	Milledgeville	506,567	61,000
Alabama	Tuscaloosa	415,803	51,770
Mississippi	New Orleans		51,000
Louisiana	New Orleans	215,575	48,220
Tenessee	Nashville	684,282	43,000
Kentucky	Frankfort	688,844	37,680
Ohio	Columbus	937,679	40,000
Indiana	Indianapolis	341,582	34,000
Illinois	Shawneetown	157,575	58,900
Missouri	St Louis	140,074	63,000
Michigan	Detroit	31,260	34,000
Arkansas	Little Rock	30,383	121,340
Florida	Tallahassee	34,729	54,000

LEAVING HOME.

Many persons shrink from the idea of emigrating, because it seems like a confession that they have been baffled at home, and that, where others have been successful, they have failed. From this weak feeling, they continue to linger on, struggling with discouragements, and wishing rather to gain the credit of patient well-doing and resignation to unavoidable troubles, than to encounter what they think the reproach of leaving the country. Such persons (who are often the worthiest of society) should recollect that the same perseverance and steadiness which in this country is only sufficient to keep their families out of distress, will, in a more favourable field of industry, place them in comfort and independence. In this country every man's exertions are met and thwarted by the competition of his neighbours; whereas, in the new lands, the increasing density of population and neighbourhood as yet only adds to a man's wealth, and to the profits of his industry. It used to be thought (and many still foolishly think so), that, to *leave the country*, was a man's last resource, and was only adopted by those who *could not do better*; but it is now discovered that America, instead of being only an asylum for the baffled and despairing, is, like an immense harvest-field, calling for reapers, who have skill and ability to labour, from all quarters. The abundance of unoccupied land in that country only requires the hand of man to convert it into the means of human subsistence, and every one who goes creates work for another to follow him.

The competition of one man against another in this country is so great, that young people, bred to laborious occupations, often seriously hurt their constitutions by working beyond their strength, merely to keep their places, or gain employment. There is hardly a man who has wrought as a farm-servant, a mason, a blacksmith, or such crafts as require the exertion of much strength, but can tell of some of his early acquaintances who *wrought themselves done*, in order to keep up with their neighbours, and this, because they were apprehensive of losing their situations. In America, the competition of one man against another is by no means so keen; good wages may be made by moderate exertion at all the ordinary useful trades; and men who have been accustomed to farm work will find a ready demand for their labour, with fair and even high wages, without the fear of losing employment when their youth and strength is exhausted. It requires a little firmness to determine on leaving one's country, and that is all. The resolution once taken, the chief difficulty is surmounted. The success and comfort of the numbers who have taken the step already, leave little room for perplexity or uneasiness with regard to others.

The difficulty which farmers have for this considerable time had in finding farms for their sons, and the very large capital which is required to stock a young man beginning life in that way, render it worthy of consideration whether parents would not do better to buy land for them in Canada or the United States, where one hundred pounds would make them proprietors of their farm, and stock them sufficiently with all that is necessary for thriving and becoming wealthy. A number of half-pay officers, who had served with credit in the late war, had the good sense and gallantry to begin establishments of this kind, in the woods at Lake Simcoe, and, by so doing, conferred a service on their country, much greater than if they had fallen in battle. The example of these brave men will doubtless have influence with many of their own rank in society, and may point out to thousands of anxious parents a way in which they may provide for their children, greatly superior to that of sending them into the army, or even to waste their constitutions in the enervating and destructive climates of India. They would have here healthy and thriving occupations; the labours of the farm, and the amusement of the rifle; the prospect of long life; and of becoming, as they advanced in years, the proprietor of a well improved estate, and the patriarch of a respected family. In going into the army, or to India, it is needless to say that all these prospects are much more uncertain. We make these observations principally, however, with reference to our own colonies in Canada, among whom the step we have mentioned would be the means of introducing a number of men of education, attached from principle to Britain, and exercising a powerful influence in securing the future attachment of the country of their adoption to that of their birth.

THE VOYAGE.

When the determination is once taken to emigrate, the next step is to make arrangements with a ship-owner, or captain, for the voyage. A passage may be taken either to Philadelphia, Baltimore, or New York, with almost equal advantage: Philadelphia or New York are perhaps preferable; but no passenger should go to Boston, except he has friends or business there. Take no furniture whatever, but plenty of good warm clothing, and bed-clothes. We need not repeat here the directions which have been already given; the steerage passengers generally lay in provisions for themselves, which consist of oatmeal, potatoes, some eggs, milk boiled with lump sugar, and some salt beef, or ham; these provisions should be calculated for fifty days; whatever remains after the passage, will be useful afterwards on the way to a settlement. A tin pot, or kettle, with a flat side and a hook, for *hanging upon the ribs of the fire*, will be very useful, because it is often impossible to pot every thing *on the fire* together at cooking times; and this pot can be boiled without occupying the room of others. It is particularly recommended to those who make the voyage, never to feel alarmed at appearances of stormy weather and what they may think danger; because there is really no danger: there are as few examples of ships sinking in the open sea, as of houses being burned on land. It is only when, by some mischance, they are driven upon lands and rocks, that danger occurs; and then it will be sufficiently evident to every body.

Men on board should pay the greatest attention to females, who are apt to be fluttered when they hear the noise of the waves, or of high winds, or the sailors trampling about in a bustle on the deck above. In such cases, passengers have only to keep themselves tranquil, and to recollect that the squall may cause hard work to the sailors, but no danger to any body, except there be land within sight, and the wind blowing them on it against their will. On coming into harbour, be in no hurry, or rather let your hurry put you in no confusion; get all your things ready, and have some lodgings fixed on to take your baggage to before moving.—Passage from Leith to New York, in the steerage, L.3, 10s. to L.4; children, from 7 to 14 years, one half; under 7, one third; under 12 months, no charge; passengers find their own provisions. The ship lays in water, firewood or coals, cooking apparatus, and fits up sleeping births. One-third of the freight to be paid before the passage be secured, and the remaining two-thirds on sailing. Cabin passage, L.14 to L.15; children, L.10.

LANDING IN AMERICA.

Supposing the emigrant landed at Philadelphia, New York, or Baltimore, his next step, if a tradesman, is to consider where he is most likely to find work. Except shipwrights, and one or two other trades, it is perhaps better to proceed to some of the considerable inland towns, where wages are generally higher, and the cost of living less. On this subject, the emigrant will find ready information from people of his own business in whatever city he may land; they are seldom unwilling to put strangers in the way of finding employment. There is an emigrant society in Philadelphia, which has done a great deal for this purpose.

If the emigrant wishes to purchase land, and has fixed on the district where he intends to settle, he ought to take his passage accordingly to the port which is nearest to his intended destination. If he means to purchase a farm in the settled districts of New York, such as those in the valley of the Hudson, or about the lakes of the River Mohawk, Genessee, &c., he should sail immediately for New York. The same port is the fittest for those who mean to proceed to Michigan, but these may also go by Montreal, whence the Rideau Canal, now opened, affords an easy passage to Kingston, instead of a disagreeable route by the rapids of the St Lawrence, formerly followed, and which made emigrants formerly prefer going, even to our own settlements, by New York, instead of Montreal. The passage by the canal now opened, from that place to Kingston, costs 9s. 4d., with one trunk; other luggage must be paid for. Supposing the emigrant at Kingston, he will find a direct passage to Michigan, by proceeding up Lake Ontario, and then through the Welland Canal, whence he will go up Lake Erie to Detroit. If he goes by New York, he proceeds up the River Hudson, thence along the Erie Canal to Buffalo, and next to Detroit by the Lake. By New York, the expense of the whole passage may be reckoned: passage to New York (in the steerage), L.3, 15s.; to Albany on the Hudson, 9s. 6d.; to Buffalo, L.2, 2s.; to Detroit, 9s.; the whole amounting to L.6, 15s. 6d. If there be considerable luggage, it will, of course, add to the expense, but L.7, 10s. will cover it in general. By Montreal, and the facility now afforded by the Rideau Canal, the expense will be somewhat less.

The above, we have said, is the cost of a passage to Michigan; that to the Ohio may be reckoned as a trifle more. We have not received intelligence of the completion and opening of the canal which is in progress from Lake Erie by Columbus and Chilicothe to Portsmouth in Indiana, so that it will be necessary for travellers, who think of proceeding to any of the western countries, to journey partly by road, and partly by canal, to Pittsburg, and thence down the Ohio. This they can do, either from Baltimore or Philadelphia.

Emigrants who intend to settle in the Highlands of Pennsylvania had better take passage immediately to Philadelphia, which will be cheapest; but if that be impossible, as ships are not always to be found for the desired port, the journey either from New York or Baltimore to that place is short, and not expensive. Readers may see it mentioned in our notice concerning the "Expenses of Travelling."

After landing, emigrants ought to make no delay in lingering about the sea-ports, either from curiosity or the persuasion of fellow-passengers. Let them immediately proceed to business. If in search of land in Ohio or Michigan, let them instantly set out thither; they will find a land-office in every principal town of the districts, where they may look at the surveys, learn what townships or lots remain unsold, and get such information as the surveyor possesses concerning their qualities. But in every case let the settler examine and search for himself; no one else can or will judge for him. The surveys are made out, delineating the lines of the most considerable rivers and hills; and they are covered over with a number of small squares, like checks, which represent the different townships of six miles square, sections of one mile, and quarter sections. There are some principal lines marking larger squares; these are the meridians and base lines, by which the positions of the smaller portions are fixed, according to their distance from each. No smaller quantity is sold than 80 acres; and the price of government land is every where the same, that is, one dollar and a quarter per acre, or 5s. 9d. —though emigrants cannot always reckon on getting a situation to fit them at that price; perhaps four to eight dollars may procure a choice.

If the settler wishes to have land in Pennsylvania or New York states, it is to be bought there from individuals, the government having no land for sale in these states. The price here varies according as the land is improved or not; and on this subject the reader will find information under the head "Prices of Land." If the emigrant should not, immediately on landing, find any one who has land to sell, an advertisement inserted in any of the papers will bring some of the owners or their agents to wait on him, and to direct him concerning purchases to be examined. His family should remain in New York or Philadelphia till he sees the land and fixes on a situation.

...igrants, on landing, are advised to lodge their money in some of the banks. If they have any considerable sum in gold, they can generally dispose of it to advantage to the brokers; but it is better, in the meanwhile, to place it in bank as a *special deposit*, taking a receipt from the cashier, bearing that he will return *the same* to you or your order. The proceeds, after exchanging your gold, may be left in the bank, from which you will receive a book giving you credit for your deposit; and you may then draw upon the bank as you need the money.

To those who wish full information on the subject of America, we would recommend the splendid work lately published by J. Howard Hinton, Esq., which contains every thing relating to the history, natural capabilities, and statistics of the country. The recent work of our countryman, Mr Stuart of Dunearn, has been quoted frequently in these pages, but not more often than its accuracy and impartiality deserve. The volume of Mr Fergusson of Woodhill is full of interest to agricultural emigrants. Other works may be perused with advantage—Flint's Letters from America, Duncan's Travels, &c.

DISTRICTS FOR EMIGRANTS.

Three districts are pointed out as highly worthy of consideration by emigrants. These are, 1st, The Highlands of Pennsylvania; 2d, The western countries lying on the Ohio; and, 3d, The district of Michigan, or the country lying around that lake.

The Highlands of Pennsylvania.

This is a fertile and healthy country, situated to the north-west between Philadelphia and Pittsburg. It lies in the middle of the settled districts, and has hitherto never been occupied by population, from the circumstance that there were no roads or channels of carriage open between it and the large towns and rivers; so that the settlers, whatever might be their produce, had no means of sending it to market. The mountainous nature of the ground rendered it long before lines of communications to the requisite extent could be carried through it; this has now, however, been effected; so that the whole resources of the district are at length laid open to cultivation and industry. Coals, lime, and iron ore, are here found abundantly, and canals or railroads have been formed to the mines. The lands in the vallies and sides of the lower ranges of hills are of great fertility, and, from the mildness of the climate, some of the mountains admit of cultivation to their very summits. The meadows are in the highest degree luxuriant, and the hills are covered with abundance of pasture for cattle, sheep, hogs, deer, and goats. The timber found on the lands in their wild state is different, according to their quality (a circumstance which the intending settler should observe carefully); that on the best lands being walnut and chestnut; the next best, maple, beech, oak, and hickory; the third quality, pine, spruce, and hemlock (a kind of fir-tree); and the poorest lands are encumbered with shrubs, brambles, and bushes. When the lands are brought under cultivation, their produce, in Indian corn, wheat, buckwheat, potatoes, &c., equals that of any of the eastern sections of the Union; and the soil, especially in the hilly parts of the north, is well adapted for grazing. Mr Flint mentions that produce in this district may be stated at from twenty to twenty-five bushels of wheat, and from twenty-five to thirty bushels Indian corn. These, he adds, are raised under slovenly management, and without much labour. A farmer expressed his contentment with the crop under existing circumstances. "A dollar a bushel for wheat," he said, "made a fair price, where he has neither rent nor taxes to pay. His own farm paid about four or five dollars a-year for the support of the state and county officers." The expense of taking cattle from these inland parts, where they are easily fed, to the market at Philadelphia (where they always command cash), is about 5s. 9d. a-head. The great roads from Philadelphia and New York, to Pittsburg, on the Ohio, pass through part of the district. There is also a canal between Philadelphia and Pittsburg, which intersects the southern parts of it, and affords means for transporting the produce of the country to markets on either side.

This country presents a climate more healthy, and less different from that of European countries, than most others in America. Its hilly surface, and clear rapid streams, seem more congenial to the habits of persons accustomed to the same scenes in this country, than the flat though rich carse lands of the western rivers. The price of land here, as in all other parts of the Union, varies according to the advantages commanded by the property; fertile land, well situated for roads, selling considerably higher than soil of an inferior quality, or more remote from markets. The medium price of unsettled land is from two to four dollars per acre, and the best situated about eight dollars; the amount of the purchase will always be taken in instalments of a dollar per acre, each year, till the whole be paid up. If the account be discharged in six years, little fault will be found. Many labourers, working at the canals in this district, of which there are several in progress, receive four dollars and a half per week; and as they can be boarded (with *meat* twice a-day) for about two dollars per week, they can save eight dollars at least every month, and, by the produce of their industry in this way, may be enabled, in three years, or a little more, to command as much money as will purchase 100 acres of land. As they are not required to pay for the land on entering this sum will enable them at once to settle on their property, though for such emigrants it is generally advisable not to purchase more land than they can quickly bring into cultivation, which is about fifty acres. Mr Cobbett mentions, that while in America, he was at an inn one night, where he met a Connecticut farmer on the road to Pennsylvania, with his daughter; the rest of his family had gone thither already. His reasons for migrating were these: He had five sons, the eldest nineteen years of age, and several daughters. Connecticut is thickly settled, and land dear. He had not means to buy farms for his sons there; he therefore goes and gets cheap land in Pennsylvania; his sons will assist him to clear it, and thus they will have a farm each. Mr Cobbett does not, however, think this an advisable plan, except for those who are accustomed to hard and steady labour.

There are numerous lots of land always on sale, and to be heard of in Philadelphia; but if the emigrant has any difficulty on this head, he has only to insert a notice, mentioning his wishes, in one of the public papers, when he will be waited on by one or other connected with the sales. Let him, however, by all means, see the land himself, before concluding a bargain; this caution cannot be too often repeated. It is not to be expected that every desirable object should be united on one property; but many inconveniences can be observed by a man's own eye, which no one will point out to him. It must in general be borne in mind, that the best carse lands, or the rich bottoms of vallies, are not the most healthy; and a situation near marshes, or pools of shallow water, is always to be avoided even in the healthiest districts. There are about twelve millions of good arable land on sale in this district.

The Countries on the Ohio and Mississippi.

The climate of this extensive region is not unsuited to European constitutions, though perhaps requiring greater caution on a first arrival than in the old states; because, being an inland country, the heat of summer and the cold of winter are not softened by those breezes from the ocean which moderate the temperature of islands and sea-coasts. In marshy situations, and close by the banks of rivers, especially if the woods in the neighbourhood have been left uncleared, agues and fevers are not uncommon during autumn, but these, with due caution, are seldom fatal, and are looked on by the inhabitants with little apprehension. None of the large towns have been set down in unhealthy situations; and the settlers, in selecting lands, can at present have their choice of fine upland grounds, which are not liable to any disease.

With this drawback, which it was necessary to state at the outset, the region we have now mentioned presents a scene of promise to the industrious settler, which is hardly to be equalled. The greater part of the land is a fine black mould; in some parts, particularly the river sides, where the grass continues rank all the year, it is covered with heavy timber; in others, where burning of the dry grass in summer prevented the growth of trees, it lies in fine meadows, called here *prairies*; and in the hilly, or rather *knolly* districts (for the land is generally flat), there is a growth of shrubs and underwood. The soil of the last portion is lighter than the others, but it is still excellent, and in that fine climate produces every kind of crop abundantly. These situations, too, are often the healthiest, in a degree which compensates for their inferiority in point of richness to the carse and meadow lands: it is even said that they are the best lands for growing wheat. The natural productions of the country are in the principal matters the same as those of the other states—Indian corn, wheat, oats, barley, buckwheat, potatoes, sweet potatoes, and rye. Of these, oats, barley, and buckwheat, are, we believe, hardly natural to the climate, and do not thrive so well; but, to make amends, there are tobacco, cotton, hemp, the grape vine, the papaw tree, the tomato, and other productions, which are not cultivated in the north of America or Britain. Wheat produces a good and sure crop of about 30 to 35 bushels of 60 lb. per acre: it is not uncommon to have it weighing 66 lb. Mr Flint mentions, as a proof of what can be done in this country by industry, that he met a settler who had that year raised nine hundred bushels Indian corn and wheat, by his own individual exertions. Mr Flint had previously heard of a negro, settled on the prairies near Vincennes, who had the same year raised one thousand bushels. The soil is well adapted for growing the European vegetables; as a proof of which, we find it mentioned, that cabbages grow to the size of 13 and 17½ feet in circumference: those of nine feet round in the head are common. Parsnips, carrots, and beets, are remarkable for their size and flavour; peas excellent, and very prolific; onions are raised with no other trouble than sowing the seed, and keeping the ground clear of weeds. The following extract from the memorandum of a naturalist in that country, will give an idea of the periods of the seasons:—April 1st, Peach trees in blossom. 2d, Asparagus in blossom. 3d, Peas, beans, and onions planted. 10th, Spring had completely opened, and the prairies were green. 18th, Lilac and strawberries in bloom. 27th, Lettuce and radishes fit for use. 30th, Roses and honeysuckles in full bloom.—It is mentioned, also, that turnips, sown on the 10th September, will grow to a very large size before winter. Besides its capability for rearing grain, &c., it is one of the best cattle-feeding countries in the world. "A farmer," it is said, "calls himself poor with a hundred head of horned cattle around him." Hogs, from the abundance of all kinds of vegetables, are reared and fattened in great numbers; and the demand at New Orleans affords a ready market for all. Nothing is more common than for an Illinois farmer to go among his stock, shoot down and dress a fine "beef" (as they call the ox), whenever fresh meat is wanted. This is often divided out among the neighbours, who in turn kill and share likewise. It is common at "camp meetings" (*tent preachings*) to kill a "beef" and three or four hogs, for the subsistence of friends from a distance. A three-year-old heifer is fed to about 421 lbs. (whole carcase), and sells for 5¼ dollars, or 24s. 6d. By the 1st of June or middle of May, the young cattle on the prairies are fit for the market. Common cows, if suffered to lose their milk in August, become fit for table use by October. Every farmer, besides his own land, has the range of the meadows around him, both for his cattle, hogs, turkeys, and poultry; so that they are reared in immense numbers, and at small expense. They are purchased readily, both, as mentioned formerly, for the New Orleans market, and by drovers, who take them to the east coast, Philadelphia, &c. This district affords, indeed, the chief supply of live stock for the Union. Altogether, the fertility of the country, and the abundance of its natural productions, are such, that the inhabitants are afraid of not being believed in mentioning them to the other Americans. "Our New England friends," says one of them, "must not put down every statement about this country as romance, because its vegetable productions so far exceed the scanty growth of the granite regions of the west. I am well aware," he adds, "that one hazards his reputation for veracity by narrating such things to a New Englander." All the favourable impressions, however, which had been made concerning this country, by the reports of former visitors, have been confirmed, in the most satisfactory manner, by one of the best-informed and most candid travellers of our day, Mr Stuart of Dunearn, who passed through the whole territory in 1832, and conversed with the most intelligent of its inhabitants and public men. His account agrees in every thing with what we had previously heard of the great fertility and growing importance of the country.

The influx of emigrants into Ohio, and the neighbouring states, has continued for these twenty years in multitudes, and without intermission. They can now travel by canal, and partly by railroad; but in the absence of these, the poorest emigrants still urge forward, over every difficulty, to the western land of promise. "It is truly interesting," says Mr Flint, "to see people of different countries, and of different dresses, coming forward in the mail-coach, on horseback, and on foot. At first view, this great migration leads to the conclusion, that oppression, and the fear of want, are in extensive operation somewhere to the eastward."—"On Sidelong hill," he says in another place, "we came up with a singular party of emigrants—a man, with his wife and ten children. They were removing from New Jersey to Pittsburg, a land journey of 340 miles. The eldest of the progeny had the youngest tied on his back, and the father pushed before him a wheelbarrow, containing the moveables of the family. Abrupt edges of rocks, higher than the wheel, occasionally interrupt the passage: their humble carriage must be lifted over these. A little farther onward, we passed a young woman carrying a sucking child in her arms, and leading a very little one by the hand. We could scarcely look, before or behind without seeing some emigrants travelling. No pilgrims were ever so diversified or interesting as these."

Mr Flint seems to have been surprised at the numbers whom he saw on the roads, all moving in one direction. His description reminds one of the multitudes seen streaming on in pilgrimage towards the Indian temple of Juggernaut; but the pilgrims of the Old World are generally going to seek a relief from their misery in superstitions or death; here they appear to have been led on by much more comfortable anticipations; at least if the next extract may be trusted.

"We arrived at a tavern. The bread was not prepared; but the people were obliging, and made it ready for us in a short time. The landlord was a farmer. He told us that Indian corn sells here at 13½d. per bushel, and that he could procure 20,000 bushels of it within three miles of his own house. Wheat sells at 3s. 4½d. per bushel."

The principal districts in the western country are Ohio, Indiana, and Illinois. There are considerable towns settled in each of these, the most advantageous situations, and those likely to become important in the commerce of the country, having been immediately pitched upon for that purpose. Some of these have hardly been longer in existence than fifteen years; few of them, except those on the river Ohio, longer than thirty; yet, from the influx of new settlers, and the facility these find in maintaining themselves and their families, such places are already populous and thriving. The country is generally flat, so that the towns do not, as in some of the western states, owe their origin to favourable situations for water-power. Manufactures, grist-mills, &c., if ever established here, must derive their power from steam; for which, indeed, the abundance of coal offers great facilities, while the smooth course of the numerous rivers makes the mines available over the whole district.

Cincinnati, a town situated on the Ohio, on the confines of the two states, Indiana and Ohio, is a place of great trade. In 1800, it contained only 750 people, and in 1805 only 960; it was then surrounded by a wild country, occupied by the Indians. The country around is now cultivated, and the number of inhabitants in the town is about 35,000, composed of people from all parts of Europe and the United States, who have been attracted by the advantages of the place. On the opposite side of the Ohio, in the state of Kentucky, there is another town, which is divided into two by the river Licking; these two parts are laid out on the same regular plan as Cincinnati, so that the whole appears one city. There are many great manufacturing works here: steam-mills, glass and iron-works, &c., and the bustle of the place gives the farmers an excellent market for their produce. This advantage is farther increased by the trade of the numerous large steam-boats which here take in cargoes of beef, pork, flour, &c., for their voyage down the Ohio and Mississippi to New Orleans. Formerly, they could not easily ascend the river, on account of rapids which occur farther down at Louisville; but these have been now overcome by a canal two miles in length, cut through the rock at that place. Louisville itself is situated in Kentucky, and is a place of considerable trade.

Other large towns in this tract of country are, Pittsburg, Wheeling, Steubenville, Marietta, Chillicothe. They afford a considerable market for agricultural produce; and the free navigation to New Orleans, as well as the facilities now afforded by a canal cut to intersect the country from the Ohio, at Portsmouth, to Cleveland, on Lake Erie, secure a constant and steady demand for grain, salted beef, pork at the mall, &c. The Americans look forward to this district, and the vast countries surrounding it, as the future pivot of their national grandeur.

Michigan.

The reader will observe on the map a tongue of land, situated between the two lakes, Huron and Michigan; this tract, with another which lies on the west, between Lake Michigan and the Mississippi, has been lately begun to be settled by emigrants from the old states of America. The two, together, possess great recommendations to agricultural emigrants. The capital is Detroit, a town situated on the river which connects Lake Huron with Lake Erie, and containing 2500 inhabitants. These lakes, with their rivers and canals, give the district access to the markets of New York, New Orleans, and Montreal.

The climate is temperate and healthy; winter sets in generally about the middle of November, and continues till about the middle of March. At Detroit, in 1818, the mean heat of January was 24°, and, in 1820, the mean heat of July was 69°, of December, 27°. The country is situated upon limestone rock, rather hilly, and possesses what the Americans call good water privileges—that is, numerous falls of water for mills, &c. It is better watered than any other in the United States, being finely diversified with lakes and brooks, rising in most parts from copious springs.

The soil is in general a good fertile loam, upon limestone; in some places a calcareous earth is turned up, mixed with the common soil; in others, the loam is mixed with a little sand; both are extremely productive. The country is, in some districts, under heavy timber, and in others, an open prairie, where the settler has nothing to do but start his plough. Horses cost here from L.16 to L.22, 10s.; oxen, from L.15 to L.18, a pair. The produce of the land runs from 25 to 50 bushels wheat, after one bushel of seed. The cotton plant, the grape vine, the sweet potato of Carolina, the tomato, and egg-plant, have all been successfully cultivated. Rye, barley, oats, peas, beans, and potatoes, as well as all kinds of vegetables usually cultivated in the same latitude, produce here in great abundance. Peaches and pears have been tried, and both produce delicious fruit; near towns, pears sell at from 2s. to 4s. per bushel; apples vary from 6d. to 2s. per bushel; currants, blackberries, raspberries, and strawberries, thrive exceedingly. Indian corn is less luxuriant than in the valley of the Ohio, the climate being somewhat colder. This country, on the whole, seems more congenial to European constitutions and habits than the other western settlements.

The richest, and, perhaps, most beautiful part of the territory, is generally thought to be that adjacent to the St Joseph's River, on which twelve new counties are formed. The soil is excellent, and there are numerous falls of water, for mills, &c.

At any of the government land-offices (which are established, wherever there is land to sell, in all the states), a settler may provide himself with a farm, at the usual rate of 5s. 7½d. per acre. No quantity smaller than 80 acres is sold by government. Should he chance to fancy one in some favoured spot (most of which are already secured along the great public road for 300 miles through the country), he will have little difficulty in procuring it for 12s. or 15s. an acre. An extensive tract of country upon the river and bay of Saganaw (on the west side of Lake Huron) is spoken of in terms of high admiration for the richness of the soil, and beauty of the natural scenery; and also, as presenting uncommon inducements to enterprising and industrious farmers and mechanics, from its central and advantageous position for business. The river Saganaw is navigable for boats, 20 miles from the head of the bay, and a road is made to Detroit. Fox River, on the west side of Lake Michigan, is also specially noticed as highly desirable for settlers, in regard to quality of soil, beauty, and local advantages: a canal is projected to connect this river and the lake with the Mississippi.

Mr Fergusson, to whom we are indebted for the above particulars, gives an estimate from the experience of persons acquainted with the district, of a purchase in Michigan, and of its returns:—

Price of 160 acres, at 1¼ dollar per acre	L.45	0	0
Seed, labour, and rail-fence, at 6 dollars, for, say, 150 acres	202	10	0
Harvesting, at 2 dollars	67	10	0
Dwelling-house, stables, &c.	180	0	0
	L.495	0	0
Returns.			
Produce of 150 acres, at 20 bushels per acre, at 1 dollar per bushel	L.675	0	0
Profit	L.180	0	0

No allowance is here made for maintenance; but it is to be recollected, that the wheat crop may be repeated for three or four years without manure, and in the succeeding years the charge for purchase disappears, so that the advantages of the latter are obvious. These are properly appreciated by the Americans, the number of emigrants flocking to Michigan being immense. Its population, in 1831, was estimated at 32,000.

Detroit, the capital of Michigan, is the embryo Constantinople of the inland seas of North America. It is situated on a narrow channel, which connects the two lower lakes, Ontario and Erie, with the three upper, Huron, Michigan, and Superior. Having access in every direction to countries of more fertile soil than those of Greece or Asia, and possessed of an equally favourable climate, it begins its career with political institutions far more propitious to human welfare than were possessed by the celebrated city we have mentioned; and it promises one day to be the abode of a more numerous, as well as happier population.

Other Districts.

The three districts we have mentioned are those in which the greatest quantities of land are yet unoccupied, and where it is to be had cheapest; but there are others in which settlers may *locate* themselves with advantage. Among these is the district of Genessee, in New York state; and, indeed, the whole valley of the River Hudson presents, at intervals, spots on which good land may be purchased, especially by those who would rather sit down on a place partially cultivated, and near markets, than in the heart of the forest.

DIFFERENT CLASSES OF EMIGRANTS.

Men with Capital.

There are three different classes of emigrants, each of whom will be guided by different motives in their choice of a situation. The first is composed of persons who are possessed of capital to some amount, and who have been accustomed to move among the wealthier classes of society in this country. If these individuals intend to devote themselves to agriculture in the country to which they are bound, every circumstance leads us to believe, that unless they are prepared to submit to very great sacrifices of personal comfort, and that for no inconsiderable time, they ought to purchase land partly improved, and as near some of the towns as they can find it. The hardships of a new settlement to persons who have not been accustomed to labour, are hardly such as can be anticipated by description; while the total change of habits—labouring in the woods, living in log-huts, and the want of regular food—often induces disease, of which such persons may feel the effects during the whole of their after lives. Abundance of half-improved properties may be found (as we have mentioned under the title "Purchasing of Land"), upon which moderate labour, and the exertion of some skill and attention, will secure excellent returns. These may be heard of at any of the large towns, but chiefly at New York, or at Albany, Genessee, Rochester, Geneva, &c., in that state. In Philadelphia also, in the state of Pennsylvania, most eligible purchases of this kind may be made; and at Pittsburg, a very busy manufacturing town in the same state, on the river Ohio, there are many properties on sale which must rise in value every day with the increasing commercial importance of the place. There are immense beds of coal, iron ore, and limestone, in the vicinity of the town, and the navigation of the Ohio is uninterrupted (though there are some inconsiderable rapids) the whole way to its junction with the Mississippi. Communications by canal and railroad are also opening, or now completed, to connect the Ohio at this place with Baltimore and Philadelphia; so that the town of Pittsburg is already of great wealth, and promises rapidly to increase. The land in the neighbourhood is of uncommon fertility, and may be obtained now at prices lower than can be expected in a few years, when a greater number of settlers shall have arrived to occupy it. Properties within twenty miles of the town already sell very high—say fifty dollars or more. Almost the same observations may be made with regard to Louisville, Cincinnati, and Jeffersonville, which are situated in the states of Ohio, Kentucky, and Indiana; these places already possess great trade, and from the abundance of minerals, coal, lime, iron, salt, and lead, which are found in the neighbourhood, they must continue to increase. Farms, therefore, purchased in their vicinity, are certain to rise in value, and, with attentive cultivation, will, in the meantime, pay the cultivator abundantly for his labour and capital. Cincinnati particularly is a place of great activity, and persons who settle in its neighbourhood will easily find society to their liking; it presents, indeed, though so remote from European cities, no difference nor any inferiority in this respect. It is right to mention, however, that the whole of the western country, and, indeed, of all the countries which are in progress of settlement, are overrun with a swarm of speculators in land, and in projected establishments, new cities, manufactories, &c., all whom the monied emigrant ought to avoid as a set of leeches. Americans may deal in those matters, and may perhaps profit by them; but emigrants never can do any thing but involve themselves in difficulties by such schemes. Let them look to *certainties exclusively*; the quality of the land, the healthiness of the site, the neighbourhood of a market already established; these are the only considerations that should weigh with them, and no other. In short, to those who have capital, we would say, without hesitation, choose your abode near some of the principal towns; it is almost indifferent which. The soil of the western countries on the Ohio is the richer, and its produce more varied and luxuriant, but the prices of agricultural produce are lower than in the old states, and labour dearer. This is the sole and essential difference; except, indeed, to those who wish to speculate in buying land, by adding to its improvements, and then selling it at a higher rate, when their own labour, and the increasing density of the busy population around them, shall have added to its value. To persons who wish to make money in this way, the vicinity of the rising towns in the western states is certainly a field of high promise, and many have already realized large sums there by proper management in that manner.

Mechanics, Farm-Servants, and Labourers.

Mechanics and labourers, in looking for a situation where they may settle, will be guided by very different views from those of persons possessed of capital. The latter, if they wish to buy land, will prefer to have it in a place where labour is cheap and farm produce sells dear. The man who lives by his wages, on the other hand, would have labour high, and all manner of provisions cheap. We have advised those possessed of capital to look for settlements as near the large towns as possible, where markets and labour are most easily procured. The other class we would refer to the lists we have already given concerning the rates of wages and the cost of living; they will find there all the information which is requisite, or can be given, for determining whether they should proceed to America or remain in this country, as well as for their settlements when there. It was impossible to obtain accounts of the wages of every description of tradesmen; but by comparing the rate at which those in any one business are paid there, with the wages which the same persons receive in Britain, a pretty safe conclusion may be gained with respect to the rest. In regard to the places to be chosen for settling by mechanics, farm labourers, and others who look for work, we believe, that to those who possess funds sufficient to carry them forward to the western or inland states, there can be no doubt but these afford the preferable field for them, both in respect to wages and cheapness of living. The towns on the Ohio are all gaining rapidly in population and importance, from the richness of the country with which they are surrounded; and the immense quantity of minerals found there, coals, &c. (as already remarked) make it probable, that if manufactures be ever established any where in America, it will be here. The carriage of foreign manufactured goods is very expensive to a country so remotely inland, and to which they have to be carried through so many canals, rivers, or railroads; and the district itself produces cotton, silk (if cultivated), iron, lead, coals, &c.; so that there is here a *bonus* for manufacturing on the spot which hardly any other country possesses. The consequence begins to be already felt; manufacturing establishments are begun, wages are high, and the price of living is withal exceeding low. To mechanics and labourers, therefore, who have money to defray the expenses of the journey, we cannot but say that the western states present by far the most favourable opportunities. The following extract of a letter is from Cincinnati, on the Ohio:—

"The improvements in Cincinnati are rapidly increasing: the communications opened by means of the canal and the new roads give an impetus to trade. Whatever number of artizans, mechanics, and labourers come out, they will find abundant occupation. The soil is excellent. Engineers are in great demand. Engravers, particularly those who will work in general work, as maps, names, &c.; card-manufacturers; tinmen and braziers; bell-hangers, with a knowledge of casting or directing in that department; baking, brewing, and malting; are good trades. Glovers, stocking weavers, first-rate plane-makers, turners in steel, iron, brass, and wood, are much wanted. Carpenters, joiners, builders, plasterers, bricklayers, stone-masons, plumbers, all who are good at their business, and labourers, can get plenty of work, at 3s. or 4s. per day. Gardeners and mechanics average 4s. 6d. to 9s. per day, curriers, 9s. per day, journeymen's wages. Tailors get 20s. for making a coat. Hatters do well."

Let it be recollected, that, with these wages, flour is at 9s. per 112 lbs.; mutton at 2d. per lb.; sugar, 4d. to 5d. per lb.; coals, 5d. per bushel.

It may now be asked, what additional expense will be required to take a mechanic to Cincinnati, after he has reached New York or Philadelphia? To this we find it answered, that the journey from New York to Wheeling (a town on the Ohio) costs 25 dollars, or L.5, 12s. 6d.; and from Wheeling to Cincinnati, by steam-boat on the Ohio, the fare is 10 dollars, or L.2, 5s. The whole expenses, therefore, from New York to Cincinnati, are L.7, 14s. 6d. The journey may now be made, by the canals and steam-boats, to Buffalo, on Lake Erie; thence to Cleveland; and from that place, by the canal, to Cincinnati. This will reduce the expense somewhat. The same letter from which we have quoted above, mentions, that a family of respectable persons had arrived at Cincinnati from England, and that the whole expense of their journey (with 2500 lb. luggage) was L.75. But there is no occasion for going even so far as Cincinnati; Wheeling itself, or Pittsburg, which, though still on the Ohio, is much nearer New York, present quite the same inducements to mechanics of all descriptions.

Labour is in the greatest demand every where. The people are not able to avail themselves of the riches of the country which they inhabit without assistance. Mr Flint, who travelled on foot, was stopped by the farmers asking him anxiously if he "*knew of any traveller who would rest himself, and thrash for a few days;*' and Mr Stuart of Dunearn, after telling one of the Ohio settlers the work usually done by farm-servants in Scotland, was charged, on departing, not to neglect sending some of them to America, if possible.

It is not in one or two districts of the Union that this demand for work-people exists, but every where. The towns immediately on the coast are generally better supplied with tradesmen, labourers, &c., than those inland, because emigrants first land there, and often apply for employment as soon as they go on shore: but in all that we have heard on the subject, we find no instance of a person who was willing to work, and who did not find employment.

Persons who wish to buy Small Lots of Land.

Besides emigrants possessed of good capitals, there are often men who are acquainted with farming business, and with that only, but who have not money to buy improved land, and who wish, therefore, to depend on their own industry for clearing ground for themselves. Many such men, after persevering for years, with their families, in unrequited labour in this country, have gone to America, and become proprietors of well-improved and rich farms. We could quote numerous examples of this kind: the following is taken from Mr Flint's interesting publication:—

"J. M., a man from the county of Edinburgh, arrived here (near Pittsburg), and had settled with his family, seven sons, two daughters, and a son-in-law, about ten months before I met him. He has purchased 480 acres of land; built two log-houses and a small stable; cleared and enclosed about 22 acres, which is nearly all under crop; deadened the timber of about 80 acres more; and planted an orchard. In addition to these improvements, his sons have wrought for a neighbour to the amount of a hundred days' work. He has a horse, a cow, a few hogs, and some poultry. I inquired if he felt himself happy in a strange land. He replied, that he would not return to Scotland, though the property of which he formerly rented a part were given him for nothing."

This instance—and hundreds of others might be quoted—will show that people from this country, with a stock of from L.50 to L.100, may establish themselves well in America. A smaller sum than these will hardly suffice to land with, if the settler intends to buy land immediately; because eighty acres of land (which is the least quantity sold by government) costs L.22, 10s.; and though something were done to raise a crop the first season, the other expenses of a log-house, &c. would absorb every thing. The price of government land is required to be paid immediately. We shall not dwell farther on the subject of settling on new land, clearing the ground, &c., but beg to refer our readers to what has been already said concerning it in the article on Canada, where the practice is the same as in America.

We shall only give the following quotation, describing the situation and life of cultivators in the woods:—

"The settlers in the woods appear to be the most contented and independent people, in their way, I ever met with: perhaps with only a log-house unplastered, containing two rooms, one above and one below, sometimes only one below, with a large open fire-place and a log-fire. The chimney back and hearth built of stone, picked up about the farm; a boarded floor unplaned, perhaps hewed only, if too far from a saw-mill; one or two small glass sash windows, and sometimes at first none; doors and gates with wooden hooks and hinges. A few articles of common household use; two spinning-wheels, one for flax and one for wool, with reaves of spun-yarn hung round the inside of the house on wooden pegs driven into the logs; an upright churn; a rifle-gun; a dog or two; an oven out of doors, at a little distance from the house, built sometimes of clay, sometimes of brick or stones, often placed on the stump of a tree near the house, and with a shed covered with tree bark to keep it dry; a yoke of oxen, some young steers, 2 or 3 cows, 8 or 10 sheep; perhaps a horse, or a span (yoke); a sleigh waggon, a plough and barrow, the last perhaps with wooden teeth; these form all their riches except their land, and on this they often raise 100 or 200 bushels of wheat, 80 or 100 of Indian corn, some oats, peas, and perhaps buckwheat and a patch of flax; and fatten three or four hogs and a cow, or a yoke of oxen, in a season, besides seven or eight more store pigs, and a sow or two. Those who brought a little money with them, or were fortunate in having a family of industrious sons, get perhaps a good frame-house, or, at all events, a good frame-barn, 80 or 100 acres of land cleared; grow 400 or 600 bushels of wheat; other things in proportion; with 2 or 3 yoke of oxen, 12 to 30 fat hogs, 2 to 5 horses, &c., half of them or more brood mares."

The following is a ruder picture of industry:—

"In Maquapin county (Illinois), one of our frontier men settled himself on government land three or four years since, with 4 or 5 sows for breeders, worth as many dollars. In 1829, he drove 42 fat hogs to market, which he sold for 135 dollars (L.30, 7s. 6d.) The amount of corn given to the whole before he drove them did not exceed one bushel. They lived on the *range*, and grew fat on *mast*, that is, beech-nuts, walnuts, acorns, &c.; had they been fed on corn, they would have sold higher. Of the proceeds, 100 dollars (L.22, 10s.) were applied to pay for 80 acres of land on which he had settled; the remainder served to pay some small debts, and to purchase his salt, iron, and groceries for the year. This is not an extraordinary occurrence, but one common in that country."

PURCHASING LANDS.

Lands are sold by the British and American governments in much the same manner, and at nearly the same prices. In our colonial possessions there are public sales of land at upset prices, and at these they may afterwards be obtained, if necessary, by paying instalments. In the United States there are public land-offices in the chief towns, at which maps of the sold and unsold lands are kept for inspection. Lands are first offered for sale by public auction, and are put up at from a dollar and a quarter to two dollars per acre. If no one offers these prices, they are exhibited on the land-office map, and may be obtained at any subsequent period. On the maps, sections of a square mile, and quarter sections of 160 acres, are laid down; six miles square constitute a township. The sixteenth section of each township is reserved for the support of a school. The lands when bought are payable one-fourth part of the price at the time of purchase, one-fourth at the expiry of two years, one-fourth at three years, and the remaining fourth at four years. For money paid in advance at the land-office a discount of eight per cent. per annum is allowed, till instalments to the amount of the payment become due. For failures in the payment of instalments, interest at six per cent. is taken till paid.* There is thus little difference in the mode of disposal of public lands in Canada and the United States. The deed which confers the right of property in the states is very simple. It is printed on a piece of parchment of the quarto size; the date, the locality of the purchase, and the purchaser's name, being inserted in writing, and the instrument subscribed by the President of the United States, and the agent of the general land-office. It is delivered to the buyer free of all expense, and may be transferred by him to another person without the intervention of stamped paper, law practitioners, or those absurd feudal usages which continue to disgrace the transfer of landed property in Great Britain. Emigrants in going into the woods to make a selection of lands, will do well to take with them an extract from the land-office map applying to the part of the country they intend to visit, and by this they will discover entered from unentered lands.

The public land is, of course, totally uncleared, and untouched by the plough; some of it is more heavily timbered than other portions, and it is of very various quality, that on the banks of rivers and alluvial grounds being exceedingly fertile, and other parts being either rocky or marshy, so as to be either too unhealthy, or too unprofitable to be cultivated. The settler, however, has his choice, and, by going out into the woods, he may fix upon a lot to his own mind. An enterprising cultivator, particularly if he be a stout man, with a family of sons, may do very well upon such lands, because the original price is small; and after clearing them to some extent, and erecting one or two log-houses and barns, he can either extend his cultivation (which is easy after crops are got for the first three seasons), or he may sell at a considerable advance as population begins to increase around him, and as settlers arrive, who are not inclined to make first beginnings in the woods for themselves.

When lots are advertised for sale, there are persons who make it their business to go out to survey the whole tract before any one else has examined it; and by remaining in the woods for months, sleeping often in the open fields, and undergoing great hardships, they get acquainted with all the natural advantages of the land, the spots where there are water-power, minerals (such as salt-springs, &c.), healthy, open, or fertile grounds, and select such of these as they choose, in order to sell them again at a profit. This practice raises the price of the best lands, and it is one which can only be followed by natives well acquainted with the face of the country; but it cannot be said to have much effect in retarding settlements, as the persons who follow it seldom have very large capitals, and are soon willing to dispose of their purchase at a reasonable advance to those who intend really to avail themselves of the natural advantages which the former have been at the trouble to search out.

A speech of Mr Clay, of Alabama, furnishes an account of the lands belonging to the general government which remained on sale in 1828. The whole quantity was 83,110,873 acres, of which, however, only about seven twelfth parts were of quality for cultivation. Of more than seven millions of acres in Ohio, only 200,000 were considered first-rate, and 666,000 unfit for cultivation. Of more than ten millions of acres in Indiana, less than one and a half millions were considered first-rate, and about two and a-half millions unfit for cultivation. Of more than thirteen millions of acres in Illinois, three millions were considered first-rate, and six millions unfit for cultivation. Of about thirteen and a half millions of acres in Missouri, 159,000 were considered first-rate, and 5,700,000 unfit for cultivation. Of about thirteen and a half millions of acres in Alabama, 687,000 were considered first-rate, and nearly 7,000,000 unfit for cultivation.—No account seems to have been given of the lands in Michigan, a large and very fertile district lying around the lake of that name, and on the west borders of the Huron. The greater part by far of this immense territory is still unappropriated, and remains for sale.

These are the public lands, but there are vast quantities of ground in the hands of individuals which have not yet been cleared, or only partially so; and the prices at which this is to be had vary according to the quality of the land, its situation with regard to roads and markets, or the work which has been already done upon it. Large quantities of this description of lands are to be had in the north-western districts of Pennsylvania, at from two to four dollars per acre; many portions of it are fertile, situated on healthy mountain sides, and in a climate more nearly resembling that of Britain, than is to be expected in the low, though rich vallies of the western states, where (except those of Michigan) the public lands are chiefly situated. In the other old settled states there is not so much of this kind of unoccupied land; though, certainly, when it comes to be in America as it is here, where every inch of ground is wanted for raising food, an immense quantity of what is now despised, will, by the operations of draining, trenching, and reclaiming, be brought into productive cultivation. In these states, particularly New York, there is, however, always abundance of properties in the market, parts of which have been long farmed, and which have houses and offices erected on them, for extending the cultivation of their remaining acres. These are offered at various prices, according to their advantages; and to gentlemen who have skill and enterprise to introduce better and more careful modes of farming, they offer admirable capabilities. The profit which has been hitherto realized in America, has been by merely breaking up the woods and prairies into corn land in the roughest and most unskilful manner; but a new field of enterprise and wealth remains to those who shall introduce, in the settled states, better breeds of cattle, and more scientific modes of agriculture. The Americans, as has been already stated, entirely neglect the use of manures; they often shovel the refuse of their stable-yard into the nearest river; and one farmer is mentioned, who, rather than remove a dunghill which had gathered in his court, chose to build a new set of barns.* The national habits lead them continually to think of breaking up new land, and they always choose to do this, rather than manure the old. They prefer, in short, taking their crop off a large field carelessly and unexpensively cultivated, to getting the same returns from a smaller piece of ground skilfully prepared. This is obviously a want of thrift as well as of science, and it is for this reason that we say that good farmers, with some capital, might take advantage of the half-improved lands which are on sale in the settled states,† and by buying them at the very moderate prices at which they are offered, enrich both themselves and the country, by the introduction of more business-like modes of farming. An attention to dairy produce, an improvement of the breeds of cattle, and the introduction of kinds which would produce fat of better quality, and with less expense or trouble than the kinds now known, would be of essential benefit.

The prices at which cultivated and half-reclaimed lands are offered in the district of Genessee (a very fertile one), are from twenty to forty dollars per acre. Mr Fergusson mentions several farms which he saw on sale: one near Geneva was of 250 acres, "consisting of good loam, and some indifferent clay, well watered, but without any mill power. The wheat and Indian corn were excellent; the hedges thriving and in good order, with a double rail-fence; the mansion-house and offices were very respectable. The price asked was 25 dollars per acre, or L.1406, 5s. for the whole farm."

* In an American publication, quoted by Fergusson, the following passage occurs relative to the Michigan territory:—"The emigrants to the territory are mostly enterprising, industrious farmers, who, from not being allowed to purchase the land on credit, thereby become immediately the real owners of the soil, and, being free from debt, bid fair to become wealthy citizens. The price of unsold wild land is fixed and uniform, being one dollar and a quarter (5s. 7½d.) per acre; the terms ready money." It is here apparent that instalments are not taken, at least, as regards Michigan; and this contingency should be borne in mind by intending emigrants. Most travellers concur in stating, that the plan of purchasing lands on credit, or by instalments, is mischievous, and should if possible be avoided.

* Flint's Letters from America.

† The experiments of Mr Cobbett, while residing on Long Island, are an illustration of this remark. His mode of cultivating and preserving *ruta-baga*, turnips, and other green crops; his less expensive method of feeding hogs; his sheltering of poultry during winter, to procure eggs and chickens early in the spring; are all examples which were much needed in America.

Mr Fergusson mentions the prices at which some other farms were offered; we subjoin an abstract of the notices:—

"1. Captain Davenport's farm, on the east bank of the Hudson. It contains 350 acres, 100 of which are in wood: the soil is partly clay, partly sandy loam, and a large portion is a rich holm on the river side, of the finest quality. The price demanded is L.7, 10s. per acre, and it was sold at somewhat more than that sum soon after. The return might reasonably be expected to reach L.112, 10s., *clear of expenses*, from the flat land; and L.70 from the profit on a sheep stock on the upper portion of the farm; in whole, L.182, 10s. The price given was L.2000, and L.1000 more was required for building, fences, and drains—in all, L.3000; for which there is a return of L.180. An industrious Scots farmer, in Mr Fergusson's opinion, would not fail to realize L.200, clear of all the expenses of subsistence, &c.

"2. Next to this farm was that of Mr Knickerbocker, containing 275 acres. There is a fine holm on this farm, and the upland seemed fully better than No. 1. It was let in shares last year, and the owner received L.63. The price asked was L.4 per acre, or L.1100; and L.200 more would be requisite for houses, fences, &c. There was no more timber than seemed requisite for the use of the estate.

"3. Mr Cherney's farm, 106 acres, with wood sufficient for the use of the property—about 40 acres of very fine holm, capable of yielding, I was assured, forty or fifty bushels of oats, or other grain in proportion. This farm could be had for L.530, and would certainly return L.45 or L.50 clear.

"4. Mr Valy's farm, 118 acres; 40 acres of most superior holm; the upland good; with a stream running through it. The houses appeared to be new. This farm could be had for L.400, and the return could not be less than from L.35 to L.40, clear of all charges.

"5. A farm of 300 acres, occupied by Colonel Grant, at a rent of 300 dollars (L.67, 10s.) The soil is good loam; nine parts of it are clay: a new dwelling-house, and good barn, with a valuable wood lot. It might be bought for L.1500.

"The whole of these properties were evidently susceptible of great improvement, though in foul and bad condition. The local situation is good, the Champlain canal passing within half a mile, though separated by the river. The roads are tolerable."

The account given of these properties by an intelligent observer and agriculturist, will serve to convey an idea of the prices of land, and the returns of the capital and industry employed in American agriculture. In all cases we believe it to have been well proved, that no person should buy more land, however cheaply offered, than he can immediately cultivate with advantage. The capital expended in buying superfluous ground is completely locked up from use; and that circumstance, in a country where every disposable dollar can be employed with certain profit, is a downright and pitiable loss. There are some persons, indeed, who, as has been already mentioned, speculate in land, buying large quantities in order to sell it again, as it becomes more valuable by the increase of population; but such adventurers require to have well studied the natural advantages of the district, and it is not a speculation for emigrants.

To conclude, then, on this subject: Land in new districts, chiefly in the western states, may be had for a dollar and a quarter per acre; in places partially settled, unreclaimed land fetches from two to four dollars; in very favourable situations, perhaps a little more. Ground partially opened, and cleared of trees, is offered at all manner of prices, according to the labour bestowed on it, from four dollars to forty.

RENTING LAND.

There is little of what is called renting land in any part of the states; but where there is, the produce is generally divided into certain proportions between the owner and tenant. Sometimes each receives an equal share; sometimes the owner gets a third, according to the improvements on the land, and its quality; sometimes tenants take land "*on shares*," with the landlord, on condition that he furnishes them with seed-corn and firewood; and then he receives one-half of the crop. In the western country of Illinois, &c., it is not uncommon for the owner to give a man "team, tools, and board, besides one-third of the crop," for labouring a farm. Mr Pickering mentions that, in the neighbourhood of Baltimore, he was asked a rent of 18s. per acre for a lot of fifty acres, only half cleared; for another lot of very rich land, the rent asked was twelve dollars, or L.2, 14s. per acre.*

These lands had the recommendation of being situated near the markets of Baltimore; and it must be recollected also, in explanation of the high sums demanded, that the rent of land in America by no means bears the same proportion to its price as it does in England. With us, it brings twenty-five years' purchase of the rent. In America, it is freely sold at sixteen and seventeen years' purchase. This must be owing to the many profitable ways in which ready money can be employed in that country.

CHOICE OF LAND FOR SETTLING, IN RESPECT OF HEALTH AND NEIGHBOURHOOD.

It is of the greatest consequence that the land which is selected be in a healthy situation, in whatever district it be chosen; and for ascertaining this, the emigrant must examine the spot himself. Let him trust the report of no other person: land dealers and others naturally commend tracts of ground which they have an interest to sell. The people of the neighbourhood are also to be distrusted, because they are all anxious to have settlers near them, from the additional value an increasing population gives to their property. There can, however, be little difficulty in making the choice. In the first place, the neighbourhood of all marshes is to be avoided, as well as of rivers, which, from their sluggish course and low banks, appear to overflow and stagnate in time of floods. Such situations are almost always liable to agues and fevers. The same may be said of low moist prairies (meadows), whose great fertility should never tempt any settler from this country to establish himself in them. An elevated spot, where the air circulates freely from all points of the compass, is most desirable. If circumstances should induce the settler to fix himself near any of the great rivers, it is asserted that a residence chosen as near as convenient to the margin of the stream will be more healthy than those situated a few hundred yards distance, in what is called the "Interior of the bottom." Along the Mississippi and Missouri, the banks are generally higher than the ground a little distance inward; and from the porous nature of the soil, this interior land absorbs moisture from the river, and remains always damp. So much is this the case with regard to the Missouri, that all the waters which it receives from its tributaries do not increase the stream, which is, therefore, as large 1000 miles from its mouth as it is where it falls into the Mississippi, after having received more than a hundred rivers in its course. This circumstance is attributed chiefly to the water being absorbed by the porous soil, whence it is partially evaporated in the surrounding air. This peculiarity renders the immediate vicinity of the rivers (except where they have a rocky channel) unfavourable to the health of persons lately arrived in the country, and whose constitutions have not been yet accustomed to the climate and atmosphere.

To emigrants from Britain, we would say, that the country of Michigan and the Highlands of Pennsylvania are likely to be least injurious to their constitutions, and that more caution is required in selecting a situation in Ohio, Indiana, and Illinois—the whole western country indeed—than in the former places. That country, from the number of years it has now been settled, however, has been thoroughly explored, and all its healthy and unhealthy situations ascertained; so that a settler will seldom be at a loss, in the neighbouring towns, to find some clue by which to guide himself.

In whatever place a settlement be chosen, it is of the utmost consequence that the *house* be on a dry and airy spot, and that it have a spring, or clear running stream, of good water, close by, for household purposes: some, to secure this object, pitch on the banks of a pool or small lake as an eligible situation, which is the worst place possible, both because the water is often stagnant and unwholesome, from the dead leaves and vegetables lying in it, and because the effluvia from such water is apt to generate disease in those who are constantly near it. The floor of the house should, if possible, be laid with some hard dry substance; and a little fire should be kept in the evenings, even when the weather hardly seems to require it, because this serves to maintain a wholesome circulation of air, and to dry more quickly the green logs of which settlers' houses are first constructed. With regard to clothing, it is of consequence that those who enter upon this new life should make themselves somewhat comfortable in this respect; and though they must for a time submit to hardships, by no means to imitate the savage affectation of many of their neighbours, who think that, as they are in the woods, they ought to take a pride in living like Indians. These people often neglect all cleanliness and comfort, both in their persons and dwellings, and are vain of telling how much they expose themselves to the weather, both in sun and dew, and how well they have stood it for years. Let none of these vain-glorious boastings have any influence with the new settler: he ought, in every point, to maintain habits as little removed from his former way of life as is consistent with his situation; keep his clothes and house as snug and comfortable as he finds it possible at the present time to make them; and expose himself neither to the weather nor fatigue, except where there is some useful purpose to be gained by it; never at least to do so for the mere sake of braggadocio, or to imitate the ostentatious hardiness of some of his neighbours. He will find the Scots proverb, "hooly and fairly gangs far," as true in the back woods of America as at home. Steady and continued perseverance in clearing his lands and securing his harvests, with patience and good humour under such privations as are unavoidable, are chiefly essential to the success of the emigrant.

As a farther advice to settlers entering into the woods or new lands, we would say, that if two or three can go together, it assists them materially: a family with several stout sons has a very great advantage in this respect. A few acquaintances joining together, and taking a piece of land to divide among them, can assist one another in clearing it, or in getting in their harvest; and if any accident happens in one of their families, the good offices of the rest serve greatly to relieve its inconveniences. It may happen, for instance, that some of them gets a hurt, or is laid by for a week with sickness; and if this were to occur during harvest, or in seed time, every thing would be lost without the assistance of the rest of the company. If such partnerships cannot be formed before leaving home (which, when the emigrants are not from the same neighbourhood, cannot be expected), they may be and often are arranged to much advantage during the passage; and intending settlers will often find it advisable to sacrifice some of their own views as to the district in which they mean to settle, in order to have the assistance of steady companions elsewhere. Should no prospect of this kind occur, and should the emigrant resolve to choose a spot and settle for himself, his next object ought by all means to be to study the dispositions and characters of his nearest neighbours, and accommodate himself to them with cheerfulness and good humour. In return, he will almost always find them obliging, and ready to afford him information and assistance. Both after he is settled, and while on the voyage, he ought to avoid all bargain-making people, many of whom he will find, who have continually something to sell or to exchange, of the very best kind, as they say. These insidious bustling characters ought to be specially marked, and emigrants ought never to buy any thing but what they have already determined on, or see to be absolutely necessary.

AGRICULTURE, SOIL, AND NATURAL PRODUCTIONS.

In North America, oats do not produce nearly so heavy a crop as in Scotland; and wheat, though of excellent quality, is not quite so productive as it is here. Part of these deficiencies may be attributable to the careless cultivation of the Americans, who seldom manure their lands; but part also is undoubtedly owing to the difference of climate.

The grains usually cultivated are wheat and Indian corn. The former, with such cultivation as the Americans bestow on it, produces about 30 bushels (or 7¼ bolls) per acre. The Indian corn yields 50 bushels (or 12½ bolls) per acre; this vegetable is cultivated in rows or drills, which are placed four feet apart, and hoed much in the same way as turnips are here; the stalk grows to a great height, and affords in the leaves a kind of grass, which cattle eat with greediness. The corn is used as food for man in a great variety of ways—as bread, as porridge (when it is called *mush*), and in puddings. When unripe, and in the green pod, it is not unlike green peas, and in that state is sold as a vegetable. Horses, cattle, and poultry are all fond of this grain, and thrive well on it.

Potatoes are also cultivated, and yield very profitable returns, good land producing 300 bushels per acre (60 bolls Scots). Wheat, however, is the most valuable crop; and though the produce is generally smaller than in Britain, the flour is of excellent quality. This crop usually succeeds maize, and is followed in succession by barley and oats, sown down with grass—although this rotation is as frequently inverted; and as maize is a culmiferous plant itself, it is not thought, by observers from this country, so useful in preparing the ground for wheat as our green crops are. With good management, oats yield from 40 to 50 bushels, and barley about one-fifth less. Rye and buckwheat are more generally cultivated than in Britain. Buckwheat cakes are one of the standing dainties of an American breakfast. The process of manuring is much neglected, both by the use of ordinary stable manure, and that of lime and gypsum. The Americans say that the labour required in the application of manure would be so expensive, from the high wages of all their servants, that the returns would not be profitable. But the truth seems to be, that they are more familiar with the process of breaking up new land, of which they have abundance generally within reach, and that they have never yet given manure and scientific agriculture a fair trial. Mr Stuart of Dunearn calculates, that, under their present system of management (the slovenliness of which is universally remarked), the average crops of all sorts of grain, maize excepted, are nearly a half less than in Britain. The climate is favourable for the making of hay, which yields a good return. Turnips, ruta-baga, pease, lucern, are all cultivated to advantage.

The following notice of the produce of some *well-cultivated* land, in the northern part of the state of New York, will give an idea of American agriculture:—

10 acres	of orchard ground produced		25	tons hay.
26	...	maize ...	1580	bushels.
4	...	wheat ...	140	...
1	...	flax ...	600	...
8	...	oats ...	560	...
1	...	barley ...	60	...
2	...	potatoes ...	1000	...
2	...	vegetables fattened 400 chickens.		

Much of the industry of the American farmers is exercised in rearing cattle, hogs, and poultry, for the market of the towns. The hogs are fed a good deal on Indian corn, and the plenty of that kind of grain often makes it be given to them, when they might be fattened on much cheaper stuff. The rearing and feeding of cattle is carried on very systematically, and to a great extent; there being drovers, as in this country, who purchase the beasts from the farmers, and often drive them as far as 600 miles to be sold. New York consumes about 700 oxen per week; these weigh on an average 55 stone of 14 lb., and the butcher

* The rents asked in America are certainly higher than might be expected from our ideas of the relative proportions of the price of land and its rents in this country. But as Mr Pickering, on whose authority we state the above facts, did not really take the land, and only inquired concerning it to gratify his curiosity, we are disposed to think a real bidder might have heard a lower price. In another place, Mr Pickering says he was asked three guineas per acre of rent—a sum quite incredible *to be paid*.

pays for them from L.12 to L.14 per head. Men employed as drovers receive 4s. 6d. a-day, with food for themselves and cattle. It is allowed that a great deal might be done in all the states to improve the breeds of fat cattle, who, though always in good condition, often take more care and more feeding to bring them into that state, than some of the profitable English kinds would do.

The horses of America are highly praised by good judges. Mr Fergusson of Woodhill says (speaking of those in New York state), that he seldom passed a farmer's door without noticing horses, which, for their action and figure, were worthy of being transferred to any gentleman's stud. They are, he adds, kindly treated, well fed, and *remarkably* docile. They are in general about 15 or 15½ hands high. Those of settlers in the less improved parts of the country are, of course, a smaller and inferior breed, but hardy, tractable, and easily fed and stabled.

The sheep of New York state are Saxon and Merino, and the wool brings 2s. 8½d. per lb. in good years; in others, only 2s. 1d. They raise fine crops of turnips (where this management is attended to), and rear many sheep, the prices fluctuating: ewe fetched in 1831, 9s.; the year before, only 4s. 6d. Some farmers brought a sheep-doctor from England, and gave him 27s. each 100 sheep for his attendance to this kind of stock only.

The prices at which farm produce sells vary exceedingly in different places, according to the demand and the distance from markets. In New York state, wheat brought 1 dollar to 1¼ dollar per bushel; maize, 2s. to 2s. 6d.; oats, 1s. 2d. to 1s. 6d.; barley, 2s. 11d.; potatoes, 1s. 3d. Good ordinary horses, L.20 to L.25. Oxen, per pair, with yoke and chain, L.20 to L.30. Cows, L.4, 10s. to L.6. Merino sheep, 9s. to 18s.; Saxony, 13s. 6d. to 45s.; common sheep, a sort of coarse small Leicesters, 4s. 6d. to 9s. after shearing. Brood sow, L.2, 5s. to L.3, 10s. Hogs, 1d. to 1½d. per lb. on live weight. Geese, 2s. 10d. a pair. Turkeys, 2s. 1d. each. Fowls, 6½d.—*Utensils* cost: Farm-waggon, L.13, 10s.; ox cart, L.10; ploughs, L.1, 10s. to L.1, 16s.; good double harness, L.18.

Dairy articles, from the labour and attention they require, are high in proportion to other things; and, from the same cause, they do not pay the farmer so well, nor are they so much attended to.

Orchards are a matter of considerable attention in America, and apples, peaches, and cherries, thrive in the greatest beauty and luxuriance. The orchard itself is a considerable ornament to a farm-house, and its fruit can be disposed of to advantage either fresh or preserved, if near a town; and if not, it yields a luxury to the farmer and his family, which their whole earnings could hardly purchase in this country. Little attention is paid to the appearance of gardens, which are in general ploughed; labour being too dear to admit of spade husbandry; the Americans, indeed, scarcely know how to handle that instrument.

Many parts of the Union are highly propitious for the growth of flax and hemp, the hemp of Kentucky being found not inferior to that of Riga. Hops thrive well in New England. The rearing of the silk-worm is a profitable occupation in Connecticut. Cotton, tobacco, rice, indigo, and sugar, may be said to form the staple products of the more southerly states. The vine, which seems to be indigenous to America, and is found in the forests, has within these few years been successfully cultivated in Indiana, and in many other parts of the western states, the first cultivators being a body of Swiss settlers. Of one of these vineyards, Mr Flint thus speaks—

"We have witnessed nothing in our country in the department of gardening and cultivation which can compare with the richness of this vineyard in the autumn, when the clusters are ripe. Words feebly paint such a spectacle. The horn of plenty seems to have been emptied in the production of this rich fruit. We principally remarked the blue or Cape grape, and the Madeira grape. The wine of the former has been preferred to the claret of Bourdeaux."

In the northern states, farmers make sugar from the maple tree; and as the produce is of excellent quality, and cheaply procured, this becomes a branch of industry well worth attending to, at least for domestic consumption. The tree flourishes best in hilly districts, where it rises to the height of sixty or seventy feet, with a thickness of one foot or more. The work of making sugar from its juice commences in February or March, when the frosts are most intense, and no other farm-work can be done. Holes are bored, ascending about half an inch obliquely into the tree, by means of an auger three quarters of an inch thick; into these, small pipes of the branches of the elder tree are inserted, and the sap flows through them into troughs placed below. After a quantity is collected, it is put into boilers holding eighteen or twenty gallons, and boiled to a syrup, which, after cooling, is strained through woollen cloths. It is then boiled repeatedly to a proper consistency, and afterwards put into moulds. The whole process is carried on in the woods, where small sheds or tents are erected for the boilers, and for sleeping. Three persons will attend 250 trees, from which they produce 1000 lbs. of sugar (20 lbs. to each tree), better than the brown sugar of the colonies, and, when refined, as beautiful as any that can be made in England. The West India sugar can be brought to market cheaper than the produce of the maple; but to those farmers who make it for themselves in the winter season, this American sugar may be said to be got for nothing.

There are some fruits cultivated in the United States which are not known in this country. Among these is the papaw-tree, which is not uncommon in the bottoms which stretch along the rivers of the middle states, but is most plentiful in Kentucky and the western parts of Tenessee. It attains the height of twenty feet, about four inches thick. The fruit resembles a cucumber, and, when ripe, is of a rich yellow: the pulp resembles egg custard in consistence and appearance; it has the same creamy feeling in the mouth, and unites the taste of eggs, cream, sugar, and spice. It is exceedingly nutritious, and in its native woods was a great resource for food to the Indians. So many tastes are compounded in it, that it is said no person at first eats it without being tempted to laugh at the unexpected and whimsical combination. The *persimon* is another fruit not known in this country, which grows to considerable perfection near New York: the ripe fruit is about as large as the thumb, of a reddish complexion, round, fleshy, and furnished with six or eight stones; but it requires to be mellowed by the first frost before it be eaten, when it becomes very palatable. The fruit is produced in amazing abundance, and is used either for eating from the tree, for making a kind of beer, or for distillation. The tree, however, is not, upon the whole, more advantageous than the apple and peach.

There are few persons established on farms in the states who have not access to some stream in their neighbourhood for fishing, if they are fond of that pursuit, either for amusement, or as a means of providing food for their families. Every one has the privilege to avail himself of all the treasures of the waters, without let or hindrance; and they are worth taking advantage of. The shad and the salmon, of excellent kinds, abound in the rivers of the eastern states, and beautiful trout are taken in those of the north. Among the fish of the western waters are noticed the perch, one of which, the buffalo-perch, is a fine fish for the table, weighing from ten to thirty pounds. The pike, the perch, and other fish of the Illinois, and the rivers connected with it, are represented as excellent; a line called a trot-line, drawn across the mouth of the Illinois, with hooks at regular distances, took five hundred pounds in one night. The whole of the fish of the Mississippi are not, however, of equal quality for eating; the kinds which are chiefly admired are the trout, the small yellow catfish, the pike, the bar-fish, and the perch.

In recounting the privileges of the farmer, it would be improper to pass over the game, which is abundant in the American woods, and which may sometimes afford amusement, sometimes an agreeable variety of food. The mallard, or common wild-duck, is found in every fresh-water lake and river of the United States. The canvass-back duck is an American species, altogether unknown in Europe; they are found in the rivers Hudson and Delaware, but principally frequent the waters of the Chesapeake, where they feed on the roots of a certain grass-like plant abundant in these streams; they float about in shoals, but are exceedingly shy, and difficult to be shot. The delicacy of their flesh, and the high price they bring in towns, render them an object of lucrative pursuit to numbers. In general, however, with regard to game of all kinds, though plentiful and excellent, it is no object with the chiefly colonist, who does not care to waste his time in following it. Mr Fergusson of Woodhill met in Canada with a young Scotsman who had been a poacher in Scotland, but was now settled and thriving well on a farm of one hundred acres in his new country. Mr Fergusson said to him, "You will need neither certificate nor qualification here: what do you principally shoot?" "Indeed, sir," said he, "if you'll believe me, I scarce ever think about it, for there's naebody here seeks to hinder us." A herd of deer only two days before had wandered past him while at the plough, yet Walter felt no inclination to run for his rifle, though it stood loaded in the house.

WAGES OF LABOUR, AND COST OF LIVING.

The price of articles varies in different places, so that no general average can be stated either of wages or of the cost of living: both are different in different circumstances. But we have selected, from the best authorities, such lists, for several of the chief towns and districts, as will enable the reader to judge for himself.

Albany.

For Albany, on the river Hudson, we have, from good authority, the following statement:—

Wages.—Men for general farm work—Summer, L.2, 5s. per month; winter, L.1, 7s. per month. Harvest work, cradling wheat, 4s. 6d. per day. A cradle scythe is said to cut four acres a-day, and requires one man to bind to each cradler. Hay cutting, 2s. 7d. per day. Board found besides to all these. A steady active farm overseer or bailiff has about L.45 money wages, a capital house, a cow, and some other advantages. A man gets 8 guineas (or 21 dollars) for three weeks' work drying hops. Good cooks, 18s. to 27s. per month; chambermaids, 13s. 6d. to 18s. per month; washerwomen, 4s. per day; servant girls, 18s. to 24s. per month.

Provisions.—Wheat, 6s. 6d. per bushel; beef, per quarter, 18s. to 23s.; per lb., 2d. to 4d.; mutton, 1½d. to 2d.; veal, the same; pork, 22s. to 27s. per cwt.; butter, 5d. per lb.; cheese, 2d. to 4d. per lb.; eggs, 4d. to 5d. per dozen. Brandy (French), 4s. 6d. per gallon; gin, 3s. per ditto; whisky, 1s. to 1s. 1d. per ditto; excellent table beer, 4s. 6d. per barrel of 32 gallons. Firewood, 13s. 6d., country price; 22s. to 27s., town price, per cord of 128 cubic feet, delivered four feet long, and cost 2s. per cord to cut to lengths required for use.

"The American farmers," says Mr Fergusson, "live comfortably, and at a very moderate expense. Candles and soap are generally manufactured from kitchen refuse. A good housewife assured me that the butcher-meat for her family, 15 in number, did not exceed, in *whole*, one shilling per day (three meals), except when she allowed them turkeys and other poultry, when she reckoned the expense at 2s. 6d. The flour consumed did not exceed 4s. 6d. per week. They have fruit, both fresh and preserved, in the utmost profusion; and the cider barrel is always ready broached. A good many articles of clothing are spun and woven at home; and the geese are subjected to periodical contributions, towards the bedding of the household, or the feathers are sold at a good price."

Baltimore.

Mr Pickering, who went to this town to look for a situation as overseer of a farm, mentions the following prices as current there:—

His own lodgings and board, at a respectable ship-carpenter's (including washing and mending), 13s. 6d. per week.* In the markets, beef, 2d. to 3½d. per lb., the best cuts, 4½d.; pork from 2d. to 3½d. per lb., and sometimes lower; veal and mutton, by the quarter, 1s. 2d. to 2s. 3d.; good lamb, 4d. per lb. Turkeys, 1s. 2d. to 2s. 3d. each; fowls, 6½d. to 9d. each. Cabbages (drumheads), 1d. to 2d. each; potatoes and turnips, 10d. to 14d. per bushel. Wild-ducks, 3½d. to 5d. each; the canvass-back duck, a large bird, and esteemed a great delicacy, 13d. to 18d. each.; partridges, 4d. to 7d. each; quails, 1d. to 2½d. each; hares and rabbits (small), from 6d. to 1s. each; shad (a fine fish like a herring, but ten times the weight), 13d. to 18d. a pair. Apples, very fine, 13d. to 2s. 3d. per bushel; green peas, 1s. to 1s. 8d. a peck.

Ship-carpenters' wages from 7s. to 8s. per day, which was higher than the usual rate, on account of a great demand for hands at the time. A young man, bound apprentice to a shipwright, had 13s. 6d. per week, wages for first year, and 22s. 6d. per week second year, to board himself.

Philadelphia.

In the "Price Current" of Philadelphia we find the following rates given on wholesale articles:—Mess beef, per barrel of 196 lbs., 45s. to 47s. 2d.; butter, per lb., 4½d. to 5d. (best quality); biscuit, best, per lb., 2d.; mould candles, per lb., 5½d.; dipped candles, 4½d; cheese in casks, 3d. to 4d.; coffee, 5½d. Brown shirting, 3d. to 4½d. per yard. Flour, superfine, per barrel of 196 lbs., 20s. 1d.; Indian corn meal, per 196 lbs., 13s. 1d.; hams, 5d. to 5½d. per lb.; honey, per gallon, 2s. 1d.; loaf sugar, per lb., 6½d. to 8d.; brown sugar, 3½d. per lb.; brandy, per gallon, 7s. 2d.; Virginia tobacco, 1½d. per lb.; Cuba tobacco, 5½d. per lb.; wine, Madeira, per gallon, 5s. 2d. to 13s. 6d.; Port wine, per gallon, 4s. 6d. to 5s. 9d.

These are the wholesale prices; articles of provision are furnished in the markets as follows:—The best beef from 3½d. to 6¾d. per lb., according to what part of the animal is selected; fat mutton, of excellent quality, 3d; chickens about 2s. 1d. a pair; turkeys from 3s. 6d. to 7s. a pair. Butter varies, according to the time of the year, from 6½d. to 18¾d. per lb., averaging about 12½d. Superfine wheat-flour, 10s. 8d. per barrel of 196 lbs.; kidney beans, 1s. 1½d. per peck; cherries (good), 2½d. per lb.; good rye whisky, 1s. to 1s. 2d. per gallon; corn do., less.

As to the prices of labour in Philadelphia, and the surrounding country, we find it stated, that a labouring man gets from 3s. 2d. to 4s. 6d. per day, in the cities; and at farm-work, in the country, he receives from L.1, 10s. to L.2, 14s. per month, besides board and lodging. An attentive handy servant girl is readily engaged at 4s. 6d. per week (besides her board, of course).

New York.

The provision market here seems to be cheaper than that of Philadelphia, as we find the best beef quoted at 2d. per lb. Journeymen mechanics are hired at 6s. per day, and some that work by the piece earn 8s. per day. House-carpenters, bricklayers, and brick-makers, find ready employment (except in the dead of winter), at 4s. 6d. to 7s. or 8s. per day; and shoemakers, tailors, and persons well acquainted with any common or useful trade, easily find work, according to these rates. It must be remarked, that tradesmen in America work long hours, that is, from sunrise to sunset. Mr Stuart of Dunearn says of this circumstance, that he does not think the employer gets any additional work done by it, the people being much more disposed to loiter than when the hours are shorter. It may be remarked, also, that the long summer day at New York is about an hour and a half shorter than that of London.

With regard to prices generally, it deserves to be mentioned, that those of imported articles, such as

* The living was, a roast turkey once or twice a-week, fowls, beefsteaks, ham, sausages, and a kind of pudding; pies, soup, fish, &c. A variety of the above was placed on the table at every meal, and generally three kinds of vegetables, with coffee or tea at breakfast and supper.

tea, sugar, coffee, &c., are higher in places at a distance from the sea and the great towns, and that articles of home provision are cheaper there. This arises from the expense of carriage in both cases, what is produced and sold at home having always less charges on it than what is brought from a distance. Clothing is rather dear in the states, especially woollen; worsted stockings and worsted mits, for instance, are considerably higher than in England.

These notices will serve to convey an idea of the cost of living and of wages in most parts of the eastern states, where emigrants first land. They will be found to vary, as we have already mentioned, in different places, and according to circumstances; but it appears generally that there is full employment for labour, with wages according to the kind of business, from 3s. 6d. per day, with board, to 9s. per day without board, the most laborious or most ingenious trades receiving the highest remuneration. The cost of living may be inferred from the prices of beef and wheat, the former varying from 2½d. to 4d. per lb., according to the quality or the demand, the latter generally about 4s. 6d. per bushel, or 18s. per boll.

Wages and Living in the Western States.

We find the following list given for the prices at Cincinnati, on the Ohio, which may be reckoned the capital of the west, and is the point to which emigrants first direct their steps in that quarter.

Flour, 9s. per cwt. of 112 lbs.; Indian corn, from 6½d. to 8d. per bushel; mutton, 2d. per lb.; cider, 4s. 6d. per barrel; bacon, 2d. and 2½d. per lb.; shoulders, 1½d. per lb.; hams, 2½d. per lb.; freesold butter, 2½d. and 3d. per lb.; mould candles, 5½d. and 6d. per lb.; dip candles, 4½d.; coals, 4d. and 4½d. per bushel afloat, 5d. and 6d. in the yard; coffee, 6d. and 9d. per lb.; teas, 1s. 6d. to 2s. per lb.; sugar, 4d. to 5d. per lb.; copper sheeting, 18d. per lb.; old copper, 9d. per lb.; cigars, 20s. per 1000.

We have mentioned these prices for the sake of comparison; but as the western states form a country in some measure different, and almost foreign to the Americans themselves (those of the old settled districts), we shall give an account of them separately, to which we refer our readers in another page.

EXPENSES OF TRAVELLING.

Mr Pickering, to whom we have formerly referred, travelled in search of a situation as land steward, and has been particular in noticing the expenses of his journey. The following are some of his notes:—From Brunswick in New Jersey, to New York, partly by steam-boat, and partly by coach, 196 miles, 11s. 3d., luggage included; dinner on board, 3s. 4½d.—the fare, fish, flesh, fowl, puddings, pies, tarts, brandy, &c. On landing at New York, he got lodgings, after some search, at a tavern, where he paid for lodging 6½d. per night, and 13½d. for each meal; five beds in the room he slept in. Went on board the steam tug-boat for Albany; the fare 4s. 6d., one trunk included, and paying 1s. 1d. for the other. In the steam-boat the fare is higher; the distance is 145 miles; he took provisions with him for 24 hours, as did the rest of the passengers. From Albany he took passage in the canal to Lockport, near Lake Erie, distance 300 miles—fare, a little more than one penny per mile for himself and one trunk, paying 3s. 4½d. for the other, which weighed 75 lb. Passed over a ferry on the Niagara river, to Canada—charge, 13½d. This was in the year 1826.

Mr Fergusson of Woodhill travelled the same route from New York to Albany, some years later (1831). The charges of freight were then considerably lower; he went in the cabin of the North America, a magnificent steam-boat, and paid only 9s. fare for the whole 145 miles, with a very moderate charge for meals—being 2s. 3d. for dinner, including brandy, whisky, and Hollands, placed on the tables at the discretion of the passengers. He returned from Canada by the Erie Canal to Rochester: the fare from Buffalo to Rochester, 94 miles, 15s. 9d., three capital meals included—the boats good, the cabins amply supplied with books and pamphlets, and the tables with good cheer. Travelled by hired coach from Geneva to Albany, 170 miles, L.1, 11s. 6d. No extra charges given to coachmen or other persons.

Mr Fergusson afterwards went from New York to Washington, and found the charges as follows:—From New York to Philadelphia, by Bordentown (where Joseph Bonaparte lived), by steam, with 30 miles of land-carriage, 18s., including breakfast and dinner; went in the William Penn steam-boat from Philadelphia to Baltimore, 120 miles (going through the Delaware and Chesapeake Canal, 14 miles), fare 18s.—breakfast and dinner, both excellent, were charged 2s. 3d. each. From Baltimore to Washington in the stage-coach, 38 miles, fare 13s. 6d.; got a neat light coach, a pair of sleek well-fed horses, and a black driver to go to Mount Vernon (the former residence of General Washington), a distance of about 12 miles, fare 13s. 6d.

In the account of travelling expenses, it must be noticed, that passengers may always carry their own provisions when in steam-boats, or canal boats, and, by that means, reduce the amount very considerably.

MANNERS OF THE PEOPLE, AND THEIR CONDUCT TOWARDS STRANGERS.

We have now presented a fair and impartial view of the United States of America, as regards their suitability for the purposes of intending emigrants; leaving for another sheet a historic account of the country, and a variety of details relative to its commercial character and resources, but not of such immediate interest to settlers. As the preceding information has been very carefully drawn from every accessible source, and rendered as complete as possible, nothing remains to be mentioned which can concern the interest of emigrants, unless it be a few observations on the manners of the people they have an intention of residing amongst.

Few persons know or care about those little peculiarities of speech or manner in which the people of one county or district differ from those of another; as, for instance, in what the dialect of the natives of Yorkshire differs from those of London, or that of the people of the south of England from the same class in the north of Scotland. These matters are of very slight importance to the comfort of a stranger going to reside among them; but it is of some consequence for him to know if the new people with whom he is going to pass his life are kind and hospitable to those who come among them, or if they are jealous and intolerant in this manner, and disposed to repel the advances of strangers. There are many such people look on all new comers as intruders, and take every means to make them feel that the country they have come to belongs to others. Is this the case with regard to America? may be naturally asked by emigrants who think of proceeding thither. On this subject we might appeal to the many invitations which are daily circulated by the Americans and their friends, calling on all who are destitute of employment and subsistence in Europe, to come freely to that country, where they are assured of cordial welcome and abundance. But the following extracts from the journal of Mr Fergusson may show how our wealthy travellers are received there; and we shall by and bye subjoin a similar specimen of what the poor are to expect.

"I could say much," says Mr Fergusson, "were it proper, of the hospitality of New York, and of the unostentatious kindness with which my letters of introduction were received. The style of living is elegant and comfortable, and the domestic circles which I had the pleasure of joining seemed truly unaffected and happy. The quiet, modest, and amiable tone of female society particularly pleased me."

We give a second extract from the same traveller.

"I learned also, from a Scotsman in Mr Thorburn's employment, whose family had suffered heavily from sickness last winter, that flowers and parties by no means engross the sole attention of the ladies of New York. He assured me, that, within his own observation, it was quite wonderful what they continued to do, in visiting, clothing, and attending to the poor. This man left Glasgow in great destitution about a year ago. He is now in comfortable circumstances, and his family provided for; but the first fortnight which honest Saunders Lee spent in New York, a total stranger, without money or engagement, he described with a shudder, as '*perfectly awful*.'"

Mr Pickering, who arrived a total stranger, and without employment, lodged at the house of a ship carpenter, where he says he was treated with great kindness. Speaking of Christmas day, he says—

"The moment I arose this morning, I was presented with a glass of 'egg-mogg,' as they called it—a compound of rum, eggs, milk, and sugar; also with ginger-cake, and a cake with raisins in it, which is their 'Christmas cake'—all for merry-making and parties. I was pressed to one in the evening with the carpenter and his wife; a number of fine females and young men present; quite a sociable party; the females easy and unaffected; broke up early, by request of our host, next day being Sunday."

It must be recollected that the person who was thus kindly entertained was a total stranger to the whole party—an Englishman—without friends, and with very little money.

The following extract is from the letter of a female emigrant, whose husband had fallen sick on his arrival. The letter is dated

"*Brooklyn, Long Island, near New York*, 18[illegible].

"We hired a room, and my husband bought a saw, and went sawing wood, and doing any thing; and we thought we should get through the winter pretty well; but after about three weeks, he was taken ill, and it proved to be a typhus fever. We had no parish to apply to for relief; but you would be astonished at the friends we have found; for people that were quite strangers have called to know *if the sick Englishman lived here*; one kind gentleman sent for a doctor, and another good old Methodist gave me leave to go to the grocers for any thing in his name; and others were equally kind. I never thought I should meet with such friends among strangers. Husband is now mending fast."

Mr Flint says—

"To-day a vessel from Dumfries arrived; and a few minutes after she was moored, one of the brothers Messrs Ronaldson went aboard, making inquiries after the views and circumstances of the poorer classes of emigrants. He employed one of them, pointed out where several others would find work, and gave advice to the rest. This is not a new or rare instance of benevolence on the part of these gentlemen."—"Every day numbers of European emigrants are to be seen in the streets (of Philadelphia); I have never heard of another feeling than good wishes to them."

It is frequently mentioned that difference of rank or of wealth is not so much thought of in America as in this country, and that the industrious labouring man stands more nearly on an equality with his employer than with us. The following extracts relate to this subject.

Extract of a letter from a labourer:—

"A person must not think of coming here without working; and they despise drunkards; but if a person keeps steady, he is respected much more than in England; he is admitted at table with the farmer."

The following extract is illustrative of American manners in various respects. It is from Mr Stuart:—

"When they meet us walking, they, whether acquainted with us or not, frequently stop their vehicles, and very civilly offer us a ride with them, and will hardly believe us to be serious when we decline to avail ourselves of their kindly meant invitations, and tell them we prefer to walk. There are few more striking points of difference between this country and Britain, than in the numbers of people who ride and walk on the public roads. It absolutely seems disgraceful to be seen walking. The circumstance, no doubt, proves the easy circumstances of the mass of the people, as well as the value of time to a mechanic, whose wages may be from one to two dollars a-day, and who can better afford to pay for a conveyance and spend less time, than to walk and spend more."—"We have not hitherto," he adds, in another place, "seen any thing like a poor man's house, or a beggar, or any one who did not seem well-clothed and well-fed."

Such are some of the traits of character of the inhabitants of North America, who, although speaking the English language, and living under institutions strictly English in their character, differ, as may be supposed, in several respects in their manners from the people of this country. They do not lay claim to that artificiality and polish which distinguish what is called "good society" in Great Britain; they are more downright and frank in their behaviour, less ceremonious, and are in every way a more independent people in their thoughts and actions than the generality of English and Scotch. From all that we can understand of their character, they seem to possess less of the quality which produces "cringing" than any people on the surface of the earth. It may be conceived, from the extraordinary mixture of classes of persons from most European countries, and the wide field offered for adventure and enterprise, that the Americans have little of that staidness of disposition and subdued tone of mind which are characteristic of the British nation. Society, in the partially settled districts, is, therefore, still in a loose condition; and emigrants will require to be more alert in regard to their interests, and much more on their guard against deception, than in this old established country. It is deeply to be regretted, that, for a number of years, there has been a class of writers in Great Britain—we would particularly instance those of the *Quarterly Review*—and a few travellers, whose deeply-rooted object it has been to vilify the American nation in the gross, and to hold up not only their institutions and usages, but all that belongs to the country, whether in nature or art, as fit subjects of ridicule and contempt. The unworthy calumnies which have been industriously circulated by these splenetic writers, need not in the smallest degree produce hesitation among emigrants in reference to settling in the United States. The citizens of the North American Union are essentially British in their origin and character. Their other peculiarities have naturally arisen from the fortunate circumstances under which they are placed; and in which peculiarities we would equally partake, had we fewer public burdens, fewer causes to be careworn, as well as a greater scope for the profitable exercise of our industry. In comparing Canada with the states, every intelligent traveller allows, that the citizens of the Union are infinitely more active than the subjects of Great Britain. Within the colonial territories, all public works, and most of the settlements, proceed slowly, the system seeming to be rather inert; while on the states' side of the boundary, every species of work proceeds with the most astonishing rapidity—canals being cut, railways formed, and towns built, in an inconceivably brief space of time. As Upper Canada has nearly the same natural advantages as the states, and as the people, it may be presumed, are as well educated and as generally intelligent, it would seem that the true cause of the difference we specify is in the mode of conducting public affairs. It may be conceded, that the provinces are as well managed as they could possibly be; but it must also be allowed, that it is not in the nature of things that a country, with its seat of government three thousand miles distant, can be so advantageously conducted as another country, where the government is not only on the spot, but consists of the people themselves. It is not, however, our object here to draw any comparison betwixt the political condition of the colonies and states. Both have free institutions, and both possess those capabilities which can yield comfort to settlers. The honest, the industrious, and the enterprising, will do well in either, and will command respect and ascendency wherever they may fix their place of settlement.

EDINBURGH: Printed and Published by W. and R. CHAMBERS, 19, Waterloo Place; also by W. ORR, Paternoster Row, London; and W. CURRY, Jun. and Co. Sackville Street, Dublin. Sold by John Macleod, Glasgow, and all other Booksellers in Scotland, England, and Ireland.—Published once a fortnight.
Numbers, containing accounts of New South Wales, and Van Dieman's Land, with maps, for the use of emigrants and others, are in preparation.
Stereotyped by A. KIRKWOOD, St Andrew Street, Edinburgh.

CHAMBERS'S
INFORMATION FOR THE PEOPLE.
CONDUCTED BY WILLIAM AND ROBERT CHAMBERS, EDITORS OF "CHAMBERS'S JOURNAL" AND "HISTORICAL NEWSPAPER."
No. 6. PRICE 1½d.

ACCOUNT OF THE GLOBE.

The above Engraving represents some of the more remarkable Phenomena of Nature, which will be found described in full in the body of this article.—On the right is a view of Fingal's Cave, one of the most remarkable specimens of Basaltic Columns.—On the extreme left, a Submarine Volcano is seen belching forth its red-hot melted rocks from the bosom of the deep.—In the distance is a Volcanic Mountain, and to the right of it, Granitic Rocks.

ASTRONOMICAL DESCRIPTION.

The Earth, or Globe, which we inhabit, and which for many ages was supposed to be the centre and principal part of the universe, is only one of eleven primary planets, or similar globes, which revolve round the sun at various distances, and the whole of which together, including the sun, form but one of innumerable similar systems, which are disposed in the immensity of space.

The Earth is the third of the planets in point of distance from the sun (that distance being ninety-five millions of miles); in point of size, it is one of the smallest—Jupiter, for instance, being many hundred times larger. Its thickness from pole to pole is 7898 miles; in the other direction, it measures 7924. The difference of 26 miles causes an imperceptible departure from the spherical, into what is called the *spheroidal* shape; and it is assumed, as a proof of the originally fluid state of the earth, that this is exactly the form which a melted or liquid globe naturally takes in revolving in space. The revolution of our globe round the sun occupies 365 days, 5 hours, 49 minutes, and 57 seconds, which, as every one knows, constitutes a year of time. It has another revolution round its own axis, which is performed in 24 hours: this again, as every one knows, constitutes a day. The former revolution produces the seasons; the latter, day and night.

SURFACE OF THE EARTH.

The greater part of the surface of the globe is covered by sea, and the land appears insulated in larger or smaller masses within that envelope. A mass of the larger kind is called a continent; of the smaller, an island.

Of continents there are properly two. The larger and first known overspreads a great part of what is called the eastern hemisphere or half of the globe, and is divided into Europe, Asia, and Africa. Another continent of less extent exists in the western hemisphere, and is divided into North and South America.

Of islands there is a great multitude, the largest being New Holland, in the Southern Ocean, while the most important is that of Great Britain, on the north-western confines of Europe.

The mass of the earth is composed of the various substances which we are accustomed to call land, and the sea is only a covering of greater or less depth. The vast ocean called the Pacific, which in some parts interposes thousands of miles between America and Asia, is supposed to be only four miles deep at an average, and the Atlantic, which separates Europe from America, is supposed to be only three. In order that such a large mass of waters might be preserved from putrifaction, it is replete with salt, of which the Southern and Mediterranean Seas are said to contain a somewhat larger proportion than others. The other substances found in the sea are sulphates of soda, magnesia and lime, and carbonate of lime and magnesia, which, collectively with salt, exist in the proportion of three to four per cent.

The surface of the land, from being very uneven, is in many places indented by large sheets of water, which have obtained the name of inland seas; such are the Mediterranean, Baltic, and Red Seas. If the extent of such seas be less, and the openings larger, they are called gulfs or bays. The still smaller portions of sea, surrounded to a considerable extent by land, and which afford a shelter for ships, are called ports, creeks, or roads. Those masses of salt water which are enclosed by the land on all sides, and have no communication with the main ocean, are termed Caspians, from the Caspian Sea, which is the largest of them. The saltness of these bodies of water has been variously accounted for, some supposing that they have been cut off from the ocean by a change in the relative level of land and water; and others, that the saltness arises from their occurring in countries impregnated with that matter. In support of the latter theory, it may be stated that salt springs are numerous where the Caspian, and the Lakes Aral, Baikal, &c., are situated.

LATITUDE AND LONGITUDE.

In order to describe accurately the position of any place, geographers have divided the circumference of the globe into 360 degrees or parts, each of which contains 69½ English miles. A quarter, or 90 degrees, of this circumference, lies between the equator or girth-line of the earth, and its poles, in all directions. A half, or 180 degrees, lies between any one point on the equator, and the spot exactly opposite. Thus, when it is desired to indicate the position of any place, the geographer first mentions how many degrees and parts of degrees it is either to the north or south of the equator—which is called *latitude*; and then points out how many degrees and parts of degrees it is from an imaginary line cutting the equator, of which almost every nation has established one for itself; and this is called longitude. In Britain, the great Astronomical Observatory at Greenwich is held to be the starting point for measuring longitude.

There are other circles on the face of the earth, all established for astronomical and geographical purposes.

MOUNTAINS AND PLAINS.

The surface of the land is composed of slopes of every degree of inclination, extensive and nearly level plains, grooves, depressions and cavities, ridges and eminences of all kinds; the highest of which bear so insignificant a proportion to the earth's diameter, that the globe, if reduced to the size of an orange, would not present asperities so palpable as those on the surface of that fruit. The bottom of the sea presents inequalities similar to those exhibited on the surface of the land.

The most remarkable elevations are those series or *chains* of mountains, which stretch through large tracts of country—such as the Himalayas of Asia, the Andes of America, the Alps, the Appenines, and the Pyrenees, in Europe. The Himalayas are the highest hills of which the height has yet been ascertained, being 25,000 feet and upwards above the level of the sea. These chains are intersected by vallies, which slope towards the surrounding countries, and afford the sources of the numberless streams which carry off the rain waters to deposit them in the ocean. The tops of hills are sometimes like sharp cones, sometimes are round and swelling, and occasionally present extensive plains, or what are called table-lands. In obedience to the laws of nature, such waters as rise out of the ground, or fall from the heavens in elevated districts, glide into the hollows, or vallies, and there form rivers, which, in proportion to the extent of country drained by them, are either large or small. The longest and largest river in the old continent is the Danube, which runs through Germany and Turkey. In America, however, there are streams of much greater magnitude—such as the Mississippi, which runs 4300 miles, or a fifth part of the circumference of the globe, and the Amazon, which is only 300 miles shorter. In some instances, water rests in large basins or hollows, and forms what are called lakes: the largest of these is Lake Superior, in North America, which measures 381 miles in length, and 161 in breadth. Sometimes lakes occur on the tops of mountains: one, called the Lake of Mica, on the platform of Antisana, in America, is 13,123 feet above the level of the sea.

The land is in many places nearly level for a considerable space, and thus forms what are called plains. In general, there are levels of more or less extent along the banks of all rivers, being formed by matter brought down and left there by torrents, and which, therefore, is called alluvial deposit. In other instances, but seldomer in Europe than in the other parts of the globe, there are vast plains unconnected with rivers. The Pampas of South America stretch from the base of the Andes to Buenos Ayres, over a space of 900 miles; and in Africa are vast expanses of nearly level ground, where the traveller, day after day, sees the horizon preserving the same distance as he proceeds, and bounding an ocean of arid sand. Large plains also occur at great elevations above the sea, such as those of Tartary, Thibet, and Mexico. In North America there are similar expanses, called prairies (*i. e.* meadows), which present a thick covering of natural grass. Among other remarkable indentations or hollows of the earth, may be mentioned the two great Scottish vallies, called Glenmore-nan-Albin, and Strathmore: in both of these instances, a straight line is observed for nearly a hundred miles, and the hollow is not in either case filled regularly by natural water, though the former has become the bed of a canal.

ALTERATIONS OF THE SURFACE.

All these substances, which, by the action of the atmosphere, and other causes, separate from the more solid parts of the earth's surface, are carried to a lower level by the agency of water in the shape of rains, rivers, &c. The effects thus produced are very remarkable. The hardest rocks, such as granite, are liable to decomposition, which has been attributed, and justly so, to the chemical as well as mechanical influence of the atmosphere. This destruction of the surface is common to almost all countries; it goes by the name of weathering. In some parts of England, the rubbish thus accumulated in the bottoms of vallies is thirty feet thick.

The fall of rocks is common in mountains whose lofty ridges are exposed to the alternations of frost and thaw. Water is the grand agent of destruction in this case. In filtering through porous rocks, it sometimes meets with clays, which do not admit of its passage. The clays become moistened; and if a large mass of rock repose upon them, it is loosened, and descends, like an avalanche, upon the plains below. Many falls of this kind occur; one which took place in Switzerland, in 1806, covered a beautiful valley with stones and slime, crushed one village with masses of rocks, overwhelmed another with mud, and destroyed above [illegible] individuals.

Rivers.—An immense quantity of mud, sand, and other substances, is carried down by rivers, and these accumulating at their mouths, are called deltas. During a flood, the transporting power of rivers is augmented, and sometimes trees and animals are hurried along, and entombed in the bottom of the sea. Lakes collect immense quantities of this matter: the Lake of Como, for instance, is nearly filled with it at the higher part.

The subject of deltas is a very interesting one. During a succession of ages, the Nile has transported an enormous quantity of mud and other rubbish into the Mediterranean, which at the mouth has accumulated into a constantly increasing delta. It has been calculated that the Nile has raised the surface of Upper Egypt about six feet four inches since the commencement of the Christian era. The delta of the Po advances at a rapid rate, in consequence of the shallowness and placid character of the Adriatic Sea, into which it flows. Adria was, in the time of Augustus, situated on the shores of the Adriatic: it is now twenty Italian miles inland, from the filling up of the sea by the Po, and other rivers. The Rhone, Rhine, Danube, Ganges, Congo, Mississippi, and all other rivers, accumulate immense quantities of mud, &c. at their mouths.

Action of the Sea on Coasts.—Many coasts bear ample evidence of the destructive effects of the sea upon them. In the eastern part of our own island, the sea has made very considerable encroachments within the lapse of a few centuries. The breakers, however, sometimes throw up a barrier against their own ravages, in the shape of shingle and sandy beaches. The former frequently become an excellent protection to the land, but the latter sometimes prove very destructive to it. When the sand is forced forward by the breakers, and accumulates into hills known by the name of *dunes*, it is often drifted inland by the winds, forming a sandy desert, and large tracts of country are thus overwhelmed by it. The progress of these dunes, according to Cuvier, is irresistible, forcing even lakes before them, and covering forests, houses, and cultivated lands. Many villages have been entombed by them; and in one department of France, ten are at this moment threatened with destruction.

In Africa, there are immense deserts of moving sand, which have made a desolating progress over vast tracts of territory. To the westward of the Nile, between the temple of Jupiter Ammon and Nubia, innumerable cities lie buried beneath them. Whole caravans are said to have been overwhelmed by the Lybian sands; and Burckhardt, the traveller, informs us, that after passing the Akaba, near the head of the Red Sea, the bones of dead camels are the only guides of the pilgrim through the wastes of sand.

Tides and Currents.—Tides are caused by the attraction of the sun and moon, and currents principally by the winds: the motion of the earth, however, has also some effect upon them. They are of importance in geology, as they may be the means of distributing the matter brought from the land by rivers over the bottom of the ocean. The stream caused by tides has a velocity of one mile and a half per hour, when there is nothing to oppose it. The transporting power of tides is very small, except in shallow seas. This is proved by the fact, that the bottom of various parts of the ocean, though consisting of sand and mud, has, according to the soundings of navigators, remained the same for a long period of time. Currents, like tides, have little transporting power in deep water, and it is only on coasts, and seas of small depth, that their effects can be traced.

Volcanos.—Those conical masses, through whose orifices various gases, cinders, ashes, stones, and rivers of red-hot melted rocks, are projected, have obtained the name of volcanos. The changes which these produce upon the surface of many parts of the earth, have been very great in all ages. Taken as a whole, they are always more or less in a state of activity over the globe, acting like safety-valves for the escape of that combustible matter, whose confinement would otherwise rend it asunder. The eruptions of volcanos are sometimes tremendous, scattering utter desolation for miles around, and converting a flourishing tract of country into a black and barren desert. One of the most terrible on record is that of Vesuvius, which happened in the year 79: besides laying waste the luxuriant vegetation that clothed the sides of the mountain, it overwhelmed the cities of Pompeii and Herculaneum, which are at present in the course of being redeemed from the subterranean darkness that has enveloped them for seventeen centuries. Volcanos abound in all quarters of the globe, and in some parts fill up the bed of the sea with ashes and other matter, for an extent of several miles. It is not uncommon for volcanic islands to emerge from the bottom of the sea: Monte Nuovo, near Naples, was thrown up in a day and a night, in 1538; its height is 440 feet above the sea, and its circumference about a mile and a half. Islands thus ejected sometimes disappear again, as was the case with Graham Island, which rose in 1831, off Sicily, and went down again early in 1832. Iceland may be considered as one vast volcanic mass, and the eruptions from its various craters have been frequent: that of 1783 is the most terrible recorded in the modern annals of the island; it destroyed twenty villages, inundated others with water; and immense quantities of cattle, together with nine thousand human beings, perished. The melted matter flowed in two directions, nearly opposite to each other: the one was forty, and the other fifty miles in length. It is unnecessary to multiply instances of the violence of volcanic eruptions, and their power in obliterating the beauty and changing the surface of the globe. We shall only mention the remarkable disappearance of a volcanic mountain, which took place in Java, in the year 1772. The largest volcano in the island, for two successive nights, was enveloped by a luminous cloud; the inhabitants betook themselves to flight, but before they had all escaped, the mountain fell in, accompanied by a sound resembling the discharge of artillery; vast quantities of volcanic matter were ejected, and scattered over a circumference of many miles: the extent of ground swallowed up was estimated at fifteen miles by six. Forty villages were engulfed or entombed in the substances thrown out, and nearly three thousand individuals perished.

Earthquakes.—The connection between earthquakes and volcanic eruptions is now almost universally admitted. They frequently occur simultaneously, and seem to be the effects of some cause as yet unknown to us. Every theory which has hitherto been offered as explanatory of the phenomena, is liable to serious objection in one respect or another. Earthquakes produce a motion of the ground, sometimes tremulous, and at other times undulatory; the latter is by far the most dangerous, and frequently spreads devastation far and wide. Instances of the destructive effects of earthquakes must be familiar to our readers, and scarcely require to be mentioned here The shock of an earthquake is sometimes felt over an immense circumference. That of Lisbon, in 1755, sent its undulations over nearly the whole of Europe, and even as far as the West Indies and the continent of America. Vast tracts of country have occasionally been elevated by earthquakes. The coast of Chili, in South America, to the extent of one hundred miles in length, was raised three or four feet in consequence of the earthquake which took place in 1822. In Mr Lyell's able work on geology, there is a great mass of evidence which goes to prove that earthquakes have produced such elevations in other places, and that depressions have likewise taken place. The following instance of such an occurrence will be read with interest:—In the year 1692, the Island of Jamaica was visited by a violent earthquake; the ground swelled and heaved like a rolling sea, and broke into rents, in which many people were engulfed, and some of them were vomited forth again, along with great quantities of water. Three quarters of Port Royal, then the capital, sunk down, with their inhabitants, entirely under water; and after the earthquake had ceased, the chimney-tops of houses were seen just projecting above the waves. A tract of land round the town, about a thousand acres in extent, sunk down in less than a minute, during the first shock, and the sea immediately closed over it.

Hurricanes.—The terrible violence of these visitations is well known. The velocity with which they travel, and the deluges of rain with which they are accompanied, effect considerable changes on the surface of a country. Whole towns are sometimes scattered in that confusion which the playthings of a child present, when, in a fit of anger, it strews them about, and tramples upon them. Not only buildings and animal life are destroyed, but whole forests are swept to the deep. A large amount of terrestrial animals and vegetables, along with the land-detritus, must, upon these occasions, be hurried into the ocean, and there deposited. Hurricanes are sometimes accompanied with submarine earthquakes. In Jamaica, in 1780, during a storm, a great wave burst upon Savanna la Mar, and swept the whole town away in a moment, leaving "not a wreck behind."

Springs.—Springs are generally impregnated with various kinds of matter, which they deposit in abundance. Many springs have the power of changing vegetable matter into a fossil, or stone. This process of petrifaction, as it is called, is carried on to a great extent in the hot springs of Furnas, of which Dr Webster gives the following account:—He found "branches of the ferns which now flourish in the island completely petrified, preserving the same appearance as when vegetating, except the colour, which is now ash-grey. Fragments of wood occur, more or less changed; and one entire bed, from three to five feet in depth, is composed of the reeds so common in the island, completely mineralised, the centre of each joint being filled with delicate crystals of sulphur." Travertino is a substance somewhat of the same description, and is to be found deposited from springs in layers of immense thickness. Those of Tivoli present an extraordinary accumulation of horizontal beds, from four to five hundred feet thick. The Bakie Loch, in Forfarshire, produces a marl used in the agriculture of the country. Mr Lyell is of opinion that it was immediately due to the shell-fish of the lake, which derive the lime either from the water or the food which they live upon, and that dying, their remains accumulated into heaps of shell marl. This was converted into rock by the action of the water, which was impregnated with an acid. Certain springs deposit a pitchy substance, called asphaltum; and others are covered with a combustible fluid, called naphta, which floats upon the top. Those of Rangoon, in a province of the Burman empire, are said to produce 92,781 tons a-year.

Coral Reefs and Islands.—These are the works of myriads of small insects, called corals. They occur in various parts of the world, but are most numerous in the Pacific Ocean and Indian seas. Their extent is sometimes almost incredible. On the coast of New Holland, there is a coral reef which stretches out to a thousand miles in length. The Pacific Ocean is studded with coral islands, some of which are of considerable magnitude. Corals do not commence their laborious operations at a great depth below water; from 60 to 100 feet is considered the utmost extent to which the islands extend downwards. They are generally of a circular or oval shape; and Mr Lyell is of opinion that corals build upon the rims and in the craters of submarine volcanos. The outer wall of the building emerges first above the waves, enclosing a pool of tranquil water. The seeds of vegetables are either brought there by sea-birds, or wafted by the ocean, and the islands soon become clothed with a mantle of green. The substance of which these islands and reefs are composed, is lime, which the corals extract from the sea-water, and cement together with a glutinous matter contained in their bodies. Mr Lyell, while surveying the Isthmus of Panama, detached a quantity of these animals, and placed them on some rocks in a shallow pool of water. On returning to remove them a few days afterwards, he found they had secreted stony matter, and had firmly glued themselves to the bottom.

Submarine Forests.—This name has been applied to those accumulations of wood and plants which are laid bare at the retreat of the tide, and are covered at high water. There are several both in England and Scotland. One occurs in the Firth of Tay, another in the Firth of Forth, at Largo Bay, and in the islands they are numerous. On the west coast of the mainland of Orkney, one was discovered, which has been thus described:—"Stems of small fir trees, ten feet long and five or six inches in diameter, are found partly imbedded in, and partly resting on, the surface of an accumulation of vegetable matter, principally composed of leaves. The stems were still attached to the roots, and the whole was greatly decayed, so as to be easily cut by the spade." At Mount's Bay, in Cornwall, there is a submarine forest. The vegetable bed consists of a brown mass, composed of the bark, twigs, and leaves of trees, which would appear to be almost entirely hazel. Intermixed with this are numerous branches and trunks of trees. At a foot beneath the surface of this bed, the chief part of the mass consists of leaves, amongst which are an abundance of hazel nuts. In this layer, there are also filaments of mosses, and portions of the stems and seed-vessels of small plants. Fragments of insects of the beetle tribe were also dug up, which at first displayed the most beautiful shining colours, but these small objects crumbled to dust on being exposed to the air.

Taking these facts in connection with the raised beaches and masses of shells, which are not unfrequent, it would appear that the relative position of land and water has been changed at some remote period by earthquakes, as we have seen was the case in Chili. It is impossible that trees and vegetables could have grown where they are now found, with the sea breaking over them. Besides their occurrence in other places, there are at Plymouth the remains of a beach, over which the sea has, without doubt, formerly flowed; it is now, however, at an average, thirty-three feet above it, clearly indicating that some internal convulsion has either raised the land, or sunk the bed of the ocean. In the Isle of Jura, in the Hebrides, there are six or seven terraces, or lines of beach, which appear to have been successively upheaved above the present level of the sea.

OF PEAT, AND THE VARIOUS REMAINS FOUND IN IT.

Peat bogs are formed in those situations which admit of vegetables decomposing without putrifying. A vast extent of surface in Europe is covered with these mosses, and in Ireland they are said to extend over one-tenth of the whole island. One of them, which borders on the Shannon, is fifty miles in length, and from two to three in breadth. Many of the peat bogs in the north of Europe occupy the place of immense forests of pine and oak, which have many of them disappeared within the historical era. "Such changes," observes Mr Lyell, in his able work on geology, "are brought about by the fall of trees and the stagnation of water, caused by their trunks and branches obstructing the free drainage of the atmospheric waters, and giving rise to a marsh. In a warm climate, such decayed timber would immediately be removed by insects, or by putrifaction; but in the cold temperature now prevailing in our latitudes, many examples are recorded of marshes originating in this source." A species of moss constitutes a considerable part of the peat found in marshes; and reeds, rushes, and other aquatic plants, can be traced. It would appear that many of the peat bogs are not more ancient than the age of Julius Cæsar. A great number of Roman coins, axes, arms, and other utensils, have been found in British and French mosses: and several of their famous roads (for even in road-making the Romans built "not for a day, but for all time") are now covered with peat several feet in thickness.

Peat possesses the remarkable quality of preserving animal substances for, it would appear, any length of time. In June 1747, the body of a female was discovered in a peat moor in the Isle of Axholm, in Lincolnshire. Her feet were furnished with antique sandals, and it has been supposed that she was an ancient Briton. Her nails, hair, and skin, are described as having shown scarcely any symptoms of decay. In Ireland, a human body was dug up which was completely clothed with garments made of hair. The clothing of the inhabitants was manufactured from this material before the introduction of wool; but many ages have transpired since this took place, so that the body must have lain an immense time, yet it was perfectly fresh and unimpaired. Amongst a number of cases of this description which might be brought forward, we shall quote the following, as particularly interesting:—"At the battle of Solway, in the time of Henry the Eighth (1542), when the Scotch army, commanded by Oliver Sinclair, was routed, an unfortunate troop of horse, driven by their fears, plunged into this morass (the Solway moss), which instantly closed upon them. The tale was traditional, but it is now authenticated, a man and horse in complete armour having been found by peat-diggers in the place where it was always supposed the affair had happened. The skeleton of each was well preserved, and the different parts of the armour easily distinguished."

Besides the human body, there have been found in peat bogs bones of the stag, ox, hog, horse, sheep, and other animals that feed on herbs, and in Ireland and the Isle of Man, skeletons of a gigantic elk. There are no remains, however, of animals such as the elephant and rhinoceros, which are only now to be found in warm countries, though, as we shall shortly see, they are quite common in mud and other rubbish. Upon this Mr Lyell remarks, "that they had ceased to live before the atmosphere of this part of the world acquired that cold and humid character which favours the growth of peat." This reasoning appears perfectly conclusive.

With regard to the question whence peat derives its antiseptic property, it has been conjectured by some, that the carbonic and gallic acids which issue from decayed wood, and also charred wood, which occurs in the lower parts of many peat mosses, may account for it. Vegetable gums and resins will also have an effect. Dr Macculloch states, in his work on geology, that the occurrence of tannin in peat is too casual, and its quantity too small, to produce effects of any importance. The power of tannin to prevent decay is well known, and its presence in almost all trees, but particularly, and in considerable quantities, in the oak, is also well known. Now, as has been already observed, many peat beds occupy the sites of forests, especially those of *oak* and *pine*; so that tannin, in these at least, must have been present in great quantities. It may have entered into various combinations, but that it really is to be found in such peat bogs, and to a considerable extent, either in a simple or compound state, appears to us beyond a doubt.*

DENSITY AND TEMPERATURE OF THE EARTH.

Various opinions have been entertained on the density of the earth;† but its attraction is such, that it is now no longer disputed that the density must continue to increase, in a somewhat regular manner, from the surface downwards. The mean density of the earth is about five times greater than that of water.

Whether the temperature of our planet be entirely owing to solar heat or not—for philosophers still differ upon this point—there can be no doubt of its being very materially influenced thereby. We have only to recollect, that the difference of seasons and climates depends upon the more or less vertical descent of the sun's rays. Local circumstances, such as the proximity and size of mountains and seas, have certainly a very considerable influence in varying the temperature; but the principle seems incontestible, that, under equal circumstances, the temperature decreases from the tropics to the poles.

That the temperature of the earth is not the same at present as it was formerly, but has considerably decreased, is proved by the organic remains of vegetables and animals having been found in situations of latitude, where, from a want of congenial temperature, they could not now exist. Plants and animals, now peculiar to a tropical climate, have been discovered imbedded in various rocky formations in Scotland, England, and other places even farther north. These interesting relics of a former world, as they may be called, will be described when we come to treat of the internal structure of the earth. Various causes, but none completely satisfactory, have been assigned for this change of temperature. By one party it is insisted upon, that the axis of the earth was by some cause or other shifted, and, consequently, that the poles were differently situated formerly from what they are at present. Sir J. F. W. Herschel supposes that a diminution of temperature might have been effected by a change in the ellipticity of the earth's orbit, which, though slowly, becomes gradually more circular. The theory of an internal heat has also been had recourse to for the explanation of this point. From the earliest periods, philosophers have entertained the opinion that a central heat exists; but it was only at a comparatively recent period that direct experiments were made, in order to put the hypothesis to the test. The temperature of mines has particularly attracted attention; and, notwithstanding that the experiments made on them are liable to error from various causes, they would seem to indicate an increase of temperature from the surface downwards.

The temperature of springs has also been appealed to in support of this theory. Many of these, rising from considerable depths, have a heat independent of solar influence, which heat varies from the boiling point of water downwards. They occur in all situations, and sometimes far removed from volcanos. In many parts of the Himalaya range they have been found, and Bakewell discovered them amongst the Alps. A great burst of thermal or hot springs takes place near the base of the Ozark mountains, in North America, and at a short distance from the Washita, from which they derive their names. They are about seventy in number, and occur in a ravine between two slate hills. The hot springs of Iceland are well known; those called the Geysers are the most remarkable. Sir J. Mackenzie witnessed an eruption of the great Geyser, which commenced with a noise resembling the distant discharge of a piece of ordnance. "The sound," says he, "was repeated irregularly and rapidly; and I had just given the alarm to my companions, who were at a little distance, when the water, after heaving several times, suddenly rose in a large column, accompanied by clouds of steam, from the middle of the basin to the height of ten or twelve feet. The column seemed as if it burst, and, sinking down, it produced a wave, which caused the water to overflow the basin in considerable quantity. After the first propulsion, the water was thrown up again to the height of about fifteen feet. There was now a succession of jets to the number of eighteen, none of which appeared to me to exceed fifty feet in height; they lasted about five minutes. Though the wind blew strongly, yet the clouds of vapour were so dense, that, after the first two jets, I could only see the highest part of the spray, and some of it that was occasionally thrown out sideways." The water at last sunk into the pipe in the centre of the basin to the depth of ten feet. It rose again, gradually however, and was found to have a temperature of 209°, only three degrees below the boiling point. There can be no doubt that heat is communicated to these springs at some distance from the surface of the earth, but whether or not from the supposed great fountain of central heat, is yet uncertain.

It has also been attempted to account for the superior temperature of the earth in remote ages of its history, by supposing that volcanic influence was formerly more active, and that, consequently, a more copious communication of internal heat to the surface would take place. But we have no proof that an activity in volcanos, sufficient to account for the phenomena, did ever really exist.

Mr Lyell has examined the subject with his usual philosophical acuteness, and his opinion is, that such a change in temperature may be accounted for according to the present order of nature. The degradation of old, and the elevation of new continents, is a demonstrated fact; and the influence of such a change in the relative position of land and water upon climate, is unquestionable, from what we know of it by actual observation.

If we compare the two continents of Europe and North America, we shall find that places situated in the same latitudes differ very considerably in temperature, sometimes to the amount of seventeen degrees of Fahrenheit's thermometer. The principal cause of the difference observed in corresponding latitudes of North America and Europe, is, in the first place, the connection of the former country with the polar circle, by a tract of land of considerable height; and, in the second place, in the separation of Europe from the arctic circle by an ocean. All large bodies of water have a tendency to preserve an equilibrium of temperature, which is communicated to the contiguous land; and hence the climate of islands and coasts differs very materially from that of the interior of continents. Mountains which rise into the colder regions attract and congeal vapour, which communicates its cold to the adjoining country. Greenland, which forms part of a continent stretching northward to the 82d degree of latitude, experiences under the 60th parallel a more rigorous climate than Lapland under the 72d parallel.

Upon this subject Mr Lyell observes—"If, for example, all other circumstances being the same, the land is at one time more divided into islands than at another, a greater uniformity of climate might be produced, the mean temperature remaining unaltered; or if, at another era, there were mountains higher than the Himalaya, these, when placed in high latitudes, would cause a greater excess of cold. So, if we suppose that at certain periods no chain of hills in the world rose beyond the height of 10,000 feet, a greater heat might then have prevailed than is compatible with the existence of mountains thrice that elevation."

THE INTERNAL STRUCTURE OF THE GLOBE.

Taking a superficial view of the continents and islands we have just been considering, they awaken no further idea than that they are a mass of rocks, sands, clays, and other substances, confusedly mingled together without order or arrangement. More careful inquiry, however, soon shows this conclusion to be erroneous. Phenomena of a very singular and unexpected character display themselves when we take a survey of the side of a mountain which has been laid bare, or look into the interior of a coal mine or a quarry. Instead of the miscellaneous accumulation of heterogeneous substances anticipated, we find a remarkable degree of order and arrangement. Successive layers of rocks appear regularly disposed, one above another, like so many volumes of books piled horizontally. Further inquiry shows that this is not an accidental and rare occurrence, which is confined to particular and far separated localities; for such an order is found to prevail universally over the whole surface of the globe; and even where it would appear to fail, the exception proves the rule, as there will always be discovered, in such cases, ample evidence that violence from beneath has been exercised in breaking the continuous and horizontal lines of rocks, thereby introducing anarchy and confusion; and we need not travel far for an explanation of all this: no one can be ignorant of the fact, that at the present moment, volcanos are at work in belching forth rivers of liquid fire through the solid floors of the earth, and not only destroying its internal organisation, but changing its external appearance.

This, however, is not all. When we come minutely to inspect what sort of substances compose the various rocks, we find that many of them are as thickly studded with the remains of animal and vegetable life, as is the midnight sky with stars. The strata thus cease to be, but accumulations of particular kinds of matter, interesting only in so far as their own origin and deposition is concerned: and we recognise them as tablets, wherein are inscribed in hieroglyphics, which are universally understood, and can neither become obsolete nor perish, the records of nature's history. The decay of man is hereditary in his works; and when these become dust, like the hands which

* We have been informed by Mr Stevens, an experienced land-drainer, that in Sweden, where he has drained an immense quantity of soil, the peat bogs almost invariably occur above prostrate forests, and that the trees for the most part consist of oak.

† Density is a term employed in science to express the comparative closeness or compactness of the particles of which bodies are composed.

fashioned them, it is once and for ever. They are destitute of the elements of renovation which we see in nature's, whereby they are made to reappear again, "another and the same;" or of that perpetuity of being which sets the lapse of indefinite periods of time at defiance, and to which, emphatically, a thousand years are as one day. The grapes of Zeuxis, and all the splendid pictorial achievements of antiquity, have long since been gathered up with the other spoils of time. But the myriads of animals imbedded in the bosom of the cold rock, uncounted ages before the creation of man himself, still exist, completely entire—all but alive—and reveal to us not only the minutest parts of their organic structure, and sometimes also their various shades of colour, but their habits and modes of life, where they lived, and what they fed upon. Such is the state of perfection in which the process of embalming is carried on in the grand museum of nature. We shall now proceed to give a more particular account of the

STRATIFICATION AND OTHER GENERAL CHARACTERISTICS OF ROCKS.

Rocks are said to be stratified when they occur in layers parallel to or above each other. When they are found, as granite is in a mass, without any such form or order, they are called unstratified. Strata differ in being more or less distinct, regular or irregular, straight or undulating: they are seldom found perfectly horizontal, and are of very unequal thickness.

Rocks, taken in the mass, are very nearly related to each other, nineteen-twentieths of the whole mineral contents of the earth being composed of five substances, namely, silex, alumine, lime, magnesia, and iron—(for a description of which, see below).—There are other minerals found in the solid parts of the globe, but they occur usually in veins, and are more especial objects of attention to the mineralogist.

To those unacquainted with the subject, many of the terms which we must necessarily employ will appear as unintelligible as Egyptian hieroglyphics, and to obviate this difficulty, the following alphabetical list of them, with explanations, is prefixed:—

Acids are compound substances, which have a sour taste, and, amongst other properties, they dissolve alkalies, earths, metals, &c.

Alumine is one of the earths, and enters most largely into the composition of rocks, clays, and loams, of which it is the plastic principle. When washed and thoroughly dried, it is of a white colour, and destitute of taste or smell. It is the base of alum, and hence its name.

Arenaceous, formed of sand.

Argillaceous, formed of clay.

Bitumen is an inflammable mineral substance, which burns with flame in the open air. There are numerous varieties of this substance which have obtained distinct names, such as naphtha, which resembles common tar, and asphaltum, similar in consistency to common pitch. All the varieties of pit-coal contain more or less of this substance.

Calcareous, formed of lime. Calx is the Latin name for that substance.

Carbonate, Carboniferous.—Carbon, or charcoal, is a simple body, of which the purest and most valuable specimen is the diamond. Combined with oxygen, one of the gases composing the atmosphere, it forms carbonic acid, an air which is fatal to animal life when inhaled: a carbonate of any thing—for instance, of lime—is carbonic acid in combination with lime. A carboniferous body is one in which carbon prevails.

Chemical action differs from mechanical action thus: —When a river washes away and carries any portion of the earth to the sea, the waste thus borne down is only mixed in the water, not intimately united with it by any chemical affinity: when, however, oxygen or an acid combines with any of the substances composing rocks, and forms a body different from either of the former two, then this is a case of chemical action. In the first instance, the integral particles were only separated from each other; in the second, they are both separated and united again with the solvents. In the one, a sediment is deposited; in the other, a precipitate.

Conglomerate is a mass of rounded pebbles cemented together.

Cretaceous, having the properties of chalk.

Crystalline.—When fluid bodies are allowed to cool with adequate slowness, their particles are arranged in regular figures, which are called crystals:—Ice, for instance, is a crystal.

Decompose, to separate into more simple parts; to decay.

Detritus, or *Debris*, the waste of rocks and other substances.

Fissure, a cleft, or chasm, where a breach has been made.

Formation, a certain series of rocks, supposed to have been produced under certain general circumstances, and at about the same epoch.

Fossils, organic remains.

Igneous origin, and *aqueous* origin; the first results from the agency of fire, and the second, from that of water.

Lime, a well-known earth, which exists in great abundance, and under various forms in nature. It is a metallic oxide, that is, a metal in combination with oxygen. Common limestone is a carbonate of lime; gypsum is a sulphate of lime, that is, sulphuric acid, or vitriol, in union with lime. The carbonate is widely distributed in nature, and frequently occurs in beds of immense extent. There are a great number of other calcareous minerals, such as oolite or roestone, which will be described as they occur. Chalk is a very common species of calcareous earth.

Magnesia is another earth, which has also a metallic base. It exists in nature under various states of combination, with acids, water, and other earths, and is found in various mineral springs, and the water of the ocean, united with sulphuric and muriatic acids.

Marl is essentially composed of carbonate of lime and clay, in various proportions. Marl frequently contains sand and other foreign ingredients, and some of them are more or less hardened, while others are friable and earthy.

Organic, having the structure peculiar to living bodies. Organic remains are living bodies converted into earth, stone, bitumen, &c., but preserving the appearance of their original forms.

Oxides are metals and other substances, combined with oxygen. They differ from acids, in having less oxygen.

Oxygen gas forms about a fifth part of the atmosphere, and water contains about eight-ninths of it. It is more amply diffused in nature than any other material body, its attractions being very numerous and powerful.

Shale is slate clay and bituminous slate clay.

Silex, or silica, is an earth: it is a crystalline substance, and presents itself in nearly a pure state in the varieties of flint, agate, &c.

Strata [singular, *stratum*], layers of substances placed above or beneath each other, as slates, &c.

Supracretaceous (*supra*, over or above, *cretaceous* chalk), above chalk.

Travertine, one of the varieties of lime.

Vertebræ, back-bone.

CLASSIFICATION OF ROCKS.

To facilitate the acquisition of knowledge regarding rocks and their organic contents, they have been classified by various philosophers. No classification that we have seen, after consulting a great number of authors, seems to be either so free from theory, or to come so closely up to the present state of the science, as the following, which has been employed by De la Beche in his recent valuable work on geology. This author, in his classification of rocks, has divided them into groups. For the accommodation of those who may prefer what is termed the improved Wernerian classification, it is also given, in the second column.

1 Modern Group.	Alluvial.
2 Erratic Block ditto.	Diluvial.
3 Supracretaceous ditto.	Tertiary.
4 Cretaceous ditto.	Secondary.
5 Oolitic ditto.	
6 Red Sandstone ditto.	
7 Carboniferous ditto.	
8 Grauwacke ditto.	Transition.
9 Lowest Fossiliferous ditto.	
Inferior stratified, or non-fossiliferous.	Primitive.

Unstratified Rocks.—These in the improved Wernerian are arranged among the stratified rocks, according to the order in which they are supposed to occur.

1. MODERN GROUP.

This name distinguishes the detritus, or waste of various kinds produced by existing causes, such as have already been described under the head "Alterations of the Surface." It likewise includes the coral reefs, submarine forests, and peat bogs, which have also been noticed.

The organic remains of this group, of course, for the most part consist of existing animals, and are hence not of so interesting a character. Those, however, which are most important, belonging either to extinct animals, or those which are at present found on the globe, will be noticed in the next group.

2. ERRATIC OR TRANSPORTED BLOCK GROUP.

This group, says De la Beche, is merely one of convenience, formed for the purpose of presenting certain phenomena to the reader's attention, which, in the present state of science, could not so easily be done under any other head. It comprises all those gravels, sands, blocks of rocks, and other mineral substances which have been scattered over hills, plains, and on the bottoms of vallies, and which, though often referred to one epoch, may belong to several.

In various parts of Britain, and also of the Continent, great quantities of rocks, sometimes of considerable size, are to be found strewed upon the sides of mountains, and in hollows, which, as far as can be at present ascertained, must have been conveyed there by the influence of "moving waters." The fact of their having been transported from a great distance, is proved by their differing from any rocks in the neighbourhood, and their identity with others of the same formation far seperated from them. Between the rivers Thames and Tweed there have been pebbles, and even blocks of rock, found, which, according to their mineralogical character, must have been transported from Norway. From these, and various other circumstances which might be mentioned, it seems probable that a body of water has proceeded from north to south over the British Isles, and that by this means these fragments of mountains have been conveyed across seas. Whether this current may correspond with the Mosaic deluge or not, is still a matter of great uncertainty. Indeed, the facts are not sufficiently numerous to justify us in drawing any conclusion on this difficult point. It is very dangerous to impress the Bible into the service of philosophy; it was not given for any such a purpose, and religion has almost invariably suffered by the connection. Many cases in proof of this might be enumerated, but that of "the starry Galileo" stands conspicuous. He maintained that the earth revolved round the sun, and for this the holy see of Rome imprisoned him, because it was in opposition to certain expressions in Scripture, which they had an over-scrupulous desire to preserve intact. The fact is so well authenticated now, that, were any clerical personage to maintain the contrary before the same see, it would consider him as hopelessly unqualified for a mitre.

The remains of animals discovered in the gravels, sands, clays, and other rubbish, referable to a passage of water over the land, and hence called in scientific works, *diluvial*, are very numerous and interesting. They consist not only of animals which at present exist either in the same country where they were found, or in tropical climates, but also of those which differ altogether from any living thing that moves upon the face of the earth at present. A description of them all cannot be expected here: indeed, a full account of those which were found in the Kirkdale cavern in Yorkshire, would alone more than occupy the whole of this journal. This cavern was discovered by cutting back a quarry in 1821, and was shortly afterwards visited by Professor Buckland, to whom the world is indebted for a minute and able description of it. Its greatest length is about 245 feet, and its height so inconsiderable, that only in a few places will it permit of a man standing upright. The following are the animal remains found in it: Elephant, rhinoceros, hippopotamus, hyæna, tiger, bear, horse, wolf, fox, weasel, ox, three species of deer, hare, rabbit, water-rat, and mouse. Of birds, there were the raven, pigeon, lark, a small species of duck, and a bird about the size of a thrush. It is the opinion of Professor Buckland, from the manner in which the remains were strewed about the cavern, and the great proportion of hyæna teeth over those of other animals, as well as the way in which they were gnawed and fractured, that this was the den of hyænas for a long succession of years. It may be inferred from appearances, that they brought in as prey those animals whose remains are now intermixed with their own, and that this state of things was put a stop to by an eruption of muddy water into the cave; for the latter is covered with a stratum of mud, and in it the bones were found.

At other places in England, various interesting remains have been dug up, such as those of the mammoth and bison. Amongst the numerous animals found, which differ in some part of their structure from any living thing that now exists, there are several of immense size. The mammoth, or fossil elephant, demands particular attention, as the entire body of one was discovered in an iceberg, near the embouchure of the river Lena, in Siberia. It was a good deal mutilated by bears; but from what remained of its flesh and hair, and from its physiological structure, philosophers were enabled to determine that the animal had belonged to a race of elephants inhabiting cold regions, but which is now extinct. The remains of great numbers of the same species have been found in the same country, and in other northern regions. Its height appears to have been from ten to twelve feet, and its length from sixteen to twenty. Its tusks are larger than those of the common elephant; one was discovered which measured fourteen feet in length. In every respect the extinct species appears to have been stronger, larger, and clumsier, than any which is now to be met with on the globe.

The megatherium is another gigantic remnant of the past. It is found in few places; but four nearly complete skeletons have been collected. In height it would appear to have been about seven feet, and in length about seventeen. In structure it is between the ant-eater and the sloth; hence it has been termed the gigantic sloth. Its bones are of great size and strength; and, from some parts of its conformation, it would appear to have been a climbing animal. Its neck is long, and Cuvier is of opinion that it had a trunk. It is furnished with that which no other quadruped has—a chin. There are other animals of nearly similar dimensions, such as the mastodon and megalonix, as well as great numbers of smaller size, but our limits will not permit of us describing them.

Besides the Kirkdale cavern, above noticed, many others of a similar description have been discovered; and the ascertaining the relative ages of these accumulations of animal remains, is at present occupying the attention of geologists. This is a question of vast moment; for should the remains of man be discovered in them—which has never yet occurred—and if the mouths of these caverns be closed with detritus and fragments of rock brought from a distance, such transport not being due to actual causes, and there being no other communication between the outside and the place where the bestial and human bones are entombed, there would appear to be no doubt that man was a contemporary with the extinct species of elephants, rhinoceroses, hyænas, and bears. Upon this interesting subject, Mr de la Beche has the following remarks:—

"If the co-existence of man and these extinct animals should ever be satisfactorily proved, it would become a curious question whether his so found remains are those of an extinct species; or undistinguishable, like the bones of the horse, from those which now exist. It is a singular circumstance, and one which demands attention, notwithstanding the ingenious remarks that have been made on the subject, that the remains of the monkey tribe should not yet have been discovered among the undisturbed bones and other substances in caves, or in the old transported gravel, or *diluvium* of Professor Buckland. It has been objected, to a remark that man and the monkey tribe were created about the same period, and were of comparatively modern appearance on the earth's surface, that the countries have not been geologically well examined where the monkey race now exists. This is perfectly true. But is there any reason why monkeys should not have lived in climates and in situations where elephants, rhinoceroses, tigers, and hyænas were common? for the climates and regions in which existing elephants, rhinoceroses, tigers, and hyænas' abound, are precisely those where monkeys are now found. To the objection, that if they did then exist, their bones would not be discovered, as their activity would secure them from falling a prey to hyænas and other predaceous animals, it may be opposed, that they must have died like other animals, and that their dead carcasses must have fallen to the ground, and that they were quite as likely to have become the food of less nimble creatures, as the birds found in the cavern of Kirkdale."

3. SUPRACRETACEOUS OR GROUP ABOVE CHALK.

This group is identical with the tertiary rocks of most English authors. It consists of a number of substances, such as sands, marls, plastic clays, &c., in which there is a great abundance of organic remains. In France, MM. Cuvier and Brongniart first pointed out the importance of these rocks, and, during their observations on the beds around Paris, they discovered that the organic remains were not all marine, but that a number of fresh-water shells, and terrestrial animals of a description now unknown, were by no means uncommon. They also found that these remains were deposited in beds, each holding a certain place in a certain series. In England, Mr William Smith was employed upon more ancient rocks, and was in the habit of identifying certain formations by the organic remains embedded in them. These facts instantly led to a generalization; and it was a theory received for a long time, that particular formations or beds contained the same organic remains which were not to be found in the rocks either above or beneath. The opinion, however, gave way before after observations; and it is now generally admitted, that certain shells are not peculiar to certain strata, but that they are, nevertheless, to be found in far greater abundance there than in any other place. It would also appear to follow, as a necessary consequence, that the older the series, the more, and the newer the series, the less, the uniformity. However, this is merely a conjecture, and the truth of it can only be determined by an accurate examination of rocks in distant parts of the world.*

The varieties of the supracretaceous group, and the theories which have been advanced to account for their formation, it will be impossible to give here. A description of the Paris rocks, and also some of those in England, with the organic remains peculiar to them, will suffice to convey a pretty accurate idea of this part of our subject. The rocks of the Paris basin have indeed long been considered the most perfect specimen of the kind to be found; and the following is their classification, according to the illustrious philosophers, whose labours have been so essential to the advancement of the science, MM. Cuvier and Brongniart—(order ascending):—

1. Fresh-water formation,	Plastic clay. Lignite. First sandstone.
2. First marine formation,	Calcaire grossier.
3. Second fresh-water formation	Siliceous limestone Gypsum, with bones of animals. Fresh-water marls.
4. Second marine formation,	Gypseous marine marls. Upper marine sands and sandstones. Upper marine marls and limestone.
5. Third fresh-water formation,	Millstone without shells. Shelly millstone. Upper fresh-water marls.

Plastic Clay.—This substance has been so named from its easily receiving and preserving the forms given to it, and, from possessing this property, it is used in the potteries. It rests upon a surface of chalk, which is very irregular, and furrowed out so as to present an alternation of hills and vallies. This clay is of various colours; and above it, and separated by a layer of sand, there frequently occurs another bed of clay, which scarcely can be called plastic. It is black, sandy, and sometimes contains organic remains. In this deposit, considered as a mass, it is stated that organic remains do not occur in the lower parts. In the central portion, fresh-water animals commonly occur, and in the upper part there is a mixture, sometimes an alternation, of marine and fresh-water remains.

Calcaire Grossier, as its name implies, is composed of a coarse limestone, which is employed for architectural purposes. It is frequently separated from the plastic clay beneath by a bed of sand, and it alternates with argillaceous or clayey beds. The animal and vegetable remains enclosed in it are numerous, and generally the same in corresponding beds, presenting considerable differences when the beds are not identical.

Siliceous Limestone is sometimes white and soft, sometimes grey and compact, and penetrated by silex. It is often full of cells, which are occasionally large, and communicate with each other in all directions.

Gypsum and Marls.—Gypsum is a crystalline substance composed of lime, in union with sulphuric acid and water. Its colours are grey, white, and yellow; but different varieties of it have different hues. It was used in ancient times for window glass. The gypseous rocks consist of an alternation of gypsum and limey and clayey marls; these marls are also found in thick beds above this alternation. Abundant remains are there found, and palms of considerable size are discovered prostrate. The gypseous strata contain the remarkable remains of several extinct animals which suckled their young. These beds are considered as having been deposited in fresh water, and above them are others, which, from their organic remains, are believed to have been deposited in the sea. Amongst other marine animals, the remains of oysters, sometimes of a large size, have been found, and they have evidently lived in the places where they are now entombed. Besides fishes, birds and reptiles have also been discovered in the gypseous beds.

Upper Marine Sands and Sandstones.—These consist of irregular beds of siliceous sandstone and sand. The animal remains in the lower portion of these beds are broken, and very rare. In some situations, however, millions of small bodies have been found. These beds are occasionally covered with a species of rock which is filled with marine shells.

Upper Fresh-Water Formation.—This rock sometimes consists of white calcareous marls, at others of different siliceous compounds; from one of these, millstones of a celebrated kind are formed. They are sometimes charged with shells and petrified wood.

The Paris basin, as the space in which the above group of rocks is found, affords one of the most remarkable instances to be met with of the various vicissitudes to which the surface of the earth has been formerly subjected. There are three fresh-water and two marine deposits, which alternate with each other; the former composing the first and the last of the series. A glance at the foregoing table of the classification of rocks will place the fact in a clear point of view. As an explanation of this phenomenon, we may suppose, that, at the period when these rocks were deposited, large inland lakes had become numerous; and that this basin was a gulf of the sea into which a large river emptied its contents. There is no evidence, however, of a violent rush of waters, the organic remains having apparently been quietly deposited.

The supracretaceous rocks of England are commonly known by the names of plastic clay, London clay, Bagshot sands, the fresh-water formations of the Isle of Wight, and the crag of Norfolk. We can only afford a short account of some of these.

Plastic Clay.—This deposit, though it occasionally contains an abundance of clay, employed for various useful purposes, is also mixed with beds of pebble, irregularly alternating with sands and clay. It thus differs from that of Paris, but it agrees with it so far as it reposes upon an uneven surface of chalk. The organic remains are principally marine, but those of fresh-water and terrestrial animals are intermingled with them.

London Clay.—The great argillaceous deposit which underlies the London district, has obtained this name. It is of a bluish or blackish colour, and contains a portion of calcareous matter; beds of sandstone are also said to be occasionally present in it. This clay varies considerably in thickness, sometimes from seventy-seven to seven hundred feet. Besides the remains of a great variety of shell-fish, those of a crocodile and turtle have been found; masses of wood have also occurred in this stratum.

Bagshot Sands.—These rest upon the London clay, and consist of layers of various kinds of sands and marls containing fossil shells.

The Isle of Wight and London formations, although differing considerably in the nature of their deposits from those of Paris, present such an analogy in the organic remains of some parts of the group, that we are justified in referring the deposit to the same epoch, local circumstances and accidents having determined their characters.

It is the opinion of many philosophers, that at the deposition of the supracretaceous group, the world was passing from a state in which animals were somewhat different from those which exist at present. The lower part of the Appenine mountains, in Italy, has been appealed to as a good example of the truth of this hypothesis, for among the shells discovered in them, there are some which bear a resemblance to those now existing in the Mediterranean; while there are others whose analogies are only to be found in warmer latitudes, and many are wholly unknown. We do not see that this theory will stand the test of facts; for we have already seen, that many animals which are now only to be found in warm climates, and also those now extinct, have been discovered in cold regions; and may we not with equal plausibility generalize upon these facts, and say, that they indicate a transition of the earth from an ancient to a modern state of things; perhaps both may be correct, and we may therefore conclude, that the earth has passed through a variety of changes, and has gradually been fitted for the habitation of those numerous animals that now people its surface. This will be more clearly shown as we proceed in our examination of the more ancient rocks which constitute the crust of the earth.

It may be observed, that volcanic agency has been very active during the formation of this group. Etna, it would appear, has for a long series of ages given forth its igneous products, and a considerable portion of these rest upon supracretaceous rocks. In Central France, where extinct volcanoes are numerous, this is still more evident; a volcanic mass, called the Plomb du Cantal, appears to have burst through, and fractured the fresh-water limestones of the Cantal, which, according to Mr Lyell, are equivalent to the fresh-water deposits of Paris, and some of those in England.

4. CRETACEOUS OR CHALKY GROUP.

This group, and the three which follow, belong to the secondary rocks of the improved Wernerian classification. Throughout a large portion of Western Europe, the cretaceous group occurs in the well-known form of chalk. Chalk is a carbonate of lime. It is very plentiful in England; and at Dover and other places, it runs along the coast in cliffs and mountains of considerable size. It is well known that nodules or masses of flint are abundant in chalk, and it is extremely difficult to account for their presence there. These nodules often contain the remains of shells and animals. In the lower parts of the English chalk deposits, the flints disappear, becoming gradually more rare in the passage downwards. From this circumstance, the group has been sometimes divided into upper, or chalk with flints, and lower, or chalk without flints. But this characteristic does not universally prevail. Beneath the chalk, there is a rock called greensand, which in Normandy is used as a building stone. An argillaceous deposit called gault also occurs; it is of a bluish-grey colour, and is frequently composed of clay in the upper, and marls in the lower part.

The cretaceous group, taken as a mass, may in England, and over a considerable portion of France and Germany, be considered as cretaceous in its upper part, and sandy and clayey in its lower part. The group is extensively distributed over Europe; and Mr de la Beche makes the following observations upon its mineralogical character in general: "Throughout the British islands, a large part of France, many parts of Germany, in Poland, Sweden, and in various parts of Russia, there would appear to have been certain causes in operation, at a given period, which produced nearly or very nearly the same effects. The variation in the lower portion of the deposit seems merely to consist in the absence or presence of a greater or less abundance of clays or sands, substances which we may consider as produced by the destruction of previously existing land, and as deposited from waters which held such detritus in mechanical suspension. The unequal deposit of the two kinds of matter in different situations would be in accordance with such a supposition. But when we turn to the higher part of the group, into which the lower portion graduates, the theory of mere transport appears opposed to the phenomena observed, which seem rather to have been produced by deposition from a chemical solution of carbonate of lime and silex, covering a considerable area." Mr de la Beche goes on to state, that no springs or set of springs could have produced the great deposits of chalk which cover immense surfaces. "But," says he, "although springs, in our acceptation of the term, could scarcely have caused the effects required, we may perhaps look to a greater exertion of the power which now produces thermal waters for a possible explanation of the observed phenomena." Mr Lyell states, that chalk must have originated in the sea, in the form of sediment, from tranquil water; and that, before the existence of the rocks above, it must have been raised in large portions above the water, and exposed to the destroying power of the elements.

An immense number of organic remains have been discovered in this group. In various parts of France and England, fish have been observed. Reptiles also have been found; one of them was of considerable size. Shell-fish, and great numbers and varieties of small animals, have been discovered; but the remains of mammalia (animals which bring forth their young alive, and feed them from their breasts or dugs) have not yet been detected. The fossil vegetables in this group are principally marine; and much of the fossil wood is pierced by a boring shell, as if it had been long drifted about in the sea.

A species of rocks called the Wealden rocks occur beneath the lower green sand of the English series, and are characterised by the presence of terrestrial and fresh-water remains in abundance. It would appear that these rocks underwent changes similar to the Paris basin already noticed. Near Weymouth, and in the Isle of Wight in particular, fresh-water and marine remains occur alternately. Amongst the animal remains found in these rocks are varieties of land and fresh-water tortoises, crocodiles, and a species of monstrous terrestrial reptiles.

5. OOLITIC GROUP.

This group is composed for the most part of alternating clays, sandstones, marls, and limestones, many of the latter being oolitic. Oolite stones are a carbonate of lime, intermixed with other ingredients. Those which are found at Bath, Portland, and Purbeck, are much esteemed in building. This group of rocks has been separated by various authors into a number of subdivisions, which, however, can only interest those who

* De la Beche's Geological Manual, p. 195.

have studied the subject minutely. As it occurs over a considerable part of western Europe, there is a general uniformity in its structure. In other parts of the world, however, it differs very considerably, especially in its mineralogical character; and when this is the case, in order to determine whether certain rocks belong to the group or not, recourse has been had to the organic remains contained in them. In some parts of Europe these are very abundant, and in other places the reverse. To account for this difference, it has been supposed that in those parts of western Europe where they are abundant, shallow seas existed; while in those places, such as Italy and Greece, where few remains are found in the formation, the waters were deep.

With respect to the deposition of the oolitic group, nothing very satisfactory can be said. Whence came the immense quantity of carbonate of lime, is a question not easily answered. To account for it by springs, similar in size and saline contents to those we now see, appears to be unphilosophical. Many limestones are nearly altogether composed of organic remains; and this has led to a theory, that these animals extracted lime from the water, leaving their shells, produced through millions of generations, to be gradually converted into limestone. Notwithstanding all that we can suppose was deposited from springs and organic bodies, "there remains," says De la Beche, "a mass of limestone to be accounted for, distributed generally over a very large surface, which requires a very general production, or rather deposit, of carbonate of lime contemperaneously, or nearly so, over a great area."

The organic remains in this group of rocks are very numerous, and several remarkable species of animals have been discovered. There has been one strange reptile, called Ichthyosaurus, found; it was of a very large size, as its jaws are occasionally eight feet in length. In shape it somewhat resembles the crocodile, and, from its form, appears to have been adapted for buffeting the waves. Another, named the Plesiosaurus, had a very long neck, and probably, from its appearance, fished in shallow creeks and bays. From the indigested remains of vertebræ and other bones found in them, we have become acquainted with the food upon which they lived. They not only devoured fish, but preyed upon each other, the larger devouring the smaller. Most voracious and singular inhabitants of our globe these animals certainly were. Cuvier informs us that the Ichthyosaurus has the snout of a dolphin, the teeth of a crocodile, the head and breastbone of a lizard, the extremities of cetacea (being, however, four in number), and the vertebræ of fish; and the Plesiosaurus has, with the same cetaceous extremities, the head of a lizard, and a neck resembling the body of a serpent. It is unnecessary to observe, that no living specimens of these monsters exist.

Mammalia have been found only in one place—Stonesfield. Crocodiles, tortoises, turtles, fish, great varieties of shell-fish, and many kinds of curious reptiles, are abundant. Millions of small animals called Ammonites have been discovered in this series. The shells are shaped something like a ram's horn, and they are furnished with various cells, which the animal appears to have had the power of filling with air or water, as it wished to rise or sink in the sea. Belemnites are another plentiful class of shell-fish to be met with. The destruction of these animals in certain places must have been exceedingly great, beds of rock of great size being almost wholly formed of them. From the vegetable remains discovered, it would appear that some parts of the globe were clothed with a vegetation widely different from that which we now see around us.

6. RED SANDSTONE GROUP.

This group, the next in order as we descend downwards, is sometimes of considerable thickness; the rocks composing it are as follows:—Variegated Marls, Muschelkalk, Red or Variegated Sandstones, Zechstein, and Red Conglomerate or Todliegendes.

Variegated Marls.—Those which lie immediately below the oolitic group, sometimes gradually pass into it. As their name implies, they are generally of different colours:—those of the Vosges, a chain of mountains in the east of France, are principally wine red, and greenish or bluish grey. In the central portion of these marls are beds of black clay, bluish-grey sandstone, and a species of greyish or yellowish limestone. The sandstone and clay contain vegetable impressions, and even coal. In Poland, the rocks which immediately succeed the oolitic formation are termed white sandstone, from their colour. The upper part of this alternates with thick beds of grey-blue marls, partly red, and more rarely variegated; beds of limestone, and a valuable one of iron ore, are found in it.

Muschelkalk is a limestone varying in texture, but most frequently grey and compact; it is sometimes so hard as to be employed as marble; it is unknown in England and the north of France, but, in the east and south of the latter country, and in some parts of Germany and Poland, it occurs. Amongst other organic remains found in it, are those of the Plesiosaurus and Ichthyosaurus, already described. Shell-fish are also abundant.

Red or Variegated Sandstone, or new Red Sandstone of English authors, varies in colour, being red, white, blue, and green; the former, however, predominating. In France and other countries, this rock is sometimes used for building. A bed of it runs from Nottinghamshire into Yorkshire, but it is generally coarse, and often incoherent. A variety of vegetable and animal remains have been found in this rock.

Zechstein, or Magnesian Limestone.—This rock has been variously divided in Germany and England. In the latter country, Professor Sedgwick has separated it into, 1. Marls, slate, and compact limestone, or compact and shelly limestone, and variegated marls. 2. Yellow magnesian limestone. 3. Red marl, and gypsum. 4. Thin-bedded limestone. Like the rest of the group, it is plentifully supplied with organic remains.

Red Conglomerate.—This rock is sometimes called new red conglomerate, and Exeter red conglomerate. As its name implies, it is composed of various substances, a detail of which would be but of little interest here: it occupies the lowest position of the group, and seems, for the most part, to have been formed from the partial destruction of those rocks upon which it reposes.

These five various kinds of rock are not always all present at the same time in the group, sometimes more than one being wanting. Taken as a mass, the group may be considered as a deposit of conglomerate sandstone and marl, in which limestones are occasionally to be found. The conglomerate commonly occupies the lower, the sandstones form the central, and the marls the higher part. "When we look for the causes which have produced this mass," says De la Beche, "we may perhaps in some measure approach them, by observing the state of the rocks on which it rests. These are found, in the greater number of instances, highly inclined, contorted, or fractured, evidences of disturbance which the inferior and older rocks have suffered previous to the deposit of the red sandstone group upon them. These appearances are not confined to particular districts, but are more or less general in western Europe. From an examination of the lower beds, no doubt can exist that the fragments of rocks contained in them have, for the greater part, been broken off from the older rocks of the more immediate neighbourhood.

It therefore does not appear unphilosophical to conclude, that, as far at least as regards these lower conglomerate beds, we have approached to something like cause and effect—the cause being the disruption of the strata, the effect being the dispersion of fragments consequent on this violence over greater or less space, by means of water, probably thrown into agitation by the disturbing forces. That these forces have, in some places at least, not been small, is attested by the large size of the fragments driven off, and the rounded condition of some of them, as may be well seen in the vicinity of Bristol, where the rolled masses of carboniferous limestone are sometimes considerable. Of the evidence of the great force employed, I know of no better or more easily observed example, than that at the cliff named Petit Tor, in Babbacombe Bay, Devon, whence so large a portion of Devonshire marble is obtained."

"This group," says the same author, "would seem to constitute the base of a great system of rocks, which, when not deranged by local accidents, has filled numerous hollows and inequalities of land of considerable parts of Europe. Such a hollow is well seen in our own island, where the central counties are occupied by the red sandstone series, apparently filling up a previously existing depression in that situation, but is here without that great capping of the oolitic group, which, for the most part, rests so conformably upon it; so that, taken as a whole, and abstraction being made of minor derangements, they would both seem to fill up great depressions in Europe; sometimes, as is the case in Normandy, the oolitic rocks overlapping and coming in contact with strata older than the red sandstone group, upon which latter they nevertheless rest so conformably, that the one seems a tranquil deposit on the other. We must of course consider that numerous local disturbances would produce a marked difference in the deposits, even amounting to a perfectly unconformable position; yet the conformable nature of the two groups, taken in the mass, is somewhat striking. During their deposit, great and remarkable changes were effected in animal and perhaps vegetable life; and it seems somewhat necessary to admit, that considerable differences in the relative levels of sea and land were produced at various times, causing changes in the character of the inhabitants of the sea, from variations of pressure, and other circumstances, while no small difference might be effected from the filling up and rise of the bottom."

7. COAL OR CARBONIFEROUS GROUP.

There are three kinds of rocks comprehended in this group, namely, Coal Measures, Mountain or Carboniferous Limestone, and Old Red Sandstone.

Coal measures are composed of various beds of sandstone, coal, and shale. Coal is certainly the most valuable mineral product of the globe. To Britain, it has been, and still is, of inestimable importance, inasmuch as the commercial prosperity of the country in a great measure depends upon it. Our coal is not only the best in the world, but the quantity seems to be almost inexhaustible. It has been ascertained that the coal mines in South Wales alone, which are yet nearly unwrought, would supply the present demand for the article for 2000 years to come. Coal measures abound in vegetable remains, and their origin is now universally ascribed to an immense accumulation of plants and other vegetable matter at some remote epoch. They were distributed upon a previously deposited surface of sand or mud, but principally the latter, which is now compressed into shale. Sands and mud were again accumulated upon the vegetables, and this process went on irregularly for a considerable time, during which successive tribes of the vegetable world sprung up upon the detritus which covered plants formerly entombed, thus giving rise to those irregularly interstratified beds of coal, sandstone, shale, &c., of which this group is composed. At Newcastle, there is a mine containing forty successive coal beds, all separated from each other by layers of sandstone and other rocks. The length of time required for such accumulations must have been immense. The transporting power which deposited these vegetables appears to have been moderate, and the distinct intervals of vegetable growth would require considerable time; for coal beds, now only six or ten feet thick, must, before pressure was applied to them, have occupied a much greater depth. The terrestrial vegetable remains so abundantly preserved in the coal strata, are for the most part laid flat. But there are cases where they occur in a more upright position, and some of them are found vertical, with their roots downwards. This is precisely the manner in which submarine forests are found; and if several of such forests were discovered above each other, we would thus have a series of deposits similar to the coal strata, in so far as vegetable remains were concerned. From the state of preservation in which some of the delicate leaves of plants are found, there is some difficulty in reconciling their deposition with the supposition that strong currents of water bore them down, and distributed them over the extensive areas where we now find them. Such rough transport must greatly have injured the leaves; and how are we to account for vegetables occurring with their roots downwards? On the other hand, De la Beche remarks, "If we are to consider parts of the coal measures as in any way resulting from a series of similar deposits" (to those of submarine forests), "we are certainly called upon to admit a very remarkable series of changes in the relative surface-levels of land and water." There is no doubt of this, but how are we otherwise to account for phenomena? The deposits of the Paris basin already adverted to are quite as remarkable, and they both in a general sense seem to have resulted from similar causes.

The vegetable remains found in coal measures are sometimes of considerable size. Stems of plants fifty or sixty feet long are not uncommon, and in Craigleith quarry one was discovered forty-seven feet in length, the bark of which was converted into coal. With respect to the character of the vegetation in the coal group, botanists inform us that it is insular, and not continental; and that many plants unequivocally indicate an extremely hot climate, even greater than that of the torrid zone. This is another indisputable proof that the temperature of the earth has decreased. The remains of both terrestrial and marine animals have been found, and amongst them were some palates of fish—a very remarkable circumstance.

The coal strata are frequently twisted and shattered, and these dislocations, in the technical language of the miner, are called faults. The occurrence of these, although they may interrupt mining for a time, are highly advantageous. Fractured strata are often bounded by faults, which prevent the passage of water from one mass into another, and thus prevent an overflow of water, which would otherwise paralyze the operations.

Mountain Limestone.—This is a very prevalent rock, and many picturesque mountains of Britain, and other parts of the world, are composed of it. It is frequently traversed by beautiful veins of calcareous spar, at times appearing to be principally composed of organic remains, while at others not a trace of these can be detected. This rock is of various colours, but mostly grey, varying in intensity of shade. In some situations it affords good marble, which is susceptible of a considerable degree of polish. From its durable nature, it is likewise used in building. That stupendous work, the Breakwater at Plymouth, is composed of it. Many valuable mines of lead ore occur in this rock. Shell-fish, and other organic remains of the lower class of animals, are plentiful.

Old Red Sandstone.—This rock consists of grains of sand, or fragments of older rocks, cemented together, and rendered compact; hence it is termed a conglomerate. It derives its red colour from the oxide of iron which it contains. It is of very variable thickness, sometimes very thin, and at others swelling to the depth of several thousand feet. A specimen of it may be seen at Hawthornden, where it frequently occurs under coal strata. Few organic remains have been discovered in this rock.

The line of separation between the three members of the carboniferous group is generally well marked; in some parts of Scotland, however, we can scarcely say that this is the case. Considerable difficulty is felt in making distinctions in this country, which is increased by the presence of rocks belonging to another group altogether. This is otherwise in the northern districts of England, where the red sandstone rocks have evidently been deposited upon the limestone and coal after the latter had suffered violent dislocations. A considerable portion of the surface of Ireland is covered by this group, the limestones being very abundant. With respect to the deposition of the series, great changes in the power by which it was affected must have taken place at various times. In some parts it is evidently a mechanical formation, and in others, for instance the limestone, in which myriads of small animals are found where they have apparently lived and died, there is evidence of a slow, or perhaps a chemical formation. But the subject is still involved in considerable obscurity, and an investigation of it cannot be entered into here.

8. GRAUWACKE GROUP

This group, and the one which follows, are the Transition Rocks of the Wernerian classification:—Grauwacke is a very prevalent rock, and consists chiefly of argillaceous matter, for the most part of a slatey texture, in which numerous fragments of other rocks and stones are imbedded. Viewed as a whole, the grauwacke series consists of a large stratified mass of arinaceous and slatey rocks, intermingled with patches of limestone, which frequently extend to considerable distances. Roofing slate is not unfrequently met with amongst the grauwacke rocks. The group occurs in Norway, Sweden, and Russia. A portion of southern Scotland is formed of it, from whence it proceeds down western England into Normandy and Brittany. It appears abundant in Ireland, and patches of it are found in other parts of the globe. There is in North America a large deposit, closely agreeing with it in many respects, "so that," says a writer upon the subject, "there is evidence to show that some general causes were in operation over a large portion of the northern hemisphere, and that the result was the production of a thick and extensive deposit, enveloping animals of similar organic structure, over a considerable surface." From the character of the substances composing the grauwacke group, it would seem to have been slowly deposited. The origin of the limestones has afforded matter for much speculation. We cannot, as we formerly did for the previous limestone rocks, suppose them to have resulted from the exuviæ of marine animals, because we would be thus called upon to consider that carbonate of lime was once more abundantly present in the sea than we now find it, and that it has been gradually deprived of it. This supposition would naturally lead us to expect that the sea, having been deprived of a considerable portion of its carbonate of lime, the rocks composed of it would become less and less abundant as we rose from the older to the more modern formations. But this is the very reverse of the case: it has been supposed that the carbonate of lime has been derived from the interior of the earth; and as it is not unfrequent in volcanic regions, great disruptions of the strata may have produced circumstances more favourable for its deposition at one time than at another. "Be this as it may," says an eminent writer upon the subject, "the limestones in the grauwacke series most frequently run in lines parallel to the general direction of the beds; and although the calcareous matter may not be altogether continuous, there has evidently been some cause in operation at the same time, within a given district, more favourable to the production of limestone, than at another. It is also worthy of attention, that when the limestones occur, then also do the organic remains become more abundant, appearing as if the calcareous rocks and the organic remains were connected with each other." That animals, by secreting lime from the medium in which they lived, may have contributed considerably to the mass, is evident from their remains occurring in abundance; but that it may all be attributed to their operations, appears impossible, for in certain districts not a trace of animal exuviæ is to be found.

In the organic remains of the grauwacke group, there is a mixture of existing and extinct animals, which is remarkable, considering the antiquity of the rocks. A family of small animals, called Trilobites, appear to have been the first living creatures who inhabited our earth. Their forms vary considerably; and in some which we have examined, the head and mouth extended over the whole diameter of the body. They seem now to have entirely disappeared from among existing animals. Several families, such as the genus called *Spirifer*, survived the deposition of this series of rocks, as they occur in after formations; but in these they must have been finally entombed, since no living trace of them is now to be found: others again have weathered the various vicissitudes and revolutions of the globe, and are continued up to the present day; amongst these are several species of corals.

With respect to the vegetation existing at this early period of the earth's history, from the remains found, it would appear to have been similar to that which is so abundantly preserved in the preceding series of rocks. Indeed, the formation of several coal mines has been referred to this epoch—an important fact, as it proves the existence of dry land, with vegetables upon it, contemporaneously, or nearly so, with the dawn of animal life. What other creatures may have existed at this period besides fish, and the other organised beings already mentioned, it is impossible to say; but there is no presumption in supposing, that, since vegetation clothed the dry land to some extent, terrestrial animals, suited to the circumstances of the time, were not wanting, for this is only in accordance with the general harmony we at present observe in nature.

9. LOWEST FOSSILIFEROUS GROUP.

Although this group is little more than one of convenience, being but the lower part of the preceding series, it is the opinion of some geologists that it may be separated from the grauwacke mass. The study of this part of our subject is very difficult, and presents few attractions to any class of readers but those who have paid some attention to the science. The rocks composing this group are intermixed with those of igneous origin, so that the most deceptive appearances prevail, thus rendering a fine distinction between them and the group below obviously impossible. We have thus, in a descending order, arrived at a period when there was a combination of those causes which produced fossiliferous and non-fossiliferous strata—when there was, as it were, a conflict between the powers of fire and water, until "nature reclaimed her order," and the latter prevailed. "That there should be a transition or passage," says De la Beche, "even effected by the alternate operation of particular causes from that condition of the world's surface, when chemical action prevailed, to that when mechanical action became more abundant, is what we should expect, since it is in accordance with our knowledge of rock deposits generally; for we observe, however suddenly certain changes may have been produced in particular situations, that, viewed on the large scale, a general change of circumstances attending rock formations has been more or less gradual."

The remains of organic life discovered in this formation are few, and similar to those in the group above; but we are not to infer from this that animal life was scarce. We have said, that trilobites were probably the first creatures that inhabited the globe, but this is only inferred from their being the lowest specimens of organic life hitherto found. There may have existed previous to them myriads of fleshy and gelatinous animals which perished without leaving one solitary trace behind that they had ever lived, and moved, and had their being in the waters. Indeed, Dr Turner has suggested, that, if we suppose these animals to have been abundant at an early period, we may thus account for the bituminous nature of some of the earlier limestones, especially those which do not contain a trace of organic remains.

INFERIOR STRATIFIED OR NON-FOSSILIFEROUS ROCKS.

Hitherto the hardest and most compact substances that we have met with have been characterised by the presence of organic remains, but we now enter upon the examination of a class of rocks which were formed at a period when, as far as our knowledge extends, neither animal nor vegetable life existed on the globe—a period antecedent to that when the Divine Spirit, which Milton so sublimely invokes,

> "With mighty wings outspread,
> Dove-like sat brooding on the vast abyss,
> And made it pregnant."

This group, and that which follows, have long gone under the name of primitive or primary rocks, because, from their occurring lowest in the series of rocks, and also from their containing no organic remains, they are supposed to have been first in the order of formation. Before describing them, it will be necessary to give an account of four substances which enter largely into their composition, namely, Quartz, Felspar, Mica, and Hornblende.

Quartz, or silica, is a crystalline substance of various colours, but generally in appearance something like white glass. It scratches glass, strikes fire with steel, and is sometimes nearly transparent. It presents itself almost pure in the form of rock crystal, in the varieties of flint, agate, chalcedony, and siliceous sand. It is a metallic oxide, its base is called silicium. The scientific world is indebted to Sir Humphry Davy for its decomposition. Quartz is very extensively used in the arts. When combined with soda, it forms glass, and, with alumina, porcelain and pottery ware.

Felspar is another crystalline stone, which displays various colours, and refracts the light. It principally consists of a mixture of sandy and clayey matter. Lime and potash are also present, and oxide of iron occasionally colours it of a reddish hue. Its colours are usually white, red, and grey. It is softer than quartz, but harder than glass, and therefore scratches it. Felspar is used in pottery, that of Cornwall, from its fine quality, to a considerable extent. Some beautiful varieties of it are employed in jewellery. It is one of the most abundant minerals in nature, and enters largely into the composition of a number of rocks, as we shall shortly see.

Mica is very common, and easily recognised. It also consists principally of flint and clay, with a little magnesia and oxide of iron. It is of a lamellar or leafy texture, and easily splits into thin layers or plates, which are transparent, and highly elastic. Before the invention of glass, it was employed as a substitute for that useful article. Indeed, in some parts of the world it is still used in place of glass. It is soft, and may be scratched with the nail. Its usual colours are brown and light grey, but sometimes it is black. Those shining specks and small thin plates observed in sand and various other substances are mica. It is sometimes, but very rarely, found crystallized.

Hornblende is another plentiful mineral. It is crystalline, and of a dark green colour, approaching to black. Its constituents are alumina, silex, magnesia, and a considerable proportion of the black oxide of iron, from which it derives its dark colour. Whipstone is composed of this mineral and felspar.

The individual rocks of the inferior stratified series are not so easily distinguished as those which lie above them, they are so confusedly mixed up with each other. The strata very seldom exhibit one species of rock extending over a large tract of country, except, perhaps, the clay slate.

Clay Slate contains a considerable portion of argillaceous matter. It is disposed in layers, which are easily split into thin slabs. In colour it varies from a greyish white to a deep blue or black. Extensive beds of it occur in Scotland and Cornwall, as well as in other parts of the globe. It is used to a great extent as a roofing for houses. The best slates for this purpose found in Scotland are those of Easdale, and some neighbouring islands off the coast of Lorn, in Argyle, and in Ballachulish, in Appin. The finest kinds of clay slate are used for writing on, and the pencils employed are a softer species of the same rock. Those little metallic masses which we discover in this and other slates, are iron pyrites. Pyrites are native compounds of metals and sulphur. These slates are often so very like those of the grauwacke series as to be undistinguishable from them, which renders their origin very ambiguous. *Chlorite Slate* is chiefly composed of a substance called chlorite, resembling mica, but softer, and of a green colour. It is sometimes mixed with quartz, felspar, mica, and hornblende, in various proportions. *Talcose Slate* is a rock into which clay slate graduates, and not unfrequently it passes itself into mica slate. Talc is a substance similar to mica, or is rather a species of mica.

Quartz Rock.—Quartz we have already described. The rocks composed of it vary in texture, sometimes apparently of a chemical, and at others of a mechanical origin. It is pretty abundant in Scotland; and in South America, Humboldt takes notice of a mass more than 9500 feet in thickness.—*Hornblende Rock and Slate.* Under this head are included all those compounds, evidently contemporaneous with the rocks amongst which they occur, of which hornblende constitutes the principal ingredient.—*Mica Slate* is essentially composed of mica and quartz, and forms extensive tracts of country, as well as thin beds, included amongst other rocks.—*Eurite* is principally, and in many cases entirely, composed of the substance called compact felspar. It is generally subordinate to gneiss or mica slate, and does not appear to constitute any extensive tracts of country.

Primitive Limestone.—This is an important rock, and is easily known from other limestone, by containing no organic remains. To it belong those various kinds of statuary marble so valuable in the fine arts. An account of the varieties of marble is incompatible with our limits. It is found in several parts of Scotland; but the finest is the Parian marble, of which the famous statue, the Venus de Medici, is formed. It is almost incapable of decay. A question here arises, under what circumstances could marble have been produced? It is a carbonate of lime, and must have been, from its compact texture, subjected to great heat. Now, carbonate, when heated, gives out its acid, but the acid is still present in the marble. Sir J. Hall has thrown considerable light upon this obscure subject. He subjected common carbonate of lime to heat, under a high pressure, which prevented the escape of the acid. The consequence was, that the lime was fused, and a substance obtained which in every respect was identical with the finest marble. We are therefore justified in inferring, that, under a high pressure in the bowels of the earth, nature formed her extensive beds of statuary marble.

Gneiss is composed of quartz, felspar, mica, and hornblende, with an occasional mixture of other minerals. It occupies very considerable tracts of country, and we are informed by Professor Jameson, that all the useful metals, except mercury, occur in this rock. *Protogine* may be arranged with gneiss, as they are very nearly similar, and both are closely allied to granite. These are the most remarkable of the inferior stratified rocks, but they are far from being the whole of them, for the varieties and transitions of the one into the other are endless, and set classification at defiance.

We cannot enumerate the various situations where these rocks are to be found. They occupy a large portion of the earth's surface, and they always occur with constant general characters, so that we may suppose them all to have resulted from common causes, and those of a chemical nature, since the prevalent mineralogical characteristic of the mass is confusedly crystalline.

UNSTRATIFIED ROCKS.

This group, which is widely diffused over every part of the globe, comprises those rocks usually called Volcanic, Trappean, Serpentinous, and Granitic. They are found mixed with almost all the stratified formations, and bear every mark of having been thrown up from beneath. For the most part, they either occur as "protruded masses, as overlapping masses which have resulted from the spread of matter after ejection, or as veinstones filling up fissures, apparently consequent on some violence to which the strata have been subjected." The substances principally entering into the composition of these rocks are quartz, felspar, hornblende, and mica, which have been already described individually. The compounds which they form either when they are all present, or when two or more constitute the elements, are exceedingly various in their aspect and texture.

Granite.—The most prevalent and important rock of this class is a confusedly crystalline body, composed of the four substances above named; but these are not always all present; sometimes only two of them are found in a mass, which obtains the name of granite. This rock was long considered the fundemental one on which all the others were accumulated; but this opinion was abandoned when examples occurred of its resting upon stratified and fossiliferous rocks of comparatively recent origin. Granite is common in Scotland, forming a great proportion of the Grampian mountains which intersect the country; it is also found in England, but not so abundantly. It forms a beautiful stone for building, and though used for that purpose, it is not so to an extent commensurate with its value. "In general," says Mr Brande, in his Outlines of Geology, "granite is the most durable of nature's productions, and long resists the destroying hand of time; and though, in common cases, its extreme hardness is against its employment, its use should be enjoined for public edifices." There is assuredly no danger of exhausting the material. Mr Williams, in his Natural History of the Mineral Kingdom, informs us, that there is as much granite in the mountain of Ben Nevis alone, and that "perhaps the best and most beautiful in the world," as were adequate "to serve all the kingdoms of the earth, though they were as fond of granite as the ancient Egyptians." Some idea of its durability may be formed from the excellent state of preservation in which the grand head of Memnon is found, and that of the celebrated column vulgarly called Pompey's Pillar, which still stands entire, amid the mouldering ruins of the ancient city of Alexandria. The obelisk in the Palace of St Jean de Lateran, at Rome, which was quarried at Syene, in the reign of Zetus, King of Thebes, thirteen hundred years before the Christian era; and that in the Place of St Pierre, also at Rome, which a son of Sesostris consecrated to the sun, has, for three thousand years, survived the vicissitudes of nature and of time.

The most common granitic compound is that which has quartz, felspar, and mica, for its constituents; when hornblende is present, instead of mica, it is called Syenite, from its abounding in the island of Syene. When quartz and felspar occur alone, and the crystallization is such that the former appears disseminated in the latter, it is termed graphic granite, from its bearing a supposed resemblance to antique graphic characters. Granite is sometimes porphyritic, large crystals of felspar being disseminated through the mass. The porphyry of Ben Nevis is a beautiful stone, in which the pale rose and colours of a yellowish white are finely blended and shaded. The porphyry of the ancients was chiefly of a red colour, and from this quality it derived its name.

Serpentine.—A rock of this class has been so called from its resembling the skin of a serpent, in the delightful admixture of various colours which it exhibits. Several fine specimens of this stone are found in Britain, particularly at Portsoy, in Banffshire. A curious substance called asbestos occurs in this rock. There are five varieties of it, and all are more or less fibrous and flexible. From one of these the ancients made *cloth*, which was incombustible. When these habiliments required cleaning, it was only necessary to throw them into the fire, whence they came forth completely purified, and as uninjured as the three Jewish youths who went through the ordeal of the furnace. The Esquimaux use it as a substitute for wick in their lamps. Mountain cork, another kind of asbestos, floats on water. *Soapstone*, or *Steatite*, is also found in serpentine rocks. It derives its name from having a soft feel, somewhat resembling that of soap. Humboldt assures us, that some of the North American savages use it for food, although there is not a particle of nourishment in it. It writes on glass, the characters remaining invisible until breathed upon; far from being fugitive, they can only be destroyed with the glass itself.

Trap Rocks.—Certain rocks have obtained this name from their presenting very often the appearance of steps and stairs. Arthur's Seat and the Calton Hill, and the principal mountains surrounding Edinburgh, are composed of them. Trap rocks consist of basalt, clinkstone, greenstone, amygdaloid, &c.

Basalt.—This rock very frequently presents the most remarkable appearances; the most wonderful of which are Fingal's Cave, in the Island of Staffa, and the Giant's Causeway, in Ireland. The entrance to the former resembles a Gothic arch, and is about seventy feet high; the length of the cave is 227 feet, and the breadth from forty to fifty; the sides are composed of masses of basalt arranged in columns, with considerable regularity throughout. This magnificent temple of nature has been frequently described by scientific and other travellers, but all description would seem to fall short of the reality. The following are the impressions which it made upon the mind of a great poet:—

> "Where as to shame the temples deck'd,
> By skill of earthly architect;
> Nature herself, it seemed, would raise
> A minster to her Maker's praise!
> Not for a meaner use ascend
> Her columns, or her arches bend;
> Nor for a theme less solemn tells,
> That mighty surge that ebbs and swells."
>
> *Lord of the Isles.*

The Giant's Causeway consists of three piers of columns, which extend several hundred feet into the sea, and are walled round by towering rocks, some hundred feet high, in which are clusters of columns of various forms and inclinations. Basalt frequently shoots upward in abrupt masses, without displaying any columnar appearance. The rocks upon which the Castles of Edinburgh, Stirling, and Dumbarton, rest, are examples of this kind. Clinkstone, another species of trap rock, derives its name from emitting a ringing sound when struck. Greenstone is of a pale green colour, and composed of felspar and hornblende. Whinstone is a rock of the same kind. Amygdaloid is so called from small nodules of an almond shape occuring in it.

Walls or dykes, that is, long ledges or walls of greenstone intersecting a different description of rock, are very prevalent in this formation. These appearances may be seen on the western side of Salisbury Crags, and in several positions on the Calton Hill, in the neighbourhood of Edinburgh. In the coal strata these dykes also occur. The trappean rocks are so common in nature, that any further notice of their "local habitation" is superfluous. They are found mingled with stratified rocks in every possible way; and for a more minute account of them, and also of all the rocks in this group, we may refer the reader to Macculloch's Western Islands. Mr Gregory Watt has made several most interesting experiments to ascertain the causes which have produced the columnar and globular structure of these rocks. He fused a considerable quantity of basalt, and allowed it to cool very gradually; by this means spheroids were formed in the mass, which explains the phenomena of globular basaltic rocks. His remarks were also extended to the columnar structure, and the theory of their origin, hence deduced, is exceedingly plausible, but an explanation of it would carry us far beyond our limits. We can, therefore, only refer the inquirer to the Philosophical Transactions for 1804.

We have now passed in review before the reader the various stratified and unstratified rocks of which the crust of the earth is composed. A more minute account of the almost endless diversity of substances, and their intimate and complex relations to each other, it was impossible to give within our necessarily circumscribed limits. But we hope enough has been done to satisfy the minds of that numerous class of individuals who wish a comprehensive view of a subject presented to them without being fatigued with minute details, or entertained with barren speculation; while in other minds there may have probably been awakened a desire to prosecute the study by reference to more laborious and amplified compilations devoted to the subject, or to that most perfect and sublime of all works—Nature herself.

From the foregoing detail of unquestionable facts, we may with perfect safety infer, First, That all solid bodies have formerly been in a soft or fluid state, that they were either fused by fire or held in suspension by water; for how otherwise can we account for the presence of organic bodies in them? Secondly, That some terrible convulsion, or a series of convulsions, has rent the solid pavement of the earth, and upheaved the bed of the sea, in many instances beyond the regions of perpetual snow; for how otherwise can we conceive of marine remains being imbedded in elevated mountain rocks? Not assuredly by means of the deluge; yet such an explanation of the phenomena has been given, with all due gravity, in works published so late as the year 1832. The theory of Voltaire, in one of his numerous and very absurd essays on geology, was even more plausible than this. That singular man hated the Christian religion so much, that he hated every thing which was brought forward to support it. When it was stated that the shells found upon the Alps afforded a proof of the deluge, he replied, with admirable tact, that they were eastern species, which had fallen from the hats of the Syrian pilgrims. On another occasion, he observed, "that the bones of a rein-deer and hippopotamus, discovered near Etampes, did not prove, as some would have it, that Lapland and the Nile were once on a tour from Paris to Orleans, but merely that a lover of curiosities once preserved them in his cabinet." Thus he threw doubt indiscriminately on all geological subjects. Thirdly, That the globe has existed many (it is impossible to calculate how many) thousands of years previous to the creation of nature's "chief ornament," man. Amongst other facts which support this conclusion, the absence of his remains, and those of his works, in strata where vegetables and the lower animals occur in infinite number and variety, is one which cannot be explained away, and appears to be decisive of the point. Let not the Christian reader be startled at this statement, and sarcastically exclaim with the pious Cowper—

> "Some drill and bore
> The solid earth, and from the strata there
> Extract a register, by which we learn,
> That he who made it, and revealed its date
> To Moses, was mistaken in its age."

It goes directly to corroborate the Mosaic account of the time which has elapsed since the human race first appeared upon the globe. This is now agreed upon by all philosophers whose opinions are worthy of notice. With regard to the creation of the earth itself, the language of Scripture, particularly with regard to *time*, is metaphorical; so that to found any argument upon it would be quite unphilosophical.

THEORIES OF THE EARTH.

There is nothing so important to science as a correct generalization of facts, which go to prove that nature has adhered to a certain number of fixed principles, from which she never deviates, in developing particular parts of the mighty scheme of creation, unless, perhaps, it be the collection of the facts themselves; and yet there has nothing retarded its progress more than the hasty deductions from too limited observation. The truth of this is more strikingly exemplified in the history of geology than in that of any other science. The theories and conjectures as to the manner in which the substances composing the globe were first amassed, and the vicissitudes to which rocks and strata have been subjected, so as to account for their present positions, and the alternation of hill and valley, are various and conflicting. Two, however, stand conspicuously forward—those of Werner and Hutton. The Wernerian or Neptunian theory, as it is called, supposes that the whole materials of the earth were held in solution by water, and that they were gradually deposited in layers or strata, the granite falling down first, and the other formations following in succession, according to the order of superposition. The Huttonian or Plutonic theory supposes a continual decay and reproduction to be taking place on the earth's surface. Mountains and rocks are worn down by the agents already noticed at the beginning of this article, and, being arranged in strata at the bottom of the ocean, are acted upon by the agency of fire, and thrown up again in the shape of mountains, &c. The characteristic feature of Hutton's theory is the exclusion of all causes but those which belong to the present order of nature. Its great defect is the undue influence ascribed to subterranean heat, supposed necessary for consolidating submarine deposits. It was the opinion of the Scotch geologist that there were alternate periods of disturbance and repose; that, when the ruins of former continents had furnished sufficient materials for new ones, they were heaved upwards by violent and paroxysmal convulsions. These two theories for several years kept the scientific world in a ferment. Each had its partisans, and the virulence and rancour with which the belligerents carried on the warfare is without a parallel in the history of philosophy. Religious zeal added a fearful contribution to the amount of abuse and contumely heaped upon the heads of the heretical volcanists. "In the economy of the world, I can see no traces of a beginning, no prospect of an end," said Hutton. He threw the creation of the globe many ages farther back than what was then deemed the orthodox period of cosmogony. He may be said to have exhausted time, according to all previous notions, of the extent of its duration, and to have borrowed largely from eternity; and yet there are now comparatively few who will be disposed to doubt the truth of what Hutton advanced. How should there be any traces of a beginning or of an end? The works of the great Creator are not like those of man, which have inherent in them the elements of their own destruction. "He has not permitted in his works," says the gifted Playfair, "any symptom of infancy or of old age, or any sign by which we may estimate either their future or their past duration. *He may put an end, as he no doubt gave a beginning*, to the present system at some determinate period of time; but we may rest assured, that this great catastrophe will not be brought about by the laws now existing, and that it is not indicated by any thing which we perceive."

The lamentable exhibition of human frailty displayed in this philosophical crusade, for a time retarded the progress of just views with regard to geology, but in course, a third party took its rise, and rapidly gained ground. The members composing it observed a strict neutrality, and were zealous in collecting facts, not for the purpose of supporting speculative doctrines, but of ascertaining truth.

It is now pretty generally admitted, that, after all, neither of the two theories answers the various conditions of the problem to be solved. A third theory is at present gaining ground, and it appears to be a very rational one. It is reared upon, and partly constructed of, the ruins of the Huttonian. Discarding the idea of paroxysmal convulsions at particular epochs, and an extraordinary influence of subterranean heat for the consolidation of submarine deposits, it explains the former changes of the earth's surface, by reference to causes now in operation. Professor Lyell has published an admirable work in support of this opinion. It would be doing injustice to the author were we to attempt to give an abstract of his various arguments, deduced from an unusual mass of evidence, which goes to support the doctrine. We take pleasure, however, in referring the reader to the work; and if he be not convinced of the correctness of the fundamental view there entertained, he cannot fail to admire the ability and eloquence with which it has been advocated.

With respect to Mr Lyell's theory, we have, in conclusion, one observation to make:—Since it is now pretty generally admitted, that the temperature of the earth was a good deal higher formerly than what it now is, would not the causes at present in operation, under such circumstances, act with a greater degree of intensity, and produce more extensive results?

EDINBURGH: Printed and Published by W. and R. CHAMBERS, 19, Waterloo Place; also by W. ORR, Paternoster Row, London; and W. CURRY, Jun. and Co. Sackville Street, Dublin. Sold by John Macleod, Glasgow, and all other Booksellers in Scotland, England, and Ireland.—Published once a fortnight.
Numbers, containing accounts of New South Wales, and Van Dieman's Land, with maps, for the use of emigrants and others, are in preparation.
Stereotyped by A. KIRKWOOD, St Andrew Street, Edinburgh.

THE COTTON, SILK, WOOLLEN, AND LINEN MANUFACTURE.

THE COTTON MANUFACTURE.

The Cotton Manufacture of Great Britain is, altogether, one of the most wonderful triumphs of mechanical invention. To it are we mainly indebted for the commanding position which Great Britain at present holds amongst civilised nations. It has alike proved our "prime sinew" in the struggle of warfare, and (next to agriculture) our main prop in the time of peace. It has at once called forth the resources of British genius, and furnished a boundless field for active industry, and the employment of capital. Perhaps the surest way of commanding the attention of our readers to the subject, and impressing upon them its immense national importance, is simply to state, that the cessation of our cotton manufacture at this moment, were such a contingency possible, would at once throw idle, and expose to all the miseries of poverty and privation, nearly a *million and a half* of our countrymen, and dry up a source of national produce of the annual value of nearly *forty millions sterling*, whereof *twenty millions' worth are consumed by foreign countries!* But even these facts, startling as they may seem, are not the most remarkable features of this branch of art. That so large a field for industry, and the employment of capital, should have been opened up within the short space of little more than half a century; that, after travelling five thousand miles for the raw material, returning with it to our shores, incurring all the outlay of dressing, manufacturing, &c., we are able to carry it back, in its finished state, and actually dispose of it *at a profit*, to the growers themselves, amongst whom the cost of labour is not a twentieth part of what it is with us!—these circumstances, we say, appear almost incredible. And the seal of the miraculous is put to the whole by the fact, that all this has been accomplished by the inventive genius of a few humble, and, for the most part, poor and illiterate individuals!

HISTORY.

The period at which the cotton manufacture was first introduced into Great Britain, is conjectured to have been in the early part of the 17th century, as we find the first mention of it made by Lewis Roberts, in his "*Treasure of Traffic*," published in 1641. From the same authority, we learn that Manchester is entitled to the credit of being the first seat of the art—that our cotton wools were originally brought from Cyprus and Smyrna, to which places, as well as to other foreign parts, they were even then re-exported in a manufactured state. As a source of commercial profit, however, this species of traffic must have been, at the above period, very insignificant, the only mechanical power employed in the fabrication of the yarn being the common one-thread spinning-wheel. From the above period until far on in the last century, that simple instrument continued to be the only machine used for the spinning of cotton yarn. During that long interval, the *weft*, or transverse threads of the web, only, were cotton, it having been found difficult, if not reckoned impossible, owing to the want of proper machinery, to manufacture cotton *warp* (the longitudinal threads) of sufficient strength, and in place of which, *linen* yarn, principally from Germany and Ireland, was substituted. The cotton manufacture was then wholly conducted on what may be called the *cottage system*. Every weaver was a master manufacturer; his cottage was his factory, and himself the sole artisan. He provided himself with the weft and warp as he best could; wove them into a web, and disposed of it at market to the highest bidder. As the demand for the manufacture increased, however, it began to attract the attention of the merchants, or purchasers of the ready-made goods; and, about 1760, a new system was introduced. The Manchester capitalists began to send agents through the country, who employed the weavers at so much *per piece*, furnishing them with the foreign or Irish linen yarn for warp, and with raw cotton for weft. The carding and spinning of the cotton (the latter process being, even then, generally done with the spindle and distaff), by giving employment to all the branches of the family above a state of infancy, was a wonderful benefit to these domestic manufacturers, who were thus also relieved from the expenditure of their time and limited means in the providing of the materials; although it must be obvious, that, in a commercial point of view, it was impossible to prosecute the manufacture, on any very extensive scale, by such a mode. By the custom-house returns, it appears that in 1705 the average weight of cotton-wool imported into Great Britain amounted to only 1,170,881 lbs.; nor did any considerable increase take place for upwards of sixty years afterwards. It was estimated, on the accession of George the Third, in 1760, by Dr Perceval of Manchester, that the entire value of all the cotton goods at that time manufactured in Great Britain did not exceed L.200,000 a-year. The year 1767, however, was destined to form a new era in this branch of manufacture, and to witness the commencement of a series of mechanical inventions altogether unparalleled in their nature and results. James Hargreaves, a common weaver at Stanhill, near Church, in Lancashire, and, according to some, originally a carpenter at Blackburn, having by chance seen a common spinning-wheel, which happened to be overturned, continue its rotatory motion for some time whilst lying on its side, conceived the idea of his *spinning-jenny*, which he afterwards constructed with his own hands in a very rude manner, containing only eight spindles driven by bands from a horizontal wheel; but which, by subsequent improvements, was soon so much enlarged as to enable a little girl to work no fewer than from *eighty* to *one hundred and twenty* spindles at the same moment. The amazing facility derived from this invention in the process of spinning, soon of course became publicly known, and excited, as all such beneficial inventions generally do in the minds of the ignorant, the greatest alarm and indignation amongst those who earned their living by the old mode of spinning. Their fury at last broke out into open violence; they attacked Hargreaves's house, forced the door, and broke his machine to pieces. Nor did they stop here. Several years previous to the invention of his *jenny*, the same ingenious individual had effected a great improvement in the process of carding, by which one man was enabled to perform double the work, and with more ease, than by the original method. Although soon superseded, it unquestionably had given rise to the *carding-engine*, the real author of which is not exactly known; but it has been ascertained that the grandfather of the present Sir Robert Peel was the first manufacturer who erected one of the latter, which he did with the assistance of Hargreaves, at Blackburn, in the year 1762. With the latter fact also still fresh in their minds, the old one-thread spinners and hand-carders became so exasperated against poor Hargreaves, that they rose in a body, scoured the country in all directions, and demolished every piece of the new machinery on which they could lay their hands. The unfortunate object of their dislike was compelled to flee from his native place, and retired to Nottingham, where he took out a patent for his invention. But even there he was not allowed peaceably to enjoy the fruits of his ingenuity. His patent was invaded, and he found it necessary to apply to the courts for redress. A numerous and powerful association was in consequence formed to defeat his efforts, the wealth and influence of which, he was, unassisted, unable to contend against; and he was obliged to give up the contest, and submit in silence to see himself robbed of his just rights. He soon after fell into a state of extreme poverty, and, to the disgrace of his age and nation, was permitted to end his days in Nottingham workhouse! It must here be mentioned, however, that Hargreaves's *jenny* was only of use in the weaving of *weft*, or the transverse threads of the web, the warp continuing to be spun of Irish or foreign linen yarn. The honour of discovering the mode of spinning cotton yarn of sufficient strength and texture for the latter purpose, was reserved for another, who, almost contemporaneously with Hargreaves, was employed in perfecting an invention which soon produced a complete revolution in the whole art of cotton-spinning.

Having in an early number of our Journal given a sketch of the life and mechanical inventions of Sir Richard Arkwright, our readers might reckon a repetition of it here superfluous. We shall, therefore, for the sake of preserving the chain of our narrative of mechanical improvements unbroken, do little more than glance at the nature and dates of his various inventions, referring such as may not have seen the biographical sketch alluded to, to No. 16 of our Journal, or to the "Library of Entertaining Knowledge," whence it was taken. Arkwright was born at Preston in 1732, of very poor parents. He was the youngest son of thirteen children, and was bred to the trade of a barber, at which he continued until nearly thirty years of age, when he gave up shaving and cropping, and became an itinerant dealer in hair. It was whilst engaged in this peripatetic occupation that he first turned his thoughts to mechanics, and commenced an ardent search for the discovery of the *perpetual motion*. At an after period of his life, Arkwright (then Sir Richard) used to state that he derived the first hint of his great invention of the *spinning-frame* from seeing a red-hot bar of iron elongated by being made to pass between rollers. The precise time when he received this hint is not exactly known, but it is conjectured to have been nearly about the same time with Hargreaves's novel conception of the *spinning-jenny*; as it is ascertained, that, when the latter made his valuable invention known, in 1767, his rival in ingenuity was busy in the construction of his spinning-frame. Arkwright's want of funds, however, together with his utter ignorance of mechanism, long hindered his getting the conceptions of his genius embodied in a visible and tangible shape; and, even after his model was completed, by the assistance of a watchmaker named Kay, at Warrington, whom he employed to prepare the parts of the machine, the benefit of his invention was nearly for ever lost to mankind, for want of friends and patrons to assist him in giving it a trial on a proper scale of magnitude. Like poor Hargreaves, too, he began to experience the persecution of the ignorant and deluded rabble of Lancashire, who soon got notice of the important nature of his machine; and he, too, took refuge in Nottingham in 1768. But his future fortune was destined to be of a far different description from that of his unfortunate mechanical rival. Having procured an introduction to the celebrated Jedediah Strutt (the first adapter of the stocking-frame to the manufacture of *ribbed* stockings), to whom he explained the principles of his machine, that sagacious man perceived at a glance the value of the invention, and immediately entered, conjointly with his partner Mr Need, into partnership with Arkwright. Accordingly, in the following year, 1769, a patent for spinning by rollers was taken out in Arkwright's name, and the first mill upon that principle, driven by horses, was erected at Nottingham in the same year. The working by horse-power was soon found too expensive, and a second factory, upon a much larger scale, was erected at Cromford, in Derbyshire, in 1771, which was driven by a water-wheel. It is from the successful application of the latter power to the process that the invention has derived its denomination of the *water-frame*, and the yarn manufactured by it that of *water-twist*.

If ever any invention deserved the appellation of *original*, it was that of Arkwright. The discoveries of Hargreaves, and others who preceded him, can only be viewed as *improvements* upon previously established principles, wonderful and ingenious although they certainly were. The *spinning-frame*, on the other hand, bears not the least affinity to any mode of spinning previously known, or from which the inventor could derive the most distant suggestion. It was the genuine offspring of natural genius, conceived, matured, and brought into operation under difficulties and privations which only the ardent mind of an enthusiast could have borne up against and overcome. For a full description of the *spinning-frame*—a machine which performs in itself the whole process of spinning, leaving to man only the trouble of feeding, or supplying it with the raw cotton—we refer our readers to the biographical sketch above alluded to; the article on "Cotton Manufacture," in *Brewster's Encyclopædia*; the Supplement to the *Encyclopædia Britannica*, Vol. III.; and a very valuable work on cotton-spinning, published by Mr Niven, jun., bookseller, Glasgow, in 1832, entitled, the "Carding and Spinning Master's Assistant." We shall here only shortly mention the principle of its operation. It consists of two pairs of rollers turned by machinery. The lower roller of each pair is furrowed or fluted longitudinally, and the upper one is covered with leather, to make them take hold of the cotton. As soon as the carding, or *roving*, as it is technically called, of cotton, has begun to pass through the first pair of rollers, it is received by the second pair, which are made to revolve with three, four, or five times the velocity of the first pair, according to the desired tenuity of the thread. A twist is, at the same time, given to it by the adaptation of the spindle and fly of the common flax-wheel to the machinery.

As in the case of poor Hargreaves, the vast importance of Arkwright's discovery speedily raised up against him a host of opponents, rivals in trade, who left no effort untried to get his patent set aside, and to appropriate to themselves the merit and profits of his ingenuity. For the sake of brevity, as well as for the credit of the nation, we refrain from recapitulating the particulars of these disgraceful and malicious ebullitions of envy and avarice. The result of the first of these, in 1772, terminated in the discomfiture of his enemies. A verdict was given in his favour, and he was permitted to enjoy the benefit of his patent, without further opposition, until the expiry of the term of fourteen years. Having subsequently taken out another patent, however, for further inventions in other departments of the carding and spinning processes, the exertions of his opponents were more successful, and his patent was set aside on the score of *deficiency in the specification of the various inventions.* But the most extraordinary and invidious feature of these proceedings was, that, on the latter occasion, in 1786, *sixteen years after* Arkwright's claim to the invention of spinning by rollers had been fully established, a poor reed-maker at Bolton, of the name of Highs, or Hayes, was brought forward, *for the first time*, to dispute the originality of it with him. This man, who had also formerly attempted to deprive poor Hargreaves of the merit of the spinning-jenny, deponed to his having invented the roller-spinning machine previously to 1768; that he employed the watchmaker, Kay (above mentioned), to make a model of it; and Kay was brought forward to swear that he had communicated that model to Arkwright. The utter falsity and groundlessness of this trumped-up story is too apparent to need refutation—were it only from the fact of the pretender remaining for such a length of time, not only in the most abject poverty, but maintaining the profoundest silence, whilst the alleged pilferer was accumulating a princely fortune before his eyes. Independently, also, of this circumstance, the testimony both of Hayes and Kay is evidently unworthy of any credit—the former, from his previous base attempt on Hargreaves' patent; and the latter, from having, according to his own statement, betrayed a secret invention, entrusted to his keeping, to a stranger. Sir Richard Arkwright (having been knighted on the occasion of presenting a congratulatory address to his Majesty George the Third, in 1786, upon his escape from the treasonable attempt against his life by Margaret Nicholson, when he (Sir Richard) was high sheriff of Derbyshire) died at his seat, at Cromford, on the 3d of August 1792, in the sixtieth year of his age; a noble and encouraging example, even to the humblest of mankind, of the wonders to be achieved by sober industry, habits of observation, reflection, and perseverance, and a virtuous and well-regulated moral conduct.

Great, incalculably great and important, however, as were the results of Sir Richard Arkwright's spinning-frame to the art of cotton-spinning, it nevertheless had its drawbacks and deficiencies. Although, by its means, the previously insurmountable difficulty of spinning the *warp* from cotton had been overcome, it was found that the yarn it produced was of too firm and hard a texture to render it suitable for weft, and that it could not be used with advantage in weaving cloth of a finer quality than what is technically termed No. 50. But this objection was soon obviated by the ingenious contrivance of another individual, who may be termed the *third* great benefactor of this branch of our national manufactures. In 1775, and during the currency of Sir Richard's first patent, Mr Samuel Crompton, of Bolton-le-moors, Lancashire, invented his *mule-jenny*, being an union of the essential properties of the inventions of his two predecessors in discovery. With this machine commenced an entirely new era in the art of cotton-spinning, in as much as it was found capable of producing varieties and qualities of yarn before unattainable; and all the finer descriptions of cotton fabrics may date their origin from its introduction. As an illustration of the degree of tenuity or fineness of which it has been found practicable to spin cotton yarn by this machine, we may mention, that a single pound of raw cotton has been spun by it into 350 hanks, each hank measuring 840 yards, and forming together a thread 167 miles long! The usual price paid by the muslin manufacturers of Glasgow for the finer yarns at first spun by the mule was *twenty guineas per pound.* The mule, however, did not come into general use until after the dissolution of Sir Richard Arkwright's second patent in 1785, ten years after its discovery; yet so rapid was the progress it made, that, in 1787, only two years after its introduction, no less than 500,000 pieces of cotton muslin—a species of fabric never before attempted—were made in Great Britain, the manufacture of it having been begun simultaneously in Bolton, Glasgow, and Paisley. Mr Crompton never took out a patent for his invention, but upon an application to Parliament, which he was advised to make in 1812, a reward of L.5000 was voted to him. During the investigation that took place at the time before a Committee of the House of Commons, it was proved that there were then *four millions* of spindles employed on Mr Crompton's principle; that two-thirds of the steam-engines for spinning cotton, turned *mules*; and that the value of the buildings, machinery, &c., employed on the same principle, amounted to about *four millions* sterling.

The mule was originally wrought by the hand; one man being able to manage two mules, each containing 144 spindles. But, in 1792, Mr William Kelly, of Glasgow, then manager of the Lanark mills, invented, and took out a patent for, a mode of moving it by machinery. By this new mechanical power, it was found practicable for a man to manage 800 spindles at the same time! Like poor Hargreaves, however, Mr Kelly never derived any substantial benefit from his invention. His patent was immediately invaded by others, of too much wealth and influence for him to contend against; and, though the undisputed inventor of the machine, he chose rather to submit to that most cruel and intolerable of robberies, than involve himself in an expensive, and, at best, doubtful litigation.

Whilst Arkwright and others were contributing the efforts of their genius to raise the character of manufactures in England, the celebrated James Watt, of Glasgow, was employing all the powers of his original mind in endeavouring to adapt his steam-engine to almost every species of machinery, particularly to *rotative motions.* In this he at last perfectly succeeded, and, in 1782, erected the first engine on this principle at the Bradely iron-works. In 1785, Messrs Bolton and Watt were employed by the Messrs Robinsons, Popplewick, Nottingham, to erect a steam-engine in their manufactory there; and this was the first instance of the application of that power to the spinning of cotton. What must have been the emotions of Watt and Arkwright had they been (and we cannot say they were not) present together at this first union of their great inventions, and seen the plans brooded over so long and earnestly in the hidden recesses of their minds, brought thus practically, and upon so splendid a scale, to co-operate together for the benefit of mankind! During the same year, no less than eight other engines were erected by Messrs Bolton and Watt, in as many cotton manufactories in England; and it is needless to say how far, since then, that power has gone to supersede the employment of every other, in all branches of manufacture. The above year, indeed (1785), may be regarded as the first of the "golden age" of British cotton manufacture, not only from the circumstance just named, but two others, which equally contributed to give an impetus to the trade altogether unprecedented, and which has never since showed symptoms of a reaction. These were—the cancelling of Sir Richard Arkwright's second patent, and the discovery of the power-loom.

The invention of the *power-loom* was attended with circumstances every way as singular as those which marked any of the inventions which preceded it. The Rev. E. Cartwright, a clergyman at Hollander House, Kent, happening to be in company with some Manchester gentlemen at Matlock, in 1784, the conversation turned upon Arkwright's inventions, when these gentlemen all stated their conviction, that, upon the expiry of the patent, so many mills would be erected, and so much yarn spun, that it would be impossible to procure hands to weave it. Mr Cartwright observed, that Mr Arkwright must in that case set his wits to work to invent a weaving-mill. The Manchestrians all declared this to be impracticable; but Mr Cartwright denied there could be any greater impossibility in inventing a machine to weave than to spin; and having subsequently set his *own* wits to work, actually produced, in the following year, a loom, every movement of which was performed by machinery. Previously to the construction of his machine, he states that he knew nothing whatever of the principles of mechanics, had never seen a loom at work, and was utterly ignorant of the process of weaving. In an interesting account which he sent to Mr Bannatyne at Glasgow (author of the article on Cotton in the Supplement to the *Ency. Brit.*) of this his first initiation in the mysteries of mechanism, he gives a ludicrous picture of the style in which his machine wrought when first set a-going. "The warps," says he, "were placed perpendicularly; the reed fell with the weight of at least half a hundredweight; and the springs which threw the shuttles were strong enough to have thrown a Congreve rocket! In fact, it required the strength of two powerful men to work it at a very slow rate." He took out a patent for his invention in 1785, and a second, upon an improved system, in 1787. Many years elapsed, however, ere power-loom weaving became general, or was even found at all advantageous. The first power-loom mill, erected by Mr Cartwright himself at Doncaster, failed, as did also subsequent ones at Manchester and Glasgow. The first approach to any thing like success was made in a large weaving-mill, erected at Catrine, in Ayrshire, by Messrs James Finlay and Company. This was in 1805, eighteen years after the invention was made public. In 1806, the same spirited Company erected another mill at Doune, in Stirlingshire, the two establishments containing between them 462 looms. The great defect in the system of power-loom weaving was, that it was found necessary to stop the loom from time to time, in order to dress the webs, which made it impossible for one man to attend to more than one loom at a time. Owing to this great drawback, it is more than probable that the plan would have been long since abandoned, but for the invention of a beautiful and ingenious machine by a Mr Thomas Johnson of Bradbury (but which is generally attributed erroneously, even by Mr Bannatyne, in the *Supp.* to the *Ency. Brit.*, to Mr Ratcliffe of Stockport, from that gentleman's being the first to render it effective, and bring it into notice), for warping and dressing the warps without stopping the loom, and by which means a boy or girl of twelve or fourteen years of age can now manage two looms, and produce three times as much cloth, and of a better quality, as the best hand-weaver could produce! The date of this last invention was about the year 1813, since which time the employment of power-looms has spread with astonishing rapidity. The number at present at work in Great Britain is estimated at considerably above 50,000, of which 10,000 are conjectured to be in Scotland. Is it too much to predicate, judging from what we have already seen, that hand-weaving will speedily be entirely superseded by machinery? Mr Cartwright afterwards obtained a Parliamentary grant of L.10,000 for his discovery.

A great improvement on the power-loom was subsequently made by Mr Peter Marsland of Stockport, by the invention of the *double crank*, the value of which consists in making the lathe strike the cloth a quick blow, in coming in contact with it, which renders it more stout and evenly.

From what has been before stated, it will at once be inferred that Scotland followed considerably in the wake of the sister kingdom in the art of manufacturing cotton cloth. Yet it is a singular fact, that, almost immediately upon its introduction amongst us, we took and have uniformly kept the lead in the fabrication of all the finer and more fanciful sorts of cotton goods. Although checked by many unavoidable obstacles—the chief of which was the want of experienced mechanics and other workmen—it was not long ere Arkwright's plan of spinning by water began to be acted on. The first cotton spun by that power in Scotland is supposed to have been in the island of Bute, in what had previously been a lint-mill, and afterwards became the corn-mill of Rothsay; and about the same period it was also begun to be spun at Pennycuick mills, nine miles south of Edinburgh. In 1780, the Barrhead mill, in the parish of Neilston, was completed; soon after, that of Busby, in the parish of Mearns. In 1782, a large mill, of six stories, now the property of Browns, Malloch, and Company, was erected at Johnston, in Renfrewshire; shortly after this, a large establishment was erected at Blantyre; and next followed Mr Dale's works at Lanark, in which Mr Arkwright himself was for some time a partner. Without further detail, suffice it to say, that there are now considerably above one hundred cotton-spinning mills in Scotland.

What are called *fancy goods*, were first manufactured of cotton, at Paisley, which had previously been the chief seat of the silk gauze manufacture. All the yarns for the finer cotton muslins, nevertheless, continued to be brought from Manchester, not from any defect in the machinery, or scarcity of proper machine-makers in Scotland, but owing to a peculiar adroitness or sleight of hand acquired by a few out of the great bulk of the English cotton-spinners. About the year 1815, a most ingenious machine was invented by Mr John Duncan, of Glasgow, for *tambouring.* Each machine, at the very outset, contained forty tambouring needles, and was superintended by a little girl, whose duty was to piece the threads together when they broke. For this invention, Mr Duncan took out a patent, which afterwards became the property of the Messrs Mitchell, at Glasgow. Pullicat handkerchiefs were first made in Glasgow, in 1785, which place still continues the principal mart of that article. Blue and white checks and stripes for exportation, were, until Sir Richard Arkwright's discoveries, entirely composed of linen, but are now wholly made of cotton, and are manufactured in great quantities in various parts of Scotland. The chief seat of them, however, is Carlisle. Cotton cambrics began also to be made about the same time—the manufacture of which separated itself *spontaneously*, if we may use such a term, into two branches—namely, that of cotton-cambric for garments, in a white or printed state; and cambric, in imitation of French linen-cambric, and intended to be used as garments along with that article. The first of these was adopted by the Lancashire, and the second by the Lanarkshire weavers; nor have either of the parties ever been able to rival the workmanship of the other in their respective departments. Bandana handkerchiefs were first manufactured in Glasgow, in 1802, nor have they ever been attempted to be made any where else. They are first dyed of a bright Turkey red, and the colour afterwards discharged from those parts which form the pattern or figure, by passing a chemical preparation through them. Calicoes were not wrought in Scotland until the year 1801, unless upon a very insignificant scale at Perth. The total value of the manufactured cotton goods in Scotland—that is to say, the expenses of labour and profit, superadded to the price of the raw material—was estimated some years ago by Sir J. Sinclair at very nearly L.7,000,000; but that its present amount is much beyond this, is evident from the ascertained fact, that in and around Glasgow alone, the value of the goods manufactured at this moment is upwards of L.6,000,000 sterling.

PRESENT EXTENT AND VALUE OF THE COTTON MANUFACTURE IN GREAT BRITAIN.

The present prodigious extent of the cotton manufacture in Great Britain, can only be properly judged of by comparing it with what it was formerly. To go no farther back than 1781—fourteen years, even, after the invention of Hargreaves's jenny—we find that in that year there were imported of cotton wool 5,198,778 lbs. In 1831, the imports were 280,800,000 lbs.! In the former year the exports of cotton yarn were 96,788 lbs.; in 1831, they exceeded 70,125,000. The number of yards of cotton *cloth* exported in 1829 was 402,517,196, valued at nearly L.13,000,000 sterling. Since that time, however, a great increase has taken place. In 1760, the value of the whole cotton goods, when manufactured, was, as we have stated, estimated at L.200,000; at present they may be rated at L.40,000,000! Mr M'Culloch calculates the amount of capital employed in the manufacture at fully L.50,000,000. L.23,000,000 is employed in the payment of wages alone; L.35,000,000 invested in spinning mills, power and hand looms, workshops, warehouses, &c.; and L.6,000,000 in the purchase of the raw material.

Suppose the quantity of cotton wool consumed and converted into yarn in England and Scotland, in 1831,

to be - - -	262,500,000 lbs.
allowing 1½ oz. per lb. lost in spinning	24,609,375
Quantity of yarn produced -	237,890,625 lbs.
Suppose the average size to be No. 50, the number of hanks produced would be -	11,894,531,250
Number of spindles employed, supposing each to produce 2½ hanks per day, 300 working days in a year - - - - -	15,859,375
Number of persons employed, supposing each to produce 120 hanks per day - -	330,400

This is supposed to include merely those that are employed within the factories; it does not take in machine makers, founders, carriers, warehousemen, engineers, wrights, masons, cardmakers, &c. &c.

Suppose the above yarn, No. 50, to be woven into 10.00° jaconet, with warp and weft the same quality, 2½ lbs. of yarn will make 24 square yards of cloth. The quantity of yarn produced in one year would make 2,283,750,000 yards, sufficient to cover a space of 1,208,153 square miles, which would about eleven times cover the whole surface ground of England, Scotland and Ireland, the superficial extent of which are 57,960—29,167—30,370 square miles respectively, equal to 117,497 square miles. If the number of spindles employed be 15,859,375, allowing 500 to each horse power, then to move the above spindles will require 31,719 horses' power.

EFFECTS ON THE POPULATION.

But there is no point of view in which the rise and growth of the cotton manufacture appears so remarkable as in its results on the population of the districts where it is carried on, being chiefly in Lancashire and Lanarkshire. The parish of Manchester, for instance, which in 1774 contained 41,000 inhabitants, had increased in 1831 to upwards of 187,000. The population of Preston, which in 1780 was 6000, is now 34,000. In Bolton, Blackburn, Wigan, &c. &c., the ratio of increase is equally great. But the progress of Liverpool (not properly a seat of the manufacture, but one of the sea-ports, where the consequent importing and exporting are carried on) is, perhaps, the most extraordinary. In 1700, its population amounted to 5145. In 1770, before mechanical invention had given such an impetus to the cotton manufacture, it had increased to 34,000; in 1801, it had risen to 78,000; and in 1831, to 176,000. In 1780, Glasgow contained about 43,000 inhabitants; in 1801, 83,000; and in 1831, they reached nearly 203,000. The case of Paisley is even more striking. In 1782, the number of inhabitants, including the Abbey Parish, was 17,700; in 1831, they amounted to nearly 60,000.

But however gratifying a picture of increasing national prosperity the foregoing results may present, there are one or two considerations therewith connected which have given rise to much anxious reflection in the minds of philanthropists. One of these is the effect on the moral character of the community, which must ensue from the crowding together under one roof, and in promiscuous communication, of such masses of human beings as the factory system—the direct result of mechanical invention—has introduced. On a question of such delicacy and importance, however, it is not our province here to enter. Neither would it suit our limits to discuss the merits of another subject, which has long engaged the sympathies of the humane, but which, we trust, is now in the course of being thoroughly investigated, and, where wrong, corrected—the treatment of the many thousands of helpless little children employed in the various factories.

In Ireland, the cotton manufacture is as yet of little importance in a national point of view, but it has been thriving very rapidly since the abolition of the protecting duties in 1823, in so much that the increase in the two subsequent years—viz. to 1825—was no less than *twelvefold*. The return for the latter year showed 6,418,645 yards of manufactured cotton, of which the chief proportion is of yarn sent from England. In fact, it has in many places utterly superseded the great staple manufacture of linen. The chief seat of it is around Belfast; but it is also carried on to a great extent at Dublin, Kildare, Wicklow, Wexford, and Louth. Calicoes and muslins are likewise extensively manufactured in the counties of Wicklow, Cork, Down, and Queen's County.

THE COTTON PLANT—REARING, GATHERING, AND STORING THE COTTON.

The name of "cotton" is supposed to be a corruption, or modification, of its Arabic denomination, *cootin*. The plant is indigenous to all the tropical regions of Asia, Africa, and America. It is also partially cultivated in Russia, Spain, and other countries of Europe; but, latterly, to a very great extent in the southern states of the American Union. Herodotus records, that in India there are wild trees that produce a sort of wool superior to that of sheep, and that the natives dress themselves in cloth made from it. The cotton plant has even been known to ripen in some sheltered situations in England. J. Blackburn, Esq. M. P. had a gown made from cotton grown in his own garden, for a dress for his lady to appear in at court. Four ounces of the raw material made 7½ yards muslin, 1½ yard broad. The cotton plant is raised from seed, and consists of two distinct kinds, *annual* and *perennial*, which require different modes of rearing, and treatment. At first, the young plants are extremely tender, and are easily killed with frost. These are all pulled up by the roots when they are six or seven inches high, and transplanted into regular beds. Light showery weather is most favourable for the crop. The seed is generally planted in March or April, and, in September and October, the gathering of the cotton is general; but it usually continues till Christmas, as the pods ripen very slowly and gradually. The *perennial* cotton tree is almost exclusively raised in Guiana and the Brazils upon the alluvial soil thrown out by the overflowing of the great rivers. The cotton tree is frequently attacked by a large caterpillar, which commits great destruction; and one singular peculiarity attending its ravages, and which has never been explained by naturalists, is, that, when feeding, a fragrant odour is emitted from the plant, although neither the plant nor the insect possess any scent whatever when separate. All cottons, except Upland and New Orleans, yield black seed; but these two give green seed. Between three and four leaves, with which the unripe nuts are surrounded, grow flowers larger than roses, of a yellow colour, streaked with red. These blossoms afterwards change into a green fruit, which becomes black as it ripens, resembling exactly in shape and colour our common small black plum. When fully ripe, this fruit bursts into three parts, thrusting out white cotton full of black seeds. After the cotton is gathered, it is exposed to the rays of the sun till it is perfectly dry and hard. The seeds are then separated by passing through between two wooden rollers, slightly grooved, and about ⅝ths of an inch in diameter; this is called ginning the cotton. It is then carefully picked to free it from broken seeds, leaves, &c. A method of switching it for this purpose was at one time tried, but it was found to break the cotton too much. The cotton is next compressed into bales by means of a screw-press, and in this state it is sent to Europe.

DIFFERENT GROWTHS AND QUALITIES OF COTTON—WHERE IMPORTED FROM.

Few vegetable productions vary so much in quality and kind as cotton. It is distinguished in commerce by its colour; the length, strength, and fineness of its fibre: that of a natural yellowish hue is reckoned the best. Cottons are classed into *long* and *short stapled*. The East India cotton, from Surat, Bengal, &c., was long reckoned the best quality, but it now stands lowest in the market. Smyrna wool was, as we have before noticed, the first imported into Britain, but a very trifling quantity is now used, and that chiefly for candle-wick. The cotton grown in the West India islands is in general a strong, coarse article, and little of it is now imported. It is said, however, that the finest cotton ever brought to England was raised by a Mr Robley, in the island of Tobago, about the year 1790, and it is thought the plant might still be cultivated there with success and profit. The imports from the Brazils have been remarkably steady for upwards of twenty years; in 1831, they amounted to 29,786,970 lbs. Those from the other parts of South America have been decreasing for some years. Wool from Egypt was first imported in 1823, and is of a very superior kind. It is from North America, however, that the great proportion of wool is imported into Great Britain—exceeding considerably, it is estimated at the present moment, *two hundred and thirty millions of pounds annually*; although, previous to 1790, not one single pound of raw cotton was derived thence. By far the finest cotton known is that raised in the southern states of Georgia and Carolina, where it only began to be cultivated after the conclusion of the American war. American cotton is known by the names of *Sea Island, Upland, New Orleans, Alabama*, &c.; of these, the *Sea Island* is far superior to all other kinds. It is grown on the low sandy islands, stretching along the shores of Georgia, and on the low grounds bordering the sea. The *Upland* is that grown farther into the interior; but, from the difficulty at first found to separate this cotton from the seed, it was scarcely thought worth cultivating, until a Mr Whitney, in 1793, invented a machine for performing this so effectually, that upwards of 100,000,000 pounds of this cotton are now imported into Great Britain.

PREPARATION OF RAW COTTONS FOR MANUFACTURE.

As it is quite impossible, without the aid of diagrams, to give the unskilled reader any intelligible idea of the numerous and complicated machines employed in the preparing, dressing, spinning, &c. of cotton, we must confine ourselves to a brief enumeration of the various processes which it undergoes in its way to the hands of the weaver.

The first, and one of the most important things to be attended to, is the *mixing*, by spreading in a *bing* of regular layers, of the peculiar sorts of cottons found most advantageous for weft or warp, as the case may be. There is only one *general* rule which obtains in this part of the process, viz. that all the cottons thus mixed be, as nearly as possible, of equal length in the staple. All the rest must be left to the skill and experience of the manager, who regulates the mixing according to the quality of yarn required, &c. The cottons, when well mixed, are then put through a machine called the *willow*, the use of which is to tear asunder the lumps of cotton, which are almost as hard as wood on their arrival in this country. After the cotton is thus opened up, it is put into the *scutching machine*, which beats and opens out the fibres of the cotton, so as to make it spread easily and equally, and also cleanses it of sand, seeds, dead cotton, &c. This was formerly all done by the hand with switches; but that mode was latterly found far too tedious, as well as too expensive. After being thus beaten and cleansed, the cotton is placed on the *spreading machine*, a recent substitute for hand labour, the use of which is to spread a given weight of cotton into a given length and breadth, so as to prepare it, of a uniform thickness, for the cards. This is a most important process, and but for the *economy* of the machine, hand-spreading would still be most in use, being found much more certain and uniform. The next process is that of *carding* the cotton, the nature of which all our readers must be familiar with. We have before mentioned the improvement in this stage by the invention of the carding-engine. The cotton on coming out of the engine is formed into a thick soft ribbon, called an *end*, which is conveyed by machinery into the *drawing-frame*. This was the great triumph of Arkwright's genius. Previous to his time, the *drawing* was all done by the finger and thumb; but his double rollers, the principle of which we have before explained, at once entirely superseded that mode, being at once incalculably cheaper and more perfect. Between the *draw-frame* and the *mule-jenny*, by which the cotton is finally converted into finished yarn, there are various other subsidiary processes, which it is needless here minutely to describe. Their principal use is to reduce the grist of the end, preparatory to its being spun into a thread of the required tenuity. The machines for that purpose, some of which are fast becoming obsolete, and others just newly introduced, are severally termed the SLABBING-FRAME, the CAN-FRAME, the SKELETON-FRAME, the JACK-FRAME, the THROSTLE-FRAME, the FLY-FRAME, the TUBE-FRAME, the STRETCHING-FRAME, &c. &c. In addition to these machines, it is of importance to notice, that a new throstle-frame has been invented by Mr Robert Montgomery of Johnston, Scotland, for which he last year (1832) obtained a patent, which it is considered will soon supersede all the machines hitherto used for spinning low numbers and for making copes.

SILK MANUFACTURE.

It is universally agreed that to the Chinese the world is indebted for the discovery of this beautiful species of fabric. The period of its origin is, however, totally unknown, like almost every other national art and attribute of that extraordinary and exclusive people. Their written records date it nearly 3000 years before the Christian era, but the subject is so much enveloped in traditionary mystifications, as to baffle all attempts to get at any thing like certainty on the subject. It need only be mentioned, therefore, that long before even the very existence of the material was known to other nations in ancient times, the weaving of silk had attained a degree of perfection in China which appears altogether extraordinary and unaccountable. The period of the first introduction of silk amongst the Romans is conjectured to have been during the reign of Julius Cæsar, but for a long time afterwards it was merely used as an article of theatrical decoration. Laws were even made prohibiting its being worn as male attire, both on account of its costliness and the effeminate disposition it was supposed to denote. The voluptuous and profligate Emperor Heliogabalus was the first to break through the prohibition, and the custom of wearing silk speedily became a national one, although its high price necessarily restricted the luxury to the wealthier classes. Down to the time of Justinian, about the middle of the sixth century of the Christian era, the manufacture of silk continued to be wholly monopolised by the Chinese, the intercourse between whom and the Romans was carried on by means of caravans, which traversed the interior of the Persian empire. About the period just mentioned, however, war having broken out between the Romans and the Persians, the usual supplies from China were at once stopped; and this circumstance, which, of course, was regarded at the moment as a great national misfortune, was the direct means of the first introduction of the manufacture into Europe. As silk, from being a luxury, had then become an indispensable article of apparel, the Roman Emperor, after the breaking out of hostilities with the intermediate state, offered splendid rewards for the discovery of a mode of cultivating and weaving silk in his own territories. Encouraged by these promises, two Persian monks, who had gone as Christian missionaries into China, and had resided long enough to make themselves perfectly acquainted with the then mysterious process, contrived to secrete a quantity of silk-worms' eggs in a hollow cane, which they brought to Justinian at Constantinople. These eggs were duly hatched and propagated under the care of the monks, who, at the same time, instructed the Romans in the whole process of manufacturing their production. The insects thus produced were the progenitors of all the silkworms which have since been reared in Europe and the western parts of Asia, and ultimately became the means of establishing a source of manual industry throughout many nations of the world, the extent and importance of which it would be no easy task to calculate. From Turkey, the silk manufacture, together with the rearing of the insects, rapidly spread into Greece, Italy, Spain, and Sicily. In 1480, that sagacious and politic monarch, Louis the Eleventh, who clearly saw the value and advantages of the silk manufacture, invited workmen from different parts of Italy, and by bestowing on them many important and exclusive privileges, induced them to establish themselves at Tours. Little progress, however, was made in the manufacture until the reign of Francis the First, who, upon getting possession of the Duchy of Milan, in 1521, prevailed upon some of the native artisans to remove to Lyons, and establish themselves under his protection. The art quickly spread into Provence, and other provinces of the south of France, where the rearing of the silk-worms was carried to great perfection, and continued to thrive still faster under the subsequent reign of Henry the Fourth, who rewarded the early manufacturers, who had pursued the trade for twelve years, with patents of nobility.

The weaving of silk, that is to say, raw silk, imported from abroad, appears to have been practised in England long previous to its introduction into France, and at an early period of the fourteenth century, as mention of it is made in an act of Parliament, in the year 1363 (37 Edw. III). But little progress appears to have been made in it, whether as respects quality or quantity, until the time of Elizabeth—and, even then, only in such small wares as ribbons, purses, and girdles. It is worthy of mention, that Elizabeth herself was the only individual of her court who wore silk stockings. It was near the close of the reign of James the First before the manufacture of broad silk was first begun in England by some throwsters, dyers, and weavers, who were induced to emigrate from the Continent, and establish themselves in London. From that moment, the trade increased so rapidly, that, in 1629, the throwsters of London formed a body of sufficient importance to be incorporated. A short interruption to the progress and prosperity of the manufacture took place during the Parliamentary wars, but it speedily revived after the Restoration; and we learn from an act, passed in 1661 (14 Car. II.), that the incorporation of silk throwsters at that time employed 40,000 men, women, and children. It must here be observed that, hitherto, although several temporary prohibitions had from time to time been laid on the importation of woven silks, these were seldom enforced, and the trade may almost be said to have been quite free.

But it was not until the famous revocation of the edict of Nantes, in 1685, by Louis the Fourteenth, that the English silk manufacture assumed much importance in a commercial point of view. Upon that event, which drove nearly a million of individuals, most of them merchants, manufacturers, and artificers, from France, a large number of silk weavers emigrated to London, and established themselves in the district of Spitalfields, London, which has ever since continued to be the chief seat of this manufacture in Great Britain. The stimulus thus given, both in numbers and mechanical skill, speedily placed the English silks on a par with, if not superior to, the workmanship of foreign countries; yet, strange to tell, it was at this very time, when all cause of apprehension from foreign competition seemed to be at an end, that that blind system of prohibitions against importation of silks from abroad commenced, which has continued, until the last few years, to operate so fatally against the prosperity of this important branch of art. In 1692, an act was passed in favour of the Spitalfields refugees (who were at the same time incorporated by charter, under the name of "the Royal Lustring Company," prohibiting the importation of lustrings and alamodes, the articles then most generally in use. That this measure was passed from the most patriotic motives, and as a special mark of national gratitude to the Spitalfields emigrants, there can be no doubt; and it is only to be regretted that such short-sighted policy has been persevered in up to so late a date. The immediate consequence of the act was a relaxation of exertion and industry, from a sense of security from foreign rivalry, on the part of the monopolists. Inferior manufacture and discretionary prices again gave rise to a contraband traffic; and as one bad act generally germinates, like a fly-blow, a host of others in the statute-book, so, in 1698, a new charter was granted greatly enlarging the privileges of the Spitalfields Company, and extending the term of prohibition in their favour, which was made to include various other articles of manufacture besides those formerly prohibited, to fourteen years. The ingenious Frenchmen immediately adopted a new expedient for assailing their self-secure rivals; they set themselves to improving, with all their ingenious skill, those articles not underlying the bans of prohibition, and the result was, that, long before the expiration of their patent, the fashions underwent an entire change, and the Spitalfields Company, indolently trusting to a reaction in their favour, instead of pushing forward in the new field of competition, was completely ruined.

The popular doctrine of the present day, that governments are ever in the rear of the people as regards liberal views of policy, does not seem always to have obtained in practice. Upon the settlement of the treaty of Utrecht, in 1713, a commercial treaty was at the same time drawn up between England and France, for the mutual importation of the manufactures of each kingdom at a low *ad valorem* duty. So violent and general, however, was the outcry immediately raised against this contemplated measure, that it was found necessary to withdraw the Parliamentary bill for its ratification; the chief arguments against its adoption being the extraordinary ones, that the silk manufacture had increased twenty-fold in the course of fifty years—that almost every sort of silk fabric was made as good in England as in France—and that black silk for hoods and scarfs, which formerly was all imported, was now made at home to the amount of L.300,000, whereby an immense increase had taken place in the exportation of woollen and other goods, to Turkey, Italy, and other countries abroad, whence the raw silk was imported.

Up to 1718, our silk weavers were almost wholly dependent upon the throwsters of Italy for the supply of organzined silk; but, in that year, a Mr (afterwards Sir Thomas) Lombe, having, in the disguise of a common workman, succeeded in taking accurate drawings of the throwing machinery at Piedmont, erected a stupendous mill of five stories high, and one-eighth of a mile in length, for that purpose, at Derby, and obtained an exclusive patent for fourteen years. This enormous erection contained 26,586 wheels, and 97,746 movements, which worked 73,726 yards of organzined silk thread, with every revolution of the water-wheel, whereby the whole machinery was driven; and as this wheel revolved three times in each minute, no less than 318,504,960 yards of organzined silk could be produced daily. Sir Thomas's patent expired before he had received any thing like an adequate remuneration from his establishment for the expense of its erection, and an application for the renewal of it was rejected. The sum of L.14,000 was, however, awarded to him by Parliament. Dr M'Culloch states as his opinion, that the introduction of throwing-mills into this country has greatly deteriorated, instead of having benefited, our silk manufacture; but, we confess, we do not very clearly see the force of his reasons for coming to this conclusion.

For nearly a century after the above period—that is to say, from the decade of 1730 to 1824—the history of our silk manufacture presents little else than a succession of complaints, by the manufacturers, of the importation of foreign silks, ineffectual attempts on the part of the legislature to check it, and combinations and outrages amongst the workmen. Motions and suggestions innumerable were made in Parliament, Committees appointed to investigate and report, &c.; but all the legislative attempts on the subject seem to have been conceived with a narrowness of view, and a partiality of application, which rather tended to aggravate than ameliorate the evil. These attempts consisted almost solely in eking, altering, and patching old acts, or devising limited new ones, to suit temporary emergencies and appease troublesome clamour. In 1773, an act was passed, called the "Spitalfields Act," by which the *magistrates of Middlesex* were empowered to settle the rate of wages between master and workman, and severe penalties were exigible both from him who gave and him who received more than the fixed sum; while the manufacturers were forbid from employing any other than Spitalfields weavers! This act, after producing incalculable mischief, was repealed in 1824, when more liberal views began to be entertained on the subject of the silk manufacture. At that time the duty on organzined or thrown silk was no less than 14s. 7½d. per lb.; on raw silk from Bengal, 4s. per lb.; and from other places, 5s. 7½d. At the suggestion of Mr Huskisson, the duty on the first was reduced to 7s. 6d. (it was further reduced to 5s. in 1826), and the duty on raw silk to 3d. per lb.; great reductions were also made in the duties on dye stuffs. It is most gratifying to know, that, since 1826, when the removal of the previous restrictions took place, our silk manufacture has rapidly increased in value and importance; and it is no exaggeration to say, that it has, within the last six or seven years, made more progress than during a whole century preceding. The greatest importation of raw and thrown silk during any one year previous to the repeal of the prohibitory system was in 1823—namely, 2,432,286 lbs.; whereas, in 1831, it amounted to 4,693,517 lbs., being nearly twice the quantity imported when the monopoly was in its vigour. (Perhaps it ought here to be mentioned, that the removal of the restrictive duties on foreign silk was first suggested and strenuously recommended by a Committee of the House of Lords.) Most of the machines and processes known on the Continent have been introduced amongst us, and many of them materially improved. In every species of plain and substantial silk fabrics, the manufacture of Britain is acknowledged to be infinitely superior to that of France, as well as in all mixed manufactures, such as silk with wool, silk with cotton, silk with linen, &c. For many years bypast, Edinburgh has been much distinguished for the manufacture of shawls, which, for richness and substantial quality, we believe, are now second to none produced in any part of the world, with the exception of India. In the manufacture of ribbons, gauzes, and other light fancy goods, as well as in the style of *finish*, the French still maintain the superiority, but the difference is becoming daily less perceptible. Since the alteration of the duties, however, the importation of French gauze goods has driven our own almost entirely out of the market. Several Paisley manufacturers are now working for the London market in imitation of French gauzes.

The best black dye of silk is reckoned to be that used in Genoa. The next is our own. From the great depression of prices in consequence of foreign competition, our silk dyers are at present vying with each other in endeavours to dye the silk without discharging the gum. This is a great deterioration in the silk fabrics. It is called supple; the French first commenced the practice.

One great cause of the inferiority of the British silk fancy goods to those of the French, is, that in this country there is no common standard of fashion; every manufacturer makes goods for the year which his own taste suggests, so that there is no certainty of the article coming into general fashion. In France, the leading manufacturers communicate with each other, and fix on one or two colours and kinds of goods, which are submitted to the taste and decision of some leading person of fashion. By this means, the energies of all the manufacturers are engaged in competing for the superiority in producing the best fabrics of the same pattern.

We obtain the greatest part of our plain ribbons from Switzerland.

Having thus given a brief outline of the rise and progress of the silk manufacture up to the present time, we shall now advert in detail to some of the more curious processes in its production, dressing, weaving, &c. And it is proper we should here state, that in what follows we have been indebted for much of our information to an admirable Treatise on the Silk Manufacture, lately published by Dr Lardner, in his Cabinet Cyclopædia.

THE SILK-WORM, OR BOMBYX.

We have already noticed that the discovery of the valuable properties of this little animal belongs to China. It is a species of caterpillar, and undergoes a variety of changes during the short period of its life, assuming, in each of three successive transformations, a form wholly dissimilar from that with which it was previously invested. It is produced from eggs, laid in summer by a greyish kind of moth. These eggs are about the size of a grain of mustard seed; their colour, when first laid, being yellow, but afterwards becoming of a bluish hue. In temperate climes, and with proper precautions, these eggs may be preserved a long time without hatching or rotting. The three successive states of being of the silk-worm are those of the caterpillar, the chrysalis or aurelia, and the moth; and, in addition to these, it undergoes five other distinct modifications of being. When first hatched, it is a small black worm, about a quarter of an inch in length. On being brought forth, it almost immediately begins searching for its natural food, the leaves of the mulberry tree, which it devours with avidity. In about eight days, the head grows much larger, and the worm is attacked by its first sickness. This lasts for three days, during which time it refuses food, and remains perfectly motionless. It then begins to cast its skin, which it accomplishes after much pain and exertion. So complete is this moulting, that not only the covering of the body, but of the feet, the skull, the jaws, and even the teeth, is cast off. The insect then begins to feed with recruited appetite, and continues for five days, when a second moulting takes place, exactly like the first, and so on through a third and fourth course, the animal progressively increasing in size. After the last moulting, it feeds voraciously, and increases rapidly in size during ten days, when it has attained its full growth—being then generally from two and a half to three inches long. At this period, it begins to leave off eating, and soon entirely ceases—becomes restless and uneasy, and looks out for a convenient place to commence its spinning labours. Its colour is now a light green; but as the material for forming the silk gets digested, it becomes glossy, and somewhat transparent. The silky substance is secreted in the form of a fine yellow transparent gum, in two vessels, which are wound, as it were, on two spindles in the stomach. When the animal has found a suitable angle, or hollow, for the deposition of its silken ball, or cocoon, it begins to spin thin and irregular threads at first, the silk being drawn through two minute apertures beneath the jaws. In four days the cocoon is completed, the labourer remaining, of course, always on the inside of the sphere it is forming. The cocoon resembles a pigeon's egg in shape and colour, but is not quite so large. As may be imagined, the insect, from the continual emission of the gummy silk, together with the want of food, gradually contracts in size, and if the cocoon be opened after it is finished, the animal will appear in the form of a chrysalis (something like a kidney bean), with a smooth brown skin—its former covering lying beside it. The silk-worm goes through all the transformations above mentioned in the space of from twenty-two to thirty days, according to the temperature to which it is exposed. The cocoons containing the insects intended to be preserved for laying eggs, are left undisturbed, and the chrysalis gradually undergoes a transformation into the state of a moth. This change is accomplished in the space of about twenty days; and the moth, by great labour and ingenuity, works its way through the cocoon, but without injuring it, and sets itself at liberty. It then appears as a large moth, of a greyish-white colour, furnished with four wings, two eyes, and two black horns, or antlers, of a feathery appearance. This moth enjoys its existence only a very short time. It remains almost entirely fixed to one spot, the wings never being used for the purpose of flying, but only in assisting it in fluttering while seeking its mate. When this object is attained, the female deposits her eggs, and both end their being in the course of two or three days afterwards. The number of eggs laid by the female varies from 250 to 500; and these eggs, in about six months after, produce larvæ as before. It will scarcely be credited, but is nevertheless true, that in a few short weeks—that is to say, from its being hatched to the period of its full-grown size—the weight of the silk-worm is increased more than nine thousand fold.

Repeated efforts have been made at different periods to naturalise the silk-worm in England. The first of these was made by James the First, seemingly from a feeling of rivalry to the French monarch. He sent circulars to all the counties of England, strongly recommending the planting of mulberry trees, which, it seems, "were to be had in London at the rate of ¾d. per plant." But the scheme, as well as many other subsequent attempts of the same nature, was quite unsuccessful, although prosecuted for some time with great ardour; and we believe it is now generally admitted that the climate of Britain is too cold for cultivating the propagation of the silk-worm with success. At one period (1718), a joint-stock company was formed for producing raw silk, the growth of England, and Chelsea Park, from its convenient situation and favourable soil, was fixed upon as the spot for conducting the operations. A lease of this ground for 122 years was granted; and upwards of 2000 mulberry trees were actually planted, and several expensive edifices erected, the remains of which may still be traced, but the result ultimately turned out as above stated. It will be in the recollection of all our readers, that, during the joint-stock mania in 1825, a company was formed under the name of the "British, Irish, and Colonial Silk Company," for producing raw silk in Ireland. Between 80 and 90 acres were selected for the purpose in the county of Cork; about 400,000 white mulberry trees were planted, with buildings for the hatching of the silk-worms, &c. The project, like most others of that date, at first promised well, but it was ultimately found prudent to abandon it. In British India, the rearing of the silk-worm has been rapidly increasing for many years. In the Bengal establishment alone, there are eight principal silk factories belonging to the East India Company. The number of people employed in each, including mulberry planters, worm-feeders, &c. may be stated at from 10,000 to 40,000. The rearing of silk-worms has also been introduced into the Mauritius of late years with decided success. In Russia, it was first introduced and encouraged by the Empress Catherine, and the production of raw silk is now rapidly increasing. It is calculated that upwards of fourteen millions of silk-worms annually live and die to supply Great Britain with the luxurious fabric of silk.

TREATMENT OF THE COCOONS FOR SILK.

The cocoons vary both in size, colour, and quality, and great care is taken in separating these into different assortments. The first proceeding is to destroy the vitality of the chrysalides. In tropical climes, this is done by exposing the cocoons to the burning heat of the sun, and in more temperate climes, by baking in an oven or steaming them above hot water. Great nicety is required in this part of the process, so that they get just so much heat as to kill the insect, and no more. The test of determining when this is accomplished, is by a profuse moisture or sweat which comes out upon the blankets or cloths wherein they are enveloped, and which exudes from the body of the insect. The cocoons are then spread out to cool very gradually, still carefully covered; and after this they are exposed to the sun and air to dry. The cocoons lose in weight about 77 per cent. by the desiccation of the chrysalis. The weight and strength of reeled silk that can be obtained from each cocoon are very variously stated, and they in fact actually vary much according to circumstances. Count Dandolo, perhaps the most trustworthy authority on the subject, found that a cocoon, weighing about four grains, when drawn out, extended 625 yards, which is certainly a most astonishing quantity, considering the short period employed by so small a creature for its production. It has been calculated that 1 lb. avoirdupois would extend 585 miles, and 47 lbs. would encircle the globe! Owing to the quantity of floss, or loose, inferior, silky fibres which encircles the firm ball of the cocoon, it is found, on an average, to require twelve pounds of cocoon to obtain a pound of reeled silk. A pound of reeled silk is capable of being converted into sixteen yards of gros de Naples, or fourteen yards of the best description.

REELING.

Previous to reeling the cocoons, it is necessary carefully to separate them from the outer floss above mentioned, which is very simply done, by merely opening the floss at one end, and pushing out the hard compact ball. Great care is here necessary in classing the cocoons according to their quality, as each quality requires a different mode of treatment in the reeling. The cocoons are all submerged for some minutes in hot water almost boiling, in order to soften the viscidity of the gummy substance which envelopes the whole silken portion of them. This is done by means of a copper boiler, eighteen inches long and six deep, set in brickwork only so far off the ground as to admit a fire beneath it, and filled with *soft* water. This small oblong boiler stands at one end of the reeling-machine, at the other is the reel itself, which is merely a wooden spindle turned with the hand by a crank handle at one side of the frame, and to which the skeins are guided by small wire loops or eyes attached to the end of the frame immediately above the boiler. Two skeins are generally wove at one time. When the water in the boiler is nearly boiling, two or three handfuls of the cocoons are thrown into it, and allowed to remain a few minutes. The reeler then takes her seat at the sides, and presses the cocoons with a brush about six inches long, made of the finest twigs or tops of heath bound together and cut evenly at the ends. By this operation, the loose threads of the balls adhere to the brush, and are drawn out by its means, when the reeler disengages them, and draws their ends through her fingers, in order to clear them from any loose flossy silk. These preliminary steps are called the *battue*. The ends of four or more (according to the fineness of the silk wanted) of these threads, thus cleared, are passed through each of two holes in an iron bar raised upon the inner rim of the boiler. Two of these compound threads are then twisted twenty or more times round each other, in order that the filaments may better unite by these mutual crossings; they are thence led through the two wire loops or eyes, and from there conducted to the reel, where they are made fast. The proper heat of the water is judged of by the manner in which the filaments come away from the rest of the cocoon, and by this also must the rapidity with which the reel is turned be determined. These, however, with all the other minutiæ of the reeling process, depend so entirely upon the attention and experience of the reeler, that it would be endless as well as useless here to detail all the various rules for the management of them. Silk may be wound of any size, from one cocoon to a hundred, but it is difficult to unite more than thirty in one thread. The great point in reeling is to make the thread of as even a thickness as possible; *perfect equality* is scarcely attainable. An experienced reeler, with the assistance of a girl to turn the wheel, can with ease wind off a pound of silk in a day. Six or eight pounds may be wound off in a day; but a coarse, foul, and ordinary silk, will be the produce. The modes of reeling silk in Italy and France are very different, but that of the former is reckoned the best. The floss or inferior silk of the cocoons is not reeled, but spun, after being mixed with the silk of the injured or inferior cocoons.

THROWING.

After reeling, the next process for preparing the raw silk for the weaver is that of throwing. It has already been mentioned, that this branch of the art was introduced by Sir Thomas Lombe into England in 1718, from models surreptitiously obtained by him at Piedmont. Considering the remarkable perfection now attained in this country in the science of mechanics, it will not appear strange that these throwing-mills have been long since superseded in Great Britain by subsequent improvements; but it is certainly not a little remarkable, that, in Italy, the same machinery is still employed, without alteration or improvement of any kind; and even in France, the organzine used for the manufacture of the best fabrics continues to be almost wholly imported from Italy. Raw silk, preparatory to weaving, must be made to take one of three forms, respectively termed *singles*, *tram*, or *organzine*.

Singles is merely the raw silk twisted, in order to give more firmness to its texture. All raw silk, for whatever manufacture designed, must undergo this process.

Tram is formed by twisting together, not very closely, two or more threads of raw silk, and this generally forms the weft, or transverse threads of the web.

Organzine, which is principally used for warp, is produced by a very elaborate process, of which it would be impossible to convey any correct idea to the general reader without the aid of a diagram. The principle of the process, however, may be generally stated to be like that of making rope, where the combined strands are twisted in an opposite direction to that given to the separate threads, and this is accomplished by giving a reverse motion to the machinery; whereas, singles and tram are twisted only in one direction, similarly to twine, or to the individual strands of which the larger rope is made. Silk thread intended for organzine is in the first process twisted in a left hand direction. The organzine, when finished, is transferred to reels instead of bobbins, whence it is made up into skeins, and sorted for sale or use. Previously to this, however, the reels are subjected to a process of steaming for two or three minutes, in order to prevent any after crinkling. The silk thus thrown is called hard silk, and must be boiled for some hours with a quantity of soap, in order to discharge the gum, and thereafter well washed in a current of clear water to discharge the soap, after which the silk appears soft and glossy.

PLAIN WEAVING.

The principle of the weaving-loom, whatever be the material which it is employed to manufacture, varies little or nothing. The date of the invention of the loom is completely lost, and that of the whole art of spinning and weaving, indeed, is shrouded in impenetrable obscurity. With the exception of the more recent improvements in the particular details of the various processes, however, the nature and action of the weaving-loom is so generally understood, that it would be utterly useless to enter upon an elaborate description of it in this paper. That the art of weaving had its origin in the East, there can be no doubt; and so little has the first rude principle of the loom been departed from, or improved upon, that the wretched Indian, performing his labours in the open air, with his threads tied to pieces of bamboo and stick fixed in the ground, the cords for raising and depressing the alternate threads of the warp attached to a branch of the tree which shrouds him from the noon-day sun, and seated upon the bare ground, with a hole dug for the reception of his feet, can yet produce fabrics, which, for delicacy of texture, cannot be surpassed, and scarcely rivalled, by the European weaver, who is possessed of the most elaborate machinery. The improvements of modern times have been more for increasing the power and productiveness of the loom, than improving upon its principle.

FIGURE WEAVING

Is the art of producing various patterns in the cloth, either by the introduction of threads of different colours, or by a different arrangement of the threads, or by using in the same fabric threads of different substances. The art is of ancient invention, as it is known to have been practised by the Egyptians at a very early period. The improvements more recently made in it have been many and important. Stripes which occur throughout the length of the piece are the effect of using threads of different colours or substances in the warp alone, and give the weaver no additional trouble. Stripes which run across the piece, or in the direction of the shoot, are caused by using different shuttles, furnished with threads of the requisite colours and substances for the formation of the shoot. The only additional labour here is that of changing the shuttle at certain intervals. A combination of these two methods produces, of course, a chequered pattern, and in the same way a great variety of rectilinear patterns is obtained. To call forth figures, flowers, or patterns of any description, different means are necessary. By dividing the warp between several leaves of heddles, which can be depressed at pleasure by separate treadles, threads of different colours may be either concealed or brought forward upon the face of the goods at the pleasure of the weaver. These threads may be made to change places one with the other, so as to reveal or conceal each in such a way as to make out the particular pattern wanted. The regularity and precision necessary in producing fanciful patterns in great variety, required a very different sort of loom from the common loom; and to meet which, the draw-loom and "*draw-boy*" was invented, by means of which, the most comprehensive patterns are wrought, with an immense saving of trouble, labour, and expense. The working of this apparatus at first required the constant attention and utmost care of two persons, but subsequent inventions and improvements simplified, as well as perfected it, to an extraordinary degree, the most of which were devised by practical weavers in our own country. All previous modes and machinery for silk figuring, however, including the draw-loom and draw-boy, were superseded of late years by the "*Jacquard machine*" (named after its inventor, a practical weaver at Lyons), which effected almost as great a revolution in this department of silk manufacture as Sir R. Arkwright's spinning-frame caused in the spinning of cotton. It is a great drawback, and proves a source of much regret to us, that our being necessarily restricted to mere verbal description debars us from giving the general reader any clear idea of the nature and construction of those complex machines we are now treating of. The *Jacquard* loom has proved especially beneficial to the poor weaver, by simplifying the most difficult, and, at the same time, utterly profitless portion of his labour, the preparation of his loom for figuring, which, previous to its invention, sometimes cost him many weeks' incessant toil and care, ere he got properly adjusted for weaving. Great improvements and simplifications have of late been made in the *Jacquard* machine, in Great Britain, while in Lyons, the city of its birth, it remains unaltered from the day of its invention.

SILK POWER WEAVING.

The substitution of machine for hand-weaving, introduced by the Reverend Mr Cartwright into the manufacture of cotton, has also been applied to that of silk; and various improvements and modifications, in its application to the latter material, have subsequently been made, the most important of which are those of Mr Austin of Glasgow, and Mr Sadler of Paddington. But it is very doubtful if the power-loom will ever prove of any advantage in silk-weaving, unless in the very coarsest species of the manufacture. Owing to the peculiar nature of silk, little or no saving of labour is accomplished by it, as it is not possible (as in the case of linen or cotton-weaving) for one man to manage more than one power-loom at a time, while an actual waste of time takes place.

SILK-VELVET WEAVING.

This branch of the silk manufacture, although it has now been made and used for several centuries in Europe, is comparatively a modern invention. It had its origin in Italy, and was for a long time solely made in that country, particularly in Florence, Milan, Venice, Lucca, and Genoa. After its introduction into France, however, the French weavers speedily excelled their instructors. At the period of the revocation of the edict of Nantes, before mentioned, it was introduced by the French refugees into England, and established at Spitalfields. Velvets are also manufactured in China, but these are not equal in point of quality to the very worst of European production. The soft shag or pile which distinguishes velvet is produced during the process of weaving, by inserting short pieces of thread doubled under the shoot or weft, and which stand upright in such a way and so close together as entirely to conceal the interlacings of the warp and shoot. In the production of every yard of velvet, six yards of pile at least are used. The loops of the doubled threads intended for the pile are supported by grooved wires, and the loops are afterwards divided by running a sharp instrument, called a treval, along the groove. This is done by the hand, and, of course, requires great dexterity, as the slightest deviation from the proper line would infallibly injure, if not wholly destroy, the silk. It is considered a good day's work for one man to weave one yard of plain velvet, for which he is paid about five times as much as for weaving gros-de-Naples. The warp, shoot, and pile of silk-velvet should all be of organsined silk. The cotton-velvet introduced of late years is only fit for ornamental hangings, &c., not subjected to much wear, which they will not stand.

GAUZE.

The manufacture of this light and transparent fabric (which is supposed to derive its name from Gaza, a city on the frontiers of Egypt) was many years ago very extensively carried on at Spitalfields. About the year 1760, it was introduced into Paisley, where it was soon brought to the very highest perfection. The patterns and designs were originally composed in Paris; but it was not long until the Paisley manufacturers established draughtsmen of their own, and opened warehouses in London, Dublin, and even Paris itself. The Spitalfield weavers, unable to rival their northern brethren, have entirely discontinued the gauze manufacture; but it is one of the few light fabrics in which the French are still acknowledged to excel all others.

We have now enumerated all the principal sorts of silk fabrics manufactured in Great Britain. There are various other descriptions of silk goods made, distinguished by different appellations, but as these are in a great measure only modifications, varying in thickness, quality, dressing, &c. of those above mentioned, we have thought it unnecessary to enter upon a description of them. The old, stiff, costly, and magnificent brocades and damasks, the pride and glory of our great-grandmothers, have now utterly fallen into disuse; and as their extinction is, in our opinion, any thing but a matter to be regretted, we will piously refrain from disturbing their slumbers, or seeking "their merits to disclose," unless in the event of their again showing a disposition to enter into fashionable society.

WOOLLEN MANUFACTURE.

The manufacture of wool, as it was the earliest, so it continued to be the most important branch of British manufactures up to a very recent period, when that of cotton, with a rapidity of progress altogether unprecedented, took the precedence of it. There can be no doubt that the art was first introduced by the Romans, previous to whose invasion the inhabitants were wholly clothed in skins; and it is recorded that the first manufacture was established at Winchester, for the purpose of supplying the Roman army with clothing. After this, all trace of the manufacture is lost for many centuries. Some stray notices of it occur in the tenth, chiefly referring to the great progressive increase in the price of fleeces, which, in 1135, is stated to have advanced fifty per cent., while that of the sheep themselves had decreased to the same amount. But it seems certain that this rise in the value of wool was occasioned almost solely by the demand for it abroad, especially in Flanders, where the cloth manufacture then flourished most. In a history of the state of the woollen manufacture of Great Britain, drawn up in 1813 by "John May, Deputy-Aulnager," it is observed, that "the antiquitie of wool within this kingdom hath been beyond the memorie of man so highly respected for those many benefittes therein, that a customable use has always been observed to make it the seat of our wise learned judges, in the sight of our noble peers (in the Parliament house), to imprint the memorie of the worthie commoditie within the mindes of those firme supporters and chiefe rulers of the lande." We have evidence, however, that the woollen manufacture had been domesticated, and reached no small perfection in England early in the thirteenth century, when fine Spanish wool began to be imported. This article was soon prohibited, and the importation of cloth itself encouraged; and this was done, both on account of the superiority of the foreign cloths, and with the view of promoting the foreign demand for English wool. This interchange of English produce and foreign industry continued upwards of a century; and it was not until the reign of Edward the Third that the manufacture of broadcloth began to be patronised in England. In 1331, John Kemp, a Flemish manufacturer, came over and established himself, by the invitation and under a special "letter of protection" of Edward, who, at the same time, induced fullers, dyers, &c. to emigrate. These foreigners fixed themselves at Cranbrook, in Kent; and for their encouragement acts were passed, prohibiting the importation or wearing of foreign cloths, and the exportation of English wool. These, however, were shortly afterwards repealed. In the "Memoirs of Wool," by John Smith, LL. D., published at London in 1747, there is much curious information regarding the ancient laws regulating the export and import of wool, the customs imposed, &c. &c. From the same author we learn that the first *staple* for woollen cloths, *i. e.* market, or public place, whither the merchants were obliged to carry their cloths for sale, was fixed at Canterbury, in honour of *St Thomas*. From the time of Edward the Third, the woollen manufacture may be considered as firmly established in England, and it rapidly spread through Suffolk, Yorkshire, Lancashire, and all the north of England. It is recorded, that, in 1520, there were three famous clothiers in the north—Cuthbert of Kendal, Hodgkins of Halifax, and Martin Brian of Manchester, each of whom had large establishments of spinners, carders, weavers, fullers, dyers, &c. Rippon and Halifax were the two first places in Yorkshire where the manufacture was introduced. In 1614, a great improvement took place in the west of England woollen manufactures, by the invention of what is called medley or mixed cloths, for which Gloucestershire is still famous. Worsted goods were first produced at Worsted, a small town in Norfolk, from which the yarn they were made from takes its name. This species of manufacture seems afterwards to have been mostly transferred to Norwich, as, in an act of Henry the Eighth, we find worsted yarn denominated "the private property" of that town. Perhaps one of the most extraordinary pieces of legislation ever devised for the encouragement of national produce, was an act passed in the reign of Charles the Second, ordering that all persons should be buried in *woollen shrouds!* and yet this act continued in the statute-book down to the beginning of the present century. In the year 1700, the value of woollen goods manufactured in England was estimated at no less than L.8,000,000, of which L.2,000,000 worth were exported. From this period up till 1777, little increase took place in the exports, although unquestionably the manufacture throughout the country continued progressively to increase with the immense increase in the wealth and population of the kingdom. The highest official value which the exports of woollen goods from England ever attained was in 1802, when they reached L.7,321,012 sterling. From 1812 to the present time, they have alternated between L.4,500,000 and L.6,000,000.

The great increase of the cotton manufacture after 1780, contributed much to check the progress of that of woollen in England, but the latter has, nevertheless, continued steadily to augment. In 1800, a Committee of the House of Commons was appointed to investigate into the state of the wool trade in England, when almost all the principal manufacturers in Yorkshire and the west of England were examined. The results of their evidence are both interesting and important, and fall naturally to be stated here. It was estimated that the number of sheep then kept in England and Wales was about 26,000,000, and the produce of the fleeces from these sheep was 600,000 packs, of 240 pounds each pack. Rating the wool at L.11 per pack, the total value of it was L.6,600,000. The next point investigated was the increased value of the wool, after being manufactured. This was found to vary much; in some goods being scarcely double, in others nine-fold. By striking an average, the total value of the whole manufactured woollen goods was estimated at nearly L.20,000,000. The manufacturing of these was supposed to give employment to about 3,000,000 of men, women, boys, and girls; it being at the same time stated, that, from the late inventions in machinery, 35 persons were able to do as much work as 1634 persons could do in 1785! The capital vested in the machinery, buildings, &c. appropriated to the woollen manufacture, was estimated at L.6,000,000 sterling. In the West Riding of Yorkshire alone, which has been at all times the most important and extensive seat of the woollen manufacture, the annual value of the goods of *every* description, broad and narrow cloths, kerseymeres, blankets, &c. was calculated to be about L.8,000,000.

The accuracy of many of these statements of the English manufacturers has been much canvassed, and there seems little doubt as to some of their calculations being somewhat exaggerated, especially as regards the quantity of wool manufactured, and number of hands employed. At the same time, Mr Stevenson, who has always been esteemed a veracious authority, and whose calculations have uniformly been found rather under than over the mark, states the total value of the manufactured woollen goods at L.18,000,000. The number of adults employed in producing them he reckons at 480,000 or 500,000. A statistical estimate made so late as last year (1832), was to the following effect: sheep fed in England and Wales, 36,000,000, each of which yields a fleece of four pounds weight, or one hundred and forty-four millions of pounds, which, at one shilling per pound (or L.12 per pack), is worth L.7,400,000. These, manufactured, produce L.20,000,000, leaving a profit of L.12,000,000 per annum to the various manufacturers.

The woollen manufacture is divided into two principal heads—the weaving or manufacturing of yarn into cloth, blankets, carpets, &c.; and the worsted fabrics, such as stockings, gloves, mits, pantaloons, &c.; and we shall now shortly enumerate the various seats of these branches of manufacture.

The principal seats of the former kind are the West Riding of Yorkshire, and the western counties of Wiltshire, Somersetshire, and Gloucestershire. The manufacturing district of the West Riding extends over an area of upwards of 200 square miles, including, however, the hardware manufacture in and near Sheffield. Of the northern cloth manufacture, Leeds, Bradford, Halifax, Huddersfield, Saddleworth, and Wakefield, are the principal centres. Leeds is the chief mart for coloured and white broadcloths. The former are sometimes called mixed cloths, and are made of dyed wool. These two branches are for the most part kept quite distinct and separate. The principal woollen manufactures in and near Halifax are flannels and baizes. The blanket and flushing manufacturing district lies between Leeds and Huddersfield, at the latter of which places narrow cloths are also made. *Blankets* take their name from an individual, Thomas Blanket, at Bristol, who in 1339, after the passing of the act prohibiting the exportation of English wool, first set up a loom in his own house. The manufacture of stuffs is chiefly carried on at Bradford and Halifax. At Shuttleworth the manufacture of very fine broadcloths as well as kerseymeres is likewise carried on. Wakefield is chiefly distinguished for the importance of its wool market, and its mode of dyeing. By various stamping acts, returns are ordered to be made every Easter to the justices at Pontefract sessions of the quantities of broad and narrow cloths made in the West Riding during the preceding year.

In Gloucestershire, the manufacture of broadcloths, but chiefly superfine, made of Spanish wool, is carried on to a great extent. The parish of Stroud exhibits a remarkable picture of manufacturing industry, almost the entire population, men, women, and children, being engaged in one or other of the branches of the woollen trade.

In Wiltshire, the town of Bradford is reckoned the chief centre of the superfine broadcloth manufacture of England. Thin woollen cloths are also made at Wilton.

In Somersetshire, the principal seats are Taunton, Frome, and Shepton-Mallet—the first for coarse fabrics, the second for second cloths, and the last for superfine. Stourminster-Newton, in Dorsetshire, is also famous for broadcloths and flannels.

The woollen manufacture of England is carried on in three different modes—that of the master clothier, who buys his own wool from the importer, and afterwards gives it out to be manufactured, either in factories or at private houses; the factory system, by which every process of the manufacture is carried on under the same roof; the last is the domestic system, in which private weavers purchase wool from the dealer, and employ themselves, wives, children, and sometimes several journeymen, in the various manufacturing processes under their own roofs. The factory system is evidently the one best adapted for carrying the manufacture to its utmost extent.

The mode of disposing of the various woollen cloths is different in Yorkshire and the west of England, but in both upon a scale in keeping with the magnitude of the manufacture and the commercial importance of the kingdom. In the west of England the goods are exposed at periodical markets or fairs; in Yorkshire, in cloth-halls, of which there are three at Leeds, besides others at Halifax, Bradford, Huddersfield, Wakefield, &c. These halls consist of long walks or galleries, through the whole length of which the master-manufacturers have their stands in double rows. Between these the merchants pass, and make their purchases. At a certain hour a bell rings, and the market closes, those goods which are purchased being then carried to the merchants' quarters, and those unsold remaining in the stands. The goods are bought in their undressed state, the merchant afterwards getting them finished for himself. Dressing and finishing has of late years become a business entirely distinct from the manufacturing department, and in which to attain perfection has been the chief aim of the Yorkshire merchants. So proficient, indeed, have they become as to defy any but the most experienced judges to distinguish their cloths from the more costly fabrics of the west of England. Almost all the machinery now used in the *manufacture* of cloth is borrowed from that of cotton—the spinning-jennies, the slubbing-mill, the carding-engine, &c.

In almost no species of British manufacture has there been such great improvement in recent years as in the article of superfine broadcloths. Till not a very distant date, the continental fine black and blue cloths were eminently superior to those produced in this country. But the peace having opened the ports to the importation of the finest foreign wools, and an impetus being collaterally given to the spirit of enterprise, the fabrics have since been made of the most delicate texture; and as the art of dyeing has at the same time been wonderfully advanced, superfine cloths, in black and blue, as well as in tasteful fancy colours, are now made in England, which far transcend in excellence and beauty the manufactures of any continental country. Every year the appearance of these English superfine cloths is improving, while, from the effects of competition and ingenuity, the price is not only not advancing, but falling. Thus the lower and middle classes of the community are now, in a great measure, as well dressed as the higher; and it is hardly too much to say that this circumstance alone has a powerful tendency to produce better moral feelings among the people, and to sustain Great Britain in its elevated and enviable condition among the nations of the earth.

Several departments of the woollen manufacture have been rapidly flourishing in Scotland of late years. That of cloth is nearly confined to two places —Galashiels and Aberdeen. At the former place, so great an improvement has taken place in the making of broad and narrow cloths, that the goods are reckoned fully equal to those of Yorkshire, except as regards the final dressing and finishing. Almost all the yarn, however, used in this, as well as the other branches of the manufacture, is procured either from England or abroad. Our inferiority in the making of yarn may be accounted for by the fact, that the business of wool-stapling is as yet little practised or understood amongst us. The kinds of yarn chiefly spun in Scotland are for hosiery, which was formerly exported to a great amount. Aberdeen and Hawick have always been the principal seats of the hosiery manufacture. At the latter place, especially, the stocking manufacture has increased of late years to a very great extent. Fully six hundred looms are now busy. Many of the stocking-weavers are also yarn-spinners, a great proportion of the yarn being sold to the manufacturers in Leicestershire, Derbyshire, and Glasgow. The stocking manufacture was first begun in Hawick in 1771, by a Mr Hardie, and it was by individuals trained up with him that the manufacture spread into the adjacent towns and districts—Kelso, Jedburgh, Langholm, Melrose, Selkirk, Wooler (in Northumberland), &c. Scotch worsted is in great request abroad, the coarse worsteds used for Scotch carpets and shawls being chiefly made at Tillicoultry, Kilmarnock, Bannockburn, and Stirling. The Board of Trustees have this year (1833) offered liberal premiums for the best worsted yarns spun in Scotland of various sorts, particularly one large premium of L.300, to encourage the introduction of the spinning of the Cashmere or Thibet wool (wool of the Thibet goat), used in the manufacture of the finer shawls. Our artisans are entirely ignorant of the principle upon which the spinning of this material is conducted. Upwards of 50,000 individuals are at present engaged in the manufacture of shawls from Thibet wool in Scotland, while the whole of the *yarn* used for that purpose is spun in France. The most of it, however, is dyed in this country.

The manufacture of carpets has been improving and increasing amazingly in Scotland in recent times, chiefly from the encouragement given to it by the Board of Trustees. More than ten years ago, Brussels, and others of the finer kinds of carpets, were made at Kilmarnock and Bannockburn, almost all the yarn being brought from England. Of late years, however, several mills have begun to spin the kinds of yarn used in the manufacture of these carpets, and, from the premiums offered by the Board, specimens have been brought forward at some of the latest annual exhibitions in imitation of Turkey and Persian carpets, but decidedly superior to the originals, both in quality and brightness of colours. Carpets of the value of L.60 and upwards have been sold to Scotch families, and many sent into England. These finer carpets are principally made at Stewarton, in Ayrshire, and at Edinburgh. At the latter place a rich carpet of a perfectly new kind has lately been brought forward, for which the manufacturer has obtained a patent.

The largest manufactory of Scotch carpets, we believe, is that of Messrs Wilson and Company, at Bannockburn, where there are upwards of one hundred looms constantly at work. Fully 10,000 stones of Scotch wool are there annually consumed in the manufacture of Scotch carpets and hearth-rugs. Besides this, the same gentlemen have about forty looms employed in fabricating Brussels carpets. Imitation Turkey rugs have been very successfully made.

LINEN MANUFACTURE.

This manufacture is of very ancient introduction into England. It is ascertained to have existed to a considerable extent so far back as the year 1189, and was undoubtedly, as well as the culture of flax, introduced by the Romans, who, again, gained their knowledge of the art from the Egyptians. Even in the time of Joseph, the manufacture of linen had risen to a considerable height. For a long time, however, the greatest part, as well as the finest qualities, of the linen first used in England, was brought from Flanders; but that the art soon attained considerable perfection in Britain, appears from a royal mandate of Henry the Third, who in 1253 enjoined the sheriffs of Wilts and Sussex to send a large quantity from these counties for use in his own wardrobe. In 1386, a company of Flemish linen weavers established themselves in London, under the patronage of Edward the Third.

The manufacturing from native produce, however, progressed very tardily, as is evident by a mandate of Henry the Eighth, a century and a half later than the period just mentioned, ordering a certain quantity flax to be raised for the purpose of providing nets for the fisheries. This fact, together with the circumstance, that, during the reign of Elizabeth, the fabrication of sail-cloths, if not then first commenced, was, for the first time, improved and encouraged, leads to the conclusion that only the very coarsest articles were, up to a comparatively recent period, attempted in England, the woollen continuing to be the great staple manufacture of the kingdom. About the year 1550, the manufacture of linen was engaged in in the county of Norfolk, and a particular privilege extended to it for the making of a linen cloth called *dorneck*. About a century later, linen yarn began to be imported in large quantities from Ireland, and manufactured at Manchester, the want of proper machinery preventing the Irish themselves from prosecuting this trade as an article of foreign traffic, although it had for many previous generations been established amongst them as a domestic manufacture from flax raised by themselves. Towards the end of the seventeenth century, the importations of linen from France amounted, it has been calculated, to nearly L.1,000,000 sterling, although the English manufacture itself was then rapidly increasing. Besides the French manufacture, large importations of linen into England took place from Germany, from Holland, and even Scotland—from the latter, to the value of no less than L.100,000 sterling. Mr King, in his "*British Merchant*," rates the consumption of linen in England, in the year 1702, at L.1,700,000, of which the English manufacturers supplied L.746,569. Previously to this, in the reign of Charles the Second, duties were for the first time imposed on foreign linens, and Parliament seems, from this time forward, to have taken an interest in the success of the linen manufacture, more particularly in Scotland and Ireland. It seems questionable, however, how far this patronage, especially as regards the latter kingdom, proceeded either from patriotic or disinterested motives. Great outcry had been made in England against the increasing manufacture of woollen goods in Ireland, by which, of course, the demand for that staple manufacture of England was much deteriorated. In 1698, both Houses of Parliament addressed his Majesty, William the Third, complaining of this national grievance, and recommending that the Irish wool manufacture should be discouraged, and that of linen established in its stead; to which his Majesty replied, "I shall do all that in me lies *to discourage the woollen manufacture in Ireland, and encourage the linen manufacture, and promote the trade of England!*" The duties imposed on foreign linens seem to have benefited our own manufacturers little; and, in the year 1743, a new expedient was tried, by granting a bounty on the exportation of British linens. Even this temptation seems to have had little effect, as we find, from the custom-house books, that, prior to 1746, not more than 200,000 yards were exported from England, and only 00,000 from Scotland. The progressive increase in this manufacture, which afterwards took place in the former country, will appear from the following facts:—In the year 1753, the quantity exported, drawing bounty, was 641,510 yards; in 1763, 2,308,310 yards; in 1773, 5,868,230 yards; and in 1783, 8,667,915 yards. On an average of ten years, from January 1776 to January 1786, the linen, drawing bounty, exported from England, was 5,315,354 yards, and the total average quantity of what was exported, and what was consumed in England, was, in 1786, estimated to be 30,000,000, in value nearly L.1,600,000 per annum, and employing and supporting fully 200,000 people. It ought also to be remarked, that the increase in the exportation of the finer linens not entitled to bounty, between 1743 and 1783, was nearly as great in value, though not in quantity. Notwithstanding this rapid increase, however, in the English linen manufacture, the importations from Ireland gradually increased. Those from foreign countries, at the same time, proportionally decreased, in so much, that, in thirty years, viz., from 1743 to 1773, there was a diminution of nearly 6,000,000 of ells, in the foreign importations.

The general introduction of the cotton manufacture, about the year 1780, greatly deteriorated that of linen. Besides the substitution of printed cottons for printed linens, in dress, the latter trade suffered by the general adoption of cotton stockings for thread ones, whilst the great increase in the importation of Irish linens discouraged another branch of the trade. The amount of the latter may be judged of by the fact, that, from the Union of Ireland till the year 1813, there were, on an average, annually consumed in England very nearly 33,000,000 yards of Irish linen.

We shall now mention a few of the principal places in England where articles are manufactured from flax and hemp:—

Canvass for sail-cloth is manufactured at Werrington, Kirkham, and other places in Lancashire, Whitehaven, Workington, Stockton, Whitby, Hull, Retford, Reading, Oxford, Bridport, and in various other places in the shires of Dorset and Somerset. During the late war there were, at one time, no less than twenty-three contractors for the manufacture of sail-cloth for the navy, having twenty looms each, constantly employed; but yet, so far were these from supplying the requisite quantity, that by far the greatest portion was obtained from Scotland. A considerable quantity of hemp is grown in Suffolk, and manufactured into sacking and cordage. The latter, however, are chiefly made in the vicinity of Stowmarket. Sheeting is made at Broomsgrove, in Worcestershire; in Berkshire, many thousands of people are employed in the manufacture of sacking, for hops. Great quantities of linen thread are manufactured by poor people in cottages, near Workington. These, with some other manufactories in Westmoreland, Lancashire, Durham, &c. are the principal in England. Mills for spinning flax were first erected at Darlington.

In Scotland, the manufacture of linen was, in all probability, introduced, as in England, by the Romans, but there are no means of tracing its origin or subsequent progress up to a very recent period. From the continual state of turmoil in which Scotland existed, however, equally from internal dissensions and foreign broils, previous to the Union of the crowns—a state of society totally incompatible with the successful cultivation of the peaceful arts—it is improbable that the manufacture of linen was prosecuted otherwise than as an article of merely domestic occupation and consumption. Until 1728, indeed, every description of manufacture was at a very low ebb in Scotland. In that year a Board of Trustees was appointed "for overseeing, directing, and better improving the linen and hemp manufactures in Scotland," under whose fostering care, and by means of premiums, bounties, and various other modes of encouragement, they have ultimately obtained great prosperity and importance. From the extensive powers conferred on the trustees, they have greatly extended their patronage, and continue still to watch over the trade in all its branches, from the sowing of the flax, to the finishing of the bleached cloth.

Very little flax is raised in Scotland, and it is supposed that there are not altogether 20,000 acres under this crop in the whole country; the yarn being principally imported from Russia, Germany, Holland, &c. The raising of flax has been tried to its greatest extent in and around Airdrie, but the superiority of foreign flax is so great, that it is now almost entirely given up. It is entirely from Holland and Flanders that the flax for the finest linen manufactured in this country is drawn. At Dunfermline, the Scots flax is nearly unknown. The difference between Scotch and Dutch flax lies principally in this peculiarity, that the Scotch flax becomes progressively worse in the process of manufacturing; whereas the Dutch flax goes on always improving in the course of working, as long as it is wrought within what is called the *grist*, or its natural point of strength. The spinning of flax was, of course, anciently performed by the distaff, or rock and spindle, these being afterwards superseded by the spinning-wheel, which is still to be found in almost every cottage and farm-house of Scotland. This mode of spinning was formerly carried on to a very great extent in some of the northern counties, more especially in the districts of Aberdeen, Angus, Perth, Orkney, &c. As was formerly the case with cotton in England, the linen yarn is given out by agents to females, who spin it at so much per spindle. The spinning by machinery was first introduced in 1790, the first flax-mill being erected at Inverbervie in Kincardineshire. Since then, this branch of the manufacture has increased immensely, and it is calculated, that, at the present time, there are upwards of 6,000,000 of spindles of linen yarn spun annually by the hand and machinery together. (Each spindle contains four hanks, and each hank twelve cuts, of 120 threads, ninety inches in length.) But the yarn spun by the latter mode, although strong and even, cannot be made nearly so fine for the lighter fabrics as by the common wheel; the latter machine, therefore, is likely to keep its place. From the manufacture, however, being of late years principally confined to coarse articles, such as osnaburghs, bagging, &c., hand-spinning is little practised (except in the places above stated), and that only by private families for domestic use.

The progress and extent of the linen manufacture, since the year 1727, can easily be traced by the records of the Trustees' Office. In 1728, the number of yards stamped was 2,183,978, value L.103,312, 9s. 8d. sterling; the quantity stamped in 1812 was 18,975,862½ yards, value L.1,020,403, 11s. 2¾d. sterling.

One somewhat remarkable circumstance must here be noticed, namely, that, from 1728 up to 1812, and notwithstanding the many changes, by machinery, bounties, competition, &c., the average value of linen cloth has not varied more than fourpence sterling per yard, the original price being about ninepence, and scarcely ever after, up to the foresaid year, having exceeded a shilling.

Fifeshire (including part of Kinross-shire) is the busy seat of the Scottish linen manufacture, which was introduced to it about sixty years since, when the London trade was opened up. In the course of the intervening period of time, the county has been overspread with spinning-mills, bleachfields, weaving-looms, and other essentials for carrying on a great trade. From time to time, considerable changes have occurred, according as the demand for particular articles varied; and in the present day the weaving o fine diapers and shirtings is the chief employ. Some of the most meritorious improvements in the art of bleaching and hand-weaving have been the discovery of natives of Fife. Dunfermline, in this county, enjoys the reputation of being the first town in Scotland for fine linens. The value of the table linen annually manufactured in Dunfermline is estimated to exceed L.100,000. There are six or seven large establishments for the spinning of linen yarn; the weaving is done by the hand, and employs a vast number of looms in the town and adjacent country. It may be mentioned that the Dunfermline linens have long been disposed of in Scotland principally by salesmen or hawkers, who travel on foot over the whole kingdom. Great improvement has taken place in the *patterns* of table linens of late years, in consequence of a drawing establishment having been instituted.

The yarns used are from foreign flax, and are mostly spun and bleached on the river Leven. The Kirkland spinning-mills, near the sea-port town of Leven, are the most extensive in the county. In the weaving of linens, whole towns, villages, and hamlets, are constantly employed. The cloth produced is, for the greater part, exported to London, as the Scotch themselves wear almost none of their own goods, being contented with the cheaper linens of Ireland. Blankets and plaidings are also manufactured in this shire. The operative weavers of Fife form an independent respectable class of artisans, thoroughly national in their habits and sentiments; and being, in most instances, provided with gardens and potato grounds, if not pigs and cows, near their cottages, they live in a state of peace and comfort, perhaps nowhere equalled, at least not surpassed, among the working classes in any portion of the United Kingdom.

Forfarshire, which lies immediately north from Fife, has the chief trade in manufacturing coarse flaxen and hempen goods, principally from Baltic produce. The seat of this lucrative branch of manufactures is at Dundee, a town which, like Paisley and Glasgow, has made extraordinary advances within the last fifty years. The precise period at which the trade was established is not ascertained, but is conjectured to be about the beginning of the last century. It made little progress for some time, as in 1745 only 74 tons of flax were imported, and no hemp. The quantity of linen then exported is estimated at one million of yards, but there is no mention of sail-cloth or bagging. In 1791, the import of flax amounted to 2444 tons, and of hemp 299 tons. The quantity of linen exported that year had increased to 7,842,000 yards, besides 280,000 yards of sail-cloth, and 65,000 yards of bagging. After the general introduction of machinery in 1814, the importation of flax at Dundee increased from 3000 tons to 15,000 tons per annum, and the exportation of linen in an equal proportion. The following abstract of imports and exports for the year ending 31st May 1831, shows an increase of the trade almost wonderful. Flax imported, 15,010 tons; hemp, 3062; linen shipped off, 356,817 pieces, measuring about 50 millions of yards; sail-cloth, 65,522 pieces, measuring about 3½ millions of yards; bagging, 62,199 pieces, measuring about 4 millions of yards. Total, 57½ millions of yards.

Brown linen has always been, and continues to be, the largest article of manufacture in Dundee. It is of a great variety of fabrics; but osnaburghs, for clothing to the negroes in the West Indies, is the chief. There are also bleached linens, or imitations of the sheeting and duck of Russia, and the dowlas and sheeting of Germany. The yarn of this article is generally bleached before it is woven, and the chemical process of bleaching has been introduced and practised with great success. Bagging used for packing cotton is likewise a staple article. It is generally made of hemp, and is exported to the United States, the West Indies, &c. Coarse linens for household purposes are also made. A great proportion of these goods are woven by the hand in the town and neighbourhood, and employ great numbers of workmen in Forfar, Kirriemuir, Glammis, Cupar-Angus, Alyth, and other places. Dundee is the grand depôt of these places, into which all the home-made stuffs are brought either for sale, or on payment of wages. The introduction of spinning machinery, in which great improvements have recently been made, has been the means of preserving the manufactures of Dundee against foreign competition. There are at present between twenty and thirty spinning-mills, each being an edifice of from four to six or seven stories high, with spindles and carding-machines on every flat, all moved by steam, and tended by boys and girls. Almost all the flax is imported from Russia.

Besides the hemp used in the making of sail-cloth and bagging, it is most extensively used in the manufacture of ropes, cordage, twine, &c. In every town of any extent there is one or more ropewalks, the product of which is generally applied to mercantile and agricultural purposes in the town and surrounding districts.

The manufacturing of thread was introduced in 1720, and has ever since been carried on to a considerable extent; but cotton thread has now in a great measure superseded that of linen throughout the kingdom.

Owing to the discontinuance of stamping the linen for sale in Scotland after the year 1822, it is impossible to give the returns up to a later period. In that year the number of yards stamped was 36,268,530¼; value, L.1,396,296; averaging rather less than 9½d. per yard—the manufacture having very nearly doubled since the year 1813 *in quantity*, though not exactly in *value*, owing to the depression in the price of linen cloths.

It has been calculated that about 80,000 persons are engaged in the linen manufacture in Scotland. The value of the linen cloth manufacture cannot be less than L.1,500,000. The average amount of the bounties paid on the exportation of linen goods was about L.50,000 sterling. These are now in the progress of being abolished, but it is satisfactory to know that this measure does not as yet seem to have had a prejudicial effect on the manufacture.

The amount of the various premiums offered by the Board of Trustees for 1830, on all sorts of Scottish manufacture, was L.1330.

In point of quality, the Hollands sheeting manufactured in Edinburgh is reckoned the best in the market.

Linens and yarns are now lower in price in Scotland than ever they were before.

The manufacture of linen has long been the staple one of Ireland, and is conjectured to have been domesticated there previous even to its introduction into Great Britain, at least it is ascertained to have been brought to much greater perfection in Ireland at a very early period than it had attained in England. In a description of Ireland, published at Leyden in 1627, it is stated that "this country abounds in flax, which is sent ready in great quantities to foreign nations." "Formerly," says the writer, "they wove great quantities of linen, which was mostly consumed at home, the natives requiring above thirty yards of linen in a shift or shirt, from the numerous plaits or folds made in it." This inclination to dandyism appears to have excited no small jealousy in their English conquerors, as we find an act passed in the reign of Henry the Eighth, prohibiting, under a severe penalty, the use of more than seven yards of linen to a shirt or shift in Ireland! What would be said to such an interference with the arrangements of the toilet at the present day? It was to the Earl of Strafford, when Lord Lieutenant under Charles the First, that Ireland was indebted (as Scotland was to Mr Pelham) for the first effectual legislative encouragement given to her manufactures, particularly that of linen. He imported flax-seed from Holland, and brought spinners and manufacturers from France and Flanders, and embarked an immense private capital of his own (some say L.30,000) in the business. Its next patron was the Duke of Ormond, under whose long administration, notwithstanding of the interruption given to all the peaceful arts by the Parliamentary wars, the linen manufacture was fully established, and left by him in a flourishing condition. In the beginning of the eighteenth century, the English government took the linen trade under its especial protection; but it is questionable how far its motives in doing so were entirely disinterested, and the patronage seems to have been extended chiefly with the view of discouraging the Irish woollen manufacture, the amount of which was then exciting the jealousy of the English.

A Board of Trustees, upon the plan and for the same purpose as that in Scotland, was afterwards established, and bounties were granted upon the exportation of Irish linen. In 1737, the manufacture of cambric was first introduced from France. The introduction of cotton affected, of course, the linen manufacture in Ireland, as it did in every other part of the United Kingdom, but the latter has nevertheless continued to increase, and, in some places, at this moment, exhibits more favourable symptoms than it has ever yet shown. In 1825, the imports of Irish linen into Great Britain amounted to 52,560,000 yards, the declared value of which was L.2,803,618. Of these, 38,784,908 yards were retained for home consumption. The raw material is almost exclusively grown in Ireland, and it is calculated that there are at present between 130,000 and 150,000 acres sown in flax. Up to the beginning of the present century, the spinning of flax was done entirely by the hand, and even yet the spinning by machinery bears no proportion to the old method, as the work is executed not only better, but actually cheaper, by the poor female peasantry, than can be done by machinery even in England. These poor creatures can scarcely earn more than twopence or threepence a-day, even with the most diligent labour. Another and very sufficient reason for the continuance of hand-spinning, is the circumstance that, by that mode, from twelve to twenty hanks to the pound of flax may be spun, whereas by machinery scarcely more than three hanks can be spun. The Irish women have always been celebrated for their skill in spinning, which is supposed to arise from the delicacy and suppleness of their fingers.

We have already mentioned that great quantities of linen yarn were formerly exported to England, and even yet the spinners are much more numerous than the weavers. In many districts, indeed, the manufacture is entirely confined to the spinning, while, in not a few, the flax is grown, dressed, spun, and woven by the same family. The earnings of a linen-weaver will average about 7s. a-week. Ulster has long been the chief seat of the linen manufacture, but it is also extensively pursued in Galway, Mayo, Sligo, Drogheda, &c. For the most part, each particular district has its own particular kind of manufacture. For instance, unbleached linens of 32 inches wide are manufactured in Londonderry, Donegal, Antrim, and Tyrone—cambrics, lawns, and diapers, at Belfast, Lisburn, and Lurgan; and so forth. There is an extensive manufacture of sail-cloth at Cork. Most of the bleaching-greens are in the counties of Fermanagh and Sligo.

The United States of America have lately passed an act for admitting Irish linens into their ports free of duty after January 1834. This will, no doubt, have a most powerful effect in stimulating the manufacture in Ireland.

The demand for foreign linens in Great Britain is but trifling. During 1825, the real or declared value of those entered for home consumption only amounted to L.2301, 12s. 4d.

In 1829, the exports of linen from the United Kingdom amounted to 57,693,372 yards, of the declared value of L.1,953,007, exclusive of L.52,037, the value of the thread and small wares exported. The exports from Ireland direct to foreign countries were about one seventeenth part of the whole. The United States, the West Indies, and South America, have always been the best markets for British linens. Of the total quantity exported in 1829, 18,367,899 yards were destined for the United States, 11,854,207 yards for the British West Indies, 5,700,962 yards for Brazil, 6,822,637 yards for Spain, &c.

There are no means by which to form any accurate estimate of the entire value of the linen manufacture of Great Britain and Ireland. Dr Colquhoun estimated it at L.15,000,000.

It is worthy of notice, in reference to manufactures in general, that great evils have resulted of late years from the introduction of an entirely new system of business. Individuals, going under the name of money-lenders and commission-agents, in London, contract with manufacturers to transmit to them their stock in hand for disposal, for which they grant bills to a certain date. If the goods are disposed of at the prices fixed by the manufacturer, so far all is well; but if not, the broker is, of course, at liberty to sell the goods for what can be obtained, paying himself the amount of his bills, but under the temptation of *collusively* disposing of his goods at a lower rate to one dealing in a similar way with himself. The articles, when the bills are not paid, are seldom disposed of at full price. In either case, however, these money-lenders, or commission-dealers, retain samples of the article as a pattern, which they employ subordinate manufacturers to imitate upon an inferior scale of quality, thus deteriorating the value of the fair article in the market.

A Statement showing with sufficient clearness the slow but sure progress of the manufacture of Scotland, of her domestic consumption, and of her trade—linen representing the manufacture; the excise, the domestic consumption; and the customs, the foreign trade:—

Years	LINEN FOR SALE. Yards.	LINEN FOR SALE. Value.	EXCISE. Gross.	EXCISE. Net.	CUSTOMS. Gross.	CUSTOMS. Net.
		£	£	£	£	£
1707	1,500,000	—	—	33,500	34,000	30,000
1727	2,183,978	103,102	69,758	40,815	67,928	6,077
1737	4,721,420	183,691	65,124	43,788	69,324	16,444
1747	6,661,788	262,866	67,190	40,057	106,565	24,233
1757	9,764,408	401,511	68,301	42,636	148,421	13,546
1767	12,763,043	633,854	61,792	63,447	190,544	9,201
1817	26,784,967	1,492,680	1,072,901	1,575,647	913,937	709,081
1819	29,334,428	1,157,923	2,166,900	1,800,476	906,090	896,371

EDINBURGH: Published by WILLIAM and ROBERT CHAMBERS, 19, Waterloo Place; also by W. ORR, Paternoster Row, London; and W. CURRY, Jun. and Co. Sackville Street, Dublin. Sold by John Macleod, Glasgow, and all other Booksellers in Scotland, England, and Ireland.—Published once a fortnight. Stereotyped by A. Kirkwood, and printed by Ballantyne and Company, Paul's Work.

No. 8. PRICE 1½d.

ACCOUNT OF THE HUMAN BODY.

WHEN we see a beautifully constructed machine, as a steam-engine, with its piston rising and falling, and its valves opening and shutting with the greatest precision and accuracy, and the whole of its parts conjoining to produce the necessary power and motion required, we are irresistibly led to inquire into the structure of its parts, and how these are arranged and set together so as to accomplish with such wonderful facility their various movements. The animal body is a machine far more admirable in its construction, and more wonderful in its offices, than any devised by human art; and although there has hitherto existed an aversion to inquire into its form, founded on vague prejudice, happily such feelings are rapidly passing away; and a laudable curiosity to know something of the most perfect of the works of the Great Architect of the Universe is beginning to be excited among mankind in general. A general knowledge of the parts of the human body and of their several offices may be very easily obtained; the study is within the comprehension of all; and as human reason was given us, not only to "know ourselves" morally, but to minister to our physical or natural wants, the total ignorance of these must be culpable. A knowledge of the human frame, so far from exciting in us fear or alarm, is rather calculated to call forth feelings of gratitude and admiration. We find in it very nice, and delicate, and complicated parts; but yet we find all these so admirably fitted and adjusted for performing their several offices, that they very rarely, indeed, go wrong, unless deranged and interrupted by the ignorance, the neglect, or wilful folly of man.

The human body is composed of several parts or systems, which serve particular purposes, and perform distinct offices, all conjoining to one general end. There is a skeleton or frame-work of bones on which the whole is built, and which gives solidity and strength; a system of muscles and tendons, which are the means of motion; a system of blood-vessels and absorbents, for conveying the fluids of the body; a nervous system, for imparting sensation; a stomach and digestive organs, for supplying nourishment; lungs, for respiring the air which is necessary for upholding the principle of life; and several inferior parts, which call for less prominent notice. All these parts come to be described in their order.

THE BONES.

The bones are composed of the earthy matter of lime, and of gelatine, or animal glue. The lime gives them hardness and solidity—the animal matter renders them pliant, and not so readily broken. The outer surface of the bones is smooth, firm, and compact, while the inside is spongy and porous, with numerous vessels running through them. The large round bones of the body, such as the arm and leg, are hollow, like pipes, by which their strength is increased, while the necessary lightness is preserved. The marrow is contained in the hollow inside, and also the blood-vessels that nourish the bones. In the human body there are altogether 248 bones. The skull or head bone is composed of several pieces joined together by ragged or toothed edges, somewhat like the teeth of a common saw. In the new-born child these bones do not meet together, but are joined by the membrane below; as the child grows, and the head increases in size, the bones gradually extend, till, at last, when the size of the brain is complete, they join together, and form what is called *sutures*, or seams. Thus the bones form a strong and firm arch around the head, well suited for the safe protection of the important organ within—the brain. Proceeding from the lower part of the skull, there is a chain of twenty-four bones, firmly and curiously jointed the one into the other, and extending down the back; these bones are called vertebræ, and the line or chain which they form is called the spine, or back-bone.

The second of these bones in the neck contains a projecting pinion, or tooth, which is received into a corresponding depression in the first bone of the series, and on which the head turns round from side to side. The bones of the spine end in the pelvis, a large hollow basin-shaped cavity, which composes the lower part of the body, and gives to it firmness and stability. At the top of the spine, immediately below the neck bones, are situated on each side the thin shoulder bones or blades, to which are attached the bones of the arm; these shoulder blades lie above the ribs at the back; they are not joined to them, or to any of the neighbouring bones, but are kept in their position by numerous muscles attached to them on all sides; by this means they have a free and easy motion. To the shoulder blades on each side are attached the arm bones, which move in a beautifully formed ball and socket joint, that admits of motion in all directions; with this, and the yielding motion of the shoulder bones, the arm has every facility of movement. At the elbow-joint the arm divides into two bones, and these are so fitted on each other as to permit of extensive motion to the hand. Eight small bones, firmly wedged together, form part of the hollow of the hand; from these proceed five other small straight bones, which form the remaining part of the palm. To these are attached the fingers, which consist of three bones each. The thumb contains only two joints. On each side of the pelvis, in the lower part of the body, the thigh bones are attached. At their upper ends they move in a ball and socket joint, formed by a deep hollow circle in the pelvis. From the knee proceed two bones, which compose the leg. The front one is the larger; the side bone is thin and slender, and is attached to the other like a spring or clasp. A small bone covers the knee in front, called the patella, or knee-pan. To this bone are fixed the strong muscles that move the knee-joint. A round projecting bone forms the heel, which, with six wedge-shaped bones, compose the foot; from these, four bones proceed, to which the toes are fixed; each of the toes, like the fingers, consists of three small bones, the great toe having only two.

The ribs proceed from the vertebræ, or back-bones, and are twelve in number on each side; they bend round in a circular manner to the front, and join by means of long elastic cartilages to the breast-bone; thus forming a hollow space for the lungs, the heart, and other parts contained in the chest. The ribs move in an easy joint, fixed by tendons into the spine bones; and with the elastic cartilage in front, they expand and contract to suit the motions of the lungs. Thus the skeleton or frame-work of the body is completed. All animals have not this frame of bones; it is only found in a certain number of classes, including man, quadrupeds, birds, reptiles, and fishes; and from all these having a series of vertebræ, or back-bones, they are called vertebrated animals. Some of the other tribes of beings have their frame-work corresponding to bones, on the outside of the body, in the form of a coat of mail; this is the case with shell-fish, as the lobster, and with many insects that have a hard horny external covering, as beetles.

THE MUSCLES.

The soft fleshy substance of the body, which gives plumpness and form to the whole, is the muscular part, or muscles. These are the instruments of motion. And when we consider the various positions which the different parts of the body assume, the agility and quickness by which the most intricate movements are made, the ceaseless play of the heart, the heaving of the lungs, and the singular rapidity of articulation or speech, we need not be surprised that these muscles should be many in number, and important agents in the human economy. The muscles are thick fleshy substances, of a red colour: they are composed of numerous fibres, or layers, placed lengthways, sometimes straight, and sometimes oblique. They are of an elastic nature, somewhat like a piece of India rubber, and contract and extend at the impulse of the will, by which they are lengthened and shortened alternately. A muscle is generally thick or swelled out in the middle: it gradually gets thinner towards the extremities, and, in many instances, passes at one or both ends into a tendon, or tough white substance, which is attached to a bone, and serves the same purpose as a rope or cord, to fix the muscle to a point from which it is intended to act. These tendons are most numerous about the joints, especially the larger joints, where they allow of free and unrestrained action, and yet occupy little space in situations where a large swelling muscle would have been inconvenient. About the larger joints of the body also, such as the knee, elbow, and shoulder-joints, there are numerous glands, which pour out an oily substance, that serves to lubricate the joints, and facilitates the play of the tendons. There are from four to five hundred muscles in the human body, all necessary for performing the various movements and operations of the complicated machine. On each side of the back-bone there are several layers of strong muscles, which are fixed by tendons to every projection of the numerous bones which compose the spine. These muscles keep the trunk of the body erect, and also permit of the various motions of the back. There are a number of small muscles about the face, and head, and eyes, whose various action imparts that expression to the human countenance which indicates the prevailing feelings and passions of the individual. The tongue, besides being of muscular form itself, is also supplied by a number of intricate muscular fibres, which give that amazing volubility of action by which the vast number of sounds composing language are expressed. Several are attached to the lower jaw; but two in particular, the temporal muscles, proceed upwards through an arch formed by a projecting arm of the temple-bone, and are fixed to the tendons of the head. These two muscles are the most powerful in moving the jaws in the operation of chewing the food, and are very large in several animals of prey. Another flat muscle inside the cheek is called the trumpeter-muscle, because it assists in blowing from the mouth, and in sounding wind instruments. The chest is supplied with numerous muscles, which move the ribs upwards and downwards in the action of breathing. A large flat muscle, called the diaphragm, stretched across the lower ribs from side to side, and separating the hollow of the chest from that of the belly, also contributes to the process of breathing. The arm and hand are rolled inward and outward by a set of muscles, which are placed on the outside and inside of the respective bones; thus, the outside muscles act in a contrary manner to the inside, and reverse motions are thus alternately performed. The muscles of the fore-arm are fixed to the scapula, or shoulder blade, at one end, and to the bone of the arm at the other. The fingers are moved by muscles situated in the fore part of the arm, and have long slender tendons, by which they are attached. Two beautiful provisions of nature are here observed; at the wrist, a circular ring of tendonous substance binds down the long tendons, which would, in their various motions, otherwise start up from their places at the same time that this ring permits their free and unhampered play; the other is in the construction of the tendons of the fingers. There are two principal muscles which move the joints of the fingers, and two sets of tendons, which are inserted, the one into the middle bones of the finger, the other into the third row of bones, or the extremities of the finger. In order to preserve their free action, and to make them lie in the most convenient manner, there is a loop or slit in the shorter tendon, by which the other passes through to its insertion in the point of the finger. By this means the longest and strongest muscle moves the extremities of the finger, where the greatest power is wanted. The muscles which move the lower extremities are much of the same kind, but thicker, and more powerful than those of the arms. Several large muscles, acting in opposition to each other, are situated around the thigh joints, and move them. They are fixed, one end to the trunk of the body, some pretty far up, especially two, which are half-way within the abdomen, or belly, on each side of the spine, with the other end attached to the thigh bone. Several thick muscles also are situated at the back, forming the hips. Two large muscles compose the calf of the leg, and join to form the tendon of Achilles, which is fixed to the heel bone; these muscles act powerfully in bending the leg and supporting the body in walking. The foot and toes are moved by several long slender muscles, situated in the leg, which have tendons attached to them exactly like those of the hand and fingers. The pelvis and lower limbs of man differ greatly from those of all other animals in their superior proportional strength, and in the number and fullness of the muscles. This was necessary, as man is evidently intended by nature for the erect position. In the monkey tribe, whose general form approaches nearest to that of man, the narrowness of the pelvis, or hip bones, and the smallness of the muscles of the lower extremities, clearly show that they were not destined by nature for the erect attitude; in fact, all animals of this class are furnished with four hands, the hinder pair exactly resembling those in front. When they attempt to walk on the hind extremities, they cannot put the sole to the ground, but press on it edge-ways. By the nice balancing of the muscles, and the great force which they exert, man is enabled to stand erect, and to maintain a firm position, or move forward at pleasure, notwithstanding that the body is without the perpendicular line of the centre of gravity; and consequently, according to the laws of inert matter, it would have a constant tendency to tumble down. This is the case not only with the trunk of the body as a whole, but the head also is balanced upon the neck by means of strong muscles, whose constant exertion is necessary to maintain it in its position; for in young children, when the muscles are as yet weak, the head has an inclination to droop, and in the dead body it falls down on the shoulder or breast.

THE BLOOD-VESSELS.

These consist of the heart, with its arteries and veins, that branch out through every part of the body, and carry the blood, by a constant circulation, through them. The heart is placed in the left side of the chest, and midway between the back and breast bones; it is of a round conical shape, with the base or broad part uppermost, and the point slanting downwards to the left. It is of a thick muscular form, with hollow cavities inside, and numerous cords or pillars of fleshy or tendonous substance stretching through these to give them support. In man, and all the more perfect animals that breathe air through the lungs, it is double, or has two distinct sides, each performing separate offices. In fishes, again, the heart is single; in insects there is no proper heart, but a vessel that runs along the back, somewhat like an artery, through which the fluid, corresponding to blood, circulates through their bodies; other animals, still more simple in structure, have no trace of heart or blood-vessels. The heart not only sends the blood through the whole body by means of the arteries, which blood is again returned by the veins, but it also sends this venous blood through the lungs, to be renewed and purified by the air, from whence it is carried back to the heart, to be again circulated through the body. The heart, then, consists of two sides, a right and a left; and each of these sides contains two hollow cavities; the one called an auricle, from its fancied resemblance to a dog's ear; the other a ventricle, or belly. The manner in which the blood is circulated is as follows:—Two large veins, one from the upper part of the body, the other from the lower, enter the right auricle of the heart, and carry the blood, which has made the round of the body, into this cavity. Here it is of a dark purple colour, and is called venous blood, from its coming from the veins. From the right auricle it is sent, by a sudden contraction or forcing together of the two sides of the cavity, into the right ventricle immediately below the auricle, and communicating with this by a small opening furnished with a valve; by the right ventricle contracting, it is conveyed by the pulmonary arteries into the lungs, which are two large cell-formed substances on each side of the chest, surrounding the heart. In the lungs the blood undergoes an important change, to be afterwards mentioned, by which it changes from a dark purple hue to the colour of scarlet. After passing through the lungs, it is returned by the pulmonary veins to the left auricle of the heart; from this it is sent into the adjoining left ventricle, and by a powerful contraction of this muscular cavity, it flows out by the great artery of the heart, the carotid, which distributes it through every part of the body, again to be returned by the veins; and thus the round of circulation is continually going on.

The heart being so extremely thick muscle, the force with which it contracts is very considerable. The left ventricle of the heart, too, although somewhat smaller, is much thicker and more muscular than the right, it having to send the blood through the whole of the body. A beautiful provision is observable in the heart, to prevent the flowing back of the blood into its different cavities, during their alternate pulsations. In the passage of communication between the left auricle and ventricle are placed valves, which, when the ventricle contracts to send the blood through the aorta, close accurately, so as to prevent a reflowing into the auricle. There is the same provision between the right auricle and ventricle, and also at the mouth or commencement of the aorta and pulmonary arteries, and the veins which communicate with the right auricle. These valves are of beautiful structure: they are composed of three flaps that join accurately over each other; and to prevent their being pushed by the impetus of the blood beyond their proper position, they have little tendonous cords attached, of exactly the length required. In the child before birth, as it cannot breathe, and therefore the lungs are not used, there is a small hole or communication between the right and left auricles, by which the blood from the veins flows directly through to the arteries, and thus avoids going to the lungs; at birth this hole closes up whenever the child begins to respire. The aorta, or great artery of the body, after it leaves the heart, passes upwards in the form of an arch, when it gives off the carotid branches to supply the brain, and face, and arteries, to the arms and chest. It then bends downwards, and gives off branches to the stomach and other viscera; and when it comes to the lower part of the belly, it divides into two parts, which pass out and become the arteries of the thighs and legs. The arteries of the body are composed of three coats or coverings, the principal one being a thick muscular ring, which encircles the artery, and which contracts and expands so as to assist in sending the blood onwards. The principal trunks of the arteries lie deep in the fleshy parts of the body; but their ramifications are so numerous and minute, that they may be said to pervade every particle of the human structure—bones, tendons, and every other texture. These extreme branches of the arteries being so minute, anatomists have had great difficulty in tracing the exact point at which they pass into veins. They do so, however, as is seen on the surface of the brain. The veins are another system of vessels which return the blood from the extremities of the body to the heart. They are larger and more flaccid than the arteries, and are distinguished from them by having no pulsation. A large vein generally accompanies the corresponding artery, but the great proportion of the veins lie more towards the surface, and are easily distinguished swelling out under the skin. The numerous veins from the lower extremities join into one trunk in the belly, which vein, after passing through the liver, as will be afterwards described, joins the right auricle of the heart, the blood from the upper half of the body joining also by another similar vein. In the veins of the extremities that hang downwards, and are apt to be gorged with blood, there are inserted numerous valves, at short distances, which prevent reflux of any kind.

THE BRAIN AND NERVES.

Like the arteries, the nerves branch out into every part of the body, however minute; and it is by the influence of the nerves communicating with the brain, that motion and sensation are derived. The brain is the great centre of the nervous system; it is contained within the bones of the head, and consists of a large pulpy mass, formed on its surface into numerous waved or convoluted furrows; inside, it is of a whitish cream colour, and of the consistence of soft cheese: there are two large cavities in the centre, called ventricles, and three smaller ones below, all communicating with each other. The brain is also supplied with numerous blood-vessels, and there is always more or less of a fluid serum in its hollows. The internal structure of the brain has been accurately studied and minutely described by anatomists, but still these descriptions throw no light on the nature of its functions. The human brain is divided into the cerebrum, or brain proper, and the cerebellum, or lesser brain. The cerebrum is the uppermost portion, and is much larger in man than in any other animal, in proportion to the cerebellum, which, in the lower animals, always has the preponderance. From the lower part of the brain proceeds the spinal cord, or marrow, as it is sometimes called, although it has nothing in common with the marrow of bones. It is a long round cord, of the thickness of the finger, of the same kind of substance as the brain, and formed of a number of smaller nervous cords, running parallel to each other: it descends in a groove or circular cavity, formed in the numerous small bones composing the spine, and runs along the whole length of the back down to the pelvis. The nerves are small whitish-looking cords, which proceed from the brain and spinal marrow, and spread out in innumerable branches to every part of the body. A large branch of a nerve generally accompanies every large artery, and every important part of the body has a branch of a nerve sent off to it. The nerves for supplying the organs of sight, of smell, of hearing, and of taste, together with the great sympathetic nerves, which give branches to the heart, lungs, stomach, and other important viscera, proceed directly from the brain. The nerves of motion and sensation to the muscular parts of the body, take their origin, with a few exceptions, from the spinal cord. Two sets of nervous branches proceed from the cord on each side, corresponding to the junction of every vertebral bone; and it is found that a branch of these nerves imparts motion, and the other the sense of touch, of heat, and of cold. The brain has a covering of three thin membranes; the outward one strong and thick, the inner extremely thin and delicate. The nerves, which are soft and pulpy inside, have also a thin external covering which protects them. The nervous branches are never seen or felt in the living body, and what are vulgarly called nerves, are the tendons of the muscles, especially those about the wrists, fingers, and ankle joints. Their great numbers and minute divisions are manifest, however, because we cannot prick any part of the body with the sharp point of a needle, without wounding some of them, and thereby causing the sensation of pain. When the nerves are completely destroyed by disease, the sense of feeling in the part is entirely lost. The brain in the lower animals is not generally nearly so large, in proportion to their bulk, as in man; and the cerebrum, or upper brain, is greatly smaller than the cerebellum, or lower brain. In many classes of the inferior animals there is no distinct brain, but only nerves running along their bodies, and joining into knots or ganglions. Insects and worms are of this description. In the polypus, and some other similar animals, a distinct nervous system can scarcely be traced.

THE LUNGS.

In the highest part of the cavity of the chest, on each side of the breast-bone, the lungs are situated. A membrane passing from the breast-bone to the back, divides them into two lobes, the right and the left—the left lobe lying immediately above, and partly encircling the heart and its great blood-vessels. The lungs have a dark-bluish appearance, a familiar example of which is afforded in the *lights* of sheep, that part generally appended to the heart and windpipe. Inside they are composed of an immense number of cells, which alternately inflate or collapse as the lungs are filled and emptied of air. When an inspiration is made, and the lungs are filled with air, these cells become expanded; and the blood sent from the right side of the heart, and spread over the cells, is exposed through an extremely thin membrane to the air. An important change here takes place on the blood: from being of a dark purple colour, it immediately changes to a bright scarlet; it is found that it has absorbed or taken up all the oxygen, or vital part of the air, and has parted with a corresponding volume of carbonic acid gas or fixed air, which it had acquired in its circuit through the vessels of the body. So essential is the matter imparted by the air to the blood for sustaining animal existence, that the breathing cannot be suspended even for a very short period without extinguishing life. It is probable, too, that the heat of the body is generated, and constantly kept up, in some way or other, by means of this process of breathing, and the change which the blood undergoes. The lungs, like every other internal organ, are covered with a thin transparent membrane called the pleura: this membrane, as well as the substance of the lungs themselves, is liable to inflammation; and hence the name of the disease called pleurisy. The trachea or windpipe, the communication between the mouth and lungs, is a hollow tube, having a series of cartilaginous rings passing round it, to prevent the possibility of its being compressed either by external means, or from the food in the act of swallowing, and, in consequence, the breathing obstructed. It takes its rise from the bottom of the mouth, and passes in front of the neck, where its strong cartilage may be seen and felt. At its lower part it divides into two parts, like the prongs of a fork, one going to join the right lobe of the lungs, the other the left. Lungs for breathing air are only found in the higher classes of animals. Fishes are furnished with gills, those comb-like substances which lie within a flap on each side of the head; over them a stream of water is constantly sent by inhaling it at the mouth in a similar manner to breathing. The air, which is always present in considerable quantities in water, is thus absorbed by the blood-vessels while ramifying over the gills, and all the purposes of breathing are answered. In insects there are no lungs, nor do they breathe by the mouth, but along the sides of their bodies, by numerous holes with small tubes or spiracles, leading to a longer middle tube, by which the air enters and mixes with their fluids. When we descend lower in the animal scale, even this substitute for breathing ceases, and probably the vital air is absorbed by such animals by simple pores, or openings in the skin.

THE STOMACH.

Behind the windpipe, taking its rise also from the bottom of the mouth, lies the œsophagus, or tube which passes into the stomach. This tube expands at the top into what is called the pharynx, forming the whole of the upper part of the throat immediately behind the tongue. Into this cavity the windpipe opens, and, to guard against any particle of the food or drink passing into the windpipe instead of into the passage to the stomach, there is a little tongue or valve which closes accurately over the mouth of the windpipe every time food or drink is swallowed. When the substances have passed, the valve again springs open, and admits of free breathing. To show how accurately and precisely every part of the human machine performs its duties, a celebrated writer has instanced this same valve, which, in a multitude of persons dining together, not one time out of a hundred in any one individual instance is at fault. When a drop of fluid or particle of food does by chance insinuate itself into the windpipe, so sensitive is this tube that a convulsive cough is excited, till it is again expelled. There is another little tongue or flap attached to the roof of the palate, and seen above the tongue when the mouth is opened. This, which guards the passage to the nose, is not, however, to be confounded with the other, which is farther down the throat, and invisible. The œsophagus passes down through the chest in a ring formed by the tendons of the diaphragm, that large muscle which stretches across the lower ribs, and which assists so materially in breathing. Immediately below this muscle on the left side is situated the stomach, which is suspended in its place by being attached to the œsophagus, or tube from the mouth. The stomach is an oval bag of considerable size, occupying a slanting position immediately below the heart, with its right side overlapped by the edge of the liver, and extending to the lower end of the breast-bone. The stomach has three coats, an external membranous one, a muscular, and a soft villous inner covering. The upper passage, by which this bag communicates with the œsophagus, is called the *cardiac* opening; the lower, where the first gut commences, is called the *pyloric* orifice.

THE LIVER.

Opposite the stomach on the right side lies the liver, a large flat substance, of a dark brown colour, divided into two lobes. The liver has a round, convex, outer surface, and is hollow or concave below; it is also thick and solid at the back part, and its edge becomes thinner towards the front, where it lies over a portion of the stomach and bowels. It is suspended in its place by several ligaments attached to the surrounding parts. In the under side of the liver, in a small hollow, is situated the gall-bladder, a small oval bag which contains the bile. A tube from this bladder, called the bile-duct, passes into the upper portion of the bowels, carrying the bile there. The liver is supplied by several branches of an artery in the usual way that the other organs are, but it has also a peculiarity which no other intestine has. The large veins, which return the blood from the lower part of the bowels, before going to the heart, enter the substance of the liver, and there spread into innumerable branches throughout its whole surface. From this venous blood the bile is secreted, and after having yielded this substance, the vessels collect again into one large trunk, and join the large vein which carries the blood to the heart. The liver weighs, on an average, from three to four pounds weight, and the quantity of bile which it secretes, taking into account its large supply of blood, must be very considerable. The greater proportion of animal beings are provided with an apparatus of some kind or other for preparing a supply of bile, and in many the liver bears a large proportion to the other contents of the belly. In some animals, as the horse, the gall-bladder is awanting, where there is merely a duct to convey the bile into the intestines. In the lowest classes of animals, all traces of liver or gall-ducts disappear.

THE SPLEEN.

This substance is situated below the stomach, on the left side, between it and the ribs. It is in shape a flat oval, and of a dark iron colour. No duct or opening has been discovered proceeding from it, nor has its use been as yet accurately ascertained. It is probable that it serves to relieve the stomach of its surplus quantity of blood while this organ is distended with food; or it may be the medium of conveying fluids from the stomach into the blood. It has been frequently cut out from living dogs, without causing any apparent derangement in the health or digestion of these animals.

THE PANCREAS.

This substance, known under the name of the sweet-bread, is a large oblong gland, lying across the back part of the belly, extending between the spleen and the middle of the liver. This gland pours out a substance something like the saliva, or spittle of the mouth; and by means of a small duct or canal, pours it into the upper bowels, along with the bile from the gall-bladder, both these substances aiding in digestion, and the preparation of the nutritious fluid to be afterwards mentioned.

THE BOWELS.

From the lower, or pyloric orifice of the stomach, the duodenum, the first portion of the intestinal canal, takes its origin. This gut passes below the liver and receives the bile-duct, and the duct from the pancreas, when it terminates in the jegunum, which again passes into the ileum, or small intestines. These are of great length, and occupy the greater part of the lower belly, being folded and twisted backwards and forwards in many intricate windings. At the end of the ileum, the colon, a large gut, makes an arch upward towards the right side, and across the belly, and descending at the back part, ends in the rectum, the termination of the intestinal canal. The whole length of the intestines in man is generally about six times that of his average height, or from thirty to thirty-six feet. In all animals that feed on vegetables, the guts are of great length; whereas, in those that derive their nourishment from animal food, the intestines are of much shorter proportions. Two membranous substances, called the omentum and mesentery, run along the whole length of the intestines, and serve as a means of their attachment and proper suspension in their places. The bowels have three coats—an external one, common to them with the other viscera, a muscular coat, and an internal villous covering.

LACTEAL VESSELS.

These are innumerably small tubes, proceeding from the ileum or small intestines, along their whole course, and spreading along the mesentery, where they form an immense number of small knots, or glands, by joining together. These are the vessels which take up the fluid chyle, or milky-like substance, after it has been digested and properly prepared in the stomach and bowels. From these mesenteric glands, the chyle is conveyed by these ducts, or canals, to another large gland, situated in the loins, on the right side of the aorta, and immediately below the diaphragm, called the receptacle of the chyle. From this receptacle the thoracic duct arises, and passing upwards by the side of the aorta, or great artery of the body, it joins the left subclavian vein, lying under the left clavicle, or collar-bone, and thus pours the whole of the chyle into the general circulation.

THE KIDNEYS.

These are situated in the loins, one on each side of the back-bone, about one-third up the spine. They are in shape somewhat like a French bean, and their internal form consists of a number of minute porous tubes. They each at the middle hollow part receive a large artery, and their use is to filter from the blood the superabundant fluid, and salts and juices unnecessary for the system, and transmit these, by means of two small tubes, or ureters, to the urinary bladder. These tubes enter the back part of the bladder in a slanting direction, which serves the purpose of valves, preventing a flowing back of the fluid when the bladder is full. The bladder is situated in front, immediately above the bone of the pelvis, called the pubis.

The whole cavity of the belly is lined by a thin membrane, called the peritoneum, above which is the muscular fibre. This peritoneum is liable to inflammation, in the same manner as was mentioned of the pleura, which produces a very violent disease. The coats of the intestines, too, are also subject to the same affection.

THE LYMPHATIC VESSELS, OR ABSORBENTS.

These are another distinct set of vessels spread over all the inner cavities of the body, and also throughout the skin, on which they open by innumerable small porous mouths. Their office appears to be to take up from the blood a thin lymph, which they convey into the receptacle of the chyle and thoracic duct, and also to exhale or carry off from the skin the superfluous moisture of the body. This moisture forms the sweat, and several pounds of fluid are daily drained off from the body in this manner, even when little or no bodily exercise is taken. These vessels are composed of a series of extremely small tubes, and, joining and interweaving, form numerous glands, especially in the groin, armpits, and neck; when swelled by disease, they harden and enlarge, forming knots like a pea or bean. But they are no less numerous on the surface of the inner cavities of the body as on the skin; they are found in the brain, on the surface of the lungs, where they give out a large proportion of vapour at every expiration of the breath, and in the abdomen or belly. It is a disease or sluggishness of these vessels, whereby they do not perform their necessary duty of taking up all the superabundant fluids, that causes dropsies of the chest, belly, and legs. The branches of the lymphatics of the lower half of the body join the receptacle of the chyle; those of the upper part enter the thoracic duct just before the latter pours its contents into the subclavian vein.

THE SKIN.

An external compact membrane or skin covers the whole body. The outer skin, or cuticle, is unprovided with any blood-vessels or nerves, consequently is insensible; in this manner it is well suited for a protection to the parts beneath; it is pierced by innumerable minute pores, which are the mouths of the exhalent vessels: it is thicker in the palms of the hand and soles of the feet than in any other parts of the body. Below the outer skin is a thin membrane, called the rete mucosum, which, assuming different hues in different nations, gives rise to the variety of colour in the human race. In Europeans, it is white, passing into yellowish brown; in native Americans, of a copper colour; in negroes, of a deep black. It is highly probable that climate has the effect of modifying this colour of the skin, as the black skin only occurs in tropical regions, and it is found that there it is a protection against the scorching influence of the sun's rays. Negroes will remain cool and comfortable exposed to a sun which would be intolerable to a white-skinned person. Immediately below this net-work is the cutis, or true skin, an extremely sensible membrane, so thickly studded with minute blood-vessels and branches of nerves, that the smallest pointed needle cannot prick it without touching many of them. On the points of the fingers, lips, and other parts of the body, these vessels are very numerous; and hence these parts are endowed with exquisite feelings of touch. Below the skin is situated the cellular membrane, which is a net-work, whose interstices are filled with fat, and it thus serves to fill up the spaces between the muscles, and to make up the shape, and preserve the symmetry, plumpness, and beauty of the whole frame. In cases of emaciation, this fatty matter is sometimes entirely taken up by the absorbent vessels; as, after a tedious fever, or other lingering disease, when the rough outlines and indentations of the muscles, and the projections of the bones, become painfully apparent.

THE TEETH.

These are placed in the upper and lower jaw, to which they are attached by roots, which sink into the porous sockets of the jaw, somewhat in the same manner as a nail is fixed in a piece of wood. The teeth are composed of bony matter, and covered externally with a thin coat of an extremely hard substance, called enamel. The teeth are furnished with nerves and blood-vessels, which run in hollows of thin substance; they have thus vitality like the rest of the body, although possessing life in a less perfect degree than most other parts of the structure, and hence they are very liable to disease and decay. In decaying teeth a blackish spot is first perceived upon the outer crust or enamel; this substance gradually gives way, and then the bone below proceeds to rapid decay. The irritation of the air, and particles of the food, inflame the nerves and soft pulpy parts inside, and thus the excruciating pain of toothach is produced. The first set, or temporary teeth, begin to make their appearance in the child about the fifth or sixth month, and towards the end of the eighteenth month generally the whole set of temporary teeth, consisting of twenty, have cut through the gums. These teeth continue till about the sixth or seventh year, from which time, till about the twelfth or thirteenth year, they gradually fall out one by one, and are succeeded by the second or permanent teeth. The roots of the temporary teeth are much smaller, and sink less deep into the jaw than their successors. The rudiments of the second set of teeth begin to form early in cavities below the others, and gradually growing and pressing upwards, displace them. The number of the permanent teeth is thirty-two, consisting of sixteen in each jaw. The four front teeth are called the incisors, and have one long root; on each side next to these is one eye or dog tooth; then there are placed two small grinders on each side, having double roots, and three large grinders, or molar teeth. The last of these is called the wisdom tooth, from its making its appearance latest in the jaw, from the seventeenth to the twentieth year, or even later. By this change and gradual succession of teeth, we have a beautiful provision of nature for permitting the jaws to increase in size, and, at the same time, for preserving the relative positions and regularity of the different teeth; for had the first teeth of childhood been permanent, it is impossible that the jaw could have increased in growth without deranging the order and position of the whole. The teeth of various animals differ according to the kind of food on which they live. In carnivorous, or flesh-feeding animals, the teeth are sharp-pointed, and adapted for tearing their prey to pieces; in those animals called graminivorous, that live on grasses and other herbage, the teeth are of a rounded form, with broad surfaces, and the grinders are furnished with several layers of the hard enamel following each other in succession, with a slight layer of common bone interposed; so that, when the grinder is worn down by the friction of chewing, it is not rendered useless, but a new layer of the enamel is presented at the worn-down surface. Some animals, as the hare, rabbit, beaver, and mouse, have the front teeth of a chisel shape, with enamel only on the outer side of them. These animals are called gnawers, because they chew or gnaw down their food in this particular manner; and by the inner soft part of the tooth being liable to be worn down, while the outer is harder, the enamel is thus always kept with a sharp edge. Some animals have large projecting tusks for defence, as the elephant, wild boar, &c.; others, as fishes, are provided with teeth more for holding fast their prey than for mastication. Many have no teeth at all, as birds, worms, and other soft formed animals. Man is characterised by having all his teeth set close to each other in a half circle; they are of a medium form, between that of carnivorous and herbivorous animals; the front teeth are adapted for cutting; the canine are sharp, though not of undue length; and the grinders are suited for masticating vegetable and farinaceous matters, as nuts, &c. In short, the form of the teeth of man evidently points out that he is adapted to live on either kind of diet, or a conjunction of both vegetables and flesh.

THE HAIR AND NAILS.

The hair grows out from the skin somewhat in the manner of a vegetable production. Hairs are fixed by roots in the skin, from whence, by a series of minute vessels, they draw nourishment, and continually increase in length. They possess no sensibility, however, and, unlike the other parts of the frame, may be cut off without producing the least pain. Hair is of different colours in different individuals—is fair in those of light complexion, and deep black in the swarthy. As old age approaches, and even in many young persons, where there is a particular disease in the hair, or dryness in the skin, this colour changes to grey and white. The colouring matter of the hair is contained in the centre, which is of a hollow form, and consists of an oily substance, in which carbon or charcoal, in minute particles, is more or less mingled. The nails are somewhat like hair in their production and composition; they are, like hairs, insensible to the touch, and may be cut or pared without producing pain. They receive nourishment from the blood-vessels of the extremities, and have a constant growth or renewal of their substance. Nails serve as a defence to the tender parts of the fingers; in animals they form formidable weapons of attack. The horns of cattle are exactly of the same nature as nails, and are chiefly composed of animal gelatine.

THE EYE.

We now come to consider the organs of sense. The eye may be compared in its structure to a telescope, the purpose of both being to collect the rays of light proceeding from the surface of bodies, to concentrate these rays, by means of a refracting lens, into a focus, and, therefore, to form a very small image or picture of the object before them. The human eye is placed in a large hollow or socket in the upper bones of the face, surrounded by fatty substance, and the various muscles necessary for moving the eye-ball and eye-lid. At the upper and outer angle of the eye-socket is placed a gland, which secretes the tears that serve to moisten the delicate surface of the eye, to wash off any dust or other substance, and to keep the eye continually wet and transparent, for the purpose of perfect vision. The tears, after spreading over the eye-ball, collect at the inner angle, where, at each corner of the eye-lid, both above and below, there is a small opening visible, which carries the tears down a passage into the nose. The edges of the eye-lids are also supplied with glands, which pour out a mucus that prevents them from adhering together; and these, when irritated and inflamed, are often the seat of disease. The membrane which covers and imparts the white colour to part of the eye-ball in front, is called the sclerotic coat. The middle transparent part of the eye in front is called the cornea, which is filled with the aqueous humour of the eye. Immediately behind the cornea is seen a circular fringed-like substance, which varies in colour in different individuals, being blue, black, hazel, &c.; and hence it is called the iris, or rainbow curtain. This iris has the property of opening and closing, according to the quantity of light which falls upon the eye; and thus the pupil, a black circle contained within the iris, is enlarged or lessened. Behind the iris is situated the crystalline lens, in shape resembling the small lens, or ground glass of a common telescope, but of unequal swell on each side, being more flattened before than behind. This lens is contained within a capsule, or thin covering of delicate membrane. A familiar example of the lens of a fish's eye is presented every day in that white globular substance found in such eyes after boiling. The heat coagulates the lens, which is of the same nature as the white of an egg; and in the fish it is nearly a circular body, to adapt the animal's vision to the dense medium of water. The lens is the substance which receives the rays of light entering the eye, and refracts or bends them inwards, whereby they are collected into one point upon the back chamber of the eye or retina, and thus a minute picture of the object seen is formed. If a bullock's eye is taken when fresh, and a hole cut in the skin covering the back part, and then presented to the light with a piece of white paper put opposite the hole, a representation of the objects in front of the eye will be distinctly traced on the paper. When through disease the lens becomes of an opaque white colour, and will not transmit the rays of light, the affection is known as the cataract, producing blindness. The fluid filling the lens is called the crystalline humour. Behind the lens is the back chamber of the eye, filled with a fluid, called, from its thickness, the *crystalline* humour. Over this back chamber the retina is spread out like a lining or covering. It is covered over with a black pigment, the better to prevent the intermixture or reflection of the rays of light. On this membrane the optic nerve, which comes from the front part of the middle brain, and enters the eye-ball at the back part, spreads out in numerous branches; and here the small images of the outward objects presented to the eye are painted in miniature. All these objects are painted on the retina in a reversed position, or turned upside down, the same as happens in a common microscope; and how they are perceived in their upright position through the medium of sensation, is a curious question, not easily admitting of explanation. Each eye, too, forms a distinct impression of every object, and yet things are not seen double, but both eyes combine to give one impression to the brain or seat of perception. Besides the numerous muscles which roll the eye-ball in various directions, to adapt it to the various positions of vision, there seems also a power, in the cornea or front portion of the eye, whereby it can flatten or become more convex according as the object viewed is at a greater or less distance from the eye, thus adapting itself to the focus of vision in a similar manner as the joints of a telescope are drawn out or pushed inwards. When the cornea is, from its natural form, of too rounded or convex a structure, distant objects are always seen imperfectly, hence causing what is called nigh-sightedness; on the other hand, when it is too flat in form, near objects are then seen indistinctly. This change occurs generally to the cornea as old age approaches, and hence spectacles, or artificial rounded lenses, to aid the flatness of the eye, are in such cases made use of with the desired effect. From the different densities of the three humours composing the eye, the refraction, or breaking of the light into the various coloured rays, is avoided. This for a long time was a great objection to telescopes, till different kinds of glass were joined together in the lenses, thus imitating the resources of nature in the eye. The eyes are supplied by two large optic nerves, proceeding by separate trunks from the brain; they join together for a short space within the cranium, where they again separate, and each entering an opening at the back part of the orbit, spread their branches over the retina. Sometimes these nerves lose their power of sensibility, and total blindness is occasioned without any perceptible disease of the eye; this is called *amaurosis*, and is in most cases incurable. All the larger and more perfect animals are possessed of eyes. Birds have in general very acute vision, especially birds of prey, to enable them to distinguish their victims at a great height in the air. They have also a third eye-lid or transparent membrane, which covers the eye-ball when they are darting suddenly through the air, and which thus protects the delicate organ of the eye from injury, at the same time that it allows the transmission of a sufficient quantity of light. Fishes have eyes of a somewhat different form from land animals, to adapt their vision to the denser medium of water, through which the rays of light pass to their eyes. Insects have great numbers of small eyes clustered together, and most probably they are of microscopic structure. Many of the inferior animals, as shell-fish, worms, &c. have no eyes.

THE EAR.

This is the next organ of sense whose situation is the most complicated. The outer part of the ear is formed so as to collect and transmit the currents of air into the passage which leads to the drum. This passage is of a winding description, and, besides being defended at its mouth by a number of small hairs growing up in it, there is also a waxy substance constantly secreted, which keeps the whole moist, and is an effectual bar to the entrance of insects or other offensive substances. At the inner end of this winding passage is the thin membrane, or drum, which is stretched out on four small bones, and which, by its vibrations, conveys, through the medium of the nerves, the sensations of sound. There are also attached to these small bones, several muscles which, by their contraction and relaxation, modify the tension of the thin membrane, and prevent sounds from acting too strongly on it, or render it tighter, in order to be even sensible to feel vibrations. Behind the cavity of the tympanum, or drum, there is another passage which leads from the ear to the mouth, called the *Eustachian tube*, the object of which is most probably the same as the holes in the common drum, to allow the air to escape from behind, and thus promote the vibration of the membrane of the tympanum; for it is found, that if such holes are not made in a drum, little or no sound will be produced; and in the human body, when this tube, leading to the mouth, is choked up by the inflammation of a common cold, deafness is produced. There is another cavity called the vestibule of the ear, covered over also by a thin membrane; on this membrane the nerves of hearing are expanded, and convey the sensations of sound to the brain. The sense of hearing is very acute in some animals, especially those that live by prey. In the lower orders of beings the sense is awanting, but is compensated in a considerable degree by the extreme acuteness of feeling, or touch, which is so diffused over their bodies as to make them sensible of the least agitation in the air by which they are surrounded.

THE NOSE.

The nose is the organ of smell, and is of comparatively simple structure. The bones forming its inner cavity are of a spongy nature, or rather are composed of a number of very thin plates, covered with a soft membrane, over which the branches of the nerves of smell are minutely exposed. The effluvia proceeding from bodies, and which imparts their peculiar odour, must pass in a stream or current through the nose before the odour is perceptible. If the air is perfectly still, and no current allowed in the nose by suspending the breathing through that organ, the strongest smells will make no impression. In some animals the sense of smell is acute and powerful, beyond the conception of human beings; thus a dog, by the acuteness of this sense, will distinguish the footsteps of his master amid those of a hundred other people, and can thus trace him for miles, although he has been a long while out of sight; pointers also scent game at a great distance. On the other hand, this sense is entirely denied to many of the lower animals. In man it is in many cases very imperfect, and may be blunted, or even extinguished, by disease. In colds affecting the delicate membranes lining the nostrils, the smell is very much diminished.

THE MOUTH.

The sense of taste is nearly allied to that of smell. The nerves of taste are spread over the upper surface of the tongue, and are raised up in innumerable small points, like the pile of velvet. In the lion these papillæ are very large and easily distinguishable. No other part of the mouth is endowed with the property of tasting, except the tongue, as may be proved by touching any part of it with a piece of salt or sugar, when no sensation of taste will be communicated until the tongue has come in contact with the part so touched. That the taste or flavour of many bodies is heightened by the accompanying effects on the organ of smell, is evident; because, if the nose is stopped up so as to prevent the exercise of its functions, many substances having different flavours will taste alike. This is the case with the various kinds of wines, but especially with the ardent spirits. It is almost impossible to distinguish between the flavours of different kinds of spirits if they be tried in the dark, and with the passage to the nose accurately shut up. The tongue and whole cavity of the mouth and throat are kept moist by the saliva, or spittle, which continually flows into them from repositories placed around the cheeks and under the tongue, called salivary glands, which communicate with the mouth by means of small ducts. This saliva flows in greatest quantity during meals, and may even be excited by the sight of food when the appetite is good. It is of essential service in moistening the food, and preparing it for the process of digestion in the stomach. The sensation of taste is in all probability diffused among every class of beings, however low in the scale of existence, although it is probable many animals possess little of it in their mouths, especially when these are fond of hard, horny, or even earthy substances, as in many insects—the lobster, crab, &c.—and where any organ corresponding to a tongue is wanting. Even many birds that feed on grain and hard bodies, not chewed or broken down in the mouth, must have little sensation of taste.

SENSE OF TOUCH.

The sensation of touch is diffused more or less over every part of the body, but is most perfect at the points of the fingers, which in man are generally used to examine the figure and texture of bodies. For this purpose they are furnished with a large supply of very minute blood-vessels and nerves. It would appear that there are different nerves that convey the sensation of touch, distinct from those which are the nerves of motion; and that these proceed in pairs from the spinal marrow; and that, moreover, the sensation of heat or cold may be perceived very distinctly, in cases where the pricking of a needle or contact of other bodies is never felt. The sense of touch may be said to belong to every animated being, and is one great characteristic of animal existence. Vegetable bodies possess a certain degree of life, and show what is called irritability of their fibres; but they have no sensation properly so called; they are not sensible of pain or injury, as the lowest and simplest sentient animal is; neither have they the compensating perceptions of pleasure. It is probable, however, that sensation is not by any means equally acute in all animals: some feel more intensely than others, and it is a [illegible] provision of nature that it should be so. The lower insects and reptiles, from their structure and habits, are continually exposed to injury; and did they feel it as acutely as the larger animals, the degree of animal suffering throughout nature would be excessive. Many animals bear the loss of limbs with impunity, and have the power of restoring these lost members in a very short time. It is probable, that, according to the perfection of the nervous system, is the acuteness of animal sensation.

On thus reviewing the different parts of the human body, it will be observed that most of its organs are double. On a line being drawn in the middle, on each side will be found parts which are exactly similar to the corresponding side. This is the case with the brain, which is a double organ, having two series of nerves proceeding out from each side of it to go to the respective sides of the body. There are two eyes also, each reflecting a distinct image on the retina; yet the nerves communicate so that only one impression is conveyed to the sense. The arms are double, to suit the various purposes for which they are employed, and so are the lower limbs, an essential requisite for the support of the body, and for progressive motion. The lungs, too, may be said to be double, having two distinct lobes; and it sometimes happens that one of them is entirely shrunk or diseased, and yet the important office of respiration is still carried on. The stomach, the liver, and some of the other viscera of the abdomen, are, however, single, their several offices being common to the whole body.

DIGESTION.

One of the most important operations in the animal economy, is that of digestion, whereby the various substances used for food are dissolved in the stomach, and undergo changes, by which they are formed into matter fit for entering into the composition of the different parts of the body, to nourish its growth, and supply the daily waste which takes place in the system; for such is the constitution of animal bodies, that the substances of which they are composed are liable to constant waste; the solid parts are worn down, and taken up by the absorbent vessels, and a large quantity of fluid is as constantly given off by the exhalent vessels, both from the skin and the surface of the lungs. This is manifest in the sweat and the vapoury exhalations constantly passing off by the mouth; and there is also an imperceptible perspiration regularly proceeding from the surface of the body, which has been computed to amount to several pounds in the course of a day. It must be evident, therefore, that if this waste was allowed to proceed but for a very short period, the body would soon be reduced to a state of complete decay. A constant supply of new material is therefore daily needed, to replace that which is wasted; and thus it has been supposed that a human body changes its whole materials many hundred times from the period of its birth till death; and that an individual, as regards his mere corporeal structure, is not at all the same at the period of manhood to what he was when a boy, nor in old age what he was in his prime. Although this change then is complete, even to the bones and most solid parts of the frame, it is brought about so gradually, and with the regular and minute substitution of one particle for another, that it is never perceptible; and even the marks of spots and blemishes, and the healing scars of wounds, are accurately preserved. Man has been called, with relation to his diet, omnivorous, from his being adapted to live on every kind of food, whereas most other animals are confined to one particular description. The carnivorous animals live on flesh alone, the graminivorous on grass and green herbs, and the granivorous on grains and other smaller seeds. These animals never change their respective diets; nor, from the construction of their teeth, stomachs, and intestines, were they ever intended to do so. But in man it is plainly evident, from his anatomical structure, that he was intended to feed on every sort of food promiscuously, or that he could adapt himself to either animal or vegetable fare, as habit or necessity impelled him. Man also differs from brutes in resorting to the arts of cooking, whereby the food is put into a state more fitted for digestion, and for yielding a sufficiency of nutritious aliment. The food being received into the mouth, is broken down and masticated by the teeth, which are of two kinds, the cutting teeth and the grinders. It is here also reduced into a soft pulp by the saliva, which flows into the mouth by the salivary glands; and thus being sufficiently broken down and softened, it passes into the stomach. The stomach has numerous glands situated on its inner coat or surface, which secrete a peculiar fluid called the gastric juice, which is clear and colourless, with little taste, or smell, or sensible qualities. On this fluid depends the important office of digestion. It has the power of coagulating substances in the stomach, of preventing the contents of the stomach from passing into a state of fermentation or putrifaction, and of dissolving the whole into one homogeneous mass. When the stomach is first filled with food, it appears to remain there for a short period without undergoing any change; gradually, however, successive portions of the food as they come into contact with the gastric fluid are dissolved; till at length, in a shorter or longer period, the whole is collected into a thin greyish paste, called chyme. In the upper or left division of the stomach, it would appear, from some recent observations, that the food is freed from its superabundant moisture, which drains off by some undiscovered means to the blood-vessels, and from thence to the kidneys. The chyme then, as it is gradually formed, moves to the other extremity of the stomach, called the pyloric, where it passes out to enter the intestinal canal. It would appear, also, that the pylorus, or lower mouth of the stomach, has a sensitive power, whereby it freely permits the digested chyme to pass out, but refuses exit to the undigested matter. The chyme having passed into the first part of the intestines, or duodenum, is then mixed with the bile from the gall-bladder, and with the pancreatic juice. Both these substances, especially the bile, seem essential for the conversion of the chyme into proper alimentary matter, but their peculiar action has not yet been satisfactorily explained. That the liver and bile ducts are of the utmost importance, however, cannot be doubted, from their magnitude, and the care by which they are supplied with numerous vessels, and from their being universally present in a great proportion of animals. The chyme having passed through the duodenum, and having been mixed with the bile and pancreatic juice, now changes its appearance and properties, and becomes the chyle, or nutritious matter destined to supply the various parts of the system with nourishment. The digested mass is passed gradually along the course of the small intestines, urged forward by what is called their *peristaltic* motion, which is effected by a successive contraction of their fibrous coats. Here the minute mouths of the lacteal vessels, opening on the inner surface of the small intestines, take up the chyle, and carry it, as has already been described, to the receptacle of the chyle, and from thence, by the thoracic duct, it joins the blood-vessels. The refuse of the aliment which has not been taken up by these lacteal vessels passes on through the large intestines, and at length is ejected from the body. It is conjectured that, in the colon, or large gut, which follows after the smaller intestines, the fatty matter of the body is secreted. Digestion is not brought about, as has by some been supposed, by any mechanical means, as by the grinding powers of the coats or sides of the stomach, nor by heat alone, nor fermentation, nor by the simple solution of the food in a fluid, but it is evident that it undergoes a series of chemical actions in the stomach and bowels, whereby its nature and properties are completely changed; and thus animal and vegetable substances, however different, are reduced to one peculiar kind of fluid, the chyle, which, though it may be found to vary slightly according to the kind of food, is, in its general properties, always the same. The gastric juice varies in different animals. In those which feed on vegetable matter, it dissolves these substances only; whereas, grain and vegetables pass through the stomach of a carnivorous animal without undergoing any change. It has this singular property, too, that although it readily dissolves dead animal matters, and reduces them in a short time to a thin pulp, it will not usually act on the living fibre; so that, after death, the coats of the stomach have been found dissolved into holes, by the same juice, that, when living, had no such effect. A stomach of some kind or other is found in all animals; for it is by this organ that nutrition and growth are solely promoted. There are some very simple animals whose whole body consists of a membrane formed into an oval hollow bag, or stomach, with a simple outlet for the mouth to take in nourishment, and no other organ whatever. Of this kind, too, is the polypus, which has a mouth and hollow stomach, with several tentacula, or arms, by which it seizes the worms and grubs on which it feeds; these it swallows, abstracts their juices, and then voids the remainder from its mouth. The common leech has its whole body divided into a number of small cells, like a piece of honeycomb; and these receive the water, and sometimes blood, on which it feeds. Flesh-feeding animals have a simple bag for a stomach, and their food is easily and soon digested. Those animals, again, that feed on grass, which is of more difficult digestion, have three and four stomachs, into which the food successively passes after it has been masticated or chewed a second time in the mouth. This is the case with cows, sheep, deer, &c. Birds that feed on grain have first a sap-bag, or crop, into which the food enters, and remains for a considerable time, mixed with a juice somewhat like saliva; here it is softened and rendered moist, preparatory to its passing into the true stomach, or gizzard, which is an extremely strong muscular bag; in this, with the assistance of a number of sharp-pointed pebbles, which such birds always swallow, it is ground down and acted on by the gastric juice. This compensates for the deficiency of teeth in fowls. Crabs and lobsters have no teeth in their mouths; but in their stomachs will be found three or more teeth, which assist in grinding down the tough sea-weed on which they feed. By domestication, the qualities of the gastric fluid may be so changed, that animals accustomed to live entirely on flesh will exist and thrive on a vegetable diet. This is the case with dogs, and many birds.

THE BLOOD.

The blood is the medium by which all the solid and fluid parts of the body are supplied with nourishment. In its composition, therefore, will be found all the various substances of which the body is composed. The blood consists of a solid coagulable matter, called fibrin, or animal jelly; of a series of red globules which form the colouring matter; and of serum, or whey-like matter, which gives the whole the necessary fluidity. The circulation of the blood through the arteries, and its return to the heart by the veins, has already been explained. The purpose of its thus making the circuit of the whole body, is to supply the necessary materials for increasing the bulk and repairing the daily waste which takes place by perspiration, and the absorbing actions of the lymphatic vessels already described. The blood, again, is replenished by the chyle, or nutritious juice formed in the intestines from the digested food; this chyle enters the venous side of the heart, by one of the large veins called the left subclavian; from the right side of the heart it goes along with the venous blood to the lungs, and there it is mixed with the oxygen, or vital portion of the atmospheric air, by which process it is converted into bright-red arterial blood. In this state it now contains the material of the bones, of the fleshy or muscular parts of the brain and nervous cords of the hair, nails, enamel of the teeth, and, in short, of every different structure of the system. The average quantity of blood contained in an ordinary sized person, is calculated at about 30 lbs. weight. The coloured globules of blood do not enter into the smallest vessels of the body, but only the thinner part of it which has no colour; thus, in the eye, there are numerous blood-vessels, but these are so minute as not to admit the red parts of the blood; and this is a necessary provision of nature, in order that these organs may retain their pure transparency for the purpose of vision. In inflammation of the eyes, when these vessels are much enlarged, the red globules sometimes enter, and the eyes are then said to be bloodshot. What is called the pulse, is the flow of the blood through the arteries, which is caused partly by the impulse of the heart's contractions, or beatings, and partly by the contractions of the coats of the arteries. The rate of pulsation in a person in the prime of life, is from 65 to 75 beats in a minute. In childhood the pulse is much quicker, from 100 to 140 beats; and in old age it again becomes slower than the medium standard. In fevers, inflammations, and other diseases of excitement, the action of the heart is increased sometimes to 100 and 140 pulsations in a minute.

SLEEP.

As a constant supply of food is necessary to repair the waste of the grosser parts of the body, so sleep is essential for the repose and renovation of the finer and more subtile nervous energy. Mere rest alone will not recruit the animal frame, but sleep, or a profound oblivion of feeling and sensation, and of every external circumstance, seems essentially necessary at every periodical revolution of the day. Toward the close of a day of exertion, the muscular powers which have been employed in motion, and in sustaining the body erect, begin to suffer particularly; the eyes become dim and heavy, and the eyelids close involuntarily; the lower jaw falls down; the circulation of the blood through the lungs is sluggish, hence frequent yawning is caused; the head nods forwards; all external objects affect us less and less; the thoughts become confused; and at last the profound oblivion of sleep ensues. We are unconscious of the exact moment when we pass into sleep, but occasionally it happens that immediately afterwards we are awaked by a convulsive start, which is caused by the sudden breaking in of the powers of volition, when as yet but newly and imperfectly lulled to rest. Sleep is quite essential to existence. Deprive a person of sleep, and the body sinks under the privation more rapidly than under famine. Indeed, no circumstances, however urgent, will prevent the approaches of sleep for any length of time; and under the severest calamities, and even while in the hour of battle, or when suffering from extreme fatigue, or cold, or hunger, sleep steals upon us to steep the senses in oblivion. Healthy sleep is so profound as to resemble, in all that regards self-consciousness, death itself. Sometimes, however, the mind exerts its activity, though it is but a partial exertion; and hence dreams, or the thoughts of sleep, are made up of all incongruous associations, such as thoughts of the past day and incidents of long bygone years; scenes of actual experience, and others totally imaginary, being all mixed up and jumbled together. In sleep the heart continues to beat with regularity, and the circulation of the blood is carried on throughout the body; the lungs perform their functions, the stomach digests, and the bowels, and all the glands for secretion, carry on their operations; in short, every thing is carried on connected with the sustenance of the body and the existence of the vital powers; but for the most part all other powers, such as those over which we have a control in our waking hours, are at rest. This is not always the case, however, as walking during sleep, or somnambulism, is a peculiarity which some individuals are liable to. Dreams are most common when the sleep is imperfect or too long continued, and thus they occur frequently towards morning, or through the night, if the stomach is loaded and oppressed with food, or the mind harassed and deeply impressed with cares and solicitudes. In a state of health and serenity of spirits, the most profound and most refreshing sleep is during the first period of the night. When asleep, the circulation and breathing are both somewhat slower than when awake, hence the animal heat becomes diminished; and this is the reason why more clothing is required in bed than during the day. This is the reason, too, why a person lying down to sleep out of doors, or on a sofa, with the usual allowance of clothes, feels chill and uncomfortable on awaking. Digestion, too, would appear to go on less vigorously during sleep; and hence the impropriety of going to bed with a full stomach. During the night and darkness is the most natural and obvious time to select for repose, and it is only the absurd encroachments of fashion that have well nigh turned day into night. By going early to bed, the damps and colds of night are avoided, which is of essential consequence, especially for the delicate. There is also a natural connection of the functions of the body with the periods of day and night, which makes sleep taken in the first part of the night peculiarly refreshing. The absence of every irritation of the head and other parts of the body—the perfect rest of the mind and external senses—have also great influence in promoting sleep. Again, a variety of causes which weaken and debilitate the body, incline to sleep; such as great losses of blood, cooling medicines, purgatives, coldness of the atmosphere; and narcotics, such as opium and tobacco, drinking largely of wine or spirituous liquors, by first causing great excitement, and afterwards a corresponding debility of the system, also predispose to profound and lethargic sleep. Injuries of the head, by pressing on or otherwise interrupting the functions of the brain, also induce sleep; and great corpulency, by retarding the return of blood through the veins, and thus keeping up a pressure upon the head, is generally accompanied by a disposition to sleepiness.

The period required for sleep, by different individuals, depends much upon temperament and peculiarities of constitution, as well as on mode of life and habit. While some cannot sleep beyond five, six, or seven hours, others, again, cannot well do with less than eight or nine hours. Children sleep more than half of their time, and require it, and thrive under it; while adults need much less repose. On a general average, eight hours has been reckoned a good allowance. Certainly, sleep, beyond this, does no good, and often does harm. In order to enjoy grateful and uninterrupted sleep, it is necessary that due exercise shall have been taken during the day; that temperance in food and drink shall have been observed; that strong tea or coffee, which have a stimulating effect on the system, shall not have been taken within an hour or two of going to bed, and that there has been no supper, or a light one. It is true, gluttony and intoxication produce sometimes deep sleep, but it approaches more to an apoplectic stupor, than the calm repose of the temperate. It is in such cases that the curious circumstance which has been called "nightmare" occurs. When a person is seized with an attack of this kind, if it is very severe, it generally disturbs sleep so much, that the sufferer at last becomes conscious that he is in bed, and only half asleep. He feels to be oppressed with some weight which confines him to his back, and prevents his breathing, which now becomes extremely laborious, so that the lungs cannot be properly filled by any effort he can make. The sensation is now the most painful that can be conceived. The person becomes every instant more and more awake and conscious of his situation. He makes violent efforts to move his limbs, especially his arms, with a view of throwing off the incumbent weight, but not a muscle will obey the impulse of the will. He groans aloud, if he has strength to do it, while every effort he makes seems to exhaust the little remaining vigour. The difficulty of breathing goes on increasing, so that every breath he draws seems to be almost the last that he is likely to draw. The heart generally moves with increased velocity, sometimes is affected with palpitation, the countenance appears ghastly, and the eyes are half open. The patient, if left to himself, lies in this state generally about a minute or two, when he recovers all at once the power of volition, upon which he either jumps out of bed, or instantly changes his position, so as to wake himself thoroughly. If this be not done, the fit is very apt to return again immediately, as the propensity to fall again asleep is almost irresistible, and, if yielded to, another paroxysm of the same kind is for the most part inevitable. Speaking during one's sleep is not an unfrequent occurrence, and takes place with some individuals much more commonly than with others. It would appear to be accompanied frequently with certain dreamy imaginations affecting the mind, and at other times is simply the articulating muscles of the voice called into action without any distinct dreams, at least without the person being capable of recollecting any thing if awakened during his harangue. Many of the lower animals extend their periods of sleep to one-half of the year; this is called a state of torpidity, and occurs in those animals during winter. This state of torpidity resembles, in most respects, a common sleep, only that it is more profound and longer continued, and the vital functions are suspended in a more complete degree; still there is a feeble circulation of the blood in the larger hybernating animals, as bears, hedgehogs, badgers, and a waste of their substance, indicating the actions of the secreting vessels. In many insects and reptiles, the torpidity is so great, and the interruption of the vital functions so complete, as almost exactly to resemble death.

NERVOUS INFLUENCE.

The brain is, in all probability, the seat of thought and consciousness, and, through the instrumentality of the nerves, of motion and sensation. In what manner the brain acts, however, or nervous sensation is conveyed, has as yet, and must always, it is presumed, remain an impenetrable mystery. As the nervous branches have a common origin in the brain, or the spinal marrow, as they extend to every part of the body, and as the branches of even remote parts often join and intermix with each other in various ways, that sympathy of one portion of the frame with another, and those curious flittings and alternations of pains, which so frequently occur in disease, may be readily explained and accounted for. Thus the great sympathetic nerve, which arises from the brain, descends into the chest and abdomen, and gives off branches to the lungs, stomach, heart, and diaphragm. When any one of these organs, then, is diseased, it is not to be wondered at that the others should sympathise with them, or that severe headaches should arise from disorder of the stomach. The brain and nerves, too, being parts of the animal system, it is not surprising that affections of the mind, and excitement of the passions, should have such an influence on the health and general economy of the body, and, on the other hand, that disease of the body should reciprocally affect the mind. Man surpasses all other animals in the height and proportions of the forehead, and in the mass of brain in the upper part of the skull. In the human head the lower parts of the face bear a smaller proportion to the forehead than in the brutes. The face is placed in nearly a perpendicular line with the forehead, instead of projecting outwards into a snout, as in the lower animals. The brute face is merely suited for the purpose of animal wants, and for defence; the jaws are long and narrow, supplied with thick, strong muscles, and short teeth; there is not the elevated nose which in man forms a distinguishing feature—the arched eyebrows—the exquisitely formed lips, and the rounded chin; above all, there is not that play of varied expression, that air of intelligence, and that indescribable emanation of a rational mind, that ray of divinity, at the appearance of which the most wild and ferocious of the brute creation are awed and subdued. But, besides, the Creator seems to have affixed characteristic marks to the passions of the mind, that in social life man might not easily impose on his fellow man; for the various muscles of the face, more especially those employed in the voice and eyes, express the several passions of the mind so faithfully, that they may be even represented in painting. This is said to be the natural expression, and would appear to be understood by animals, as well as practised by them; for a dog, on looking to the countenance of his master, easily recognises the mute expressions either of commendation or dissatisfaction. From the action of these muscles being so often repeated, physiognomy arises; so that the constant expression of the face retains something of the action of the prevailing muscles; and thus some traces of frequent anger often remain in the countenance after the passion itself is gone off. With the power of speech and reason, man has also the means of expressing his feelings and passions by laughter and weeping, which is almost unknown to the lower animals. Weeping proceeds from a deep emotion of the mind, and seems an effort of nature to relieve the system of grief. It begins with a deep inspiration of the lungs, after which follow short alternate inspirations and expirations, and it is finished with a deep long-drawn expiration, which is immediately followed by an inspiration. Hence it has nearly the same good and bad effects, and, when moderate, it relieves the distress arising from grief. Laughter has its rise from some ludicrous ideas impressed upon the mind, and would seem to arise directly from the titillation of the branches of the internal nerves, probably those of the diaphragm; immediately to this succeeds a number of imperfect inspirations and expirations, which seem to be checked by the contraction of the glottis in the throat or larynx. Laughter in a moderate degree may be conducive to health, as it gives a concussion to, and ultimately promotes, the circulation; carried to excess, however, it may prove dangerous, from accumulating too much blood in the lungs. Sneezing consists of one deep inspiration, succeeded by a powerful single expiration, and seems to consist of a convulsive effort of the muscles of breathing to throw off some cause of irritation in the sensitive membrane of the nostrils. The common hiccup is a spasmodic action of the muscles of the stomach, most probably similar to sneezing, and caused by something irritating the stomach itself. Some of the causes by which the felicity of our minds is either increased or diminished, proceed entirely from the bodily sensations. Thus pain is caused by disagreeable sensations, which seem to be produced by every sensation in a nerve that is too strong; and pleasure, by those in which the nerve is irritated beyond what is usual, but in a gentle and moderate degree. Itching is akin to pleasure, and in both the flow of blood is increased into the part in which either pleasure or titillation is perceived; but when farther increased, it degenerates in[illegible] pain, or excessive sensations in the nerves. Anxiety arises from the blood being retarded in its passage through the lungs. Anger violently excites the motion of the spirits, increases the motion of the heart, the frequency of the pulse, and the strength of the muscles; forces the blood into the extreme vessels; and even bursts the smaller vessels themselves: thus passion also increases the secretion of bile. Grief weakens the strength of the nerves and action of the heart, retards the pulse, destroys the appetite, and produces paleness, looseness of the bowels, indigestion, and those slow or lingering diseases that take their rise from an interruption of the secreting glands, and a disease of their structure. Fear diminishes the force of the heart, weakens the muscular motions, relaxes the whole system, and, if long continued, causes a general sinking of the body. Excessive terror increases for the moment the muscular strength, even to convulsions; excites the pulse, interrupts the course of the blood, and in not a few instances has produced sudden death. Love, hope, and joy, promote all the salutary actions of the body, gently quicken the pulse, promote circulation, increase the appetite, and aid the cure of diseases. Excessive and sudden transports of joy, however, often prove fatal, by increasing the motion of the blood, and exciting a fit of apoplexy. Shame, in a peculiar manner, retains the blood in the face, as if the veins were obstructed; when felt in an extreme degree, it has also been known to prove the cause of sudden death. The higher manifestations of the mind are imagination, memory, judgment, &c. The investigation of these does not belong to the present subject, farther than they appear to be connected and influenced by the organization and successive developement of the body.

Imagination consists in that power which the mind has of calling up impressions of scenes and circumstances which are not immediately present to the external senses. This definition is confirmed by the example of the great strength of fancy in certain persons, and in those who are delirious, and in every person, in the case of dreams, in which scenes arise in the mind not at all less vivid than those which originally impressed it by the actual perception of the senses. Attention, quiet, and the absence of all external objects, serve to make such impressions of the mind even more forcible than realities; for the will is much more powerfully determined in those who dream than in those who are awake, and some voluntary muscles perform during sleep functions which, while awake, they never could accomplish, even when the nerves of such muscles were most strongly affected by the real object. It thus appears plain how a very vivid internal impression in delirium may so impose upon the mind as to be mistaken for the perception of a real external object. Memory is a subordinate faculty of the mind to that of imagination; we have the memory of past scenes, past events, words, colours, &c. The imagination is early developed in children. In the first periods of infancy we have scarcely memory; it grows and is strengthened with the accumulation of incidents and scenes that pass before us; in childhood it is quick and retentive. In old age, again, the power of retaining the memory of recent events fails, while the circumstances of long past years are pertinaciously retained. Imagination is most active in the first period of life, from childhood to maturity. Judgment then assumes its sway, and the brilliancy and activity of the fancy somewhat subsides.

INFANCY.

At the moment of birth, the infant begins to exercise an independent existence, whereas, before, it formed a part, and was nourished by the vessels, of its parent. A general similarity takes place in the embryo growth of most animals, and the familiar instance of the chick in the egg may be taken as an example. The egg is composed of a centre part, or yolk, and of the albumen, or white part surrounding it. In this white part, a small darker speck may be seen floating, from whence the first rudiments of the chick are derived. In a few days after the hen has sat on the egg to impart to it the necessary heat, a small whitish spot will be observed, which is the first rudiments of a brain; in a few days more, vessels will be seen spreading out from a central heart, and forming a net-work all around; gradually an appearance of a head is seen, with indications of brain and spinal marrow; the eye-balls next are formed, then the several parts of the viscera, the projections of the wings and legs, and, lastly, the skin and rudiments of the future feathers. During these periods of incubation, the chick has been nourished by the yolk of the egg, which has gradually been absorbed by its vessels for this purpose. At last, when its growth is perfected, and the whole contents of the egg converted into the materials of its body, the little animal begins to pick a hole in the shell, and, by repeated efforts, bursts from its shelly prison, and assumes an independent life. The infancy of man is of much longer duration, and of a much more helpless nature, than the same state in any other animals. A child cannot walk till it is at least twelve months old; and even for a considerable time after that period, it has to be fed and tended with the utmost care: whereas, after a very short time, the young of most animals are able to provide for themselves; in a great many, a few minutes after birth, they are able to walk about, to search for and distinguish the teat of their mother, and to pick up the food that is suitable for them; and having remained under their maternal protection for a short space, they leave their parents, and never know or distinguish them more. It is very different with the infant: during a long and helpless period of childhood, it is tended by a fond mother, who anticipates all its wants; while it, on the other hand, watches her smiles, and imitates her most minute actions; and thus a reciprocal bond of union is established, by which not only every species of knowledge and experience is acquired for the conduct of after life, but those moral ties and affections established which constitute the great boast and solace of human society. Man proceeds from infancy to maturity by a slower and more gradual expanse of the bodily structure than any other animals, and this may be one reason of his superior organization, his greater fitness for supporting labour and fatigue, and the longer period to which his life is prolonged. From infancy upwards, the mental powers also gradually expand. This is also different from animals; for in them the faculty of instinct at once is perfected, and never afterwards increases or undergoes any change. In childhood, the mental faculties are constantly active, and on the alert to catch new information, inquisitive to know every thing, and imitate every gesture. The facility with which children acquire the knowledge of words, and in a few months master a language, is very astonishing, when we reflect for a moment how much time and pains it takes a grown-up person to become a proficient in any unknown language: and our astonishment will be heightened when we consider, that, in the case of children, they have not only to acquire the words and their proper applications, but even to master the articulation of sounds, with all their infinite combinations. The age of puberty, or that period when boyhood terminates and manhood commences, varies somewhat in different climates, according to their high or low temperature: the mean period may be reckoned about fourteen years; and, about the age of twenty, the growth of the body generally terminates. About the age of thirty, man may be said to be in his full vigour, with his mental and bodily powers completely developed. Females arrive earlier at a state of maturity than males: in warm climates females are full grown as early as their ninth or tenth year; in more temperate regions, about their fifteenth or eighteenth year. The proportion of male children born to that of females, is as 21 to 20: there is thus a small superabundance of males; but, from various causes, it so happens that there is generally rather a superabundance of females actually existing in society. Among these causes may be mentioned, the greater hardships and labours to which men are exposed, the effects of war, and, on the whole, the longer life enjoyed by females. This regular proportion of male and female births throughout mankind in all ages, and in all parts of the world, shows the admirable design and precision of an unerring nature.

THE SEXES.

In almost all animals the sexes are distinguished by a difference of form and texture of their bodies; and in many a superior gloss of colour in the hair or fur, or a superior brilliancy of the plumage, very generally characterises the male of the species. In most animals, too, the males are of superior size, and endowed with greater muscular strength. In the human species man is marked by a larger and more muscular body than the female; his chest is square and capacious, and particularly at the shoulders, from whence it tapers gradually downwards; his bones are large, and his joints firm and sinewy; his muscles are round, tense, and conspicuously marked; his limbs thick and fleshy, and his arms powerful; his skin is firm and tense, and his hair strong, crisp, and often curly. The female figure, again, is smaller, less powerful, and, in every respect, more delicately formed; the bones are less projecting, the muscles softer, less conspicuous, and more smoothly blended one into the other; the shoulders are narrow and rounded; the greatest breadth of the body being at the pelvis, from whence it gradually tapers upwards; the skin is soft and delicate; the hair smooth, and of a silken appearance. The mental qualities and dispositions differ somewhat also. Man is commanding, resolute, daring, adventurous, addicted to deep and abstract thought, as well as to high and imaginative speculations. Woman is gentle, submissive, timid; with a mind, perhaps, little inferior in compass to man, she is more commonly distinguished for acute penetration, nice and delicate discrimination, refined and chastened taste, and elegant and playful fancy. It was the opinion of Plato, that, with regard to the mind, there is no natural difference between the sexes, but in point of strength. "When the entire sexes are compared together," says he, "the female is doubtless the inferior; but in individuals, the woman has often the advantage of the man." With warm and tender attachments, pure morals and high religious feelings, she is admirably calculated for the sacred charge of watching over and training up the young, and of instilling into their tender and susceptible minds the beautiful lessons of early wisdom—of faith, truth, and charity. All nations, as they have advanced in civilization, have uniformly increased in that respect and refined attention which is due to the softer sex; and one of the most powerful minds and of the most splendid endowments has been the foremost to appreciate those superior qualities which are to be found in a gentle and unsophisticated female. The late Professor Dugald Stewart thus introduces a quotation from a well-known traveller, which affords a just and beautiful estimate of the tender disposition of woman:—"From the greater delicacy of their frame, and from the numerous ailments connected with their temperament, combined with their constant familiarity with distresses which are not their own, the sympathy of women with the sufferings of others is much more lively, and their promptitude to administer relief, wherever it is possible, is much more eager than in the generality of men. To the truth of this remark every day's experience bears witness; and, from the testimony of travellers, it appears that the observation extends to women in all the different stages of society. The strong testimony of Ledyard, the celebrated pedestrian traveller, on this point, may be regarded as perfectly decisive. "To a woman, whether civilized or savage, I never addressed myself in the language of decency or friendship, without receiving a decent and friendly answer; with men it has been often otherwise. In wandering over the barren plains of Denmark, through Sweden, Lapland, Finland, Russia, and the wide-spread regions of the Tartar, if hungry, dry, cold, wet, or sick, the women have ever been friendly to me, and uniformly so; and, to add to this virtue, these actions have been performed in so free and kind a manner, that, if I was thirsty, I drank the sweetest draught; and, if hungry, I ate the coarse meal with a double relish."

TEMPERAMENT.

There are certain conditions of the bodily frame which evidently constitute varieties of the human constitution, and which have been called temperaments. Thus the sanguineous temperament is characterised by a florid fair complexion, rather tall stature, hair of a flaxen or chestnut colour, a certain plumpness of the form, blue eyes, transparent skin. The accompanying mental qualities are, a quick perception, ready and tenacious memory, lively imagination, a mind disposed to hope, fond of anticipations, amorous, delighting in pleasures, of an active habit, generally healthy, but if attacked with disease, this will be of an inflammatory nature. This temperament descends into the muscular or athletic when the animal powers are in perfection, but the mental less developed; thus the head is small, and the forehead low, but the muscles are well marked and swelling, the shoulders broad and full, the chest large, and the feet and hands small and well proportioned. The bilious temperament is indicated by the hair being black, or dark coloured, the skin brown or yellowish, the muscles firm, the outline of the features well formed and expressive. The mind is also bold in the conception of designs, firm and persevering, courageous, active, inclined to sudden bursts of passion, and the powers of intellect will be found to be generally very early developed. When the body is diseased, and especially when there is any enlargement of the liver, this temperament passes into the melancholic, when there is a great sluggishness of action and of thought, a melancholy foreboding mind, most generally plunged into torpid despair, or occasionally excited by fits and bursts of mirth and transient cheerfulness. In the nervous temperament, the flesh is soft and flabby, the skin fair, the hair flaxen or sandy, the pulse weak and low; the muscular part of the body bearing a smaller proportion to the brain and nerves than in the other varieties of the constitution. The mental faculties are delicate and sensitive, but variable and irresolute. Perhaps the *beau ideal* of the human frame cannot be better described than in the words of Hufeland:—"He has a proper and well-proportioned stature, without, however, being too tall. He is rather of the middle size, and somewhat thick-set: his complexion is not too florid; at any rate, too much ruddiness in youth is seldom a sign of longevity; his hair approaches rather to the fair than to the black; his skin is strong, but not rough; his head is not too big; he has large veins at the extremities, and his shoulders are rather round than flat; his neck is not too long, his belly does not project, and his hands are large, but not too deeply cleft; his foot is rather thick than long, and his legs are firm and round; he has, also, a broad arched chest, a strong voice, and the faculty of retaining his breath for a long time without difficulty. In general, there is a complete harmony in all his parts; his senses are good, but not too delicate; his pulse is slow and regular; his stomach is excellent, his appetite good, and digestion easy. The joys of the table are to him of importance; they tune his mind to serenity, and his soul partakes in the pleasure which they communicate; he does not eat merely for the sake of eating, but each meal is an hour of daily festivity; a kind of delight, attended with this advantage in regard to others, that it does not make him poorer, but richer: he eats slowly, and has not too much thirst. Too great thirst is always a sign of rapid self-consumption. In general, he is serene, loquacious, active; susceptible of joy, love, and hope; but insensible to the impressions of anger, hatred, and avarice; his passions never become too violent or destructive. If he ever gives way to anger, he experiences rather a useful glow of warmth, an artificial and gentle fever, without an overflowing of the gall. He is fond also of employment, particularly calm meditation and agreeable speculations; is an optimist, a friend to active and domestic felicity; has no thirst after honours or riches; and banishes all thoughts of to-morrow.

MAN ADAPTED TO LIVE IN ALL CLIMATES.

Man has this superiority over all other animals, that he can inhabit every different region of the globe, however extreme the degree of temperature. He is found under the scorching sun and amid the arid plains of Africa, as well as in the frost-bound regions of Spitzbergen; and he is found to live and thrive under these different extremes, not only after a gradual naturalization of ages, but can even move from one country to another, and undergo a vicissitude of climate with comparative impunity. Thus we see, even from our own country, emigrants going forth, and naturalizing themselves amid the cold regions of the north, onward to the very verge of the equator. The Esquimaux and the Canadian savage will prosecute their usual employments of the chase in a temperature where mercury freezes into a solid mass, and where even brandy congeals to ice in apartments containing fires; while the African negro, again, feels quite at his ease in a burning climate, where the thermometer in the shade ranges from 90° to 100°, and upwards. Man has an equal facility in adapting himself to the pressure of the atmosphere attendant on low or elevated situations. In Mexico, he is found living in elevated regions, from 6000 to 9000 feet above the level of the sea; and the hamlet of Antisana, in Quito, is 15,500 feet above the level of the ocean. On the contrary, we find almost all animals only adapted to live in the regions in which they are naturally found; and if they are removed from such localities, they seldom enjoy the natural period of their life. Even the dog and the horse, the domesticated companions of man, degenerate and change their natures under extreme varieties of temperature; and the monkey tribe, which, in the structure of their bodies and in the substances on which they feed, approach the nearest to man, become sickly and diseased, and never propagate their species, when removed into any of the colder regions of the globe. In order to enable man thus to subsist in regions having such a diversity of natural productions, he is endowed with the power of feeding on and digesting every possible variety of food—he is, as compared to other animals, in respect to diet, omnivorous. We thus find the Greenlanders and inhabitants of frozen regions living almost exclusively on the fat and flesh of land and sea animals, the only species of food which the barren and ungenial nature of the climate affords, and a species of food, which, from its stimulating and nourishing nature, is the very best for enabling them to live under such an extreme depression of temperature. The inhabitants of hot countries, again, will be found living on rice, fruits, and other vegetable substances, which the warm and genial soil produces in abundance, and which, from their nature, are less heating and stimulating than an animal diet. In the intermediate and temperate regions, a mixed diet of animal and vegetable food is preferred. Much discussion has arisen whether man be more a flesh-feeding or herb-eating animal; experience demonstrates that he is equally adapted to become both—that he will live on an almost purely animal diet, as well as on one purely vegetable; although, were we strictly to compare the form of his jaws and teeth, and the general structure of his intestines with those animals that live on nuts and other fruits, and farinaceous or mealy substances, as, for instance, the monkeys, the near approach of these to the human structure would indicate to us that at all events a farinaceous diet is the most suitable to his natural organization. We thus find among all civilized nations that bread, and the grains and mealy roots, in some shape or other, have always a preponderance in every meal. But the art of cooking, which man resorts to even in the first dawnings of civilization, enables him to change the nature of his various food, and to render it more suitable both for digestion and the purposes of nourishment, and thus gives him a wonderful superiority over all the rest of the animated world. Indeed, it is by this improved mode of preparing his food, perhaps, as much as by original strength and perfection of frame, joined to the other comforts of civilization, that he is enabled to brave the vicissitudes of climate, and to prolong his life to a longer period than the great majority of other animals.

Man has been formed with a naked skin, with the evident intention that he should clothe himself by his own labour and ingenuity. Almost all the larger and more perfect animals have a covering of hair, of feathers, or of down, which is at stated periods renewed, and in some animals in greater length and abundance at particular seasons, to suit the variations of temperature. But man can always adapt his clothing to the climate he inhabits, or to the varying alterations of the seasons; and he can at all times, by his own industry, vary or renew his suits. Man, too, builds for himself a comfortable habitation, to protect him from the inclemency of the weather; and is not contented with a burrow under ground, or the casual shelter of the woods and coppices, as is the case with the animals of the forests. It is true the architecture of bees, and some other animals, is curious, ingeniously combined, and admirably suited to their necessities; but in comparative taste, splendour, or even convenience, how far are all these surpassed by the houses, and temples, and cities of mankind! Though man is naturally defenceless and unarmed, how soon does his ingenuity enable him to obtain a mastery over the beasts of the field and forest, and furnish him with weapons of defence against all his enemies! How soon does his ingenuity enable him to improve and cultivate the soil—to drain marshes, cut down woods, level mountains—to select and cultivate the best species of grain, and the most wholesome and nourishing vegetables, for food—to invent tools and engines, by which he acquires a command over the sea and land, by which he erects bridges, constructs machinery, and launches the towering vessel upon the wide ocean! And, lastly, with what skill he constructs instruments of art and of science, by which he can examine and investigate the most minute objects of nature, as well as bring within his sphere of observation other planets and other suns in the vast dome of the universe!

VARIETIES OF MANKIND.

From comparing the anatomical structure of all races of men throughout the world—from their general similarity in every material point—there can be no doubt but they are all of one species, and consequently must have all sprung from one original pair. The diversity of features, of stature, and of colour, only constitute varieties of this great family, and take their rise from particular circumstances, as climate, food, habits, and the degree of civilization to which they may have arrived. That there is an intimate relation between colour and the climate, is shown by this remarkable fact, that the northern regions exhibit a fair skin, and that, as we gradually proceed southward, the tint deepens. Thus, the Norwegians and Danes are fairer than the English, the English than the French, the French than the Spaniards and Portuguese, and these than the Moors, while the negroes in the burning regions of Africa are darkest of all. Even in this country, exposure to the sun darkens the complexion. Europeans who have been in warm climates come home with a skin permanently darkened in a slight degree, and the yellowish hue which prevails among the Americans of the present day shows the gradual effect of climate in the course of a few centuries. Captains Lewis and Clark were so much browned during their expedition to the Missouri, as to be often taken by the natives for Indians belonging to hostile tribes, and it was only on showing the whiteness of their skin in such parts as were covered that their suspicions were removed. In Lord Amherst's expedition to China, it was observed, that persons who were in the habit of working in the heat of the sun, with their bodies uncovered from their waist upwards, became of a dark copper colour; but when they stripped, either for the purpose of bathing, or of going into the water, in order to have a better view of the expedition, the comparative whiteness of the skin which was usually covered gave them the appearance at a distance of wearing light coloured pantaloons. It is true this effect of the sun is only temporary; but if we are to consider, that races of men, in the first ages of the world, lived the life of rude and unclothed savages for thousands of years, exposed to the full influence of a tropical sun, the gradual effect of altering the colour of the rete mucosum, or under net-work of the skin, is not at all improbable. In warm regions alone, we find this black colour prevail; and the more savage and rude the people, the deeper, climate being the same, is the tint. The final use of this tint is explained under the head of "The Skin." Considerable variety of feature and form of the head prevails among different nations, and five striking varieties have been pointed out. 1st, The Caucasian, or European variety, is distinguished by all the shades which characterise the white inhabitants of the globe. The head is large, especially the upper and fore part of it; the face is oval and straight; the outline of the features distinct and regularly marked, and falling in a nearly perpendicular line below the forehead. All Europeans, except the Laplanders, are included under this division; as are the inhabitants of Western Asia, as the Turks, Georgians, Circassians, Arabs, Persians, and Hindoos of high caste; comprehending all those nations that have been distinguished for civilisation in either ancient or modern times.—The second division is the Mongolian, or yellow race. This variety is distinguished by black eyes; black, straight, strong, and thin hair; little beard; head of a square form, with small and low forehead; broad and flattened face, with the features running together; nose small and flat; rounded and projecting cheeks; eyes placed obliquely; narrow half-shut eyelids; large round thick lips; and skin of a yellowish hue, somewhat like dried lemon-peel. This division includes the Moguls, a numerous tribe, living in the centre of Northern Asia; the Calmucks; the Chinese and Japanese; the inhabitants of Thibet, Cochin-China, Ava, and Siam; together with the Laplanders and Esquimaux inhabiting the northern regions of Europe and America.—In the third, or Ethiopian variety, the skin and eyes are of a jet black; the hair black and woolly; the skull narrowed at the sides and lengthened out in front; the forehead low, narrow, and slanting; the cheek-bones projecting; the jaws narrow and jutting outwards; the upper front teeth oblique; the chin receding; the eyes prominent; the nose broad, thick, and flattened on the face; the lips, and particularly the upper one, thick; the projecting jaw and the retreating forehead distinguish the negro's head from the two foregoing. All the inhabitants of Africa, not comprehended in the Caucasian variety, are comprised in this.—The American variety is characterised by a dark skin, of a more or less red tint; black, straight, and long hair; small beard; countenance and skull very similar to that of the Mongolian tribes; forehead low; eyes deep; face broad, particularly across the cheeks, which are prominent and rounded; mouth large, and lips rather thick. All the native tribes of America, except the Esquimaux, are comprehended in this variety; but the skin in many of them is much more of a brown than a copper colour.—The fifth division is the Malay variety, and it has in it less of a peculiar character than any of the other divisions: the colour is brown, from a light tawny to nearly a black; the hair is black, abundant, and more or less curled; the head rather narrow; bones of the face large and prominent, more full and broad towards the apex; the mouth large. The inhabitants of Malacca, Sumatra, Java, and of most of the adjacent Asiatic islands—of the Molucca, Philippine, and neighbouring groups—of New Holland, New Guinea, New Zealand, and the numberless South Sea islands, are all of this variety; and it may be remarked, that among the East India islands there is a division resembling the negro in the character of the hair, in colour, and in the general form of the skull and features.

Although there is no foundation whatever for the stories related of giants, yet the inhabitants of a district of South America, the Patagonians, are distinguished for considerable strength of body and a height above that of the average size: this is the case also with the inhabitants of the Carribbee Islands, the Cherokees in America, the South Sea Islanders, and the Caffres of the Cape of Good Hope: but, on the whole, savages are not distinguished either for height or strength of body, a European being a match for them in either of these respects. The Esquimaux are remarkable for diminutive forms, and so are the Calmucks and Monguls. Extraordinary instances of dwarfs have occurred, of the height of only sixteen and forty inches; but these are aberrations of the ordinary occurrences of nature.

OLD AGE.

We have seen that there is, within the animal frame, a system of operations, by which a constant supply of nourishment is afforded to make up for the daily waste and decay, and that every part is constantly undergoing a renewal. To view a man in the full vigour of life, then we might suppose, that, excepting accidents, he was calculated to go on, in the course of existence, for an indefinite period. The principle of life, however, seems to have limits sets to its duration, beyond which, it fails to keep in healthy motion the animal faculties. The apparatus of life is evidently destined but to last for a certain time. Old age creeps on apace, and the vital flame burns fainter and fainter, till at last it sinks in the socket, and is seen no more. The commencement of decay is perceptible even in youth itself. The child at first grows quickly, from the soft and yielding state of all its vessels; but gradually these begin to thicken and get harder—a greater proportion of earthy matter is adding to the bones. The extremities grow out large, while the heart itself does not increase in an equal degree; hence the circulation becomes less and less quick, till the period of full growth. When the growth of the body can proceed no farther, a degree of fatness not unfrequently occurs. This proceeds from the superabundant nourishment produced from the food, which, from the impetus or force of the circulation being more lessened by the greater extension and resistance of the body, accumulates in the cellular textures, and by the sides of the extreme vessels. In every part of the body, the induration produced by approaching age becomes conspicuous; in the bones now wholly brittle, in the skin, in the tendons, in the glands, in the arteries, and in the brain itself, which gets firmer and drier. Moreover, the arteries continue to get denser, narrower, and even shut up in their minute branches. At the same time, the nerves become more and more callous and insensible to the impressions of the senses, and the muscles to irritation; thus, the contractile force of the heart, and the frequency of its pulsations, are diminished, and, of consequence, every force which impels the blood into the ultimate vessels. The quality of humours is diminished in the denser body; the moisture which lubricates the solid parts every where manifestly decreases; nor is the quantity of humours only diminished; they themselves likewise become vitiated. They were mild and bland in children; they are now acrid, salt, and fetid, and loaded with a great quantity of earthy matter. This circumstance, of the superabundance of earthy matter, is evident in the gouty concretions in the joints of old people, in the frequency of stone, and in the arterial tubes, and even the heart itself, being frequently converted into real bone. The rigidity of the whole body, the decrease of the muscular powers, and the diminution of the juices, constitute old age, which sooner or later comes upon all men; sooner if subjected to violent labour, or addicted to pleasure, or fed upon a too scanty or unwholesome diet; but more slowly if they have lived quietly and temperately, or if they have removed from a cold to a moderately warm climate. There are three obvious divisions of human life—a period of youth, including the period before the age of 30; of maturity, from 30 to 50; and of old age, commencing about the period of 50 or 60. David speaks of the age of man being, in his time, only three-score years and ten, or in rare cases four-score years, which may be reckoned the average limit of human existence; nor does it appear that the ancients at all exceeded the moderns in the duration of their lives. Of course we set aside that extraordinary duration of existence which is described in the early part of the Mosaic history, and which was evidently intended as a means of more rapidly peopling the earth. After the period of 50 or 60 years, varying of course in different constitutions, the marks of old age begin to make their appearance. The skin becomes more lean and shrivelled; the hair changes to a grey colour, or baldness occurs; the teeth drop out, and, in consequence of this, the lower parts of the face, about the mouth and jaws, incline inwards; the muscular motions of the body become less free and elastic—this is especially seen in walking, old people generally treading on the whole base of the feet, and hence having a shuffling gait; the blood circulates slowly; the animal heat is diminished; the pulse occasionally intermits, and the whole energies of the animal frame become lessened; the eyesight begins to fail, and dullness gradually comes over all the senses; the memory undergoes a remarkable change, while recent events pass through the mind and make no impression; the occurrences of early life continually suggest themselves, and are minutely called to remembrance. Dr Rush mentions the case of a German woman, residing in America, who had learned the English language after she was 48 years of age, and could speak it fluently, and continued to do so for many years. At the age of 80 she completely forgot every word of the English language, but spoke the tongue of her infancy with fluency. The same author mentions the case of an old man, of 101 years, who declared that he had forgotten every thing he had ever known except his God. Anthony Benezet, another American, made the following remark to a friend who questioned him regarding his memory:—"You can read a good book with pleasure but once; but when I read a good book, I so soon forget the contents of it, that I have the pleasure of reading it over and over, and every time I read it, it is alike new and delightful to me." The digestion of old people is not in general vigorous, although the appetite for food is, as in the case of children, craving, and they are fond of eating frequently. They are also similar to children in the marks which slight contusions or impressions leave on their skins, in their being soon fatigued with excercise, in being as soon refreshed with rest, in their disposition to detail immediately every thing they hear and see, in their general garrulity, and their aptitude to shed tears on slight occasions; lastly, the fear of death is less strong in old age than in early or middle life. Although usually seventy years is the extreme period of human life, yet a small proportion of those born ever reach even this; a few rare instances occur where one hundred years or upwards are attained. The famous Parr lived to the age of 159 years; he married at the age of 120, and, when 130, was able to thrash, and to do every description of farmers' work; he was at last brought from the pure air, and the homely diet of the country, into the family of the Earl of Arundel, in London, where he drank wine, and lived luxuriously. The sudden change of diet and circumstances, however, proved quickly fatal to him. Henry Jenkins, another poor man, lived to the astonishing age of 169 years, and retained his faculties entire. Some time ago, a statement appeared of the ages of the resident pensioners of Greenwich Hospital, which contained at the time 2410 inmates. Of this number, 96 had attained to or passed the age of 86; one only was above 100; 15 were 90 or more; and 80 were eighty or upwards. About 42 of the 96 were of aged families, and in some of this number both parents had been aged. Longevity has in a great number of cases been found to be hereditary. Eighty of the 96 had been married; 79 were in the habit of using tobacco in some form or other, and 48 had drunk freely; 20 were entirely without teeth; 62 had bad, and 14 good teeth. But the oldest man in the house, who was 102, had four new front teeth within the five preceding years. The sight was impaired in about one half, and hearing only in about a fifth part of the number. Old people are not generally inclined for much exercise, nor is it suited to their stiff joints and impaired vigour; for the same reason they cannot endure much cold. Cheerful company, especially the company of the young, is peculiarly grateful to old people. Innocent amusements and recreations are also of great consequence, and the mind should be exercised in some useful or amusing pursuit. Cities, or at all events constant and agreeable society, are favourable to the condition of old age. In lonely secluded country places, the mind sinks prematurely into a total gloom and blank, for want of sufficient stimulus and variety to keep up the vigour of thought and play of ideas. Few deaths occur from what is commonly called old age, or a gradual and simultaneous decay of all the functions. It may be said to happen when the powers gradually decay, first of the voluntary muscles, then of the vital muscles, and lastly, of the heart itself, so that, in an advanced age, life ceases through mere weakness rather than through the oppression of any disease. The heart becomes unable to propel the blood to the extreme parts of the body; the pulse and heat desert the feet and hands, yet the blood continues to be sent from the heart into those arteries nearest to it, and to be carried back from them. Most commonly, however, some one part gives way, and disease gradually coming on, cuts off the lingering flame of existence. Thus the body, after having grown up to maturity, and flourished in its prime, sinks to the earth, and moulders into the dust of which its several parts are composed.

CONCLUSION.

The admirable structure of the body of the human being, its superiority in every respect to that of the lower animals, has frequently afforded a proof of design in the all-wise Creator, and is one of the most striking instances of the impossibility of our formation being the result of blind chance. Paley, after going over a great number of examples of this kind of design in a Creator, goes on to state that, in all "instances wherein the mind feels itself in danger of being confounded by variety, it is sure to rest upon a few strong points, or perhaps upon a single instance. Amongst a multitude of proofs, it is *one* that does the business. If we observe in any argument (he continues) that hardly two minds fix upon the same instance, the diversity of choice shows the strength of the argument, because it shows the number and competition of the examples. There is no subject in which the tendency to dwell upon select or single topics is so usual, because there is no subject, of which, in its full extent, the latitude is so great, as that of natural history applied to the proof of an intelligent Creator. For my part, I take my stand in human anatomy; and the examples of mechanism I should be apt to draw out from the copious catalogue which it supplies, are, the pivot upon which the head turns, the ligament within the socket of the hip-joint, the pulley or trochlear muscles of the eye, the epiglottis, the bandages which tie down the tendons of the wrist and instep, the slit or perforated muscles at the hands and feet, the knitting of the intestines to the mesentery, the course of the chyle into the blood, and the constitution of the sexes as extended throughout the whole of the animal creation. To these instances, the reader's memory will go back, as they are severally set forth in their places; there is not one of the number which I do not think decisive; not one which is not strictly mechanical; *nor* have I read or heard of any solution of these appearances, which, in the smallest degree, shakes the conclusion that we build upon them.

The works of nature want only to be contemplated. When contemplated, they have every thing in them which can astonish by their greatness: for, of the vast scale of operation through which our discoveries carry us, at one end we see an intelligent Power arranging planetary systems, fixing, for instance, the trajectory of *Saturn*, or constructing a ring of two hundred thousand miles diameter, to surround his body, and be suspended like a magnificent arch over the heads of his inhabitants; and, at the other, bending a hooked tooth, concerting and providing an appropriate mechanism for the clasping and reclasping of the filaments of the feather of the humming-bird. We have proof, not only of both these works proceeding from an intelligent agent, but of their proceeding from the same agent: for, in the first place, we can trace an identity of plan, a connection of system, from Saturn to our own globe; and when arrived upon our globe, we can, in the second place, pursue the connection through all the organised, especially the animated, bodies which it supports. We can observe marks of a common relation, as well to one another as to the elements of which their habitation is composed. Therefore one mind hath planned, or at least hath prescribed, a general plan for all these productions. One Being has been concerned in all.

Under this stupendous Being we live. Our happiness, our existence, is in his hands. All we expect must come from him. Nor ought we to feel our situation insecure. In every nature, and in every portion of nature, which we can descry, we find attention bestowed upon even the minutest parts."

THE STORY OF THE FRENCH REVOLUTION.

INTRODUCTION.

It is humbly conceived that a clear and impartial account of the French revolution ought to be in the hands of every individual in this country; for there is no man, be his station and his opinions what they may, who is not liable to receive a lesson from its events. The possessor of power is taught, by the French revolution, to use what he possesses in a rational and humane spirit. The advocate for ancient institutions is taught to beware lest bigotry be mingled with his views, and reform be postponed so long that revolution becomes the only alternative. The subject of power is taught, on the other hand, that, in seeking to avoid certain evils, he is not perfectly sure to avoid others, and that it is safer for himself, as well as for those above him, that he prosecutes the business of political improvement in a spirit of moderation, and with a regard not merely to his own particular desires, but to the general tendencies and capabilities of the nation of which he forms a part.

CAUSES OF THE REVOLUTION.

France, it is hardly necessary to remind the reader, was, previous to 1789, one of many states in Europe which owned the absolute sway of one sovereign. The king, it is true, was required, by the idea of a supposed constitution, to take the advice of the people (as represented by what was called the Tiers Etat, or Third Estate) before imposing new taxes; but as he never did so, or had not done so for upwards of a century, this part of the system is hardly worth mentioning. In addition to the evil of obeying a despotic prince, whose measures were sometimes dictated by favourites of the basest kind, the clergy, a body of about 130,000 persons, and the noblesse, or nobility, who were 200,000 in number, possessed various invidious privileges and powers, being, for one thing, completely exempt from all taxation, so that the public burdens fell exclusively upon the industrious classes of the community. The people were also heavily oppressed by the farmers-general, a set of people who paid the court a certain sum for being allowed to collect the revenues, and who had frequently recourse to the most unjustifiable means of raising the money. The peasants were also oppressed in various ways: they were liable to be called out to work upon the roads for a certain time every year, at any distance from their homes, and at any season their taskmasters chose; while they paid, in most cases, a perpetual tribute for their freedom to their feudal lords. Nor were the grounds of inferiors ever secure from the trespasses of the nobles, who pursued at pleasure their sports through them, trampling down vineyards or crops of corn or hay without remorse, and without any species of redress on the part of the injured. But perhaps the most odious part of the whole system of things was the exclusive nature of the order called the Noblesse: this body was already considered as completely formed; no man, be his worth or talent what they might, could ever rise to take his place in it; nor was any man ever permitted to receive so much as a commission in the army, unless he could produce a certificate of the four last generations of his family having belonged to this sacred order. Who, on looking at this catalogue of erroneous regulations, though comprising but a part of the grievances complained of at the beginning of the revolution, can wonder that the enlightened and patriotic of the nation concluded a reform to be necessary to the well-being of their country?—or that the superficial and ignorant, keenly feeling their wrongs, should, without possessing sense or forethought to calculate on consequences, be led into the most cruel excesses, when told, by designing men, that it was necessary in order to the attainment of their political liberty?

The writings of several men of genius, and particularly of Voltaire, had also tended in no small degree to loosen the restraints of religion, and to prepare the minds of the people for throwing off its yoke. These writers attacked, with all their powers of ridicule, the well-known peculiarities of the Roman Catholic doctrines and worship, without paying respect to the Christian religion, which was the foundation of both, and thus overthrew the whole of the sacred fabric. Besides the causes already enumerated for fostering a spirit of revolution, there were still others, the most conspicuous of which was the American war, which had impoverished the treasury, and, as a colleague and patron of revolutionists, placed the despotic monarch in the light of an encourager of insurrection, and of demands for popular rights. This was an enigma; and the endeavours to solve it had no good effect on the nation at large: neither had the consideration of the American principles of republicanism, which, on the return of the French officers after the war, were discussed by them with great enthusiasm. To that country the youth of France had gone as to a theatre of glory, and they returned from it, after a successful struggle with the British armies, imbued with new ideas of government, and an insatiable thirst for liberty.

FIRST MOVEMENTS—MEETING OF THE STATES-GENERAL.

With all the other causes for discontent among the people, the elements of nature seemed to combine their influence, for, in the month of June of the preceding year, the greater part of France was assailed by one of the most terrific storms on record. Thunder and lightning, wind and hail, appeared to contend for the mastery; but the hail, which fell in pieces of incredible size, was the grand agent of devastation, and rendered the destruction of all the fruits of the earth nearly complete. This caused a famine to prevail, and gave but too good an excuse for the clamours with which it was accompanied. Nor was it possible, from the almost bankrupt state of the finances, and from its being unfortunately a time of scarcity throughout all Europe, by any devisable means to find bread even for the immense population of Paris. De Brienne, archbishop of Thoulouse, who was at this epoch minister of finance, after trying in vain to raise the necessary supplies, and meeting with the most determined opposition from all quarters, abandoned his situation, and recommended his majesty to convoke the states-general—a measure which had not been adopted since the year 1614—and to recall M. Necker, in whom, as an able and economic minister of finance, the people had always expressed the greatest confidence. This minister, when returned to office, immediately set about organising the convocation of the three estates, and allowed the tiers etat a double representation, which prepared for the superior orders an inevitable extinction. The states-general met on the 4th of May (1789), at Versailles, in conformity with the wish of the king and Necker, and assembled in a superb hall of the palace. The meeting of the three estates placed his majesty in a new situation. He had consented to this measure from knowing it to be the wish of his people; yet he was entirely deprived of the credit arising from it, which was given to Necker, the idol of the people. He was also much grieved and annoyed by the reports of a deficit in the finances, which was represented as most disastrous in its consequences, and which was unceremoniously attributed by his subjects to the enormous expenditure of the court, while his evil government was also accused of being the primary cause of the famine. Add to these causes for uneasiness, that the tiers etat commenced the sittings with some tumultuous attempts to acquire an ascendancy over the other two estates, and we shall see that all together combined to distress and embarrass him. It is true his authority was as yet undiminished by any act of the assembly, yet every exhibition of it was cavilled at, and attended with difficulty. Whatever he did with a view to conciliate the people, obtained him but an evanescent approbation, which speedily passed away as a transient gleam of sunshine, leaving a gloomy day still more dreary.

The violent proceedings of the tiers etat were encouraged by their Parisian brethren, who were prompted to this by the Duke of Orleans and his faction. Philip Duke of Orleans was presumptive heir to the crown, failing the king's children and brothers; and having formed the dishonourable purpose of supplanting Louis the Sixteenth in the affections of his people, and it is also suspected in the possession of his throne, he affected to treat the meanest of his countrymen as his equals, while he expended a part of his immense revenues in paying for the writing and distribution of multitudes of inflammatory pamphlets, and in an ostentatious display of humanity in the distribution of money, bread, and soup, to the populace. Respecting the infamous character of this man, all who have written a just account of the revolution are agreed. One of his aims was to be appointed by the people lieutenant-general of the kingdom, but in this he never succeeded, from his naturally cowardly disposition, and from being utterly destitute of that energy necessary in a leader at so momentous a crisis. The declarations of the people were at first loud in his favour; and had he possessed the courage, the military talents, and address of Cromwell, he might, like him, have overcome all parties, and succeeded to the power of his murdered sovereign; but when exposed to personal danger, his mean qualities became so conspicuous, that they ruined him in the estimation of his partisans, by convincing them that he was a man unfit either to lead or to rule. Yet as he was possessed of consummate art, he continued for a long time to influence the people by means of his money, and his congenial though sanguinary councils.

ASCENDANCY OF THE TIERS ETAT.

On the second day of the meeting of the states-general, the three orders convened separately. The deputies of the tiers etat amounted to 600, and the nobles and clergy to 300 each; and the question of the greatest consequence which first necessarily underwent investigation, was the commissions of the different members, and their validity. The tiers etat was anxious that the three estates should meet in one common hall, to verify their commissions, and debate immediately on the scarcity of provisions and the state of the finances. To this proposition 114 members of the clergy consented, but the nobles insisted on the verification of their powers in a separate assembly. The tiers etat, well aware, however, of the financial difficulties of the nation, which must soon bring matters to a crisis, paid no attention to this proceeding, and suffered five weeks to elapse without taking any farther steps. During this period of inaction, all was done by the ministry that could be thought of to conciliate this difference, and bring the three estates to act in concert; but nothing could persuade the refractory commons to depart from their resolution, and the disappointed nation, who had expected every thing from this convocation of the states-general, were seized with no small dismay at this unpropitious commencement of its proceedings. The people universally took the part of the commons, while the nobles became every day more unpopular, and were insulted whenever they appeared. All who took their part shared in the opprobrium; and they were even opposed by a number of their own body, with Orleans at their head, and deserted by a part of the clergy. Still the majority of them stood their ground, well knowing, that, if they consented to the terms of the commons, they would be outvoted on every question, and their consequence and power annihilated. The leaders of the tiers etat, who were bold and skilful men, now suddenly shook off their apparent sloth, and, availing themselves of the state of public opinion, seized with a daring hand the reins of government; and after again issuing a summons for the clergy and nobles to join them without effect, they solemnly voted themselves the legislators of their country, with the title of the "National Assembly of France." By this decree, the revolution was constituted. All the acts of this assembly were decidedly expressive of sovereign power, and they determined, in concert with his majesty, to new-model the affairs of the nation, and take into consideration the national debt.

In the midst of their rejoicing at this victory, an event happened which seemed to inspire them with new enthusiasm in the path of opposition. On the 20th June, when the president and members of the assembly repaired to the hall of debate, they found the doors shut, and surrounded by a detachment of guards, who informed them that they could not enter, as his majesty meant to hold a royal sitting on the 22d, for which the hall was then preparing. Surprised at this proceeding, and apprehending that an immediate dissolution of their body was determined upon, they adjourned to a neighbouring tennis-court, and took an oath that nothing should prevent their meetings till they had settled for the country a new constitution. This resolution was universally applauded. They then took possession of the church of St Louis till the decorations of the hall were completed, and on the third day the royal session was held in the ancient form. In this meeting, his majesty presented the outline of a new constitution, containing many important reforms, but retaining the different orders, and the obnoxious right of issuing lettres de cachet; in virtue of which power it had been the custom of the monarchs of France to imprison their subjects without trial, at the suggestion of a concealed enemy, or in compliance with their own arbitrary will, without the friends of the victims either being able to discover the crime of which they were accused, or the place of their confinement. This royal sitting was concluded by the king's desiring the deputies to retire, and resume their places next day. He then withdrew, and was followed by the clergy and nobles; but the commons still continued to sit. When the grand master of the ceremonies repeated the king's order, the Count de Mirabeau started on his feet, and exclaimed, "the commons of France have determined to debate. Tell your master we are here by the power of the people, and will only be expelled by the bayonet." This rallying defiance was greeted with enthusiastic cheers, and they proceeded to business. In this sitting they declared their unanimous determination to adhere to all their former decrees, pronounced the persons of the members inviolable, and agreed that they should continue their sittings. On the 27th, they at length obtained a complete triumph over the clergy and nobles, by the deputies of the two orders returning to the hall at the earnest solicitation of his majesty.

UNPOPULARITY OF THE KING.

It was now that the situation of the nation became truly alarming. The sovereign, to whom the people of France had for so many ages been devoted by a superstitious feeling of idolatry, was now beginning to be assailed by loud clamours of disapprobation. Necker had solicited his dismission; and the fear of being deserted by a minister in whom they placed implicit confidence, was the means of increasing their murmurs. At length he gave them a promise that he would not forsake them, and they were pacified for a short time. Meanwhile, the news of the royal session had created a sensation of disappointment and disgust at Paris, which, joined with the famine now raging there, caused tumultuous agitations among the populace, and inclined them to listen with increased avidity to the incendiaries in the pay of Orleans. Even the military were beginning to be seduced, and on the 23d of June, they refused to fire on a riotous mob. Those who were put in confinement for this offence were directly liberated by the people; and the guards, who were then called in to assist in bringing the populace to order, grounded their arms. For this, however, they were pardoned by the king. It was the advice of the aristocracy that the king should endeavour to overawe the people and the assembly by a strong military force. This measure being violently opposed by Necker, he was dismissed, and thirty regiments were placed round Paris and Versailles, camps were marked out, and Marshal Broglio, a skilful veteran, was appointed their commander.

In the dismissal of Necker, and this movement of the troops, the people thought they perceived the seal of their final ruin. The assembly addressed the king, praying for the removal of the troops, and taking upon themselves the responsibility of keeping order in the city. The answer to this was, that "the monarch was the best judge of the way to employ his troops, and that the assembly could not influence Paris while their presence was necessary at Versailles." This reply was no sooner received than the Marquis de la Fayette moved that the ministry should be responsible to the people for their conduct, that the troops ought to be withdrawn, and that the assembly should persist in all its former decrees. The Marquis de la Fayette was a French nobleman, enthusiastic in his ideas of liberty, and an eager aspirant after fame. He had gone to America, and volunteered his services in its cause even before his king took part with it against England, and it was his example, so much admired by his countrymen, that influenced many of them to devote their talents to the same cause.

ARMING OF THE PEOPLE—THE BASTILE DESTROYED.

But to return to the history of events: As soon as the news of Necker's departure reached Paris, preparations for resisting all authority were made. The inhabitants of the city armed themselves with whatever weapons they could procure, and formed themselves into a national guard, amounting to 100,000 men, of which La Fayette was appointed the commander. A great acquisition was made in the discovery of 30,000 stand of arms, and 20 pieces of cannon, in the Hotel des Invalides, of which this army took possession. The fortress prison of the Bastile had always been an object of jealousy and detestation to the people of Paris, and their first act was one of hostility against it. They summoned the governor, M. de Lannay, to surrender, which not being immediately complied with, they proceeded to take it by storm, and, putting him to death, carried his head in triumph through the streets. Only seven prisoners were found in the Bastile, and the keys were sent to M. Brissot, a man of talent, who had studied the law, and who was destined to cut a figure in a subsequent period of the revolution. Brissot had been but a short time previous to this confined in the dungeons of the Bastile, on a charge of having been a co-operator in a seditious publication, and was now one of the Orleans party, who were most active in the destruction of that prison. The city of Paris was now entirely in the hands of an unruly mob, who waited for no authority to sanction their deeds of violence. Many of the citizens, who had no wish to employ arms either against king or people, were under the necessity of assuming them, that they might not be sacrificed to their fury as suspected persons. It has been much lamented by the friends of the unfortunate Louis, that he did not at this juncture assume the authority with which he was still nominally vested. He was not yet deposed from his throne, and, therefore, still had a right to enforce his royal prerogative. He had still his faithful gardes du corps, and some other regiments, which it is probable would have adhered to him; and by their aid, and that of the nobles and well-affected among the gentry, he might have succeeded in overawing the Parisians, and restoring order. At all events, had his life been the sacrifice, he would have died nobly in the discharge of his kingly duty. He could have taken this course without obstructing that reform which he had pledged himself to support; for there was a wide difference in a monarch resorting to arms, in order to oppress his people, and his having recourse to force only to protect the lives and properties of his peaceable subjects. But indecision, and an unwarlike disposition, were the two great blemishes in this monarch's character, and were the real causes of all his misfortunes. Though able to bear his own personal calamities with fortitude and magnanimity, his amiable nature shrunk from the idea of being the cause of pain to the meanest of his subjects.

FIRST VIOLENCES.

The ministry at this time consisted of Marshal Broglio, minister of war; the Baron de Breteui, minister of finance; M. de la Galozier, comptroller-general; M. de la Port, intendant of the war department; and M. Foulon, intendant of the navy, all in subjection to the king's younger brother, the Count d'Artois, and the other aristocratic leaders. The court party received the news of the capture of the Bastile, and, with it, the astounding intelligence from Marshal Broglio of the revolt of the troops under his command, who had refused to act against Paris. The Count d'Artois, with the members of the ministry, were now become so hateful to the people, that their names were enrolled in a list of bloody proscriptions, and flight becoming their only safeguard, they crossed the frontiers with all speed. The king now again entered the national assembly, entirely divested of all pomp, and intimated that he had commanded the removal of the obnoxious troops. This condescension created general applause; shouts of attachment again rent the air, and his majesty was conducted back to the palace by the whole of the assembly. The queen, with the dauphin in her arms, stood in a balcony to receive them, and the most extravagant joy prevailed.

The city of Paris was now governed by 120 municipal officers, who assembled frequently, and made laws for themselves; while the citizens, having acquired a taste for meeting together, formed clubs, at which much intrigue and party spirit prevailed. We have informed our readers that the late minister escaped with the Count d'Artois; but M. Foulon, intendant of the navy, was an exception to this general emigration. He returned to his estate in the country, but was soon dragged to Paris by his own vassals, charged with the crime of having said that he would "make the people of Paris eat hay." To atone for this, a bundle of hay was placed on his back, and after being paraded with it through the streets, he was hanged on a lamp-post without trial, while his son-in-law, attempting to avoid the same fate, was cut to pieces, and the heads of both exhibited by the mob, who were now become familiar with butcheries.

RETURN OF NECKER—PRIVILEGES OF THE NOBILITY AND CLERGY GIVEN UP.

Orders were once more sent for the return of Necker, which, being accompanied by the entreaties of the assembly, he immediately obeyed. His exile had been regarded as a public calamity, and his return was celebrated as a triumph. On the day following his arrival, he addressed the municipality of Paris from a balcony of the Hotel de Ville, where he urged the people to grant an amnesty for the past, and reconciliation for the future. This speech was hailed with seeming transport, but it was by those who had no power to realize the blessings it sought to obtain. The subject was, however, agitated in the assembly, and it was decreed that it was the duty of that body to maintain justice in all cases. The meeting of the assembly, on the 14th of August, was rendered memorable by the proposal of the Count de Noailles and the Duke d'Aguillon, that taxes should only be levied in proportion to the means of the contributors, that no order of the state should be exempt from public burdens, and that feudal claims should be redeemed at a fair valuation; those claims, however, which consisted of personal service in the vassal, to be abolished without compensation, being contrary to the rights of man. The noblemen who made these proposals were possessed of extensive estates, which, of course, enhanced the value of their intended sacrifice, and set an example, which seemed for the time to create an emulation which knew no bounds of reason, the members vieing with each other in a frenzied eagerness to renounce their rights, and strip themselves of every privilege or distinction. At the same time, this mania of generosity was made an instrument of destruction to the clergy, by requiring them to submit to an act which deprived them entirely of their revenues. During this sitting of the assembly, many laws were made, reformed, or abrogated, all in unison with the wishes of the people; and, as a sequel to the whole, it was decreed that a solemn *Te Deum* should be performed, a medal struck in commemoration of that, and a deputation sent to his majesty, to inform him that they had bestowed on him the title of "Restorer of Gallic Liberty." Thus in this sitting was the power of the people rendered complete, by the entire spoliation of the clergy, who still, in common with their monarch and the nobles, retained their nominal dignity, without riches or a shadow of influence.

RESTRAINT ON THE KING'S PERSON.

A short peace followed these popular acts; and a new ministry was formed, who declared the revenue to be in the most miserable state; nor could M. Necker, though he exerted his utmost powers, procure a loan to more than half the amount of what was required. In this emergency, many people made voluntary gifts of their plate and jewels, and the royal plate was sent to the mint. The next question which agitated the assembly and the minds of the people, was, whether the king should be allowed the privilege of a veto, that is, a right to forbid or reject any particular act which had obtained the sanction of the assembly; but, to prevent farther discord, his majesty declared, in a message to the assembly, that he was content to possess a suspensive veto. He also gave his sanction to the past decrees of that body, but expressed his doubts if some of them would answer the purposes for which they were framed. The debates on the veto had given rise to much irritation in the minds of the people, and every thing again bore the stamp of a speedy approach to some important crisis, which was hurried on by a report that it was intended to convey the king to Metz. The place of the French guards, who had revolted from their allegiance to the monarch, had been filled from that time by the national guard of Versailles, which, in concert with the gardes du corps, composed entirely of gentlemen, were the protectors of the royal family; but, on the report of the king's intended flight, they requested, at the instigation of the disaffected at Paris, to be allowed to resume their attendance on his person, for the purpose of watching his movements. The most violent of the revolutionists eagerly seconded the people in bringing about this desired object, having in view the farther intention of conveying the king and the national assembly to Paris, where they would be under the influence of their own authority. The Count de Staing, who commanded the national guard of Versailles, which, together with the Swiss guard and the gardes du corps, were then all the troops stationed at that place, being aware of the state of matters at Paris, requested an additional regiment to assist in protecting the royal family; and accordingly the regiment of Flanders was immediately added to the force commanded by him. On the arrival of this new regiment, the gardes du corps, in compliance with a usual custom, invited their officers to dinner, where the officers of the national guard of Versailles, and of the Swiss guards, were also present. The entertainment was given in the opera hall of the palace. To this scene of festivity, their majesties, taking with them the dauphin, repaired, at a time when, after many loyal toasts having been drunk, the company were already excited by wine. The royal presence gave rise to unbounded enthusiasm. Songs and music became vehicles of the most loyal devotion; and the ladies who attended the queen assisted in decorating the officers with the white cockade. But this imprudent and transitory triumph of the royal family was, alas! the last they were ever doomed to witness, and proved the immediate cause of inevitable ruin to their every remaining hope.

MARCH OF THE MOB TO VERSAILLES—OCT. 5, 1789.

The circumstances connected with this military entertainment were reported, with all the exaggerations of malice, to the starving mob of Paris, who, inflamed with envy and indignation at the very idea of a costly and sumptuous banquet having been given in the palace of their king while his people were driven to the extremities of famine, determined to demand bread at Versailles. The first insurgent party which put this determination in practice was composed of women, and some desperate and worthless men who assumed the female attire. This mob was headed by a man named Stanislaus Maillard, who had played a conspicuous part at the taking of the Bastile. They set out, vociferating, "To Versailles! to Versailles!" This riotous movement was opposed by Fayette to the extent of his power; but it was in vain that he ordered or remonstrated, for the only answer he received from his soldiers was, that they "could not turn their bayonets against women." This army of amazons, already intoxicated with brandy, were addressed from time to time by the armed brigands who accompanied them, and who inflamed them to a pitch of the utmost fury against the queen and the gardes du corps, representing them as the principal delinquents in the affair of the banquet, and whose assassination they by all means advised. The remaining populace of Paris caught the infection from those who had departed from Versailles, and determined to follow. The guards, commanded by Fayette, and the other military force of the city, insisted on his leading them to the same point of attraction. All Paris had risen, and in this dilemma Fayette applied to the assembly of the commune for directions, and received orders to comply with the wishes of the people, who in reality could not have been restrained by any authority. He therefore put himself at the head of the national guard, and marched for Versailles. Meanwhile, some hours in advance of him, the female army, which now amounted to 6000, having augmented as it proceeded, reached Versailles.

DISTRESS OF THE ROYAL FAMILY.

The king was hunting when apprised of the approach of this singular force, and he returned to the palace immediately, where the officer in command asked for orders. "What!" said his majesty, with a smile, "against women?" And all the precaution thought necessary was to shut the iron gates of the palace, and draw out the military. When the women arrived at Versailles, their commander Maillard took fifty of them with him into the hall of the assembly, where the members were sitting, and began a harangue, in which he told the president that the people had resolved to execute justice on traitors; that they must have bread; that they had come to demand it; and that the gardes du corps must be punished, unless they consented to wear the national cockade. This address was accompanied by the beating of drums, and all those confused and tumultuous sounds which arise from a brutal and infuriated multitude. To get rid of this noisy rabble, a deputation was sent from the assembly, accompanied by twelve of the women, who were courteously received by the king, and on whom his humane regrets at the state of want which they represented, had such an effect as to change their threats into shouts of "Vive le Roi," with which they joined their companions on the outside of the palace. The popular fury seemed now for a short space to slumber, but such a state of inaction was not consistent with the hopes or designs of those who had first set it in motion, and it was suggested that the delegates had been bribed in the palace to give a favourable report of their reception. This was enough. The mob had already observed that they were in the good graces of the national guard of Versailles, and also of the regiment of Flanders, who would not act against them. The gardes du corps were then the only foe they had to encounter, and, satisfied that they were kept in check by the fear of producing a general attack, the outward avenues of the palace were quickly occupied by a multitude of the women. Meantime, the gardes du corps were placed in the court of the palace, in front of the national guard and regiment of Flanders, while the space between them was filled up by the women, and by the armed brigands who had accompanied them from Paris. In this unnatural state of contact, a fray arose, in which, it is said, an officer of the Versailles guards struck one of the Parisians with his sabre, and in return had a shot fired at him, which it suited the purpose of the mob to say came from one of the gardes du corps. This was sufficient to fasten a stigma upon that body as the aggressors, and the national guard immediately took part with the people against the gardes du corps, two of whom were wounded, and another narrowly escaped. His majesty was urged to flight, but determined on waiting the arrival of La Fayette with his civic troops. The gloom of approaching night came on, accompanied by torrents of rain, and the utmost confusion and uproar prevailed, when La Fayette made his appearance, followed by the Parisian army, and others, amounting in all to 30,000, and, in a short time, his exertions, and the good conduct of his soldiers, seemed to restore some degree of order. La Fayette visited the palace, and re-assured the king and its inhabitants, by explaining the measures he had adopted for their security, and, before he left them, advised their retiring to rest, which they did at two o'clock in the morning, after a night of the most cruel agitation and alarm. But though they lay down in bed, it may be supposed they were unable to find repose while the palace was still surrounded by a threatening mob, who were increasing their ferocity by intoxication. The concourse of people was so great, that multitudes could not obtain shelter, and all the avenues to Versailles presented, during that horrible night, the most novel and extraordinary spectacles. Thousands sat in separate groups around huge bonfires, which cracked and blazed, and threw the red glare of their flames on the ferocious and wild countenances of a savage people, who were eating and drinking, singing, shouting, and cursing, while a shot was now and then fired, and a bloody threat uttered in attestation of their still keeping in mind that their main errand to Versailles was not yet accomplished. Towards morning, a band of the most desperate again approached the palace, and while prowling round it like wild beasts in search of prey, they unfortunately discovered a door that was neither fastened nor guarded. Only one hundred gardes du corps remained within the palace as its protection, while it was surrounded outwardly by the French guards, whom Fayette, in his late audience with the king, had succeeded in persuading him to reinstate in their former duty. The mob, finding an open entrance, and knowing how slenderly the palace was guarded within, very soon announced, by dreadful shouts, that they had succeeded in penetrating to its interior. Crowds now ran up the grand staircase, uttering the most vehement threats and abuse against the queen, whom they accused in the grossest language of being an enemy to the wishes of the people, and of having, by her extravagance and evil councils, brought the nation to its present state of poverty. The gardes du corps advanced to meet them in the galleries, and, by thus bearing the first shock of their onset, gave their unfortunate queen time to escape. This she did by starting from her bed, and flying through a secret passage to the apartments of the king, while the clamours that demanded her head still rung in her ears. But in spite of the appalling situation in which her majesty was placed, she still maintained the courage which was never known to forsake her, and which, on trying occasions, so frequently, during the latter disastrous period of her life, showed itself in the most exalted acts of heroism. She had now no sooner reached the king's apartment, than she sent for her children, and then dressed herself hastily in such habiliments as it became her to wear when she showed herself to the people, a course which she was determined to adopt.

The secret passage between the apartments of their majesties remained undiscovered when the mob forced their way to the bed-chamber of the queen, and they were thus prevented from following her. Their disappointment, however, only tended to increase their rage, and they now endeavoured to force their way to the king. During the brief space since the palace was entered, several murders had been committed; and the gardes du corps, apprehensive for the life of the king, had barricaded the entrances to the part of the palace now occupied by him, which they determined to defend with the last drop of their blood. It has been a matter much disputed, whether La Fayette, on this memorable night, allowed the palace to be so ill guarded from treachery to his royal master, or from a disbelief in the evil intentions of the mob. Candour must certainly acquit him of any sinister motive, when he is judged by his previous character; though it must still remain matter of regret that he should have yielded to fatigue, and sought repose, while his exertions were so necessary to prevent the disasters which were the consequence of his absence from his troops, whose hatred to the gardes du corps was the principal cause that the insurrection was not suppressed in time to prevent all the evils to which it gave rise. La Fayette, however, roused from his slumbers, at last arrived at the palace, just as the mob had beaten in the barricades of the king's apartment. He was accompanied by the grenadiers of the national guard, whom he earnestly enjoined to save the gardes du corps. In this he was obeyed, and the insurgents were driven from the palace just as they were beginning to pillage it. The gardes du corps, to save their brethren, many of whom were on the outside of the palace, assumed the national cockade, and showed themselves at the windows, at the same time taking off their bandoleers, and throwing them down to the people, who, satisfied for the time by this concession, answered it by repeated cries of "Viva le nation!—Vive le roi!—Vive le gardes du corps!"

ROYAL FAMILY REMOVE TO PARIS.

While these shouts were resounding, the gardes du corps who were among the multitude were caressed and embraced by them, and the others invited to descend from the palace, and participate with them in those acts of kindness which they thought it prudent to do. Amid the manifestations of joy which now prevailed, there was suddenly a loud demand made for the appearance of the queen, which was immediately complied with, and she entered the balcony with her two children. Voices among the crowd were heard to vociferate, "No children, no children!" This heroic woman, not intimidated by the sanguinary intention against her implied in this cry, immediately dismissed the children, and stood alone before a cruel multitude thirsting for her blood, with her hands crossed upon her bosom. Her beauty, her magnanimity, and her majestic dignity, struck her intended assassins with astonishment and awe. They forgot that the arms were in their hands which could, in one moment, terminate that life they had so lately sworn to sacrifice; and, instead of remaining the object of their implacable hatred, the queen became for the moment the idol of their admiration, and they hailed her with a general shout of "Vive la reine." The Duke of Orleans, who was all this time busy among the mob, and had been even seen to point the way to the queen's apartment at the time of its attack, now entered the palace as a friend, to congratulate their majesties, while his emissaries were exciting the people to insist on the removal of the king to Paris; and, accordingly, the next cry which arose from them was, "To Paris, to Paris!" La Fayette's advice to the king was to yield immediate obedience to it; and his majesty expressed to the crowd his willingness to accede to the wishes of his people, provided he was to be accompanied by the queen and his children. "Yes, yes," was the reply. "I also demand safety for my gardes du corps." This was also granted. Fayette then made the military under his command seal this compact by a general discharge of artillery, and a volley of fire-arms.

The assembly was now sitting, and, when informed of the intention of the king to depart for Paris, Mirabeau moved that the national assembly of France was, during that session, inseparable from his majesty. It had been the earnest wish of Mirabeau and his party to remove the assembly to the capital, from the greater facility it afforded them of working on the minds of the people; but the present resolution carried the appearance of an attachment to the person of the king, and it was unanimously agreed to even by the moderate and more conscientious members. There were four parties in the national assembly at this time. The leaders of one were Mounier and Malonet; of the other, Mirabeau and the Abbé Sieyes. The former were the moderates. Mounier was enlightened, consistent, and firm; and it was his long-cherished wish to model the constitution of France after that of England. Malonet was honest, and always guided by conscience, but not so well qualified to judge or act as his colleague, from his having accustomed himself to trust in the self-evidence of truth, without troubling himself to bring conviction home to others. Mirabeau possessed splendid abilities, but his character was so immoral, that, before the breaking out of the revolution, he had lost that place in society to which his high rank and extraordinary talents entitled him; and he was now devoting all his efforts to raise himself, not only into notice, but to attain the highest possible distinctions, which his irresistible eloquence bade fair to accomplish. Mirabeau professed to be a friend to limited monarchy, while, at the same time, he aided and encouraged the republican party. The Abbé Sieyes was scrupulous in allowing his wish of equalization to be known. The third, or republican party, of which Fayette and Baillie—the latter of whom was then mayor of Paris—were members, wished for that form of government which was established in America; and though they still retained a partiality for the person of their amiable and unfortunate king, it was consistent with their principles that he should be divested of every attribute of royalty. Before we attempt to give a sketch of the fourth faction, it will be necessary to say something of the club called Jacobin, from its being held in the hall of the Jacobin friars. This was a society formed at first by able but violent men, whose ideas of liberty were so extravagant, that they imagined it would be cheaply purchased at any sacrifice of lives or principles; and, thus united, they became a common centre for all those throughout the nation who held the same opinions, and were open enemies to the plan of constitutional government. These men, however, were so profligate in their manners, and so brutish in their feelings, that they were held in detestation by all those who had not thrown off a regard for the decencies of life. The Jacobins were the avowed friends and courters of the lowest order of the people, whose habits they affected, and whom they stirred up to spurn at laws and every species of order. It was the purpose of these men to make shipwreck of the state, that they might individually be enriched by her plunder. It was among these persons, who formed the fourth faction in the national assembly, that the partisans and emissaries of Orleans were found.

Let us now again follow the course of events: Upon passing the decree which was to remove the assembly to Paris, it was determined that a hundred of the deputies should accompany his majesty. Mirabeau offered himself as one, and complained bitterly when he found his name excluded from the list by the president, Mounier, who was always jealous of him as a concealed enemy to the constitution. The king, the queen, the princess Elizabeth, the two royal children, and two of the members of the assembly, were put into one coach, which was followed by the carriages of the deputies; while a detachment of brigands, as an advanced guard, carried in triumph the heads of two of the gardes du corps, fixed upon spears. The fishwomen, and a number of the most abandoned of their sex, forming a sort of bacchanalian procession between them and the royal carriage, escorted as captives the gardes du corps, whose military accoutrements they bore aloft in their hands, and who, dejected and wan from bodily fatigue and anxiety for their royal master, were pushed and dragged along, many of them with their dress soiled and torn, and without hats. Waggons of flour and corn from Versailles were accompanied by women bearing large branches of poplar, while they vociferated to each passer-by, that "bread would be no longer scarce at Paris, as they were conveying thither the baker and his wife, and the little journeyman." The carriages were followed by the cannon, on which women were mounted, and by three regiments; while the rear consisted of the stragglers from the Parisian mob. It was remarked that the queen sat amid this motley and disgraceful procession with unshrinking firmness and apparent tranquillity of mind, though nothing was omitted during the journey, which lasted six hours, or at their entrance into the city, which could tend to degrade or to hurt the feelings of royalty. One of the representatives of the commune arrived in advance at Paris to communicate the intelligence of what had passed at Versailles, and presently a mob appeared, with the bearer of the heads of the two murdered gardes du corps, which they had in cruel mockery caused a hair-dresser to friss and powder. On the approach of his majesty, M. Baillie, the mayor, went, as is customary, to receive him at the barrier, where he is said to have insulted the fallen monarch, by hailing with triumph the splendid day which restored him to his capital, and remarking, as he presented him with its keys, that these were the very same received by Henry the Fourth when he entered Paris as the reconqueror of his people, but that in the present instance the people had reconquered the king. His majesty and the royal party were then conducted to the Hotel de Ville, where their sufferings were protracted by a long speech from Baillie, in which he assured the monarch that the love of his good people of Paris was founded on his having adopted the constitution so much approved of by them. The king replied to this, by saying that it was always with pleasure and confidence that he found himself among his good people of Paris; and this farce then being terminated, the royal family were permitted to take possession of the old palace of the Thuilleries. This building had been abandoned by royalty for more than a century. All about it was antique and desolate; the apartments were not in a habitable state, and, of course, there was no preparation for its present unexpected guests; but still it was a relief to its persecuted inhabitants to be left in it for a time in quiet. No cries of gratulation or loyalty from the people accompanied them to this new abode, where their forebodings from what they had already suffered must have been sufficiently gloomy.

CHARACTER OF THE KING.

It is not to be doubted that Louis the Sixteenth was a conscientious and benevolent man, who really had the happiness of his people at heart; but his fatal destiny made him monarch of a great people at a crisis when the most splendid military and political talents were necessary to meet and guide the prevailing spirit of the times, and when perhaps they would hardly have sufficed to cure the long-accumulated distempers of the state, or avert the evils which were destined to descend on his own devoted head. Of these high qualities Louis was entirely destitute. How, then, could he possibly expect to escape from the sad fate that at once involved him and the nation in misery? And yet it is probable, that, during his whole existence, he had never once contemplated the most distant probability of ever witnessing the spectacles which now every where met his eyes, of his kind, light-hearted, obsequious, and adoring people becoming sanguinary, insolent, and dictatorial. He was, therefore, unprepared for this singular change, and undecided how to meet it.

CONDITION OF THE NATIONAL ASSEMBLY.

The removal of the king to Paris was a grand triumph to the popular party, but the nobles considered it as a final blow to their hopes of ever recovering their ascendancy; while Mounier and the conscientious members of his party abandoned all idea of obtaining a free constitution, whose laws should assure the free and unbiassed deliberations of its representatives. The assembly had been removed to Paris by an armed force, and this they considered as the first step in depriving them of their liberty. And, in truth, the revolution now changed its object—liberty was no longer the mark at which it aimed. The deputies of the people were now placed under the surveillance and control of the Jacobins, who soon began to assume an ascendancy over the moderate party. Mounier, the president, and Lally Tolendal, one of the supporters of his party, a respectable man and eloquent orator, indignant at the scenes of discord, murder, and tumult they had lately witnessed, and foreseeing a continuation of these enormities, abandoned their seats in the assembly on the 9th of October, and emigrated from their country. The good Malouet, supported by M. de Clermont Tonnerre, who was at the same time possessed of just thought and shining talents, were left at the head of the moderate party, but were quite unable to stem the torrent poured in upon them by the Jacobins; and there were often at that period no debates save between those of opposite opinions. The Duke of Orleans was, meanwhile, so generally acknowledged by all parties to have acted a double part in the late transactions at Versailles, that he was waited on by La Fayette, who insisted on his leaving France; and, alarmed by this demand, he accordingly took his immediate departure for England. The king was now literally a prisoner in his palace, which was strictly guarded, while he was, partly on their own account, obliged to disband his faithful gardes du corps.

FRAMING OF THE NEW CONSTITUTION—FEB. 1790.

The national assembly, once more settled down to business, proceeded to attempt the formation of a free constitution. But laws, in which the varied interests of so populous a nation were concerned, could not be made without much murmuring. One of the first steps toward the new constitution, was the confiscation of the whole of the church lands for the benefit of the national finances. It was in vain that the clergy remonstrated on the injustice of this decree: they were, after some fruitless endeavours, obliged to submit. All distinctions of the ancient names and divisions of the French provinces were obliterated on a motion of the Abbé Sieyes, and the territory divided into 83 departments, subdivided into 600 districts, and these again divided into 48,000 communities or municipalities. This measure was evidently contrived for the purpose of getting quit of old recollections, and calculated for introducing that levelling principle of equality of which Sieyes was the supporter. All titles of honour, all distinctions of the different orders of society, and all armorial bearings, were abolished. A decree was also passed, suspending the parliaments of the kingdom from their accustomed functions; and the dissolution of those privileged bodies which had been so long looked upon as the only successful opposers of despotism, was little regarded. The freedom of the press and toleration in religion were guaranteed; but while liberty of conscience seemed thus to be allowed, a civil constitution was imposed on the French Roman Catholic clergy, declaring them independent of the see of Rome, and bestowing the nomination of their bishops on the authorities of the departments; and to this law, priest and prelate were required to adhere by an oath. But, to the everlasting credit of the clergy, there were few who thus consented to outrage their consciences by giving up an article of their faith, and those few became despised and contemned by all parties. The next event of importance was that of the king's making his appearance in the national assembly, to declare it to be his wish that it should be universally known that the monarch and the representatives of the nation were united in purpose, and that he and his queen would imbue the mind of his son with feelings of approbation towards that change of government which had been found necessary.

The framers of the new constitution had been careful to render it in all essentials a republic, while certain functions of the king still constituted him as its head, though without a vestige of real power; while every attempt in his favour made by the more moderate part of the assembly, was put down by the Jacobins. About this time an event happened which tended to inflame the minds of the people to a violent pitch. The court expenditure had never yet been made public, but an account of it was kept in what was called the red book. This book was in the possession of M. Necker, and a sight of it was obtained by a member of the assembly, under promise of secrecy, which was so far from being kept, that, in a few days, there were copies of it in every bookseller's shop. This publication disclosed some court secrets; and the people were especially exasperated at learning by it, that, during the administration of M. Calonne, the king's brothers had received above two millions sterling, in addition to their stated allowance. This, together with a catalogue of what they deemed extravagant expenses of their majesties, irritated the lower class, particularly against the queen, who, for a long time past, had the misfortune to be an object of hatred to the most of her subjects. The reluctance of Necker to make this book public, and his indignation at having been deceived by the deputy, created a violent prejudice against him, and he began, along with the other ministers, to lose his popularity. And now again affairs were verging on a state of anarchy and confusion. Partly to please the multitude, and to give a sanction to all the proceedings since the commencement of the revolution, it was decreed that an anniversary of the taking of the Bastile should be held. For this purpose, the 14th of July was to be celebrated by a meeting between the king and people, called the federation, in the Champ de Mars, to take an oath of fidelity to the new constitution; and to be present at this fete, the Duke of Orleans returned to Paris. Here an altar was raised, at which the civic oath was administered. The assemblage consisted of the electors of Paris, the representatives of the commons, the administrators of the municipality, and parties from the troops of France, and from those of the departments. The king first took the oath, then the president of the national assembly. Fayette was on this day the object of popular idolatry. Necker's popularity had been for some time on the wane, and he now gave in his resignation, and quitted France unregretted by any party.

DEATH OF MIRABEAU.

At this time all Paris was thrown into affliction by the death of Mirabeau, who expired after a few days' illness. The national assembly put on mourning, and decreed him unprecedented honours. He was the first person interred in the magnificent Pantheon consecrated to great men, in the name of a grateful nation. His body was, however, some time afterwards removed, on its being discovered that he had not been inaccessible to bribery. In fact, at the time of his death, he was, in consequence of being richly bribed by the royalist party, labouring seriously and artfully in the work of re-establishing royal authority, and had pledged himself to assist his majesty in escaping to Metz, where a sincerely attached subject of the king, the Marquis de Bouillé, was governor. This course appeared to their majesties the only one left for them to adopt, and, provided it could be accomplished, it seemed to hold out a hope, that, when at a distance from Paris, all their faithful subjects would assemble around them.

FLIGHT OF THE ROYAL FAMILY.

Some time previous to this, the king had, in order to ascertain what degree of restraint it was thought proper to put upon his motions, attempted to remove for a time to St Cloud. No sooner, however, had he and his family entered their carriages, than they were prevented from proceeding by the populace and the national guard, who were the troops then stationed at the palace, and who declared that they should not leave Paris. Nor was it possible for Fayette, by means either of commands, entreaties, or threats, to change the determination of the guards, which so disgusted and enraged him that he resigned his command, though, on the repentance and at the earnest entreaties of his soldiers, he assumed it again. Thus, more than ever convinced that they were considered as prisoners, they determined on making their escape; and having made secret preparations for their departure, the king, the queen, and the two royal children, left the palace in disguise, on the night of the 20th of June (1791), entered the carriage which waited for them on the Boullevard, and took the road for Montmédy. When it was made known in the morning that they had fled, without their route being known, the rage and vexation of the multitude knew no bounds. Fayette and his guards, and the mayor, Baillie, were accused by the people of being accomplices in the flight of the king, in which they fancied that they beheld the invasion of France, the triumph of the emigrants, and the return of despotism. The assembly, however, seemed to take it more coolly, for there it was rather matter of rejoicing to the republicans and anarchists. One of these parties saw in it the deposition of the king; and the other, a stimulus to the commission of outrage, from its probable influence in delaying the return of order. The sincere constitutionalists alone regretted it; while at the same time this regret chiefly arose from the necessity that their constitution, as it was framed, had need for a monarch at its head. All the measures which were necessary, however, to meet this emergency, were immediately taken. Messengers were dispatched, in all directions, to intercept the royal fugitives. The constitutionalists, with Fayette at their head, were determined not to abandon a form of government which it had cost the most talented statesmen of their country so much trouble to form. They succeeded in calming the people for the present by a proclamation; assumed the executive power; made known their pacific disposition towards all the potentates of Europe, by means of the foreign minister; sent to all the troops to receive their oath of fidelity in their own name, instead of the king's. Thus the national assembly was in a few hours invested with all the rights of the sovereign, and the government went on without impediment—a dangerous lesson for the interests of royalty. Meanwhile, the royal party were pursuing their journey with all possible speed, and, after many narrow escapes, arrived at St Menehould, where they were furnished by M. de Bouillé with an escort, under the pretence of guarding money to pay the troops. But while they halted for a short time at this place, the king was recognised by the postmaster, who had been formerly a dragoon, and who immediately mounted a horse, and reached Varennes, which was the next stage, before they had time to come up. Here he informed the municipality of the approach of the king, when he was arrested, after a journey of 156 miles, and when nearly arrived at the frontiers. The royal deserters were immediately brought back to Paris by a deputation from the assembly. Thus ended an ill-arranged and ill-fated attempt, which had no good effect at a future period, and which immediately caused the emigration of many more of the nobles and clergy.

EFFECTS OF THE REVOLUTION OUT OF FRANCE.

In the mean time, these extraordinary proceedings of the French nation were exciting much interest in other countries, and had various effects upon the minds of men. In Britain, and other monarchical countries even less open to liberal impressions, a large portion of the community, comprising many of the most active and powerful intellects, beheld the French revolution as a grand example for the regeneration of other nations, and began to press accordingly upon their own respective governments. These governments, along with the privileged classes and clergy, and a vast body of respectable supporters, regarded this great event as one which threatened all existing institutions, and was likely to produce more immediate evil than eventual good. A party, if we may so express ourselves, was formed beyond the limits of France, which proposed, in co-operation with the emigrant royalists, to do whatever might seem proper in order to stay the violent progress of the revolution, and protect the person of the sovereign. About the time of the king's flight, a treaty took place at Pilnitz, in Saxony, between the Emperor Leopold and the King of Prussia, when they agreed, in a secret convention, at the solicitation of the Count d'Artois, to furnish each 12,000 troops on the frontiers of the Rhine, as soon as they could be got in readiness, with a view to support an army of the emigrants, and to manifest, unequivocally, the effectual protection they were determined to afford to the cause of the monarch of France, while they demanded the concurrence of the other European powers. These proceedings stirred up still worse elements in the minds of the French nation. They suspected their monarch, even while he was accepting the constitution, and doing every thing that they required, of a secret alliance with the anti-revolution party out of the country; and he eventually fell a sacrifice to the alarm and indignation which arose in consequence of the interference of that party.

During a short time after the return of the king from Varennes, all was tolerably quiet in the national assembly; but this calm was succeeded by a trial of power between the constitutionalists and the republican and Jacobinical leaders, on the subject of dethroning the king; and a meeting took place in the Champ de Mars, where a petition to this effect was laid on the same altar at which the civic oath had been taken, in order to obtain signatures. The better, however, to prepare the minds of the multitude for this act, which was to seal the fate of their monarch, it was thought necessary by the Jacobins to inflame them, by accusing two men who were sitting under the altar, which was raised on a scaffolding, of a design to blow up the patriots. These poor wretches were instantly murdered, and their heads, as usual, paraded on pikes. The civil authorities interposed, but to no effect; and martial law being proclaimed, Fayette appeared with his troops, who, with himself, were stoned and abused, which was returned by a volley that laid more than a hundred men dead on the field. The contest was given up, and the Jacobin instigators slunk away, imprecating curses on those who had caused their defeat, and swearing a deep revenge.

THE LEGISLATIVE NATIONAL ASSEMBLY.

An act was next passed in the assembly, that, after the constitution having been presented to the king, and accepted by him, if he should retract, that he should then be considered as having abdicated, and henceforward be merely allowed the privileges of a common citizen. The constitution, with its new restrictions on the power of the king, was now again offered to him, which he signed in the assembly, and took the oath of fidelity. The constitution being now finally settled, the national or constituent assembly dissolved itself, and gave place to a "Legislative National Assembly," to which the members of the former had, by their own decree, rendered themselves incapable of being elected. It necessarily followed, that those who formed the new legislative body were possessed of less political knowledge, which made them more liable to venture on rash expedients. In addition to this, it was composed of constitutional members, who averred that all further revolutionary laws were unnecessary, the established constitution being now perfected; while these were violently opposed by the republicans, who, of course, sought to exterminate monarchy, and by the Jacobins, who were determined on establishing that reign of terror which afterwards they too fatally accomplished, and in which, as their own natural element of rapine and violence, they alone expected to thrive. At the head of the republican party was Brissot, from whom it generally took its name, its members being called Brissotines, though sometimes styled Girondists, from many of its partisans coming from the department of Gironde. The other, or Jacobin party, was called the Mountain, from their occupying the highest seats in the hall of assembly, and was headed by Robespierre and Danton, those names at which humanity shudders. Marat also, and many other desperate and profligate characters, ranked under these sanguinary leaders. These wretches were, however, used by the republican party as their sleuth-hounds, to run down those who could not be conquered in the regular way, until the republic should be established, when they fancied they could dismiss them to their kennels as no longer useful—idle dreams, from which they were to be too soon roughly awakened.

WAR COMMENCED WITH FOREIGN COUNTRIES.

Just after the meeting of this new assembly, France experienced a sensation of apprehension lest innovations should be made on its newly acquired liberty by Sweden and Russia, who, it was said, had determined to restore the old government, though the Prussians and Germans still continued to temporise. Nor did the pacific answers received from the different foreign courts, on their being informed that Louis had accepted the constitution, avail much in allaying this apprehension; for their answers bore an air of reserve, which seemed merely calculated to avoid a present rupture, while the French emigrants continued to aver that all Europe was arming to defend the cause of their king. The assembly was in consequence inundated with addresses in disapprobation of the court and its party. At this time, the period of M. Baillie's mayoralty being elapsed, M. Petion, a violent republican and Jacobin member, was elected in his place. On the 1st of March 1792, the death of the Emperor Leopold took place, and shortly after it, the assassination of the king of Sweden by one of his own subjects. Francis King of Hungary, who succeeded to the dominions of his brother the Emperor Leopold, openly avowed his determination of waging war against France, unless certain terms were submitted to by the king and legislative assembly. These demands were refused, and accompanied by a declaration of war on the part of France; and it was the miserable task of Louis thus to send a defiance to his queen's brother, and to both of his own, who had taken up arms along with the most faithfully attached part of his subjects, in order to restore to him what they considered as his rights.

MILITARY OPERATIONS.

The limits of this paper do not admit of our going deeply into the account of military proceedings; we shall therefore only give such a slight sketch of them as may enable our readers in some measure to understand the motions of the French armies. France began its hostile movements by an attack on the Austrian Netherlands, which at first proved unsuccessful, by the defeat of the troops commanded by M. Dillon, and those under several other leaders. The Austrians were, however, compelled by Fayette and his division to abandon the field. Meantime, on the 30th of October, it was decreed, that, if the king's eldest brother did not return to France within two months, he should be deprived of his right of regency. A decision was also made with regard to the clergy, that if those who had refused the civic oath persisted in their determination, they should be deprived of the money allowed them for subsistence; and on any religious dissensions arising in their communes, they should be made answerable for them. His majesty sanctioned the decree against his brother, but used his only remaining privilege of putting his veto on the other. All expedients were fallen upon to create suspicions of the king, and to render him an object of aversion to the people, in which Marat was the principal agent. This man was the son of a Swiss schoolmaster, and had practised for some years in Paris, as a physician, or rather as a quack. He had become obnoxious to the national assembly at an early period of its sittings, by publishing a pamphlet, in which he suggested the diabolical advice of hanging up 800 of their members on the trees of the Thuilleries. For this offence he was committed to prison, but was soon set at liberty, owing to some illegality in the form of commitment. His ambition never seemed to rise above that of becoming the leader of a disorderly and sanguinary rabble. Among the reports to which the incendiaries gave rise, that of the existence of what they termed an Austrian committee was boldly averred—that is, a party in the cabinet who favoured the enemies of France—and also, that it was the fixed intention of the king to escape. These reports were believed by the people, who were kept by them in a constant state of alarm. The Brissotine faction became also alarmed, though the cause was somewhat different. They felt certain that a struggle for power was approaching, between them and the Jacobins; and being aware that the latter had multitudes of the lowest order of the citizens at their command, who, armed with pikes, would constitute a force not to be resisted, they formed the plan of furnishing by ballot 20,000 men, to be armed, and trained under the walls of Paris. This scheme was highly displeasing to the people of the city, as they considered such a force as dangerous to the capital, and looked on the national guard as quite equal to its defence. They therefore petitioned the king and the assembly against it, and obtained the support of the king, who was jealous of the measure as entered into by the Brissotines to bring about a republican government.

INCREASED DANGER OF THE KING.

Dumouriez, minister of war, advised Louis not to thwart the assembly with regard to the troops from the departments, lest he should become suspected of wishing the capital to be left open to the advance of the enemy. The king, however, was not to be persuaded, and determined to oppose his veto to this measure. There was also another point of contest between the king and the ministry: a decree was passed in the assembly, that all priests who refused to subscribe the oath to the constitution should be liable to exile. This was against the conscience of his majesty, and he expressed his firm resolve to put his veto on it also. On these subjects, Roland, one of the ministers, remonstrated with the king, in a letter conceived in such a spirit of disrespect and harshness, that Louis dismissed him, and two others of the ministers who were his abettors. To retain Dumouriez, he was obliged to withdraw his negative with regard to the troops from the departments, but still stood firm in respect to the priests. Dumouriez continued, however, to press his majesty on this subject, and to threaten to abandon his office in case of refusal. This had still no effect, and, resigning his place, he was sent by the assembly to become a leader in the French army.

INSURRECTION OF THE 20TH JUNE.

Louis was now charged with all the crimes and misfortunes of the revolution, and left alone to encounter the evils which were incessantly heaped upon his head. The Brissotines and the Jacobins were unanimous in their determination of depriving him of his monarchical title, for little else was now left him; and an intended insurrection was openly announced by those who had been for some time providing the rabble with pikes and other arms; and on the 20th June (1792) it took place. Multitudes of armed people, headed by two men named St Huruge and Santerre, assembled in the streets, and, having collected all their force to the number of 40,000, appeared at the door of the national assembly, and, having entered it, continued to pass through for a space of two hours, exhibiting the sanguinary mottoes of their flags, and displaying their destructive weapons, among which were scythes, hay-forks, &c. They next surrounded the Thuilleries, and, having forced an entrance, proceeded to the apartment where the king and his sister the Princess Elizabeth were, with a few of the national guards who had rallied round their sovereign, and who now hurried him into the recess of a window. Here the king's sister remained with him for the space of five hours, crushed and heated by the crowds that incessantly poured in to heap every species of insult on the unfortunate monarch; among which, they compelled him to assume the red cap of liberty. At length the mayor, Petion, and also a deputation from the national assembly, arrived, who at once, as by magic, cleared the palace and its precincts of its extraordinary visitors, proving that those who could so easily dispel such a numerous mob, could with the same facility have prevented them from assembling. Highly offended and indignant at the scene of violence and insult which had passed in his palace, the king next day remonstrated against it in strong terms to the assembly. Petitions from the more peaceable citizens were also presented, praying that the leaders of the insurgents might be brought to punishment. Fayette, also, arriving unexpectedly in Paris from the head of his army, declared at the bar of the assembly that he had been addressed by his troops to express their dissatisfaction, that, while they were shedding their blood to maintain the constitution, it should be suffered by the authorities of Paris to be outraged and trampled upon with impunity. The energy with which Fayette addressed the assembly, in denouncing the rapid progress of faction, and demanding that a strict investigation should be made into the cause of the late outrage, and its instigators brought to justice, seemed at first to create some sensation of shame in the assembly; and some indications, accordingly, appeared of redress being granted, which, however, passed off without effect. Fayette then ordered a review of the national guards, but they did not assemble; and he next waited on his majesty, and proposed to him, as his only remaining prospect of safety, that he should again attempt an escape, in which he offered to assist him. From the queen's prejudice against Fayette, this assistance was refused, and he left Paris to join the army. The directory of the department of Paris, scandalized at the late outrage, now took upon them to declare against the mayor, and, imputing to him the blame, suspended him from his office, which he again assumed almost immediately, though his sentence had been confirmed by the king—Petion having appealed to the assembly, and carried his point by means of his friends the Jacobins. Afraid lest Fayette, whom they had so much insulted, should march his army upon Paris, and compel an adherence to the constitutional laws, or perhaps join with the foreign invaders in the king's cause, the Brissotines looked to the arrival of the troops from the departments as a fit body to strengthen their party, instead of the Jacobins, whom they found they could no longer trust as tools in the work of republicanism. These troops when they arrived at Paris showed themselves at once ignorant and overbearing, by assuming to themselves all the authority arising from their fancied consequence as armed representatives of their country. They paraded in numerous parties the garden of the Thuilleries; and if any of the royal family appeared, they insulted them in the most brutal language. A young man named Barbaroux, one of the most enthusiastic lovers of liberty, brought to Paris also a battalion of men from his native city of Marseilles. These Marseillois were received at Paris, by order of the Brissotines and Jacobins, in the most fraternal manner, by all the force they could muster; and both were destined to form an insurrection, whose business it was to be to secure the municipal authorities, to occupy the posts of the city, and to encamp in the garden of the Thuillaries; by which means it was intended to intimidate the king into an act of abdication. This plan, however, failed, through the cowardice of Santerre, who was designed to be their leader; though violence was soon again resorted to by the Brissotines, in which they were aided by a manifesto of the Duke of Brunswick, declaring the intended invasion of France, with the intention of restoring the ancient government, and threatening the legislative assembly, the national guard, all who held civil offices, and, in short, all Paris, with the most bloody vengeance. This was construed by the people into an incontrovertible proof that the king was secretly hostile to the constitution, and his deposition was resolved on by the violent party, not only on account of what they called his treachery, but as an act of proud defiance to the author of the manifesto and his allies.

The country was now declared to be in danger, and Paris assumed all the appearances of a city just about to undergo a siege. Amid these hurried and alarming movements, the king was accused in the assembly of holding intercourse with the enemies of France, and his forfeiture of the crown demanded. This motion brought on the final struggle between the constitutionalists and their opponents; and some extraordinary attack on royalty was so openly avowed and so generally credited, that the king is reported to have said, in full assurance that his days were now numbered, "I have no longer any thing to do with earth—

I must turn all my thoughts on heaven." He however recalled his Swiss guards, to the amount of a thousand, from distant barracks, and, with this slender preparation for the approaching crisis, he awaited his fate.

INSURRECTION OF AUGUST 10—THE KING DEPOSED.

On the morning of the 10th of August, or rather little after midnight on the 9th, the dreadful tocsin sounded its foreboding peal in the ears of the affrighted citizens, and was soon joined in its terrific notes by all the bells in Paris. Drums beat to arms, and the adverse parties assembled all their forces. Those on the part of royalty were small, and soon collected; they consisted of the before-mentioned Swiss guards, who occupied posts around the palace; about four hundred grenadiers, in whom confidence was reposed; and fifteen hundred gentlemen, including military officers, all enthusiastically devoted to the king, and who, with the grenadiers, were stationed within the palace, but so ill armed, that rapiers, hangers, and pistols, were their only weapons. Mandat, the commander of the national guards, did indeed select sixteen battalions of his troops, which made a show of protecting the king; most of these were ill-disposed towards him, especially the artillery, and the rest remained to be determined by events whether they should act as friends or enemies. Petion gave an order to Mandat, who was a faithful royalist, if attacked, to repel force by force, and who did his utmost to dispose of his force effectively. While thus employed, he received several messages from the municipality to attend them for orders, and unsuspiciously repairing to their hall, which he unexpectedly found filled with Jacobins, he was arrested as having formed a design to massacre the people, and, as he passed down stairs on his way to prison, met his death by a pistol shot. The palace was soon completely beset by its assailants, who occupied the Pont Royale, in the vicinity of the Thuilleries, and placed fifty pieces of cannon on the opposite side of the river. About eight o'clock in the morning, Rœderer, the procureur-general-syndic, informed his majesty that the national guard was not to be depended on; that, from the overpowering force coming against him, nothing was to be expected but the murder of himself and family; and that the only way to prevent this fatal catastrophe was to take refuge with them in the legislative assembly. The queen, who was present, penetrating at once the motive of this advice, and indignant at the thought of appearing as petitioners for protection in the assembly, the great majority of whose members had always shown themselves so inimical to the royal interests, exclaimed, with energy, "Nail me rather to these walls than remove me from the palace." But there was no alternative for Louis but to accept this offer, or place himself at the head of the guards; and he did not hesitate to prefer the former, and overcame the scruples of his consort, by reminding her that this measure would place the children in safety. The king, queen, the two children, and the Princess Elizabeth, went on foot, escorted by three hundred Swiss, to the hall of the assembly, and arrived safely there, though not without encountering many perils and much insult. The appearance of the king in the assembly was a real victory gained by the conspirators against his crown. His majesty addressed the members, and said, "Among you I believe myself in safety, and I have come to prevent the commission of a great crime." It was moved by a member of the Mountain, that the debates could not proceed in presence of the king; and he was removed, with his family, to a small box or closet behind the president's chair, usually appropriated to the reporters of a public journal. They had, however, hardly seated themselves, when the attack of artillery began on the palace, and the king dispatched an order to the Swiss guard to lay down their arms; but his order arrived too late. He had forgotten, in the agitation of the moment when he left the palace, to order it to be surrendered, and the consequences of this neglect were most disastrous. The palace was forced, the greater part of the Swiss, and his other faithful adherents, cut to pieces, and even the lowest menial found in the palace put to death. As soon as the intelligence of the capture of the palace arrived, the suspension of the king was immediately decreed in a tumultuous sitting, where the deputies were mixed with bands of ferocious men, fresh from the carnage at the palace, and reeking with the blood of their victims, and with a ragged rabble of men, women, and children. During this last day of the ill-fated Louis's kingly dignity, he sustained innumerable insults with a calmness truly astonishing. At one o'clock in the morning, the king and his family were removed to the neighbouring convent of the Thuilleries, after having remained fourteen hours listening to debates in which they were treated with the greatest indignity. The plate, jewels, and money found in the palace, were brought and delivered up to the assembly; and one man, who appeared, from his dress, of the most indigent description, entered with a hatful of gold, and threw it down before the president. In fact, many of the poor deluded people seriously believed, that, in joining the insurgents in order to put down the constitution, they were acting a meritorious and heroic part, and therefore wished to avoid casting a stain on their proceedings by the imputation of theft.

INVASION OF FRANCE.

The news of the fatal events of the 10th August no sooner reached the ears of La Fayette, who was then at Sedan, than he addressed his army in favour of the king and constitution; but, finding them ill affected to the cause, he abandoned them, and with three of his staff attempted to leave France, but was made prisoner by a party of Prussians on the frontier, and thrown into a dungeon, from which he did not make his escape till 1794. Dumouriez recognised the decrees of the assembly in the separate army commanded by him, and in return was appointed by them commander-in-chief. The combined armies of Austria and Prussia entered France. The Duke of Brunswick's army consisted of 50,000 men, and, together with the Hessians, the Austrians, and French emigrants, amounted to 90,000; while Dumouriez had only 17,000 collected near the point from which the enemy was approaching. The allied army at first proved successful; and the intelligence of their having taken two garrisoned towns, and their approach towards Paris, spread general alarm and consternation. Meanwhile, the unfortunate monarch and his family had been removed to the Temple. The place so called was a small division of Paris, enclosed by gates of its own, within which debtors were accustomed to find refuge, the thronged state of its inhabitants rendering it peculiarly dirty, unhealthy, and dismal. In one of the angles of the enclosure was situated the palace of the grand prior of the order of the templars. It was built between a narrow court and a small garden, isolated from the main building; and its numerous turrets arose—which were called the great tower—a hundred and fifty feet in height, and consisting of four arched stories besides the ground floor, the circumference of which was only thirty feet within the walls. This tower was particularly gloomy within, from the immense thickness of the walls, and the impediments opposed to any view from its windows, by the iron bars and wooden outside lattices. It was surrounded by a deep moat; the staircase leading to the apartments was divided by six iron doors, provided with massy bolts; and it was guarded by three hundred men.

MASSACRE OF ROYALISTS.

On the alarm of the approach of the allies, the heads of the commune, or common council, who were now Robespierre, Danton, and Marat, summoned the populace by means of alarm guns, and enrolled them to march against the enemy. It was then proposed by those infuriated men that the domestic foes of the state should be destroyed before the foreign ones were attacked; and the force assembled marched to the place where the Swiss officers had been confined since the 10th of August, and, bringing them forth, along with numbers of nonconforming priests, and multitudes of suspected persons, with whom the prisons of Paris were then crammed, after having given them a mock trial, they were butchered in the most horrible manner, by the axes, pikes, and sabres of the mob, consisting of men and women, who, wading in blood, and covered with the same sanguinary tide, performed their dreadful office with transports of delight. Numbers of ladies were thus murdered; among whom, the innocent Princess de Lamballe, whose only fault was a sincere attachment to the queen, was literally cut in pieces, and her head—which still retained its uncommon beauty, and from which its fair ringlets hung in long tresses—fixed on a spear, and carried to the Temple, in order to be presented to the unfortunate cause of her accusation. This carnage lasted four days, and it is computed that not less than 4000 suffered. Nor did its frenzied contrivers intend that the massacre should stop there; for they had laid a plan to make it universal throughout France, in which they were, however, frustrated, from the people of the provinces being less excited than those of the capital, and less inured to blood. Disappointed in this, however, they caused about sixty royalists of distinction to be brought from Orleans and murdered at Versailles. Will it be believed that the legislative assembly was silent during these butcheries? But so it was; and not till the 16th of September was there any notice taken of them, when it was decreed that in future the communes should be answerable with their own lives for the security of their prisoners. The Duke of Orleans, who, we have said, returned to Paris at the federation, was believed to have been a prime instigator of these enormities; for though all despised him personally, yet his money was capable of being used as a powerful engine.

FORMATION OF THE NATIONAL CONVENTION.

The legislative assembly now ceased to act, and members from it and the constituent assembly were chosen, with others, to form the "NATIONAL CONVENTION." Robespierre, Danton, and Marat, were among the members, and occupied the place of leaders in the Jacobin party of the representatives of Paris, which, consisting of twenty, had not among that number above four or five who had not assisted at the late massacre. One of the first motions moved in the convention was for a decree to remove the king and the seat of government to the other side of the Loire, and to draw the army of Dumouriez round Paris; but this was overruled by Danton, who strenuously resisted the measure, and prevailed on the convention to reinforce that general. Danton, by this success, gained an ascendancy among the members, and was enabled to encourage and contrive with impunity many of those subsequent events of blood which have given his name so dreadful a distinction.

THE INVADERS OF FRANCE WORSTED.

Meantime, Dumouriez, who had received a reinforcement of federates from the provinces, was endeavouring to protract the march of the enemy till he could form a junction with the army of General Kellerman, consisting of 20,000 men, and Bonrnaville, from Flanders, with 13,000, together with new levies which he expected from Chalons. Before he could, however, accomplish this, he was attacked by the Duke of Brunswick, for two successive days, with little effect, and on the third the Prussians forced him to retreat. On the fourth day, Dumouriez encamped at St Menehould, and fortified it, where Bournaville's army joined him. The Prussians now attacked the army of Kellerman, who had 400 killed and 800 wounded, the loss of the Prussians amounting to a much greater number; and Kellerman, no longer opposed, formed a junction with Dumouriez. The Duke of Brunswick encamped his army within a short distance of his enemy, but it soon began to experience great distress for want of provisions, which were supplied to the French in great abundance. Heavy rains began to fall, and the cold, the wet, and the scarcity of food, together with the imprudence of eating in great quantities the grapes of Champagne, brought an epidemic distemper into his camp, which raged to such an extent, that 10,000 men were unfit for duty. Still the duke possessed an army much more numerous than that of Dumouriez, without attempting to attack his camp, or to force him to a battle. The secret of this conduct, which so much surprised his adversaries, was, that he had entered France with the idea of meeting but a feeble resistance from an ill-disciplined and ill-provided army, in which contrary factions prevailed, and also with an idea that the people, in general, were inimical to the measures adopted by their rulers. But it only required him to come in contact with their skilful and experienced generals, and to hear the enthusiastic shouts of "Vive le nation," which burst simultaneously from the French ranks at every onset, to convince him that he was in the midst of an able, hostile, and united people; and he foresaw, that, though he should prove successful in a general battle, his army must be weakened, and, in all probability, at length defeated by a reinforcement of the enemy, the strength of which he had no means of calculating. He therefore proposed a truce, and commenced a retreat towards Grandpré.

MONARCHY ABOLISHED.

The Austrians, under the Duke of Saxe Teschen, now laid siege to Lisle, which, after a fortnight's fruitless labour, they were obliged to abandon. War had been declared by France against the king of Sardinia, and the French army were every where victorious. They took possession of Saxony, of Nice, and the countries round it—of Spires, from whence they drove the Austrians, taking 3000 prisoners—and of Metz and Frankfort. In short, the revolutionists were triumphant, and the immediate consequence was an unanimous decree, that royalty should be eternally abolished in France; and this decree was, by the influence of the Jacobins, received with unbounded approbation in Paris, and throughout the provinces, where a thousand of their clubs were established. At the same time all titles, save that of citizen, were annulled; and it was decreed that the public acts should be dated from the year of the French republic.

TRIAL OF THE KING DETERMINED ON.

The Mountainists, having now triumphed in so far over the Brissotines, scrupled not to adopt any plan which afforded the smallest prospect of ruining their opponents; and they therefore brought forward, without delay, the question of how the deposed monarch was to be disposed of. The opposite party wished to save his life, and this of itself would have been sufficient to determine his unfortunate destiny. The Brissotines felt their weakness, and submitted to their enemies, because they knew any violent opposition would prove ineffectual—though they made a faint show of support, on the side of the king, to the last. A committee was appointed by the convention to make inquiry into the delinquencies of the king, and innumerable accusations were the consequence. In these charges against Louis, not even a show of truth or probability was attended to; and after torturing every event during his reign to which blame could be attached, into voluntary acts of his own, the whole was summed up by an absurd assertion that he had harboured an intention of massacring the whole convention, protected as it was by the national guard, and by all the other troops and people of Paris. Self-evident as these monstrous falsehoods were, the convention decreed that Louis should be brought to their bar to answer for them, and stand his trial for life. Robespierre exclaimed, "Summon him to the bar, and let us demand a reckoning for his crimes!"

At the time that the decrees were passing in the convention, which, one by one, led to the final unhappy fate of the royal family, they were subjected, in the gloomy and wretched apartments of the Temple, to every indignity, and treated with a malignant harshness, in order to account for which it is only necessary to say, that they were completely in the power of the communes of Paris, who, swayed in all their actions and opinions by their leaders, took pleasure in treating their distinguished prisoners with every refinement of cruelty. And this being the object kept in view by these individuals, it was of course their study to place such men only round their victims whose hearts never knew the touch of pity, and who could look, unmoved, on the meekness of the monarch, who never manifested, by word or sign, a spirit of revenge against those whose sole delight it was to wound his feelings, and add contumely to his misfortunes; and who beheld, without compassion or admiration, the pious, the pure, the noble-minded and disinterested Princess Elizabeth, devoting her every thought and action to alleviate the misery of the little band of sufferers. Surely she had done nothing to merit the hatred and contempt which she shared. And though the heroic, but, perhaps, not guiltless Marie Antoinette, whose unsubdued spirit was less resigned, refused to truckle to her persecutors, by exhibiting an appearance of what she did not feel, yet less brutal jailors would have respected this sincerity, and been moved by the strong attachment of the wife, and the yearning feelings of the mother, which were always so conspicuous in her. It was for the enjoyment of the domestic circle, and for its ornament, that the amiable Louis had been formed, and not for the ruler of a mighty nation, at a juncture when firmness of purpose was necessary, and great skill and talent would have been required to reform the state without revolutionising it, and to reconcile neighbouring potentates to the change. But we have said that the convention had determined to act at once as his accusers and judges, and he was accordingly summoned to appear at its bar on the 11th of December 1792.

TRIAL OF THE KING.

On the morning of that day, the king had retired, as was his usual custom, with his little son, to impart to him instruction, and to foster those talents which, even at the early age of seven years, were conspicuous to his paternal eye. But it was now resolved that he should be separated from this fondly cherished child; and he was torn from his arms, at the same time that it was announced to him that he was about to receive a visit from Chambon, the new mayor of Paris. Two hours, however, interposed between this intimation and his arrival, during which period the king, who heard the noise of the trampling of horses, and the sound of wheels incessantly increasing round his prison, was left to all the horrors of an impression that had fastened on his mind, that he was to be immediately murdered. When the mayor at length appeared, and read to him the decree of the convention, ordering him to their bar, his majesty's first remark was, "I could have wished not to have been deprived of the society of my son during the two hours I have been expecting you, but it is of a piece with the usage I have experienced for four months."

The king proceeded in Chambon's coach to the convention, which had now established itself in the palace of the Thuilleries, as it befitted the monarch of the people. The procession which accompanied the king consisted of three field-pieces, which moved in front, with a detachment of horse, while a body of 600 foot formed a line three deep on each side of his carriage, and the rear was brought up by three more field-pieces, and an escort of fusileers. At one o'clock it reached the Thuilleries, and Santerre appeared in the convention, and said, "Louis Capet" awaits the orders of the assembly. This announcement was followed by a deep silence; even the most tumultuous and lawless occupiers of the galleries became still as death, and every eye was turned on the door through which the king was to enter. Presently he made his appearance, with an air of majestic dignity. His misfortunes had overcast his features with an expression of the most touching melancholy, but it was unmingled alike with fear or with contempt for the tribunal before which he stood. This impressive silence was broken by Barrere, the president, who desired him to seat himself in an arm-chair provided for the purpose, and then informed him why he was brought before the convention. His majesty then listened attentively to a long string of charges brought against him, on which he was separately interrogated, many of them accusing him of the most cruel tyranny, and the most consummate hypocrisy. He answered to them, though shortly, with the utmost precision and frankness, and never seemed in the slightest degree to lose his self-possession, excepting twice, when accused of having distributed money to the poor for the purpose of acquiring popularity, and enslaving the nation, and when taxed with causing the bloodshed on the 10th of August. To the first charge he replied with animation, "I never knew pleasure equal to the power of relieving distress;" and to the second, he answered with deep emotion, "It was not I." All the written documents brought forward against him were then shown to him, most of which he decidedly disavowed any knowledge of. His majesty was then asked if he had any further defence to make. "I request," said he, "to have a copy of the accusation, and of the charges on which it is founded, and to be allowed counsel of my own." He was then informed that his two first requests were already decreed, and that he should in due time be informed of their determination respecting the other.

The king was then desired to withdraw, and was conveyed back to the Temple in the same way in which he was brought from it. His majesty had no sooner left the convention, than all was tumult and uproar. The leaders of the Mountain demanded that the king's execution should take place that very night. This was opposed, however, by a large majority, who insisted on indulging him with the nomination of counsel in his defence. His majesty being informed of this, Trouchet and Target were immediately named by him. The former accepted the office, but the latter, shrinking from the implied danger, refused the task. But M. Lamoignon Malesherbes, a man eighty years of age, in spite of his infirmities, and all personal risk, offered his services, which his king gratefully accepted. This old man had been twice nominated by the king, in the day of his prosperity, to be a member of his council, and he now magnanimously claimed a right to a similar office when it was attended with danger. Many of the Parisians were now softened, and in some measure convinced, by this zeal of Malesherbes—who was universally acknowledged to be a man of the most unstained probity, as well as of the soundest sense and respectable talents—and began to take some interest in the person of their sovereign; and De Seye, another lawyer of genius, added, by permission, his name to those of the king's counsel, from whom he was doomed to receive no effectual aid. Nor indeed did he expect it; and, therefore, his short remaining time was much occupied in preparing for that state "where the wicked cease from troubling, and the weary are at rest."

CONDEMNATION OF THE KING.

On the king's return from the convention, he was not allowed the society of his family, and his respectable and faithful valet, Clery, was the only person, save his counsel, allowed to approach him, from whom he could derive the smallest degree of consolation. Before his majesty's second appearance in the convention, he commanded his counsel to abstain from every effort to excite the passions of their audience in his favour, and to adhere exclusively to sound deductions from the evidence. The king left the Temple, on his second summons to the assembly, about nine in the morning, and was conveyed, as before, in the coach of the mayor. De Seye began the king's well-known defence, which he read without interruption. This defence was an able appeal, in the first instance, to the rights which had been allowed him as a constitutional king, and, should these at the present moment be disallowed, to that justice to which he was entitled as a private citizen; while he treated it as an absurd chimera, that Louis could, with the slender force under his command, ever for a moment have thought of turning their arms against the convention. When De Seye concluded his defence, the king added a few words, expressive of his conviction that he addressed the members for the last time, and solemnly avowing the clearness of his conscience with regard to any intended injury to his people. When the king withdrew, a long and fierce debate took place, on the motion of Manuel, to adjourn for three days, that the king's defence might be printed, and sent to the departments. On the contrary, it was insisted upon that judgment should be pronounced without separating. Such contradictory opinions inflamed the violence of the contending parties, and the Jacobins becoming perfectly infuriated, expelled Manuel. Vergniaut, one of the most able of the Brissotines, pled in vain, in a strain of almost unrivalled eloquence, that the fate of the king should be decided by the people. He even went so far as to reproach the Jacobins as the contrivers of the past massacres, and to prophesy the horrors that would ensue if ever Paris was given up to their rule—a prediction that was more than verified when that event did take place, and the reign of terror began. His representations were, however, now totally disregarded, and a final appeal was demanded on the question of the king's sentence, while the ferocious emissaries of the Jacobins surrounded the hall of convention on every side, and inspired the members with terror by uttering loud threats of vengeance if the sentence was not death. They swore, if he was acquitted, to go instantly to the Temple, and, having murdered him and his family, to inflict the same fate on all who had favoured him. This was sufficient, and the votes were immediately taken. When it came to the turn of the Duke of Orleans, the strong interest which pervaded the whole convention at that moment when they were sealing the fate of their sovereign, appeared much deepened: every eye was fixed on him; and when he pronounced the word "Death," a simultaneous shock seemed to be felt throughout the assembly. When the voting was finished, it appeared that there was a majority of fifty-three for the king's execution. At this juncture, Dumouriez arrived in Paris, with the intention of saving the king, if possible. He had gained a victory in the battle of Jemappe, by which he had secured the conquest of Flanders or Belgium, and, presuming on this, he expected to find his influence greater than it proved; but being, like his predecessor La Fayette, foiled in his attempt, he, like him, withdrew also to his army, and left the king to his fate. In fact, no one now seemed to intermeddle in the matter, so completely were the more moderate members of the convention overawed by the immense and sanguinary power of the Jacobins, whose overwhelming and increasing influence was soon to teach them that they were to derive no benefit to themselves from their tame and dastardly submission. When his majesty was informed by Garat, the minister of justice, of his sentence, he remained calm and composed, and delivered to him a paper containing a list of requests, which was read in the convention. It commenced with craving three days' respite; it then went on to beg that he might be allowed to see a person he should name; that he should be freed from the harassing watchfulness of the commune; that he should be permitted to communicate in private with his family; that they might after his death be allowed to retire whithersoever they pleased; and that those persons who were dependent on him might not be abandoned to poverty. The delay of the sentence was refused, which, when reported to the king, he said, "Well, I must submit." He was, however, gratified by an accession to his wishes respecting his family and dependents; for what would have been his feelings in his dying moments, could he have anticipated the horrors in store for them! The Abbé Edgeworth, who nobly braved all personal danger, was permitted to attend his majesty, and, accompanied by Garat, went to the Temple, where, after being narrowly searched, and treated in the most insulting manner by the guards, he was introduced to the presence of the king, at whose feet he fell, and bathed his hand with his tears. This manifestation of attachment, to which he had been lately so little accustomed, melted the unfortunate monarch also into tears. He read over to the abbé his last will, so full of religion, of affection, and of justice, in which his mind is pourtrayed in so lively a manner, but a copy of which we have not room here to insert. He then conversed on various topics, inquired for his friends, and forgave his enemies, among whom he particularized the Duke of Orleans. After this, he rose to make his last visit to his family, in order that, when this heart-rending trial was over, he might fix all his thoughts on heaven.

THE KING EXECUTED—JAN. 21, 1793.

This interview lasted an hour and, in its commencement, gave hopes which had long been strangers to the bosoms of the affectionate circle, who, seeing him enter their apartment without the usual restraints, and being ignorant of the fate to which he was doomed, believed that this was the dawn of a brighter day. He was without guards—he was comparatively at liberty—and it must be so. But they again looked upon him, and there was no joy in his countenance; he was also silent—he embraced them with convulsive clasps—his firmness gave way, and the tears he could no longer repress burst forth. They anticipated their misfortune, and their cries became so frantic, that they were heard beyond the precincts of the Temple. When his majesty was obliged to leave them, he could scarcely separate himself from their clinging embraces. He gave them hopes of another meeting; but the last expressive look he threw upon them told another tale, and laid his wife and his sister senseless at his feet. He returned to the Abbé Edgeworth. "Alas," he said, "why do I love with so much tenderness, and why am I so tenderly beloved?" Strong emotion overcame him, and he sighed deeply, and wept for a few minutes, before entering on religious subjects with the abbé. He then prepared himself by confession, and was granted the request to have the sacrament administered to him the next morning. The abbé, seeing that the king was much exhausted, prevailed on him to lie down, and, though certain that he had not many hours to live, he slept tranquilly. At five in the morning, he rose, dressed himself, heard mass, and partook of the sacrament with the deepest feeling of devotion and trust in God. At about eight o'clock, the commissioners of the commune came to announce that the hour of execution was fast approaching. The king descended the stairs with a firm step and placid countenance to the carriage which waited for him. Silence reigned among the crowd, and he proceeded with the Abbé Edgeworth, and guarded by 1200 men. His majesty continued to read a book of devotion with great fervour, till he arrived at the guillotine, which stood in the Place Louis Quinze. He ascended the platform, and addressed a few words to the people, in which he solemnly protested his innocence, and prayed for and forgave his enemies. He was still speaking, when the ferocious Santerre caused the drums to drown his voice, and, in a few moments more, his head was severed from his body. A request was made by a faithful attendant, to be allowed to bury him at Sens, where the royal family were interred; but this was refused, and the monster Legendre moved that it should be cut into eighty-four pieces, one sent to each department, and the heart to the convention. The body was, however, thrown into a hole in the churchyard of St Mary Magdalen, which was filled with quick-lime, and guarded till it was consumed, when pains were taken to obliterate all marks of where he had been laid, by levelling the ground.—Thus perished Louis the Sixteenth, by a sentence unanimously pronounced unjust and infamous by all Europe, and which finds no parallel in history. Benevolence seems to have been the paramount quality of this monarch, from which his abhorrence of being implicated in the shedding of blood arose, and which at last caused his own to flow on a scaffold.

DESERTION OF DUMOURIEZ.

Having arrived at this epoch, our remaining details must be still more contracted, while we give an account of some of the leading events which took place in France, till the time arrived when a greater degree of tranquillity was restored to the nation.

A short time before the death of Louis, Dumouriez, as we have related, gained the battle of Jemappe, and became the conqueror of the Flemish provinces. These provinces were immediately taken possession of by the convention, who treated their inhabitants with every indignity, pillaging and tyrannising over them without remorse. This conduct was indignantly resented by Dumouriez, who had passed his word for their good treatment, and who, putting an implicit but rash faith in the subordination of his troops, and their attachment to his person, resolved to oppose the measures of the convention, and make a stand in favour of the king, in which we have seen that he failed. But though disappointed at the time, he did not abandon his intention of reducing within bounds the power of the convention, and the course of the revolution. Meantime, he obeyed orders for making an attack on Holland, which, from the manner of disposing his troops, was unsuccessful. In short, the French forces were so entirely defeated in their attacks on various places, that Dumouriez was suspected of treachery, and commissioners were sent from the convention to inquire into his conduct. These persons craftily insinuated that they had come to advise with him on a counter-revolution. Deceived by this false pretence, and being, from the confidence he placed in his army in general, no way slack in expressing his opinions on the subject, he at once made known to them his determination of putting an end to the reign of the convention, and re-establishing the constitution, with a king at its head. The convention, informed of his designs, summoned him to appear before it. He had, however, too great a respect for his head to attend on this summons, and disobeyed. Four deputies were again sent with orders to arrest him at the head of his army, but Dumouriez took them into custody, and sent them to the Austrian army as hostages for the safety of the French royal family, and presently followed them with only 700 cavalry and 800 infantry, the rest of his army preferring to retain their allegiance to the convention, who set a price on the head of their general. Of the troops which passed into the Austrian army with Dumouriez, the greater part deserted from him, and after residing in Germany for some years, he came to England, where he remained till his death, which took place a short time after the restoration in 1814.

COMPLETE TRIUMPH OF THE JACOBINS.

The Mountainists accused the Brissotines of a participation in the conspiracy of Dumouriez. Feeling that it was a fortunate moment to rid themselves of all opponents, Robespeirre attacked them violently in the convention, and Marat in the Jacobin club, and it was proposed to bring them to trial, or rather to decide on their heinous crime without attending to a form of trial. Failing in this measure, the Jacobins had recourse to their old mode of warfare, and prepared an insurrection to attack them while in the hall of the convention, on a certain day. Warned, however, of this, the Brissotine party did not appear, but procured a body of federates, consisting of 400, from Brest, which sufficed, though a weak number, to keep the murderers in check for a time. Fear prevented the Brissotines from imputing this plot against them to the opposite party, and they affected to believe it the contrivance of the nobles and priests. Encouraged by this pusillanimity, Robespierre impeached by name, in a short time afterwards, the leaders of the Brissotines, as implicated in Dumouriez's crime. He was, however, in his turn denounced with the Jacobins, against whom it now seemed the intention of the opposite party to make a stand. They nominated a commission of twelve members, composed partly of their own party, and partly of neutrals (who formed a part of the convention called the *Plain*, which we have never mentioned from its being occupied by the neutrals), to watch the citizens disposed to anarchy, in which employment they showed much energy, by arresting and committing to prison one of the most furious ringleaders of the late insurrections. But this bold step was not followed up; and taking advantage of this want of decision, the convention was surrounded by a mob, who compelled the recal of the commission of twelve, and the liberation of the man they had imprisoned. This concession showed plainly that the power of the Brissotines was at an end, and that a mob could at any time command them; and the Jacobins determined to be rid of them by a final stroke. On this occasion, during a sitting of the convention, it was surrounded by an armed force of 2000 federates instructed for the occasion, who brought in their train artillery, with grape-shot and shells, and who, with the multitude on the outside of the building, vociferated a demand for the death or banishment of twenty-two of the Brissotines, who were pointed out as accomplices of Dumouriez, including in this list the ministers. After experiencing great terror, and during a degree of confusion, where debate was impossible, it was, however, determined to increase the number of the proscribed to thirty, most of whom were arrested; while those of the party who escaped were scattered in the provinces, where they endured all manner of hardships, and were many of them at last put to death. Meantime, sentence of death was executed on twenty-two of the imprisoned deputies, who were guillotined.

FATE OF THE ROYAL FAMILY.

The unfortunate queen was now, too, to suffer the same fate as her husband. She was separated from her family and sent to the prison of the Conciergerie, where she spent her time in tears and prayer, till, on the 10th of October, she was dragged to execution in an open cart, amid the most cruel insults, and guillotined in the same place where Louis suffered. The pious Princess Elisabeth was also doomed to the guillotine, and met her death with the most saint-like resignation, on the 20th of May (1794). Of the dauphin, it is almost impossible to relate the dreadful end, without a shudder of horror. This poor innocent child was delivered to the keeping of one of the most atrocious and blood-thirsty villains in Paris, with an order not to *murder* him, but to *get rid* of him, which this monster accomplished by slow degrees, and by means of hardships, ill usage, and starvation, till he found refuge in an early grave. And last of all, we shall mention the princess royal, who was exchanged with the Austrians for La Fayette, and some other distinguished prisoners.

Let us also mention here, that a few days after the death of the queen, the same fate overtook the infamous Duke of Orleans, who had assumed for some time past the absurd appellation of Citizen Egalité. Neither this assumption of a name so much to the taste of the Parisian mob, nor his many other disgraceful acts of conciliation, availed him at last; and after being tried as a conspirator against the government at Marseilles, he was acquitted, but sent to Paris, where he shared the fate so common at the period, and was brought deservedly under the axe of the guillotine, amid the execrations of all parties.

ASSASSINATION OF MARAT.

It was now that Marat, glutting his sanguinary appetite with the blood of proscribed royalists, became such an object of detestation to a young maiden, named Charlotte Corday, residing at Caen, that she formed the extraordinary resolution of putting an end to him and his enormities. She accordingly journeyed to Paris; and demanding, at his own house, to see him, she was ushered into an apartment where he was taking a bath. After some conversation about the refugees in Normandy, Marat remarked, that, within the space of a few days, they should all lose their lives by the guillotine. These words were the signal for his own death, for at that instant the young woman drew a knife from under her robe, and plunged it to the haft in his heart. She was instantly seized, tried, and condemned to death. Her answers on her trial were all given in the most heroic spirit. She professed to have considered deeply, before its perpetration, all the consequences of the deed she meditated, and to glory in having killed one execrable monster, to save the lives of many thousands of her unhappy countrymen. It is related as a singular circumstance, that, at her execution, she was not insulted by the mob. Charlotte Corday was beautiful and young, dignified and modest; and these advantages, together with her having evidently acted in this deed of self-devotion from a principle of love to her country, was probably the reason that she was treated with comparative respect. After the death of Marat, Robespierre and Danton were the principal leaders of the Jacobins, and began their career by a public renunciation of all religion, and the denial of a Supreme Being; and marriage being declared only a civil contract, to be entered into and abandoned at will, these enactments led to the abolition of all domestic virtue, and paved the way for the bloody acts which were to follow.

ENGLAND PROVOKES WAR WITH FRANCE.

It now became the determination of England to require of the convention an explanation of a sort of manifesto which had been published by it some time before, declaring, "that they would give assistance to any nation that wished to recover its liberty;" as also why the Scheldt had been opened contrary to a former agreement. To these questions the convention refused to reply, and immediately decreed a war against England; upon which an auxiliary army was sent to Holland, with the Duke of York as its commander-in-chief. France was at this time waging an unsuccessful war against various antagonists, while an unheard-of system of terror was carried on in her interior, where a mere charge or suspicion was sufficient to deprive any one of life and goods. The effects of this were dreadful. There was no appeal from the horrid court, designated the revolutionary tribunal, in which the suspected person appeared; and it became so crowded with unhappy people in this predicament, that it was necessary to divide it into four sections, in each of which the work of death went on with equal vigour. And here it was that Danton, who had incurred the hatred of Robespierre, was condemned to perish by the guillotine, in company with many more whose names were equally infamous, although all were condemned on false charges.

FATE OF ROBESPIERRE.

Robespierre now became an object of universal dread; there was no one hardy enough to attempt even to contradict him. At that time it is said that "fifty were put to death each day as regular task-work." In the midst of this work of destruction, he proposed to acknowledge the existence of a Supreme Being by a public act, the details of which are shocking to the Christian ear. But his many murders began to stir a spirit of resentment in the inhabitants; and, though still supported by the Jacobin club, he had his enemies also among the Mountainist party, who feared for themselves the fate of Danton. Robespierre saw with some alarm that he was losing his popularity, even among the most ferocious of the people, and he began to affect sentiments bordering on the puritanism of Cromwell's time; and in this spirit he framed a law, in which so many crimes were stated as being subject to the penalty of death, that it was thought no one could be exempt from impeachment. This decree gave especial alarm to the convention, as they observed that no mention was made of their personal inviolability; but that, on the most frivolous pretence, Robespierre could transfer them, without ceremony, from their seats in the assembly to the guillotine. But from this moment secret revenge was vowed against him by his old associates of the Mountain. In these circumstances, he sought comfort and courage from his still staunch friends in the Jacobin club, where he was encouraged to denounce his enemies in the convention. After a considerable delay, he determined on this course; and once more took his seat there, and stormed against a thousand abuses in the different departments conducted by the separate members; but, being foiled in this attempt by the general voice, he again withdrew, to carry his complaints to the Jacobin club. Meantime, a list of proscribed members, said to be copied from one in the handwriting of Robespierre, was handed about, and a league was formed against the common enemy, whose fall it was believed was now at hand. On the first visit he again paid to the convention, he was received with every hostile indication, and, after a most furious meeting, the result which followed was the arrest and imprisonment of this blood-thirsty man, and a few of his no less sanguinary associates. They were not suffered to live many hours after, but perished on that scaffold which had been so long the scene of their own unhappy triumphs.

RESTORATION OF ORDER.

After the execution of Robespierre, the government set themselves vigorously to the task of freeing the convention entirely from the dominion of the Jacobins, and by condemning some to death, and others to banishment, effected their purpose in spite of one of the most desperate mobs which had ever been raised in Paris, and which violently assailed the convention. The firmness, however, with which they were attacked in return by the national guards, restored order, and society began to recover its confidence, and some portion of its usual tone; and very soon the natural character of the nation, with an elasticity peculiarly belonging to it, once more exhibited its usual vivacity.

MILITARY TRIUMPHS OF THE FRENCH REPUBLIC.

The last time we mentioned the armies of France, that of the north was thrown into utter confusion by the defection of Dumouriez, while it still remained in the neighbourhood of a large body of the enemy; while the most active operations were determined on by the allies, which consisted of every European nation, excepting Switzerland, Sweden, Denmark, and Turkey. Thus the republic was menaced by foes on all its frontiers. But in 1705, when we now again notice the state of the French armies, the tide of fortune had turned in their favour, and they were victorious on all sides. England had been, after great loss, forced to leave the continent; the Duke of Brunswick had made peace with France; the Prussians, Russians, and Austrians, all owned her superiority, by being no longer able to give her effectual molestation. Much of this triumphant success is to be accounted for by the numerous levies raised to reinforce the armies, and the determined spirit of resistance to any attempt against the republic manifested by the people, while it seemed as if, for some wise purpose, Providence itself assisted the French arms. The further triumphs of this gallant nation—the subjection of the republic by one extraordinary spirit, who became a more arbitrary ruler than any of its kings—and the final restoration of the Bourbon family by the arms of combined Europe—are events which cannot be treated of in the present sheet,, but may be taken up at some future time. We must in the mean time entreat the pardon of our readers, if, in describing the sanguinary excesses into which the revolutionisers of France were plunged, any one should think that we have used language—not too strong perhaps to be applied to such violations of humanity, but not sufficiently tempered with a reference to the imminent fear which the revolutionists had reason to entertain lest a reaction might be produced by foreign arms, and a worse fate befall themselves. In so limited a sketch as the present, it is difficult to advert on all occasions to motives and to palliating circumstances; but we are ready to allow that he who judges of the French reign of terror without a consideration of the irresistible principle of self-defence, and some allowance at the same time for a free-spirited nation just let loose from the most odious bonds, not only does injustice to his fellow-creatures, but commits a solecism in philosophy.

EDINBURGH: Published by WILLIAM and ROBERT CHAMBERS, 19, Waterloo Place; also by W. ORR, Paternoster Row, London; and W. CURRY, Jun. and Co. Sackville Street, Dublin. Sold by John Macleod, Glasgow, and all other Booksellers in Scotland, England, and Ireland.—Published once a fortnight. Stereotyped by A. Kirkwood, and printed by Ballantyne and Company, Paul's Work.

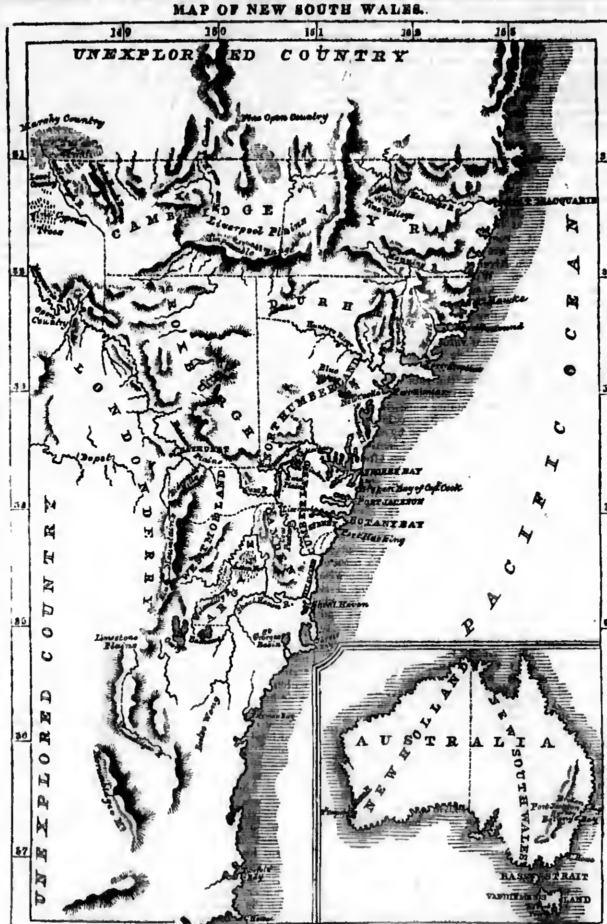
EMIGRATION TO NEW SOUTH WALES.

AUSTRALIA, or New Holland, is an immensely large island, situated in the Pacific or Indian Ocean, at nearly a similar distance from the south pole that Great Britain is from the north, and is thus with relation to us at the opposite extremity of the globe.* It is by far the largest island in the world, and is indeed entitled to the name and character of a continent, being in length from east to west nearly 2000 miles, and in breadth from north to south 1700. It lies between 9° and 38° of south latitude, and 112° and 153° east longitude. New Holland was discovered by the Dutch in 1616, and it was by them it was so called. The Dutch, however, having done little more than merely point out the island, it was afterwards visited and more minutely explored by several English navigators, and amongst these by the celebrated Captain Cook, who bestowed upon its eastern coast the name of New South Wales. Its distance from Great Britain is about 16,000 miles by ship's course. The circumstance of its being situated at the opposite end of the globe, has the effect of reversing the seasons in their relation to ours. Their winter is our May, June, and July; their summer our November, December, and January. Its being situated so much farther east than we are, again affects the relations of time with regard to day and night. The sun rises there ten hours sooner than with us; and thus, when it is five o'clock in the morning in New South Wales, it is about seven o'clock of the previous evening in London. As these changes, however, come gradually upon the voyager to these lands, he is unconscious of their taking place, and is only made aware of that which has occurred in the position of the seasons by the names of the months. Van Dieman's Land, another Australian colony, which we intend to describe in a subsequent sheet, lies to the south of New Holland, from which it is separated by Bass's Strait, a narrow channel of the sea.

MAP OF NEW SOUTH WALES.



GENERAL DESCRIPTION.

The general appearance of New South Wales from the sea is very far from being inviting, presenting immediately on the coast a continuous front of bold cliffs and mural precipices, unbroken for many miles together; behind these, again, and running generally parallel with them, at an average distance of about 40 miles, rises a chain of rocky, precipitous, and almost impassable mountains, extending along the whole eastern coast. These are called the "Blue Mountains." This unpromising appearance of the shores of New South Wales is not removed upon your landing. For five or six miles interiorly the land continues barren and rocky, presenting little other signs of vegetation than a few thinly scattered stunted shrubs and dwarf underwood. At this distance, however, inward, a marked change begins to take place: the soil improves, and begins now to be encumbered with tall and stately trees, which soon again thicken into a dense but magnificent forest, indicating, indeed, a more luxuriant soil than that passed, but scarcely less discouraging to the settler. Still progressing inwards, however, from six to nine miles farther, another change takes place. You have cleared the forest, and the promised land lies before you; improving now with every step you advance; now presenting an endless variety of hill and dale, covered with the most luxuriant vegetation; now extensive plains, resembling the finest parks in England—a resemblance which is made the more striking from their being similarly interspersed with magnificent trees, just numerous enough to add beauty to the land, without encumbering it. This scene, which is bounded interiorly by the Blue Mountains already spoken of, is, with few and not very important exceptions, that which the whole of the eastern coast of New Holland exhibits, and, as a general description, is agreed to by all who have spoken of it. The colonized portion of New South Wales is divided into ten counties or districts: these are, Ayr, Cumberland, Cambden, Argyle, Westmoreland, Northumberland, Durham, Cambridge, Roxburgh, and Londonderry. The first seven of these counties lie between the Blue Mountains and the sea; the three last interiorly beyond them. Ayr, Durham, Northumberland, Cumberland, and Cambden, have all of them the coast for their eastern boundaries; thence stretching each of them more or less inward. The other four counties are entirely inland. This disposition the reader will at once perceive, by referring to the map. Taking the coast line, we begin with the county of

AYR.

the most northerly of the range of counties, bounded by the sea on the east. Its length, from east to west, is about 120 miles, stretching inward; and its breadth, or line of coast from north to south, about 65 to 70. This county is remarkable for the vast proportion of high, rocky, barren, and mountainous land which it presents; it is also, in general, so thickly timbered as to give the greater part of it the appearance of one immense forest. The quantity of cultivatable land, therefore, in this district, is comparatively exceedingly small; and though there are some good tracts occasionally to be met with, it is not, on the whole, by any means a desirable quarter of the colony to settle in. The climate, too, has been found to be highly unfavourable to wheat; and the hills are bleak, poor, and brushy, and not well adapted for grazing. Port Macquarrie, one of the penal settlements of the colony, is in this county.

DURHAM.

The limits of this district are not yet properly defined. On the map it is laid down as extending on the coast from Farquhar's Inlet to Port Hunter,

* The authorities from which this sheet has been chiefly compiled, and to which we refer the reader for further information, are, "A Description of the Colony of New South Wales," by W. C. Wentworth. Whittaker, London.—"Present State of Australia," by Robert Dawson, Esq. Elder and Co., London.—"Two Years in New South Wales," by P. Cunningham, surgeon, R.N. Colburn, London.—"Authentic Information Relative to New South Wales and New Zealand," by James Busby, Esq.—Observations on the Colonies of New South Wales and Van Dieman's Land," by John Henderson. Baptist Mission Press, Calcutta.

a distance of about 75 miles, and stretching about 100 miles exteriorly. There is, however, but a small portion of this located, as it is called, that is, possessed by settlers; the general appearance of this district, so far as it has been explored, like the greater number of the other districts, is exceedingly varied, often presenting the most beautiful scenery, and equally often the reverse: on the whole, it does not seem to be by any means rich in suitable localities for the agricultural emigrant. Notwithstanding, however, this unfavourable character when generally spoken of, it yet contains some of the finest lands in New South Wales; these are to be found in the neighbourhood of the Hunter and Patterson rivers, on the south and south-east side of the county, as laid down in the map. The fertile vallies and soft green undulating hills of this part of the country are spoken rapturously of by all who have seen them; they are, however, of course, all already located, and not an acre worth taking can here be had, except by purchase from the present proprietors. In this district is situated the large and commodious harbour of Port Stephen, and the township of Maitland, the capital of the district, consisting of upwards of 700 souls. The next district pursuing the line of coast is

NORTHUMBERLAND,

lying between Port Hunter and Broken Bay, a distance of about 55 miles, and extending inland about 80 miles. This county possesses the usual proportions of grazing land, barren tracts, and fertile regions, but, like every other part of New South Wales, is greatly deficient in good roads. The best lands here, though it possesses many other beautiful and desirable localities, are to be found in the neighbourhood of Patterson River, which divides it from the county of Durham. Within this county is situated the town of Newcastle, so called from the abundant supply of coal which it affords; the whole surrounding country, as well as a line of coast extending from 60 to 70 miles on either side of it, presenting evidence of its abounding with that valuable mineral. A considerable trade in this article is carried on between this port and Sidney, the metropolis of New South Wales, where it is sold at the rate of 20s. to 21s. per ton, the price at the pit mouth being 5s. to 6s., and the freight 15s., the distance somewhat less than 100 miles. The coal mines at Newcastle are in the hands of government, and are worked by convicts, or, as they are called in the colony, *second* sentence men, being those who have committed offences after reaching their first destination; men, in short, who are banished not to, but from, Botany Bay. The New South Wales coals are said to be of good quality, burning well, but generally small and dirty. Notwithstanding the abundance of coal, however, wood is preferred in the colony for burning, perhaps in some measure owing to the circumstance of their fire-places being exclusively fitted for the latter. The town of Newcastle itself, besides its collieries, is not otherwise remarkable than as being a government station, as it possesses only about 200 free inhabitants. It contains, however, a church, barracks, storehouses, and jail, with a small depôt of military. About 25 to 30 miles south of Newcastle, and still within the county of Northumberland, there is another bay or harbour, bearing the whimsical name of "Reid's Mistake," and which we notice chiefly on account of that whimsicality, and of the circumstance which gave rise to it. A worthy skipper of the name of Reid had been dispatched from Sidney for Newcastle, to procure a cargo of coals. Not being so well acquainted with the coast of New South Wales as with that of Fife, he entered the harbour which now so flatteringly perpetuates his name, found abundance of coals, loaded his ship, and returned with flying colours to Sidney, never dreaming all the while but he had been at Newcastle. The "mistake" was soon discovered, and poor Reid's blunder put in a fair way of being handed down to a remote posterity.

CUMBERLAND.

Following out the line of coast as originally proposed, we now come to the county of Cumberland, which has a coast line stretching southward of about 56 miles, viz., from Broken Bay to Coal Cliffs, about 18 miles south of Port Hacking, and running inland about 40 miles. This county, though one of the smallest, and in point of fertility of soil one of the worst in New South Wales, is nevertheless the most important of the whole, from its containing the principal towns in the colony, and amongst these Sidney, the capital. In this county also is situated the celebrated Botany Bay, a name associated in this country with every thing that is infamous. This celebrity it has acquired, however, merely from the circumstance of its having been one of the first penal settlements, or receptacle for banished convicts, which was established in New South Wales. There are many places in that country to which they are now sent as well as Botany Bay; indeed, thousands of them never see the latter place at all, being sent to stations at a great distance from it. The towns in this county are Sidney—the metropolis, as we have already said, of New South Wales—Paramatta, Windsor, and Liverpool. Sidney is situated about seven miles inwards from the head of Port Jackson, one of the noblest harbours in the world. It is built upon two necks of land, with a valley between called Sydney Cove, possessing a depth of water which enables vessels of the greatest burthen to come close to the land. Thirty or forty years ago, the ground on which Sidney stands was a barren desolate wild, covered with wood, and tenanted only by savages and the beasts of the forest. It is now occupied by a large and thriving town, with a population of upwards of 10,000 souls, and where are to be found more than all the conveniences and luxuries of a British town of the same extent—regular and handsome markets, public seminaries, banks, extensive warehouses, hotels, distilleries, breweries, steam-engines, stage-coaches for different parts of the colony, four newspapers, the Sidney Herald, the Sidney Monitor, the Sidney Gazette, and the Australian, equally respectable looking periodicals with any published in this country; and, in short, every thing, as we have already said, of which a British town of similar size can boast.

Next to Sidney in importance, though much inferior to it, is Paramatta, situated at the head of the narrow inlet of the sea in which Port Jackson terminates above Sidney. Between the latter place and the former, a distance of about 16 miles, there is frequent and regular communication both by land and water; two coaches, one morning and evening, and two passage-boats, daily plying between the two places, the fare of the former 4s. inside and 2s. outside. Nothing can exceed the beauty of the scenery which presents itself on all sides as you proceed to Paramatta by water, the sea generally smooth as glass, or but gently rippled by a slight breeze; innumerable little promontories covered with wood to the water's edge, stretching into the sea, and forming a corresponding number of beautiful little bays and inlets in endless succession and variety. Paramatta contains about from 2000 to 3000 inhabitants. The greater part of the houses here are built of brick or white freestone, and being for the most part unconnected with each other, cover a greater extent of ground altogether than its population would seem to warrant. The situation of Paramatta is exceedingly delightful. It lies in a spacious hollow, covered with the richest verdure, and surrounded by hills of a moderate height. Here, too, are churches, hotels, taverns, seminaries, &c., and all the other appendages of a considerable country town, with a military and convict barracks, jail, government house, and the female factory, an establishment for the reception of incorrigible female convicts. Many of the private houses are of elegant construction, with parks and gardens attached; the place altogether thus forming rather an assemblage of cottages than a town: the streets, however, are regularly laid out, running north and south-east and west. Pursuing an inland course for about 21 miles, the traveller next arrives at Windsor, containing a population of about 1000. From Paramatta to this little town a coach runs three times a-week. Windsor, which, in the description of its buildings, much resembles Paramatta, is built upon a hill close by the river Hawkesbury, which forms the north and the north-western boundary of the county, and which, after a circuitous route of about 140 miles, discharges itself into Broken Bay. Windsor also contains a government house, and a very handsome one, with extensive gardens, &c.; two churches, a jail, court-house, military and convict barracks, taverns, inns, shops, &c. The lands in the neighbourhood of Windsor are exceedingly fertile, but this advantage is more than counterbalanced by its extreme liability to inundation from the Hawkesbury, which has been known to rise to the almost incredible height of 93 feet above its ordinary level. Inundations of 70 and 80 feet are of frequent occurrence, and the consequences to settlers within its reach are often fatal to their lives, and always ruinous to their circumstances. The town itself, which is built on an eminence of about 100 feet above the level of the river, has hitherto escaped these tremendous overflowings; but as it seems to be but a matter of a few feet, at best their safety does not seem very securely established. Of course, no new settler would, or at least no settler ought to establish himself within the reach of this fearful calamity, by which in one moment he may not only lose the fruits of many a year of toil and labour, but also his life. It may be readily conceived what an extent of country must be laid under water by these inundations, when they rise in the channel of the river to a perpendicular height of 70 or 80 feet. The cause assigned, and with good reason, for these great and sudden rises of the Hawkesbury at Windsor, is its near vicinity to the Blue Mountains, which, as we have already said, run parallel to the coast at an average distance of 40 miles, and from which the former is but a few miles distant, and is thus immediately under the influence of the mountain torrents, which run through various channels into the river. Next to Windsor in importance is Liverpool, at the distance of about 18 to 20 miles from Sidney, in a south-west direction. Between these two places a stage-coach runs three times a-week. Liverpool is situated on the banks of George's River, which discharges itself into Botany Bay. It contains about 1000 inhabitants; possesses a church, two or three good inns, stores, court-house, jail, and the usual accompaniments of a town in New South Wales, a convict and military barracks. The soil around Liverpool is of a very indifferent quality; but as the town occupies a central situation between Sidney and some fertile districts in the counties south and west of it, it is, notwithstanding, a place of considerable bustle and of rising importance. George's River, on which it is situated, and which is about half the size of the Hawkesbury, is navigable for boats of about 20 tons burthen as high up as the town. Recurring again to the coast line, we come to the county of

CAMDEN,

extending south from Coal Cliffs to Shoal Haven, a distance of about 35 to 40 miles, and stretching interiorly north about 60 miles, with an average breadth of about 20 miles. There are not yet any towns in this county. It possesses, however, an average quantity of fertile land, but is greatly deficient in water; the very limited supply which it possesses chiefly proceeding from branches of the Cow Pasture and Wingecarabee rivers. This important desideratum—the want of water—operates, as might be expected, greatly against the prosperity of the district, since, without it, its fertile plains can have no temptation for the settler. Nor is this deficiency of water confined to the mere shortness of the supply necessary for the irrigation of the soil, but to human existence. Cunningham, one of the authorities referred to at the bottom of the first page of this sheet, relates, that he "travelled for 12 miles once along one of the main roads (in this county) in the height of summer, yet could only obtain one solitary drink of hot muddy water throughout all that distance." Cambden, though not remarkable for its extent of cultivatable land, possesses, perhaps, a larger proportion of pasture land than any in the colony, and this of an acknowledged superiority in point of quality. The most flourishing local district in this county is the Illawarra, situated at the foot of a mountain of that name, a few miles inland from the sea-coast, and one of the most beautiful and fertile localities in the whole colony. Leaving now the sea-coast, we take the range of inland counties: these we have already described all lying between them and the sea. The first in this order is

ARGYLE.

This county is about 60 miles in length, and of an average breadth of about 25 to 30. About the one-half of it is indented, as it were, between the county of Cambden on the coast, or eastern side, and the county of Westmoreland interiorly. This is one of the finest districts in New South Wales, producing wheat and other agricultural commodities of the first quality, and in the greatest abundance. Large tracts, too, of the best pasture land are here every where to be met with, and, from its geographical position, its climate is of the most delightful kind, highly favourable not only to the rearing of every description of cattle, but rendering it capable of producing, in great perfection, all the fruits and vegetables of Europe.

All these advantages, however, have been hitherto counteracted to a great extent by the want of good roads, and more particularly by the want of one to Sidney, the great mart for all colonial produce. One serious effect of the absence of roads in this beautiful and delightful district, has been to prevent the raising of a greater quantity of grain than was necessary for the mere consumpt of the grower, who, having no means of bringing a superfluity to market, is without any inducement to produce it. This evil, however, is likely to be soon remedied, if indeed not already done, as we perceive, by a Sidney newspaper of 28th June 1832, that the landholders and others of the county had received a favourable reply to an address on the subject, which they presented to the governor on the occasion of his making an excursion into the southern districts of the colony—his excellency promising them that a road to Sidney would be completed without delay. When this shall be done, and some good interior roads besides constructed, the county of Argyle cannot fail to become one of the wealthiest and most important districts in the colony. Adjoining Argyle, and now proceeding northward interiorly, we come to the county of

WESTMORELAND,

stretching from north to south about 80 miles, and averaging in breadth about 40. This is the most mountainous district in the settled portion of New South Wales; and although none of these are of any great height (the highest not much exceeding 3000 feet), yet they are so numerous, extensive, and withal so barren, that but a very small portion of cultivatable land is left. It is not, however, without some fertile spots, and some excellent grazing districts. Amongst the best of these is an extensive flat called Emu Plains; but the general character of the country is highly unfavourable to the agriculturist. There being little more deserving of particular notice in this county, we proceed to the adjoining county of

LONDONDERRY,

situated behind the Blue Mountains, and bounded on the north and east by the counties of Westmoreland and Roxburgh, and thence stretching south and west interiorly, but without any definite limits being yet assigned to it in that direction. This county presents an irregular and varied surface. It is, however, comparatively lightly timbered, and generally easily accessible; but, although particularly adapted for grazing, it presents but a small portion for the plough, and that consisting merely of occasional patches on the banks of rivers and streams. As a grazing district, however, it is not inferior to the best in the colony, and, in this point of view, is an exceedingly desirable place for the settler, who will the less regret its general unfitness for agricultural purposes, that its distance from a market, and the almost impassable tract of mountainous country which intervenes between it and Sidney, renders live stock the only description of property which could be made available to any extent. Proceeding northward, we next enter the county of

ROXBURGH,

separated from the sea by the counties of Northumberland and Durham, and lying beyond the Blue Mountains. The county of Roxburgh is about 100 miles in length, north and south, and about 70 miles of average breadth, from east to west. Here there is also a great proportion of hilly and barren land; but it possesses one tract in particular of remarkable beauty and fertility, called Bathurst Plains, consisting of many thousand acres of the finest pasturage. These are now covered with the flocks and herds of settlers to an immense amount, this territory alone furnishing the greater proportion of the whole quantity of wool exported from the colony. It has also acquired great reputation for its dairy produce, and is considered, with regard to its cheese, as the Cheshire of New South Wales. Settlers here, however, labour under the same disadvantage with all those in the interior districts, viz. the being far distant from any market. This, however, materially affects the agriculturist only, and not the grazier, whose property can transfer itself. The rich territory of Bathurst Plains was discovered only a few years since, and was then considered, as it still is, a discovery of the highest importance to the colony. Nearly the whole of the available lands in the counties near the sea, occupying the space between the barren range of mountains and the coast, having been already located, or in the possession of settlers, there was none left for the thousands that were yearly arriving in the colony.

On the discovery of these fertile plains, therefore, the superabundant emigrant population which had been pent up, as it were, on the narrow stripe between the mountains and the sea, left that territory, and, crossing the mountains with their flocks and herds, poured down upon this new land of promise, spreading themselves and their flocks far and wide over its rich domains.

The climate at Bathurst, from its great height above the level of the sea (about 2000 feet), is considerably colder than in the eastern districts near the coast, and on this account none of the tropical productions, which thrive so well in the latter, can be grown there to any perfection. In the midst of these fine lands is a thriving town of the same name, viz. Bathurst Town. Here there are several institutions, bespeaking the wealth and intelligence of the surrounding settlers. Amongst these are an academy, literary society, and public library. Proceeding still northerly, we arrive at the county of

CAMBRIDGE,

separated from the sea by the county of Aye, and with the latter forming the northern boundary of the colonized portion of New South Wales, on its eastern coast. This county is about the same extent with the latter, viz. about 120 miles in length, or from east to west, and about 65 miles in breadth, or from north to south. Like Roxburgh, this county also presents us with one tract in particular of valuable land. This is called Liverpool Plains, and is situated beyond a range of lofty mountains, running east and west. Although of a very inferior description of land to Bathurst Plains, these are, notwithstanding, well adapted for grazing cattle and horses; but from their being subject to inundation in the rainy season, the best portion of them being under water during that period, they are neither adapted for agricultural purposes nor for the rearing of sheep. The Liverpool plains are about 40 miles in extent, each way. There are few settlements in this county besides those on the plains just named, although it possesses some very eligible lands; but they are remote, and of limited extent.

SUMMARY.

We have now run over all the counties which compose, with the exception of two or three remote settlements, the whole of the colonized portion of New South Wales; and on glancing at the map it will be perceived how very small a part that is of New Holland, occupying, of a coast line on the east of nearly 2000 miles in extent, only about 340, and stretching interiorly, at the broadest part, into a region of similar extent not more than the same distance; whilst, at its narrowest point, it proceeds no farther inward than 80 to 90 miles: the whole forming a triangle, with its base on the coast, stretching inward, and its apex southerly; the sea-coast and the interior line constituting its two sides: the whole space within forming little more than a mere point as compared with the vast extent of territory which lies beyond it. Little is yet known of the interior of this extensive region—so little, indeed, that when individual research has stumbled on a fertile tract some 150 miles inland, it is reckoned and called a discovery, as in the case of the Bathurst Plains, which are not at a greater distance in a straight line interiorly from the coast than that just named. The continued pressure, however, of emigrant population pouring into the districts adjoining the sea, will necessarily, in the course of time, extend the British settlements inwards; and with such a boundless territory behind, it is not easy to say when or where this extension will stop, since there is no reason to conclude that the country yet unexplored is in any respect inferior to that already occupied.

The general character of the settled part of the country, and probably of the greater part of New Holland, is that of a land better adapted for the rearing of cattle than for agricultural purposes, there being, throughout, a much larger proportion of grazing than arable surface. The next general feature is its hilliness; high, rocky, and barren ground pervading, to a greater or lesser extent, every district in the colony, contributing more to the beauty of its scenery than to its utility for human purposes. Its last prevailing characteristic is its woodiness, the extent and frequency of its forests giving a decided character to the whole colony.

These are the prominent and leading features of the country on the eastern coast of New Holland. Its natural and factitious wants are water and roads, of both of which it is exceedingly deficient; the former, whether in the shape of rivers, lakes, or springs, bearing no proportion at all, either in extent or number, to the great expanse of territory over which they are spread. It is not improbable, however, that, as the colony progresses, this natural defect may be in some measure overcome by mechanical skill—by the digging of wells, cutting canals, &c.

The formation of roads, again, will necessarily and naturally follow, as one of the first consequences of increasing prosperity. Although New South Wales certainly does present all those characteristics of which we have spoken, yet they are only general; the exceptions on a nearer inspection are both numerous and important. Its pasture land is more extensive than that adapted for the plough, but it nevertheless possesses many districts of great fertility, capable of producing an unlimited amount not only of every species of grain cultivated for human use, but of all the productions of the tropics—the cotton plant, oranges, lemons, grapes, tobacco, &c., and every other vegetable native of the most favoured climes. Mountains and high barren grounds prevail, but there are yet plains of many miles in extent, and large tracts of gently undulating hills, clothed in the richest verdure. Its woods are frequent and extensive, but there are large portions of the country in which there are not above twenty to thirty trees on an acre, and which, standing thus widely apart in the midst of the most beautiful plains, or on the faces of low and gently sloping eminences, impart a character of surpassing beauty to the scene, giving it altogether the appearance of an English domain in the highest state of natural perfection. From the hilly and woody character of the country, too, it presents throughout its whole extent, in numberless places, scenery of a highly romantic and picturesque description, equalling in beauty the finest in Scotland.

CLIMATE AND PRODUCTIONS.

The climate of New South Wales, confining ourselves of course to the settled portion of that country, although varying considerably in different districts, is altogether highly agreeable and salubrious, and is particularly favourable to children; scarcely any of those diseases to which they are so subject here, and which yearly carry off so many thousands, being at all known there. Neither is it less favourable to all the other stages of human existence. In summer, the heat is not more oppressive than in England, and in winter the cold is much less severe, snow rarely falling but in the remote inland districts, which are situated at a great height above the level of the sea; and even there, excepting on the highest peaks of the hills, it lies but for a short time. In the lower districts where it is hotter, the air is tempered by a cool and delightful sea breeze, which blows steadily and regularly throughout the day, and is succeeded at night by an equally steady and grateful breeze from the land; in short, altogether the climate of New South Wales is one of the most delightful and healthful on the face of the globe. The bright and sunny skies of Italy are here rivalled, and all the luxuries of the tropics produced, without the intolerable warmth of these sultry regions. We have already pointed out two or three contrarieties between New South Wales and Great Britain; another is to be found in the temperature of the different winds, that from the south being there the coldest, and that from the north the warmest. This naturally arises from its geographical position, from its being situated about as near to the south pole as we are to the north. The degree of cold, and accumulations of ice and snow, being equally great in both of these extremities of the earth, it follows that the winds from the south must be there the coldest.

As might be expected from its genial climate, New South Wales is remarkable for the variety and beauty of its natural vegetable productions; the most gorgeous flowers and shrubs growing wild, and in the greatest profusion, every where delighting the eye. Its trees are tall and stately, often reaching to the height of a hundred feet; and thus in comparison reducing to absolute dwarfishness the trees of Great Britain. They are, however, inferior to the last in point of beauty, as they throw out much fewer boughs, and these short and stunted; they are, too, without the luxuriant foliage of the latter; and being all evergreens, none of them casting their leaves annually as ours do, they constantly present one dull dark uniform appearance, the prevailing complexion of all the forest scenery of the colony. The woods, therefore, in this part of the world, are entirely without the beautiful and ever varying tints and hues which mark the different seasons in this and most other countries. The natural grasses are on the whole rather rank than luxuriant, growing to the height of several feet, and thus presenting an appearance of vegetation which does not in reality exist; the settler being at first often surprised at the bareness of the ground when this long grass has been cropped. The better districts, however, present immense tracts of the richest and most luxuriant pasturage. Amongst the foremost of the animal productions of New South Wales is the kangaroo, a harmless, inoffensive quadruped. These animals furnish the principal part of the food of the natives, and are reckoned excellent eating by the colonists, who find much amusement in hunting them. There are no beasts of prey here, neither lions, tigers, leopards, hyænas, nor any other description of animals dangerous to man, excepting a few of the serpent tribe, and accidents from these are of as rare occurrence as in England. Besides the kangaroo, there is a species of animal called a flying-fox; it is a sort of bat of immense size, and most hideous appearance, but perfectly harmless; here also are native dogs, native cats, and opossums and squirrels, in abundance. Of birds there is a greater variety than any other country can produce, and many of these of the most beautiful and varied plumage; amongst these are parrots, a very numerous class.

The principal mineral productions of the country, so far as these are yet known, are coal, ironstone, limestone, potter's clay of the finest quality, whinstone, granite, slate, &c. The three first—of one of which, viz. coal, we have already elsewhere spoken—are to be found in inexhaustible quantities. Some metallic ores have also been found, consisting of lead, tin, and copper; but as these have not yet attracted any attention, little can be said regarding them.

ABORIGINES, OR NATIVE INHABITANTS.

These are now very inconsiderable in numbers. They lead the usual wandering life of savages, roaming throughout the interior in small tribes, each claiming as head-quarters a respective territory. They are jet black in complexion, and in general tall and thin in their persons, with large heads, large lips, and wide mouths, and are altogether the reverse of beautiful, according to our ideas of that quality. They have been considered, although the opinion is not completely borne out by experience, as amongst the lowest of all known savages in the scale of intellect. There is certainly less mechanical genius amongst them—fewer contrivances to improve the original condition of man than are to be found amongst the natives of any other quarter of the globe. Their only arms are a rude spear, or rather pointed pole, which, however, they throw with great force and precision; and a short club, called by themselves a waddie. Their huts are of the poorest description, and they wear no sort of covering whatever on their bodies. The very opposite instances of their general conduct with regard to the colonists, leave it a difficult matter to decide whether they ought to be considered as a harmless or a mischievous race. For the mischief they have done to the settlers, they have in general had sufficient provocation; and the murders they have committed—not a few in number—have been for the most part perpetrated in a spirit of retaliation for similar crimes committed by the whites. All attempts to civilize them, and to induce them to abandon their wandering life, have hitherto been next thing to ineffectual; and with the exception of a few in the neighbourhood of Sidney, and some other of the colonial towns, whom this contiguity has, in some degree, forced into a half-domesticated state, they still wander about in roving tribes throughout the interior, to the no small danger frequently, even to this day, of the more remote settlers, whose establishments they are very apt to visit, and that with no friendly purpose. On the whole, however, they are by no means formidable, the bare sight of a musket instantly putting them to flight, though in considerable numbers. Cannibalism is said to exist amongst some of the tribes; indeed, proofs of this horrible propensity, too strong to leave the matter in doubt, have been frequently discovered.

In some of the counties, however, and in several of the towns, particularly Sidney, many natives are found employed in various descriptions of labour, for their own benefit and that of their employers, the whites. Those of them who have much intercourse with the colonists are said to become most amusingly polite in their manners, bowing and scraping after the very best modes by which these courtesies are practised.

COLONIAL GOVERNMENT AND POPULATION.

The internal policy of New South Wales was, until within the last year or two, conducted by a governor and council composed of military officers, the governor himself always belonging to that profession. The courts there, therefore, had more the appearance of courts-martial than of judicial tribunals. This state of matters was the natural result of the original character of the colony, which was first intended merely as a place of banishment for convicts—a class which required to be dealt with in the most prompt and summary manner when they made themselves again amenable to the law. The government of New South Wales is now carried on by a governor, a legislative and executive council; both of the two last, as well as the governor, are appointed by the ministry at home. The legislative council is composed principally of persons holding official situations, and these chiefly residing in the government towns. The executive council, again, is composed of persons filling the high-

est government appointments. There are, besides, a class of functionaries called police magistrates, distributed throughout the colony, with salaries of L.400 per annum each. These take especial cognisance of offences committed by convicts, whom they have a power to punish by flogging or condemning to work in irons.

Sidney is the chief seat of the colonial government, comprehending the supreme court, and the heads of all the civil and military establishments of the country. These are all maintained by the home government, at an expense, including the charges for the convict population, of L.120,000 per annum. Being a colony of Great Britain, the laws by which New South Wales is governed are the same in their leading features with those of England, differing only in instances where such difference was found necessary to adapt them to the peculiarities of the country.

The population of the white colony, including the convicts, who amount to about 15,000 or 16,000 in number, is estimated at 40,000—an amount of population but little proportioned to the vast extent of territory which it occupies.

SOCIETY.

The title of this department of our sketch will be very apt, we dare say, to produce a smile on the countenances of those of our readers who have not hitherto thought of New South Wales but as a receptacle for the expatriated thieves of England, and who have, therefore, accustomed themselves to look upon it as a land especially and exclusively appropriated to crime and immorality, contaminated and disgraced throughout all its relations, a sink of impurity, and not to be thought of as a place of abode for any honest man. In truth, nothing can be more absurd than the ideas generally entertained of New South Wales on this particular head. These ideas have arisen, of course, from the circumstance of its being a penal settlement, one of the places to which convicts are sent. As this, therefore, we conceive, is presumed, however erroneously, to give a tone and character to the society of the colony, and to render that country a dangerous one to live in, we cannot do better, in an attempt to remove these impressions, than to give a short history of the convict after his arrival at New South Wales. On reaching Port Jackson, whither he is generally sent, the convict is, in the first place, instantly marched under a proper guard to barracks established for his reception. He is immediately afterwards either handed over to a government superintendant of works, to be employed in the formation of roads, bridges, &c., or he is assigned to a settler to assist him in clearing lands, or any other manual labour he may have to perform. Neither in the one case nor the other is his work made oppressive, and in both he is well fed, though kept under the strictest surveillance. When disposed of to the settler, he is provided by the latter with the means of erecting a hut to himself, the first employment to which he is put, if no such accommodation is already on the settler's station. The allowance of food—for he receives no wages but at the option of his master—which the latter is bound to afford him, is 11 lb. of flour, a peck of wheat, 7 lb. of beef, 4 lb. of salt pork, 1 lb. sugar, 2 oz. of tea, and 2 oz. of tobacco, weekly. The settler is farther obliged to supply him with two full suits of clothes annually, bedding, blankets, and the necessary culinary implements to prepare his food. The hours during which he is required to work are from six in the morning until six at night, with the allowance of an hour for breakfast and another for dinner. When a convict conducts himself with propriety for a certain length of time, and which is proportioned to the term of his sentance, he is entitled to claim from the colonial government what is called a ticket of leave, a sort of warrant or licence, which enables him to live where he pleases, and to employ himself in any legal way he may choose. This, of course, is recalled if he commits any new offence; and many advertisements are from time to time to be seen in the Sidney newspapers intimating such recall, and naming the individuals. Though, while he conducts himself with propriety, the convict's peculiar condition in society is not obtruded upon him by any peculiar treatment, yet the slightest departure from this brings him immediately within the reach of the colonial laws. If refractory, or even merely insolent to the settler, his master, he may be taken before a magistrate, and either flogged, or sentenced to work for a certain period on a short allowance of food in what are called the government chain-gangs, composed of convicts who have offended a second time, and are, as a punishment, worked in fetters. On the expiry of his original term of banishment, the convict becomes, in colonial phrase, an emancipist, and is then his own master. Many of these, now altogether a large body in the colony, acquire extensive properties, and become in their turn employers of convicts, and even dispensers of the law. Many of them, too, though less fortunate, become useful, and even respectable members of the community, if one circumstance in their lives could be forgotten; and it is not more politic than just that it should, seeing that, besides their having paid the full price of their transgressions, and having thereby established a right to demand their restoration to that society which has itself offered and received that price, it does not by any means necessarily follow that he who has done wrong once will do wrong again; neither must the commission of a single crime be held as an indubitable proof of a naturally vicious or depraved disposition. Any objections, however, which prejudice may still urge against the emancipist, cannot, without a violation of every religious and moral principle, be applied to their descendants—a fine, manly, and by all accounts an exceedingly amiable race, now springing up in the colony, remarkable for the sobriety of their habits, their industry, honesty, and general kindliness of disposition. Strongly attached to their country, and evidently anxious to efface, by their own good conduct, the recollection of the guilt of their unfortunate parents, they are every day becoming a more and more interesting and important class in our Australian population. In the facetious nomenclature of New South Wales, the class of which we have been speaking is called currency, in contradistinction to those born in the mother country, who are again called sterling. Currency lads and currency lasses is therefore the language in which they are spoken of. From what we have said, it will be seen that the emigrant is in no other way brought into contact with the convict than as master and servant. The line of demarcation between them is distinct; there is no jostling, and there need be no offensive association; the laws keep the convict strictly within his province, and it will be the fault of the settler himself if he permits him to step out of it. With regard to the emancipist, it is different: he is his own master, as well as the emigrant; and, so far as honesty goes, strange as it may seem, although easily accounted for, he will find fully as much of it amongst that class as amongst his brethren the free settlers; and this is not paying the latter an equivocal compliment either; for where principle might be wanting, a desire to redeem their forfeited reputation induces those of the emancipists who have really a desire to do well, to act generally with the most scrupulous honesty; and be it recollected, besides, that the offences for which many of them have been banished, have not been of a nature at all affecting their integrity. With this class, however, the emigrant has it always in his power to mingle just as much or as little as he pleases, since he will find, in almost every part of the colony near townships or settlements, abundance of such society as he may enter without any sacrifice of feeling. In Sidney, where the best and the worst is to be found, there are many hundreds of families, not only of the highest respectability, but nothing short of what is called fashion, enjoying all the elegancies of refined life, exchanging its courtesies, and cultivating its amusements and pleasures: splendid equipages are to be seen rolling along its streets; its public dancing and assembly rooms blazing with light, and filled, as our newspapers would say, with "beauty and fashion;" music parties and theatricals filling up the measure of the happiness of a Sidney life. Next to Sidney, Bathurst has probably the highest pretensions to a superiority in the general character of its society. Besides its literary institutions, it boasts an association called the Bathurst Hunt, composed of all the sporting gentlemen who reside in the district; these wear a uniform, and are, as a body, no way inferior to any similar society in England.

TRADE AND REVENUES.

The shortness of the time since this colony became an object of attention to the speculator and emigrant, leaves little reason to expect that its trade should be very extensive. It has scarcely yet emerged from a state of infancy; but it is fast gaining strength; and if no unforeseen circumstances arise to check its prosperity, New South Wales will one day become, if it is not so even now, by far the most important of all the British settlements abroad. Its leading export articles are wool, and seal and whale oils; a great part of the latter is of that valuable kind called sperm oil, produced by a description of whale found in the South Seas only, and which generally brings here double the price of the common whale oil. Here, then, in these articles alone, is a source of immense wealth. From the boundless pasture land of the colony, and the highly favourable nature of the climate, the increase of sheep is without any limits, and the ocean and its products are yet more unbounded. The quantity of wool exported from New South Wales is yearly increasing, and is likely, indeed certain, to go on improving. In the article of oil, which has only very lately become an object of serious consideration to the colonists, the improvement has been equally rapid, there being now 36 vessels, averaging a tonnage of 8700, belonging to and sailing out of Port Jackson alone, exclusively engaged in the whale fishing. The produce of this branch of the colonial trade in the six months preceding the 30th June 1832, amounted to L.49,800. The whole exports of the colony for the same period amounted to L.249,641, and the imports to L.251,229, the former falling short of the latter to the amount only of about L.2000—a proof that the colony is now nearly able to walk alone, and a reasonable ground of hope that it will very soon be in a condition to afford much more than the extent of assistance which it has hitherto required. A still more striking evidence of the increasing prosperity of the colony is to be found in the circumstance of its having in four years, in some instances, nearly, and in others more than doubled the amount of its property in cattle and sheep, and the extent of its cultivated land; and in a few years more it is found to have more than doubled the value of its imports and exports and amount of revenue.

In 1824, the colony was calculated to possess of horned cattle .	120,000
— 1828, . .	263,000
Increase	143,000
— 1824, of sheep . .	350,000
— 1828, . . .	600,000
Increase	250,000
— 1824, the average amount of its exports for one year was .	L.100,000
— 1832, it amounted for a similar period to . .	249,641
Increase	L.149,641
— 1824, its revenue for one half year was	L.25,000
— 1832, for the same space of time it was	68,211
Increase in one half year	L.43,211

All these increases are still progressing onwards, and with yet greater rapidity than the preceding instances evince. Between the corresponding half years of 1831 and 1832, there was a difference in the amount of revenue of not less than L.13,244 in favour of the latter year.

The principal source of colonial revenue is the duties exigible on liquors, and for licences to dealers, &c.; and in this particular, it must be confessed, the picture is rather an astounding one, and presents our brethren at the other end of the world as indeed "jolly companions every one." Out of a half yearly revenue of L.68,211, some odd shillings and pence, L.51,028 has been derived from liquors and licences alone!! The stock in hand of the former on 25th February 1832, was

Rum . .	57,201	gallons.
Brandy .	25,917	—
Gin .	8,421	—
Other spirits .	5,356	—
Total	96,895	gallons.

And of tobacco there was at the same period a stock in hand of 65,111 lb.

The supply of the former thus averages about two and a half gallons to each individual in the colony, males, females, and children, and, confining the distribution to the adults of the first class, would probably not be short of the proportion of eight or nine gallons to each man in the colony. On the days of the 23d and 25th June 1832, there were granted in Sidney alone no fewer than 193 new licences to inn and tavern-keepers and publicans. On the whole, it has been calculated that there is a quantity of liquors consumed in this colony alone, at least ten times greater than in any other part of the globe besides, of similar extent and population. In the June following the February in which the stock of spirits in the colony is given, the quantity of rum had amounted to 136,063 gallons, and the brandy decreased to 19,370.

The production of wool has for some time back been a primary consideration with the settlers, and they have of late begun to pay more attention to the quality than they did formerly, quantity alone having been at one time all they aimed at. From the improvement which has taken place in the breed of sheep, as well as in the mode of preparing the wool for the market, the New South Wales wool has now become an object of much interest to the dealers and woollen manufacturers in England, where it is greatly prized for the peculiar softness of the cloth produced from it, and which, if combined with a little higher degree of fineness—a result that must soon follow the care and attention that is now bestowed on it—would place it on a level with the best growths of other countries, and consequently direct an inexhaustible stream of wealth into the colony; and there are two important considerations at this moment operating to produce this effect. The first of these is the readiness of the market, and the fair remunerating price which the settler obtains for his wool; the next, the necessity which the distance of the extensive interior settlements from Sidney imposes on their occupants, of directing their whole attention to the rearing of cattle and sheep in preference to agricultural productions.

EMIGRATION.

Having now given such an account of New South Wales as our limits will permit, we proceed to speak of it as adapted to the emigrant, and to point out the manner in which he should proceed, and the hopes he ought to entertain in the contemplation of his making it the place of his abode. This we propose to accomplish by first enumerating the different classes most suitable to emigrate to that colony, and then treating of each separately, and under their different heads. The persons, then, most suitable to emigrate to New South Wales, are of five descriptions: farmers or those who have some knowledge of farming, farm-servants, mechanics, labourers, and unmarried females. The first of these may include, as all to be said under this head will apply equally to, any person, who, having a small spare capital—an indispensable requisite, however—and who, although without any previous knowledge of agricultural affairs, may be desirous of emigrating with the view of turning farmer. A previous acquaintance with husbandry, and treatment of sheep and cattle, would certainly be a very great advantage to any one going out to settle as an agriculturist and grazier; but thousands are thriving in these pursuits in all our colonies who had little or no knowledge of them before they left Britain. Proceeding on the plan we have laid down, we begin with the

FARMER AND GRAZIER.

Although New South Wales presents, perhaps, one of the most eligible quarters of the globe to which the farmer, oppressed by high rents and low prices of agricultural produce in this country, can go, he must not think that, with all its vast extent of fine lands, pastoral and agricultural, its delightful climate, and the general abundance of all the necessaries of life which it produces, that he will therefore have nothing to do on landing on these favoured shores but sit down and enjoy himself; much less must he think, that, though it requires capital, less or more, to commence farmer with any reasonable prospect of success here, that none will be required there. Both privation and hard work, and considerable expenditure besides, will be demanded of him before he reaches a state of comfort and independence. These submitted to, however, for a time, he will soon find himself in as comfortable and happy circumstances—so far as regards exterior things—as perhaps the lot of man will admit. Above all things, however, he must not think of going out without a capital, less or more, but of course the more the better. L.200 or L.300 free on landing there will do very well; L.500 or L.600 a great deal better; and L.1000 or L.1200 will secure him, with proper management, certain and speedy success. In short, the first sum is the lowest which he should think of emigrating with; and although there need be no limits to the extent, yet the latter sum is ample. Let him not remain here until he is entirely ruined, but set off at once, while he has yet any thing left. If he be already penniless, let him not think of emigrating unless he can find a friend who will assist him. As there are many industrious and respectable persons, however, who cannot command a sum equal to the amount of the lowest of these we have named, it has been recommended, and has been found from experience to answer well, that individuals possessing but small capital, say from L.50 to L.100 or L.150, should unite their funds, regulating the numbers of the association so formed by the amount which each contributes—say three or four, if each possesses L.150, five or six if L.100, and eight or nine if L.50; lower than this in amount of money, or higher in point of numbers, it would not be advisable to go. If these united heart and hand, as well as purse, in the work before them, there is little doubt that they would soon place themselves in exceedingly comfortable and independent circumstances—such circumstances as are unattainable in this country with ten times the capital.

Land, of course, will be the object of the farmer, or the person intending to turn farmer, on going out; and it therefore forms the most important part of this department of our subject. As might be expected, all the good lands in the neighbourhood of Sidney and the other markets are already located, that is, in the possession of settlers; but there are abundance of these from two acres up to two thousand, and beyond, always on sale, or to be had on lease, varying in value with soil and situation; and, speaking generally, this is by far the most advisable way for the emigrant to become possessed of land. All the labour and expense of clearing and preparing new land is avoided; an eligible situation, near a market or some point of embarkation, is secured—a consideration of the last importance; and the vexatious delays and troubles of all sorts, which but too often accompany the purchasing of crown or unlocated lands, is escaped, to say nothing of the difficulties and fatigue which the intending settler encounters in roaming through the country in search of a suitable location. The purchasing of improved land of course presumes the possession of capital, but, as we have said, less or more of this is necessary in any event; and such lands as we speak of, if not in the immediate vicinity of Sidney, or of any other town or township, may be had at about 10s. to 12s. per acre. As the system of agriculture in New South Wales does not materially differ from that pursued in this country, an intending purchaser, or renter of land there, though but newly arrived, if previously acquainted with agricultural affairs, will have no difficulty in perceiving, on a personal inspection, whether or not the property which he intends to purchase or rent be properly furnished with all the necessary buildings and erections of a farming establishment. Let him, however, look carefully to this, for all the barns, sheds, cart-houses, &c. necessary here, are necessary there also. It would not be advisable in the newly arrived emigrant to enter into any *private* bargain with any individual regarding the purchase or renting of land; let him rather attend the public sales and auctions of private property, which are almost every day advertised in the Sidney newspapers; he will then have the advantage of all the information which competition can afford, and that is nearly all that need be desired. If he sees an anxiety to purchase amongst the old hands, who may be presumed to be good judges of the value of the subject exposed to sale, he may believe it is worth looking to. If they bid L.1 per acre, he cannot be far wrong in bidding a trifle more, provided always that his previous personal inspection of the property, and the information he may have been able to acquire regarding it from *disinterested* persons—(take care of this)—concur in rendering it advisable.

The next, or rather the only other mode of acquiring land in New South Wales, and that which is most general, is by purchasing or renting it from the government. The latter does not now (since the year 1831) *grant* any lands as it formerly did. The lands which the government have to dispose of are called crown lands, and include all the land in the colony not already possessed by private individuals. On this part of the subject we cannot do better than place before the reader the government regulations, which, after premising that no land shall in future be disposed of in New South Wales or Van Dieman's Land otherwise than by public sale, and that a division of the whole territory into counties, hundreds, and parishes, is in progress, proceed to enact, that

"All the lands in the colony, not hitherto granted, and not appropriated for public purposes, will be put up to sale. The price will, of course, depend upon the quality of the land and its local situation; but no land will be sold below the rate of 5s. per acre.

"All persons proposing to purchase lands not advertised for sale must transmit a written application to the governor in a certain prescribed form, which will be delivered at the surveyor-general's office to all persons applying, on payment of the requisite fee of 2s. 6d.

"Those persons who are desirous of purchasing will be allowed to select, within certain defined limits, such portions of land as they may wish to acquire in that manner. These portions of land will be advertised for sale for three calendar months, and will then be sold to the highest bidder, provided that such bidding shall at least amount to 5s. per acre.

"A deposit of 10 per cent. upon the whole value of the purchase must be paid down at the time of sale, and the remainder must be paid within one calendar month from the day of sale, previous to which the purchaser will not be put in possession of the land, and, in case of payment not being made within the prescribed period, the sale will be considered void, and the deposit forfeited.

"On payment of the money, a grant will be made in fee-simple to the purchaser at the nominal quit-rent of a pepper-corn. Previous to the delivery of such grant, a fee of L.40 will be payable to the colonial secretary for preparing the grant, and another fee of five shillings to the registrar of the supreme court for enrolling it.

"The land will generally be put up to sale in lots of one square mile, or 640 acres; but smaller lots than 640 acres may, under particular circumstances, be purchased, on making application to the governor in writing, with full explanations of the reasons for which the parties wish to purchase a smaller quantity.

"The crown reserves to itself the right of making and constructing such roads and bridges as may be necessary for public purposes in all lands purchased as above, and also to such indigenous timber, stone, and other materials, the produce of the land, as may be required for making and keeping the said roads and bridges in repair, and for any other public works. The crown farther reserves to itself all mines of precious metals."

It will be perceived, that, by these regulations, a capital of at least L.160 (640 acres at 5s.) for the purchase of land alone is in general cases required; but smaller lots are very easily obtained, and the former is thus little more than a nominal restriction. Besides procuring lands from government by purchase, these may be also had on yearly leases, or as tenants at will, to any extent, at 3s. 1½d. per 100 acres; but this is not an advisable way of occupying land, for you are sure to be turned out of it, sooner or later, according to the advantages it may possess (and if it have none, it is not worth even the small sum asked for it), by some intending purchaser coming forward and making an offer for it to the government, unless, indeed, you can yourself out-bid him, for it can be sold only by public sale. As all the good lands in the colony, in the district lying between the Blue Mountains and the sea, are already located, new comers, unless they have the means of purchasing private lands, or are contented with inferior soils, will have to look for their location on the other or interior side of these mountains. Thus being thrown at a great distance from the market, their views ought to be confined almost entirely to the rearing of sheep and cattle, particularly the former, raising as much grain only as will serve for their own private use. Particular circumstances may alter this relation of matters, but in general, and at the present moment, these are the views that ought to be entertained; nor need the settler regret this, since wool is one of the most profitable and saleable commodities which he could bring to market. The London sales of this article, the produce of New South Wales and Van Dieman's Land, averaged, in 1832, about 1s. 3d. to 1s. 5d. per lb., while Merino ewes, according to the Sidney Monitor, may be bought in the colony for 10s. each, and milch cows for L.5. Let the intending settler, therefore, as he values his future success, pay his utmost attention to this department of the pursuits which will engage him in his adopted country; and to enable him to do so with an increased certainty of a good result, we give the following

"DIRECTIONS FOR THE MANAGEMENT OF WOOL," BY MR WALTER BUCHANAN, ADDRESSED TO THE AUSTRALIAN WOOL-GROWERS,

premising that the want of attention to such proceedings, regarding the management of that article, as these directions point out, has hitherto operated most seriously to the disadvantage of the Australian wool-growers. The intending settler will also observe, from these directions, the necessity of locating as nearly as possible to a supply of water for washing his wool.

Washing.—"It is of great importance that the fleece should be well washed, that the wool may be brought to market with as bright a colour as possible. Every convenience, and a very plentiful supply of pure water, should therefore be provided, a running stream being most desirable. The preferable mode of washing is that which is performed before shearing, according to the German manner. Some growers have tried the plan of washing after the fleeces have been shorn and sorted, and, as is supposed, to have used tepid water, following the French and Spanish method; but this has not been approved of by the buyers generally, and particularly by those who buy for combing purposes.

The breaking of the fleece and washing after shearing, gives the wool more the appearance of Spanish than of German wool, and consequently reduces it to a lower standard of comparison. It is well known that the sheep of those German flocks that are best washed, are, after that operation, driven into some shed, strewed with clean litter, or penned up with hurdles, on clean grass; that the utmost care is taken to prevent their exposure to dirt, or whatever else might tend to sully their whiteness; and that they are *not* shown until a sufficient degree of moisture is deposited in the fleece, by perspiration, to impart a soft handle to the wool. It may here be added, that it is very important, if possible, to prevent the sheep from filling their fleeces with grass seeds, broken leaves, and other extraneous substances, which cannot be removed in the operation of washing, and which are productive of labour and expense in every process of manufacturing, in some cases indeed rendering wool almost unsaleable. It may be here observed, that so conscious are the Spaniards of the superiority of the German mode of washing and assorting, that they are making every effort to introduce it.

Assorting and Accommodating.—In order to assimilate the Australian wool as much as possible with the German, in preparing it for market the fleeces should not be broken, but merely divested of the breech and stained locks, and so assorted or arranged that each package may contain fleeces of the same character as to colour, length of staple, fineness of hair, and general quality.

If the washing has been performed at the same time and place, and with an equal degree of care, the colour is likely to be uniform, and it will then only be necessary to attend to the separation of the fleeces as to length, fineness, and general quality: but if a larger grower has flocks of different breeds, and fed on different soils, care should be taken that the fleeces be separated, first as to colour, and then again as to length, fineness, &c.

Packing.—The fleeces, being assorted, as already suggested, should be spread one upon another, the neck of the second fleece being laid upon the tail of the first, and so on alternately, to the extent of eight or ten fleeces, according to their size and weight. When so spread, the two sides should be folded towards the middle, then rolled together, beginning at each end, and meeting in the centre, and the roll or bundle so formed held together by a slight pack-thread. The bagging should be of a close, firm, and tough nature. The material hitherto most generally used has been sail canvass, which very ill resists bad weather on a long voyage, and when received here even in favourable condition, is so dry and crisp, that it will tear like paper: a thicker, twilled, more flexible, and tough material, would be preferable. The size and form of the package may be in length about nine feet, and width four feet, sewed up on the two long sides and at one end, the other end being left open, and the sheet so formed being suspended, with the open end upwards, to receive the bundles, made up as before directed, which are to be put in one at a time, one of the flat sides of the roll or bundle being put downwards, and so on in succession, being well trod down, until sufficiently filled for the mouth to be closed. This is the German mode of packing; but it is doubtful whether smaller packages, of the dimensions that have been hitherto sent from the two colonies, may not be more convenient for so long a voyage. The operation of screwing should be discontinued where it has been practised, as the pressure by the screw, and remaining compressed during the voyage, occasions the wool to be caked and matted together in a manner that is highly prejudicial to its appearance on arrival. The practice also of winding up each fleece separately, and twisting a portion into a band, is productive, in a minor degree, of the same prejudicial effect, and it is to avoid this that the making German bundles of eight or ten fleeces is suggested."

The Australian emigrant agriculturists and graziers, as we have seen, will fall into two classes, as it were—the one, those who purchase improved land, ready made to their hands; and the other, those who locate on new land bought from the government. The latter will be almost exclusively engaged in the rearing of sheep and cattle, for the reasons already given. The former, again, will, in most instances, have more to do with agriculture than grazing. As this, however, as we have elsewhere said, is pursued on a similar system in New South Wales as in England, we need not enter here into any details on the subject, there being nothing at all peculiar in the case of the former. Nor can we, from the usual casualties of seasons, soils, &c., venture to fix any probable rate of produce which the settler might expect his acres to yield. That, however, with the exception of wheat, may be said generally to be equal to that of corresponding lands in England. In the case of wheat, the quality is superior to that of any grown in Europe, but the quantity per acre is below the average rate of England, seldom exceeding 24 bushels per acre.

The following "return," however, from the Sidney Herald, will give an idea of the prices of produce:—

Average wholesale prices of farm produce at Sidney, from 1st to 8th August 1832.

Wheat, best, N. S. Wales,	L.0	5	0	per bush. of 60 lbs.
Do. 2d,	0	4	0	" "
Do. 3d,	0	3	0	" "
Barley, best,	0	3	0	" of 50 lbs.
Maize,	0	2	5	per measurement.
Colonial tobacco, best,	0	1	7	per lb.
Do. 2d quality,	0	1	4	"
Potatoes,	4	10	0	per ton.
Butter, best salted,	3	14	8	per cwt.
Cheese, good,	2	2	0	"
Pork, salted,	1	10	0	"
Bacon,	2	6	8	"
Ham,	3	0	8	"

As the system of agriculture is the same, or nearly the same, with England, so also is the description and rotation of crops, with the exception of tobacco, which thrives well, and is beginning to attract some degree of attention in the colony. The proper management of this crop, however, will be best learnt on the spot. With regard to the intending settler who purchases the unimproved lands of the government, his course is neither so simple nor so easy. On arriving at Sidney, he gets into lodgings, which he will obtain, including bed and board, at a rate varying from ten to twenty shillings per week. Let him, however, remain here as short a time as he possibly can, otherwise he will spend money idly, which, at all times valuable, is now to him not doubly, nor trebly, but incalculably so, as on the few pounds which he now has in his pocket his future success in a great measure depends. Let him not, therefore, spend a single shilling that he can avoid spending. If he intend to purchase improved lands, let him look after these in the market immediately, and proceed, as soon as he can after purchase, to take possession and commence operations. If he intend to buy crown lands, he had better not waste time in searching for a location in the lower districts, for the reason already specified—viz. that all good lands there are already located—but proceed at once into the interior; probably about Bathurst or the county of Argyle, both elsewhere spoken of, are the best points to which he could direct himself, if he find that there are government lands there advertised for sale; and although there should not, he will perceive, by the colonial regulations quoted, that he may, nevertheless, if he discover a spot which he thinks would suit him, and which is not the property of another, procure it to be put up to sale. The greatest drawback, however, in this case, is, that he must wait until the expiry of the period (three months) during which, by the regulations, it must be advertised before being brought to the hammer. But during this time he need not by any means be altogether losing; let him purchase immediately as many ewes as his means will admit, reserving, of course, for other expenses; and these he will get readily quartered with settlers who have more land than they can stock, for one-third of the proceeds of their wool; thus the emigrant getting the other two-thirds is already establishing a source of income, and without trouble; and he may do the same by cattle. Such description of settlers as will readily enter into this arrangement with him are numerous, and will easily be found upon inquiry.

The newly arrived emigrant will of course, of his own judgment, take care to select land as lightly timbered as possible, that the expense and trouble of clearing may be the less.

Leaving his family, if he has one, at Sidney, until he return from his exploratory expedition, the emigrant who is about to look out for a suitable location sets out on horseback, provided with changes of clothes, a blanket to wrap himself in at night, and a light cord with which to secure his horse while he is himself asleep; and if his route be through thinly inhabited districts, he had better be accompanied by a pack-horse, with provisions. His train of assistants ought to be composed of a steady white man and a black native: these, if fortunately chosen, will be exceedingly useful to him in guiding him and in supplying him with various information. Thus equipped and provided, he roams through the country until he falls in with such a location as he thinks will suit him. Having fixed on this—not always easily done—he returns to Sidney, pays his deposit of 10 per cent. on the purchase, or the whole price if he chooses, or in the event of its not being advertised land, presents a written application to the governor, in terms of the colonial regulations before referred to. Providing himself now with cart, plough, and set of harrows—which, by the way, he had better not bring from England, as, though somewhat dearer, he will get them of a description better suited to his purpose in Sidney—he proceeds with his family to the scene of his future labours. There are two or three considerations of importance to the newly arrived settler which may be thrown in here together. Let him take every means in his power to ascertain, before returning again to Sidney, that the land he has fixed upon is not either altogether or in part the property of another. This is not always by any means easily made out, mistakes often occurring, and giving much trouble and annoyance to the new settler, who may, if such a thing happen, find himself compelled to set out on a second expedition. He should endeavour to find out, at Sidney or elsewhere, the surveyor of the district in which he purposes making his search, and make such inquiries of him regarding the point just spoken of, and such others as may seem necessary to him.

The newly arrived settler must not allow himself to be influenced regarding the location he has fixed upon by any thing he may be told by the neighbouring settlers, it being their interest, at least they think it so, to dissuade new comers from establishing themselves in their neighbourhood. Nor must he mind what he hears to the disadvantage of the country whilst at Sidney, from any one of the scores of idle dissipated loungers who hang on there, and who, themselves ruined and disappointed through their own folly, are ever ready to fasten on the stranger, and to entertain him with the most dismal accounts of his adopted land. Let him, we say, avoid these people, and pay no attention to their croakings; but come to the resolution, under the blessing of God, of setting stoutly and manfully to work, and there is no doubt he will speedily find himself in an infinitely better condition than he was at home.

The sheep and cattle which he may have bought previous to his fixing upon land, as before recommended, he must on no account remove from the settler's grounds on which he has placed them, until he has prepared the proper enclosures for their reception at his own location, otherwise they will give him much trouble by straying, and thus consume that time in running after them, and in collecting and keeping them together, which is so necessary for his other numerous and pressing avocations.

New South Wales, besides presenting to the emigrant all the advantages which are to be found in America, affords two peculiar to itself, and these very important ones. The first is to be found in the short distance which he has to travel after landing in search of a location, this seldom exceeding 100 to 140 miles in the former, while in the latter he has often to perform a journey of 1000 for the same purpose. The next is in the seasons. The Canadian has to provide for a long and severe winter, during the greater part of which he is necessarily thrown idle. In New South Wales there is scarcely any winter at all, and the farmer may, consequently, carry on his operations throughout the whole year.

For his labourers the settler has to look to the convicts. These he obtains by a written application to the governor, who will immediately assign him a requisite number to assist him in clearing and preparing his lands. On this subject, which appears somewhat startling, and has, we believe, operated unfavourably on Australian emigration, we beg to lay before our readers the following extract from a series of remarks on emigration to New South Wales, in the Sidney Monitor of 1st August last:—"Convict servants, we admit, are not so good as the servants of England. They are not so skilful, except one in four or five, and in point of industry and good manners not equal, of course, though kept down by a vigorous discipline. But they are more skilful and industrious than slaves, and, in lieu of costing from L.30 to L.50 a-piece, they cost the assignee (employer) only L.1 a-year per head, which poll-rent has not yet been levied upon the assignee, but it is expected it will be laid on very shortly, and for a salutary end.

"The man who feeds and clothes his convicts according to the law, giving them rather the advantage in the adjustment as to quantity and quality of their food and clothing, and who treats them with civility, is as safe on his farm in residing with convicts as he is with freemen."

Settlers, however, if very fastidious on the subject of convicts, *may* employ free labourers; but the comparatively high wages which these demand, and the insolence towards their employers—punishable in a convict, but not in them—in which they are but too apt to indulge, knowing that they can easily find another employer, will soon reconcile him to convict labour.

As our limits will not admit of our entering into further details regarding this department of our subject, we now conclude it with the following judicious remarks from the authority just quoted, viz. the Sidney Monitor:—

"Strangers coming to New South Wales should bring letters to as many persons as they can, provided they be men of character. But let them not expect any thing more from the people here than a kindly feeling towards them. This they will receive. If they meet with hospitality, it will be likely to do them harm. It will tend to raise in them expectations of rank and expense, which will retard their success, and probably ruin them, by inducing them to borrow money on mortgage, &c. &c.

"However respectable men may have been at home, they should have firmness enough to lay all rank aside when they come here. Let them for this purpose, sell all their blue coats and yellow buttons, and silk stockings, and enter the colony in a berragon shooting jacket, waistcoat, and trousers, their wives and children wearing dark stuffs for cheapness in washing and for durability; and however they may be rallied and tempted by their new friends here to put on better attire, let them turn a deaf ear to such allurements. Let them buy nothing in the way of furniture but rush-bottom chairs, and the commonest tables, and bedsteads without posts, which are sold here at 10s. each; and, in short, let them endure the constant reproach of being mean and stingy until their wool, salted beef, butter and cheese, shall have enabled them to dress and furnish their houses according to their taste. By that time, however, they will have learned to see the folly of attempting any thing in New South Wales but to be warm, dry, and well fed. And in lieu of improving their external appearance, they will learn the wisdom of laying out their profits in building barns and stables, in fencing in more paddocks, in buying more milch cows, and fine woolled ewes, and in buying and renting more land in the distant interior to keep them."

FARM SERVANTS AND SHEPHERDS.

Men of this description are invaluable in New South Wales, and much wanted. The amount of wages, however, which they may earn is not easily, or, rather, cannot be stated, as much depends upon the proportion which they may be disposed to take in property, that is, in farm produce, less or more of which is always understood to form part of the farm servant or shepherd's income. The general rate, however, of the wages of this class, may be said to be about L.15 per annum, sometimes as high as L.20, but the lower will be the safer calculation. This, however, is not the money-rate. Part of it, to what amount depends upon bargain, must be taken in property. Besides this fixed rate of wages, however, they have an ample allowance of animal food, flour, &c., generally more than they can consume. Though the net amount of wages, therefore, may appear not very tempting, the latter consideration fully makes up for it, making the condition of the cottar or farm servant there infinitely more comfortable than it is here; besides, his children, if he has any, contribute there much sooner, and to a much greater extent, to the family's comforts than they can do here, work of all kinds being in much greater demand. The boy or the girl either will get their rations of meat, flour, &c., with proportionable wages, as soon as they are able to do any thing; and thus an ample abundance of all the necessaries of life, and these, too, of the best description, may always be found in the cot of the shepherd or farm labourer in New South Wales, presenting a striking contrast to his straitened and impoverished condition at home, where, amongst other privations, animal food rarely crosses the threshold of his door.

MECHANICS.

The demand for mechanical skill in the colony is exceedingly great, and it will probably be many years before either this demand abates, or the remuneration of the emigrant artisan suffers any diminution. In the meantime, at all events, the scarcity of mechanics in New South Wales amounts to an absolute famine, and the eagerness with which they are sought is fully proportioned to this scarcity. If any particular class can be said to be more wanted than another, where all are wanted, the following might be named:—Coopers, ship and house carpenters, cabinetmakers, joiners, wheel-wrights, brick-makers and layers, stone quarriers, cutters, and masons. This selection does not in every instance correspond with that in the circulars or bills issued by emigrant ship-owners and agents, but as it is taken from a newspaper published in Sidney, in August 1832, it is no doubt correct. It has at any rate the advantage of being more recent than the former, none of which that we have seen are dated later than 1831, and even these refer to the rates obtainable in 1830. As our object in this paper is not either to dissuade or to encourage any one to leave their native land, but to state facts as we find them, leaving it entirely to parties to judge for themselves, we feel not only under a restraint, but in particular difficulty, in speaking of the wages which the mechanic may look forward to in New South Wales, the more especially that we find the rates spoken of in one of the Emigrants' Guides to New South Wales," published in this country, characterised by a Sidney newspaper as being "many of them notoriously untrue." There is, however, no occasion to exaggerate. The real and true state of matters there is, we should think, sufficiently tempting to most tradesmen. The wages of mechanics in general, besides the certainty of immediate employment, may be safely stated as ranging from 5s. to 8s. per day; few get at any rate so low, and certainly none lower, than the first; and in some cases, such as that of a very expert workman in any of the trades above named, a sum even beyond the highest may be obtained. Let the intending emigrant, however, calculate on the lowest only, and he will run no risk of disappointment: if he gets more, so much the better, and the chance is, that, if a good tradesman, he will. Nor is the mere amount of wages, much as it is beyond that of this country, the only advantage which Australia holds out to the mechanic. There is, besides, to be coupled with it the extremely moderate price of some of the principal necessaries of life, though certainly *all* of them are not lower than in this country; on the contrary, many of them are much higher, and many of them at least equally high. Animal food, however, and tea and sugar, particularly the two former, are extremely cheap; but it must be observed of the first, that, cheap as it certainly is, there has been something like a deception practised regarding it. In all the bills, circulars, &c. published on the subject of Australian emigration, beef and mutton are stated as selling there at 1½d. per lb.; so it is; but then this is of an inferior description, and, moreover, it means when a whole carcass is bought: the best is 2d. per lb. when the whole carcass is taken, and 3½d. when purchased in smaller quantities. A mechanic is not likely to buy animals by the carcass: the real price, therefore, which he will pay in Sidney, going to the market for a few pounds of beef or mutton, will be 3d. to 3½d. In order, however, to give him and others as correct an idea as possible of what living there may cost, we subjoin the following price current, "compiled for the Sidney Herald, 30th August 1832."

Ale, Eng. per hhd.	6l. 10s a 8l.	Pork, salted	4d a 8d
do. doz.	14s a 18	Bacon, per lb	0 a 7
Colonial, per hhd.	60 a 80	Hams, per do.	9 a 1s
do. doz.	6 a 0	Veal, quarter, per lb	3 a 0d
Beer, Eng. per hhd.	6l. 10s a 8l.	joint, per do.	5 a 0

Horns, per 100	8 0 a 0 0	log.	1 0 a 1 1
Leather sole, per lb	0 6 a 0 0½	Firewood, p. load	4 0 a 5 0
Kip	1 0 a 9 0	Treenails, per 100	4 0 a 0 0
Dressed shoe, each	3 0 a 10 0	Wine,	
Meat, beef, per lb	1½d a 2d	Port, per dozen	35s a 40s
joint	3 a 3½	Madeira	35 a 40
salted	3½ a 4	Sherry	35 a 40
Mutton, carcass	1½ a 2	Claret	10 a 60
joint	2½ a 3	Cape, per gallon	4s 6d
Pork, carcass	2½ a 3	Elder	5s 6d
joint	4½ a 5	Wool, per lb	4d a 2s

The expense of the passage out is the most serious drawback in the case of emigration to New South Wales. But the mechanic who has not the means of defraying the whole of this expense may have assistance from government. The following are the regulations on this subject:—

"No one family will be allowed an advance exceeding L.20; and therefore it will be useless for parties who may not possess the remainder of the sum requisite for engaging their passage, to apply to the commissioners (commissioners for emigration, London.) No advance will be made except to persons who are competent workmen in some of the ordinary mechanical arts, as, for instance, blacksmiths, carpenters, &c.; and the advance will be further confined to men who are married, and intend to take their wives with them.

"Every person desirous of receiving the proposed advance must fill up and send back to the secretary to the commissioners the return* hereto annexed. If the information contained in this return shall be considered satisfactory, the applicant will receive notice to that effect. He may then proceed to make his agreement with the owners or masters of ships proceeding to New South Wales or Van Dieman's Land; and as soon as any shipowner or master shall notify to the commissioners for emigration (in a form which will be provided for the purpose), that the emigrant has taken the other necessary steps for engaging his passage, an order will be granted for the payment in the colony of L.20 to the agent or the master of the vessel in which the emigrant may arrive. The emigrant will of course be able to obtain a corresponding deduction from the amount to be paid by himself in this country.

"The order for payment will be entrusted to the master of the vessel in which the emigrant is to proceed, and will consist of a sealed dispatch to the governor, containing the name and description of the party on whose account the money is to be paid; but arrangements will be made by which the delivery of this order to the master will not take place until the emigrant shall have signed the acknowledgment which will be required from him of the debt he will contract with government; for it is the intention of his majesty's government—and it cannot be too clearly understood by all persons who may accept this loan—that repayment of the debt (in such proportions and at such intervals as may not be unsuitable to the circumstances of each emigrant) shall be strictly enforced by means of ample powers which the laws of the colony render available for that purpose.

"Should the number of applications to the commissioners be greater than the funds at their disposal will enable them to comply with, priority of date will form the rule of selection among applications in which there shall appear no other ground of distinction."

From these regulations it will be perceived that no *unmarried* person, or other than a mechanic, need apply for the aid of government; that the emigrant must be accompanied by his wife; that L.20 is the utmost sum which will be advanced in any case (excepting where there are daughters in a family, between the ages of 15 and 30, these being over and above provided for—*See unmarried females*;) and that he must be prepared to show that he has the means of paying the difference of the expense of his passage, which, it will be seen from the article under that head, is about double this sum for two, or man and wife; and, lastly, that the repayment of the loan will be strictly, though not oppressively, enforced after he has become fixed in the colony.

LABOURERS.

The demand for labourers in New South Wales is scarcely less eager than that for mechanics. Exaggerated accounts, however, of the encouragement as to remuneration which these may expect in Australia, have also got abroad. If stout able-bodied men, they are sure of immediate and constant employment; but their wages are not, as is stated by some, L.25 or L.30 a-year, or about 2s. per day, with board and lodging, or 3s. per day without, but 1s. per day, with a ration consisting of 12 lbs. fine flour, 12 lbs. fresh beef, 2 lbs. sugar, ¼ lb. tea, and ½ lb. of soap. In some cases labourers may meet with more advantageous terms, but those stated will be found the most general, at least they are those offered to labourers by advertisement in the Sidney papers in repeated instances, and are likely, therefore, to be near the truth, since the advertisers would not, of course, offer *more* than was necessary, and could not reasonably expect any success from their advertisements if they offered less.

UNMARRIED FEMALES.

The demand for these is not less, or rather it is now greater, than that for mechanics and labourers. Those who have some knowledge of the dairy, however, are preferred, though all are welcome, if not old or decrepid. "Female servants," says the Sidney Monitor, "of all kinds are wanted by the thousand, especially if young. All under 40 years of age," continues the same authority, "if sober and honest, may calculate on husbands, good, bad, and indifferent, within a year of their arrival, should they prefer a married life. If they keep single, they may save money." The wages of good female servants is just now L.15 per annum; these, however, would, of course, fall if the numbers that go out be very great.

To this description of emigrants the government also offers assistance, with this important difference in the terms from those on which it is offered to the mechanic, viz. that the money advanced is not again demanded, but is a free gift. The following are the government regulations on this subject:—

1st, The commissioners (of emigration) will contribute L.8 (it is now raised to L.12) towards the passage of unmarried female emigrants.

2dly, When emigrants of the above description, and between the ages of fifteen and thirty, are members of families which are about to proceed to New South Wales or Van Dieman's Land, they will, on applying to the commissioners for emigration, be furnished with orders payable in the colony for the above-mentioned sum of L.8 (now L.12). This money will be paid at the option of the emigrants, either to the heads of their families or to the captains of the ships in which they are conveyed; but it will be necessary that they should make their option before departing from this country, as the orders will be framed accordingly.

3dly, Females desirous to emigrate to New South Wales or Van Dieman's Land, and not forming part of any family proceeding to those colonies, are required to send in an account of the particulars enumerated in the annexed paper.* If they be between the ages of *eighteen* and thirty, and possess the funds which would be necessary, in addition to the sum allowed them by the commissioners, to complete the price of their passage, they will be admitted as candidates for the bounty of government.

As soon as a sufficient number of such persons shall have signified their wish to emigrate, they will be called upon to pay into the hands of an officer appointed for that purpose, their share of the charge of the passage, and the commissioners will then take up a vessel (into which no other passengers will be admitted) for the conveyance of these emigrants to their destination.

4thly, Should the number of applications to the commissioners be greater than the funds at their disposal will enable them to comply with, the preference will be given, first to females emigrating (as described in paragraph 2) in company with their families, and next to those who are qualified to make themselves useful as servants in a farmer's family. Females who may offer to pay a larger proportion than others of their passage, will also be considered entitled to a preference. In the absence of all other distinctions, priority of application will form the rule of selection.*

MISCELLANEOUS.

There is yet another description of persons who might find it for their advantage to emigrate to New South Wales, but whom we have not classed under the general head of persons suitable to emigrate to that quarter of the world—not, however, because we thought them unsuitable, but because we thought that the idea of emigrating thither was with them, more particularly than any other class, a matter of personal consideration: those whom we mean are officers of the army. The government holds out encouragement to them also to emigrate to Australia; but as the nature and extent of this encouragement will, we presume, of course, have been communicated to them officially, and as the details can interest none else, we need not here enter into them; and, on the other hand, as all that could benefit or interest any of them in the contemplation of emigrating to New South Wales has fallen to be treated of under the different heads of this article, there is nothing that might be reckoned peculiar to their circumstances to be spoken of.

Having now said thus much of those who *are* suitable to emigrate to New South Wales, we may bestow a word or two on those who *are not*:—These are men who have been brought up to no particular business, profession, or trade, and those who have been bred only to the quill, book-keepers and clerks generally being there altogether out of request; as a proof of this, there were no less than fifty applications lately in Sidney, where there is a population of only 10,000, for some small clerkship about the dock-yards. We have been the more induced to add this negative information regarding Australia, that there are many deserving men of both of the descriptions alluded to, who might possibly be tempted to try their fortunes in that new field of enterprise. Such persons, then, as we have spoken of—and we may also name weavers—ought not to think of going out unless with the means and the intention of betaking themselves to agricultural pursuits.

PASSAGE.

The distance from this country to New Holland, as we have already elsewhere said, is about 16,000 miles ship's course, that is, making an allowance for all the variations from a straight line which a ship must necessarily make. The time occupied in this voyage is generally about eighteen weeks, or four months and a half, but, on the whole, may be calculated at five months. It will be seen, on looking at a map of the world, that the course of the ship in which the emigrant embarks for New South Wales is, if she sail from Leith, Liverpool, or London, through the Straits of Dover, across the mouth of the Bay of Biscay; then she passes the opening of the Straits of Gibraltar; then the island of Madeira, where the wine bearing that name is produced; next the Canary Islands; then the Cape de Verd Islands; then crossing the equator or equinoctial line—an ideal boundary describing a circle round the middle of the earth, and dividing it into two equal parts, or into the northern and southern hemispheres—she next rounds the Cape of Good Hope, generally touching there, as well as at some of the islands named; then proceeding in a straight line due east (hitherto she had been sailing almost due south), she crosses the Southern Ocean, and finally rounding the most southerly point of the Australian land, enters Port Jackson on its eastern coast.

The price of a passage out to Sidney, including provisions, is, for a single man in the steerage, about L.23., in the cabin about L.55; for a married couple, somewhat less than the double; and for single females the charge is about L.3 less in the one case, and L.5 in the other. Children are rated according to their ages from sixteen, at three-fourths of the above rates, down to six, at one-fourth; when under twelve months old, no charge is made. Each passenger is allowed half a ton of luggage. They furnish their own bedding, and, in the case of steerage passengers, their own spoons, knives, forks, &c. These are the terms of one respectable ship agent,† and are, we believe, as liberal as those of many of the

* Printed forms of these returns may be had from any of the emigrant ship agents in Leith, Liverpool, London, &c., on application to them (post paid); and they will take the further trouble of negotiating this business for the intending emigrant, on the understanding, of course, however, that he takes his passage by one of their ships.

* As in the case of mechanics, printed forms of such a paper as is here alluded to may be obtained from any of the emigrant ship agents or owners, who will in this, as in the former case, also conduct the negociation with the commissioners for the female emigrant.

* *Note.*—Since the matter of this sheet was written, government has signified that the funds appropriated to the payment of loans and bounties to mechanics and unmarried females are temporarily exhausted. Inquiry must therefore be made by intending emigrants of these classes whether the loans and bounties are again begun to be granted. Masters of vessels and shipowners at the different ports will afford this information.

† Mr John Broadfoot, Leith, whose ship arrangements generally evince a much more than ordinary degree of care for the health and comfort of his passengers. Those for the conveyance of female emigrants are such as may reconcile the most timid to the voyage, and are judiciously calculated, in every respect, for the purposes they intend to serve.

others in the trade, whose terms and conditions differ from each other sometimes considerably. When the passage money, however, is found to be lower than that stated above, it would be well for the intending voyager to see that the difference is not made up by a deficiency in the quantity or quality of his provisions, or that it is not perhaps much more than compensated by some such arrangement, probably, as putting three grown-up persons into one bed, when there are no ordinary ship beds that can with any degree of comfort accommodate more than two. This, though apparently a trifling circumstance, and likely on that account to escape the notice of the passenger until it be too late to remedy it, becomes a serious evil on getting into warmer regions. It is then found exceedingly distressing, and in the last degree uncomfortable. Let the intending emigrant, therefore, look sharply to both of these particulars before finally engaging his passage.

THE SETTLEMENTS AT SWAN RIVER AND KING GEORGE'S SOUND.

SWAN RIVER SETTLEMENT.

This settlement is wholly unconnected with the colony of New South Wales; but being in the same quarter of the world, in the same island, it naturally falls to be spoken of in an article on our Australian possessions. The settlement takes it name, as is obvious, from the river in whose vicinity it is. This river is situated on the south-west coast of New Holland, a little way north of the most extreme southern point, on the west side of the island. Its neighbourhood was first proposed as a place of settlement in the year 1828, when Captain Stirling was appointed lieutenant-governor. The latest accounts of the progress of this little colony are upon the whole favourable, although they do not certainly hold out any very great inducements to any one to go thither.

The difficulties and privations which a new settler has to encounter at his outset in both Van Dieman's Land and New South Wales, are here still more formidable—a necessary consequence of its younger state, and its dependence on foreign supplies. The first impressions of the newly arrived emigrant are exceedingly unfavourable and disheartening. The soil appears, and really is, until you have gone about fifteen to twenty miles inland, extremely poor and barren. At this distance from the coast, however, it greatly improves, exhibiting many beautiful and fertile tracts, and bearing some of the most magnificent trees in the world. Here, also, is the same profusion of those gorgeous flowers which form so remarkable a feature of the natural vegetable productions of New South Wales and Van Dieman's Land. Its animal productions are entirely similar to those of the two former colonies, and it is equally free from any that are dangerous to man. The heat, however, would appear to be more oppressive than in either of the places just named. Whether this arises from a greater intensity in the sun's rays, or from a lighter or more irregular visitation of these cooling breezes which prevail in both New South Wales and Van Dieman's Land, is not explained, but the complaints by the settlers there of the warmth of the climate are frequent, while there are none in this particular from either of the former. The climate, however, is nevertheless exceedingly healthful. Not only have no complaints of any kind whatever, attributable to the country, appeared amongst the colonists, but they are enabled to bear exposures with impunity, which, in most other climates, might be attended with the most serious consequences.

The best land, indeed the only land yet discovered sufficiently near the settlement worth cultivating, is on the banks of the Swan River, and on those of an adjoining river, called the Canning; but even there it rarely extends on either side more than two miles from the stream, and not often so far, and all this land has been already located. There is, however, reason to believe that good tracts of country are to be found in the interior; indeed some have been found: but the young colony has not yet had time to devote to expeditions of discovery, or been able to avail itself of those that have been made. The pressure of emigration, however, and more leisure on the part of those already there, will no doubt very soon extend the dependencies of the settlement, and lead to some valuable acquisitions of country. The land already under cultivation has been found to be very productive, bearing crops of wheat and other grain equal to the best of any other country, but not yet in sufficient abundance to supply the wants of the colony. For grain, and many other articles of agricultural produce, it is still indebted to New South Wales, Van Dieman's Land, and the Cape of Good Hope; but the progress which it has made, and continues to make, bids fair to leave it at no distant date wholly independent of foreign aid.

Live stock of every kind, however, is exceedingly dear; good working bullocks have brought L.21 each; a cow and calf upwards of L.30; very indifferent Cape horses L.28 each; and South Wales sheep 40s. Provisions are also high. Fresh beef, by no means always to be had, is 1s. per lb.; potatoes, yams, and onions, 20s. per 125 lbs. Rice, tea, and sugar, however, are reasonable; the first 2½d. per lb., the second at 1s., and the last 4d. to 5d. The value of articles, however, in an infant colony such as that of Swan River, is so liable to fluctuation, so easily affected by external circumstances, and subject to the control of so many of the latter, that it is not possible to fix it; and it would therefore be unfair to represent those which we have given as ruling prices. Even while we write, a change may have taken place in this particular; and it is certain that a change has taken place within a year or two back in the prices, especially, of live stock, these having fallen considerably, and exhibiting a tendency to fall yet lower, so that they may be now very different from those we have quoted. There are already several thriving little towns in the colony, amongst these Freemantle and Perth; the former, the port, being built at the mouth of the Swan River, and the latter the capital. The site of Perth is represented as happily chosen. It is situated on a picturesque spot on the north bank of the river, about twelve to fifteen miles above Freemantle. A government house is about to be built here, and there are many others, substantially built of both brick and stone, fast rising on all sides. Colonel Hanson, who has lately published an interesting account of the Swan River settlement, speaking of this infant capital, says, "The society of the place is hospitality personified; for though their means are somewhat limited, yet they share them with the kindest good will." The intending emigrant to that quarter, therefore, may look forward to at least a kind reception from his countrymen who are already there; and this is no small matter to a man who has just arrived a stranger in a foreign land, in which he is in all probability to spend the remainder of his life, and where he is just about to engage in an arduous struggle for the support of himself and his family.

Mechanics and labourers, of whom there is a great scarcity in the settlement, receive high wages. Carpenters are represented as getting 10s. a-day, and as much work as they choose to undertake. Labourers 12s. a-week, with board and lodging besides, and a certain prospect of constant employment during their lives.

Although carpenters have been named in speaking of mechanics, all descriptions of artizans necessary in the constructing of houses meet with equal encouragement. While contemplating this high rate of wages, however, the mechanic must not overlook the set-off against it which is to be found in the great expense of living there. Provisions are high; and articles of clothing and other necessaries exorbitantly so, though certainly not nearly to the extent of equalizing expenditure to income, the latter always, with ordinary moderation in living, still greatly exceeding the former.

The description of persons who have gone out to settle in this colony are represented to have been hitherto superior, on the whole, to those who have gone to any other of the British settlements. "Even now," says a correspondent, who dates his letter from Perth, "we can sit down any day at dinner with a party of as gentlemanly and well-connected men as we usually associate with in England." And they already find themselves in a condition to indulge in some of the elegancies and amusements of refined society. Balls are frequently announced at the "Stirling Arms Hotel," an inn in the town of Freemantle.

The natives, who pay frequent visits to the settlers, appear to be exceedingly harmless and inoffensive—mild in their manners, and possessing considerable intelligence. They are of a dark copper colour, and in a state of perfect nudity. On the whole, they seem to be a much more amiable race than those in New South Wales and Van Dieman's Land; and there has not yet been, we believe, any instance of collision between them and the settlers. Their weapons are the same with those of the natives of the former colonies, viz. the spear and waddie. Their talent for imitation and mimicry is very remarkable. They will readily and correctly repeat any English word, or even a whole sentence, after the speaker, though, of course, not comprehending a word of it. When visiting the settlers, the men—for the females never appear—frequently bring their children along with them; but on these occasions they will not intrude themselves into any of the settlers' houses or tents, unless invited, and, after thankfully receiving any thing which may be given them, return peaceably to their woods. They are exceedingly timid, and of this timidity an amusing instance is given by a lady resident at Swan River to her friends in England. "Yesterday," she says, "there were about twenty natives in this place; they observed a horse and cart coming towards them, when they immediately to a man ran off, shouting in the most frantic manner—never before, it appears, having seen a thing of the kind."

One of the greatest drawbacks to the prosperity of the colony has been, and still is, the want of labourers, those taken out by emigrants of capital, having, in too many instances, taken advantage of the readiness with which employment from others was to be obtained, and the dependance which their masters necessarily had on their services, and become careless and inefficient. The former have been, on their part, besides, so indifferent about the characters of those whom they took out, that it was found necessary to appoint a magistracy to protect the persons, property, and rights of the settlers.

Stock of all kinds are said to thrive remarkably well here—a circumstance peculiarly fortunate for the colony, as it is a source of profit sooner available, and with less labour, than that of agriculture, and, therefore, better adapted to its present state; as it is also to all such settlements while only in the first stages of their existence. Where the soil is good, vegetation is represented as being very luxuriant, exhibiting what is a great desideratum in many parts of the neighbouring colonies, that variety in the grasses so essential to the health of cattle. All the European vegetables and tropical fruits which have yet been cultivated in the settlement have also thriven well; and amongst the latter we find the colony producing pine-apple, orange, lemon, and lime trees, vines, fig and coffee trees.

The whole population of the colony has been estimated at 2500, an amount which seems to be considered as amply sufficient in the meantime, until further discoveries of good lands have been made, as there is just now scarcely an acre of available soil but what is already located. Some partial exploratory expeditions have been already undertaken, and the result of these has been in some cases highly favourable, large tracts of fertile country having been fallen in with, particularly in a southerly direction from the settlement; but whether from their having been too remote from it, or too difficult of access, they yet remain unlocated. Dr Wilson, R. N., who explored the country between King George's Sound and Swan River, says, that in this excursion he passed "through a country beautifully diversified by moderately elevated hills, and fertile and verdant vallies, adorned and enriched by streams of the purest water." It would therefore appear to be in this direction, which is south and south-east of Swan River, that desirable new locations are most likely to be found. The country at seventy miles distant from King George's Sound is, he says, "well adapted for either agricultural or pastoral purposes, besides exhibiting, occasionally, some beautiful and highly picturesque scenery." Dr Wilson concludes by saying, that "the area which he walked over, three or four days journey, contained as much, if not more, land fit for every purpose of rural economy, as could be found in any portion of equal extent in New South Wales."

KING GEORGE'S SOUND SETTLEMENT.

There is little in this settlement that can be considered peculiar to itself, as all its natural properties and characteristics are the same with those of Swan River. It adjoins to and is a dependency of the latter, and is situated on the south side of that point or projection of land which places Swan River on the west coast of New Holland. Farmers, labourers, mechanics, and whale fishermen, are greatly wanted here, and are offered the following encouragement, by authority of Governor Stirling, to emigrate thither:—A gaurantee will be given, if desired, to such as wish to secure employment before leaving home, of certain wages, proportioned to their abilities and industry, and regulated by their different trades; these wages assured to be about one half more than what is given in this country. They will be also insured of a supply of provisions at a rate not exceeding a fourth more than the prices of this country. To those who prefer devoting themselves to agricultural pursuits, a grant of land, at the rate of one hundred acres to each family, will be made, free of all charge, with the advantage of fixing the prices of stock, provisions, &c., before starting; thus enabling the emigrant to form a correct idea of the amount of capital which he would require before leaving his native land—a piece of information which is often much too long of coming, sometimes not until it is too late. It is recommended that all who go thither should be married persons, and that they should be accompanied by their wives.

Generally, with regard to these settlements, we may say that a great deal too much has been said in their favour, and not a little too much against them. They appear entirely undeserving of either the encomiums of the one, or the abuse of the other. They are neither particularly desirable places to emigrate to, nor are they the reverse. The emigrant who goes thither encounters the usual amount of difficulties, and, by perseverance and industry, will in course of time, we believe, attain what is now a usual amount of success—a competency as to the means of subsistence, but no money-making.

We cannot conclude this notice of the Swan River, and its dependency King George's Sound, without noticing the very warm and flattering terms in which the present governor, Governor Stirling, is spoken of by the settlers within his jurisdiction. "His excellency," says one correspondent, "I assure you, has no sinecure in pleasing all parties; but, I think, of all the men who endeavour to act impartially, he is the man: upright, well-nerved, the rich and the poor man is the same to him. All private recommendations go for nothing, and he treats the settler who comes with a few hundred pounds with the same affability and condescension as the one who brings L.10,000." Considering how much of the happiness and prosperity of a colony depends upon the character, dispositions, and temper of its chief ruler, a sufficient inducement to emigrate to the settlements of which we have just been speaking, although there was little else, is to be found in the character of their present governor.

THE HORSE.

EARLY HISTORY OF THE HORSE.

But for the domestication and services of the horse, we should have yet been far behind in civilisation; and, without him, our luxuries would have been greatly limited. By his aid the labour of inland agriculture is much lessened, commercial intercourse is facilitated, and mankind transported with speed to distant parts.

Of all other animals, the form of the horse is the most perfect and elegant, and highly adapts him for speed; while his pliability of physical organisation, and his extreme docility of disposition, render him a willing and obedient servant to man. Daubenton remarks, that of all animals the horse seems the most beautiful; the noble largeness of his form, the glossy smoothness of his skin, the graceful ease of his motions, and the exact symmetry of his shape, have taught us to regard him as the first, and as the most perfectly formed; and yet, what is extraordinary enough, if we examine him internally, his structure will be found the most different from that of man of all other quadrupeds whatsoever. As the ape approaches us the nearest in internal conformation, so the horse is the most remote—a striking proof that there may be oppositions of beauty, and that all grace is not to be referred to one standard.

One of the most striking qualities of the horse is his intrepid courage, and extreme generosity of disposition. He has been used, in all ages since his domestication, in the battle-field, where he has ever been found to face danger, and even the shouting of the combatants, with undaunted boldness, and unshrinking firmness; the hottest cannonading, and the more irritating discharges of musketry, have failed to make him quail. Courage has ever been an attribute of the horse.

We find the following powerful description of the horse in the Book of Job, one of the oldest and best written of the Scriptures. He says, "Hast thou given the horse strength? hast thou clothed his neck with thunder? canst thou make him afraid as a grasshopper?—the glory of his strength is terrible. He paweth in the valley, and rejoiceth in his strength; he goeth on to meet the armed men. He mocketh at fear, and is not affrighted; neither turneth he back from the sword; the quiver rattleth against him—the glittering spear and shield. He swalloweth the ground with fierceness and rage; neither believeth he that it is the sound of the trumpet. He saith among the trumpets ha, ha! and he smelleth the battle afar off, the thunder of the captains, and the shouting."

The period is not known at which the horse was first domesticated. He is mentioned by the oldest writers, and it is probable that his subjugation was nearly coeval with the earliest state of society. The sacred writers tells us, that, 1702 years before the birth of Christ, horses were used. It is said in Genesis, "and Joseph gave them (the Egyptians) bread in exchange for horses." This is the first instance of horses being mentioned in the Scriptures; and from what is stated in the earlier chapters of Genesis, it would seem that the horse was unknown to the Israelites and Egyptians before that time; for in the 12th chapter of Genesis we read, that "Abram had sheep, and oxen, and men-servants, and maid-servants, she-asses, and camels," but nothing is said of horses; we may therefore reasonably conclude that they were unknown. This was 1920 years before the birth of Christ. It would therefore appear that it was a short time prior to the year 1702 before Christ that horses were first introduced into Egypt, but whence, we are not informed; and they seem to have propagated and increased in that country with great rapidity, for in the eleventh chapter of Joshua, and fourth verse, we are told, "they (certain kings opposed to Joshua) went out, they and all their hosts with them, much people, even as the sand that is upon the sea-shore in multitude, with horses and chariots very many." This was 1450 years before the Christian era.

The Scriptures, therefore, clear up the point to within a few years as to the time when horses were introduced into Egypt, which at that period was certainly the most civilised state in the world. At this epoch, Greece, which in after times was destined to astonish the world, slumbered as a barren and unpeopled waste.

It would appear that man first domesticated those animals which supplied him with food, such as the ox, the goat, and the sheep. The camel and ass seem next to have been subjugated, and to have been used as beasts of burthen.

The first breaking of the horse for riding is attributed by some authors to the Lapithæ, a people of Thessaly, and is thus described by Virgil in his third Georgic:—

> "Bold Erichthonius was the first who join'd
> Four horses for the rapid race design'd,
> And o'er the dusty wheels presiding sate:
> The Lapithæ to chariots add the state
> Of bits and bridles; taught the steed to bound,
> To run the ring, and trace the mazy round;
> To stop, to fly, the rules of war to know,
> T' obey the rider, and to dare the foe."

There is great diversity of opinion among authors as to the period when men first began to mount horses, for the purpose of riding. From the writings of Homer, we must conclude that horses were ridden long before his time, for, in a metaphor, in the fifteenth book of the Iliad, he compares the strength of Ajax, bounding from ship to ship, to that of a horseman on a strong steed.

> "Nor fights, like others, fixed to certain stands,
> But looks a moving tower above the bands;
> High on the decks, with vast gigantic stride,
> The godlike hero stalks from side to side.
> Lo, when a horseman, from the watery mead
> (Skilled in the manage of the bounding steed),
> Drives four fair coursers, practised to obey,
> To some great city, through the public way,
> Safe in his art, as side by side they run,
> He shifts his seat, and vaults from one to one;
> And now to this, and now to that he flies;
> Admiring numbers follow with their eyes."

It is quite evident that horses were not used for riding till long after the period that they were harnessed in war chariots. Sir George Ouseley mentions, in his Travels through Persia and various Countries of the East, that he examined all the relics of antiquity to be found among the ruins of Persepolis, from which he drew a conclusion, which is at once interesting, and in some measure confirmatory of the opinion above noticed, that the horse had been gradually subdued. He says, "There are no figures mounted on horseback, although some travellers have mentioned horsemen among these sculptures. One would think that the simple act of mounting on a horse's back would naturally have preceded the use of wheel-carriages and their complicated harness; yet no horsemen are found at Persepolis; and we know Homer's horses are represented in chariots, from which the warriors sometimes descended to combat on foot, but the poet has not described them as fighting on horseback. The absence of mounted figures might authorise an opinion that these sculptures had been executed before the time of Cyrus, whose precepts and example first inspired the Persians with a love of equestrian exercises, of which, before his time, they were wholly ignorant."

Although a general, it is an erroneous opinion, that Arabia was the native country of the horse; as we are warranted in supposing this not to be the case, from what is stated in Second Chronicles, chapter 9th, which informs us that King Solomon obtained gold and silver from that country; and, in the 28th verse, that "they brought unto Solomon horses out of Egypt, and out of all lands." However, Arabia is not expressly mentioned, which certainly would have been the case had horses been natives of that country. Solomon is said to have had "four thousand stalls for horses and chariots, and twelve thousand horsemen;" at which time the price of an Egyptian horse was one hundred and fifty shekels of silver, which amounts to about seventeen pounds two shillings sterling—a much larger price than at the present day, if we make allowance for the difference in the value of money.

ORIGINAL COUNTRY OF THE HORSE.

Left only to conjecture, we can but suppose, from a combination of circumstances, that Asia was the original country of the horse; for there he is found, to the present day, roving in unrestrained freedom, and we are without any historical record of his having been introduced by man into those extensive wilds; and one thing is quite certain, that he was not found either in America or New Holland at the original discovery of those continents.

The great desert tracts around the Sea of Aral and the Caspian Sea have been supposed the native country of the horse; but if this conjecture is correct, he must have widely extended his geographical range, for he is found in a wild state in Asia as far north as the sixtieth degree, and to the utmost southern extremes of that vast continent, and also in many parts of Africa; but we must suppose that those of the former country emigrated as the species multiplied. Even so late as the seventh century of the Christian era, when the Prophet Mahomet attacked the Koreish not far from Mecca, he had but two horses in his train; and although, in the plunder of this horrible campaign, he carried with him in his retreat twenty-four thousand camels, forty thousand sheep, and twenty-four thousand ounces of silver, there is no mention of horses being part of the booty. We are informed that the Arabians had but few horses, and those not at all valued; so that Arabia, where are now the most celebrated coursers in the world, is but comparatively of modern date as a breeding country.

History tells us that in the second century horses were exported from Egypt to Arabia, as presents to their kings; from which we may conjecture that their finest horses were originally the produce of Egyptian steeds, whence they were also exported to Ethiopia, India, Persia, Parthia, Armenia, Scythia, &c.

WARLIKE EQUESTRIAN TRIBES.

The Amazons, a nation of famous women, who, instead of their husbands, ruled the state, and founded an extensive empire in Asia Minor 800 years before the Christian era, were celebrated equestrians, and had a superior breed of horses.

Herodotus, who wrote in the fifth century before Christ, informs us that the Ethiopians had a good breed of horses, and were equestrians. He also tells us that the Indians were accustomed to the use of horses from very remote periods, and that the soldiers of that country who attended Xerxes in his celebrated march against the Grecians, fought on horseback as well as in war-chariots. That historian affirms that the ancient Persian horses were famous for their beauty, vigour, fire, and other qualities, and so celebrated on account of their speed, that the name of a horse in that country is *Asbon*, or *Wind-foot*—a term very expressive of the great speed of the courser. So essential did that people consider the accomplishment of riding, that they taught their children to mount a horse at five years of age. Vegetius, who wrote 386 years before the time of Christ, says that the horses of Persia were famous on account of their excellence for the saddle, being very sure-footed, extremely gentle, and easy and graceful in their motion, which was something between a gallop and an amble; and to those who cultivated the best breed they proved a great source of emolument. They were not, however, able to stand the fatigues of a long journey.

The Huns were a powerful people about 300 years before Christ, and their cavalry frequently consisted of two or three hundred thousand, formidable by the matchless dexterity with which they managed their bows and their horses, by their hardy patience in supporting the inclemency of the weather, and by the incredible speed of their marches, being seldom checked by torrents or precipices, by the deepest rivers or the most lofty mountains. They spread themselves over the face of the country; and, notwithstanding the elaborate tactics of the Chinese, directed in their operations by Kaoti, whose merit had raised him to the throne, were constrained to surrender to the victorious arms of the barbarians, in the year 201 before the Christian era. The Huns, while in the field, slept on horseback, scarcely ever dismounting.

The Parthians, about 150 years before the Christian era, are said to have managed horses with great skill, and were celebrated for their manner of fighting on them. When they happened to be discomfited by their enemies, such was their dexterity that they would turn round in their saddles, in the most rapid flight, and discharge their arrows at their pursuers, and then resume their proper seat. The poets who mention this, say that their flight was in consequence more destructive than their attacks. This mode of fighting, and the astonishing address and dexterity with which it was performed, gave them many advantages over their enemies. The very name of this country is expressive of their fame as riders, "Parthos" signifying *horsemen* in the Chaldee language. Their horses were active, and of an easy pace, owing to the trouble bestowed by that people in training them. They were, besides, very hardy, capable of undergoing great fatigue, and of travelling a great distance without either food or water.

The Armenian breed of horses was equal to that of the Parthians. Nisæa, a district of Armenia, was also celebrated for its breed of horses, which, for their great size and beauty, excelled all others known at that period. The chariot of Xerxes was drawn by horses of this breed in his expedition against Greece.

The Medes and Scythians were also proverbial for the excellence of their horses, which was accounted for, on the supposition that the local situation of their country was favourable on account of its dryness, and the beneficial influence of its pasture. The people of the latter country preferred mares to horses, and considered them more serviceable in war, and consequently rode them instead of horses.

The Sarmatians, both of Asia and Europe, were celebrated for their skill as equestrians, and possessed a very large and excellent breed of horses. They were in the practice of eating the flesh and drinking the blood of horses, mixed with the milk of sheep, as described by Virgil in his third Georgic:—

> "Th' inhabitants of Thracia's hilly ground,
> And Gelons, use it, when for drink and food
> They mix their curdled milk with horses' blood."

The Cappadocian horses have been much praised, both by historians and poets, on account of their stately figures and graceful movements.

The Numidians and Nasamonians, Mauritanians, Massilians, and Libians, were celebrated for their ascendency over the horse; they rode without either saddle or bridle, having only a switch to command and guide them. Their horses possessed great beauty, swiftness, courage, and strength. Hence the descent of the Barb, as the latter was its ancient name. Xenophon, Oppian, and Ælian, highly commended them. They are still much valued. The peasantry of Barbary continue to practise the same mode of governing and ruling their horses.

The colonists who emigrated from Egypt and Phœnicia into Greece, carried with them the horse, long before the siege of Troy. The horses of Thessaly were also famous, and highly valued by all the surrounding nations. Subsequently, the whole Grecian states became celebrated, not only on account of their excellent horses, but also for their superior skill in the management and application of this noble animal.

There can be but little doubt that the Romans acquired the art of horsemanship from the Grecians, and they cultivated it with such zeal and assiduity, that they soon rivalled their teachers. Oppian praised very highly the horses of Etruria. Those of the islands in the Mediterranean were highly prized, more especially the Sardinian and Corsican; and afterwards those of Venice and Agragas, in Sicily, were in great repute. Celpe and Tartessus, in Spain, became in their turn celebrated; and Austria and Boetica, now called Andalusia, acquired great celebrity, which they still preserve.

The ancients had a practice of impressing some mark on their horses—the most general were Σ (*sigma*), Κ (*koppa*), and the head of a bullock; and distinguishing them by these marks, they were called *bucephali*. Some authors have supposed that the celebrated horse of Alexander the Great derived his name from having impressed on him a bull's head; but we are informed by Aulus Gellius, that the appellation was derived from the resemblance of his head to that of a bull. This mode of distinguishing horses by marks was also followed by the Greeks and Romans, who impressed on them the initials of their owner's name.

THE HORSE IN THE MIDDLE AGES.

We are still uncertain as to the original country of the horse; we can therefore only describe him as he exists at the present day, in his state of unrestrained freedom, in the extensive plains of Asia and Africa, where he has been ascertained to inhabit the deserts in a free condition for many centuries.

Some authors have supposed that there were originally two distinct species of horses—one from the eastern deserts, and the other from the low alluvial lands of Europe. Although these two breeds are considerably different, both in bulk and general appearance, yet no specific difference is discoverable in them, either externally or in their anatomical construction. Besides, they breed indiscriminately; and their progeny are not mules, but continue their race; which is sufficient to convince us that they are but one species, altered by local circumstances.

From all that has been written by travellers in Asia and Africa, as well as those of other countries, it is evident that horses of almost every nation vary in a material degree from each other, both in external form and qualities. And we see what is the case in our own island, the small extent of which admits of but little variety of climate. In districts not far from each other, we find breeds differing as much, nay, even more than the Arabian and ordinary European horse. For these extremes we may refer to the large breed of Clydesdale, and the pigmy pony of Mull, and other islands of Scotland.

CONTRAST OF EUROPEAN AND ASIATIC BREEDS.

The European horses which have not been improved by eastern blood are very different indeed from those of Asia, not only in form, but also in the texture and shape of their bones, being usually round and porous, with thick ill-shapen joints—their heads are fleshy and clumsy—their jaws ill formed—their bodies large and bulky—their bellies slack—their chests fleshy—their legs thick, greasy, and liable to various diseases—their tendons are relaxed—and the texture of their hair is coarse and long, with thick and spongy hides—their general proportions are also less symmetrical than of the eastern breeds. These differences, no doubt, arise from the quality of their food, which in most parts of Europe is ill adapted to the nature and construction of their digestive organs. From this cause, their constitution is debilitated, and, in consequence, their movements are rendered sluggish and ungraceful, their ardour and spirit damped, and they seem to lose their natural gentleness of disposition. We find that it is in the dry pastures of Arabia, Persia, and Tartary, that the horse is to be found possessing superior strength and action, and that intelligence, spirit, and generous disposition, for which he has been prized by every nation. The plains of these countries seem peculiarly fitted for his constitution, being sufficiently elevated above the level of the sea to render the pasture dry, aromatic, and wholesome; free from those saline particles, which, although they give lustre to the hair, create that difficulty for the horse to become habituated to any other country whose climate may be essentially different. As a proof of this fact we may remark, that the horses of the Northern Crimea, the country bounded by the Volga and the Kuma, the Black Sea and the Don, seldom thrive until they have pastured a year, at least, in Volognea, Podolia, or the Ukraine. The horses of those, and countries with similar pasturage, are completely free from the strangles and other glandular diseases which are so frequent and fatal to the horses of Europe.

VARIATIONS OWING TO DIFFERENCE OF PASTURE.

These observations are in complete accordance with the opinions of the celebrated Bruce, the Abyssinian traveller, who perhaps had seen a greater variety of horses than any other individual. He says, "at Goree begins that noble race of horses, justly celebrated over the whole world; they are the breed that was introduced here at the Saracen conquest, and have been preserved unmixed to this day: they seem to be a distinct animal from the Arabian horse, such as I have seen in the plains of Arabia Deserta, south of Palmyra and Damascus, where I take the most excellent of the Arabian breed to be; in the tribes of Mowalli and Annecy, which is about the 36th degree of latitude; whilst Dongola, and the dry country near it, seem to be the centre of excellence for this noble animal; so that the bounds within which the horse is at its greatest perfection, seem to be between the 20th and 36th degrees of latitude, and between the 36th degree of longitude east from the meridian of Greenwich to the banks of the Euphrates; for in this extent of country Fahrenheit's thermometer is never below 50 degrees in the night, or in the day below 80 degrees, though it may rise to 120 degrees at noon in the shade, at which point horses are never affected by the heat, but will breed as they do at Halfaid, Goree, and Dongola, where the thermometer rises to these degrees. These countries, from what has been said, must of course be a dry sandy desert, with little water, producing short, or no grass, but only roots, which are blenched like our celery, being always covered with earth, having no marshes or swamps, fat soapy earth, or mould."

Through ages of domestication the horses of Britain seem to preserve their natural predilection for dry pasture, which they invariably prefer to that which is rank—thus proving that dry food must have been his original nutriment.

To food and climate, therefore, must be principally attributed the great diversity in the various races of horses in different countries. In support of this theory, we have only to refer to the wild horses of South America, which were taken to that country by the Spaniards. These are understood to have been principally of the Andalusian breed, which have continued to be the best in Spain since their first introduction by the Moors in the year 710 before Christ. The horses of Andalusia, having directly sprung from Barbs, have retained many of the points of the Moorish breed. This is to be ascribed to the high and dry soil of the province. The South American savannas, where wild herds browse, are high mountain tracts with an arid soil, and the atmosphere is dry and keen.

INTRODUCTION OF ASIATIC BREEDS INTO EUROPE.

The introduction of the Asiatic horse into Europe seems to be involved in as much uncertainty as the native country from which the horse sprung. It seems probable that the wars with the Greeks and the Persians was the means of introducing many of the Asiatic horses into the former country. Xerxes had in his army 80,000 horses, principally stallions, and must have left many behind, which would improve the Grecian breed, while their dry climate would contribute to their being preserved in their original purity. The defeat of Thermopylæ, and the occupation of it by Macedonius, would have a tendency to improve their horses, which would be assisted by their intercourse with the Levant. In all probability, it was at this time that the Asiatic breed was first introduced into the European states.

Horses must have been introduced into Spain by the Carthaginians, after their conquest of that country, which was occupied by them for upwards of two centuries; and to the same cause may be ascribed the excellent breeds of Sicily; from which two points, the eastern breed may have found its way into Europe by the south-west.

We shall now attempt to trace the means by which the horse was introduced into the north of Europe. The Russian Count Rzelwrzski makes the following interesting observation:—"There exists in all indigenous Asiatic horses, under whatever latitude, something peculiar in the expression of their countenance, in their mode of playing their ears, and in all the movements of their body, which evidently shows them to be of one family, and which is to be observed in none of the western horses, with the exception of the English, which have a great deal of Arabian blood. I noticed this in more than 187,000 Asiatic horses, which are brought annually by the Calmucks and Tartars to the celebrated fair of Berdyezoco. In 1814, there were brought to that place 67,000 horses from the great Steppe; and I may safely say, that, during the course of five years' residence in Russian Poland, I must have seen upwards of 240,000 horses of that country."

The Scythian blood must have been communicated to all the horses in the north of Europe, owing to their connection with the Sarmatians, and the commerce of the latter with more westerly nations. Strabo mentions, that a custom existed among the Scythians of mutilating their horses, in order to make them more obedient; and these being transported into the low, moist, and rank pastures of Germany, Lithuania, and Pomerania, as well as to the northern provinces of France, would naturally degenerate, from the nature of their food, as we find that the horses of low and moist countries are invariably of a large and clumsy make.

The moisture of the atmosphere, and the bad pasture, soon make an evident impression on these horses, and rapidly efface the beauty and qualities of the eastern breed, which, however, are less liable to such great changes in the countries lying betwixt Southern Poland to the heights of Kiow, from the chain of the Carpathian mountains, along the banks of the Dniester, owing to the pasture being of a superior quality. It is almost certain that the indigenous breeds of all the European horses have been derived from those of Scythia, at a very remote period; and although the latter possess many of the properties, and much of the general resemblance of the Asiatic horse, they are yet much inferior in the elegance of their shape, and the compactness of their joints.

There can be little doubt but that the state of the European horses was wretched indeed, before the wars of the Greeks and Persians, and afterwards the conquest of Spain by the Carthaginians; and it must be obvious that the communication Europe had with the south was of infinitely more advantage, in this respect, than that which it had with the north.

INFERIORITY OF THE ROMAN CAVALRY.

Polybius, in narrating the passage of the Trebia, where Hannibal obtained the celebrated victory over the Romans, gives a good idea of the wretched state of the horses of that nation. In describing the troops which were then under the command of the Consul Sempronius, he says—"Meantime, Sempronius sounded the retreat, in order to bring back the cavalry, who were ignorant of the proper mode of conducting themselves to an enemy by which they were fronted. They had, in fact, to deal with the cavalry of Numidia, whose practice it was to retreat in different directions, and then return with great vigour to the charge, when their enemy was not expecting it." The Roman army at that time was principally composed of infantry, and their cavalry was ill mounted on large and heavy steeds, little calculated to cope with the Numidian cavalry, which could boast of active and lively horses, by which means their evolutions were performed with great celerity.

The bas-relief horses of Marcus Aurelius are very unlike the eastern courser. In times still more modern, we find that the horses of Raphael, Le Brun, and other celebrated painters, are large heavy steeds, with coarse heads, which must have been the characteristics of the horses in their days. On the contrary, if we examine the figures of horses, given in the old Arabian manuscripts, particularly the celebrated ones concerning the arms, evolutions, &c. of the east, we find the same characteristics which the horses of that country preserve at the present time, although their execution as works of art are miserable in the extreme.

In the fourth century, the Greeks entered Europe by the north, overran it in a diagonal direction, as far as Spain, and, spreading laterally, dispersed Asiatic horses, and improved their breed. Afterwards the Moors, in the eighth century, introduced many horses from the east.

The Saracens, with a force of two hundred thousand soldiers, in the year 732, penetrated into France as far as the walls of Poitiers, the capital of the department of La Vienne, where they were totally routed by the army of Charles Martel. In consequence of this disaster, many of the superior horses of that people must have fallen into the hands of the French. The English might have obtained some of the improved breed of that district after the celebrated victory of Edward the Black Prince, on the 13th September 1354. Traces of eastern blood are still visible in this part of France; and in Limousin very fine horses are to be met with, which can only be accounted for from the dryness of the pasture.

Cardonne, in his Histoire d'Afrique, informs us, that, in the tenth century, the grand visier Abd-el-Malek ben Cheld presented, among other gifts of value, to the caliph Abdol-Rah-men the Third, fifteen Arabian horses of the best blood. Eastern monarchs were in the practice of sending presents of horses to France. In the year 800, Haroun-al-Raschid sent a variety of magnificent presents to Charlemagne, and among them some fine horses. It is also probable that during the crusades many eastern horses were imported into Europe by the princes and nobles engaged in that enterprise; indeed, it is almost certain that they would bring along with them some of these fine animals, which have been so highly valued by man from the remotest ages.

The celebrated Genguiskan, in the thirteenth century, brought all Asia under his sway. In his conquest he carried with him the armies of his subjugated states. This circumstance tended to amalgamate the breeds of India, Persia, and Arabia, which were ultimately scattered all over Asia.

Botam-chan, grandson of Genguiskan, in the year 1211, invaded the Crimea, dispersed the Cossack nation, and, crossing the Dnieper with his army, overran Poland, and advanced into Silesia, subduing Lublin, Cracow, Lignitz, and Breslau; penetrated into Hungary, and was on his march to Constantinople when his ambitious career was terminated by his death.

This adventurous incursion was followed by many others, but particularly by one of much importance—that of the famous Islam Gueray, who, in the year 1649, joined himself with 300,000 Tartars of the Crimea, under their leader Bogdan Schmielnicki: this army invaded Poland; and as these Tartars were in the practice of taking two horses with them in their wars, many must have been left in that country. Even in our own times, Prince Sanguisko of Volognia, sent his equerry, M. Buiski, to Haleb, whence he brought six Arabian stallions of great value; and General Obodynski brought with him, at two different times, from Constantinople, upwards of sixty horses.

MODERN HISTORY OF THE HORSE.

In the former section, we have endeavoured to show the progressive introduction of the eastern horse into Europe. But one thing of which we are assured is, that the first Arabian horse which was introduced into England was during the reign of James the First. Since that time, great intercourse has taken place between eastern countries and Europe, and also various wars; from which causes many different breeds have been imported, which have tended to improve the race. The southern varieties of the horse, however, have been preserved in their native purity in Great Britain and Ireland alone. Besides, in the deserts around the Sea of Aral, wild horses are also found in very large troops in those extensive upland vallies on the sides of the Mus Tag mountains, which bound the great valley of Asgar, through which flows the river Indus on the east, and the Belur Tag mountains on the west. There are also numerous herds in the vallies amongst the Great Candhur range, and also in the Hyderabad mountains.

In the Charmar mountains, towards the north of China, there are some inconsiderable troops of wild horses; and still farther north, amongst the vallies of the Altai range, and even so far as in the northern boundaries of Siberia, wild herds are occasionally to be met with; but these are an inferior race, with large heads, coarse, ill-formed limbs, and very thick about the joints. It is said that some straggling individual pairs have been seen even so far north as the plains in the district of Tungousi. Wild horses are also to be met with near the Cape of Good Hope, in the mountain plains of Graaff Reinett.

THE HORSE IN HIS NATURAL STATE.

"To have an idea," says Goldsmith, "of this noble animal in his native simplicity, we are not to look for him in the pastures or the stables, but in those wild and extensive plains where he has been originally produced, where he ranges without control, and riots in all the variety of luxurious nature. In this happy state of independence he disdains the assistance of man, which only tends to servitude. In those boundless tracts, whether of Africa or New Spain, where he runs at liberty, he seems no way incommoded with the inconveniences to which he is subject in Europe. The continual verdure of the fields supplies his wants, and the climate, that never knows a winter, suits his constitution, which naturally seems adapted to heat. His enemies of the forest are but few, for none but the greater kinds will venture to attack him; any one of these he is (singly) able to overcome; while, at the same time, he is content to find safety in society, for the wild horses of these countries always herd together."

Wild horses are always to be met with in droves of from five hundred to a thousand, seldom exceeding the former number in Asia or Africa, as food in these countries is less abundant than in America. They never attack other animals, but always act upon the defensive. Their pastures satisfy their appetites, and, when exhausted, they have only to shift their stations to places where their food is plentiful. They are seldom to be taken by surprise; but, if attacked, the assailant seldom comes off victorious, for the whole troop unites in defence of their comrades, and seldom fail either to tear their enemy to pieces, or kick him to death.

Wild horses usually retire to the confines of a forest to repose. One or more of their number are always awake to keep watch while the rest are asleep, and who warn their fellows of approaching danger, which is done by loud snorting or neighing; upon this signal they start to their feet, and either reconnoitre the enemy, or fly off with the swiftness of the wind, followed by the sentinel, and by the stallion who is patriarch of the herd.

In the desert tracts along the sides of the Don, in Russia, there are numerous troops of wild horses, which have sprung from emancipated progenitors. The Cossacks frequently take these, and breed from them, by crossing them with their domesticated horses, which are said to be thereby greatly improved. Pallas says they abound in the vicinity of the Palus Mæotis. These herds are the descendants of the Russian horses which were used at the siege of Asoph, in 1696, when taken from the Turks by Peter the Great, who was compelled, from want of forage, to set at liberty nearly the whole horses belonging to his cavalry, to seek food for themselves. They are now quite wild, and associate in troops in the same manner as other wild horses. Those herds which have remained close to the alluvial and fertile banks of the river are of a large size, owing to the rankness of their food; the ground in these situations is so extremely swampy, that no solid edifice can be erected near the river, the whole surrounding country being little better than a morass. The herds which inhabit the higher mountain districts have all the appearance of the horses from which they sprung. It is supposed that the troops found in the plains of Great Tartary are descended from the same source as those of the banks of the Don and the Ukraine.

AMERICAN WILD HORSES.

In the vast plains of South America, immense troops of wild horses are to be found, which have all sprung from emancipated individuals taken to that country by the Spaniards. The geographical range of these herds extends from the shores of La Plata to Patagonia. They have increased with such astonishing rapidity, that they are to be met with in troops of many thousands. Azzara affirms that they sometimes congregate in herds of not less than ten thousand individuals: they are invariably preceded by a leader, who appears to direct all their movements, which are performed in a manner so perfectly systematic, as hardly to be surpassed in regularity by the best trained cavalry. It is very dangerous for travellers to pass through the districts; for, if perceived by the wild herd, they will approach closely to those who are mounted on horseback. After their leader and videttes have reconnoitred the strangers, they will, at the direction of their leader, make a rapid course round the traveller, and, with loud and inviting neighing, tempt the tame horses, which are either saddled or loaded, to join them. If the rider does not use the utmost precautions, or the leader of the laden horse does not exert his utmost care, they will either fling the rider, or throw off their burden, and precipitately join the wild troop, after which they are lost for ever. The whole troop seem delighted at their acquisition, and hurriedly fly off in a body to the desert, while the neighbouring earth vibrates under the weight of these mighty phalanxes. They will frequently return, and sweep round the astonished traveller like the whirlwind of the desert, threatening instant annihilation, when, of a sudden, they will simultaneously set up the most vehement neighing, wheel in an opposite course, and disappear in the neighbouring wilderness. These immense troops do not always feed in company, and only congregate in cases of alarm, and again disperse into smaller herds when the cause of alarm has passed away.

In the province of Cumana there are numerous wild horses, associating in troops of from five or six hundred, and even one thousand. They occupy the great savannas, where it is dangerous to disturb or try to catch them. In the dry season, they are sometimes forced to travel two or three leagues, and even more, in search of water. They set out in regular ranks, four abreast, and thus form a procession of an extent of a quarter of a league. There are always five or six scouts, who precede the troop by about fifty paces. If they perceive a man, a puma, or a jagur, they neigh, and the troop stops; if avoided, they continue their march; but if an attempt be made to pass across their route, they leap on the imprudent traveller, and crush him under their feet. It is best to avoid coming in contact with them in these marches. They have also a chief, whose station is between the scouts and the squadron; he is a kind of adjutant, whose duty consists in preventing individuals from quitting the ranks. If any one attempts to straggle, either from hunger or fatigue, he is bitten till he resumes his place, and the culprit never fails to obey, but with disappointed looks, and with his head hanging down. Three or four chiefs march as the rear-guard, at five or six paces from the troop. An instinctive duty impels these horses to obey that rule which they seem to know is for their common good; and this instinct, if not absolutely reason, is very nearly akin to it. It is quite evident that all gregarious animals are aware that their safety consists in their united force, and in a principle of subordination, which in many respects is superior to the efforts of man in a savage state.

The wild horses of America are generally of a chestnut bay, sorrel, or black. The latter colour, however, is not very common, and the chestnut usually predominates, from which some authors suppose it to be the original colour of the horse; but we do not find that to be the leading colour of the Asiatic wild breeds, bay-dun being, in that continent, the most common.

When wild horses are attacked by the puma or jagur—which are their principal enemies in America—by a particular signal, which they all understand, they close into a dense mass, and trample their assailant to death; or, forming a circle, with the young and foals in their centre, defend themselves with their heels, and strike with such velocity and force, that no animal is capable of withstanding them. When an attack becomes necessary, their leader shows the example; and if he considers a retreat necessary, he gives them the signal, which they simultaneously obey.

Captain Head, in his journey across the Pampas, gives us an interesting account of his meeting a wild troop in a district of the country where the population is pretty dense. Some of the unfortunate captured horses are supposed to be forced along by their riders at their full speed; he says—"As they are thus galloping along, urged by the spur, it is interesting to see the groups of wild horses one passes. The mares, which are never ridden in South America, seem not to understand what makes the poor horse carry his head so low and look so weary. The little innocent colts come running to meet him, and then start away frightened; while the old horses, whose white marks on the flanks and backs betray their acquaintance with the spur and saddle, walk slowly away for some distance; then breaking into a trot, as they seek their safety, snort and look behind them, first with one eye and then with the other, turning their nose from right to left, and carrying their long tails high in the air."

HORSE-TAMING IN SOUTH AMERICA.

In South America there are no regular stables, their horses being either kept in pastures, which are fenced, or in what they call *corrals*, which consist of a circular enclosure of rough posts, driven into the ground so close, that a horse cannot pass through between them. In these, however, the mares and foals are never confined, but are allowed to graze about at freedom. They however usually keep one horse tied at the door of their hut, to be ready in case of immediate need, which they feed on a scanty meal of maize at night. If an additional horse is wanted, the gaucho (who is a native inhabitant of the plains) goes to the *corral* with his *lasso*, and fetches one which may have been only subdued the preceding day; or he will go to the plain where they are grazing at freedom, and bring one which he has backed for the first time; and when these horses have been once used, they are either put into the *corral* and fed with maize, or returned to the plain to feed at liberty. This *lasso* is a very simple contrivance, but of great power in the hands of the gaucho, who is accustomed to use it from his youngest years, or at least to see it done, and he puts it in practice as soon as he has sufficient strength to use it. Miers, in his Travels in Chili, gives the following account of it:—

"The *lasso* is a missile weapon, used by every native of the United Provinces and Chili. It is a very strong plaited thong, of equal thickness, half an inch in diameter, and forty feet long, made of stripes of green hide, plaited like a whip-thong, and rendered supple by grease. It has at one end an iron ring, about an inch and a half in diameter, through which the thong is passed, and this forms a running noose. The gaucho, or native peon, is generally mounted on horseback when he uses the lasso; one end of the thong is affixed to his saddle-girth; the remainder he coils carefully in his left hand, leaving about twelve feet belonging to the noose end in a coil, and a half of which he holds in his right hand. He then swings this long noose horizontally round his head, the weight of the iron ring at the end of the noose assisting in giving to it, by a continued circular motion, a sufficient force to project it the whole length of the line."

It is sometimes necessary to break in a number of horses at once: in this event, they drive a whole herd of their wild horses into the corral at one time. This scene was witnessed by Miers, who thus describes it:—"The corral was quite full of horses, most of which were young ones about two or three years old. The *capitaz* (chief gaucho), mounted on a strong sturdy horse, rode into the corral, and threw his lasso over the neck of a young horse, and dragged him to the gate. For some time he was very unwilling to leave his comrades; but the moment he was forced out of the corral, his first idea was to gallop away; however, a timely jerk of the lasso checked him in the most effectual way. The peons now ran after him on foot, and threw a lasso over his fore-legs, just above the fetlock, and, twitching it, they pulled his legs from under him so suddenly, that I really thought the fall he got had killed him. In one instant a gaucho was seated on his head, and with his long knife, and in a few seconds, cut off the whole of the horse's mane, while another cut the hair from the end of his tail. This, they told me, was a mark that the horse had been once mounted. They then put a piece of hide into his mouth, to serve for a bit, and a strong hide halter on his head. The gaucho who was to mount arranged his spurs, which were unusually long and sharp; and while two men held the horse by his ears, he put on the saddle, which he girthed extremely tight. He then caught hold of the horse's ear, and in an instant vaulted into the saddle, upon which the men who held the horse by the halter threw the end to the rider, and from that moment no one seemed to take any farther notice of him.

"The horse instantly began to jump in a manner which made it very difficult for the rider to keep his seat, and quite different from the kick or plunge of our English horse: however, the gaucho's spurs soon set him going, and off he galloped, doing every thing in his power to throw his rider.

"Another horse was immediately brought from the corral, and so quick was the operation, that twelve gauchos were mounted in a space which I think hardly exceeded an hour. It was wonderful to see the different manner in which different horses behaved. Some would actually scream while the gauchos were girthing the saddle upon their backs; some would instantly lie down and roll upon it; while some would stand without being held, their legs stiff, and in unnatural positions; their necks half bent towards their tails, and looking vicious and obstinate; and I could not help thinking that I would not have mounted one of those for any reward that could be offered me, for they were invariably the most difficult to subdue.

"It was now curious to look around and see the gauchos on the horizon, in different directions, trying to bring their horses back to the corral, which is the most difficult part of their work; for the poor creatures had been so scared there, that they were unwilling to return to the place. It was amusing to see the antics of the horses; they were jumping and dancing in different ways, while the right arm of the gaucho was seen flogging them. At last they brought the horses back apparently subdued and broken in. The saddles and bridles were taken off, and the young horses trotted off towards the corral, neighing to one another."

Captain Hall, in his journey to Peru and Mexico, describes the manner in which the gaucho takes a wild horse. He first mounts a horse which has been accustomed to the sport, and gallops him over the plain, in the direction where the wild herds are, and, circling round, by degrees gets close to one of them, which, as soon as he has approached sufficiently near, "the lasso is thrown round the two hind legs, and as the gaucho rides a little on one side, the jerk pulls the entangled horse's feet laterally, so as to throw him on his side, without endangering his knees or his face. Before the horse can recover the shock, the rider dismounts, and, snatching his *poncho* or cloak from his shoulders, wraps it round the prostrate animal's head. He then forces into his mouth one of the powerful bridles of the country, straps a saddle on his back, and, bestriding him, removes the poncho, upon which the astonished horse springs on his legs, and endeavours, by a thousand vain efforts, to disencumber himself of his new master, who sits quite composedly on his back, and, by a discipline which never fails, reduces the horse to such complete obedience, that he is soon trained to lend his whole speed and strength to the capture of his companions."

The mares are frequently killed for food, particularly on festive occasions. During the war of independence, General San Martin gave a grand feast to the Indians who had joined his standard as allies. The whole entertainment consisted of mares' flesh, and the blood mixed with gin. The Indians are in the habit of eating horse flesh raw, as well as that of other animals.

The rapid increase of horses in South America is somewhat checked by a species of madness which breaks out amongst them, owing to the scanty supply of water during the dry season. All the noble and generous qualities of this animal disappear, frenzy seizes them, and they rush precipitately into every pool or lake they meet with, trampling each other to death. On these occasions thousands have been found dead in the neighbourhood of a pool or rivulet.

There is a remarkable difference in the dispositions of the Asiatic and South American wild horses: those of the former country can never be properly tamed, unless trained very young; if taken when adults, they frequently break out in violent fits of rage in after life, exhibiting every mark of natural wildness; while those of America can be brought to perfect obedience, and even rendered somewhat docile, within a few weeks, nay, sometimes days. It would be difficult to account for this opposition of temper, unless we can suppose that it is influenced by climate.

PARTICULAR ACCOUNT OF THE HORSE.

The horse at five years of age, at which time he is in a state of maturity, has six incisory or cutting teeth in both the upper and under jaw, in familiar language termed nippers, and two canine teeth in each jaw, termed tushes, situated inside of the cutting teeth; six cheek teeth, or grinders, on each side, in both jaws; they are furrowed on both sides, and their crowns are flat, having on them several ridges of enamel. There is a void space between the canine and the cheek teeth. The upper lip of the horse is susceptible of considerable motion; his eyes are large; the pupils are of an oblong shape, and placed laterally; their sight is excellent, and they have even much acuteness in distinguishing objects in the dark; the ears are rather small, pointed, and placed erect, and capable of great motion; the feet are protected by a strong hoof; the tail provided with long flowing hair; and the neck decorated by an elegant flowing mane.

A few days after the birth of the foal, the two middle incisory teeth appear in each jaw. Betwixt the third and fourth months two others make their appearance at the right and left, and the last two within six months. These are called the milk teeth, and are reproduced at intervals of six months, between two and three years of age.

The age of a horse is known by certain marks on his incisory teeth, but no reference whatever is made to the grinders. Between two and three months, the centre nippers have reached their proper level, and the second pair grown.

The nippers are complete in number at a year old; the four middle teeth being worn level, and the two outer ones becoming flat. The marks of the two middle teeth get faint and wide; in the next two they become darker and more narrow—being darker, longer, and narrower, in the outer two.

The nippers at two years old exhibit a considerable change in the shape and markings.

At three years old the central nippers are considerably larger than the others, doubly grooved on their outer convex surface; the marks on the next two incisors being nearly obliterated, and beginning to disappear in the corner nippers. When a horse is rising three years, his two central nippers above and below fall out, and are replaced by new ones, having the hollow mark in the middle; at the end of this year the tushes will have made their appearance; there is also a visible difference in the form of the jaw.

At four years the central nippers are perfectly formed, and the sharp edges a little worn off, with the mark shorter, wider, and fainter.

At five years the jaw is nearly perfect. The tushes are much developed.

In the sixth year the marks in the centre nippers are worn out. There will, however, be some difference of colour in the centre of the tooth, as the cement, or enamel, which fills the cavity, is of a brownish hue.

At eight years the marks on the lower jaw are nearly filled up, but on the upper jaw they generally continue till ten; the two central ones are, however, obliterated at eight.

At this period the disgraceful practice of *Bishoping* is often resorted to; a term given from the name of the inventor. The marks on the surface of the corner nippers, which have now nearly become plain, are imitated, as at the age of seven, by an engraving tool. They are then burned with a hot iron, when a permanent black stain is left. This practice is sometimes employed on the next pair of nippers in a slight degree. By this infamous trick the ignorant are often imposed on. But the irregular appearance of the cavity, the diffusion of the black stain around the tushes, the sharpened edges, and concave inner surfaces, are wanting, which no art can imitate; thus an attentive observer need not be deceived.

At ten, merely the rudiment of the funnel of the nippers remains.

In a jaw at twelve years old, the nippers have lost the central enamel, and the septum of the root is rounded.

At sixteen, all the nippers have become triangular in shape, and the septum of the root forms a rounded point on all the tables of the teeth.

The ordinary time at which the mare gives up producing is from fifteen to eighteen, although there are some instances of their having foals at an advanced age.

The Limerick Evening Post for 1829 stated that at that time Mr Thomas Kepper, in the parish of Athnakisha, county of Cork, had a mare, which, in the June of that year, produced a foal while she was then in her forty-ninth year. Opposed to the above remarkable circumstance, we may mention, that, on the 12th May 1826, Mr Archibald Hamilton, Broomhill, parish of Wamphray, Dumfriesshire, had a mare which produced a foal, although at that time she wanted some days of being two years old, which is a circumstance altogether unprecedented in English breeding.

The horse will live to a great age if properly treated; the oldest on record is one which was in the stable of Ferdinand the First, which attained the very advanced age of seventy years. The most serviceable period of a horse's life is betwixt the years of five and ten, but horses have continued in unimpaired vigour till the age of twenty; and instances have been known of their being wrought till above thirty years old. Mr Ganby says, "In addition to the many recorded instances of a longer life in the horse than is commonly met with, I can adduce the following one of my own, and the best I ever possessed, whether in the field or on the road, and which I bought when he was *twenty-two years old;* and after this he was hunted hard three seasons, as well as rode as a hackney during the summers."

The mare goes with foal usually about eleven months, seldom varying more than a few days; she brings forth but one at a birth, which is covered with hair, and with the eyes open, and so strong as to be able to walk. Sometimes, however, twins are produced, but such instances are very rare. A remarkable instance is recorded in the Sporting Magazine for August 1794, of a mare producing twins; the first a few days after she had gone eleven months, so extremely weak and small as not to give any hopes of its attaining maturity, and so frightfully ill formed, that Bergem, the proprietor of it, was at first inclined, and universally advised, to destroy it, there being no hopes of it ever reaching maturity. He however permitted it to continue with the mare, who, after an interval of fourteen days, to the astonishment of every one, produced a colt-foal of the most lively and promising appearance, which, with the first weak foal, was allowed to be suckled by the dam.

The foal is suckled for twelve months, and does not reach its full adult state till five years.

INTELLECTUAL CHARACTER.

The horse is possessed of acute and delicate senses; his intellectual character is marked by a quick perception, a most retentive memory, and great benevolence of disposition. It is well known that a horse will rarely tread on a human being, if lying on the ground, but will step over him with the utmost caution.

Endowed with vast strength and great activity, the horse seldom exerts either to his master's prejudice; on the contrary, he will endure fatigue, and death itself, in the service of his owner. But it is not to man alone that his affections are confined, for he extends his attachments to all other animals with which he may be associated. Every person who is possessed of a dog and a horse must have observed their familiar attachment; cats also have been frequently the favourites of the horse, and his attentions to the goat are no less remarkable.

The horse is greatly attached to music, and listens to a band with apparent delight, and will frequently use his endeavours to get close to it. This propensity has been known from the earliest ages. We are informed by Gratius that the Libyan shepherds used to allure wild horses by the charms of music.

This valuable animal proves useful to man even after he is dead; his hide makes a valuable leather for harness and coach-work; from the hair of his mane and tail is manufactured haircloth, and it is also used for ropes and fishing lines; his bones are converted into magnesia, and ground into manure; and in Tartary and other eastern countries his flesh is esteemed excellent food.

SUPERIORITY OF THE HORSE IN ELEGANCE.

"Of all quadrupeds," says Buffon, "the horse possesses, along with grandeur of stature, the greatest elegance and proportion of parts. By comparing him with the animals above or below him, we find that the ass is ill made; that the head of the lion is too large; that the limbs of the ox are too slender and too short in proportion to the size of his body; that the camel is deformed; and that the grosser animals, as the rhinoceros, hippopotamus, and elephant, may be considered as rude and shapeless masses. The great difference between the head of man and that of the quadrupeds consists in the length of their jaws, which is the most ignoble of all characters. But although the jaws of the horse be very long, he has not, like the ass, an air of imbecility, nor, like the ox, of stupidity. The regularity and proportion of the parts of his head give him a light and sprightly aspect, being gracefully attached to his finely arched neck, which is well supported by the beauty of his chest. He elevates his head as if anxious to exalt himself above the condition of other quadrupeds. In this noble attitude he regards man face to face. His eyes are open, lively, and intelligent; his ears handsome and of a proper height, being neither too long, like those of the ass, nor too short, like those of the bull. His mane adorns his graceful neck, and gives him the appearance of strength and courage. His long bushy tail covers, and terminates with advantage, the extremity of his body. His tail, very different from the short tails of the deer, elephant, and hippopotamus, and from the naked tails of the ass, camel, and rhinoceros, is formed of long thick hairs, which seem to rise from his crupper, because the trunk from which they proceed is very short. He cannot, like the lion, elevate his tail; but, though pendulous, it becomes him better; and as he can move it from side to side, it serves him to drive off the flies which incommode him; for though his skin is very firm, and well garnished with close hair, it is nevertheless very sensible."

The way in which the head of the horse joins his neck, contributes, above all other peculiarities of his form, to give him a graceful aspect; its most advantageous position is when the front is perpendicular to the horizon. The superior ridge of his neck from which the mane issues, should first arise in a straight line from the withers, and then, as it approaches the head, form a curve nearly similar to that of a swan's neck. The inferior part of the neck should have no curvature, but rise in a straight line from the poitral or breast, to the under jaw, with a small inclination forward. If it rose in a perpendicular direction, its symmetry and gracefulness would be greatly diminished. The superior part of the neck should be thin, with little flesh near the mane, which ought to be decorated with long flowing and delicate hair. The neck, to be fine, must be long, elevated, and proportioned to the general size of the animal: when too long, the horse commonly throws back his head; and when too short and fleshy, the head is heavy to the hand in riding.

The head of the horse should not be too long, and it ought to be rather thin than otherwise. The front should be narrow, and a little convex; the eyepits well filled, and the eyelids thin; the eyes large and prominent, clear, lively, and sparkling with fiery glances. The pupil should be large; the under jaw should be a little thick, but not fleshy; the nose slightly arched, the nostrils open and deep, and divided by a thin septum or partition. The ears should be small, erect, and narrow, but not too stiff, and placed on the upper part of the head, at a proper distance from each other, but not too wide, as this always gives a horse a disagreeable aspect. The mouth should be delicate, and moderately split; the withers sharp and elevated; the shoulders flat, and not confined; the back equal, a little arched lengthwise, and raised on each side of the spine, which should have the appearance of being slightly sunk; the flanks short and full; the crupper round and plump; the haunches well furnished with muscular flesh; the dock or fleshy part of the tail firm and thick; the thighs large and muscular; the hough round before, broad on the sides, and tendinous behind; the shank thin before, and broad on the sides; the tendo Achilles prominent, strong, and well detached from the leg-bone, and the fetlock somewhat prominent, and furnished with a small tuft of hair behind; the pasterns should be of a middle length, and pretty large; the coronet a little elevated; the hoof black, solid, and shining; the instep high, the quarters round, the heels broad and a little prominent, the frog thin and small, and the sole thick and concave.

THE ARABIAN HORSE.

Although Arabia is not the original abode of the horse, as many have supposed, yet it is the country where he is to be found in a domesticated condition, exhibiting his pristine beauty, symmetry, and spirit. In that country he is preserved without the admixture of any foreign breeds, and consequently preserving the exquisite proportions, elegant structure, fleetness, and docility, for which he has been so famous for so many past ages. These are only of a middle stature, their limbs remarkable for the beautiful form and cleanness, and the make of their bodies rather slender.

The pure Arabians are somewhat smaller than our race horses, seldom exceeding fourteen hands two inches in height. Their heads are very beautiful, clean, and wide between the jaws; the forehead is broad and square; the face flat; the muzzle short and fine; the eyes prominent and brilliant; the ears small and handsome; the nostrils large and open; the skin of the head thin, through which may be distinctly traced the whole veins of the head. The body may, as a whole, be considered too light, and the breast rather narrow; but behind the arms, the chest generally swells out greatly, leaving ample room for the lungs to play. The shoulder is superior to that of any other breed; the scapulæ, or shoulder-blades, incline backwards, nearly in an angle of 45 degrees; the withers are high and arched; the neck beautifully curved, and the mane and tail long, thin, and flowing; the legs are fine, thin, and wiry, with the pasterns placed somewhat oblique, which have led some to suppose that his strength was thereby lessened, which is by no means the case; the bone is of uncommon density, and the prominent muscles of the forearm and thigh prove that he is fully equal to all that has been said of his physical powers.

Bishop Heber gives the following interesting account of the docility and mild temper of the Arabian horse. He says—"My morning rides are very pleasant. My horse is a nice, quiet, good-tempered little Arab, who is so fearless, that he goes, without starting, close to an elephant, and so gentle and docile, that he eats bread out of my hand, and has almost as much attachment and coaxing ways as a dog. This seems the general character of the Arab horses, to judge from what I have seen in this country. It is not the fiery dashing animal I had supposed, but with more rationality about him, and more apparent confidence in his rider, than the majority of English horses."

If the Arab lies down to sleep in his journey through the Desert, as he is frequently obliged to do from fatigue, his faithful mare will either browse on such herbage as may be near the spot, or will watch her master with the utmost solicitude; and if a man or animal approaches, she will neigh loudly till he is awakened.

The Arabs of the Desert have made the breeding of horses their sole occupation for ages bygone; and, from their strict attention to certain rules, they may be justly regarded as the first breeders in the world. They take infinite trouble in grooming their steeds, and are extremely regular in their hours of feeding them morning and evening. They get but little drink, and that is supplied to them two or three times a-day; they conceive that much water not only destroys their shape, but also affects their breathing. In spring they are pastured on dry aromatic herbage, and during the rest of the year they are fed on barley, with a small quantity of straw; and they are the hardiest horses in the world.

ANECDOTES OF ARABIAN HORSES AND THEIR MASTERS.

The following interesting account of the hardihood of the Arabian is given by M. Chateaubriand, who, in his Travels in Greece, says—"They are never put under shelter, but left exposed to the most intense heat of the sun, tied by all four legs to stakes driven in the ground, so that they cannot stir. The saddle is now taken from their backs. They frequently drink but once, and have only one feed of barley, in twenty-four hours. This rigid treatment, so far from wearing them out, gives them sobriety and speed. I have often admired an Arabian steed thus tied down to the burning sands, his hair loosely flowing, his head bowed between his legs, to find a little shade, and stealing with his wild eye an oblique glance of his master. Release his legs from the shackles, spring upon his back, and he will 'paw in the valley, he will rejoice in his strength, he will swallow the ground in the fierceness of his rage;' and you recognise the original picture of Job. Eighty or one hundred piastres are given for an ordinary horse, which is in general less valued than an ass or a mule; but a horse of well-known noble blood will fetch any price. Abdallah, Pacha of Damascus, had just given three thousand piastres for one.

"The history of a horse is frequently the topic of conversation. When I was at Jerusalem, the feats of one of these steeds made a great noise. The Bedouin to whom the animal (a mare) belonged, being pursued by the governor's guards, rushed with him from the top of the hills that overlooked Jericho. The mare scoured at full gallop down an almost perpendicular declivity without stumbling, and left the soldiers lost in admiration and astonishment. The poor creature, however, dropped down dead on entering Jericho and the Bedouin, who would not quit her, was taken, weeping over the body of his faithful companion. This mare has a brother in the desert, who is so famous, that the Arabs always know where he has been, where he is, what he is doing, and how he does. Ali Aga religiously showed me in the mountains near Jericho the footsteps of the mare that died in the attempt to save her master. A Macedonian could not have beheld those of Bucephalus with greater respect."

Clarke in his Travels gives the following agreeable account of the love of the Arab for his horse:—"Ibrahim went frequently to Rama, to inquire news of the mare, which he dearly loved; he would embrace her, wipe her eyes with his handkerchief, would rub her with his shirt-sleeves, would give her a thousand benedictions, during whole hours that he would remain talking to her. 'My eyes!' would he say to her, 'my soul! my heart! must I be so unfortunate as to have thee sold to so many masters, and not keep thee myself? I am poor, my antelope! Thou knowest it well, my darling! I brought thee up in my dwelling as my child. I did never beat nor chide thee; I caressed thee in the fondest manner. God preserve thee, my beloved! thou art beautiful, thou art sweet, thou art lovely! God defend thee from envious eyes!' This man's name was Ibrahim; being poor, he had been under the necessity of allowing a merchant of Rama to become partner with him in the possession of this mare. She was called Toaise; her pedigree could be traced on the side of sire and dam for five hundred years prior to her birth. The price was three hundred pounds, an enormous sum in that country."

The Arabs have no written rules for the management of horses; it is handed down by oral instruction from father to son. They will never sell their mares on any account whatever, even for any price, an excellent illustration of which will be found in the following well-authenticated anecdote:—

The whole stock of a poor Arab of the Desert consisted of a mare: this the French consul at Said offered to purchase, with an intention of sending her to Louis the Fourteenth. The Arab hesitated long, but, being pressed by poverty, he at length consented, on condition of receiving a very considerable sum of money, which he named. The consul wrote to France for permission to close the bargain, and, having obtained it, he immediately sent for the Arab to receive the mare and pay for her. He arrived with his magnificent courser. He dismounted, a wretched spectacle, with only a miserable rag to cover his body. He stood leaning upon the mare; the purse was tendered to him; he looked earnestly at the gold, and, looking steadfastly at his mare, heaved a deep sigh; the big tears trickled down his cheeks:—"To whom is it," he exclaimed, "that I am going to yield thee up? To Europeans, who will tie thee close, who will beat thee, who will render thee miserable! Return with me, my beauty! my jewel! and rejoice the hearts of my children!" As he pronounced the last words, he sprang upon her back, and was out of sight in a moment. What an amiable and affecting sensibility in a man, who, in the midst of distress, could prefer all the disasters attendant on poverty, rather than surrender the animal that he has long fostered in his tent, and had been the child of his bosom, to what he supposed inevitable misery! The temptation of riches, and an effectual relief from poverty, had not sufficient allurements to induce him to commit what he considered so cruel an act.

An Arab, who had arrived at upwards of eighty years of age without having had a day's sickness during that long life, had a favourite mare that had carried him for fifteen years through the perils of many a hard fought battle and long march, and which had produced to him several excellent foals. Being now unable longer to ride, he presented the mare, and a scimitar that had been his father's, to his eldest son, and told him to appreciate their value, and never to lie down to rest until he had rubbed them both as bright as a mirror. In the first skirmish in which the youth was engaged, he was killed, and the mare fell into the hands of the enemy. When the news reached the old man, he said, "What is life to me, now that I have lost both my son and the favourite of my heart?—they equally share in my grief, and I would gladly meet death, as my life is no longer sweet to me." He almost immediately thereafter took ill and died.*

The following amusing anecdotes are related by Sir John Malcolm:—"When the envoy, returning from his former mission, was encamped near Bagdad, an Arab rode a bright bay mare of extraordinary shape and beauty before his tent, until he attracted his attention. On being asked if he would sell her—'What

* Smith on Breeding for the Turf, p. 79.

will you give me?' was the reply. 'That depends upon her age; I suppose she is past five?' 'Guess again,' said he. 'Four?' 'Look at her mouth,' said the Arab, with a smile. On examination, she was found to be rising three. This, from her size and symmetry, greatly enhanced her value. The envoy said, 'I will give you fifty tomans' (a coin nearly of the value of a pound sterling). 'A little more if you please,' said the fellow, a little entertained. 'Eighty —A hundred.' He shook his head, and smiled. The officer at last came to two hundred tomans! 'Well,' said the Arab, 'you need not tempt me further; it is of no use. You are rich elchee (noblemen). You have fine horses, camels, and mules, and I am told you have loads of silver and gold. Now,' added he, 'you want my mare, but you shall not have her for all you have got.'

"An Arab shiek or chief, who lived within fifty miles of Bussorah, had a favourite breed of horses. He lost one of his best mares, and could not for a long while discover whether she was stolen or had strayed. Some time after, a young man of a different tribe, who had long wished to marry his daughter, but had always been rejected by the sheich, obtained the lady's consent, and eloped with her. The sheick and his followers pursued, but the lover and his mistress, mounted on one horse, made a wonderful march, and escaped. The old chief swore that the fellow was either mounted upon the devil or the favourite mare he had lost. After his return, he found the latter was the case; that the lover was the thief of his mare as well as his daughter; and he stole the one to carry off the other. The chief was quite gratified to think he had not been beaten by a mare of another breed, and was easily reconciled to the young man, in order that he might recover the mare, which appeared an object about which he was more solicitous than about his daughter."

The Arabs are most particular regarding the pedigree of their horses, and they have amongst them a breed which they pretend has descended from a horse of King Solomon's. It must not, however, be supposed that all the horses of that country are of the finer kinds, for they have three distinct breeds: the two inferior kinds they say were introduced from India and Greece. The superior kinds they call nobles, and they are never sold without a pedigree, which is more scrupulously attended to than with human beings in Europe.

PEDIGREE OF AN ARABIAN HORSE.

The following pedigree of an Arabian horse was hung about his neck when bought in Egypt by Colonel Ainslie during the last campaign:—

"In the name of God, the merciful and compassionate, and of Seed Mohammed, agent of the High God, and of the companions of Mohammed and of Jerusalem. Praised be the Lord, the omnipotent Creator. This is a high-bred horse, and its colt's tooth is here in a bag about his neck, with his pedigree, and of undoubted authority, such as no infidel can refuse to believe. He is the son of Rabbamy, out of the dam Lahadah, and equal in power to his sire; of the tribe Zazhalah. He is fine moulded, and made for running like an ostrich, and great in his stroke and his cover. In the honours of relationship he reckons Zaluah, sire of Mahat, sire of Kaliack, and the unique Alket, sire of Manasseth, sire of Alsheh, father of the race down to the famous horse the sire of Lahalala; and to him be ever abundance of green meat, and corn, and water of life, as a reward from the tribe of Zazhalah for the fire of his cover; and many a thousand branches shade his carcase from the hyænas of the tomb, from the howling wolf of the desert; and let the tribe of Zazhalah present him with a festival within an enclosure of walls; and let thousands assemble at the rising of the sun in troops hastily, where the tribe holds up, under a canopy of celestial signs within the walls, the saddle, with the name and family of the possessor. Then let them strike the hands with a loud noise incessantly, and pray to God for the tribe of Zoab, the inspired tribe."

THE ARAB'S TREATMENT OF HIS HORSE.

In Arabia the horse is treated with much gentleness and kindness: he inhabits the same tent with his master and his family. His wife and children, together with the mare and foal, associate together in indiscriminate friendship, occupying the same bed, where the little children may be seen prattling with and climbing over the body, or hanging round the necks of the docile animals, who in their turn will frequently repose with their heads resting on some one of the family. Whipping is never resorted to by the Arab: all services and affections of the horse are obtained by gentle measures; and hence the remarkable docility of disposition which is mixed up with their native fire and energy. The friendship betwixt the Arab and his horse is mutual; for should the rider fall, the horse will instantly stand still, even in his most rapid career, and wait till his master remounts.

The horses of most eastern countries are nearly allied to the Arabian blood, and now are almost entirely bred from males of that country. The Persian and Barb are, however, nearest to the Arabian in point of elegance of shape and docility of temper. Variety of climate and food are always asserting their influence on the form and size of the horse; and hence the astonishing variety which is to be found in different countries, and even amongst those of the same country.

ENGLISH HORSES.

THE RACEHORSE.

The British racehorses have a striking similitude to the Arabian and Barb, from which they have directly sprung. Indeed, their whole movements indicate their eastern origin. They are, however, much larger. In speed, the English racers are equal, if not superior, to the horses of every other country. It is certain that all the Arabian, Persian, Barb, and Turkish horses, which have been brought into this country, have been beaten by the English racehorses; and even in the eastern courses, which are most nearly allied to the soil of Arabia, as well as in the frigid temperature of Russia, the British racer has always beaten those brought into competition with him. A few years back, Pyramus, the best Arabian steed in the Bengal side of India, was beat by Recruit, an English racehorse of but moderate reputation. For carrying weight, and long endurance of exertion, or what is called *bottom*, our racers have the decided advantage over all other horses. Their high courage, determined spirit, and patience, indicate the purity of their lineage. An ordinary racehorse runs at the rate of a mile in two minutes, but the celebrated horse Childers accomplished a mile in *one* minute.

The head of the racer, in particular, is formed like that of the Arabian; his beautifully arched neck is finely set on, and his shoulders are oblique and lengthened; his hind-legs are well bent, and spread outwards, while his quarters are ample and muscular. His whole legs are flat, and rather short than otherwise, from the knee downwards, although not always so deep as they ought to be; his pasterns are long, elastic, and lie in an angle of about twenty-five degrees. Two points of those enumerated generally turn out well, viz., when the shoulder is well placed, and the hinder-legs well bent and properly spread.

Thorough-bred is a term employed in Britain to indicate the descent of a horse from an Arabian or Barb. The English racer has therefore been the progressively improved breed, from a commixture of British horses with those of Asia and Africa. The horses which are considered of the first blood, or in the nearest possible degree to the Arabian or Barbary horses, are such as are immediately produced from one or other of these horses with an English mare, which has herself been the produce of an Arabian or Barb, or by two crossings in the same degree.

The perfection of English racehorses seems to have acquired its height about a century ago; because at that time was produced the celebrated horse known by the name of the Flying Childers, which was the fleetest horse that ever ran; and although much trouble and expense have been devoted to improving the breed since his time, every effort has failed in producing an equal to him in point of speed.

There have been a very few instances of the native horses of Britain turning out good racers, without the commixture of foreign blood; among these may be particularised Sampson and Bay Walton.

All our best horses have sprung from the Darley Arabian, who was sire to Childers. From the same horse Eclipse descended, who, in point of proportions, was perhaps the most perfect which was ever foaled in Britain, and from whom the fleetest and best-bottomed horses of our country have sprung.

Although much attention is paid to the descent in breeding, yet it frequently turns out that foals of the horses and mares of the best blood prove very worthless; and it is a curious fact that first-rate horses have sometimes been produced by mares only three-fourths bred. But in breeding, a mare is generally chosen with as great a proportion as possible of the blood of the celebrated horse King Herald in her veins. She ought to be deep in the girth, long and full in the fore-arm and thigh, short in the leg, standing clean and even upon the feet, and wide and spreading in the hind-quarters. From such a mare there is every probability of obtaining a well-formed progeny, as we are convinced that fully more depends upon the form of the dam, than of the sire, in breeding.

The horse enters into the spirit of the race with as much zeal as his rider, and will in general strain every nerve to outstrip his adversary. As he advances towards the starting-post, all his motions betray the eagerness of his desire to start. When the signal is given, away he springs at a settled and steady pace. The rider becomes, as it were, a part of the quadruped, whose every motion should correspond to his movements. He proceeds forward, restrained by his rider to the pace he thinks best suited to his strength, and preserving his powers till the last. The rider knows well where to push him; he touches him to indicate his wish for a trial of his powers; the hint is speedily taken, when all his nerves are called into action, and he bounds to his utmost stretch. It sometimes, though rarely, happens that the spur becomes necessary to rouse every energy; he knows its import, and every muscle is called into action to defeat, if possible, his competitor. If he has spirit, little application of these will be necessary, and, if dull, all the punishment that can be inflicted will prove unavailing. But in general, the natural spirit of the racehorse, when roused into action from the opposition of the moment, has generally the effect of leading him through every obstacle; and the whip and spur in such a case are generally not required.

We have given a portrait of the celebrated racehorse Spaniel, winner of the Derby stakes at Epsom in 1831.

THE HUNTER.

The hunter is a combination of the thorough-bred racehorse and half-bred horses of greater strength and bone. He is less lengthy in his carcase, and ought to be from fifteen to sixteen hands high. The points most likely to discover a horse of good properties as a hunter, are a vigorous, sanguine, and healthy colour, with a lofty forehand, a head and neck as light as possible, whether handsome or not; a quick-moving and fiery eye, and a middle-sized ear. His jaws should be clean and wide, and his nostrils large and yielding; his shoulders thin, thighs strong and muscular, chest deep, back short, ribs should be large and wide, tail high and stiff, gaskins well spread, and hind-quarters lean and hard. Above all, let his joints be strong, firm, and closely knit, his legs and pasterns short; for we believe there never was yet a long limber-legged horse that was able to gallop down steep hills, and take bold leaps with a weight upon his back, without sinking or foundering; and, lastly, his feet should be moderately large and sound. With these points, a horse will in all probability have those qualifications required to make a good hunter.

It is not, however, every good and fleet horse that is a good hunter, for he may have strength and vigour for a long journey, and yet not be able to bear the shocks and strainings of a fox-chase; another may be swift enough to win a plate on a smooth turf, which yet will be crippled or heartbroken by one chase in February. The right hunter ought to have strength without weight, courage without too much fire, and speed without labour; a free breath, a strong walk, a nimble, light, but large gallop, and a sweet trot, to give change and ease to the speedy muscles. A horse should never be used for the sports of the field till he is six years of age, as his joints will not be closely knit, nor his tendons sufficiently tenacious, till that period. A horse in his fifth year may occasionally be taken out with the hounds, but then he should be ridden with moderation.

THE HACKNEY OR ROADSTER.

The hackney should be a hunter in miniature, his height not exceeding fifteen hands and an inch, but rather below than above that size. His form should be more compact than that of the hunter, with more substance in proportion to his height, so as to fit him for the fatigues of everyday work. His head ought to be small, his forehand high, but rather light, and placed on the neck in a gradually tapering manner, with his eyes full, clear, and sprightly; his shoulders deep and extensive; his back straight, with strong loins; his withers well raised; his fillets wide; the croup must not droop too suddenly, nor must his tail be too low set. The fore-arm and thighs ought to be strong and muscular, and the legs rather short than otherwise, straight, and somewhat near-set. When the shank bone is solid and flat, it is an excellent point in a hackney. It is of the utmost consequence that the bones beneath the knee should be deep and flat, and the tendon not too much tightened in. His feet should point straight forward, with the heels wide and open; the hoofs should be of a dark, tough, shining horn; the fore-legs closely set, and as straight as possible, for a horse with bent knees is very likely to fall when his feet come in contact with the smallest obstacle, especially with a heavy weight; his hind-legs should be thrown considerably behind him, and very widely set. The back should be straight, and rather short than otherwise. Some prefer a hollow-backed horse, but such will neither stand much work nor bear a heavy weight, although their paces are generally easy.

Nothing is more essential in a hackney than sound strong fore-legs, and also well-formed hind ones; his feet must be quite sound and free from corns, to which hard-ridden horses are very liable; and he ought only to lift his fore-legs moderately high. Some are of opinion that he cannot lift them too high, and conceive, while he is possessed of this quality, he never will come down. There is a medium, however, in this, as a horse that raises his fore-legs too high in trotting is always disagreeable in his action, which greatly shakes and fatigues the rider; besides, he batters his hoofs to pieces in a few years. The principal thing to be attended to is the manner in which the hackney puts his feet to the ground; for if his toes first touch the road, he is sure to be a stumbler. The foot should come flat down on the whole sole at once, otherwise the horse is not to be depended upon in his trotting. There can be no doubt that a horse should raise his feet so as to pass over projecting stones, for otherwise he is likely to be tripped by them, and thus thrown off his centre of gravity. But every horse is liable to fall while going on a road, and therefore his mouth should always be felt by the rider. A hackney can scarcely be too close before or too wide behind. It is erroneously imagined, that, if the fore-legs are close, the hoofs must necessarily cut the pasterns, as it is only when the feet are twisted, or irregularly set in one way or other, that they cut.

Our present breed of hackneys has a considerable portion of racing blood in them, varying from a half to seven-eighths. The latter are too highly bred for the general purpose of a roadster, as their legs and feet are rather tender; and their long paces and straight-kneed action are ill adapted for the road, being more fitted for cantering and running than the trot, which is the distinguishing characteristic of a good hackney. Indeed, they should never be permitted to go at any other pace than a trot, which is undoubtedly much better adapted for the road than cantering.

A hackney should be particularly even-tempered, and not given to starting. The thorough-bred hackney ought to possess two qualities indispensable to the safety of the rider: he should never shy at any thing on the road, and his motion at a trot should be much more smooth than that of a half-bred horse.

THE COACHHORSE.

When coaches were first introduced into Great Britain, the horses used were of the large unwieldy kind, as speed was not regarded in those days; for if travellers could be safely conveyed fifteen or twenty miles in a day by a vehicle, it was then considered a great feat: consequently, in those days coachhorses were just such as those now used in the lighter kinds of waggons. Such was the tardiness of their movements, that, about sixty years ago, a journey betwixt London and Edinburgh occupied from a fortnight to three weeks' time, which is now performed in forty-three hours.

The better kind of coachhorses owe their origin to the Cleveland bay, and are principally bred in Yorkshire, Durham, and the southern districts of Northumberland, and some few have been produced in Lincolnshire. The coachhorse is produced by a cross of the Cleveland mare, with a three-fourth or thorough-bred horse, which is possessed of sufficient substance and height. The produce of these is the coachhorse of the highest repute, and most likely to possess good action. His points are advantageously placed, with a deep and well-proportioned body, strong and clean bone under the knee, and his feet open, sound, and tough. He possesses a fine knee action, lifts his feet high, which gives an elegance to his paces and action: he carries his head well, and has a fine elevated crest. The full-sized coachhorse is, in fact, only an overgrown hunter, too large for that sport.

Some have supposed, that, in Britain, the rage for breeding coachhorses, for so much speed, is a prostitution of the powers of the horse, and that it is barbarous to drive them with that rapidity which is now the prevailing fashion. We do not, however, consider it so very blameable, as expedition is so desirable for the mercantile interests of the country; and if proper care is taken to shorten the stages, there can be little harm to the horses travelling short distances at a pretty sharp rate. It is quite certain, that, within the last few years, every means has been used to promote the establishing of posthorse stations at very short distances.

THE CARTHORSE.

The carthorses of Great Britain are extremely variable in point of size as well as in shape, differing in almost every county. One principal character, however, is weight, to give more physical force in the draught. They should not be above sixteen hands high, with a light well-shaped head and neck, short pointed ears, with brisk sparkling eyes; their chests should be full and deep, with large and strong shoulders, but rather low in front than otherwise. The back should be straight, and rather long, but not too much so, as this always impairs his general strength; the legs should be somewhat long, but not too *leggy*; his fillets should be large and swelling, and the bones flat; he should stand wide on all his four legs, and considerably wider behind than before; he ought to have great pliability in the knee-joints, and be able to bend them well, which assist in producing a brisk and active step in walking, a quality of much consequence in a cart or waggon horse. The height of a draught horse, however, to be desired, will depend upon the purpose to which he is to be employed; and they are, therefore, not unfrequently bred seventeen hands in height, with lofty forehands, and many of them deep in the centre, as is the case with the coachhorse. A great object is to increase strength, activity, and power, to remove weight, and to be of the height of sixteen hands for ordinary utility; and, indeed, it has been proved that horses of this height have performed feats of strength of greater magnitude than those of more gigantic proportions.

The finest breed of carthorses is the large *blacks*, the breed of the midland counties, and the Suffolk breed. An excellent breed also was the Cleveland bays. The Earl of Egremont, one of our greatest and most successful English breeders, is said to have preserved these horses in his stud, and still propagates them in purity; and it is supposed that these fine horses are purely indigenous, without the mixture of any foreign blood. The Clydesdale are highly valued to the present day. The latter are excellent for the purposes of agriculture, but particularly so on the road. They reach to a large size, and are not unfrequently to be met with sixteen and a half hands high. These animals are strong and hardy, but their heads are coarse, and they are rather flat on the sides and hinder-quarters. The usual colour of these horses is grey or brown. This breed is supposed to have originated about 130 years ago, between the common Scots mare and the Flanders horse. An excellent example of the Clydesdale breed is given in the beautiful work, by Mr Howe, on the Horse.

In the midland counties, viz. Warwickshire, Derbyshire, Leicestershire, Lincolnshire, and Nottinghamshire, there is a very large breed called the great carthorse. It was bred in the lowland rich alluvial pastures of these counties, from the Flemish and Dutch horses, with the larger English breed. Mr Bakewell introduced horses, and also mares, from the Netherlands, and thus produced those fine animals with Belgic blood, both on the side of the sire and dam. From this stock, about thirty years ago, Mr Bakewell produced one of the finest animals of the kind which was ever seen, and sent it to Tattersal's, for the inspection of King George the Fourth. His head was light and well-set on, his forehand lofty, his shoulders deep, his legs clean and flat-boned, with the general activity of a pony; and it was universally acknowledged, that, for lightness, cleanness of make, and bulk, he was a superlatively excellent animal. Mr Bakewell recommended this animal as highly adapted for the purpose of breeding, with appropriate mares, cavalry horses, hunters, and strong hacks; but his Majesty did not enter into Mr Bakewell's views, nor did he assign any reason for not trying the experiment.

In Essex and the neighbouring counties, in former times, horses were of all colours, as brown, grey, bay, and black; but since the time that Mr Bakewell became so celebrated for his breed, black is now the prevailing colour.

The very large horses of seventeen hands and upwards, are only useful for the purposes of brewers' drays, waggons, and the slop-carts of London, and of which we have given an excellent representation, engraved by Bonner of London. We, however, doubt much of their answering the better for their gigantic size; and all who have written on the subject consider that they are inferior in point of strength, on account of their bulk, for by the feeding which is required to increase their dimensions, little of muscular fibre is produced, the growth being principally in the cellular tissue and fat; and the additional quantity of food required to keep up their system must more than counterbalance any advantage to be reaped from their size.

THE GALLOWAY.

The galloway is a stout compact horse, about fourteen hands in height, and takes his name from the county of Galloway, in Scotland, where he was originally bred. These horses are now nearly extinct; they were celebrated as excellent, speedy, and steady roadsters, very sure-footed, and on that account invaluable in travelling over rugged and mountainous districts. The beauty and speed of the galloway was supposed to have arisen from the breed having been the produce of the Spanish jennets that escaped from the wreck of the invincible Spanish armada, and these, crossed with our Scottish horses, gave rise to this esteemed breed. But we apprehend they were famous at a date long prior to that event, as this district is known to have supplied Edward the First with great numbers of horses. This breed seldom exceeded fourteen hands in height: their colour was generally bright bay or brown, with black legs, small head and neck, and their legs peculiarly deep and clean.

Dr Anderson gives the following description of this variety:—"There was once a breed of small elegant horses in Scotland, similar to those of Ireland and Sweden, and which were known by the name of galloways, the best of which sometimes reached the height of fourteen hands and a half. One of this description I possessed, it having been bought for my use when a boy. In point of elegance of shape, it was a perfect picture, and in disposition was gentle and compliant. It moved almost with a wish, and never tired. I rode this little creature for twenty-five years, and, twice in that time, I rode 150 miles at a stretch, without stopping except to bait, and that not for above an hour at a time. It came in at the last stage with as much ease and alacrity as it travelled the first. I could have undertaken to have performed, on this beast, when it was in its prime, sixty miles a-day for a twelvemonth running, without any extraordinary exertion."

In 1814, a galloway performed a feat of greater magnitude than any thing mentioned by Dr Anderson. He started from London along with the Exeter mail, and, notwithstanding the numerous changes of horses, and the very rapid driving of the mail, he reached Exeter a quarter of an hour before it—thus performing the astonishing distance of 172 miles, at an average of about nine miles an hour. The experiment was of the most brutal kind, and was fatal to the farther energy of this fine animal, which, with good treatment, might have been long an invaluable servant. Twelve months after this astonishing feat, he was seen spavined, wind-galled, and ring-boned, exhibiting a picture of the utmost wretchedness, brought on by the barbarous inhumanity of man.

THE HIGHLAND PONY.

The ponies of the Highlands of Scotland, although very hardy, from being seldom kept in a stable, even in the winter season, are cross-made animals of a small size, and much inferior, in point of appearance and action, to the galloway, so long the boast of Scotland. They have large heads and long backs; their legs short, standing considerably lower before than behind, which gives them a most unpleasant action and rough trot. The only way in which they can be comfortably ridden is at an amble. They can go considerably faster up a gentle acclivity than on level ground, and are very serviceable in the higher mountainous countries, being sure-footed, and extremely cautious what road they pursue. The Rev. Mr Hall, in his "Travels through Scotland," gives the following illustration of this fact:—"When these animals come to any boggy piece of ground, they first put their nose to it, and then pat on it in a peculiar way with one of their fore-feet; and from the sound and feeling of the ground, they know whether it will bear them. They do the same with ice, and determine in a minute whether they will proceed."

It would be difficult to assign a cause for this amazing falling off in the horses of Scotland. There can be little doubt but that they had a powerful breed in early times, otherwise they never could have coped with the English in the frequent wars in which these countries were engaged from the earliest times; and it is well known that an Arabian horse reached Scotland about 450 years before we have any authentic record of this breed being introduced into England, which must have had considerable influence in improving the breed of the Scottish horses.

GENERAL ANECDOTES OF THE HORSE.

During that destructive war, which, for a space of thirty years, desolated all Germany, till it was terminated by the peace of Westphalia, the carriers, who conducted the inland traffic of the country, used to unite themselves into large companies, for their mutual defence, in order that they might travel with greater security against the numerous marauding parties which infested every part of the empire. One of these carriers had a horse which was of an extremely vicious disposition, and greatly addicted to biting and kicking, from which even his master was not always secure, and which often embroiled him with his fellow-travellers. They were one evening attacked in a ravine by three hungry wolves, which, after a long contest, they found they should hardly be able to compel to quit them, without allowing them some prey. It was therefore agreed among themselves that they should pay the owner of the vicious horse the price of that animal, and make a sacrifice of him to the wolves. The bargain was soon concluded; and the horse, having been taken out of the harness and turned loose, the wolves immediately attacked him. He, however, defended himself courageously with his teeth and heels, retreating, at the same time, into the interior of the forest, while the carriers availed themselves of the opportunity to hasten on to a place of security, not a little rejoiced at having got rid of so troublesome a companion so much to their advantage. As they were sitting at supper in the inn where they usually stopped for the night, a knocking was heard at the house door, which, on being opened by the maid, a horse pushed in his head. The girl, frightened, shrieked out, and called to the carriers, who, coming to the door, were no less surprised than rejoiced to see the heroic conqueror of the three wolves, though much wounded, yet still faithful to his master; and, on account of his meritorious conduct upon this occasion, they agreed to forgive him his former misdemeanours, and retain him in their company.

A remarkable instance of revenge in a horse owned by a person near Boston, in America, is related on good authority. A person, a few years since, was in the habit, whenever he wished to catch his horse when it was running in the field, of taking a quantity of corn in a measure. On calling to him, the horse would come up and eat the corn, while the bridle was put over his head. But the owner having deceived the animal several times, by calling him when he had no corn in the measure, the horse at length began to suspect the design, and coming up one day as usual, on being called, looked into the measure, and seeing it empty, turned round, reared on his hind-legs, and killed his master on the spot.

A gentleman rode a young horse, which he had bred, thirty miles from home, and to a part of the country where he had never been before. The road was a cross one, and extremely difficult to find; however, by dint of perseverance and inquiry, he at length reached his destination. Two years afterwards he had occasion to go the same journey. He was benighted three or four miles from the end of his destination. The night was so dark that he could scarcely see the horse's head; he had a black and dreary moor and common to pass, and had lost all traces of the proper direction he was to take. The rain began to fall heavily. He now contemplated the uncertainty of his situation. "Here am I," said he to himself, "far from any house, and in the midst of a dreary waste, where I know not which way to direct the course of my steed. I have heard much of the memory of the horse, and in that is now my only hope." He threw the reins on the horse's neck, and, encouraging him to proceed, found himself safe at the gate of his friend in about half an hour. It must be remarked, that he could not possibly have been that road but on the occasion two years before, as no person ever rode him but his master.

White, in his Natural History of Selborne, proves the sociable disposition of the horse by the following anecdote:—"There is a wonderful spirit of sociality in the brute creation, independent of sexual attachment: the congregating of gregarious birds in the winter is a remarkable instance. Many horses, though quiet with company, will not stay one minute in a field by themselves; the strongest fences cannot restrain them. My neighbour's horse will not only not stay by himself abroad, but he will not bear to be left alone in a strange stable without discovering the utmost impatience, and endeavouring to break the rack and manger with his fore-feet. He has been known to leap out at a stable-window, through which dung was thrown, after company, and yet, in other respects, is remarkably quiet."

On the evening of Saturday, the 24th February 1830, Mr Smith, supervisor of excise at Beauly, was proceeding home from a survey of Fort Augustus; and to save a distance of about sixteen miles, he took the hill road from Drumnadrochit to Beauly. The road was completely blocked up with, and indiscernible amidst, the waste of snow; so that Mr Smith completely lost all idea of his route. In this dilemma he thought it best to trust to his horse, and, loosening the reins, allowed him to choose his own course. The animal made way, though slowly and cautiously, till coming to a gully or ravine, near Glenconvent, when both horse and rider suddenly disappeared in a snow-wreath several fathoms deep. Mr Smith, on recovering, found himself nearly three yards from the dangerous spot, with his faithful horse standing over him, and licking the snow from his face. He thinks the bridle must have been attached to his person. So completely, however, had he lost all sense of consciousness, that beyond the bare fact, as stated, he had no knowledge of the means by which he made so striking and providential an escape.

A Wiltshire gentleman, in 1821, lent a well-bred and fiery mare to a friend from town, who had come down to try the Essex dogs against the Wiltshire breed of greyhounds. At the close of a very fine day's sport, the huntsmen had beat a small furze-brake, and, for the purpose of better threading it, the London gentleman dismounted, and gave the bridle of the mare to the next horseman. Puss was soon started; the "halloo" was given; the person who held the mare, in the eagerness of the sport, forgot his charge, loosed his hold, and, regardless of any other than his own steed, left the mare to run, like Mazeppa's, "wild and untutored." But, to the astonishment of all, instead of so doing, or even attempting to bend her course homewards (and she was in the immediate neighbourhood of her stable), she ran the whole course at the tail of the dogs; turned as well as she could when they brought the prey about; and afterwards, by outstripping all competitors (for the run was long and sharp), she stopped only at the death of the hare, and then suffered herself to be quietly regained and remounted. But what renders it still more remarkable, is, that she had only twice followed the hounds previous to this event, which strongly indicated her natural love of sport. The brace of dogs that were slipped at this course were the property of the owner of the mare, and the groom had been in the habit of exercising them with her. Whether this had any effect on her actions, is quite uncertain; but, be this as it may, the circumstance is not the less worthy of our admiration.

In 1794, a gentleman in Leeds had a horse, which, after being kept up in the stable for some time, and turned out into the field, where there was a pump, well supplied with water, regularly obtained a quantity therefrom by his own dexterity. For this purpose, the animal was observed to take the handle into his mouth, and work it with the head, in a way exactly similar to that done by the hand of a man, until a sufficiency of what nature called for was produced in the trough.

One of the most intelligent of horses seems, from all accounts, to have been that belonging to Mr Banks, whose renown is alluded to by Shakspeare in "Love's Labour's Lost," act first, scene second, and by Dekker, in his "Untrussing of the Humourous Poet." It is related of this horse, that he would restore a glove to its owner, after his master had whispered the man's name in his ear; that he would tell the number of pence in any silver coin. He danced, likewise, to the sound of a pipe, and told money with his feet. Sir Walter Raleigh says, "that had Banks lived in older times, he would have shamed all the characters in the world, by the wonderful instructions he had given his horse."

Johnson, the celebrated horseman, is well remembered by many persons now alive. Being at Derby in one of his excursions, he married the daughter of Alderman Howe, who then kept one of the principal inns, and succeeded him in his business. He conducted himself so as to be well esteemed by the gentlemen of the county; and his black horse, which he still kept, was one of the favourites of the Vernon hunt, then probably the first in England. The following feat, performed by him and his horse, is worth remembering:—The hunt were taking leave of Lord Vernon one day by the side of the Ha ha, when his lordship told Johnson, it was extraordinary he never had been tempted, in the course of any day, to do more as a horseman than all the members of the hunt could do. "Well, my lord," said he, "what would you wish me to do?" "I am not to choose," said his lordship; "but surely you can do something more than others." "I will go over that Ha ha, my lord." "So can others—myself for one." "But I, my lord," said he, "will go over it in a way in which your lordship cannot." He rode his black horse up to the brink, and, as he stopped, laid his hands upon the pommel of the saddle, and sprung from that posture clean over the Ha ha. The hunt applauded, but the performance was not over. He was something shaken by the fall, and did not immediately rise. The horse looked at him attentively all the while; and, when he had got out of the way, followed him over, ran up to him, and stood by his side till he mounted.

Some years ago, a gentleman farmer, in the neighbourhood of Edinburgh, who was in the possession of a very vicious hunter, happened to be relating some of his bad propensities to a party of friends at dinner, and among these mentioned was the difficulty which the groom had in trimming his fetlocks. This operation was never accomplished without the aid of several assistants, and even then attended with great difficulty and danger. During this conversation, in which he defied any of his friends present to perform the task singly, he was unconscious of the presence of his youngest child, a fine boy about three years of age. This juvenile Nimrod was by no means the inattentive observer which might have been expected from his tender years, as was evinced next morning. His father, in passing through the stable-yard, descried, with great horror and agony, his infant busily employed with a pair of scissors, attempting, with great coolness, to clip the fetlocks of the hind-legs of his vicious hunter, which, in place of exhibiting his usual determined resistance to this operation, was looking round with the greatest complacency on his pigmy groom, whom the father every instant expected to see struck dead at his feet. He, however, shortly afterwards walked away from the horse unharmed.

The above horse had a particular antipathy to strangers. On one occasion his master was returning home from a jovial meeting, where he had been very liberal in his potations, which destroyed his power of preserving his equilibrium, and rendered him at the same time somewhat drowsy. He had the misfortune to fall from his saddle, but in so easy a manner, that it had not the effect of rousing him from his sleepy fit; and he felt quite contented to repose where he alighted. His faithful steed, on being eased of his burden, instead of scampering home, as one would have expected from his habits, he stood by his prostrate master, and kept a strict watch over him; he was discovered by some labourers, at sunrise, very contentedly snoozing on a heap of stones by the road side. They very naturally approached the gentleman, to replace him on his saddle; but every attempt to approach was resolutely opposed by the grinning teeth and ready heels of his faithful and determined guardian.

A gentleman of Bristol had a greyhound, which slept in the stable along with a very fine hunter of about five years of age. These animals became mutually attached, and regarded each other with the most tender affection. The greyhound always lay under the manger, beside the horse, who was so fond of him, that he was unhappy and restless when out of his sight. It was a common practice with the gentleman to whom they belonged to call at the stable for the greyhound to accompany him in his walks; on such occasions, the horse would look over his shoulder at the dog with much anxiety, and neigh in a manner which plainly said, "Let me also accompany you." When the dog returned to the stable, he was always welcomed by a loud neigh; he ran up to the horse, and licked his nose; in return, the horse would scratch his back with his teeth. One day, when the groom was out with the horse and greyhound for exercise, a large dog attacked the latter, and quickly bore him to the ground; on which the horse threw back his ears, and, in spite of all the efforts of the groom, rushed at the strange dog, who was worrying at the greyhound, seized him by the back with his teeth, which speedily made him quit his hold; he shook him till a large piece of the skin gave way, when he fell to the ground. He no sooner got on his feet, than he judged it prudent to beat a precipitate retreat from so formidable an enemy.

EXTRAORDINARY FEAT OF A DRAUGHTHORSE.

An unparalleled instance of the power of a horse, when assisted by art, was shown near Croydon. The Surrey iron railway being completed, and opened for the carriage of goods from Wandsworth to Mertsham, a bet was made that a common horse could draw thirty-six tons for six miles along the road, and that he should draw his weight from a dead pull, as well as turn it round the occasional windings of the road. A number of gentlemen assembled near Mertsham to witness this extraordinary triumph of art. Twelve waggons loaded with stones, each waggon weighing about three tons, were chained together, and a horse, taken promiscuously from the timber cart of Mr Harwood, was yoked into the team. He started from near the Fox public-house, and drew the immense chain of waggons, with apparent ease, to near the turnpike at Croydon, a distance of six miles, in one hour and forty-one minutes, which is nearly at the rate of four miles an hour. In the course of the undertaking he was stopped four times, to show that it was not by the impetus of the descent the power was acquired. After each stoppage, a chain of four waggons were added to the cavalcade, with which the same horse again set off with undiminished power. And, still farther to show the effect of the railway in facilitating motion, the attending workmen, to the number of about fifty, were directed to mount the waggons; still the horse proceeded without the least distress; and, in truth, there appeared to be scarcely any limitation to the power of his draught. After the trial, the waggons were taken to the weighing machine, and it appeared that the whole weight was as follows:—

	Tons.	cwt.	lb.
Twelve waggons first linked together, weighed	38	4	2
Four ditto, afterwards attached . .	13	2	0
Supposed weight of fifty labourers .	4	0	0
	55	6	2

CONCLUSION.

We conclude this account of the horse by the following quotation from Captain Brown's work, entitled "Biographical Sketches and Authentic Anecdotes of Horses," which contains a great mass of curious information regarding that noble animal:—

"Plutarch says, a good man will take care of his horses and dogs not only while they are useful to him, but also after age renders them unfit for service. A beautiful illustration of this benevolent maxim is recorded of the Athenians, who, when they had finished building the *Hecatompedon*, set at liberty the animals employed in its erection. It is related that one of these, at the head of his fellow-labourers, some time after the completion of the temple, led the way to the citadel, which so highly pleased the people, that a decree was made by the senate, enacting that these faithful and willing servants should be kept the remainder of their lives at the public expense.

Every humane mind must shudder at the brutal treatment to which that noble and generous animal, the horse, is but too frequently exposed in Europe. The ass, also, a beast of great sagacity and gentleness, is almost invariably treated with savage barbarity. Let those unfeeling and unprincipled wretches look to the mutual love that subsists between the Arab and his steed, and the kindness manifested by the people of eastern nations to their asses and mules, and the benefits they derive from such a mode of treatment. If no other principle will awaken their kindly feelings, surely that of self-interest should stimulate them to adopt gentler measures.

Although the horse seldom exerts his strength and power to the prejudice of his master, we have, however, one instance of recollection of injury, and an attempt to revenge it. This is inserted in a work of D. Rolle, Esq. of Torrington, in Devonshire. A baronet, one of whose hunters had never tired in the longest chase, once encouraged the cruel thought of attempting completely to fatigue him. After a long run he dined, and, again mounting, rode him furiously among the hills; when brought to the stable, his strength seemed exhausted, and he was scarcely able to walk. The groom, possessed of more feeling than his brutal master, could not refrain from tears at the sight of so noble an animal thus sunk down. The baronet, some time after, entered the stable, when the horse made a furious spring upon him, and, had not the groom interfered, would soon have put it out of his power ever again to misuse his animals.

The first breaking of the horse should only be intrusted to persons of mild dispositions, as it is by kind and patient treatment alone that we can hope to succeed in rendering this valuable animal truly useful and docile; for although force may produce obedience, it will be found, as with man himself, that so soon as fear is removed, and the animal has discovered its own strength, revenge will generally follow. I have no doubt but in nine cases out of ten, where horses betray furious or stubborn tempers, that these have been produced from the cruelty or ignorance of their first trainers. The horse is an animal of great intelligence; but every thing addressed to his perceptions should be clear, short, and distinct, for he is incapable of following a train of spoken language. Few words delivered with precision, accompanied by caresses and gentle treatment, will be found more effectual than any other course."

It cannot be expected that we should enter into the treatment and cure of the numerous diseases incidental to the horse; but we may offer the few following cautions as preventives to many of these:—

Stables should be well aired, and have windows in opposite sides, so that the air may pass currently through them; these should be invariably open when the horses are out of the stable, and frequently even when the horses are in their stalls, taking care, however, never to allow cross draughts when the horses are heated, or after returning from active exercise, as this may produce cough, and other inflammatory diseases. Grooms are in the constant practice of keeping stables so completely free from air, that they even resort to the practice of closing up the bottom of the stable door with dung at night. Great warmth produces a fine glossy coat, but it is most destructive to the constitution of the horse.

A horse should never be ridden hard down a hill, as this has a tendency to shake and weaken his fore-legs; and he ought to get but little water on a journey, and he should not be allowed to drink until perfectly cool; nor should he be fed with oats for a quarter of an hour at soonest, after having had exercise. The first thing that should be attended to is to rub the horse carefully down, and not to leave him while a wet hair remains on his body.

EDINBURGH: Published by WILLIAM and ROBERT CHAMBERS, 19, Waterloo Place; also by W. ORR, Paternoster Row, London; and W. CURRY, Jun. and Co. Sackville Street, Dublin. Sold by John Macleod, Glasgow, and all other Booksellers in Scotland, England, and Ireland.—Published once a fortnight. Stereotyped by A. Kirkwood, and printed by Ballantyne and Company, Paul's Work.

MAP OF NORTH AMERICA.

HISTORICAL NOTICE.

THE continent of America, with all its islands, and the people who originally inhabited them, was unknown to the inhabitants of Europe till the end of the fifteenth century. They were discovered in the year 1492 by Christopher Columbus, while he was in search of a route by sea to the East Indies; and when he first saw them, he believed that they were part of China or Japan; so little idea had the Europeans of those days of the existence of the vast countries which have since exercised such a powerful influence on the fate of their descendants.*

The rude state of the native inhabitants, and the superior military knowledge of the Europeans, which they used with very little regard to right, enabled them soon to seize on all such parts of the country as they preferred, and to drive away, or reduce to subjection, the original possessors. In this way the southern part of the continent was subjugated, and partly colonised, by the Spaniards and Portuguese; while the northern portions fell into the hands of the other maritime nations of Europe, the English, French, Dutch, and Swedes, who formed colonies at different points along the coast. The whole of these, however, soon fell into the possession of the English and French alone. Under these two powers the American colonies continued to afford a refuge to people of the European countries, who considered themselves oppressed or aggrieved at home. During the seventeenth century, when extensive emigration first began to take place, it was not so much the want of employment, or of subsistence, which induced men to seek for a change of residence, as the wish of escaping from persecution on account of religion, or from the civil wars of the time. This was the case particularly in England, during that period when religious and political animosities greatly disturbed the country. Troubles of other kinds, and latterly the necessities of an overcrowded population, continued to afford a motive for the people resorting to America; and during great part of the eighteenth century, it is reckoned that from 5000 to 8000 persons yearly removed to these countries from Europe.

Some disputes arose, about 1755, between the French and English, who were now the sole possessors of North America; these at last led to a war, which terminated in the total destruction of the French power in that country, and in the transference to the English of all their colonies there, except some thinly peopled regions on the Mississippi. This result took place in 1763; but though it gave to Britain a large addition of new territory, and relieved her old possessions from an enemy, it left her burdened with large debts. In order to avoid unpopularity at home, the ministry of the day projected the scheme of throwing part of the burden of these upon the colonies; alleging as a reason, that the war had been undertaken for their benefit, and in order to deliver them from an enemy who continually hung on their frontiers. The first tax proposed for this purpose was a stamp duty (1765); but the colonies firmly refused to submit to it, saying that they were perfectly willing to pay the expense of their own governments, but that they would not endure to be taxed by a foreign body like the British Parliament, which was situated at the distance of 3000 miles, and in whose deliberations they had no voice, while it might employ the money obtained from them for purposes hostile to their own freedom or welfare. This feeling was universal among the people of the colonies; for these being generally the descendants of men who had left Europe in disgust at some real or fancied oppression, had not those habits of deference to the commands of persons in high station, which often tend to secure obedience and quiet in other countries.

In consequence of this determination on the part of the colonies, and of the obstinacy of the English ministry in adhering to their demands, a great many irritating occurrences took place. The Americans refused to import or to use British manufactures; riots took place in almost all the towns, but chiefly in

* To any one who wishes for elaborate information concerning the statistics or geography of the United States, we cannot too highly recommend "Warden's Statistical, Political, and Historical Account of the United States"—a work which we have frequently consulted in compiling this paper. Morse's Geography is an admirable work in regard to the physical features of the country; and to those who wish to compare its past state with its present, it is invaluable. Williams's American Annual Register contains a store of statistical and commercial facts of the highest value. Mr Ferguson's book of travels, and the excellent volume of Mr Stuart, contain an accurate picture of manners; to which we may add the amusing gossip of Captain Hall and Mrs Trollope, who are both excellent in their way, if readers make the usual allowance for travellers and satirists.

Boston; and the taxed articles which were sent out were destroyed. A meeting of delegates from the several colonies or districts was held in 1765, to petition and remonstrate against what they considered an injustice. Still the British government persevered. And though there was at one time an apparent disposition to recede from some of the propositions which had caused most irritation, the right of taxing the colonies was vigorously maintained. New taxes were soon after imposed (1767) on tea, glass, and paints. The pertinacity of both parties led to frequent violence, and at length to actual demonstrations of war on the part of the Americans. This war lasted for about seven years, from 1775 to 1782, and concluded at last, as might have been anticipated, by the British being compelled to relinquish a country of which every inhabitant was their enemy. The war was conducted on the part of the Americans by General George Washington, to whose talents and perseverance its speedy termination was greatly owing, and whose moderation in using the influence which success had given him over his countrymen has been too seldom imitated by conquerors. The councils of the Americans, and their negociations with other powers, were mainly directed during these transactions by Benjamin Franklin, a man who was equally distinguished as a philosopher and a lover of his country.

FORM OF GOVERNMENT.

Each of the English colonies, as they settled in America, had had a certain form of government assigned it for maintaining the necessary order. This consisted generally of a house of assembly, chosen by the people, with governor, judges, and other officers, appointed by the king, but paid out of taxes levied by the representatives. On acquiring independence after their war with the mother country, the different colonies, now called *States*, made such alterations, each in its own constitution, as they believed to be suited to their circumstances; and a general government, framed and appointed by the consent of the whole, was formed to take charge of such national affairs as the states could not manage separately. The states have each a senate and house of representatives; the members of the former are fewer in number than those of the latter, and a part of them only is chosen at each election, so that they remain in office for several years, generally four: the house of representatives is elected anew every year. The resolutions agreed to by these two bodies for the government of the state are afterwards submitted to a president or governor, whose sanction constitutes them part of the law. Both senators and representatives are paid for their attendance on the public business, generally at the rate of two dollars (or nine shillings sterling) per day, besides an allowance for travelling expenses. The right of election resides in the people under certain limitations: in some states the possession of a certain property (about L.50) is required in the electors: in others, the regular payment of certain taxes: in all, a residence in the state, varying from two years to six months, is requisite. But there are only eight of the states in which black people are allowed to give votes. The judges and other magistrates are in some states elected by the people: in others, by the governor, subject to the approval of the two houses: and their tenure of office is in some for a term of years; in others, during good behaviour; and in several, till the holder attain a certain age (about 70).

This is the form of the states' governments. The general government is constituted on the same model, consisting, like them, of a president, senate, and house of representatives, who are chosen by the same electors as those of the provincial legislatures. The members of both houses receive 36s. per day, with travelling expenses. The senate consists of forty-eight members, two from each state; sixteen of these are elected every two years, so that the whole may be renewed in six years. The members are required to be at least thirty years of age, to have lived nine years in the United States, and to be at the time of election residents in the state by which they are returned. The senate exercises most of the functions of the British House of Lords. The house of representatives is chosen annually, and the members are required to be at least twenty-four years of age, to have resided three or four years in the state for which they are chosen, and, in one or two of the districts, to possess a certain property. There is one representative nearly for every 40,000 persons, five black men being reckoned in this enumeration equal to three white. The house of representatives perform the duties allotted by the British constitution to the Commons' House of Parliament, and have the right, like them, of originating all bills for raising revenue; while the senate, on the other hand, like our House of Lords, is entrusted with the exclusive power of impeaching any officer of state for public misdemeanour. Bills which have passed the two houses have not the sanction of law till they are signed by the president, or, on his refusal, are voted a second time by two-thirds of each of the houses. The president, senate, and house of representatives, are called the Congress of the United States, and their powers in making regulations concerning the public affairs are defined and limited by the original articles of the constitution. Congress is prohibited by these from making any law concerning the establishment or free exercise of religion, the liberty of the press, and freedom of speech, or the privilege of public meetings, to express their opinions peaceably on the measures of government. The people are secured in the right of bearing arms, of fair trial, and in the possession of their property against all aggressors, either public or private. Of these rights no act of Congress, or other authority, can deprive them; and if they are invaded, the sufferer can have redress by applying to the public courts of justice.

The judicial power is vested in one supreme court, and in such inferior courts as congress may from time to time establish. The present judicial establishment consists of a supreme court, thirty-one district courts, and seven circuit courts. The supreme court consists of a chief justice and six associate justices, who hold a court in the city of Washington annually; besides which, each judge attends in certain districts to hold circuit courts with the local justices. The processes of law are in general simple and direct, and are not made difficult of access to the poor by any burdensome expenses.

EXPENSES OF THE GOVERNMENT, AND TAXES.

The following is a list of the salaries of some of the principal officers of the American government:—

	Per annum.		
President,	L.5625	0	0
Vice-President, Secretary of State, and Secretary of Treasury, each	1125	0	0
Secretary at War,	1012	0	0
Chief Clerks of Treasury, &c.,	450	0	0
Postmaster-General,	625	0	0
Chief Justice,	900	0	0
Six Associate Justices, each	787	0	0
Attorney-General,	675	0	0
Seven ambassadors to the following States:—England, France, Russia, Netherlands, Spain, Portugal, and Sweden, each with an allowance of L.2025 for outfit,	2025	0	0
Ambassador's Secretary,	450	0	0
Consuls at London, France, &c.,	540	0	0
Army.			
Major-General (with rations or provisions for fifteen men),	540	0	0
Brigadier-General (with twelve rations),	274	0	0
Colonel (with six rations),	202	0	0
Major (with four rations),	135	0	0
Chaplain (ditto),	135	0	0
Captain (with three rations),	108	0	0
Surgeon (ditto),	121	0	0
Serjeant (one ration),	17	10	0
Private (ditto),	13	10	0
Navy.			
Commodore (sixteen rations),	270	0	0
Captain of 32 gun-ship or under (eight rations),	270	0	0
Lieutenants (three rations),	108	0	0

The pay of seamen is regulated by that of the merchant service.

The expenses of the state during the year 1829 are stated as follows:—

Salaries to officers of state, expenses of managing the public lands, aids to canals, penitentiaries, and improvements, lighthouses, mint, &c.,	L.298,590
Salaries to ambassadors for protection of American subjects in other countries, and foreign intercourse,	40,722
Military establishment, pay of the army,	255,213
Repair of fortifications, militia expenses, building piers, improving the navigation of rivers, pensions to invalids, civilization of Indians, &c.,	1,155,002
Naval establishment, including pay and subsistence of the navy, expenses of stores, construction of works, repairs, &c.,	744,482
Public debt (since paid off) charge	2,786,395
Total expenses of general government in 1828,	L.5,634,980

The annual charge of the public debt is to be deducted from the above sum, as the whole has now been very nearly discharged. But in estimating the whole cost of the government, it is necessary also to take into account the sums required for the expenses of the different states. We do not find any direct notice of the amount of these; but as Captain Hall states that each person pays to the state government 3s., and to the general government about 9s. 4½d. per annum, this proportion would make the amount of expenses of the different states about L.2,087,029; and the whole cost of government is therefore L.7,722,009, amounting, according to Captain Hall's estimate, to about 12s. 4½d. for each person. The national debt having been now nearly paid off, the yearly sum paid in taxes, by each person, may be estimated at 9s. The only taxes are those on articles imported from foreign places, none whatever being levied on the manufactures or produce of the country itself; and there are no direct taxes, like the house or window taxes in this country. Part of the revenue is derived from the sale of public lands, and this amounted, in 1828, to L.290,821.

ARMY AND NAVY.

The army of the United States amounts to about six thousand men; it consists of four regiments of artillery, and seven of infantry—in all (comprising the general staff), 6188 men: it is under the command of one major-general, and two brigadier-generals. A national militia is kept up, in which the men acquire a knowledge of certain military exercises, but submit very little to subordination. There is a military academy for educating young men as officers; the number under tuition is limited to 250; and the instruction given is well fitted for training their minds to knowledge and gentlemanly feelings; the course consists of natural and experimental philosophy, mathematics, engineering, ethics, drawing, and the usual military exercises. The young men educated here are received into the army as cadets, and their promotion is afterwards regulated strictly by seniority, except in extraordinary cases.

The American navy has seven ships of the line—seven frigates of 44 guns, and three of 36; with twenty sloops of war, and smaller vessels. The number of captains is 37; of masters commanding, 33; and of lieutenants, 253. There are seven navy yards, of which the principal are on Long Island, near New York, at Philadelphia, and at Washington.

Notwithstanding the free genius of the American constitution, and the little attention paid to wealth or difference of rank in common life, discipline is enforced with great strictness in the naval service, and with the more jealousy, perhaps, because there is always a danger of the seamen and inferior officers falling into the independent habits of their countrymen, which would be inconsistent with the authority of a commander at sea. Captain Hall tells a story of a young officer who announced his intention of appealing to the people on having been reprimanded by his captain. This being reported at head-quarters, an order came down to say, that the officer was perfectly at liberty to appeal as he proposed; and in order that he might do so without inconvenience, his discharge from the navy was enclosed. Great care is taken in the selection of persons wishing to enter the naval service; and these gentlemen are also exposed, afterwards, to frequent and rigorous examinations, by which means incompetent persons are excluded.

The ships of the American navy are generally well built, and good sailers: they are constructed in great part of a wood called the *live oak*, or *evergreen oak*, which grows in the salt marshes of Florida, and which is almost incorruptible. Large plantations of this valuable tree are formed, and carefully attended to by the government, the only instance in which forest trees are at all cared for in America.

MANUFACTURES.

The Americans do not greatly occupy themselves in those manufactures which require large collections of people in one place, or a great outlay on different kinds of machinery. In England, a great deal of time and capital has been expended in training the work-people to their several departments in these large concerns; and in most places where they are established, there are a variety of different manufactures existing about the same spot, most of which are some way useful or necessary to each other, so that much expense is saved in carriage, &c. It takes a long course of time to collect all the *furniture* of a manufacturing town; but as this has been already done at many places in England, and as wages are much lower there than in America, the English manufactures can be produced more easily, and at less expense, than those of America. It is by no means from any want of ingenuity in the people that they do not succeed there; for, during the war (1812), when English goods were excluded, the Americans began to manufacture for themselves, and not only constructed excellent machinery, but produced perfect imitations of the goods which had been hitherto imported. They were not, however, so cheap, from the causes we have mentioned; and now that there is peace, English goods would be universally used, were there not high duties imposed on them, in order to favour those in America who had gone to expense in establishing manufactories, and learning the necessary processes. The northern states (by whom chiefly the American goods are made) express themselves indignant at the idea of depending on foreigners for goods which they can produce at home, where the work-people would afford a market for the farm produce of the country, while those of the south, who have no manufactures, wish to have the cheapest articles, from whatever quarter they come. There has been a good deal of angry discussion on this subject between the parties, which has now, however, been compromised, some of the prohibitory duties having been repealed, and others reduced, so that, though there is still a considerable preference given to American goods, those of England are not altogether excluded.

The manufactures which are followed with most advantage in America, and without fear of English rivalry, are those which produce articles too bulky or too heavy, in proportion to their value, to bear the expense of a long carriage, or of which the materials are found in the country, and can be wrought up there at less expense than by carrying them to cheaper tradesmen at a distance. Some of these branches may be mentioned—such as, the making of soap, candles, and hats; tanning and working in leather, particularly bulky articles; building of carriages; making of all kinds of agricultural implements; carpentry, sawing, and turning of most descriptions; building of ships and steam-boats; constructing and putting up of mill-work and machinery; distilling; the employments of goldsmiths, tinsmiths, and printers. There are several businesses, however, whose prospects depend chiefly on prohibiting the cheaper manufactures of England, and which of course are liable to be deranged by any alteration in the tariff laws; these are the making of glass and earthenware; spinning and weaving most kinds of cotton goods; making of woollens, carpets, &c.; most of the finer kinds of hardware, iron, steel, and brass; hempen goods and silk goods.

The native American manufactures, limited as they are in some respects, are sufficient to give employment to every one who wishes to work; and there is still a continual call for new hands. Capital also finds abundant remuneration in the existing state of things, so that there seems to be no necessity for the Americans troubling themselves to establish new manufactures, all their spare hands and spare money being already occupied to advantage. To prove that there is full employment for all disposable capital, we may mention what is stated by an intelligent traveller, that a hotel which let for 350 dollars per annum was sold for 2500, only seven years' purchase—a sufficient proof, as there was no poverty or bankruptcy to compel the sale, that the owner knew of some profitable way in which ready money could be employed. Another proof of the same state of things is the circumstance which we have mentioned elsewhere, that the legal rate of interest is seven per cent., while ten per cent. is very often obtained.

Household manufactures of woollen, linen, and cotton, are made to a great extent. Many families spin, weave, and make up their own clothing, sheeting, table-linen, &c. They purchase cotton, and mix it up in the yarn with their linen and woollen stuffs; blankets, quilts, coverlids, stockings, mits, &c., are made chiefly in the family. These are perhaps neither so fine nor made so expeditiously as those of regular tradesmen; but they are produced for domestic use at times when there is no other employment, and in this manner may be said to cost nothing except the material of which they are made. It is supposed that nearly two-thirds of the domestic clothing are so made in country places, many families, as in Canada, having a loom in the house. It is the same with soap, candles, and maple-sugar, all of which are manufactured by the farmers at home. The articles made by families in the state of New York for their own use, were, in 1831, reckoned at L.1,03?,360 in value. Attempts have recently been made, with great success, to introduce the manufacture of silk: the mulberry-tree grows spontaneously in the middle states, and the light easy labour which the collecting of the silk requires, would afford employment to old people and females, enabling them to add to the income of their families, when they could not otherwise be able to do any thing.

In the southern, or slave states, there are no domestic manufactures; every article of clothing which the slaves require has to be purchased; and this is the reason why these states found the operation of the tariff so oppressive.

COMMERCE.

Foreign Trade.

The wealthiest class in the United States are generally the merchants of large sea-port towns. Commerce may be considered as forming the aristocracy of that country, and is regarded every where as highly honourable. Young people are educated for it with as much care as for the army, or for any of the learned professions; and they acquire a knowledge of the languages of the foreign countries with which they propose to be connected, their modes of transacting business, &c., instead of learning dead languages, and the manners of extinct nations, as with us. The manufactures and markets of foreign states—the quality, value, and profits of every commercial article, form the objects of their study, and prepare them for engaging in business with system and advantage.

The Americans show great activity in all commercial and maritime business; ships are laden and unladen in a few days, which would have required as many weeks in some other countries; their merchant vessels are built quicker, and sail better, than those of almost any other country. The pilot schooners of Baltimore have been known to take a cargo from an American to an English port in seventeen or eighteen days; and this admirable construction of their ships is seconded by the enterprise of the seamen. Sloops of one hundred and sixty tons, and eleven men, have sailed from Albany (one hundred and sixty miles up the Hudson river) to the coast of China, where the people thought them at first the long-boats of some merchant vessel. Nantucket and New York sloops of eighty tons, with ten men, double Cape Horn, and pursue the whale fishery in the South Seas, or take in cargoes of seal-oil and skins on the coast of New South Shetland.

The tonnage employed in the foreign and internal trade of the states in 1830, was 1,741,391 tons of shipping, and about 140,000 seamen—numbers little less than those of Britain herself. In the papers presented to Congress, we have the following statement of the amount of exports and imports in the year 1830:—

Exports.

	Dollars.	Dollars.
Manufactures—		
Cotton goods . .	1,318,?83	
Other manufactures .	4,0?2,707	
		5,320,980
Product of agricultures—		
Cotton . . .	29,674,883	
Tobacco . . .	5,586,365	
Grain of different kinds	8,992,342	
Cattle, live and dead, and their products . . .	2,379,652	
Fruits, seeds, sugar, roots, &c.	277,841	
		46,077,332
Product of forests		4,192,047
——— seas		1,725,270
Total domestic exports .		59,462,029
Foreign articles .		14,387,479
Total exports		73,849,508

Imports.

Articles free of duty .	12,746,245	
Articles taxed on importation	58,130,675	
Total imports		70,876,920

Tables are given of the different countries with which this trade is carried on. The following abstract will give an idea of the extent of transactions with each in 1830:—

	Imports.	Exports.
Russia	1,621,899	416,575
Germany, Holland, and Netherlands	2,778,266	6,321,459
Sweden, Norway, and Denmark	1,173,494	476,642
Britain	24,479,214	26,229,242
Spain and Portugal .	1,160,859	791,050
France - - - -	7,922,198	11,893,959
Mediterranean, except French and Spanish ports -	1,493,479	1,747,820
Gibraltar - - -	90,028	883,398
Africa and African islands	489,183	373,601
West Indies generally -	9,813,420	9,163,752
British West Indies -	168,570	1,901
Hayti - - -	1,597,140	823,178
British American colonies	6?4,586	3,786,373
Mexico - - -	5,235,241	4,837,458
Brazil - - -	2,491,460	1,843,238
Other South American republics	4,050,021	3,024,835
East Indies and Malay islands	2,030,483	1,196,717
China - - -	3,878,141	742,193
South Seas - -	20,748	27,942
North-west coast of America	- -	53,090

The commerce of the states, therefore, to the different quarters of the world, may be summed up as follows:—

	Imports.	Exports.
Europe - -	40,726,437	47,861,145
West Indies and other parts of America - -	23,807,436	23,473,825
East Indies, China, and South Seas - - -	5,937,372	1,966,852
Africa and its islands -	489,183	373,601

Of this trade the following is the amount which is carried on with Britain and her different colonies and dependencies:—

	Dollars.
Imports to America - -	26,764,984
Exports from do. - -	31,547,761

The annual amount of the American commerce is about sixteen millions sterling in imports, and a little more than that sum in exports. It appears that these sums form about half the amount of the British foreign trade. The American shipping, however, is nearly equal in tonnage to that of Britain. This apparent inconsistency is accounted for in two ways: first, a great deal of the trade to Britain is carried on in American bottoms, and not equally in ships of the two countries; and, secondly, there is a larger quantity of tonnage occupied by the Americans in the coasting or internal trade of the country than there is in Britain. It is, in fact, the traffic between the different parts of the Union which gives its chief activity to American commerce. This is owing to the circumstance that the northern and southern states, being situated in very different climates, have products as different from each other as England and Egypt. America has here a source of permanent and secure trade, in which no foreign power can interfere, either to disturb or to share it.

INTERNAL COMMERCE.

The immense number of navigable rivers which run through the country in every direction, and discharge themselves into the ocean or the lakes, afford the means of a great internal trade. These facilities have been increased at many important points by canals, connecting the different rivers at points where they approach each other, or where they flow away in opposite directions from sources lying in the same neighbourhood. Between the southern and eastern states there is a constant interchange of commodities along the coast, and a similar trade goes on from the western states to the south, by the Ohio and its branches, down the Mississippi. New Orleans is the great entrepôt for the goods of the latter branch of internal commerce. The north-eastern states furnish rum, molasses, cordials, dried fish, European goods of all descriptions, and articles of small value, quaintly styled *notions*; and they take in return corn, grain, cotton, and tobacco, from the south; while from the western states are received hams, beef, laid flower, &c., either for use or for exportation to the West Indies, and the other parts of Southern America. To show the extent to which this traffic is carried, we may mention that there are two hundred large steam-boats on the Mississippi, making the voyage up and down in twenty-four days. The cargo of one of these is given as follows:—501 barrels of pork, 9 hogsheads of hams, 2136 kegs of lard, 3147 barrels of flour, 30 barrels gin, 92 barrels beef, 50 boxes merchandise, 32 barrels porter, 224 barrels eggs, 50 horses, 32 cabin passengers, 42 deck do., 31 way do.; and this was the usual cargo every trip. The traffic from north to south along the coast is greater than might be inferred, even from this specimen of internal trade by the rivers; because the productions of the northern and southern districts on the sea-coast are as different from each other as those inland, while the states in that part of the country have been longer and more densely peopled. This active intercourse by rivers, canals, railroads, and sea-coast, increases the value of land and of industry every where: the produce of the country agricultures can always be sent easily to the market of towns, and that of manufacturing places to those which are more exclusively agricultural. The Americans are perfectly aware of the stimulus which these accessible channels of conveyance give to the activity of their citizens, and they accordingly use every means to have them extended.

CANALS, RAILWAYS, AND PUBLIC WORKS.

When America was first settled, the people chose lands in the vicinity of the sea or navigable rivers, so as to have the means of free communication to all parts by water; and lands even of inferior quality were found more valuable in such districts than richer soils in places where the produce could not be brought to market. All the available ground, however, in these favourable situations, was soon occupied, and people who wished to settle were forced to cultivate lands very inconveniently placed for carriage and communication with markets. These lands, however rich, afforded no more than the means of subsistence to their occupants; who, as they could send little or nothing to the great towns, could buy nothing from thence; they contributed, therefore, very little to the general trading prosperity of the country. As soon as canals were heard of in Europe, the Americans saw what advantages they might produce to such secluded districts in their own country, and immense efforts were made to set such works on foot. Their enterprise has been successful. The canals and railways of that country are now hardly to be equalled in the world, and these channels have opened the tide of population and prosperity into inland districts and rich lands, which must otherwise have lain waste, and lost, except to a few slovenly and ignorant persons. One of the states alone (Pennsylvania) has, since 1826, devoted no less than L.5,800,000 to this object. New York has been even more liberal; and there is no part of the country (always excepting the slave states, which in this respect, as in all others, are greatly behind) where such means are not taken to afford the occupiers of land means of bringing their produce to the market of cities. This is a matter which very nearly concerns the settler every where; because, however good the soil of his farm, or however unremitting his own industry may be, every advantage would be thrown away, if he could not get the produce disposed of. Some of the settlers in Canada, at the head of Lake Erie, were so badly off in this respect, till the opening of the Erie canal, that their surplus wheat and cattle were worth nothing: money was not given for farm produce in that quarter. Wherever there is a good canal or navigable river, on the other hand, the prices of farm produce rise, and land which was unsaleable becomes in request, and is covered with a throng of settlers from Europe, or of the restless speculators of America.

New York State.

The Erie canal was planned by an American patriot, Mr De Witt Clinton, and was carried into effect at the expense of the state of New York. It extends three hundred and sixty miles along a rich and fertile country, which had formerly no communication with markets, but which can now send its produce to the sea in two directions. It is forty feet wide at top, twenty-eight at bottom, and four feet deep. It was finished in five years, at an expense of L.1,600,000. The average collection of dues from vessels passing in the spring of 1831, was L.450 per day.

Houses, villages, and towns, are starting up along its whole line with unexampled rapidity. Lockport, for example, is a place where the canal is carried by locks up a steep rock of seventy feet. This spot has been suddenly transformed from a wilderness into a thriving village of two thousand inhabitants. Rochester is another example of the benefits the canal has conferred on the country: at that place there was abundance of most fertile land, and there were also certain falls on the river Genessee, which were admirably adapted for giving water-power to mills and other machinery; but all these advantages existed to little purpose without good roads and markets. The opening of the canal has supplied these, and the consequence has been, that Rochester has all at once started up from a desert into a populous city, and presents, says Mr Fergusson, a remarkable instance of what may be done in the way of transition, exhibiting in its streets a perfect sample of the progress from stumps to steeples. It is not long ago since its most crowded streets were a forest. The first settlers cut down the trees, leaving the stumps standing till they had more leisure; and this place now presents as elegant buildings as any in Europe, with churches whose steeples might do credit to London or Edinburgh.

This canal terminates in Lake Erie, and forms a channel by which the trade of the large inland seas, Lake Erie, Lake Huron, and Lake Michigan, may find access to markets in the populous cities of western America and Europe. The fertile shores of these lakes will therefore be rapidly settled, and all their natural advantages soon be brought into operation for the profit of mankind.

There are a number of other large and useful canals in this state, such as the Champlain canal, the Oswego canal, the Cayuga and Seneca canal, besides several others which are in progress.

Delaware and Hudson Canals.

A canal has been made to connect the rivers Delaware and Hudson, said to be one hundred and nine miles in length, with a rail-road attached of sixteen miles. The cost of the two was L.500,000, which was wholly expended by the New York merchants. It opens a conveyance for the coals and agricultural produce of Pennsylvania to the market of New York. The same two rivers are connected at a point farther down by a still larger work, called the *Morris canal*, which, like the former, is carried forward into the state of Pennsylvania, a considerable distance.

The Delaware and Chesapeake Canal.

This is a large canal formed by cutting across the upper part of a neck of marshy land which separates two large bays or firths, the Delaware and the Chesapeake. It affords an easy and quick water communication between two of the principal cities, Baltimore and Philadelphia. It is about fourteen miles in length, sixty feet broad, and ten feet deep, with a rise of eight feet only above the tide to its summit level. The largest schooners that navigate the two bays can pass through, and the work presents the greatest excavation ever attempted. The cost is estimated at 1,200,000 dollars, or L.270,000.

Navigation of the Potomac and Shenandoah.

The Potomac and Shenandoah are two noble rivers, leading far up into the country from the head of the Bay of Chesapeake. The navigation, however, is interrupted on both by rapids, which rendered them useless for the purposes of trade: these have been overcome by the construction of canals, and lockage at each of the rapids, by which the rivers are rendered completely navigable, and an inland navigation opened west of the city of Washington, of the extent of eight hundred miles. Many works of this kind have been completed, particularly in Pennsylvania.

The Chesapeake and Ohio Canal.

This canal was commenced in 1828. The proposed length is three hundred and forty-one miles; the breadth at the surface of the water, sixty to eighty feet; at the bottom, fifty feet; the depth of water, six to seven feet. According to the plan of this canal, it will pass from the tide-water of the Potomac, above Georgetown, and will terminate near Pittsburgh, in Pennsylvania. The cost was estimated at 22,375,000 dollars, or L.5,034,375; but it is not supposed that much more than half that sum will be actually wanted.

There is another important work commenced for connecting the western countries with the Atlantic—this is the Baltimore and Ohio rail-road, which is to extend from the city of Baltimore to the river Ohio, a distance of three hundred and fifty miles. It is now in progress, and is the greatest work of the kind—ten miles of it were open in 1832.

It would be idle in us to attempt here an enumeration of even a small proportion of the undertakings of this nature which have been executed in America. Wherever the navigation of a river has been impeded by rapids or the occasional shallowness of its bed, the obstacle has been overcome, if there were either useful minerals or fertile land to be made accessible. Along the banks of some rivers of this kind, canals have been carried for one hundred miles; as, for instance, the canalling of the Lehigh and Schuylkill, in Pennsylvania. Wherever two navigable streams flowing to different seas are separated by a ridge which it is possible to penetrate by a canal, the work is attempted, and the communication made complete from sea to sea. Examples of this are found in the Champlain canal, which is completed, and connects the Hudson and St Lawrence; and in canals between the Miami and the Wabash, the Fox river, and the Ovisconsin, which are both likely to be effected. It is not that the Americans are more generous or more patriotic than other people that they undertake these works; it seems rather to arise from a spirit of restless enterprise, which cannot be satisfied with turning to advantage the land within their reach, but must be always hurrying away to secure the resources of some new region which is supposed to be more fertile than any yet discovered. Another reason for the manner in which the Americans outstrip the British in this species of undertaking, ought to be mentioned. All great improvements in this country are impeded by powerful factions of men who thrive upon ancient systems, however absurd; whereas in America all classes seem to strive to improve the country on general principles of utility, without regard to antiquated usages. Whatever may be the cause, it has had the effect of opening up to the over-crowded population of Europe rich and inexhaustible countries to which they may emigrate for ages without filling them, but which would have been of little advantage without the channels of communication now opening by the Americans. The only other work of this kind we have room to mention is the

Ohio State Canal.

This canal is to pass from Portsmouth, on the River Ohio, to Cleveland, on Lake Erie, a distance of three hundred and nine miles. Of these, one hundred and nine miles are completed, and the rest under contract to be finished by a given time (1835). This canal will complete an unbroken line of communication from New Orleans, on the Bay of Mexico, up the Mississippi and Ohio, to Portsmouth, thence to Lake Erie; and, from this point, either to New York by canal, or down the St Lawrence to Montreal and Quebec. There is also in progress a canal from Cincinnati, on the Ohio, to effect the same object: this canal, in 1831, had been executed from Cincinnati to Dayton, sixty-five miles, and the remainder is in progress to join the River Miami, which falls into Lake Erie at Laurenceville. The whole length (including feeders) is two hundred and ninety miles. The general government gives donations of land to aid in the completion of these works.

SEA-COAST, LAKES, AND NAVIGABLE RIVERS.

Bays and Harbours on the Sea-Coast.

There are some countries which are deprived of the advantage of bays, harbours, and good protection for shipping. France, for instance, with a long line of sea-coast, has but few of these natural advantages; and a more remarkable instance still, is afforded by the coast of Coromandel in India, which has not one good harbour or bay where vessels might take shelter, along its whole extent. America is very differently situated in this respect: from north to south along the whole coast which fronts the Atlantic, the country is deeply indented with large navigable bays, which afford ready protection to her shipping, and give points of rendezvous to the trade of numerous rivers which fall into them. It would be needless to mention the whole of these: the smallest of them on the coast of India, where ships are exposed to all the hazards of an open sea, and lie off, delivering their cargoes by means of rafts or lighters sent backwards and forwards to the shore, would be reckoned sufficient to give wealth and importance to a large city. They are so numerous on the coast of America, that the commercial facilities of half of them cannot be taken advantage of: among the principal, are the Bay of Chesapeake, where the mouths (or firths) of several large rivers, the Susquehannah, the Potomac, the James, the Rappahannoc, &c., meet together, and concentrate the commerce of a large tract of country belonging to each. There is hardly another bay in the world which, by the rivers that fall into it, gives access to inland places so remote from each other. North from this is the Bay of Delaware, very little inferior to it in the facilities it affords for trade, and the communication its rivers (the Delaware, Lehigh, Schuylkill, &c.) afford with the interior. North from these is the Bay of New York, which affords an entrance to the large river Hudson, besides several others; and which, by means of canals, has now a communication with the St Lawrence, the lakes of Canada, and the whole fertile country lying on the banks of these, forming an extent of inland navigable waters larger than any other which is known.

The coast north from New York has the Bays of Providence, Barnstaple, Boston Harbour, Penobscot, &c., all of the greatest utility for shipping, and enabling the people to bring all the natural advantages of the country into operation for commerce.

To the south of the Chesapeake, in the slave countries, there are also many noble harbours, bays, and rivers, which, under circumstances more favourable to the moral and commercial improvement of the people, would give to the trade of this part of the Union all the facilities which have contributed so powerfully to the prosperity of the north.

Lakes.

The American states are bounded to the north by a chain of the largest fresh-water lakes on the globe, which are all connected together by one continuous river, called, after it leaves them at its lower portion or outlet, the St Lawrence. These lakes lie along the summit of a range of elevated ground, which stretches nearly across the continent, occupying certain deep cavities hollowed out on this summit level, and they receive the waters of all those small rivers which are formed on the flat region lying around them. The principal lakes are four in number, and are called (beginning from the eastward) Lakes Ontario, Erie, Huron, Michigan, and Superior; the navigation from Lake Ontario to Lake Erie is interrupted by the falls of Niagara, where that river (the same which is called the St Lawrence after it quits the lakes) is precipitated over a rock one hundred and sixty feet high. From Erie to Huron, vessels of large size pass uninterrupted, but the communication is again impeded in the channel which connects the two latter with Lake Huron, by the falls of St Mary's. At Niagara, a canal, called the Welland canal, has been formed by the British government on the Canada side of the river, which enables vessels to pass from Ontario to Erie without impediment; and the like will no doubt be performed by one or other of the governments, for the falls of St Mary, whenever the commerce upon these more remote lakes shall justify the expense of such an undertaking. The whole chain of these inland seas will then be navigable from one end to the other; and as their shores are all of great fertility, the region lying around them may be expected at some future time to be one of the busiest and richest on the globe. At present, as they extend along the northern limits of the United States, they afford to that inland boundary nearly the same commercial advantages as those possessed by a sea-coast, and give a sensible stimulus of the industry of all the districts connected with them. The following is a summary of particulars connected with the extent, depth, &c. of the lakes:—

Name.	Length Miles.	Width Miles.	Depth Feet.	Elevation above the Sea—Feet.
Ontario	180	40	500	231
Erie	270	80	200	565½
Huron	250	100	900	618
Michigan	400	50	unknown	618
Superior	480	109	900	641

None of the navigable rivers of the United States fall into the lakes, and there is no river that flows out of them over which that country has command, so that it would appear that the advantages it can derive from them are but limited. To remedy this inconvenience, which the Americans soon perceived and regretted, they have led canals from the most of their inland districts to the upper portion of the lakes; while from their lower shore (or that which is next the sea) they have conducted others, to give them an outlet to the ocean within their own territory. The navigation is thus rendered complete, from the shores of the sea at New York, by a canal, to Lake Erie; thence to Huron and Michigan; and from thence by other canals to the inland states of the west. We shall again have occasion to allude to this in mentioning the American canals.

Navigable Rivers.

The navigable rivers on the eastern side of America are numerous and important. We may first mention the Connecticut, a large stream flowing into the Atlantic near the north-east end of Long Island; the Hudson, a river navigable for steam-boats of the largest class for one hundred and sixty miles above its mouth, and the channel which has enabled New York to extend its commerce by a canal to the lakes: the Delaware, flowing past Philadelphia, and affording communication by itself or its tributaries with a country three hundred miles in length, and of nearly equal breadth: the Susquehannah, the Potomac, the James River, and others flowing into the Bay of Chesapeake, which, by the help of canals, afford entrance to vessels of one kind or other into the deepest vallies and recesses of the eastern country. Southward are the Roanoke, flowing into Albemarle Sound, and the Pamlico river, affording channels for the commerce of North Carolina; while South Carolina and Georgia are canalled in the most complete manner (if we may use the expression) by the rivers Pedee, Santee, Savannah, Ogeechee, Alatamaha, &c.; and East Florida enjoys the same convenience in the river St John's and its branches.

But the eastern rivers, useful as they are (and they have certainly as yet been the chief seats of commerce in the country), are by the Americans themselves entirely lost sight of in the enthusiasm of their admiration for the immense streams which water the western and inland states. These great rivers are certainly not to be equalled in any other country, at least in any country which has had such skill, or such a form of government, as have enabled its people to turn the commercial facilities of their inland waters to proper advantage. The American rivers to which we allude, are the Mississippi, and the large tributaries which arrive from the east and west to fall into the channel of that great stream, of which a description has been given in a former article.

MINERALS.

There is a great variety of useful minerals distributed through different parts of the states: coal may be mentioned among the first: it exists through all the country, lying north of a line drawn from Philadelphia to the mouth of the Ohio, and is particularly abundant on the upper waters of the Susquehannah, as well as on the Allegany and the Monongahela. At Pittsburgh there is a hill principally composed of coal, and it is found at many places in this district within a few feet of the surface. There are extensive coal-mines also on the Roanoke and Appomatox, in Virginia.

The country on the Ohio is particularly rich in mineral productions. The whole district is bottomed on limestone, on which rests the wide and valuable coal formation mentioned above, extending from the head waters of the Ohio, in Pennsylvania, to the river Tombigbee. Iron ore is found abundantly in the same district, principally towards the upper part of the Ohio; bog ore is found in the vallies of the Allegany chain; and various kinds of ores, of the same metal, are met with in the New England states: at one place, carbonate of iron is found, which, on being reduced, produces steel, and is called *steel ore*. Black lead, in beds of from five to six feet wide, traverses the states of New York, Jersey, Virginia, Carolina, &c. Copper ore is found in Virginia, in Connecticut, and in New Jersey: it exists also in the neighbourhood of the lakes, and a piece of pure malleable copper, weighing three pounds, was found in Illinois.

Gold mines have been traced extending through a large tract of country in the western parts of Virginia, North and South Carolina, and Georgia; they are wrought to considerable extent, twenty thousand men being employed at the different workings; the miners, who are people of all countries, say that the produce is richer than that of any other mines on the globe; one piece of pure gold was found weighing twenty-eight pounds. The annual produce is about one million sterling; but we have not heard what proportion of this is expended in the work, or what actual profit has been realised. One singular fact is remarked concerning these mines, which is, the indubitable evidences found that they have been wrought at some period before America was known to the Europeans. Many pieces of machinery which were used for this purpose have been discovered in the workings, among which were several crucibles of earthenware, which are far better than those now in use.

Silver and its ores are not of frequent or extensive occurrence. Mercury has been found native in Kentucky, but it occurs plentifully in the ore as bituminous cinnabar, through the Ohio and Michigan territory. It is found in the soil as a black or red sand, sometimes as a fine red powder, and at other times in iron clay. There are lead mines of vast extent on the Missouri; they are said to occupy a surface of six hundred miles in length, and two hundred in breadth. One miner will raise about two thousand pounds per day, which sell for forty-five dollars, and yield twelve hundred pounds of pure lead.

Epsom salts, Glauber salts, and nitre, are found in Ohio and Indiana; the two latter in caves, the former in a thin layer on rocky surfaces. Salt, which in countries far removed from the sea is an article of great expense, is produced from salt-springs, or from borings in different parts of the western country. Mineral waters of valuable medicinal qualities occur at several places; the springs principally frequented are those of Saratoga, in New England. Oil of vitriol, or sulphuric acid, is got almost pure from the earth, in Genessee, near the town of Byron. It oozes out from the soil of a low hummock, and may be collected by digging holes in the ground. There are several places where inflammable gas issues from the earth: one is a small lake called Sodem, the bottom of which is formed of grass-green slate, the sides of white shell-marl, and the brim of black mould; the water is uncommonly transparent, so that the basin looks like an immense porcelain bowl; the water is of the quality of that of Harrowgate; the gas issues from it abundantly, and, when kindled, burns along the surface with a bright red flame by day-light.

GEOLOGICAL PECULIARITIES.

In examining the geological structure of the American continent, some singularities have been observed, which are believed not to correspond with the theories formed in Europe on this subject. We shall mention a few of those which appear to be most interesting. There is no chalk found any where in the states, neither is there any roestone (or oolite, as it is called by geologists), though the localities where both might be expected are sufficiently marked. Mr MacLure states, that some shells of the recent alluvial formations in New Jersey are identical with species found in the secondary rocks. There have been discovered in naked limestone of the elder secondary formation, the prints of human feet; the marks are those of a man of ordinary size standing erect, with his heels drawn in, and his toes turned outward; the toes are much spread, and the feet flattened, like those of people not accustomed to shoes; the impressions are strikingly faithful, exhibiting every muscular swell and depression with accuracy. Every thing seems to warrant the conclusion, that these marks were made at a time when the rock was soft, and received them by pressure, which geology dates at a period very long indeed before the general flood. They were examined by Governor Cass and Mr Schoolcraft, at St Louis and Herculaneum, on the Mississippi, and they exist also at the Cumberland mountains, always in the same kind of limestone. Other singular facts (unconnected, however, with the above) have been observed in this district. At Pickaway plains, on the Ohio, a human skeleton was found seventeen feet below the surface, in a bed of pebbles and shells deposited by water, and having nine feet of earth over them. At Cincinnati, in digging a well, an arrow-head was found ninety feet below the surface; and in Illinois, fragments of antique pottery and jars of coarse earthenware have been found at a depth of eighty feet below ground. In forming the Erie canal, the workmen, when digging this ridge of gravel, found several hundred living shell-fish at a depth of forty-two feet. They were chiefly of two kinds of *mya*, a salt-water mussel, of which several species exist in Britain; one, called *smurslin*, is used for food in Zetland, and another is eaten about Cork, where it is called *sugar loons*: we do not know if the species which were dug out of the gravel are found among the present American shell-fish. *Living toads* have been found in America, as here, in solid rock, of what has been called the mill-stone grit.

PECULIARITIES OF DIFFERENT DISTRICTS.

America is generally considered and spoken of as one country, its people as forming a single nation, and the remarks which are made with regard to one part of it are supposed to be equally applicable to all. No idea, however, can be more fallacious. The region which we term the United States is composed of sections of country as remote from each other as London is from Constantinople, or Madrid from Berlin; they lie under different climates, and the different circumstances under which their inhabitants are placed form in each a totally different set of manners. The English language is common to all, and they all profess the Christian religion; but in most other respects the difference between them is as great as between any two European nations. The great divisions under which the country ought to be viewed are the north-eastern or New England states, in which for the present may be included Pennsylvania; 2d, The southern or slave states, to which section also we may refer Kentucky and Tenessee; and, 3d, The new states of the west, which are in progress of settlement. The manners of the New England states are formed on the model of those of our own country, and there are few circumstances in the nature of the climate which tend to produce any material alteration; it is among them only that due provision is made for the education of the people or for religious instruction. The productions of the soil—the modes of agriculture—the arts and occupations to which these give rise—the alternations of season—and many other things, have all a resemblance to those of our own country. They cultivate wheat and the other European grains; their garden vegetables, potatoes, turnips, carrots, cabbages, &c., are the same as ours; they employ the same domestic animals; and they use, of course, the same agricultural implements, the same grist-mills, &c., requiring also the same tradesmen to prepare and work them

Even in these great divisions which we have pointed out, there are portions which differ exceedingly from each other. New Orleans, for instance, which belongs to the slave states, has a completely different set of manners from Charleston in Virginia: the former is a city of immense trade, situated at the mouth of the great river Mississippi; it contains a mixed population of blacks of all shades, and of white men from every nation in Europe. Its streets are crowded and speckled with people of every colour; its quays with ships of every country; and its wharfs are loaded with bales of goods from all quarters of the earth, some coming from Europe or from China, to be carried for three thousand miles up the inland rivers of America; others sent down these rivers some months' voyage, to be carried to the West Indies or the Mediterranean. The air of the place is unwholesome, and it is a mart where people hurry to make money before they be overtaken with disease and death. Such are the influences under which the manners and character of the people of New Orleans are formed. Charleston, on the other hand, is the capital of a wealthy agricultural state; the pursuits of the people are not decidedly commercial; the town is the resort of numerous country gentlemen, who pride themselves rather on the oldness and respectability of their families, and the extent of their property, than on the activity of their business habits. The gentry strive to keep up, between themselves and their slaves, an exterior resemblance to the feudal relations of Europe; coats of arms are fashionable, as are liveries for servants: there is a general air of elegance and splendour in the buildings of the town; some of the houses "are real palazzos, surrounded with orange trees, magnolias, and other trees of an almost tropical climate." There is much taste for the fine arts among the higher classes, and among the lower an absence of all that bustle and variety of language and dress, which mark a great commercial city. It is obvious, therefore, that the manners of these two places can have very little in common.

If we look again at the northern states, we shall find a difference of a similar kind existing between New York and Philadelphia. The former city is the great thoroughfare of all emigrants and commercial agents who arrive from Europe; the people passing through it daily are sometimes estimated at 15,000 or 20,000; it lies at a central point, having communication by rivers, canals, and rail-roads, with the whole northern parts of the American continent. Grain, provisions, lumber, and manufactures, are brought from countries a thousand miles inland, for exportation, or for the use of places along the coast, which have not the same facility of conveyance. People arriving there are secure of finding a passage to every other city inland or coastways; hence the streets and quays are constantly crowded with travellers and their luggage. The extent of its commercial transactions gives a facility to those who wish to engage in any kind of speculation, because here they can always learn the prices or the demand for every article of American produce; hence there is a restlessness, bustle, and continual spirit of change among its population, or a great part of them, which it would be vain to seek elsewhere in Europe or in America. Philadelphia, on the other hand, though also a place of very extensive commerce, has fewer channels of communication with the distant inland countries, and has of course a smaller variety of produce either raw or manufactured; hence there is less speculation; business proceeds with more steadiness, but less apparent bustle; there is in the streets an air of quiet regularity, where every one seems to go easily and leisurely about his business; and the transit of strangers through the place is but inconsiderable. The prevailing religion, which is Quakerism, has also a manifest influence in producing these effects. The influence of circumstances upon the manners of a people is nowhere more remarkable than it is here in the case of the negroes. Slavery is not permitted in this state; and the inhabitants do not countenance in all its severity that feeling of contempt with which black people are regarded in other parts of the Union; hence the Africans reside here in freedom and comfort, while they see their countrymen, a few miles to the southward, poor degraded slaves, and they are generally in consequence a contented, cheerful, and industrious caste.

If we look again at the western states, we shall find, that, though there is a certain uniformity of manners over the whole, they are here also differently modified, according to circumstances. Pittsburgh, for instance, with the neighbouring towns, Wheeling and Steubenville, are in the centre of a country which is rich in various kinds of minerals, coal, iron, lime, &c.; they are therefore filled with a manufacturing population, and the pursuits, appearance, and manners of their inhabitants, differ from those of the country around them, as those of Birmingham may be supposed to do, from other places in the centre of England. The town of Cincinnati, again, which is situated on the Ohio, as these places also are, is a great inland depôt for merchandise to be exported or imported. Its inhabitants are merchants, attendants in counting-houses and warerooms, owners of river steam-boats, and a population attracted by the general trade of the place, while there is also a large number who are occupied in the very peculiar business of killing and preserving for exportation the immense quantities of live stock reared in the country.

CLIMATE, SOIL, AND NATURAL PRODUCTIONS.

The state of Maine, which is the farthest north of the Union, reaches to latitude 48°; Florida, on the south, extends to within 25° of the equator; between these two points there is a great variety of climate; and the differences of temperature are increased by the flat or sheltered situation of some districts, and the mountainous features of others. The New England states and Pennsylvania, lying between 40° and 48° north, approach nearest to the climate of England; but owing to causes which are not yet perfectly understood, the whole Atlantic coast is warmer in summer and colder in winter by about 10°, than the same latitudes in Europe. Some of the plants of this country, such as the holly, and the common *whin* or furze, when transplanted thither, fade equally under the heats of summer and the frosts of the cold season, and cannot be preserved except in green-houses. In winter the rivers are frozen, so as to bear horses and waggons. The air is in general drier than in this country, and wet showery weather much less frequent; so that farm-work is conducted with more regularity and more security than with us. Winter does not set in till the middle of December; after which, frosts continue with more or less severity till March, with frequent and great changes from mild weather to intense cold. In April the season becomes again fine, sunny, and dry.

In the states south of the Potomac, the climate is much warmer; the winters, which indeed are hardly to be called winters in our sense of the word, are short and mild, frost being little felt except during the night. The heat of the warm season is like that of tropical countries; but this is felt chiefly on the sea-coast, which is in general low, flat, and far from healthy. The inland parts being more elevated and hilly, the climate there is more temperate. The whole coast from north to south is subject to tremendous hurricanes, which sometimes do much mischief.

The climate of the western states, forming what is called the Basin of the Ohio, is different both from that of New England, and from the southern districts in the same latitudes. The *average temperature of the year* is nearly the same at corresponding points on both; but there are fewer inequalities in the west, neither the heat nor cold reaching the same extremes. The thermometer seldom falls more than ten or twelve degrees below the freezing point. Frost does not become permanent till near the close of December, when standing water and small rills are frozen from three to fifteen days. Many plants, such as the cotton, the catalpa, sassafras, the Illinois nut, flourish in the western states, in latitudes where they would not thrive on the sea-coast. The air is more moist, fogs and heavy dews more common.

Soil.

That portion of the New England states which lies east of the river Hudson, is broken and hilly; the soil in general thin, unproductive, and better adapted for pasture than tillage. From New York, all along the sea-coast southward to the Mississippi, there is a tract of flat sandy soil extending inland from thirty to one hundred miles; it produces nothing but shrubs and pine-trees, except on the banks of rivers and marshy places, where rice is grown. Backward from this line to the foot of the Allegany Mountains, there is a tract of coarse land of variable breadth, but of great fertility. The Alleganies themselves are not cultivated, but the vallies between their ridges are rich and useful land. The district inland from these is the Basin of the Mississippi, a region of vast extent; it is generally bottomed on limestone, well watered and inexhaustibly productive.

Agricultural Productions.

Oats, rye, and barley, are raised in all the northern states, and also in the hilly districts of the south. Of barley, two crops in a season are obtained in favourable situations. Maize is common to every part of the Union, but thrives best in the middle states; it is a vegetable adapted to a greater variety of soil and climate than wheat, and yields a much larger produce. The sugar maple grows every where, but thrives best in the good maize districts. Wheat is also cultivated through the whole Union; but it is only a profitable crop to the north of the Potomac, or in the hilly districts of the south; in these situations it yields large returns, and of excellent quality: in the low warm districts it is not cultivated; these are more favourable to the rice crop. In general, it is remarked the late wheat countries are favourable to the European constitution, and that in rice countries, which are warm and moist, the African population has a great advantage in respect to health and longevity over whites.

The cultivation of tobacco begins in Maryland, in latitude 39°; it is raised to a greater extent in that state, and in Virginia, than in any others of the Union; but it thrives also in all the western states. Cotton does not succeed well farther north than the latitude of 37°, though some of the districts raise it for domestic use; it forms the staple of all the districts south of the river Roanoke. The best kinds grow in South Carolina and Georgia, in dry situations, upon the sea-coast. The cultivation of rice occupies nearly the same region as that of cotton; it is a very unhealthy occupation for the slaves who are engaged in it. The climate which is favourable to sugar does not extend beyond the latitude of 32°; it is raised in the states chiefly for domestic use, and is not an article of export to any extent. The crop is rather precarious, from the frosts which sometimes occur even in the most southerly districts. Indigo has been tried in America, but could not come into competition with that of Bengal.

The vine grows spontaneously in most of the southern and western states, and is cultivated as a fruit about Philadelphia. The mulberry-tree, hops, and hemp, all succeed well in the middle and western states.

The timber trees of the states are of numerous kinds, and many of them of the best quality. There are twenty-six kinds of oak, of which eleven or twelve species are in request; the best for common purposes is the *white oak*, a tree which is found plentifully over the whole country: the *live oak* grows in marshy places near the sea, and has a hard, heavy, and durable timber, much used for ship-building. There are eighteen kinds of pine, cedar, and larch; seven kinds of maple, three or four of which furnish sugar; the best is called the sugar maple; ten kinds of walnut trees; four kinds of birch, the bark of one of which furnishes the Indians with canoes; six kinds of ash (the ash of this country is not of the number); besides many other trees, of very useful qualities. There are one hundred and thirty kinds which rise to a height of more than thirty feet; while in France there are only thirty-seven of that size. The flowering shrubs, *Kalmia* and *Rhododendron*, which are cultivated here with so much attention for their splendid flowers, grow wild on the sides of the American hills, to the height of fifteen or twenty feet.

Even in the most thickly-peopled states, there are still remaining large tracts of uncleared woodlands, which give the country a wild appearance, and form an aspect on the whole very different from any thing seen in Europe, where forests have long been too valuable to be allowed to remain uncut.

RATES OF PROFIT, WAGES, AND STYLE OF LIVING.

There is abundance of fertile land in the United States, which needs only to be broken up and cleared of woods to yield large returns for a slight outlay. There are none of those obstacles to the cultivation of solitary districts which exist in the lawless or unimproved condition of some other countries. Property is secure every where, and there is hardly any spot, however remote, which has not ready communication by rivers, canals, or roads, with one or other of the large cities. Hence, fertile lands which are of easy access are to be found by every one who is at a loss for employment, or who thinks his present occupation less profitable than he would wish. On such soils, the accumulation of capital in agriculture is much more rapid than has ever been exhibited in any other nation. The valuations of 1799 and 1814 furnish interesting information on this head. From these it appears, that, in the fifteen years between these periods, the value of lands and houses (not reckoning slaves) in the seventeen states, had, on an average, increased one hundred and sixty per cent., or from a hundred to two hundred and sixty. The rate of increase for the whole is about 6¼ per cent., and the original capital is doubled in about eleven years. At this rate, capital accumulates more than twice as fast as population; or in other words, the increase of the people is always met by a double increase of the means for employing and maintaining them. These remarks are derived from the condition of the agricultural population; but they apply equally to the whole, the rate of profit being the same in all occupations. No man will submit to take small wages, or to carry on business with slender profits where he can betake himself to farming, with the certainty of acquiring, in a few years, an independent property, especially where agriculture requires as yet no particular skill or apprenticeship to secure adequate success. The legal rate of interest is seven per cent.; and when money is lent for commercial speculations in the western states, ten per cent. is reckoned favourable terms. The average price of labour was reckoned in 1815 at 80 cents, or 3s. 4d. per day; wheat at 1¼ dollar, or 6s. 9d. per bushel (27s. per boll); and at these prices, it has been computed that a labourer can earn as much in one day as will maintain himself, his wife, and four children, for three days nearly. Hence the style of living among all classes is full and liberal; there is less perhaps of that princely but invidious magnificence, which, in the palaces of Europe, is so often beheld surrounded and besieged with the importunity of beggars; but there is an equal distribution of comfort every where. The houses of the middle classes are well and conveniently furnished. As a specimen of the way in which they live, we may mention, that a man who pays 13s. 6d. per week for board, lodging, and washing, dines at the family table, where there is a roast turkey once or twice a-week, fowls, beef-steaks, ham, sausages, pudding, pies, soup, fish, &c.; a variety of these are given at every meal, and generally three kinds of vegetables, with coffee or tea at breakfast and supper.

A beggar is scarcely to be seen; but there are persons in all countries, who, from age or bodily infirmities, are unable to support themselves. In America, these are reckoned on the sea-coast at one to two hundred and thirty of the population; in the interior at one to three hundred and fifty, most of them foreigners, or worn-out negroes. In England, the proportion is one to six or seven of the population.

POPULATION OF THE STATES.

The rapid increase of population in the United States is one of the most interesting circumstances connected with their history. When the general style of living among any people is comfortable, and they continue at the same time to add rapidly to their numbers, it is a proof that their country affords abundant resources for subsistence, and that they have industry and skill to turn these to good account. England doubles the number of her people in about one hundred years, Scotland in one hundred and fifty, in America they are doubled in about twenty-five years; and it is reckoned, that, by the end of a century from this date, if the same increase continues, the American population will be more than two hundred millions; a number greater than that of any nation at present speaking one language on the face of the earth. From the rapidity with which successive generations come forward, it is generally remarked that the number of aged persons in any neighbourhood appears small compared with the multitudes of young people by whom they are surrounded; and from the same reason the number of individuals below sixteen, who in other countries form hardly a third of the population, are in America fully one-half of the whole. In Carolina and Kentucky, the number above sixteen was considerably less than that of those under it.

The population at successive periods has been given as follows from the official census:—

			White People.	Blacks.
Population	in	1790	3,929,328	697,697
„	„	1800	5,309,758	896,849
„	„	1810	7,239,903	1,191,364
„	„	1820	9,638,166	1,538,001
„	„	1830	12,856,177	2,010,436

These returns show an average increase of thirty-three per cent. in ten years; a rate incomparably greater than has ever been witnessed in any other country. The number of persons who come from Europe to settle in the states is estimated variously, from 8000 to 20,000 yearly; the most accurate accounts incline to the former statement. The number of foreigners not naturalised who were residing in the states in 1830 was 53,687; and as these persons cannot be naturalised till they have been five years in the country, this amount, with a little deduction, may represent the arrivals during the last five years, which will therefore be about ten thousand per annum.

The census for 1830 gives the number of persons who have attained the age of one hundred and upwards, as follows:—

White men above one hundred . .	297
Ditto women	234
Black people—men	1099
„ „ women	1011
	2641

The proportion of black people who live to great age appears therefore to be much higher than that of the whites. This advantage the African race seem to possess chiefly in the southern districts. In ten of the states south of the Ohio and Potomac, the whole number of white inhabitants was five and a half millions, the number of blacks one million and a half (nearly); yet of the former only three hundred are above one hundred years of age, while of the latter there are 1780—a circumstance which shows that the climate of the south is better fitted for the negro constitution than for that of white people. Of the latter, only one in nineteen thousand arrive at the age of one hundred; while of the Africans one in every nine hundred reaches that age. On the subject of longevity we may mention, that, in August 1817, within a circle of twelve miles in diameter, in North Carolina, there were living sixteen persons between eighty and ninety years of age, twelve from seventy to eighty, and twelve from sixty to seventy. A child was lately born there whose father was eighty-four and mother fifty-seven years at the time of birth (*Warden's United States—Walsh's Register*). In Cumberland county (Virginia), seven persons died between the ages of ninety and one hundred and twelve years, within a short time of each other. In South Carolina it is remarked, that all who could be found above eighty (1808) were emigrants from Europe, and living in the upper hilly country.

THE COLOURED POPULATION.

Slaves.

The states which continue to support slavery are those which lie south of Pennsylvania and the river Ohio, with the new districts to the westward of the Mississippi; in all the others it is abolished. The whole number of slaves in 1830 was two millions. The condition of these poor people is every where very low; the field slaves are fed, lodged, and attended to, exactly on the same principle as that on which farmers in this country take care of their oxen and horses; a planter is sorry to see them dying or diseased, because he loses their labour; but they meet with no farther regard. It is frequently profitable to cultivate rice in very marshy grounds, or in fields artificially overflowed, where the negroes must work up to their knees in water in the heat of the day. Numbers of them take sick and die in this unhealthy occupation, but the planter only calculates whether the profits of his crops will pay for the number of new negroes which he is obliged to buy; he never thinks of the distress of these poor people, and even takes credit to himself in being liberal in sacrificing his blacks, in order to keep those rich grounds in cultivation which otherwise must be lost to the country. Mr Stuart of Dunearn mentions that even where the slaves were well fed and attended to (as it is the interest of every proprietor to do with his cattle), he found them, in respect to knowledge and feeling, little removed from brutes, while all declared themselves unhappy and miserable in their situation. When their tasks are found deficient, they are whipt, put in the stocks, or forced to wear irons. One person was in the habit of punishing his slaves by [illegible]ing them down in coffins, and some of them had died under that treatment. The cruel owner might have been punished by law had there been sufficient evidence of the facts; but as he took care to have no one present but slaves, whose testimony is not admitted in the courts, nothing could be done.

The gangs of slaves on large estates are in general tolerably well fed and clothed; but there is a numerous class of slaves belonging to very poor, and often very improvident, white people, and these are exceedingly wretched, toiling hard, with little subsistence and the harshest treatment. In all cases, the slaves live together with little more feeling of the decencies of life than the brutes that perish. Even when they are employed as waiters in the large inns and hotels of cities, they are not furnished with beds, all lying like dogs in the passages of the house. There are laws by which every one who shall teach a slave to read, or permit him to be taught, may be imprisoned for twelve months. The advantage of having labour performed by slaves, is to the proprietor very considerable: they are maintained at an annual expense of about thirty-five dollars each; while the interest on their original cost, at ten per cent., may be forty dollars; the amount is seventy-five dollars, or about L.17 per annum. Now, the wages of a white labourer are here three times as great as in Europe, and cannot be reckoned at less than five hundred or six hundred dollars, from L.120 to L.150. It is no wonder, therefore, that the proprietors of slaves in America are jealous of any attempts to instruct or emancipate them.

Free Blacks and Coloured People.

From the black people having been first introduced into America as slaves, they are regarded every where with great contempt, whether free or in bondage. In the states where slavery remains in force, the free negroes or mulattos are treated with the greatest contumely; every impediment is thrown in the way of their obtaining education; and the senate of Virginia even voted that the increase of schools for coloured people was a nuisance which ought to be put down; by laws in the several states, any one who may instigate them to resent this ignominious treatment, or in any way to diminish the respect which is commanded to free people of colour for the whites, may be punished by fine and imprisonment. Clergymen in their pulpits, and judges on the bench, are not exempted from this regulation. But even in the free states, though laws of this kind are not in existence, people of colour are subjected to every mortification: they are not allowed to eat at the same table with white men, to attend at the same public meetings, or even to enter the same churches. From being thus always exhibited in a kind of degraded light among the more powerful class, they have not the same respect for themselves which they ought to entertain. Of the persons who are punished for crimes, a larger proportion are people of colour than whites. They have a greater difficulty in getting proper remuneration for their industry or talents than that favoured class; and their exertions are discouraged in all the higher lines of life. Numbers of them, however, notwithstanding all these difficulties, rise to great wealth, and live in a style of much elegance. They have churches and schools for themselves, with ministers and teachers of their own people. Great exertions are making by the Quakers, and other benevolent persons in the free states, to establish and maintain respectable schools for the education of black children. As the memory of their former slavery wears away, they will come to be regarded in a more favourable view. The whole number of free-coloured persons in the states is about 300,000.

The Indians.

The number of Indians now remaining within the territory of the states is estimated to be somewhere between 400,000 and 600,000; of these, about 75,000, consisting of tribes called Cherokees, Creeks, Chickasaws, and Choctaws, are in possession of tracts of land lying contiguous to each other in Georgia, Alabama, and Tenessee. There have been some disputes concerning their territory, and some of the adjoining states have used very despotic means to have them ejected from it: they still, however, retain possession; and as any violence done to them directly would excite much odium both in Europe and among well-thinking people in the states, they are likely now to remain undisturbed. They have quite renounced the character of savages, and are all more or less in progress towards civilization; they cultivate wheat, maize, pumpkins; rear cattle and horses; manufacture cloth, oil, leather, &c. The tribe which has made the greatest advances is the Cherokees, whose population, in 1824, was 15,560; in 1810, it was 12,400, so that they are not falling off in number like the other Indians. They possess a fine, well-watered, and arable country of five millions of acres; agriculture is well understood; apple and peach orchards are common; butter and cheese are produced of good qualities: they have slaves, good horses, and about 22,000 head of cattle. Several of them are good tradesmen, as blacksmiths, weavers, millers; and they have saw-mills, grist-mills, waggons, and other furniture of an improving community. They have a newspaper edited by one of their own people, in their own language. Numerous and flourishing villages are seen in every section of the country. They are remarkably clean and neat in their persons, and practise bathing universally. A young man solicited the hand of a young Cherokee woman: she refused his offer, and gave as a principal reason that he was not clean in his appearance; that he did not, as the Cherokees do, bathe himself in the river. They consider bathing and cleanliness in the light of a moral virtue.

The Choctaws, Chickasaws, and Creeks, have not been so much noticed as the Cherokees; but they, too, are in a satisfactory progress towards civilization. They have good orchards and corn fields, and some of them are the owners of inns or hotels on the roads through their country, which are found, we believe, to be very comfortable places of entertainment to travellers. There are a few books in the Choctaw language; and the Creeks produce very neat articles of pottery, jars, vases, &c., and pipe-heads of black marble. Their ploughs, spinning-wheels, &c., are a farther proof of their thriving condition, and the growth of economical habits.

The Indians in the northern part of the states, and along the lakes, retain much more of the idle unsettled habits of their ancestors than the southern tribes; and those of them who remain near the white settlers are little superior in appearance or character to the gipsies of Europe. Reserves of land have been set apart for them out of their former hunting grounds, and in many cases these have been entirely surrounded by the farms and settlements of the whites, the Indians still remaining in their original patch of forest. In this state, they appear to be like animals of prey under confinement; their natural occupation is taken from them, and they seem to have no powers for any other. Their numbers are found to be smaller upon every enumeration; and their idle, uncomfortable way of living, with the disrespect which is every where shown them by the whites, tend greatly to prevent any spirit of union among them, or any steps to prosperity. Some few of them have settled into agricultural communities, and have built houses, churches, &c.; others have submitted for a time to the instruction of missionaries. But as this adds nothing to their respectability among their own people, who prefer a good hunter to a good mechanic, they have seldom the steadiness to persevere.

GENERAL REMARKS ON AMERICAN MANNERS.

There are perhaps some national traits which may be stated of the Americans generally, and which pervade all the districts: one of these is, that among white people, there is not that deference paid to rank or wealth which is reckoned their natural right, or at least are claimed for them as such in Europe. The demand for work-people is always so great that masters are glad to get them at whatever price; and on this account the men themselves feel much greater independence of their employers; while the employer, on the other hand, is much at a loss if at any time he offend the workmen. This circumstance modifies the whole intercourse between man and man, among the white inhabitants of America. Labourers very generally sit at meat with their masters; and in families the whole establishment, masters and domestics, eat at the same table. The American working people seldom, however, bring up any of their children as house servants, which among them is reckoned a degrading employment; and if any of them submit to act in that capacity, they will still not allow themselves to be called servants, but are denominated *helps*. The name "*master*" is also disliked; and an employer is generally called *boss* in preference. In consequence of this unpleasant kind of feeling, which imposes a sense of degradation on one party, and of constraint on the other, white people are as seldom as possible sought for as house servants; these are generally blacks or mulattos, who are not allowed any where in the states to eat with white men, and who therefore never think of it, nor feel hurt about it, when in service. The difficulty of getting servants, and the high rate of wages, leads every one, as far as possible, to do his own work. A gentleman of considerable property goes to market, and brings home a turkey for dinner; if he even mend his own shoes, it is not thought anywise strange. Judge Marshall (Chief Justice) used to carry home his dinner in his hand, and no one appeared to think it unbecoming.

In their domestic manners, there are some peculiarities which may be mentioned. They live a great deal in large boarding-houses, or hotels, instead of having homes of their own; and travellers passing through the country, in stopping at any town, have frequently the opportunity of dining at the inn with a great part of the respectable persons of the place. Work-people adopt very generally the same mode of living; and there are houses in the different towns where as many as forty or fifty board and lodge together, paying at a certain rate per week or month. Even young married people frequently live in this way for some years, not troubling themselves with a separate establishment till it be absolutely necessary for their family. Marriages are generally a great deal more early with them than in this country; a circumstance which contributes to this practice of boarding, as young people, though they have always abundant employment and subsistence, cannot till after some time accumulate sufficient for furnishing a comfortable home. We have Mr Cobbett's authority for stating that long courtships receive no countenance from young ladies in America; females of every rank very quickly dismiss a lover who requires time to make up his mind. It may be noticed here that women every where receive the greatest attention, both in their families and when they have occasion to go abroad. Captain Hall, who seems at one time to doubt concerning this circumstance, says in another, "it is a rule which we saw universally attended to in America, never to think how men shall fare, till every female has been fully accommodated." As a proof that the same feeling exists among the working classes, we may mention, that, in farming establishments, the females are never asked to do any work out of doors.

There are certain laws in the United States which have a peculiar influence on the manners of the country. It is not, for instance, allowed for a rich proprietor to leave the whole of his wealth to any one of his children; the laws direct that it shall be divided equally, or nearly so, among the whole. Hence large properties are broken down, and the aristocracy of landholders, the most important class in all other countries, have no existence in the states. As it is this class which in Europe gives the tone to a great many of the observances and even feelings of society, the want of it in America has a powerful influence in forming a set of manners different from ours: the farmers there are almost universally the proprietors of the land which they occupy, and it is seldom very extensive. They have no rents to pay, and they cultivate only the best soils; hence they have always large returns on their outlay; and though few of them acquire great fortunes, the majority are in easy circumstances. Some of the southern planters, who are the richest *class* in the United States, have incomes as high as L.18,000 or L.20,000 per annum; many have from L.3000 to L.5000, but the incomes of the majority do not probably exceed L.700 to L.1500 per annum. The next class to the planters, in point of wealth, are the great merchants in the commercial cities, some of whom possess fortunes of L.250,000; these, however, are not numerous. As none of these sums are, however, equal to the large fortunes which are inherited in Europe by the accumulations of several generations in one person, it is evident that there cannot exist in America those clubs of enormously wealthy individuals, who have such a powerful influence in all the affairs of the older countries. Extensive concerns and great establishments, which in other countries are supported by single individuals, are here carried on by joint-stock companies: not only is this the case with banks and canals, but with mills, steam-boats, woollen, cotton, and iron manufactories. The shares in the stocks of these companies are generally small, and they afford a ready means for mechanics, labourers, and persons of all classes, investing their savings with advantage.

From the comfortable circumstances in which people of the middling classes generally find themselves, there are not the same restraints upon their moving from place to place, to improve their circumstances, as there are in Europe. Young persons have never the apprehension, for instance, of leaving their parents destitute, or dependent upon others, which often keep them at home with us. Married people, again, with a growing family, have generally a sufficient stock to enable them to move away with all their children, and take a long journey in whatever direction they may see a prospect of thriving. In England, where they have hardly a sufficiency from one day to another, this would be impossible; and hence the small number of working people in this country who are able to transport themselves to take advantage of the higher wages and better living of America. The journey by canal, river, and lake, to some of the back settlements there from the coast, is more expensive than that of an English family would be to Halifax, and the improvement of circumstances hardly so great; yet how few in this country, to whom this improvement would be the greatest, are able to take advantage of it! This power of shifting their place, and seeking to better themselves, has had a more peculiar effect upon the character of the Americans than any other circumstance. They have less of that superstitious attachment to one spot than is found in poorer countries, where the people cannot leave it: families think little of a journey of some hundreds, or even thousands of miles; and the numbers who are continually moving with their luggage, has made the opening of new canals and rail-roads to distant parts more profitable than it could have been in any other country.

RELIGION.

All forms of religion are equally favoured by the state in America, and the members of all have equal privileges. None of the clergy are paid by government, or out of public property, in any shape; they depend for their salaries entirely upon the congregations for which they officiate, and by which they are elected. The bishops, ministers, elders, or other officers, are chosen by the members of each persuasion, according to their several forms of church government, without the intervention of any other party. There are a great number of different denominations of Christians in America; the principal are the same as in this country, consisting of Catholics, Protestant Episcopalians, Presbyterians, Quakers, and the various classes of Independents. In some of the states there are certain denominations more prevalent than others. New England, for instance, was settled by the Puritans in Cromwell's time, and its religious condition bears the impress of that origin. Maryland was colonized by Roman Catholics, who are still numerous there; Pennsylvania by the Quakers or Friends; while Episcopacy prevailed in Virginia, the Carolinas, and Georgia. The first Presbyterians came from England, Scotland, and Ireland, and settled in Delaware and New Jersey. If the whole population of the states were divided into twelve parts, three of them would be Calvinists, chiefly of the Independent and Presbyterian sects; two Baptists; two Methodists; one Episcopalians and Lutherans. The rest include persons of many various forms of belief, and a considerable number who follow no religious profession.

There are about sixty colleges and seminaries for the education of young men devoted to the church, of all the different sects. In New York, it is found that there is one clergyman to every 1384 of the population; in Pennsylvania there is one to every 1123; in Kentucky, one to every 1377 of the white inhabitants. In Great Britain, the proportion is one to every 800 or 900—in Europe generally, one to every 1000. It must be recollected, however, that in America this whole number are actually employed in the ministry; there are none of them who are merely dignitaries, or who hold offices without labouring for the instruction of the people: this renders the proportion of actual religious teachers greater than at first sight it appears, when compared with the number of clergymen in European countries.

These remarks apply chiefly to the old settled states of the east and north; and on this subject we beg to give the following extract from the work of a recent traveller of our own country, Mr Fergusson of Woodhill:—

"The religion of the states is marked by some peculiar features. It has been too frequently disgraced by wild and extravagant fanatics, and Unitarianism has in many places made dreadful strides. Still, the conclusion to which I have come is favourable to the growth of pure and vital Christianity in the populous and civilized portion of the states. I observed, in public and in private, a decent observance of the Sabbath. The official papers of the government uniformly recognise the superintendant care of a beneficent God. No shops were to be seen open on the day of sacred rest, still less were the theatres or places of public amusement; public travelling was not in general use, and the transmission of the mail on that day had been debated in the preceding session of Congress, when the question was lost, chiefly on the ground that the constitution forbade any interference by government with matters of conscience. There can be no doubt, however, that Sabbath profanation is practised in some quarters to a great extent. As regards the fruits of religion, there can be little question, that, taking them as a people, the citizens of America are virtuous and exemplary. Conjugal infidelity is extremely rare, and, in more than one of the states, is visited by fine and imprisonment. In the large cities, at least of the middle and northern states, vice does not stalk abroad in that disgusting form which may be said to deprive respectable females in European towns of the free enjoyment of our public spectacles and walks."

We give one more extract on this subject: it is from Mr Stuart of Dunearn:—

"We went to attend divine service at Mr Stebbings' church. He had gone from home, and was unavoidably detained; and the person who had promised to officiate for him failed to appear, in consequence of the morning being stormy. The congregation assembled—a pause ensued: at length Dr Smith, one of the elders, rose, and said, that they ought not to separate without discharging those religious duties which had led them to assemble on the first day of the week. He then gave out a psalm from his own seat, and afterwards prayed. In the meantime, he had sent home one of his daughters for a volume of sermons, one of which he read. A second psalm was given out by him and sung, after which the service was concluded by a prayer from Mr Lister, a farmer in the neighbourhood, and one of the elders—the whole without any appearance of bustle or exertion." There are a great number of religious newspapers in America, which is a further proof of the serious habits of a large part of the population.

The remarks we have have made apply exclusively to the New England states, and to the older settled districts of the east; they may also perhaps be extended to the *towns* of the newly-formed western states, in which much attention is given to religion. In the slave countries, however, this condition is altogether reversed. North Carolina, with a population of 600,000, has hardly fifty clergymen; and South Carolina, with 420,000 inhabitants, has not more than forty. In Georgia there were only ten in 1818. In Virginia, the population is about one million; the number of clergymen not one hundred. The situation of Maryland is similar.

In the countries on the Ohio, Michigan, &c., which are in progress of settlement, there are no regular churches except in towns; the only opportunity the colonists have of attending sacred ordinances being at field-meetings, or *tent-preachings*, as they would be called in Scotland, which are held in the forests, and are sometimes continued for several days. The first settlers in these districts are generally rude men, and little heedful of religious matters; but these meetings serve to keep alive among them a feeling of what is due to their character in this respect, and, as the population becomes more dense, gradually lead to the establishment of regular pastors and churches.

MEANS OF EDUCATION.

The state of the people in respect to education is very different in different parts of the states. In the old settled districts, the proportion of well-informed and well-educated people is greater than in most countries of Europe. In the slave states of the south, and in the western districts, which are as yet only occupied by a thinly-scattered population, the number who can read and write is very small in proportion to the population. Some idea of these different conditions in respect to education may be formed from the following account of the number of students at college in the different districts in proportion to the whole inhabitants of each:—

In the eastern or free states,	1	student to	1231	inhabitants.
— middle slave states,	1	—	3165	—
— southern slave states,	1	—	7232	—
— western or new states,	1	—	6090	—

In the New England states, it appears, by the number of young men who are thus receiving a liberal education, that there is care taken to provide instructors for the rising generation, as well as to secure respectable attainments in those who are to exercise the professions of clergymen, lawyers, medical men, engineers, &c. In the slave states there is a lamentable deficiency of all this. In the newly-settled districts it cannot of course be expected that people so thinly scattered over the wilds should have regular means of education.

In the New England states the means of instruction provided for the children of the labouring classes are in general such as to put the knowledge of reading, writing, and arithmetic, within the reach of all. Every state has a public fund set apart for paying the salaries of teachers; and if this is not sufficient to provide one for each township, the inhabitants are expected to assess themselves to make up the deficiency. They generally elect school-committees, who build school-houses, choose teachers, and apportion funds, according to the necessities of each parish. Children are entitled to attend at these seminaries without any charge but that of paying for the books which they use. In order farther to secure the education of young people who may be obliged to go early to *service*, it is common in these states to stipulate *schooling as part of their wages*. This was in former times a regular condition in respect to young farm-servants in Scotland, only that here they were generally taught by the master or mistress themselves, whereas in America they are sent to school for that purpose. The result of all this is, that the number of people of the working classes who can read and write is here fully greater than in any country of Europe, not even excepting Scotland or Switzerland. The means of education are seldom awanting, while the wages of the labouring classes enable them to provide books, and to maintain their children at school for a longer period than can be easily done in Europe, where their services are soon required to assist in maintaining the family. It is remarked, that, "though the number of learned and scientific characters is much smaller than in France or England, the mass of the population are better informed than in either of these countries. Reading the journals universally (which are afforded at a fifth part of the price of newspapers in this country), and knowing a little of what is doing at home and the world generally, they betray none of that awkwardness which springs from conscious ignorance."

It must not be supposed, however, that this general account of the state of education applies equally to every district. It relates, indeed, chiefly to the great towns, and to the thickly-peopled places in their neighbourhood. The remote townships, which in a country so lately occupied form a large proportion of the whole area, are frequently as much deficient in the means of instruction as in regard to religious edification; and they have indeed little anxiety to improve themselves. Many of them pay no attention to the regulations for establishing schools, and, were it left to themselves, would allow their people to remain as they are, without either reading or writing. In America, however, as in most other free countries, the well-informed portion of the community is the most active, and, like the little leaven which leavens the whole lump, it is continually at work to stir up a desire for information and light in all the dark places round it. The operations of benevolent societies have the same effect in the remote districts of America which with us they have produced in the Highlands of Scotland and elsewhere; and they are ultimately more successful, because, whenever a desire for information has been excited, the comfortable circumstances of the people enable them to go on educating themselves. In all the newly-settled states, lands have been allotted for the erection of academies, and the establishment of regular district or parochial schools, according as the population increases: six hundred and forty acres are generally set apart in each township for this purpose, besides one or two entire townships in each state for university funds.

LEARNING AND THE ARTS.

America has produced several names of the highest celebrity, both in learning and the arts. Classical studies, which used to be looked on as the great test of learning, are not very extensively cultivated; but in general philology, or acquaintance with the principles of language, this country possesses several very eminent scholars—among whom we may mention Mr Duponçeau, a native of France, but naturalised in America, and celebrated for his researches into the history and affinities of the different Indian tongues. Mr Wheaton, also, who is well known for his acquaintance with the languages and history of the north of Europe, deserves to be mentioned; and a dictionary of the *English language* has been published by an American scholar, Dr Webster, which was reprinted in England, and is highly esteemed. Many American writers of the present day have attained very high fame, and their works stand side by side with the best English authors. To mention those only which are well known in Europe, there is Dr Channing and Jonathan Edwards in divinity; Irving, celebrated both as a historian and a novelist; Bryant, a poet of high power and elegance; Cooper, whose fictitious narratives have attained a fame hardly inferior to those of Scott, and which exhibit a set of manners completely original to Europeans. It is questionable, indeed, whether there is not as great a proportion of living American writers who have attained celebrity in England, as there are of English authors of the present day whose works are read on the other side of the Atlantic. The American reviews, which often give publicity to the opinions of men of talent in that country, as ours do to those of philosophers and statesmen here, produce frequently as deep an impression as any European publications of a similar kind; and the selections which appear now and then in this country from the American periodical literature, give evidence of as high talent in the writers, and of as cultivated taste in the readers for whom it is prepared, as any thing of the same description among ourselves.

In science, the reputation of Europe is so compacted of what her philosophers of former times have done, and of what is now doing by those who continue their researches, that it would be absurd to institute a comparison in this respect. It may be remarked, however, in regard to America, that she possesses men who keep pace with all the discoveries and improvements of the sciences, and who are able to canvass and examine every thing which any new train of investigation may bring to light in other countries: if we add, farther, that one of the most splendid of these original trains of investigation was derived and traced to its result, the identity of the electric fluid with lightning, by the American philosopher Franklin, we shall have said as much for the scientific fame of America, as can be arrogated to itself by any European country. Of the American journals of science, that of Dr Silliman is well known in Europe, where it enjoys a high and well-merited celebrity. The recent growth of every thing in America has not given time as yet for the formation of those extensive museums and libraries which so much facilitate the researches of learned men in the old countries of Europe; and as the legislature has not power to vote money for these objects, it may be a considerable time before any thing is witnessed there like the splendid national collections of Paris, London, and Rome. There are, however, several museums; as, for instance, those at Salem, Boston, and Philadelphia, whose fame will gradually accelerate their own increase, and may at last attract national attention to the subject. There is no public astronomical observatory in the states, and the expense would be too great for any private means.

In mechanical science, which is the absorbing pursuit of the present day, the Americans have been no whit behind other nations in devising means for facilitating and abridging such processes of labour as are carried on in their own country. Steam navigation, though certainly first discovered in Scotland by Mr Taylor, was as certainly first brought to a useful and practical result in America by Mr Fulton. The machine which was contrived by an American for separating cotton from the seed—that for distilling salt water, or procuring sweet water at sea, by separating it from the salt—some contrivances for abridging the manufacture of iron-work—and many others adapted to the peculiar circumstances of their country, show the Americans to be equally ingenious, and equally acquainted with the resources of mechanical invention, as the English or any other nation.

The science of the Americans has also been displayed in a very remarkable and useful manner, in the construction of several large canals and railways, some of which are hardly to be equalled in any other country. The same skill is seen in improving the navigation of their rivers, in constructing bridges, in architecture, and in ship-building.

FUTURE PROSPECTS OF THE UNITED STATES.

From the rapidity with which the population of the states has hitherto increased, and is diffusing itself over the wide and fertile continent of which it is in possession, the most magnificent anticipations are formed by the Americans of the future greatness of their nation. "Let us assume," say they, "what appears highly probable, that the people of the United States will ultimately spread themselves over the whole North American continent west of the Mississippi, between the parallels 30° and 49°, as far as the Pacific Ocean. This will be found to add 1,800,000 square miles to the territory east of the Mississippi, and, putting both together, the area of the United States, thus enlarged, will be 2,700,000 squares miles. A surface of such extent, if peopled to the density of Massachusetts, would contain two hundred millions; or if peopled to the density of Great Britain and Ireland, four hundred and thirty millions. If the population of the United States continue to multiply in the same proportion as hitherto, it is demonstrable that the two hundred millions, necessary to people this vast territory, will be produced within a century." These are indeed magnificent anticipations, and we know no reason why they should not be realised. But we must remark, that, whatever they may add to the national greatness of the American name, they are by no means likely to be favourable in the same degree to the individual comfort of the members of its population. It cannot be doubted but that the high rates of wages and profits, and the rapidity with which capital now accumulates in that country, are partly owing to the large tracts of fertile and easily accessible land, which are always at the disposal of its inhabitants. Were the government weak, ignorant, or partial, these unoccupied territories might exist, as they do in many other countries of the world, without being of advantage to any one. In America, the qualities of the government render them easily available, as long as they last; but nothing can renew the same advantage after it has once been expended. As those splendid prospects, in which the Americans are fond of indulging, approach to realization, the quantities of new land will be daily growing less—the rapidity with which capital now accumulates will be diminishing in the same proportion—the wages of industry will gradually fall off—and as the nation becomes greater and more powerful, in the same degree will the resources of its individual population be lessened. But the truth is, these fancies concerning the rapid increase of population, and the filling of the whole American continent with a nation of unparalleled power, "greater than the sands of the sea in multitude," are mere playthings of the imagination. Too little is known of the real numerical progress of population to enable us to say any thing on the subject; and certainly it is not the circumstance that their immense and fertile country *will one day be fully occupied*, which ought to be a subject of satisfaction or pride to the Americans, however powerful the nation might then be, but rather that their gigantic population has rich fields and abundant pasture in which to carry on its increase for many ages. During this time, it may set an example of equal government and peaceful industry to the rest of the world, which, unhappily, has been hitherto wanting; and by the reaction of just principles on the influential part of the old continent, the new nations of the west may be the means of redeeming it from many oppressions. When these are removed, it will be seen, that, in our world too, there is not wanting abundance of unoccupied and rich land: whole kingdoms and provinces of Europe, Asia, and Africa, are at present shut up from industry by one kind of barbarism or other, and the example of America may yet enable mankind to enjoy the advantages of their fertility.

EDINBURGH: Published by WILLIAM and ROBERT CHAMBERS, 19, Waterloo Place; also by W. ORR, Paternoster Row, London; and W. CURRY, Jun. and Co. Sackville Street, Dublin. Sold by John Macleod, Glasgow, and all other Booksellers in Scotland, England, and Ireland.—Published once a fortnight.
Stereotyped by A. Kirkwood, and printed by Ballantyne and Company, Paul's Work.

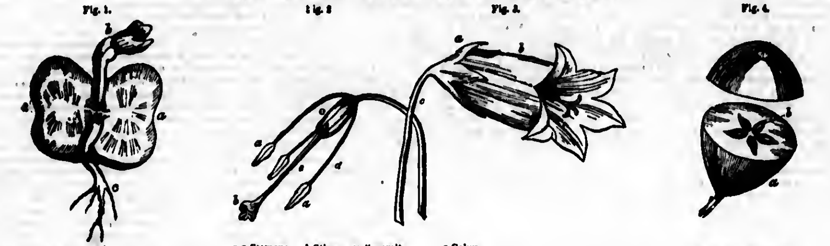
VIEW OF BOTANY, OR THE VEGETABLE KINGDOM.

THE PHYSIOLOGICAL STRUCTURE OF PLANTS EXHIBITED.

Fig. 1. Fig. 2. Fig. 3. Fig. 4.



a Cotyledons, or Seed-Lobes. *b* Leaf-Germ. *c* Root spreading into Fibrils.

a a Stamens. *b* Stigma, or Summit. *c* Ovary, or Seed-Bag. *d* Filament. *e* The Style.

a Calyx. *b* Corolla. *c* Peduncle.

a Pericarp and Pulp. *b* Seed-Vessels.

The material universe with which man is acquainted consists of two grand orders of existences—those which are organised, and those which are inorganised; or those which possess life, and those which are destitute of any living principle. Of the nature of the living principle, no idea can be formed, but we mean by it that power or quality resident in certain structures, by which they are enabled to elaborate or incorporate with themselves those nutritive particles of matter which they require, so as to enlarge without destroying the peculiar shape or form which they possess; and this they do through a series of continued changes or actions of the structure, from a state in which the body is first brought into existence, until it has reached maturity, and afterwards gradually passed into a state of decay. Organised bodies are divided again into two distinct classes—animals and vegetables; and although human ingenuity has been nearly exhausted in attempting to decide to which of these two classes certain productions belong, such as the sponge and the fresh-water polypus, yet the more perfect specimens of each class have strongly marked differences. In a general sense, when the term *plant* is used, every one knows that it signifies an organised body, which is fixed in the earth at a certain place; and when we say an *animal*, we imply an organised body, which possesses the power of locomotion, and is under the government of a sentient principle, by which it performs these operations at pleasure. Plants differ from animals in being destitute of a common gullet, a stomach for receiving food, and intestines; and there are other differences as striking, such as their having neither heart nor lungs, although they exhale and imbibe aëriform fluids. The economy of plants is limited to nutrition and reproduction; and being stationary in one place, the mechanical structure required for performing these functions is less elaborate and various than that necessary to the active, sentient, and locomotive animal. Nutrition comprises an extended series of operations both in the vegetable and animal economy. In the former, there is first included the absorption of particles of matter, their transmission to organs where they are subjected to the action of the air; their circulation through the plant, and farther elaboration in different receptacles, so as to be converted into peculiar products which enter into union with the plant, and enlarge its size or supply the place of wasted materials. For reproduction there is also required a peculiar set of organs, of which we shall speak in detail afterwards. Plants are divided into herbs and trees; and although they present almost every variety of difference in regard to form and texture, they all nevertheless possess in common certain parts or members, which are named the root, the trunk, and the branches, from which proceed the leaves, the buds, the flowers, the fruits, and the seeds. Every one is familiar with the infinitely diversified appearances which these assume in different classes of vegetables, and yet they are found to originate from a few constituent or elementary organs, whose situations, proportions, and combinations, give rise to the infinite varieties which we behold in this kingdom of nature.

According to the best physiologists, there are only two parts essentially distinct, namely, the pithy part and the ligneous part. Malpighi, a celebrated writer upon the subject, calls the two constituent parts the ligneous and utricular portions, and to these have been assigned the general appellations of the vascular tissue or system, and cellular tissue of plants. Tissue, which signifies a web, is the name given to the soft and flexible parts of animals and plants; cellular tissue is divided into cells, the vascular system or tissue into vessels. Vegetable like animal structures are composed of solid and fluid parts. Few of the latter are considered simple in their composition, as they contain more or less of a gelatinous matter, which frequently imparts to them a consistency approaching to that of a solid body. The gum which we often see exuding from trees is an instance of the viscidity of vegetable fluids. Many of them, also, contain minute globules of matter, which thicken them to a considerable degree. It has next been discovered that these often cohere and form solid masses, or unite in lines so as to constitute fibres. These, again, collect together, and compose various kinds of texture. The solid parts of a vegetable are membrane and fibre, which form the tissues referred to, and their varied combinations in the bark, wood, pith, and medullary or marrow rays. The fluid elements are watery solutions of the soluble materials of the soil, which, by chemical and mechanical agency, as well as the influence of the principle of life, are decomposed, and again united in different proportions so as to form new substances, or, in other words, the solid components, the textures, and secretions of the vegetable.

Membrane is an extremely fine, transparent, colourless film, capable of resisting the action of water and watery solutions in the plant whilst alive; but when life ceases, it is easily acted upon. It resembles a simple pellicle, or the film of a soap-bubble, varying in transparency in different plants, and in different parts of the same plant. The woody fibres consist of collections of fusiform or tapering vessels placed close and parallel to one another, with the narrow extremities of one set wedged in between those of another set. These fibres are generally collected together into bundles, and are accompanied by cells and vessels of various descriptions, and in different stages of transition. They gradually acquire a degree of rigidity, which enables them to support the plant, of which they constitute the framework or skeleton. Such is a general outline of the structure of vegetables—a more minute account will be necessary.

OF THE CELLULAR TISSUE.

The most elementary parts of the vegetable structure appear to consist of minute bags, bladders, or vesicles, the coats of which are transparent membranes of extreme tenuity. If a very thin slice of the stem of any plant be put into a drop of pure water, and examined by the microscope, it will be found to consist chiefly of these cells. Their size differs very considerably, from even the thousandth part of an inch to the thirtieth. Although in their original state they possess an oval or globular form, yet, by being variously compressed, they are made to assume other forms, such as twelve-sided figures, or six-sided, like a honeycomb, and pass by insensible gradations into the tubular structure. These various modifications of the same elementary texture have received separate technical names, which, however, it is unnecessary to specify. By the concurring observations of modern botanists, these cells consist of separate vesicles closed on all sides, and destitute of inlet or pore. It seems to have been satisfactorily established that the partitions which separate them, however thin, must consist of a double membrane, formed by the adhesion of the coats of the two contiguous vessels, and that the fluids gain access not by means of regular apertures, for none can be detected, but by exuding through the substance of the membrane. As from the shape of the cells the coats cannot be supposed to unite at every point, the spaces thus formed have been called *intercellular passages*, *canals*, &c., and they are supposed to perform an important part in the function of nutrition. The nature of the matter contained in the cells and the intercellular spaces, differs according to the part in which it exists, and the peculiar powers of the plant. Sometimes they are filled with certain liquids, the products of vegetable secretion; at other times the contents are simple watery sap, and occasionally they are only filled with air. Air-tubes and cells are most frequently met with in the centre of stems and in leaves, rarely in roots, and never in the woody part of plants. Although some plants consist entirely of cells, yet, as already observed, the greater number of them have, in addition to these, numerous ducts or vessels, consisting of membranous tubes of considerable length, interspersed throughout every part of the system. With regard to the origin of these, Dr Roget observes: "There can be little doubt, indeed, that the vessels of plants take their origin from vesicles, which become elongated by the progress of developement in one particular direction; and it is easy to conceive, that, where the extremities of these elongated cells meet, the partitions which separate their cavities may become obliterated at the points of junction, so as to unite them into one continuous tube with an uninterrupted interior passage. This view of the formation of the vessels of plants is confirmed by the gradation that may be traced among these various kinds of structures. Elongated cells are often met with applied to each other endwise, as if preparatory to their coalescence into tubes. Sometimes the tapering ends of fusiform cells are joined laterally, so that the partitions which divide their cavities are oblique. At other times their ends are broader, and admit of their more direct application to each other in the same line, being separated only by membranes passing transversely; in which case they present, under the microscope, the appearance of a necklace of beads. When by the destruction of these partitions their cavities become continuous, the tubes they form exhibit a series of contractions at certain intervals, marking their origin from separate cells. In this state they have received the names of *moniliform*, *jointed*, or *beaded vessels*. Traces of the membranous partitions sometimes remain where their obliteration has been only partial, leaving transverse fibres. The conical terminations occasionally observable in the vessels of plants also indicate their cellular origin."

OF THE VASCULAR SYSTEM.

By this term may be understood in a general sense all those parts of plants which do not exhibit the form either of membranes or of cells. It constitutes almost the entire bulk of the more solid parts of trees. If a branch be cut transversely early in spring, the sap will be found to exude, and cover the whole of the cut surface, which if examined will be found to consist of a vast number of exceedingly small fibres, vessels or pipes through which the liquid portions of the vegetable ascend or descend. These are as it were the veins and arteries of the plant. Indeed, whilst the tissue of cells above described may be said to constitute the flesh of plants, the tissue of fibres may be said to stand for the bones and other firm parts of the system. In animals, the fluids are conveyed to and from a central reservoir called the heart; but such an organ does not exist in the vegetable kingdom. The fluids enter by innumerable mouths at the root, and are conveyed by the vascular system to all parts of the plant fitted to receive them. There is little variation in the diameter of the vessels, and their general form is cylindrical. Their minuteness is quite astonishing. In a piece of oak of about the size of 1-19th of an inch, 20,000 vessels have been reckoned to exist. Hedwig measured the largest vessel in the stem of a gourd; it appeared 1-12th of an inch in diameter through his instrument, which magnified 290 times; so that its real diameter was the 3480th part of an inch. The vessels of plants do not, like those of animals, exist single, but are collected in bundles, or fasciculi as they are called, which sometimes contain hundreds of vessels. They occasionally also ramify; that is, some vessels shoot off from one parcel to unite with another, and afterwards return to that which they had left. By this ramification a reticulated appearance is frequently produced, especially in the bark and leaves of plants. They do not ramify like the vessels of animals from greater into less; but, by the division of a greater fasciculus into several smaller fasciculi, they at last become single, and thus their ramification is effected. It is generally supposed that they do not open into one another; that is, actually unite and be lost in each other, forming that kind of connection which anatomists call inosculation or anastomosing (from a Greek word which signifies to open the mouth).

These vessels have been named according to the functions which they perform, or the appearances which they assume. There appear to have been two kinds of vessels discovered in plants, the straight and the spiral. Grew describes the former as straight hollow threadlets, fifty times finer than a horse hair, forming a larger tube, as if we should suppose a walking-cane composed of small straws. Leuwenhoeck describes them as composed, like the quills of birds, of two transparent tissues, one placed lengthways and the other across, with no lateral communication. It is the opinion of the highest authorities that both fibres and straight vessels take their origin from spiral vessels. The first is called the simple spiral. If the fleshy scale of any bulb, for instance that of the water-lily, be cautiously broken, and the parts separated, the spiral vessels will be observed like screws, partially unrolled. They consist of opaque silvery shining fibres, twisted in a spiral manner, so as to form a hollow cylinder, the spires being generally in contact. This hollow tube is sometimes formed of one continuous fibre, sometimes of several parallel fibres adhering together. The fibres are tenacious, and in some plants elastic. They differ much in size in different plants, and at different stages of the growth of the same plant. They stretch through the whole of its length, from the roots to the leaves and flowers, following the various curvatures of the stem. Grew found that they alternate with the straight vessels in every part of the wood, and surround and ensheath them in the leaf-stalk, the leaf, the flower, and the fruit. The straight vessels are said to be formed in spring, the spiral vessels in summer. These spiral vessels undergo various transformations. In many cases the inner fibres of the tube, instead of forming a continuous spiral, appear in the shape of rings succeeding one another at regular intervals, and constituting what are called annular vessels (from *annus*, a ring). This is considered a primary form of vessel, and from the two simple varieties of vessels described, more complex forms are elaborated as the plant advances in age. In the punctuated vessel the spires are separated to nearly equal distances from each other, and the intervening spaces are filled up with a membrane sprinkled over with small obscure points or dots.

This is the largest in respect of diameter of the vegetable vessels; it is at first transparent, but becomes opaque by age. A fourth variety of vessel, which has the same origin as the last, being formed of rings, is that in which the separations are not filled with membrane, but with small productions proceeding from these rings themselves. These ramifications often have the appearance of network, whence they derive the name of *reticulated* spiral vessels. Neither they nor the former variety exist in the young plant, but are gradually developed as it approaches maturity, and by the same series of actions; that is, the spires or rings which were at first contiguous separate at a later period, and the intervals are filled up by ramifications from the spires themselves. The reticulated spiral vessels are found but in few plants, and they appear to differ from the punctuated variety principally in the position of the rings, which are more or less obliquely placed, and at different points send off one or more branches. A fifth variety, called *beaded vessels*, has been already mentioned. They derive their name from resembling a chain of oblong ovate cells or beads, and are classed by various writers, sometimes amongst vascular vessels, sometimes as belonging to the cellular tissue. Very contradictory opinions prevail with regard to the functions of the vegetable vessels. By some writers it is asserted that two distinct species exist, one of which is intended to convey sap and the other to convey air, and hence called *tracheæ* (windpipes); but it has been found that the latter occasionally convey sap. From the various modifications of structure which these vessels undergo at different stages of a plant's growth, it seems natural to suppose that they may perform different functions at different times. But a minute investigation of this subject cannot be ventured upon in this place. It seems to be the fact, that the spiral vessels, in all their variety, serve the office of conveying the sap throughout the whole of the plant. Besides the vessels already enumerated, vegetables contain certain organs denominated *glands*, which are composed of closely compacted cells, and which perform the function of *secretion*; that is, the conversion of the nutritious juices into particular products required for various purposes in the economy of the plant, as will be afterwards shown.

The vessels above described are those which belong to the woody parts of vegetables; but there are others peculiar to the bark, which have received various names, such as *returning vessels* (the former being occasionally termed *conducting vessels*), *proper vessels*, *cortical vessels*, &c. It must be confessed that none of these appellations are either very precise or characteristic of the functions which these vessels perform; but the following description will elucidate what is meant:—For about a month during the early part of spring, the sap rises through the wood alone, and is not distinguishable in the bark at all. In course of time, however, as the leaves become developed, the sap is rendered no longer visible in the wood, although it undoubtedly continues to ascend through that channel, and the bark becomes moist, or saturated with fluid. Now, as it has been determined beyond a doubt that no sap can reach the bark by the roots, nor enters it directly from the root, there is no other way of accounting for these phenomena but by supposing that the leaves are the organs by which the sap is carried off from the wood and conveyed into the bark. This inference has been confirmed by the fact, that the bark continues dry until the leaves shoot forth, and that, after having been moistened, it again becomes dry if the leaves be stripped from the tree. The fluids, which undergo a peculiar change in the leaves, are carried downwards by means of vessels situated near to the inner margin of the bark. They differ but little in structure from the more simple vessels of the wood. They run in straight parallel fasciculi (or bundles), a new layer of which is yearly added to the inner surface of the bark, as well as a new layer of ligneous vessels to the outer surface of the wood. Grew, a great authority in these matters, observes, that the new matter of the tree is every year distributed two contrary ways, one part falling outwards towards the bark, and the other part retaining its situation inward, to constitute the wood. By this peculiar mode of growth, vessels in the bark exhibit reticulation or a net-like appearance, the meshes being filled with cellular matter. Each vessel is an entire tube of a small size, and arranged according to the nature of the plant and its habits of vegetation.

In the foregoing observations we have attempted to give a view of the elementary organs of plants. These, again, enter into combination, and form what are sometimes called compound organic constituents, or common textures, but which, for the sake of clearness, we propose to distinguish by the name of

SECONDARY ORDER OF ORGANS.

These are the pith, the wood, the bark, and the epidermis or skin. The pith is that soft, light, and spongey sort of substance which occupies the centre of the stem (hence sometimes called the heart), where it is commonly surrounded by a circle of vessels, which construct for it an appropriate canal. When seen in its most perfect form, it is found to consist entirely of cellular tissue, rather loose in texture as in the alder, or compact as at the knot of the ash. The wood (lignum) is that hard cylinder which immediately surrounds and envelopes the pith, and is enclosed by the bark. It is essentially composed of vessels, and of cellular tissue combined in an infinite variety of ways, and exhibiting every diversity of form. If a tree of several years' standing be cut transversely and examined, it will be found to consist of a number of cylinders, enclosing one another like so many layers or concentric circles disposed around an axis. By the number of these the age of the tree may be determined. The outermost, which is spongey and less durable than the inner or heart-wood, is called alburnum. The whole are traversed by rays or lines diverging from the centre of the stem to its circumference. These are called medullary rays, or silver grain, and they are composed chiefly of large cells, extending transversely, or in the direction of the diameter of the tree, and composing by their union continuous vertical planes the whole length of the trunk. They are called medullary (from *medulla*, marrow), because they were supposed to be processes of the pith, or a continuation of it, which is not the case. Their use appears to be to keep open the communication between the bark and the pith, which the formation of the wood would otherwise have destroyed. The bark resembles wood in its component parts, being made up like it of vessels and cellular tissue, intimately connected with each other. As in trees, a new layer of vessels is annually added to the wood, so a similar but much thinner layer is also made to the bark, to which the name of *liber*, or inner bark, is usually applied, the old layer being pushed outwards. Between the vessels thus annually produced, a considerable portion of cellular tissue is interposed, the cells being commonly filled with juices. The whole is surrounded by an outer zone or envelope, to which the names of skin, epidermis, cuticle, or rind, have been given. It is an extremely thin membrane, and extends over the surface of every part of the plant, excepting the spongelets of the roots, and the summit of the pistil in flowers. The rind of plants is similar to the skin of animals in the functions which it performs. It is no doubt intended to protect the more sensible organs beneath. As the scarf-skin of the hand becomes indurated by hard labour, so the rind of the tree, if exposed to a stormy climate, becomes rough, whilst the rind of the same species of plant, if reared in a sheltered situation, like the hands of a delicate lady, remains smooth. As the plants grow, the rind stretches, and sometimes to a considerable extent; but in cases in which it is not easily stretched, as in the elm, it breaks up into innumerable cracks. The birch, and some other trees, "casts its bright skin yearly, like the snake." The rind is transparent and colourless where it is very thin; but it is usually of a brown or grey colour when thick. Various opinions are entertained respecting the origin and structure of this membrane. Some philosophers hold it to be continuous with the bark, and formed of the outer sides of its cells. Others describe it as a separate membrane, composed of minute cells or "bladders," as Grew calls them, which shrink and are dried up as the plant grows older. This opinion is now supported by the highest authorities. There has in some instances been found a very delicate, transparent, and apparently inorganised membrane on the outside of the rind. Whether it possessed pores, or, as they are sometimes termed, glands, was long a disputed point, but their existence has lately been incontestibly proved. They are a sort of minute bags opening on the outside by an oval slit with a raised border, which contracts when water or moisture is applied, and expands in dry air, or when exposed to sunlight.

Such is a view of the general component parts of the vegetable structure; we have now to turn our attention to the compound members or organs which they form. These, as already observed, have been divided into two distinct classes, namely, organs of nutrition, or, as they are sometimes denominated, conservative organs, and organs of reproduction. The principal compound organs of perfect plants belonging to the first class are, the root, the stem or axis, the buds, and the leaves, together with the appendages of these parts. Those of the second class are the floral envelope, the reproductive organs, and the seed.

THE ROOT.

The root (*radix* in Latin) is commonly defined to be that part of a plant which attaches itself to the soil where it grows, "or to the substance on which it feeds, and is the principal organ of nutrition." Exceptions to this definition occur, as in the case of some vegetables which grow floating loosely in water, as duckweed, and others, having no root at all. By far the greater number of plants, however, have roots, which perform the above functions. As the nourishment of a plant is derived from the earth, the root is that part which grows in an opposite direction to the stem, and is buried in the ground. Roots are generally found to spread much farther on the windward than on the sheltered side of a tree, and to be proportional to the branches, spreading to considerable extent in trees planted in an open field, but remaining in narrow compass in thick woods and forests. A root consists of several parts, which have been called the body or *caudex*, the collar or life-knot, the branches or radicles, when such exist, and the rootlets or small fibres, which seem to be indispensable in all roots. The body assumes various forms: the top or pivot root, which is, 1. simple, long, and taper, as in the carrot, beet, and parsnip, or like a flattened globe, as in the turnip; 2. branched, in which one principal stem sends out a number of branches, these again separating into smaller, till they become like fibres. It must be mentioned, however, with reference to carrots, potatoes, and the like, that modern botanists are disposed to consider them rather as subterranean stems than roots, because they perform the functions of stems more than those of roots. There are three sorts of these subterranean stems—the tuber, as in the potato and arrowroot; the corm, as in the crocus and meadow saffron, and cuckoopint, erroneously termed a bulb, as it has no scales; and the creeping-root stem, as in couchgrass.—*Rennie.* The same writer thus enumerates the various forms of the root:—"It may," says he, "be vertical, spindle-shaped, conical, turnip-shaped, round, twin, palmate, as in peony, digitate, abrupt, knotted, tuberculated, bundled, jointed, contorted, fibrous, hairy, or beaded." The crown, collar, or life-knot, as it is variously called, is that part which lies between the stem and the root. It is the most essential portion of the whole; for if it be removed or seriously injured, the plant will inevitably die; whilst the small fibres or rootlets, although an essential part of a plant, may be destroyed at pleasure so long as the crown remains, for it readily reproduces them. When it is of a slender make, as the seeds form it dries up, and the plant soon dies. Such plants are termed annuals, as the poppy, and most kinds of grass and corn. The crown, however, in some cases, by proper treatment, can be rendered so strong that annuals can be brought to grow two years, when they are termed biennials; or for three years, when they are called perennials. The fibrous root consists of a quantity of long thin fibres of different lengths and thicknesses, and having still finer ones springing from them, as in the case of wheat, barley, and most grasses. These small fibres or rootlets bear a resemblance to the branches and leaves of the stem. Fibrils consist of a central fasciculus of vessels, enclosed by a cellular cortex and cuticle. Like the leaves of trees that are not evergreen, they are annually produced; in some cases, dying and falling off like leaves; in others, becoming thicker, harder, and forming radicles or root-branches. The spongelets, as they are called, which take up nourishment from the soil, are situated at the extremity of these rootlets. They are minute spongey bodies of an oblong shape. We have an instance of rootlets falling off like leaves in those arising from bulbs—such as the lily, the onion, the tulip, &c. which are pushed off and perish like leaves, by buds containing the rudiments of the rootlets to be evolved next season. It is after Christmas that these root-buds become perfectly distinct. Professor Rennie observes—"The bulb is very similar to, if not identical with, what is termed a bud when found on a stem or branch, and is formed by the base " . . . e leaves becoming thick, and storing up a quan- . . . , of nourishment within them for future use." These base-leaves take different shapes in different plants: in onions they appear in the form of concentric circles, in the lily as scales placed somewhat like tiles. The stem and the branches of plants turn to the light; and some flowers, if planted in a position where light does not fall directly upon them, but upon a place a' some distance from where they are situated, will grow towards it. The reverse is the case with the root; it grows *from* the light, and in every case shuns it, and tends more or less to the centre of the earth. Besides taking in nourishment for the plant, the roots give off refuse, or what may be called excrement, as is seen in the case of hyacinths, which grow in water. The nature and qualities of the soil exert a powerful influence on the form and size of roots. If it be free and easily penetrated, the root often descends to a great depth in form of a top-root; but if obstacles opposing its descent be encountered, it then continues short, and splits into branches. Roots also extend into the richest portions of the soil, whilst the poorer parts are left nearly destitute of roots.

There are various other species of roots besides those described, but they must be passed over with the simple names which have been assigned to them, as already given. Some plants, instead of deriving nourishment directly from the ground, fix their roots into others, and subsist on the juices which they in this manner derive; hence they are termed *parasitical*—such are mistletoe, broom, rape-birds, and many lichens, fungi, &c.

THE STEM, STALK, OR AXIS.

The stem, with a few exceptions, is always above ground, and may be described generally as that thick perpendicular pillar from which various lesser growths, such as branches, shoot off laterally. There are exceptions to this definition, but it is true of by far the greatest number of plants. There are various classes of stems, the general physiological structure of which has already been given. Professor Rennie thus describes them:—"The stem is divided from the root by the crown or collar already described, which, though evident on all herbs and on young trees, cannot be recognised on trees of several years' growth. The space between the collar and the first leaf or bud is termed the bole, which is also applied to the space between two or more leaves or buds, whose base is called a node, from the Latin word *nodus*, a knot—by gardeners, an eye. The great body of a stem, whether divided into holes or not, is called the trunk. The stem of grasses, corn, and reeds, is termed the straw; the stem of palms, ferns, mushrooms, and sea-weeds, is termed the stalk; the stem of such flowers as the primrose, the daisy, the snowdrop, and the lily, is termed the scape, though flower-stalk is certainly better; the running stem, as in the strawberry and cinquefoil, is termed a runner; a shorter runner that does not root, as in the houseleek, is termed an offset; a longer one that does not root, as in the cucumber, a vinelet; and a small stem proceeding laterally from a root or stool, a sucker."

When a trunk bears permanent or perennial branches, the plant is termed a tree; when permanent branches arise, not from a trunk, but from the root, the plant is termed a shrub; when small and much branched, a copse shrub; when furnished with woody branches that are not permanent, as in the tree mignonette, it is termed an under-shrub; and when the whole stem is not woody, and dies down every year, at least as far as the crown of the root, the plant is termed an herb; when a trunk is formed like the underground stem of the iris, of the hardened bases of leaves which have withered and fallen, and is not taper, but all of one thickness, giving off no branches, as in the date and cocoa, the plant is termed a palm.

BUDS.

Buds, which have various forms, but are generally oval or roundish, consist of the young shoots, either of leaf, flower, or twig. They are usually formed either early in summer or in autumn, and are so contrived as to preserve from injury the delicate foliated structure within. The outside is composed of tough scales, which are frequently covered with a gummy resin, and they are internally kept warm by a downy substance interposed between the leaves. Buds are in most respects like bulbs, the scales being composed of cellular tissue, with distinct fasciculi running through it. This separation of the vascular fasciculi is the feature which distinguishes these scales from leaves. The inner scales perform the functions of leaves, until these are perfected and fully expanded, when they drop off; but in some trees, as in the apple and the almond, they are converted into leaves; whilst in others, as the rose, they are converted into the petioles, or footstalks of the real leaves which spring out of them. When the central part of a bud contains leaves only, it lengthens upwards as it expands into a branch; thus a leaf-bud and a branch-bud may be said to be the same. When it contains a flower, this is situated as in the bulb of the tulip, in which small bulbs are formed on the edges of the crown of the root between the scales, which gradually enlarge at the expense of the scales, are detached, become perfect bulbs, and send up leaves and flower-stalks. With respect to the manner in which the leaves are folded, they may be plaited, as in the palm and birch; doubled, as in the rose and oak; embracing, as in the iris and the sage; double embracing, as in valerian, teasel, &c.; double compound, as in carrot, mimosa, &c.; rolled inwards, as in grasses; tiled, as in pevet, lilac, &c.; rolled outwards, as in rosemary, primrose, &c.; rolled lengthways, breadthways, rolled from the tip to the base, or wrapped round the stalk.

Leaf-buds are more slender than flower-buds, and the latter are more or less bulged out and blunt at the point, but do not upon expanding lengthen upwards like the leaf-bud. As in the case of leaf-buds, the embryo of flowers is disposed in various forms within its envelope; it may be tiled, as in the rose and cherry; plaited, as in the potato; rolled up into a spiral, as in the wood-sorrel; rumpled, as in the poppy; five-fold, as in the pink; or valved, as in ginseng. Buds are usually found at the inner bases of leaves, but they occasionally occur in other places. Too many buds upon a tree are apt to cramp its growth, since it has to supply them with nourishment which otherwise would have been appropriated to itself. Leaf-buds generally contain only the rudiment of one axis or stem, but those of pine, fir, and other trees of that description, contain several, each enclosed in its own proper perula. When the plant has no stem, the buds are produced in the axillæ of the root-leaves, as in the daisy, primrose, &c.

Darwin was of opinion that every bud was a complete individual plant, and a tree an aggregate of buds. He reasoned thus from the fact, that when a bud is cut from one tree and inserted into another, it grows into a perfect branch—a circumstance which has given rise to the ingenious art of engrafting.

The buds of trees, being in a state of great sensibility, and feeling the first warmth of the sun, the vitality of the continued shoot is roused into action; it attracts the moisture contained in the neighbouring cells charged with nourishing matter; the rising sap also enters its vessels; it gradually swells, and bursting the enclosing scales, pushes into the light and air, unfolding its leaves successively as it advances, until the whole tree becomes green.

LEAVES.

With respect to leaves, we shall quote a passage from an eminent writer upon the subject:—"Much of the beauty and interest of the vegetable kingdom depends on leaves, whether we regard them as the clothing of a single plant, or of groups. To the plants themselves, they are the most important of the conservative organs, performing nearly the same functions in the vegetable economy which the lungs perform in that of the animal. Every leaf consists of two parts; the one thin and expanded, in ordinary language the leaf; the other, as thick as it is broad, the foot-stalk or petiole; these together constitute but one organ or proper leaf; and, with a few exceptions, when the leaf falls, it always separates from the twig at the base of the petiole. Leaves are more diversified in form and composition than any other of the vegetable organs; they are simple and compound; differ in situation and distribution on the branches; in direction and insertion; in respect of expansion, point or apex, or tip, base and margin; in surface, substance, composition, and appendages. In size they differ as widely; the leaves of *Hypnum trifarium* are almost microscopic objects, while those of the talipot palm (*Licuala spinosa*) have been known to exceed thirty feet in circumference. Leaves are either *caducous*, falling before summer is past; or *deciduous*, falling in autumn; or *persistent*, not falling until pushed off by the new leaves in the following spring; or *perennial*, of still longer duration.

Leaves are composed of three textures—a vascular, a cellular, and a cuticular tissue; and we expect to find these parts in the midrib and nerves, the parenchyma, and the surfaces of every leaf. When means, whether natural, as the atmosphere and the moisture contained in it, or artificial, as steeping in water, and exposure to the air, are employed to destroy the cuticle and the parenchyma of leaves, the fasciculi of vessels which constitute the ribs and nerves, as they are improperly called, remain, and constitute what is termed a skeleton leaf. In skeleton leaves we find the secondary ribs or nerves running either in straight lines from the midrib to the margin, or branching off in an infinity of divisions, so as to produce the appearance of a reticulated web. On a more close examination we find that these ribs, whether straight or reticulated, consist of fasciculi of conducting vessels, closely accompanied with proper or returning vessels. In those leaves, the ribs of which run in straight longitudinal lines, the fasciculi constituting these are united by transverse vessels at certain distances, which are not given off from the fasciculi, as Grew and others have supposed, but are distinct vessels, united with the fasciculi by insertion. In thick and succulent leaves, as those of aloe, thick cords of spiral vessels, accompanied by large bundles of proper vessels, separated only by a thin layer of cellular substance, are observed to traverse the leaf. This leaf is bordered by spines, into which cords of spiral vessels pass, given off from the fasciculus nearest to each of them. In leaves in which the costæ, or ribs, are transverse, the same communication between the costæ, by inosculating or inviting vessels, occurs, forming rhomboids; and this structure is common to all monocotyledonous leaves (or leaves of plants whose seed has only one seed-lobe). At the point of attachment between the branch and the petiole, if this be dilated, the vessels enter the petiole in distinct fasciculi, the number varying in different plants. The sap and the proper vessels are closely attached in the same fasciculus whilst in the leaf; but they separate at the point of attachment, the sap-vessels passing from the medullary sheath of the twig into the leaf, and the returning vessels passing from the leaf into the bark of the twig."

In the above extract the midrib and other terms have been employed which require explanation. Through the middle of a leaf there runs a stalk dividing it into two halves, and which has been denominated the midrib. From the sides or base of this, smaller ribs branch off, and which have been variously called veins and nerves. These tend towards the edge, and from them strike off still finer ribs, till the surface of the leaf appears like network, the meshes being filled with a green substance. Professor Rennie proposed to call what have hitherto passed under the name of nerves or veins, leaf-ribs, and their small branches ribists—a nomenclature which we think convenient, and shall accordingly follow. Grasses afford the simplest specimen of leaf-ribs. In these the bases of the leaves sheathe and embrace the stem. In some plants on each side of the midrib there is a leaf-rib nearly as large, and sometimes these ribs are more numerous, and radiate from the bottom of the leaf over its whole extent.

It would appear that the almost countless array of forms of ribs were determined by the character of the branching from the midrib. Leaves are either simple or compound: they are simple when laminæ are entire, or when, if separated into several divisions, these segments are not articulated with the petiole. Professor Rennie thus describes simple leaves:—"When the midrib and its branches form a simple leaf, it may be line-like, as in the juniper; awl-shaped, as in the jonquil; spear-shaped, as in ribwort; sword-shaped, as in the iris; riband-like, as in grass; spoon-shaped, as in navel-wort; oblong, as in the banana; egg-oblong, as in the marjoram; inversely egg-oblong, as in the cowslip; wedge-shaped, as in shrub-candy tuft; roundish, as in round-leaved mallow; or shield-shaped, as in the Indian cress or nasturtium.

When the pair of rib-branches at the base stretch farther than the others, the leaves become halberd-shaped, as in cuckoopint; heart-shaped, as in burdock; arrow-shaped, as in sorrel; kidney-shaped, as in ground-ivy; triangular, as in mercury; three-lobed, as in hepatica; four-cornered, as in the tulip-tree; fiddle-shaped, as in fiddle-dock; trowel-shaped, as in black poplar; or diamond-shaped, as in water-caltrops. Again, when more of the rib-branches besides the pair at the base are long, the plait of the leaf is often more or less regularly formed to correspond with this, and becomes five-lobed, as in the hop and sycamore; hand-shaped, as in the blue passion-flower; slashed, as in the long-stalked geranium; five-cleft, as in the spotted geranium; many-cleft, as in monkshood; cleft-cut, as in dandelion; wing-cleft, as in star-thistle; or comb-cleft, as in water-violet.

When the stalk bears more than lamina, and these are jointed to it, so that they can be separated without tearing, the leaf is said to be compound; each lamina, whether it have a stalk to it or not, is called a leaflet, and the joint is called an articulation. The horse-chestnut, rosetree, ash, sweet and common pea, laburnum, clover, and a multitude of plants, have compound leaves. When there is a common leaf-stalk supporting two or more leaflets, the compound leaf may be three-fold, as in clover; four-fold, as in four-leaved marsilea, and so on, the leaflets being termed many-fold when they are more than seven in number. They are also named according to their disposition; as umbelled, when they have the appearance of an umbrella. And when a number of distinct leaflets are placed along the sides of the common leaf-stalk, the compound leaf is said to be winged; which term is qualified by a discriminating term prefixed to it, descriptive of the peculiar combination, as unequally-winged, lyre-winged, and so on. When the small leaflets are again divided, the whole leaf is said to be doubly-compound.

In their circumference, leaves display a great diversity of characteristics. To facilitate to beginners the acquisition of knowledge on this part of the subject, the circumference has been divided into the tip, or apex, or more simply top, and the margin. The tip may be sharp, as in the lilac; spine-pointed, as in thistles; notched, toothed, and so on. The margin also displays the same diversity of form, being sometimes entire or plane; at other times waved, toothed, thorny, prickly, curled, and of various other forms; and it may sometimes be bordered by a substance different from itself, which may be gristly, horny, fringed, or glandular.

In the manner in which leaves project from the branches, the way in which they are inserted, and their distribution over the woody cylinder to which they are attached, every possible variety may be observed, of which any one may satisfy himself by casting his eye over the face of nature. The leaves of most plants possess a power of motion, which is the effect of what is termed irritability or vitality. Thus, some flowers close when night approaches, others open. The leaves of the sensitive plant, or *Mimosa pudica*, close themselves upon the slightest touch. All leaves after a certain time fall off, their place being supplied by other shoots. With respect to duration, leaves either drop off during summer, at the approach of winter, or are evergreen. When they wither, and remain without falling, they are said to be persistent, as in oak and beech.

Buds, we have already observed, give rise to branches, as well as leaves and flowers. The branch of a tree may be said to be a young stem, from which lesser shoots take their rise, and of course is in its structure similar to the stem. The solid contents of the whole branches are often a fifth more than those of the trunk which nourishes them; but trees in which branches are very numerous are stinted in their growth, and hence pruning becomes necessary. Branches, like leaves, may be opposite, alternate, whorled, irregularly dispersed, descending, drooping as in the weeping-willow, or possess various modes of bending.

OF SCALES, HAIRS, PRICKLES, SUCKERS, AND OTHER APPENDAGES.

The following account of these various growths is principally condensed from a small work on vegetable physiology, in the Library of Useful Knowledge. The term *appendages* is applied to certain organs attached both to roots and stems, which, as they are not general, are not classed with the common members of the vegetable body.

1. Scales (*squamæ*) are generally found on roots, as, for instance, on the root of toothworth. They consist entirely of cellular tissue, enclosed in a cuticle.

2. The sucker (*stolo*) is an underground bud, sprouting from the upper horizontal branches of the roots of trees; and, rising above the soil, it is converted into a stem resembling the parent-tree. Its organisation is exactly the same as that of the leaf-bud.

3. The knob (*tuber*) is a solid massive body, attached either closely or by means of a vascular cord, or wire, as it is usually termed, to the base of the stem of some plants; it is also sometimes produced on the stem. The tuber varies greatly in form and appearance; but it has in every instance nearly the same structure, and consists of a cellular parenchymatous mass, covered with an epidermis devoid of apertures, and furnished with vascular fasciculi, which either surround the central mass of cells, or are distributed through it, according as the plant which bears the tuber originates from seeds with one or with two cotyledons (or seed-lobes). The cells are filled with mealy grains; for tubers are merely reservoirs of nourishment for the young plants on their surface, which resemble the plantule in seeds, and are endowed with the same vitality, remaining latent until the tuber be placed under circumstances favourable for vegetation.

4. Radical bulbs (*bulbi radicales*) are, like tubers, reservoirs of nourishment for aiding the developement and the temporary support of the lateral progeny of a certain class of plants. They are either solid scaly, and laminated (or compounded of plaits).

5. Glands (*glandulæ*). The real existence of bodies which usually merit this appellation in the vegetable system is doubtful. There are, however, minute organs, differing in structure from the common texture of the part where they are situated, which separate some peculiar matter from the ordinary proper juice, and which may be regarded as glands. If this be admitted, these glands occupy the interior and exterior of stems and leaves, vary greatly in form and attachment, and perhaps in structure, although any attempt to demonstrate this can scarcely be depended upon. Internal vegetable glands are generally seated in the substance of leaves, with a small excretory duct or channel opening upon the surface of the leaf. These furnish the little drops of essential oil found on many leaves, as for instance that of the black currant. In some leaves, when the cells are swelled with fluids, these ducts are pressed upon and closed, so that the leaf exhales no odour, although a powerful odour is exhaled as soon as the withering of the leaf opens the ducts. This is the case in sweet-scented meadow-grass, whence new hay derives its odour. External vegetable glands are either with or without a foot-stalk; and all these glands are cellular, with the cells more regular than those in the substance of the leaf, and arranged in circles; a cord of vessels can generally be traced into the substance of the gland.

6. Pubescence, comprehending *down*, *hairs*, and *bristles*. The structure of the first is more simple than any other part of the vegetable body, consisting of tubular cells, so disposed as to form single, extended, or jointed hairs, with or without a globular point; or branched, or stellated, or uncinated, or hooked hairs. The structure of bristles is also cellular, but more condensed, and assuming a variety of forms; some of which, for instance the hooks in clivers, enable the plants to climb. Bristles are also sometimes the excretory ducts of glands, as exemplified in borage, the nettle, louse, &c.

7. Thorns (*spinæ*) are in general processes of the ligneous part of stems, and have nearly the same structure as branches. They are indeed sometimes abortive branches, as in the genus *prunus*; sometimes the lobes of the leaf hardened, as in the date; sometimes hardened stipules, as in erythryna.

8. Prickles (*aculei*) are productions of the bark and the cutis, as is well exemplified in the rose, with the bark of which the prickles separate. They consist of a mass of oblong cells, which become condensed towards the point of the prickle, and over which the common cutis of the part is thrown back.

9. Props (*fulcra*). Under this term are comprehended the tendril, the claw, the hook, and the bladder. The tendril is a long, cylindrical, slender, spiral organ, issuing from various parts of the plant. It consists of a cortex, which resembles that of the foot-stalk of the leaf, and of fasciculi of vessels imbedded in a cellular parenchyma. It has apertures on its surface, the same as the leaf; so that the tendril partakes of the nature of the petiole of the leaf, and of the cuticular system of that organ. The claw is of two kinds, the radicular and the cirrhal. The radicular claw is a small thread-like body, protruded from the stems of some flexible plants, which entering into the crevices of the bark of trees, and the cracks in rocks and walls, enables the plant to support itself perpendicularly upon such surfaces. The cirrhal claw is a combination of the tendril and the claw. It is well exemplified in the Virginian creeper. As far as regards the tendril-like portion, its structure is the same as that of the tendril; the claw itself consists of cellular matter, which being a continuation of the parenchyma of the other part of the organ, is here checked in its extension, and expands sideways, leaving the under surface almost devoid of cutis, but studded with minute warts or short fibrils. The warts and fibrils entering into the minute pores of stone, bricks, &c. swell there, and maintain the claw so firmly attached as to support the branch, and enable the plant to climb on the face of a perpendicular surface.

10. The bladder (*ampulla*) is a small membranous bag attached to the roots and leaves of some aquatic plants, containing a watery fluid and a small bubble of air.

11. Foliaceous appendages, as the name implies, have the form and structure of leaves, at least this is generally the case in the stipule (*stipula*), and in the floral leaves (*bracteæ*).

All the parts hitherto described only contribute to the growth and perfection of the individual plant, and have been named the nutritive or conservative organs. We come now to the other grand division of the subject, which treats of those organs by which the species is perpetuated, and hence called reproductive organs. It is in the flower of a plant that these are to be found; and we shall, in the first place, give a general description of that beautiful ornamental part of a plant.

OF THE STRUCTURE OF FLOWERS.

A flower consists of several distinct parts, which have obtained various and often very fanciful names. The term *inflorescence* has been given to the mode in which the flowers of a plant are distributed, or their manner of flowering, of which we shall afterwards speak. A flower is essentially constituted by the presence of sexual organs, either male or female. When there is only one of these present, the plant is termed unisexual; but more commonly these organs are both present in the same flower, which is in this case termed a hermaphrodite. In some instances, although the same plant bears both male and female organs, it is not hermaphrodite, as these organs occur in different flowers; in others, again, the male and female flowers exist only in different plants. Lastly, male, female, and hermaphrodite flowers, are sometimes found mingled together, either on the same or on different foot-stalks. Sometimes the male or female organs alone, protected in a small scale, constitute the flower; but in general they are surrounded and protected by others, named the corolla and calyx. All these are commonly borne on a stalk called the peduncle (from *pedo*, to prop or support), which expanding at its extremity, forms the receptacle or torus, as it has been called, upon which the whole of the parts above mentioned are supported. By reference to the plate on the first page, the sexual organs of a flower will be seen. *a*, fig. 3, is the calyx or flowercup, affixed to the top of the flowerstalk or peduncle *s*. Into this is inserted the corolla *b* (from *corolla*, a little crown), which is also variously called the blossom or flower, although it is not in all cases agreed what part is to be called the cup, and what the blossom. The leaves into which the blossom may be divided are termed petals, the base being called the claw, and the rest the limb. Within the blossom are situated the sexual male and femal organs, corresponding to those of animals.

INFLORESCENCE.

It must always be remembered that regular buds are formed in the axillæ of leaves, that is, at the angles of their junction with the stem, otherwise called bracteæ; and that the centre of a bud grows into an axis or stalk, bearing the leaves enclosed in that bud, the innermost of which constitute the flower; whilst other buds giving birth to new stalks, leaves, and flowers, may or may not be produced in the axillæ of the outermost, as they are unfolded on the original stalk. The inflorescence of plants is very various, and depends entirely upon the power of developing the flower-buds in the axils of the bracteæ. Inflorescence, however, may be reduced to two kinds; it is called simple when formed by the developement of one bud and one branch; and compound, when formed by the developement of several buds and branches. Professor Roeper, of Bale, has introduced the most recent arrangement of flower-stalks; and as his nomenclature is simple, and has been adopted by Professor Rennie, we shall employ it. Roeper considers the modes of flowering as consisting of an evolution, which may be centripetal, centrifugal, or mixed.

Centripetal Evolution.—Flower-stalks are either simple, supporting only one flower, or compound, supporting more flowers than one, upon stalklets. In centripetal evolution, the flowers blow first in the circumference and last in the centre, the flower-stalk always growing from the inner base or axilla of a leaf, and the stem having always a leaf-bud at the summit. Various names, very puzzling to a beginner, have been given to the various kinds of inflorescence. When there is only one flower, it is said to be terminal and solitary. When the principal stem grows past the flower-bud, and the bractea retains the form and size of a leaf, the flower is called axillary and solitary. When the buds which grow upon this elongated stem unfold into flowers, each supported by a peduncle, that is, simply a stalk, the inflorescence is called a *raceme*; if the flowers are sessile, that is, without a peduncle, and seated in the axil of the bracteæ, a spike is formed, of which there are many varieties, as corn, lavender, &c. When the bracteæ on the principal stalk are close, and overlap one another, or are imbricated, as this is called, with flowers reposing (sessile) in their axillæ, the spike is termed a catkin, or, in Latin, *amentum*. The difference then between a raceme and a spike is, that the stalks upon which the flowers blossom are longer in the former than in the latter. When these peduncles or stalks shoot so as to bear bracteæ, from which other stalks strike out, what is called a *panniele* is formed. Usually in these two, the lower peduncles are only slightly longer than the others; but when they are very long, and the upper ones very short, it is technically termed a *corymb*, from *korus*, a helmet. When all the flowers are placed together in a globular head, we have a *capitulum*, from *caput*, the head. When the principal axis is but little lengthened after the opening of the bud, and the other flowers which it contained have stalks, an *umbel* is formed, from *umbella*, a fan or screen. This is called simple when the stalks springing from the same part of the principal one bear but one flower, and compound when the stalks of the secondary buds bear smaller umbels, into which these open. These are all specimens of simple inflorescence, and as the lower flowers are first expanded, this mode of flowering is called centripetal.

Centrifugal Evolution.—"In the centrifugal evolution," says Professor Rennie, "each branch or flower-stalk terminates in a flower-bud, never in a leaf-bud; and consequently it cannot be prolonged farther, as in the centripetal, though it may shoot out fresh flower-buds from the side when nourishment is afforded. Instead of a single floral leaf, each top-flower has two or more, and from the inner base of these two or more new branches spring, each again ending in a central flower and two or more side-branches. They proceed forking off in this manner, till the supply of nourishment is exhausted. All the flowers in the centre open first. The form under this division may not inappropriately be termed in general a bouquet (in Latin, *cyma*); but when the branches from the flower-stalk are wanting, or very short, it is termed a ball (in Latin, *glomus* or *glomerulus*), though differing only from the tuft in its evolution. The bouquets crowded together are termed a fascicle (in Latin, *fasciculus*), as in sweetwilliam. The bouquet is in some instances only simply forked, as in silene and some of the pinks; triply or oftener forked, as in spurge; or not forked at all, no flowers being evolved on one side, as in bugloss and scorpion-flower. Sometimes the bouquet resembles an umbel, and sometimes a bundle, but is always distinguished by its peculiar evolution.

Mixed Evolution.—In the mixed evolution there are two leading forms—one where the central axis of the plant flowers according to the centripetal evolution, and the side-branches to the centrifugal, which is termed a bunch (in Latin, *thyrsus*), as in the lilac and the butter-burr; and also in the plants whose flowering was formerly termed the whorl (in Latin, *verticillus*), as in mint, balm, thyme, and sage; and of this there are many varieties, according as it resembles a pannicle, a cluster, or a spike; another, when the central axis follows the centrifugal evolution, and the side-branches the centripetal, which is termed a bundle (in Latin, *corymbus*), as in yarrow."

TORUS, OR RECEPTACLE.

The outer envelope (in Latin, *perigonium*) of flowers presents very different forms in different plants, and a multitude of names puzzling to the beginner have been introduced by botanists to distinguish them. The receptacle of the flower, or *torus* as it is entitled, is an expansion of the pedicel, from which spring the petals and stamina, and seems to be formed by an abortion or partial developement of one or both of these parts. Although not, properly speaking, an organ, it is of great use in the vegetable economy. It is generally inconspicuous, and is reduced to a narrow circular space between the calyx and the pistil; and according as it is placed with reference to these, and to the stamens, petals, and ovary, it is variously named. The receptacle is called proper when it corresponds with a single flower, as in the tulip. What is called the berry in strawberries, appears to be nothing more than the receptacle bearing the naked seeds on its surface. It is called common when a number of florets rest on one receptacle. The round bottom which is exposed when the downy seeds are blown from the head of the dandelion, is an instance of the common receptacle.

CALYX.

The following descriptions of the calyx and corolla are condensed from an able article upon botany in the Encyclopædia Britannica:—

The calyx is usually of a green colour and foliaceous; each segment is termed a *sepal*. These like leaves are sometimes articulated at their base, when they are either quite distinct from each other, or cohere in the form of a lid (as in *eschscholzia*) during the flowering of the plant. But they are often continuous with the peduncle, and consequently persistent. In such cases they are either distinct, or are united together by their margins. When the sepals are distinct, the calyx is said to be bi, tri, or polysepalous, according as there are two, three, or many leaves; and when soldered, it is called *gamosepalous*, or, by the strict followers of the Linnæan nomenclature, *monophyllous*; when only slightly united at the base, it is *partite* (bi, tri, quadripartitus, &c.); when united to the middle, it is termed *divided* (bi, trifidus, &c.); and when soldered till near the apex, it is called *toothed* (bi, tridentatus, &c.) If no teeth be perceptible, it is then entire; and in that case the number of parts must be determined analogically, or by other means. The cohering portion is termed the tube. Some sepals in the same calyx may cohere together in a greater degree than the others, and this gives rise to a *bilabiate* calyx. In a few genera with articulated sepals, the divisions cohere together, but separate from the tube in the form of a lid or operculum. Sometimes the calyx is reduced to a mere ring round the base of the corolla. In the valerian, this ring is afterwards developed into a *pappus*, formed of numerous long and fine radiating segments. In many *compositæ* the margin of the calyx also constitutes a pappus, appearing either in the form of a ring, or bristles, or scales, or rough hairs, or feathery hairs. The calyx may be free from or unattached to the fruit, or the tube may be closely incorporated with it, or adherent (*calyx adhærens*). This organ varies without end, and it were vain to attempt a description of all its peculiarities. One great distinction arises from its situation. When close to the fructification, it is called the perianth (from *peri*, about, and *anthos*, a flower); when distant, it has various other names: but in general, under these circumstances, it is not considered a legitimate calyx.

COROLLA.

The corolla is for the most part more or less coloured; and it exists in the greater part of the exogenous plants. (Exogenous is the name given to a large class of plants, which will be alluded to afterwards.) Sometimes it is very small, and reduced to the appearance of mere scales, and even in some genera is quite abortive; and when this happens, we must proceed with the greatest caution, and depend much on analogy, so as not to confound those groups of plants in which it ought to be present with those furnished with a perianth, in which a true corolla is always supposed to be absent. The divisions of the corolla are called petals. They are almost always articulated at the base, and consequently fall off; and when this happens at a very early stage, they are said to be caducous. When the petals have no articulation, as in campanula, they either remain for a long time, or are persistent; or are marcescent, when they wither away without falling off. When the petals are quite distinct from each other, the corolla is polypetalous; or when more or less united by their margins from the base upwards, monopetalous, an incorrect term, which ought to be exchanged for gamopetalous; and then it may be partite, divided, toothed, or entire, in the same way as in the calyx. But petals may also unite in their upper parts, though distinct below. When the lower part of a petal, as the petiole of leaves, is narrow, and consists of the union of all the vessels that expand and ramify in the upper portion, the contracted part is the claw or unguis; the dilated, the limb or lamina. If the ungues be long, straight, and closely approached to each other, even though distinct, a kind of tube is formed; but, properly speaking, it is only a tube when the claws are united. The orifice of the tube is termed the throat or faux; and this may be naked (nuda), or furnished with little scales or appendages, called sometimes a crown. The shape of the corolla is frequently of importance in distinguishing natural groups of plants. When all the petals are equal, it is said to be regular; when a monopetalous regular corolla has no tube, but swells out gradually from the base to the summit, it is bell-shaped or campanulate; and urceolate if it is swollen at the base, and contracted at the top; when there is a tube, and when it is narrow below, but dilates upwards, so that the limb is campanulate, the corolla is infundibuliform or funnel-shaped; it is rotate or wheel-shaped if the tube be very short, and the limb spreading and nearly plain; hypocrateriform, when the tube is long, narrow, and cylindrical, and the limb spreading like a star; and tubular when it is almost entirely composed of a narrow elongated tube, slightly dilated upwards. When the petals are of unequal size, or cohere unequally, the corolla is irregular; and if such petals unite, the result will be an irregular monopetalous corolla. Of the various other kinds of corolla which arise from the nature of the tube or the pistils and their relations, we cannot give an account in this place.

STAMENS.

From one to many small bodies, varying very much in form and size, lie immediately within the blossom, and these are termed the stamens, or the male organs of reproduction. In general, a stamen consists of two parts, in most cases, of a filament *d*, fig. 2 (from *filum*, a thread), which is usually white, and always of an anther, *e*, fig. 2, which is usually yellow or purple. It has been shown that the stamens are always next to the petals, that is, between their base and the base of the seed-organ. It is upon the number and arrangement of the stamens that systematic botanical arrangements have principally been founded. The following are a few characteristics of the number, length, position, direction, &c. of the stamen. The number of stamens in each flower varies from one to twenty, or more. In length, they are equal or unequal, and this disproportion is sometimes symmetrical, sometimes not. In position they may be opposed to the divisions of the petals, or they may alternate with them. Sometimes they protrude beyond the corolla, at other times they are wholly included within it. Their direction may be erect, pendent, or horizontal, and their summit is variously inclined to or reflected from the centre of the flower. The filament which supports the anther is most commonly straight and filiform; sometimes, however, it is otherwise. It varies, from being as small as a hair, to be large and flat like a petal, and its summit is either pointed or obtuse. On the summit is that essential part the anther, which is generally formed of two small membranous sacs, attached immediately to each other, or united by an intermediate connecting body. In form, anthers are subject to great variety, and, like the filaments, they sometimes cohere so as to form a sort of tube. Their colour is often yellow, orange, violet, white, &c., but never green or truly blue.

The pollen contained in the anthers consists of numerous regularly figured small particles, which possess in different plants a very different figure, size, and colour. The number of particles in a cell, which is very small, sometimes amounts to many thousands. In some flowers the pollen consists of transparent grains; in others they are of a white, purple, blue, or brown, and more frequently of a yellow colour. When a grain of pollen is dropped into water, it swells and bursts, and a minute quantity of matter escapes, which is supposed to confer the fecundating property to the pollen.

THE PISTIL.

Between the base of the filaments of the stamens and the seed-bag, there is an expansion which Linnæus entitled a nectary, but which has since been called a disc, because it is generally of a roundish form. In the centre of the flower, and always surrounded by this disc, when there is one, and when there is not, by the stamens, there may be observed from one to many small bodies, varying much in length and form; these are the pistils, and they are considered the female organs of the plant. A pistil consists of three parts, the style, the seed-organ (called the germen or ovary), and the stigma or summit, which may be seen by referring to fig. 2. *a* represents the seed-organ, *c* the style, and *b* the stigma or summit. The seed-organ or ovary occupies almost always the inferior part of the pistil. It is here that the seed is produced. When cut open, it exhibits one or more cavities or cells, in which are contained the rudiments of the seeds or ovula; and it is in it that the change of the ovula into perfect seeds is effected. It is of various forms, but most commonly ovoidal. It is generally seated upon the receptacle together with the stamens, but frequently it is placed below the flower. Its cavity consists sometimes only of one cell or loculament, in which one or more ovula are found. Fig. *d* is a representation of an ovary, in which there are several cells. The style is a prolongation from the summit of the ovarium, and supports the stigma. It is generally so situated as to be surrounded by the stamens, but sometimes it is entirely wanting, and the stigma is then said to be sessile. Any part of a plant which commonly is borne on a stalk, when it has none, is said to be sessile (Latin), *seated*. In some plants there are several styles to one ovary, in others there are several ovaries to one style. The most common form of the style is filiform; but frequently it is thick, angulated, or club-shaped. It is commonly a hollow tube communicating with the ovary, and sometimes so connected as to fall after fecundation. The stigma, which forms the summit of the pistil, sometimes terminates the style by an open mouth. Sometimes it has the appearance of a small bud, and in other instances it is variously divided or forked. Sometimes it is smooth, and sometimes covered with hairs. The number of stigmata is determined by that of the styles or divisions of the styles, and therefore varies from one to six, or more in different plants. In form and consistence the stigma varies considerably, being in the latter respect thick and fleshy, or thin and membranous, or formed of small glandular bodies.

Before entering into particulars regarding germination and reproduction, we shall give an account of vegetable nutrition, a branch of the subject too much neglected by botanical writers. In treating of this department, we shall principally follow Dr Roget, who has admirably elucidated it in his Bridgewater Treatise upon Animal and Vegetable Physiology.

FOOD OF PLANTS.

Water may be considered as the general vehicle through which nutriment is received by the vegetable kingdom; but it has been demonstrated that plants cannot live upon pure water alone, as *was* at one time believed. When plants are contained in close vessels, and supplied regularly with water, but to which no carbonic acid gas is allowed to enter, they are developed only to a very limited extent. They moreover quickly die, unless fresh supplies of water be regularly furnished. The water which goes to the nourishment of the vegetable kingdom is never perfectly pure; for besides containing air in which there is constantly a portion of carbonic acid gas, by percolating through the soil it has imbibed saline matter, as well as decayed vegetable or animal remains, which substances are soluble in a very minute quantity of water, or are so finely pulverised as to be suspended in the fluid, and carried with it into the vegetable system. From chemical experiments, it appears that the principal matters taken up by plants, besides water, are carbonic acid gas, nitrogen, chiefly in the form of humic acid, together with a few salts, such as potass, and metallic ingredients. Out of these, and the hydrogen and oxygen of the water, and the carbon supplied by the carbonic acid, all vegetable products seem to be principally elaborated. The peculiar fertility of each kind of soil depends chiefly on the quantity of vegetable and animal remains which it possesses in a state capable of being absorbed by the plant, and of contributing to its nourishment.

ABSORPTION OF NUTRIMENT.

The greater number of plants which are composed of cellular tissue absorb water with nearly equal facility from every part of their surface. This is the case with a class of aquatic plants called the algæ. On the other hand, lichens and some other plants absorb it only at particular and variable parts of the surface, whose situation appears to be more determined by mechanical causes than by any peculiarity of structure. Some, however, are said to be furnished in certain parts with stomata, which may act as sucking orifices. In plants having a vascular system—and they are by far the most numerous and important—the roots are the special organs which absorb nourishment; occasionally, however, the leaves and stems of plants absorb moisture, but this is not their natural action, the root being the proper organ. Roots are provided with suckers, called spongioles or spongelets, which De Candolle describes as resembling a minute sponge full of pores, inferred, when they cannot be detected, from the fact of fluids actually passing into them. The spongelets are always placed on the extreme tips of the rootlets or smallest fibres of the root, and are composed of an expanded tissue of small roundish cells, often as soft as pulp. They imbibe the fluids that are in contact with them, partly by capillary action, and partly also by what has been termed a hygroscopic power. But though these principles may sufficiently account for the simple entrance of the fluids, they are inadequate to explain its continued ascent through the substance of the root, or along the stem of the plant. The most probable explanation of this phenomenon is, that the progressive movement of the fluid is produced by alternate contractions and dilatations of the cells themselves which compose the texture of the plant; these actions being themselves referable to the vitality of the organs.

The absorbent power of the spongioles is limited by the diameter of their pores, so that if fluids be thick or glutinous, they are apt to block up the passage altogether. Thus, if the spongioles be surrounded by a solution of viscid matter, such as gum or sugar, its pores will be clogged up, scarcely any of the fluid will be absorbed, and the plant will decay; but if the same liquids be largely diluted, the watery portion will enter, while the greater part of the thicker materials will be left behind. The same apparent power of selection is exhibited when saline solutions of a certain strength are presented to the root, the water of the solution, with only a small proportion of the salts, being taken up; and if the remaining part of the fluid be examined, it will be found to be more strongly impregnated with the salts than before this absorption had taken place. It has been found, however, that if perfect liquidity exist, the plant will take in the liquid with equal avidity whether it be salubrious or otherwise, so that the action of the plant is mechanical, and not the result of discrimination at all.

ASCENT OF THE SAP.

The various matters held in solution by the fluid enter the plant in a perfectly crude state. The liquid rises in the stem of the plant, undergoing little or no perceptible change in its progress, and is in this state conducted to the leaves, where it experiences various important modifications. By causing the roots to imbibe coloured liquids, the general course of the sap has been traced with tolerable accuracy, and it is found to traverse principally the ligneous substance of the stem; in trees, its passage is principally through the alburnum, that is, the wood last formed, and not through the bark, as was at one time believed.

The course of the sap varies under different circumstances, and at different periods of vegetation. At the time when young buds are preparing for their developement, which usually takes place after the genial warmth of spring has penetrated beyond the surface of the earth, and expanded the fibres and vessels of the plant, there is created an urgent demand for nourishment, which the roots are actively employed in supplying. As the leaves are not yet completed, the sap is at first applied to purposes somewhat different from those it is destined to fulfil at a more advanced period, when it has to nourish the fully expanded organs; this fluid has, accordingly, been called the nursling sap. It does not rise through the alburnum, but through the wood, which is immediately contiguous to the pith, and thence passes, by unknown channels, through the other layers of wood to the buds, which it nourishes. In this circuitous circulation it is supposed to undergo a change, or becomes assimilated, in which state it is fitted for entering into combination with the plant, or becoming incorporated with the new organisation. This nursling sap has been compared to the milk of animals, which is prepared for a similar purpose at those times only when nutriment is required for the rearing of their young.

Philosophers are at variance with regard to the channels through which the sap passes in its ascent along the stem, and in its subsequent progress to its ultimate destination. De Candolle is of opinion that it passes along the intercellular spaces; and he adduces a number of arguments in support of his views. In order to ascertain the velocity with which sap rises, Hales cut off in the spring a vine branch, and enclosed the cut surface of the stump in a bent tube, when the sap flowed so abundantly, and with such force, that it sustained a quantity of mercury equal in weight to a column of water forty-three feet high, which indicates a force of propulsion considerably greater than the pressure of an additional atmosphere, or five times greater than the current of the blood in a horse. Various circumstances, however, contribute to influence the rapidity of circulation in vegetables. In experimenting upon blanched plants with coloured fluids, Bonnet found that they rose from two to three inches per hour. Heat has a very considerable influence in raising the sap, and very probably electricity may be another important agent. Perhaps they, in some mysterious manner or another, may excite the vital movements of the cellular structure already alluded to. There is no evidence that there is any thing like muscular power exercised. The simplest idea, says Roget, is, that these actions take place by means of a contractile property belonging to the vegetable tissue, and exerted under certain circumstances, and in conformity to certain laws, which we have not yet succeeded in determining.

EXHALATION.

The nutrient sap, which, as we have seen, rises in the stem, and is transmitted to the leaves without any change in its qualities or composition, is immediately, by the medium of the stomata, or orifices which abound in the surface of those organs, subjected to the process of exhalation. The proportion of water which the sap loses by exhalation in the leaves is generally about two-thirds of the whole quantity received; so that it is only the remaining third that returns to nourish the organs of the plant. It has been ascertained that the water thus evaporated is perfectly pure, or at least does not contain more than a 10,000,000th part of the foreign matter with which it was impregnated when first absorbed by the roots. The water thus exhaled, being dissolved by the air the moment it escapes, passes off in the form of invisible vapour. Hales made an experiment with a sunflower, three feet high, enclosed in a vessel, which he kept for fifteen days, and inferred from it that the daily loss of the plant by exhalation was twenty ounces; and this he computes is a quantity seventeen times greater than that lost by insensible perspiration from an equal portion of the surface of the human body.

The comparative quantities of fluid exhaled by the same plant at different times are regulated, not so much by temperature, as by the intensity of the light to which the leaves are exposed. It is only during the day, therefore, that this function is in activity. De Candolle has found that the artificial light of lamps produces on the leaves an effect similar to that of the solar rays, and in a degree proportionate to its intensity. As it is only through the stomata that exhalation proceeds, the number of these pores in a given surface must considerably influence the quantity of fluid exhaled.

By the loss of so large a portion of the water which in the rising sap had held in solution various foreign materials, these substances are rendered more disposed to separate from the fluid, and to become consolidated on the sides of the cells or vessels, to which they are conducted from the leaves. This, then, is the first modification in the qualities of the sap which it undergoes in these organs.

ORGANS OF AERATION.

The following account of the process of aëration is from Professor Rennie's work:—

"Though plants have no organs analogous to lungs or gills, nor even, I think, to the air-pipes of insects, to which the spiral vessels have been mistakingly, it should seem, compared, yet they cannot live without air any more than animals, and they die when deprived of it. The air being thus indispensable to vegetable life, must act on the plant in some manner; and experiments have accordingly proved that the leaves of plants perform some function similar to that of the lungs of animals. In animals, the air taken into the lungs in breathing through the nose and mouth becomes decomposed (in the dark it may be remarked) by giving up part of its oxygen, which combines with the blood, and receiving in turn from the blood a portion of carbonic acid gas and watery vapour. In plants this process is reversed; for the sap, which has mounted into the leaves and young green shoots, and which is composed of water, carbonic acid gas, potass, and a few other ingredients, either derived from the soil or taken up on passing up through the plant, becomes partly decomposed in the light; a portion of the oxygen being set free from the carbon which remains in the leaf, while the oxygen is given off into the air, at the same time that the large portion of the water is given off undecomposed, in the form of vapour.

The quantity of water thus exhaled by a cabbage has been proved to be seventeen times greater than that transpired by a man in what is termed insensible perspiration. The exhalation of water takes place through the pores already described of the green parts, but not the decomposition of air, which is effected, as De Candolle remarks, where there are no pores.

It is important to remark, that light is indispensable in effecting what may be called the aëration of plants, that is, in decomposing the sap in the leaves, and condensing the carbon, potass, and other matters indispensable to nutrition, while watery vapour is at the same time exhaled; none of which take place in the dark. Heat may cause a trifling evaporation, but nothing in proportion to that caused by light. It is on this account that plants exposed to much light are greatly harder and tougher than when grown in more shady places: a mountain oak, for example, more than a forest oak; or a wild carrot on an exposed bank, more than a garden one shaded by the leaves of its fellows. The green colour of leaves, as well as the varied colours of flowers, though very imperfectly understood, may be plausibly explained from the same principles.

Sennebier thinks that the real colour of carbon is dark blue rather than black, while the tissue of the cells and vessels of which the body of plants is composed, is yellow; consequently, when the blue carbon is lodged in these yellow translucent cells, a green colour is the result. Hence, in the spring, the newly expanded leaves, before they have had time to prepare much carbon, are yellowish; and when plants are kept from the light, so that no carbon can be prepared by their leaves, they become white, and also crisp and succulent from the same cause, as is seen in blanched celery and endive.

In autumn, when the leaves assume various tints, it was found by Macaire to arise from their taking in oxygen during the night, and being too feeble to open their pores for its escape during the day. The oxygen thus confined unites with the materials of the pulp, producing various acids, whose known action is to change blues to reds; and, consequently, when the blue carbon becomes thus tinged, it produces various shades of orange, and other combinations of red and yellow. Macaire was led by his researches to attribute the various colours of flowers chiefly to oxygen accumulated in the petals producing acids to combine with the other principles. It may be well, however, to caution the young beginner not to take these statements for more than an ingenious and plausible theory.

It might be supposed, as plants seem to feed chiefly on carbon, that they would thrive well in smoke, or in an atmosphere of carbonic acid gas. But it is found not to be so; for the particles of carbon in smoke are too large to enter their pores, and too much undiluted carbonic acid gas gorges them, and they will become brown, and die. Plants, it would appear, then, are destined by providence to purify the air, which is loaded from the lungs of animals with carbonic acid gas, and to give out a fresh supply of oxygen to replace what is taken up by the lungs. During the night, however, the green parts of plants take up oxygen, which is retained, and give out a small portion of carbonic acid gas; and hence it is not proper to keep plants during the night in a bedroom. When plants, indeed, are kept in an atmosphere deprived of oxygen, they soon lose their colours, and perish.

Plants can neither germinate nor live in nitrogen or azote, which kill some species almost instantly, though it is often found in small proportions upon analysing plants. Priestly imagined hydrogen to furnish nutriment to plants, but this has been disproved by experiment.

The decomposition of the air in the lungs of animals evolves heat, but this is less observable in the decomposition of air by plants. Desfontaines found, however, in the cuckoopint, that during the formation of the seed the thermometer was raised fifteen degrees. The origin of the various odours given off by plants is no better understood than that of their colour, and I shall not therefore detail mere conjectures."

RETURN OF THE SAP.

After the sap has undergone in the leaves the double processes of exhalation and aëration, it is now more abundantly charged with nutriment. It is now elaborated into a fluid corresponding to the blood of animals, and fitted for becoming incorporated with the vegetable organs. The crude fluid which enters the leaves is called the ascending sap; and after it leaves them in order to be distributed throughout the plant, it has been called the returning sap. It still contains a considerable quantity of water, but a large proportion of that which has not been exhaled by the leaves, and its elements, oxygen and hydrogen, has combined with certain other substances, so as to form proximate vegetable products, of which gum is the simplest, and generally the most abundant. The returning sap descends from the leaves through two different structures. In exogenous plants, the greater portion find a ready passage through the liber, or innermost layer of bark, and another portion descends through the alburnum, or outermost layer of the wood. With regard to the exact channels through which it passes, the same degree of uncertainty prevails as with regard to those which transmit the ascending sap. De Candolle maintains, that in either case the fluids find their way through the intercellular spaces; other physiologists, however, are of opinion that particular vessels are appropriated to the office of transmitting the descending sap. The nature of the forces which actuate the sap in its descent from the leaves, and its distribution to different parts, as well as those powers which contribute to its motion from the roots to the leaves, are involved in equal obscurity. The hypothesis that it resulted from capillary attraction is now generally abandoned.

SECRETION AND EXCRETION IN VEGETABLES.

The modifications which the returning sap undergoes, and its conversion into gummy, saccharine, amylaceous, or ligneous products, are effected by the simpler kinds of cells. But there are other cellular organs in which greater changes take place in its nature, the agents for effecting which are unknown, and are therefore referred generally to the vital energies of vegetation. The process is termed secretion, and the organs by which it is conducted, glands. The matter secreted is sometimes retained in the cells, and sometimes appears on the outside as an excretion, for the plant has the power of throwing out by the root those superfluous or noxious matters which, if retained, would injure it. This explains the fact why plants render the soil where they have long been cultivated, less suitable to their continuance in a vigorous condition than it originally was; and also why plants of a different species are frequently found to flourish very well in the same situation where this apparent deterioration of the soil has taken place. Hence the importance in agriculture of a rotation of crops in the same field.

The vessels in which the fluid secretions are contained are of a peculiar kind, and exhibit ramifications and junctions resembling those of the blood-vessels of animals. We may also discover, by the aid of the microscope, that the fluids contained in these vessels are moving in currents with considerable rapidity, as appears from the visible motions of their globules; and they present, therefore, a remarkable analogy with the circulation of the blood in some of the inferior tribes of animals. This curious phenomenon was first observed by Schultz in the chelidonium, in the year 1820; and he designated it by the term Cyclosis, in order to distinguish it from a real circulation, if on further inquiry it should be found entitled to the latter appellation.

The circular movements which have been thus observed in the milky juices of plants, have lately attracted much attention among botanists; but considerable doubt still prevails whether these appearances afford sufficient evidence of the existence of a general circulation of nutrient juices in the vegetable systems of those plants which exhibit them; for it would appear that in reality the observed motions of the fluid are in every case partial, and the extent of the circuits very limited. The cause of these motions is not yet known; but probably they are ultimately referable to a vital contraction of the vessels, for they cease the moment that the plant has received an injury, and are more active in proportion as the temperature of the atmosphere is higher.

ORGANS OF REPRODUCTION.

These have already been mentioned in our description of the parts of a flower; a more minute account of their functions will now be given, for which we are principally indebted to Professor Rennie's able little work on Botany. The essential part of a stamen is the anther, which has usually two chambers filled with a peculiar matter termed pollen, the fructifying principle of the plant. When the pollen arrives at maturity, it bursts from the cells of the anther, and sheds itself upon the summit of the pistil; either from the stamens being near it, or by the winds or insects, when they are at some distance on the same plants, as in the hazel; or on different plants, as in the hop. M. Lecoq, however, appears to have proved by experiment, that fertile seeds may be produced in the female hop-plant without the intervention of the male; and we have a similar example among animals in aphides, of which the hop-fly is a species.

The summit is well contrived for retaining the pollen that may fall upon it, from being without any rind to cover it, and in all cases moistened with a clammy fluid, which causes the grains of pollen to swell, burst, and discharge their minute granules. Some suppose that these are taken up by spongelets in the summit similar to those of the root, while others allege that the fluid matter in which the granules float is sucked up. It has been discovered that the grains of pollen, when shed on the summit, in a few hours shoot out one or more delicate tubes, which by some philosophers are supposed to extend down as far as the seed-organs, and to expand around and between the nascent seeds. Some believe them to convey thither the granules, which at least enter into the tubes; others, however, deny that this is the case. The seed-organ lies at the base of the pistil, and contains the seeds either nascent or advanced to maturity. It bears a very strong resemblance to the egg-organ of birds and insects, and its parts have accordingly received from naturalists the same scientific names. The seed-organ is usually of an egg-oblong form, and is always composed of an outer membrane, a middle membrane, and an inner membrane, all intimately united. As every seed derives its nourishment from the inner membrane, there must be a communicating point; and this point being always on the verge of the membrane, may be so termed; that on the seed being termed the seed-scar, but popularly, though improperly, named the eye. In some species the verge bears a number of smaller verges, to each of which a seed is attached, by what is named the navel-string by those who pursue animal analogies to extreme minuteness, but is better termed the verge-cord or seed-stalk. All these parts are obvious in an unripe pea or bean.

The verge of the seed-stalk sometimes occurs in the form of an expansion surrounding the seed in a greater or less degree, which has been mistaken for a part of the seed. It is this expansion in the nutmeg which forms the mace of commerce. The centre of the seed-organ is sometimes formed of a sort of support, round which the seeds are ranged, termed the pillar, and theoretically represented as consisting of several verges united in a whorl with a space between.

The structure of seeds is no less curious than that of the seed-organs. The regions of a seed are named from the position of the seed-scar, which is placed at the base; the point opposite, the tip; the upper part, the back; the opposite to that, the belly; and between, the two sides. In curved seeds, such as in mignionette, the base and the tip become opposite. The outer coat of the seed has been called the shell, and consists in most of a single membrane, which is fitted to protect the seeds, or most essential part, the kernel, from extremes of heat and cold. The embryo of a seed consists of four parts—the radicle, the seed-lobe or lobes, the neck, and the gemlet; all of which are important to be noticed in the progress of germination, and with regard to the foundation of modern systems. The radicle forms that extremity of the embryo from which the root springs in the progress of germination; and before, it is always simple and undivided, but afterwards it may divide into branching radicles, as in grasses and mistletoe. The radicle may be naked, or it may be enveloped in a sheath, or it may be incorporated with the seed-pulp, and upon these three distinctions Richard founded a system of classification. The seed-lobe is very various in form and in size; it may be divided, or it may not be divided, into lobes; upon this principle Jussieu founded his system. But it is inconsistent with this system that the lobes may be three, as in drooping cypress; five, as in larch; six, as in deciduous cypress; and even ten or twelve, as in pine fir. In some cases during germination the seed-lobes remain below ground, as in the horse chestnut, in others they appear above ground in the form of seed-leaves.

The neck is the point of junction of the root and the stem; when it is distinctly marked, it forms the crown of the radicle, and the base of the seed-lobe, and it is by the lengthening of the neck that the seed-lobes are raised above ground, as in the cabbage, radish, and mustard. The gemlet or plume is a small body, often formed like a feather, situated in the cavity between the seed-lobes, when there is but one, and between the lobes when there are but two. The number of sorts of seeds and fruits which various plants produce require to be methodically disposed in order, but the best arrangements are yet defective. Seed may be either close, or may be dehiscent, of both of which kinds of seeds there are several varieties. Fruits are considered by botanists as the ripened seed-organ, and, as every one knows, present almost endless varieties of appearance.

GERMINATION.

After the seed has been duly fecundated by the pollen, and then perfectly ripened, it must be kept from extreme degrees of heat or cold, else the proper evolution of a young plant will not take place. The external circumstances necessary to germination depend on water, heat, and air, and, as connected with these, on soil and situation. The time required for germination varies much in different species; thus mustard takes little more than one day, whilst the rose, the hazel, &c. require two years. When a seed begins to germinate, it enlarges until it bursts its shell. Whenever the embryo begins to grow, it is termed the plantlet, and consists of two parts, one descending and the other ascending; the first being the embryo root, the second the embryo stem. As soon as the embryo stem or gemlet has reached the open air, its leaflets are expanded, and begin to perform all the functions of leaves.

There are two grand classes of seeds, those having only one seed-lobe, and those having two or more seed-lobes; and each class germinates after a certain manner. Wheat may be taken as an instance of the first, and the pea of the second; but for a detail of these we must refer to larger works upon the subject. The various opinions entertained relative to the growth of a plant may all be referred to three general heads. 1. That growth in diameter is carried on by the annual change of the inner bark into pulp wood, and of pulp wood into hard wood, and by the successive renewal of the inner bark. 2. That the successive formation of the layers of wood is produced by the evolving of buds. 3. That the annual formation of woody layers is owing to the pulp, which every year forms at one and the same time a new layer of pulp wood, and a new layer of inner bark. There is a great difference amongst plants with regard to the age at which they arrive. There are some which live only a few hours, or at most a few days, whilst some trees exist many centuries.

An important part of the subject remains to be discussed, namely, the classification of plants, or the arrangement of the numerous species in some regular order. Many schemes or systems have been as various times in use to facilitate the acquisition of knowledge respecting the varieties of the vegetable kingdom, and these have been successively abandoned, as insufficient, after new species were discovered which required classification. Two systems, however, at present prevail—that of the great Linnæus, which is called the sexual or artificial system, and that of Jussieu, which is denominated the natural system. Neither of these fully answer the purposes for which they were propounded, but we shall give a brief view of each.

SYSTEM OF LINNÆUS.

The basis of the Linnæan distribution of plants rests almost entirely on the male organs or stamens; and where no sexes could be distinguished, the author termed the plants Cryptogamous; and the class including such, the last of his arrangement, Cryptogamia. The other classes, which amount to twenty-three in number, are called Phanerogamous vegetables. Some of them have the flowers hermaphrodite, or containing both sexes; others have them separate, or are declinous. To the former belong twenty classes, to the latter three. Again, hermaphrodite or bisexual flowers may have the stamens either free from the pistillum or united to it; and hence arises another division: only one class, however, belongs to the last; so that there are nineteen to the first. These nineteen are farther divisible according as the stamens are free from each other or united together. The former may be equal or unequal in length; and those again which are equal may either be definite or indefinite in number. The classes are divided into orders, each class consisting of two or more, and these orders are determined by the pistils. The botanist has merely to count the stamens to find what class it belongs to, and to count the pistils to know the division of the class where it is placed. Unfortunately for the perfection of this system, all plants have not been formed upon this principle, but it holds in a very considerable number. Professor Rennie gives the following outline from Lamouroux, as a

First Linnæan Lesson.

When a plant in flower is found, it must furnish an answer to one of the following questions:—

		Class
I. Has it stamens and pistils?	No.—Then it belongs to	24
	Yes.—Then see question II.	
II. Are the flowers with only stamens, or only pistils, and also with both stamens and pistils?	Yes.—Then it belongs to	23
	No.—Flowers with only stamens on one plant, and flowers with only pistils on another, belong to .	22
	Flowers severally with only stamens, or only pistils on different parts of the same plant, belong to . .	21
	Flowers with both stamens and pistils included in the same flower, see question III.	
III. Do the stamens adhere to the pistil?	Yes.—Then it belongs to	20
	No.—Then see question IV.	
IV. Are the stamens united by the anthers?	Yes.—Then it belongs to	19
	No.—Then see question V.	
V. Are the stamens united by the filaments?	Yes.—In more than two bundles, it belongs to	18
	In only two bundles, it belongs to	17
	In only one bundle, it belongs to	16
	No.—Then see question VI.	
VI. Are there only six stamens, four being longer than the others?	Yes.—Then it belongs to	15
	No.—Then see question VII.	
VII. Are there only four stamens, two being longer than the others?	Yes.—Then it belongs to	14
	No.—Then see question VIII.	
VIII. Are the stamens more than 12?	Yes.—Inserted upon the receptacle, it belongs to	13
	Inserted upon the flower-cup, it belongs to .	12
IX. How many stamens are there under thirteen?	Twelve.—Then it belongs to	11
	Ten.—Then it belongs to	10
	Nine.—Then it belongs to	9
	Eight.—Then it belongs to	8
	Seven.—Then it belongs to	7
	Six.—Then it belongs to	6
	Five.—Then it belongs to	5
	Four.—Then it belongs to	4
	Three.—Then it belongs to	3
	Two.—Then it belongs to	2
	One.—Then it belongs to	1

The following presents a view of the various classes, with their technical names; and although part of what is stated above be repeated, it will serve in this tabular form to give a clearer view of the classification:—

1. MONANDRIA, with 1 stamen, ...	*Ginger.*
2. DIANDRIA, — 2 —	*Olive.*
3. TRIANDRIA, — 3 —	*Valerian.*
4. TETRANDRIA, — 4 —	*Holly.*
5. PENTANDRIA, — 5 —	*Nightshade.*
6. HEXANDRIA, — 6 —	*Snowdrop.*
7. HEPTANDRIA, — 7 —	*Chestnut.*
8. OCTANDRIA, — 8 —	*Spurge Laurel.*
9. ENNEANDRIA, — 9 —	*Rhubarb.*
10. DECANDRIA, — 10 —	*Senna.*
11. DODECANDRIA, — 11 to 19	*Asarabacca.*
12. ICOSANDRIA—20 or more stamens inserted into the calyx (perigynous), . .	*Sweet Almond.*
13. POLYANDRIA—20 or more stamens inserted under the ovary (hypogynous), . .	*Opium Poppy.*
14. DIDYNAMIA—4 stamens, 2 long and 2 short, ...	*Purple Foxglove.*
15. TETRADYNAMIA—6 stamens, 4 long and 2 short, ...	*Scurvy-grass.*
16. MONADELPHIA—stamens united in 1 fasciculus or tube, ...	*Marsh Mallow.*
17. DIADELPHIA—stamens united in 2 fasciculi, ...	*Broom.*
18. POLYADELPHIA—stamens united in 3 or more fasciculi, ...	*Orange.*
19. SYNGENESIA—anthers united,	*Chamomile.*
20. GYNANDRIA—stamen and pistil united,	*Snake-root.*
21. MONŒCIA—unisexual flowers growing on the same plant, ...	*Oak.*
22. DIŒCIA—the male and the female flowers growing on different plants, . .	*Hop.*
23. POLYGAMIA—hermaphrodite, male, and female plants, growing on the same plant or on separate plants, ...	*Fig.*
24. CRYPTOGAMIA—flowerless plants,	*Iceland Moss*

The second Linnæan lesson of Lamouroux, by which the orders are determined, proceeds thus:—

Flowers with stamens of a fixed number, and equal in length

FIRST CLASS, or Monandria, having one stamen.—If they have one pistil, they are of the first order, or Monogynia; if two pistils, they are of the second order, or Digynia.

SECOND CLASS, or Diandria, having two stamens.—If they have one pistil, they are of the first order, or Monogynia; if they have two pistils, they are of the second order, or Digynia; and if three, they are of the third order, or Trigynia.

THIRD CLASS, or Triandria, having flowers with only three stamens.—If they have one pistil, they are of the first order; if two, they are of the second order; and if three, of the third order.

FOURTH CLASS, or Tetrandria, having flowers with only four stamens equal in length.—If they have one pistil, they are of the first order; if two, of the second; three, of the third; and if four, of the fourth order, or Tetragynia.

FIFTH CLASS, or Pentandria, having flowers with only five stamens.—Those having from one to four pistils are named as in the preceding classes; those having five pistils belong to the fifth order, or Pentagynia; and if they have many pistils, to the sixth order, or Polygynia.

SIXTH CLASS, or Hexandria, having flowers with six stamens.—As they have one, two, or three pistils, they belong to the first, second, or third orders; if they have six pistils, to the fourth order; and if many pistils, to the fifth order.

SEVENTH CLASS, or Heptandria, those having only seven stamens.—If they have one or two pistils, they are classed as before; if four pistils, they belong to the third order; and if seven pistils, to the fourth order.

EIGHTH CLASS, or Octandria, having flowers with only eight stamens. If they possess from one to four pistils, they rank in the order corresponding to the number.

NINTH CLASS, or Enneandria, those having only nine stamens. If they have one pistil, they belong to the first order; if three, to the second; and if six, to the third.

TENTH CLASS, or Decandria, having only ten stamens.—If they have one, two, or three pistils, they belong to the first, second, or third orders; if five, to the fourth; and if ten, to the fifth order.

Flowers with stamens of rather uncertain number, but of fixed insertion.

ELEVENTH CLASS, or Dodecandria, having flowers with from eleven to nineteen stamens inserted into the receptacle.—If they have from one to five pistils, they belong to the orders corresponding to these numbers; and if they have about twelve pistils, they belong to the sixth order.

TWELFTH CLASS, or Icosandria, having flowers with twenty or more stamens inserted into the flower-cup or the blossom.—If they have one, two, or three pistils, they belong to the first, second, or third orders; if five, to the fourth order; and if many pistils, to the fifth order.

THIRTEENTH CLASS, or Polyandria, those having flowers with from twenty to one hundred stamens inserted into the receptacle.—If they have from one to six pistils, they are classed as before; if they have many pistils, they belong to the seventh order.

Flowers with two of the stamens shorter.

FOURTEENTH CLASS, or Didynamia, having flowers with four stamens, two longer and two shorter, inserted on a one-petalled blossom.—If the four seeds appear not to be in a seed-vessel, they belong to the first order, or Gymnospermia; but if they appear to be concealed in a seed-organ, they belong to the second order, or Angiospermia.

FIFTEENTH CLASS, or Tetradynamia, having flowers with six stamens, four longer and two shorter, the blossom with more petals than one.—If the seed-organ is a short pod, they belong to the first order, or Siliculosa; and if a long round pod, to the second order, or Siliquosa.

Flowers with stamens united by their filaments.

SIXTEENTH CLASS, or Monadelphia, having flowers with the filaments of all the stamens united at the base into one bundle.—If there are three stamens, they belong to the first order, Triandria; if five stamens, to the second order, Pentandria; if seven stamens, to the third order, Heptandria; if eight stamens, to the fourth order, Octandria; if ten stamens, to the fifth order, Decandria; if eleven stamens, to the sixth order, Endecandria; if from twelve to twenty stamens, to the seventh order, Dodecandria; and if more than twenty stamens, to the eighth order, Polyandria.

SEVENTEENTH CLASS, or Diadelphia, having flowers with the filaments of all the stamens united into two bundles. If they have five stamens, they belong to the first order, Pentandria; if six stamens, to the second order, Hexandria; if eight stamens, to the third order, Octandria; and if ten stamens, to the fourth order, Decandria.

EIGHTEENTH CLASS, or Polyadelphia, having flowers with the filaments of all the stamens united into three or more bundles. If there are from twelve to twenty-five stamens unconnected with the flower-cup, they belong to the first order, Dodecandria; if the bundled stamens are inserted in the cup, to the second order, Icosandria; and if there are more than twenty-five stamens unconnected with the flower-cup, to the third order, Polyandria.

Flowers with stamens united by their anthers.

NINETEENTH CLASS, or Heptandria, having flowers composite, with all the anthers in a floret united into a tube, whilst their filaments are not united. If all the florets are equal, they belong to the first order, Polygamia æqualis; if the florets of the circumference have pistils without stamens, to the second order, Polygamia superflua; if the florets of the circumference have neither florets nor pistils, to the third order, Polygamia frustranea; if the florets of the circumference have pistils without stamens, and those of the centre stamens without pistils, to the fourth order, Polygamia necessaria; and if the florets have a partial flower-cup all within a general flower-cup, to the fifth order, Polygamia segregata.

Flowers with the stamens and pistils united.

TWENTIETH CLASS, or Gynandria, having flowers with the stamens inserted upon the style or seed-organ. If they have one stamen, they belong to the first order, Monandria; if two stamens, to the second order, Diandria; if three stamens, to the third order, Triandria; if four stamens, to the fourth order, Tetrandria; if five stamens, to the fifth order, Pentandria; if six stamens, to the sixth order, Hexandria; and if eight stamens, to the eighth order, Octandria.

Flowers of only one sex.

TWENTY-FIRST CLASS, or Monœcia, having flowers, some with pistils only, and some with stamens only, on the same plant. There are nine orders, taken from the number and bundling of the stamens as before.

TWENTY-SECOND CLASS, or Diœcia, having flowers with pistils only, or with stamens only, on two separate plants of the same species. There are nine orders founded as in the preceding class.

TWENTY-THIRD CLASS, or Polygamia, having flowers with both stamens and pistils, and also with only one of these, both on the same and on separate plants of the same species. There are three orders.

No flowers apparent on the plants.

TWENTY-FOURTH CLASS, or Cryptogamia. Stamens and pistils, if present, cannot, from being very minute, be ascertained. The class contains five orders, ferns, filices; mosses, musci; liverworts, hepaticæ; seaweeds, algæ; and mushrooms, fungi.

Such is a plain view of the Linnæan system of classification. It is certainly imperfect; for instance, in the twenty-fourth class, it fails altogether in assisting the student. But it does not seem to be less so than the natural system, which, however, is rapidly gaining ground in Britain, and is very generally followed up on the Continent. We shall now present a brief view of it also.

JUSSIEU'S CLASSIFICATION, OR THE NATURAL SYSTEM.

The author of this system, viewing the seed of a plant as a more important organ than the stamens and pistils, devised a classification which takes its leading divisions from the seed-lobes. His system has been variously altered and improved; and although in many instances the plants are more congruously associated together in it than they are in the other system, yet it is also still imperfect. In the first lesson on Jussieu's system, the learner procures the seed, and examines the seed-lobes, when an answer to the following questions must be furnished:—

1. Has it any seed-lobes? { No.—Then it belongs to division I. / Yes.—Then see question 2.

2. How many seed-lobes has it? { One.—Then it belongs to II. / Two or more.—Then it belongs to . . III.

Or if the seed cannot be found, the stem or the leaves must furnish answers to the following questions:—

1. Are there any sap and pulp vessels? { No.—Then it belongs to division . . I. / Yes.—Then see question 2.

2. Is the stem tapering upwards, covered with bark, and the wood softer on the exterior than in the interior? { No.—Then it belongs to I. / Yes.—Then it belongs to . . . . III.

De Candolle terms the first class Cellular (Cellulares), because the plants have cells but no vessels, and the two others Vascular (Vasculares), because they have both vessels and cells. The vascular plants he again divides into ingrowing (Endogens), and outgrowing (Exogens). After a knowledge of these three great divisions is acquired, the beginner then commences with the fifteen classes and their orders.

Plants without seed-lobes, or sap and pulp vessels.

FIRST CLASS, or Acotyledones. The seed when it can be discovered is simple and without parts.—There are ten orders—sea-weeds, mushrooms, &c.

Seeds with one seed-lobe; Plants with sap and pulp vessels (Monocotyledones).

SECOND CLASS, or Monohypogynæ. Flowers with the stamens inserted under the seed-organ.—There are seven orders—pond-weeds, grasses, &c.

THIRD CLASS, or Monoperigynæ. Flowers with the stamens inserted around the seed-organ.—There are ten orders—palms, rushes, &c.

FOURTH CLASS, or Monoepigynæ. Flowers with the stamens inserted above the seed-organ.—There are ten orders—black bryonies, gingers, &c.

Seeds with two or more seed-lobes (Dicotyledones).

Without Petals, or Apetalæ.—FIFTH CLASS, or Epistamineæ. Flowers with the stamens inserted above the seed-organ.—There are three orders—asarabaccas, cytini, and santali.

SIXTH CLASS, or Peristamineæ. Flowers with the stamens inserted around the seed-organ.—There are seven orders—eleagni, laurels, &c.

SEVENTH CLASS, Hypostamineæ. Flowers with the stamens inserted below the seed-organ.—There are two orders—amaranths and marvel of Peru.

With one-petalled blossoms (Monopetalæ).

EIGHTH CLASS, or Hypocorolleæ. Flowers with the petal inserted below the seed-organ.—There are twenty-one orders—plantains, primroses, &c.

NINTH CLASS, or Pericorolleæ. Flowers with the petal inserted around the seed-organ.—There are four orders—heaths, &c.

TENTH CLASS, or Epicorolleæ synantheræ. Flowers with the petal inserted above the seed-organ and the anther united.—There are two orders—chicories and boopidias.

ELEVENTH CLASS, or Epicorolleæ corisantheræ. Flowers with the petal inserted above the seed-organ, and the anthers not united.—There are five orders—woodbines, teasles, &c.

With many-petalled blossoms (Polypetaleæ.)

TWELFTH CLASS, or Epipetaleæ. Flowers with the stamens inserted above the seed-organ.—There are three orders—rhizophoras, &c.

THIRTEENTH CLASS, or Hypopetaleæ. Flowers with the stamens inserted below the seed-organ.—There are thirty-nine orders—ranunculi, rues, &c.

FOURTEENTH CLASS, or Peripetaleæ. Flowers with the stamens inserted around the seed-organ.—There are twenty-six orders—rupturesworts, gourds, &c.

With the stamens and pistils in separate flowers.

FIFTEENTH CLASS, or Diclineæ. Flowers without petals.—There are eight orders—spurges, nettles, &c.

DISTRIBUTION OF PLANTS OVER THE GLOBE.

Almost every region of the globe has its own peculiar vegetables, and these are so suited to the climate, soil, and height at which they flourish, as in most instances not to bear a change, without the fostering care and art of man. Fortunately, however, from a careful provision of nature, those vegetables which are most necessary as the food of man will be found to bear a variety of climate better than most others; this is the case with the various kinds of greens, carrots, the grains, and that invaluable article of food, the potato. Altitude, or the height above the sea at which plants grow, has an effect somewhat similar to the heat and cold of climate; and thus we find, in some of the high mountains of the tropical regions, that a beautiful succession of vegetation takes place from their bases to the summit. Thus, below, where the heat is greatest, plants of warm climates prevail; as we ascend to the middle regions, those of a temperate climate grow and flourish; and towards the top, plants only fit for a frozen clime make a partial appearance, till at last we gain a point of ever-during snow and frost, where no vegetable product dare raise its tender head. In warm climates the profusion of vegetation is much more abundant than in cold; thus, within the arctic circle, or region of the pole, only a few flowering species of plants are to be found, although the number of mosses is considerable; whereas, in the warm regions of the West Indies, in Madagascar, and the coast of Coromandel, one botanist alone enumerates from four to five thousand different kinds of plants. In warm moist climates, too, the progress of vegetation is amazingly rapid, and it is no unusual thing for reeds and palm-plants to shoot up 12 inches in 24 hours. By cultivation, and the arts of agriculture, vegetables are greatly improved, and rendered more suitable to the uses of man, and in some instances their natures are altogether changed. According to Buffon, our common wheat is an artificial production, improved to its present state by the assiduous cultivation of man; and it is most likely that rice, rye, barley, and oats, were originally but insignificant grasses, till improved by cultivation, for we nowhere meet with any of these grains vegetating in a state of nature. Thus, too, the common garden celery, which in its original state is an acrid poisonous plant, is converted by blanching into an agreeable and healthy salad. The colewort in its natural state, a plant with very scanty leaves, has been reared, by cultivation, into the different kinds of cabbages, cauliflowers, broccoli, &c. Potatoes have no doubt undergone great improvements in quality since first made known as an eatable root, and the engrafting of fruit-trees has already been spoken of. One great means of the improvement of vegetables seems to be the frequent changing of the soil in which they grow. All vegetables more or less exhaust the soil of the peculiar nourishment which they require; thus, if wheat be sown for two or three years in the same field, it will degenerate so as to be of no value as a grain; and it is the same with almost any other vegetable product. On the contrary, when changed into a well-prepared and richly-manured soil, every vegetable improves greatly in quality and size, and in the vigour of its growth.

DISEASES OF PLANTS.

Vegetables being organised substances, are, like animals, liable to various kinds of disease. This proceeds from a vitiated state of their juices, from a derangement of the minute structure of their porous organs, from the variations of the atmosphere, the attacks of minute animals, and other parasitic plants fixing on them and absorbing their proper juices. Blight is a disease brought on extensively in growing fields, or supposed to arise from a particular state of the air; perhaps it is mainly owing to its electric condition. It generally occurs about the end of July, in hot sunny weather, and after a shower. Fields of wheat, hop plantations, &c. are often blasted by it; sometimes only a part suffering, while at other times a whole field is destroyed. A kind of minute *fungus* is often found attacking the leaves and stems of our grasses and grains, such as wheat, barley, and oats. It is in appearance a brownish-looking powder: hence the appellation of rust given it by agriculturists. Upon close inspection it will be found to consist of thousands of minute globules, arranged in groups below the skin or covering of the plant. Sir Joseph Banks ascertained them to be a kind of fungus, or minute moss-plant, the seeds of which, floating about in the air, enter the pores of the leaf, especially if the plant is sickly; or they may exist in the soil or the manure, and may be taken up by the absorbent vessels of the roots. There is another kind of fungus, called the red gum, which attacks the ear of the plant, and of course is much more destructive than the former. *Smut* is a disease which attacks the seed or grain itself, converting it into a black substance like soot; and this also is supposed to be a minute fungus, or some diseased condition of the farina or mealy part of the seed. Minute animalcules and worms produced from flies also infest the grain crops in particular seasons; and many plants are preyed upon by myriads of a small insect, the *aphis*, or plant-louse, which, piercing the skin of the plant, extracts its nourishing juices. There are also mildew and honeydew, attacking the leaves of trees and vegetables, coating their surface with a thin whitish covering. A dropsy of plants also occurs from too great a profusion of juices, and this particularly happens in bulbous-rooted plants. Another similarity that plants have to animals is the power of renewing lost substances, and of entirely renovating parts of their structure. Thus, when a cut or wound is made in the bark of a tree, it is speedily filled up with new matter, and the edges completely closed up and reunited in a very short period; and the periodical decay and reproduction of leaves, and buds, and blossoms, are well-known operations of nature, thereby affording perpetual variety, and renewed freshness and beauty. When trees are entirely deprived of their bark, they immediately die; they will bear large pieces to be stripped off lengthwise; but if a complete circle be cut in the bark round the trunk, it is destructive of vegetable life.

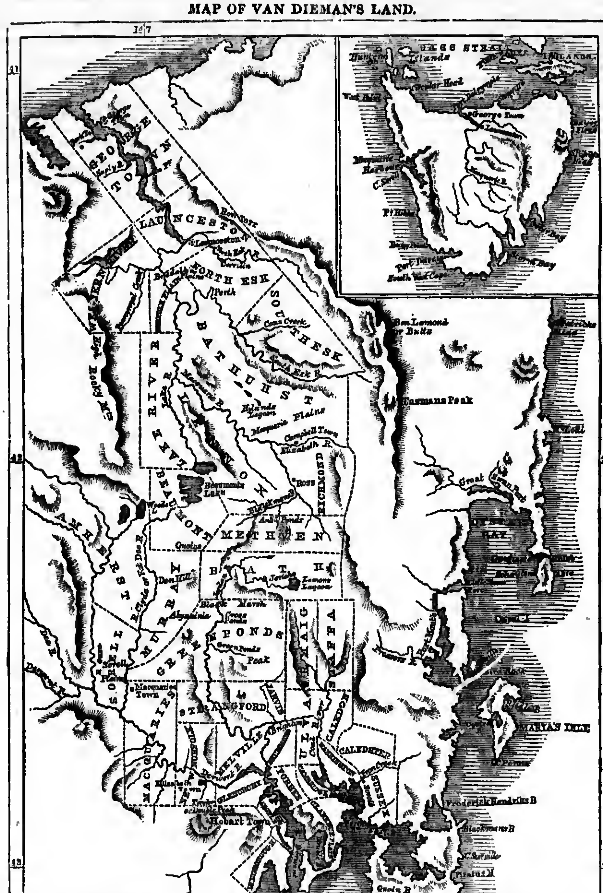
EMIGRATION TO VAN DIEMAN'S LAND.

MAP OF VAN DIEMAN'S LAND.



GEOGRAPHICAL POSITION AND GENERAL HISTORY.

This island, which, from its extreme remoteness alone, furnishes us with a remarkable instance, amongst many others, of the restless and daring spirit of British enterprise, is situated in the Southern Ocean, and is the first land of any extent, some very small islands only intervening, which occurs on the outward voyage after rounding the Cape of Good Hope. It is situated between lat. 41° and 44° south, and between long. 164° 40′ and 148° 20′ east of Greenwich. The length of the island is about 210 miles, and its breadth 150. It is thus about 34 miles less in length than Scotland, and about three miles more in breadth, and is therefore altogether considerably less in size. It is separated from New Holland by a strait of about 100 miles in breadth, the island lying this distance south of the most southern point of the former. The strait alluded to is called Bass's Strait, in honour of its discoverer Dr Bass, who, in the year 1797, first ascertained that Van Dieman's Land was an island, and that it was separated from New Holland by the channel which now bears his name. Previous to this it had always been considered as a part of the former, and was so laid down in all maps and charts.*

The island itself was first discovered in the year 1642, by Abel Jansen Tasman, a Dutchman, and was by him called Van Dieman's Land, in honour of Anthony Van Dieman, at that time governor-general of the Dutch possessions in the East Indies. Nothing, however, immediately resulted from this discovery, and for upwards of a hundred years the island was again lost sight of. In 1773, it was visited by Captain Furneau, the first English navigator who had ever touched at it; after this it was visited from time to time by several celebrated navigators, and amongst those by Captain Cook, in the year 1777. It was not, however, until 1803, that any settlement was made upon the island; in that year, it was formally taken possession of by Lieutenant Bowers, as a receptacle for convicts, with a party from Port Jackson, in New South Wales, where a penal establishment had been already fixed; and to this purpose Van Dieman's Land was exclusively devoted until the year 1819, when it was thrown open to free settlers. It is thus only since the very recent period just named that it has exhibited the character of a colony. Its progress, however, has been since then extremely rapid. With a feeling which does credit to the colonists of this island, as well as those of New South Wales, there is a strong disposition with both to call the island Tasmania, in honour of its first discoverer Tasman, in place of Van Dieman's Land, the name of its adopted godfather. Tasmania, therefore, is the favourite name by which the island is recognised, as well by its own inhabitants as by those of the adjoining land of New Holland.

GENERAL DESCRIPTION.

Van Dieman's Land has an exceedingly picturesque and beautiful appearance from the sea, presenting an endless succession of lofty mountains, covered to their summits with wood; while tall rocks and precipices, glens and hills, contribute to increase the interest of this romantic island. Nor does a nearer inspection materially alter this general character of the scene.

On traversing the island, it is found to present a constant alternation of hill and dale, with occasional flats or plains; but these are comparatively few in number, though some of them are of great extent, consisting in several instances of not less than from 8000 to 10,000 acres, and one in particular is said to be six miles in length, and from two to three in breadth. These plains are in general exceedingly fertile, and being often but thinly interspersed with trees, present a most delightful appearance. There are some of them again, however, very poor, presenting a cold thin soil, of little value.

Van Dieman's Land, though it cannot be called a well-watered country, is yet much superior in that respect to New South Wales. Besides several extensive lakes scattered throughout the interior, it possesses a considerable number of rivers; and in almost every district of the island water is to be found. The names of the two largest rivers are the Derwent and the Tamar.

In another important particular, this island is peculiarly fortunate, that is, in the number and capacity of its harbours, no place of similar extent in the world probably being equal to it in this respect. The principal of these are, the Derwent on its southern side, Port Davey and Macquarrie Harbour on the western, Port Sorrel and Port Dalrymple on the northern, and Oyster Bay and Great Swan Port on the eastern coast. Besides these, there are many other harbours, bays, and creeks, distributed all alongst its shores. The coast is in general high and rocky, particularly on the south, east, and western sides of the island; on the north, however, it presents a line of low alternate sandy beaches, on which the surf rolls with great impetuosity during the prevalence of northerly winds. From the extremely hilly nature of the country, there is but a comparatively small proportion of it adapted for the plough, though presenting abundance of excellent pasturage. The extent of really available land throughout the known part of the island, has been

* Besides the authorities consulted in the composition of the paper on New South Wales, we have been indebted for facts for the present article to a variety of colonial newspapers; the Van Dieman's Land Almanacks for 1830-31-32; Evans' Description of Van Dieman's Land, &c., as well as official documents.

estimated at one-third of the whole, and this again divided into four parts, giving one for the plough, and the other three for pasture: thus, out of 1000 acres of land, about 100 will be found fit for cultivation, and from 300 to 400 for grazing. This is, of course, a rough estimate, and will be found not to hold good in many instances, but in general we believe it will not be far from the truth.

CLIMATE, SOIL, AND NATURAL PRODUCTIONS.

The climate of Van Dieman's Land is exceedingly pleasant and salubrious, and is especially adapted to the constitutions of the natives of Great Britain; the heat in summer is not so intense as that of New South Wales, not often much surpassing that of London or the southern parts of England; while the mornings and evenings, even at the hottest periods of the year, are always cool and agreeable. The cold in winter, however, though mild when compared to what we experience at that season, is more intense and of longer duration than that of the neighbouring land, snow lying frequently on the higher mountains throughout the greater part of the year; but in the vallies and lower districts it seldom remains more than a few hours. There have not yet appeared any diseases which can be said to be peculiar either to the climate or to the island, and, on the whole, the chances of life are estimated to be considerably more in favour of Van Dieman's Land than of Britain, or any other of the most healthy parts of Europe. It is not subject to any extremes of heat or cold: the seasons are regular, mild, and agreeable; the atmosphere constantly pure and elastic; and the sky clear, unclouded, and brilliant. The average number of days on which rain falls throughout the year, is from 50 to 60. The soil of this island, generally speaking, presents a diversity equal to that of New South Wales, but, on the whole, there is a much less proportion of indifferent soil in the former than in the latter, and it is probably less encumbered with trees and brushwood. Such tracts of land as are good, are invariably of the very best description. The land of this kind in Van Dieman's Land has been represented, or at least spoken of, on the one hand, in such terms as might lead us to suppose that it was of unequalled fertility, and on the other as if it were worth nothing at all; but the truth appears to be, that it is neither the one nor the other—neither remarkably productive nor the reverse, but is in this particular much about what we are accustomed to at home. As might be expected, this mild and delightful climate is exceedingly favourable to vegetation, producing a constant verdure and the most luxuriant herbage on its plains and undulating hills, and exhibiting frequent instances of vegetable growth altogether unknown in less favoured regions, and almost surpassing belief. Trees are here found measuring 63 feet in circumference, and often stretching up to the height of 180 feet before throwing out a single branch; but it is remarkable, that with all this extraordinary power of vegetation, this universal activity of vegetable life, there is not one natural production of the island which affords the smallest subsistence to man. There is little variety in the description of its trees, the whole of them being nearly of one sort: all tall, straight, and branching only at the top—a circumstance which gives to the forests a peculiarly solemn, but not unpleasing, character. The bark of the trees is in general of so white a complexion as to give them the appearance of having been peeled, and their leaves are long, narrow, and pointed. The tropical productions which attain such perfection in New South Wales, do not thrive here, in consequence of the greater degree of coldness which prevails; but all the vegetables and fruits known and cultivated in England and Scotland, are raised without difficulty: apples, pears, plums, gooseberries, &c., to which the warmer temperature of New South Wales is unfavourable, are produced here in great abundance, and of excellent quality. Both the climate and soil are sufficiently favourable to the production of most descriptions of grain; wheat is found to thrive remarkably well; potatoes are in general a good crop, and of good quality. The island is altogether, in short, fit for all the purposes of agriculture aimed at in this country, being neither more nor less favourable to them, but in all respects nearly the same; its climate being ours, only somewhat modified, and its soil in general not materially differing in quality. Its animal productions are nearly the same with those of New South Wales, consisting of the kangaroo, opossum, squirrel, &c. The native dog, however, so well known in the former country, is not to be found here; but in its place there is an animal of the panther tribe, which, though it flies from man with the timidity of a hare, is yet extremely destructive to the flocks of the settlers, amongst which it frequently commits the most dreadful havoc. This animal attains considerable size, having been found in many instances to measure six feet from the snout to the extremity of the tail. The birds of Van Dieman's Land are the emu, or Australian ostrich, parrot, cockatoos, herons, swans, pelicans, &c. There are here, too, a considerable number and variety of poisonous reptiles, but these, on the whole, are neither so numerous nor so venomous as in the sister colony.

The seas around Van Dieman's Land abound with whales, dolphins, and seals, and its shores with shell-fish, particularly the mussel, these last literally covering the rocks on its coast, and in its bays, creeks, and harbours.

There is one remarkable circumstance attending almost all the Australian and Van Dieman's Land quadrupeds, which deserves to be noticed, because it distinguishes them from all other animals on the face of the globe. This is their being provided with bags, or pouches, on their bellies, in which they carry their young. It is not yet known how the latter get there at the first stage of their existence—every inquiry which has yet been made into the subject having failed to discover any channel of communication between the interior parts of the animal and the pouch—but it is certain that there they are found immediately after they have begun to exist, and that there they continue until they have attained sufficient maturity to shift for themselves. The parent animal has a nipple within the pouch, from which the young one draws its nourishment in the usual way; and, when somewhat advanced, it is an amusing and interesting spectacle to see the creature leaping out of and into this bag, as its humour or any alarm prompts it; nor is it less amusing to see it peeping out of the pouch, with a look expressive at once of curiosity, and a feeling of safety and comfort. It is pretty well known that this peculiarity belongs to the kangaroo, many of which have been exhibited in this country, but it is by no means confined to them: with very few exceptions, the young of every quadruped in that quarter of the world is brought up in the same way, the mothers having all pouches. The wonders in the vegetable world, in this region of the earth, are not less remarkable than those of the animal. We have already spoken of the prodigious size to which its trees attain; they have also the singular peculiarity of those of New South Wales, of being nearly all evergreens, few of them shedding their leaves, as ours do, once a-year; the consequence is, that they want that freshness which belongs to the latter, and are incapable of presenting the pleasing process of renovation so delightful in our spring, and which is scarcely compensated by their immunity from decay. In this land of contradictions, wher our cold winds are their best, our nights their days, our summer their winter, where their swans are black, and where nettles grow to the size and assume the shape of trees, we find its pears composed entirely of wood, and its cherries growing with the stones on the outside; the first are of course uneatable, being nothing better than the wooden imitations of that fruit, made for curiosity or ornament in this country; their stalks, too, as if nature took a pleasure in reversing here, in every particular, her own laws, grow from the broad end. This fruit, if it can be so called, has nevertheless a tempting appearance on the tree, and it is not until you have bitten it, or applied a knife to it, that you discover the deception.

The ornithology of this singular country, too, presents us with some curious deviations from the ordinary laws of nature: here is a bird without feathers or wings, and as tall as a man; these are the emus: they are of immense size, and are covered over with a coating of a substance between hair and feathers, but neither absolutely the one nor the other; they are provided with two short flaps instead of wings: these are incapable of lifting them from the ground, but enable the animal to run with amazing speed. The emus afford excellent pastime by hunting them, but are not easily approached, as they readily take alarm, and go over the ground with a rapidity which a horse cannot always equal. Their hind-quarters, often as much as a man can carry, is the only part of the emus that is eaten, but their eggs are reckoned delicious. These are, as might be expected from so large an animal, of great size; they are of a beautiful dark-green colour, and the shell is strong enough to admit of its being converted into a drinking-cup. This species of food is in great request by the natives, who live upon them almost exclusively at the season when they are to be had. With all the variety of birds, however, which Van Dieman's Land possesses, and the splendour of the plumage in which they are decked, there are few "wood-notes wild" to be heard amongst them—none of the music of the English groves. Few of the birds here sing, and those who do are not very melodious.

ABORIGINES, OR NATIVE INHABITANTS.

The natives of Van Dieman's Land are in complexion perfectly black; their hair is woolly, with flat features, and remarkably thin limbs; altogether, they are an exceedingly ugly race. They wear no covering of any sort, nor do they erect any huts or dwellings, but live wholly in the woods, with as little dependence on and seeking as little aid from mechanical contrivances as the beasts of the forest. They have no rites or ceremonies, either religious or otherwise, of any description, but are in every respect exactly in the same condition in which nature first placed them—affording perhaps as striking a specimen of man in the opposite extreme to that of his civilized state as the world can produce. Their numbers in the whole island are not thought to exceed 2000. All attempts to induce them to leave their native woods, and to mingle in a friendly manner with the colonists, have been yet more decidedly ineffectual than in the case of the natives of New South Wales; and no part of the internal policy of the island has been found more puzzling than that which relates to the aborigines. Hovering around the settled districts, they committed, from time to time, the most shocking atrocities, firing houses and corn-ricks, and frequently murdering the proprietors or their servants. This hostility, however, on the part of the blacks, was not without adequate provocation. The male native was shot without mercy by the settler, and the female, when taken, met but too often with the most infamous treatment at the hands of her brutal captors: mothers were torn from their children, and fathers were murdered before the eyes of both; while the whole were hunted from place to place with the most savage and unrelenting ferocity. The wretched native, then, had—we say had, because there now appears to be a better understanding between the two parties—a sufficient apology for the crimes which he committed; but as this state of matters could not be permitted to continue, it was necessary to fall upon some method of putting an end to it. One of the methods adopted was to drive the blacks into a particular corner of the island by a simultaneous movement of the whites. 4000 of the colonists volunteered their services on this occasion, and, together with the whole of the military on the island, proceeded to carry the design into execution. After keeping the field, however, for upwards of two months, and enduring in that time much privation and fatigue, the scheme was found to be impracticable, and was in consequence abandoned. Rewards were also offered for the capture of hostile blacks—L.5 for every adult, and L.2 for each child that should be taken, and delivered alive at any of the public establishments. Some late indications, however, of a better temper on the part of the natives, have induced the colonial government to withdraw this offer. The reason is thus announced in the Hobart Town Gazette of 8th June 1832, "that the present tranquil state of the colony has rendered it unnecessary longer to hold out any pecuniary reward for the capture of the aborigines."

Though sufficiently savage in their nature as well as habits, the natives of Van Dieman's Land are but a weakly race, possessing very little physical strength, and still less personal courage. Their intellectual powers, however, are not at all of so mean an order as might be expected from their condition and appearance—many of them have discovered an acuteness of sense and a quickness of perception which are not often to be met with amongst their civilized brethren. Their principal food is the kangaroo and opossum, but they readily eat any other native animal they can lay hold of. They merely warm the flesh on a fire, then devour it with the most savage eagerness. Their arms are the spear and waddy, a short club, both of which they use, it is said, with great dexterity. The spear, as with the natives of New South Wales, is merely a pole reduced to a sharp point at one end.

Although the unhappy natives of Van Dieman's Land have received much cruel treatment at the hands of some of the settlers and their servants, it is but justice to say that it has been far otherwise on the part of the colonial government, all of whose orders regarding them breathe a spirit of the utmost humanity and forbearance. The colonists are strictly enjoined, not only to refrain from offering them the slightest violence, but to treat them on all occasions, excepting of course when they come with hostile intentions, with kindness and gentleness, and on no account, but in the last extremity, to have recourse to fire-arms, either in capturing or resisting them; and that, when taken, or when they may have delivered themselves up voluntarily, it is enjoined that they be treated with the utmost care and humanity. The captured natives are sent to Gun Carriage island, situated in Bass's Strait, at the distance of 11 miles from the mainland, where they are furnished with ample means of supplying themselves with food and clothing.

The hostility which the natives evince towards the colonists, has in a great measure, if indeed not wholly, originated in an unfortunate occurrence which took place at the first formation of the colony. An officer of the New South Wales corps, who had been left in command of the military during a temporary absence of the governor, being alarmed by the approach of a large body of the natives, whom he perceived advancing towards his station, ordered the discharge of a cannon amongst them, loaded with grape and canister shot. The havoc was dreadful: numbers of them were killed and mangled by this murderous proceeding; and to add to the regret which the circumstance ought to inspire, it was afterwards ascertained that the natives were approaching with the intention of paying a friendly visit to the strangers who had come amongst them. They appear, however, never to have either forgotten or forgiven it. The tale is handed down from father to son, for it is now many years since, and to revenge it seems a part of their inheritance. Previous to this, they had always evinced the most friendly disposition towards the whites—a disposition which the latter were themselves the first to interrupt, and that in the tragical manner just spoken of.

The spirit of hostility which that unfortunate occurrence naturally engendered, has been since fostered by the wanton cruelties perpetrated from time to time on individuals of their unhappy race by the colonists, and more especially by the bush-rangers, of whom we shall speak hereafter. These ruffians have been accused of treating those of the poor, miserable, defenceless natives who fell into their hands, with a brutality and inhumanity which is scarcely paralleled in the annals of human depravity. The female aborigines are treated with great harshness by their husbands, who compel them to carry heavy loads, to perform all kinds of work, and to hunt for their subsistance. To escape from this state of bondage and servitude, they readily desert from their tribes, and place themselves under the protection of Europeans, and express great delight at the change of circumstances which attends it. Relieved from the drudgery to which they were subjected while in their original condition, they acknowledge the improvement which they perceive in their situation, and make it matter of contrast with their former state. Thus, many of them have attached themselves to the sealing parties stationed on the coast. They are said to be exceedingly gentle and affectionate in their manners and disposition, and capable of the warmest attachments. There is nothing which those who have connected themselves with the whites dread more than coming again in contact with their countrymen, the latter never failing to treat them with the utmost barbarity on every occasion of their getting them within their power. The fear, therefore, of being abandoned by their protectors, and left to the mercy of their native tribes, is constantly present to them, and makes them extremely jealous of any rival in the affection of their protectors.

The first child born by a native woman to a white man in the island, and who was taken under the protection of and brought up by a gentleman and his lady at Launceston, is thus described by Wentworth: "She is called Miss Dalrymple, and like all the other children since produced by an intercourse between the natives and the Europeans, is remarkably handsome, of a light copper colour, with rosy cheeks, large black eyes, the whites of which are tinged with blue, and long well-formed eye-lashes, with the teeth uncommonly white, and the limbs admirably formed." The women altogether of Van Dieman's Land are described as being much handsomer, and possessing a much more interesting appearance, than those of New South Wales, especially those in the neighbourhood of Port Jackson.

DIVISION, DISTRICTS, &c.

The island was originally divided into two counties, Buckingham and Cornwall, both of nearly similar extent, the former occupying the northern, and the latter the southern part of the island, but without any definite limits interiorly. They include, however, the whole line of coast on the east from South Cape, on the south, to Cape Portland, at the north-eastern extremity of the island. These counties are again subdivided into districts, and it is by the latter partition that it will be most convenient and most satisfactory to speak in detail of the various localities of the island. The districts into which the county of Buckingham is divided, are, Hobart Town district, New Norfolk, Richmond, Clyde, Oatland, and part of Oyster Bay district. The subdivisions of Cornwall, again, including part of the last-named district, are Campbelltown, Norfolk Plains, and Launceston. The first of these districts, beginning at the southern end of the island, is

HOBART TOWN DISTRICT.

This district, though the smallest in extent of any in the island, is yet the most important in the colony, as well from the circumstance of its including Hobart Town, the capital of the island, as from its possessing many superior local advantages; and, amongst these, that of its being accessible by water on three different sides—by the Huon river, which forms its southern boundary, by the Derwent on the north and east, the sea on the east. The whole district, including the island of Bruny, which lies off the mouth of the Huon river, and forms part of it, comprises 400 square miles, or about 25,000 acres. The country in this district, however, is in general so hilly, that out of these 25,000 acres there are not above 1600 under tillage; and it is said that the first cost of clearing and preparing these lands for the plough greatly exceeds what they would now bring altogether if put up to public sale. The best and principal farms here are situated on the banks of the Derwent, and south of Hobart Town in the direction of Fairlie's Cove; behind this interiorly there are but few locations, nor does the appearance of the country tend much to invite future settlers, the soil being in general so thin, and so heavily encumbered with trees, that even its vicinity to the capital is scarcely an inducement sufficient to any one to attempt its cultivation. The farms here are, in general, of a very small size, averaging little more than 50 acres each. The whole number of inhabitants in this district, exclusive of Hobart Town, does not exceed 800, or about two persons to each square mile; and of these, 220 are convict-servants, leaving only 580 freemen settlers and others. The number of live stock in the beginning of 1831 was estimated at—horses, 400; cattle, 2000; sheep, 1200.

In this district, Hobart Town, the capital of the colony, as we have already said, is situated. Hobart Town is built on the left bank of the river Derwent, at the head of a beautiful cove or bay, distant about 20 miles from its junction with the sea. The town is pleasantly situated on a gently rising ground, which, gradually retiring, terminates ultimately in hills of considerable height, covered with wood, and presenting a most romantic appearance. These, again, are overlooked by one of still greater altitude, called Mount Wallington, which rises to the height of 4000 feet above the level of the sea. Hobart Town is thus happily placed between highly picturesque hills on the one hand, and a beautiful bay or arm of the sea on the other; for, though the Derwent be here called a river, it can be so called only in a very extended sense, the water being still salt, and of considerable width. The view, then, altogether, of the bay, with its ships, the town rising gradually from its shore, and the wooded hills in the distance, with a clear Italian sky over all, is one of the most interesting and striking that can well be conceived. The town itself covers somewhat more than a square mile of ground; the houses are constructed mostly of wood, though many of them are of brick and freestone. The streets are regularly laid out, and those of them that have been completed are macadamised, and present on either side long rows of large and handsome shops—sufficiently singular this, when we consider the very short space that has elapsed since this remote spot was tenanted only by the roaming savage and the kangaroo. The town derives a peculiar and highly pleasing character, too, from the circumstance of the houses in general standing apart from each other, each having a small plot of ground, from a quarter to half an acre in extent, attached to it. Its public buildings are numerous, and many of them of such a description as would, even here, be considered handsome. Here are breweries, tanneries, distilleries, flour-mills, two or three banks, hospitals, churches, schools charitable and stipendiary, inns, taverns, hotels, and grog-shops, *ad infinitum*, and every thing else which bespeaks a thriving, bustling, industrious, and civilized community. Nor are they behind in this department of literature: two or three newspapers are here published weekly, besides a yearly Almanack,* containing a great deal of statistical and other interesting information regarding the colony, and an official gazette. The total number of inhabitants is estimated, including the immediate suburbs, the prisoners, and the military, at from 7000 to 8000. House-rents are here immoderately high, L.60 and L.80 being very common for a house of only three or four rooms and a kitchen. Houses of this and lower rental are generally paid for weekly, or once a-quarter. Altogether, Hobart Town is an exceedingly expensive place to live in; provisions are high, most of them much higher than in this country, and all articles imported from England bring a most extravagant price. It has been, therefore, reckoned that the living of each individual in Hobart Town will average L.50 per annum, exclusive of house-rent. The next district to that of Hobart Town is

NEW NORFOLK DISTRICT.

This district lies immediately behind the former, and is entirely inland, no part of it approaching the sea; its extent, from east to west, is about 50 miles, and from north to south about 30—thus comprising 1500 square miles, or 960,000 acres. This district is in general much more fertile than that of Hobart Town, returning on an average from six to eight bushels of wheat per acre more than the latter. The farms, too, are of much larger extent, many of them amounting to 2000 acres, some of these delightfully situated on the banks of the Derwent and Jordan, a small river, which, after passing through an exceedingly beautiful tract of country, ultimately falls into the latter at a place called Herdsman's Cove. In this district there is also a large proportion of rich sheep pasture. New Norfolk is intersected, in a north-westerly direction, by a chain of lofty mountains, covered with the most magnificent timber, and exhibiting snow on their summits throughout the greater part of the year. The average returns of the cultivated lands in this district are—of wheat, 20 bushels; barley, 28; oats, 30; peas, 20; beans, 15; potatoes, 3; turnip, 7. Of the 960,000 acres which this fine district contains, there were not, up to the year 1831, more than 60,000 located, and of these not more than 3000 were cleared and brought under the plough. From its vicinity to Hobart Town, and the advantage of water carriage which the lower part of the district possesses, there is a greater proportion of agricultural produce raised in it than many of the other districts. It is remarkable, however, that, with all its superiority of soil, its crop of potatoes is about one-seventh less than that of the Hobart Town district. The live stock of this district is estimated at—horses, 250; cattle, 6400; and sheep, 60,000. Here is a pleasantly situated little town or village, bearing the name of the district, viz. New Norfolk, and distant from Hobart Town about 22 miles. There are here two excellent inns, besides three or four public houses; and a coach and van, the former with four horses, and the latter with two, run daily between it and Hobart Town; besides these, there is a steam-boat plying on the Derwent between the two places. The total population of this district only amounts to 1200; and of these, 450 are convicts, in the employment of the government and of the different settlers. North-east of the Hobart Town district, and nearly directly east of that of New Norfolk, lies

RICHMOND DISTRICT,

Extending on the eastern side, or sea-coast, from Prosser's river to Tasman's peninsula, a tract of uninterrupted sterility, being rocky, mountainous, and barren to the last degree. The ridge of bleak and unproductive hills which run through this whole length are heavily timbered, and never can be made in any way available to the purposes of man. On the side next the Derwent, however, which bounds it on the south, though still hilly, there are a number of beautiful and fertile vallies; and around Pitt Water, a salt-water lake of six miles in length, and three in breadth, there is a considerable portion of comparatively level land of the first description, and well adapted for agricultural purposes. In this district there are two towns or villages, Richmond and Serrel; the first 14, and the second 22 miles distant from Hobart Town. In the latter there are several good inns, a parsonage house, church, jail, &c.; in the former there is just now only one inn, but there are several respectable private houses. Serrel is situated in the fertile locality of Pitt Water, and is surrounded on all sides with rich and highly cultivated farms. This district contains altogether about 672,000 acres, or about 1050 square miles; the total number of the former in cultivation does not exceed 12,000, and, notwithstanding that it possesses many of the finest farms in the island, the average return of its crops ranks very low; wheat, 12 bushels per acre; barley, 14; oats, 20; peas, 10; beans, 10; potatoes, 3½ tons; and turnips, 8. The whole population of Richmond district amounts to 2800; of these, 1100 are convicts. Coal and limestone have been found in this district, but neither of them has been yet wrought. The number of its horses is estimated at 420; cattle, 14,200; sheep, 95,000. Next to the district of Richmond, and bounded by it on the south, is

OATLANDS DISTRICT,

Separated from the sea by part of the Oyster Bay district, and bounded interiorly, or on the west, by the district of Clyde, and on the north by that of Campbelltown. This district is comparatively but of small extent, and forms a square of about 30 miles on each side, and contains, therefore, 900 square miles, or about 576,000 acres. Though one of the smallest subdivisions of the island, Oatlands is one of the best, possessing, perhaps, a greater proportional extent of cultivatable and grazing land, and these of the finest quality, than any other locality of similar bounds in the island; its beautiful open and extensive downs afford the richest pasturage, and its arable lands are equally fertile and productive with the best in the colony; it is besides most advantageously situated, occupying a central position between Hobart Town and Launceston, the next town on the island in extent and importance to the former. The advantages which this district presents have been duly appreciated, and a greater proportion of it, taking its limited extent into account, has been located than that of any other district in the colony. Its average return of produce is—wheat, 20 bushels to the acre; barley, 22; oats, 25; peas, 20; potatoes, 3½ tons; and turnips, 6. The town of Oatlands, situated in this district, and 51 miles distant from Hobart Town, contains a military barracks, a jail, an inn, and several extensive stores. The total number of acres in cultivation is 2700. Its live stock consists of 250 horses, 10,000 horned cattle, 90,000 sheep, and 240 goats. Coal is also found here, but in too remote a situation to afford any profit in the working. Within this district are situated what are called the Salt-pans Plains, a beautiful level tract of fertile country, of many miles in extent, terminated in the distance by lofty ranges of the most magnificent hills. These plains derive their somewhat singular name from three small lakes, or ponds, which are so strongly impregnated with salt, that they yield, by a natural process, many tons of that essential article of life annually. This salt is not equal in quality to English salt, but, nevertheless, brings 10s. a hundred-weight in the colony. The population of this district amounts to 930 souls; of these, 480 are convicts, and 450 free persons.

Next to Oatlands, on the interior, or western side, lies the

CLYDE DISTRICT,

Bounded on the south by New Norfolk, by Campbelltown on the west, Norfolk Plains on the north, and terminating in unsettled tracts on the west. It comprises about 1700 square miles, or 1,088,000 acres. This district is in general hilly, but affords excellent and extensive pasturage. Its remoteness from Hobart Town, and the difficulty of transporting agricultural produce to that market, from want of good roads, has tended to keep it almost exclusively a pastoral district. The proportion of cultivated land here is exceedingly small. Some of the best grazing farms, however, in the island, are to be found in this district, many of them covered with the immense flocks and herds of the various settlers. This district has the advantage of many of the others in the colony in the essential article of water, no less than five different rivers running through its bounds; these are the Dee, Ouse, Shannon, Clyde, and Jordan. From its elevated situation, the climate here is considerably colder than in the districts nearer the sea; and even in summer, slight hoarfrosts are not unusual at a very early hour in the morning. This circumstance has particularly affected the crops of potatoes which have been attempted to be raised there, and which in consequence exhibit such a poor return, as almost amounts to a total failure. The principal township in the district is Bothwell, distant 45 miles from Hobart Town: there is an excellent inn here, a court-house, church, and a considerable number of respectable private houses. An assistant clergyman, called there a lecturer, and who is paid by the government, performs divine service in the town every Sunday. The whole cultivated land in this district is estimated

* When speaking of these publications, we cannot refrain from noticing, in an especial manner, a little work entitled "The Van Dieman's Land Anniversary, and Hobart Town Almanack," for the year 1831, edited and printed by the ingenious Dr James Ross, Hobart Town, and to which excellent colonial production we have to express ourselves particularly indebted in the composition of the present article.

at 2600 acres; the average return of produce is—wheat, 16 bushels per acre; barley and oats, 17; peas, 20; potatoes, 2½ tons, and turnips eight. The numbers of its live stock are—horses, 250; horned cattle, 11,000; sheep, 82,000; and goats, 600. Its total population amounted, in 1831, to no more than 760 souls, and of these 400 were convicts.

OYSTER BAY DISTRICT.

This district is bounded by Richmond on the south, Oatlands and Campbelltown on the west, and the sea on the east. Oyster Bay district takes its name from a beautiful bay situated within its limits, and which affords excellent anchorage for ships, and is reckoned altogether one of the finest harbours in the island. It is separated from the adjoining districts by a lofty range of mountains, which run from north to south throughout its whole length on its interior side. This district is about the same extent with that of Oatlands, comprising 900 square miles, or about 576,000 acres. It does not exhibit any general traits of character differing from the others. In common with these, it possesses large tracts of fine pasture lands, but there is little yet under the plough. The whole of the located land here does not exceed 36,000 acres, and of these there are only about 1200 cleared and in cultivation. Its average returns of crop are nearly the same with those of the Oatlands district. From the small portion of it which is yet located, its population and amount of live stock is very small, the former amounting only to 320 souls, and of these 170 are convicts. The latter are represented to be—houses, 25; cattle, 2500; and sheep, 17,000. A great portion of the wealth of this district is derived from whale-fishing, a considerable number of these being every year taken in Oyster Bay. There are no towns nor villages yet within its bounds, nor any civil or religious establishments of any sort; it possesses, however, the usual accompaniments of a military station and a police magistrate.

CAMPBELLTOWN DISTRICT,

Lying between Oyster Bay district on the east, and Norfolk Plains on the west, comprises about 1260 square miles, or 85,000 acres. This is one of the finest districts in the whole island, and is every day increasing in prosperity and importance. The peculiar richness of its herbage adapts it in an especial manner for the rearing of cattle, and this is so well known and so universally acknowledged in the colony, that the butchers of Hobart Town come hither to make their purchases of fat stock, though at the distance of 70 miles, in preference to drawing them from the more immediate districts of less celebrity in this particular. Amongst other delightful tracts of grazing land which this district presents, there is one of superior fertility, called formerly the Ross Reserve, from its having been kept possession of by the crown for its own purposes. In June last, however, this reserve was exposed to sale by the government, and sold readily in lots of 4000 acres each—the whole tract comprising about 32,000 acres—at from 16s. to 20s. 1d. per acre. One lot sold as high as 39s. per acre. Each of these lots has a frontage to the Macquarrie river, from which they run backwards about six miles. At Ross there is an annual cattle-market, and a yearly display of horse-racing. The agricultural produce of this fine district is equally remarkable with its pasturage, and for barley especially it seems to be singularly well adapted, the average return of that crop being not less than 40 bushels per acre. Wheat exhibits 20; oats, 28; peas and beans, 11; potatoes, however, only 2½ tons per acre; and turnips, 6. More than one-third of the district is already located, nearly 300,000 acres being in the possession of settlers, and of these 6800 have been cleared, and are now under the plough. The quantity of live stock on this district is fully proportioned, when compared to others, to its superior fertility. Its number of horses has been estimated at 450; cattle, 13,500; and sheep, 160,000—all of them of the best description.

In Campbelltown, the emporium of this district, there are two excellent inns, storehouses, &c. Notwithstanding its extent, however, its amount of population is comparatively small, comprising in all only about 650 souls, and of these no fewer than 550 are convicts, leaving only 150 free settlers for the whole district—a proof, though probably otherwise disadvantageous, of the great individual wealth of its inhabitants, who can thus afford to hold in their hands such a vast extent of fine pastoral and cultivated land.

NORFOLK PLAINS DISTRICT.

By includin[illegible] district, we have now crossed the island from n[illegible] south, and arrived at the shores of Bass's Str[illegible]ch separates Van Dieman's Land from New So[illegible]les. Norfolk Plains district comprises 2250 s[illegible]iles, or about 1,500,000 acres. This division [illegible]land presents a very different aspect from that o[illegible]ch we have just been speaking, being generally mountainous and barren; and when it is not absolutely either, the soil is often poor, thin, and comparatively unproductive. About 123,000 acres have been here located, and of these 5500 are under cultivation: the average returns of the latter are—wheat, 18 bushels per acre; barley, 32; oats, 33; peas, 30; potatoes, 6 tons; and turnips, 6. From the great extent of this district, though not at all remarkable for its fertility, its amount of live stock is very considerable. These are—horses, 400; cattle, 23,000; and sheep, 75,000. The extremely bad state of the roads in some of the most important parts of the district, operates seriously against its interests;—so wretched indeed are they, that carts laden with wool, and each drawn by six bullocks, have been unable to make farther way than five miles in one day. The population of this district amounts altogether to about 1000 souls—580 free persons, and 420 convicts. There is here a boarding-school establishment, situated nearly in the centre of the plains, and which, having been lately advertised for sale, was stated to have realised to the proprietor and teacher, one and the same person, from L.900 to L.1000 per annum!! It has a lecturer, who performs divine service every Sunday to the surrounding settlers.

LAUNCESTON DISTRICT.

This district completes the catalogue of the political divisions of Van Dieman's Land, and is the largest of them all. It occupies the north-eastern corner of the island, ending at Cape Portland, having Bass's Strait on the north-east, and the Pacific Ocean on the east, with a coast-line on the former of about 70 miles, and on the latter of about 55. It is estimated to contain 3900 square miles, or about 2,500,000 acres. The greater part of this extensive district is wholly useless for any of the purposes of man, being barren, sandy, rocky, and mountainous, and in many places altogether inaccessible. Notwithstanding of this, however, it is considered the next in importance to the Hobart Town district, from the circumstance of its possessing the second largest town in the island, viz. Launceston, situated at the head of the navigable portion of the river Tamar, which discharges itself into Bass's Strait, about 45 miles below the town. Launceston contains about 2100 inhabitants, many of them enterprising merchants and traders. The number of its buildings amount to about 500 or 600, and amongst these are some very handsome public edifices; an elegant and capacious church, government house, military barracks, jail, court-house, school, &c. There are here, besides, several spacious stores and warehouses, together with a great many well-stocked shops. From the favourable nature of its situation for commercial purposes, the river being navigable for vessels of 400 tons burthen up to the town, its maritime trade is very considerable, and is every day increasing. The chief exports from Launceston are wheat, bark, wool, and whale oil. Of these, L.60,000 are shipped annually. The custom-house revenue of the port, for the quarter preceding July 1832, amounted to about L.12,000. With all its prosperity, however, Launceston does not appear by any means to be a cheap place to live in. Potatoes sell for 1½d. to 2d. per lib. in retail; butchers' meat—beef and mutton "scarcely eatable," says the Launceston Advertiser—5d. per lib.; prime joints, 6d.; and pork, 8d.; and candles, so wretchedly bad that they are next to useless, 1s. 6d. to 2s. per lib.

Amongst its other public establishments are a bank, post-office, several good inns, and two weekly newspapers. A direct communication having been established between this port and London, its inhabitants, and those of the surrounding country, are thereby saved the great expense to which they were before subjected, of bringing their imports by the circuitous route of Hobart Town. Of the extensive district in which Launceston is situated, consisting, as we have already said, of two millions and a half of acres, there are only about 63,000 located, 7000 of which are under cultivation. Its average returns of crops are estimated at—wheat, 20 bushels per acre; barley and oats, 30; peas and beans, 20; potatoes, 3½ tons; and turnips, 6. Its amount of live stock is in the following proportions:—Horses, 380; cattle, 30,000; and sheep, 65,000.

SUMMARY CHARACTER OF THE ISLAND.

The several districts of which we have just spoken in detail, include the whole colonised portion of Van Dieman's Land, with the exception of the tract belonging to the Van Dieman's Land Company, to be afterwards spoken of, and three penal establishments.

On looking at the map on the first page of this sheet, it will be perceived that these districts occupy nearly the whole of the eastern coast of the island, and that their interior line passes nearly through the centre of it; or, in other words, it will be perceived that about one-half of the island, on its eastern side, is included within their limits; beyond these, in the interior, the country is yet but little known, and, indeed, there are many tracts within the districts themselves not only unlocated, but even unexplored. From the local details alluded to, we gather, on the one hand, that, on the whole, Van Dieman's Land is decidedly mountainous and hilly; that it is much encumbered with wood; that a large proportion of it is entirely useless as regards human purposes; that much of it is sterile or unproductive; and that its best lands are not more than usually fertile. On the other hand, we learn that it possesses a large proportion also of the finest and most luxuriant pasturage; that it is, on the whole, comparatively a tolerably well-watered country; and that its cultivatable lands are, if not more than ordinarily productive, at least sufficiently so to reward any care or labour that may be bestowed upon them.

The statistical portion of the preceding local details gives us again the following results, with regard to its live stock and located lands: Of the former we find the numbers in the whole island to be, of horned cattle, about 113,000; sheep, about 666,000; horses, 3000; goats, 840; and that of the latter there is in the possession of private individuals an extent of land amounting altogether to about 763,000 acres, of which there are 42,400, or about an eighteenth part, under cultivation. But as these estimates refer to the year 1830, and as it has been computed that 200,000 acres are now annually located, with, of course, a proportional increase of live stock, we may add, for the time which has elapsed between the period named and the present moment, one-third to each; that is to say, there will now be in Van Dieman's Land one-third more cattle, sheep, &c., and one-third more of located land, with an eighteenth part more for each year since of cultivated land. Of the whole island, then, which comprises 15,000,000 of acres, there will be about 1,018,000 located, or little more than one-fifteenth part, and of these there are about 50,000 in cultivation, or about a three-hundredth part of the whole island.

PENAL ESTABLISHMENTS.

We at home here are apt to conceive, that, if a criminal be banished to New South Wales or Van Dieman's Land, that particular description of punishment ends there, and can be carried no farther; we are not, all of us at least, aware that in the lowest depth there is a lower still; that, in short, a man may be banished from the place of his banishment: this, however, is the case. There are three places set apart, and exclusively appropriated for those incorrigibles who continue to offend after they have reached their first destination. Their original sentence sends them merely to the island; but when they commit crimes there, they are again brought to trial, and, if the offence be not capital—in which case, of course, it is death—they are again sentenced to a further banishment. The places set apart for this purpose are Macquarrie's Harbour, Maria Island, and Port Arthur, all of them unapproachable excepting by water. The first, Marquarrie's Harbour, is situated on the west coast of the island, and is by sea the only way in which it can be reached—distant about 250 to 260 miles from Hobart Town. The harbour runs up into the land about 20 miles, and it is to an island called Sarah Island, near the head of this harbour, that the convicts are banished. The country around Macquarrie's Harbour is wild, desolate, and barren, exhibiting nothing but continuous rocks and precipices, and ranges of bleak rugged mountains. No part of the neighbouring country is located, or worth locating, for fifty miles round the settlement. Upon the whole, Macquarrie's Harbour seems to have been admirably chosen for the purpose to which it is made subservient, for a more dreary or more miserable place of abode could not be readily found any where. The next penal establishment is upon a small island situated on the east coast, called Maria Island, about four miles distant from the shore. It is a very beautiful romantic-looking little spot, covered in some parts with wood, and exhibiting several lofty hills. The convicts here are chiefly employed in sedentary pursuits, such as weaving cloth, making shoes, &c. The establishment is situated at the northern extremity of the island, where there are spacious barracks for the accommodation of the prisoners. The third and last penal establishment is at Port Arthur, on Tasman's Peninsula, half-way between Cape Pillar and Cape Raoul, and about 50 miles distant from Hobart Town. The country around this settlement is also rocky and barren, and that part of it which might otherwise be made available is so covered with stones, that it would not repay the labour of clearing it. The timber, however, which is in great abundance, is of very superior quality, and it is in felling and cutting up this timber that the convicts here are chiefly employed. Port Arthur is celebrated for the variety and abundance of its fish, as also for its beautiful basaltic rocks.

VAN DIEMAN'S LAND COMPANY.

This company was formed during the joint stock mania of 1825, and is incorporated by a royal charter of that date. A grant of 350,000 acres, situated on the north-western extremity of the island, with an allowance of one-fourth more for bad lands, was conceded them by government, for the rearing of sheep and agricultural purposes, these being the leading objects of the company. Its affairs are conducted on the island by a manager and several sub-agents, who are still actively and vigorously pushing forward its interests, forming roads, building steadings, stores, and farm-houses, throughout its territory. The company annually ship large quantities of agricultural produce to New South Wales, and send a great deal of wool to the English market. Their dairy produce, which is also very considerable, is mostly, if not entirely, sold in the island. The affairs of this company are but little known in the colony, their lands and establishments being all situated in a remote part of the island, with an almost impassable territory between them and the settled portion of the country. There is scarcely any intercourse with them, and the little that is, is by water. There are said to be from 250 to 300 people employed at the various stations of the company. Their capital at the outset was represented to be L.250,000. Their expenses on the colony in the year 1830 amounted to L.8857, 6s. 0d., and the returns from their agricultural and dairy produce sold in the island at L.2305, 19s. 5d.—leaving an actual outlay of L.6551, 7s. 1d. Their possessions there have been valued—Land at L.125,000—live stock, shipping, &c., L.50,000—annual produce, L.10,000. Total, 185,000.

This company have just issued a series of "preposals," for the encouragement of emigrants as tenants to their settlements in the island. These will be found spoken of at length under the head "Emigration," to which we refer the reader for this particular description of information.

TRADE AND REVENUE.

The principal articles of export from Van Dieman's Land to the mother country are wool and oil. For their agricultural produce they have to look for a nearer market, and this they find, although only to a limited extent, and but occasionally, in New South Wales and the Swan River—the latter at all times inconsiderable, and the former uncertain, as Van Dieman's Land grain can be in demand there to any extent, only when their own crops have fallen short—a circumstance which has indeed more than once happened, to the great benefit of some of the settlers on the latter island.

Until, therefore, some new outlet for the agricultural produce of the country presents itself, it does not appear that it would be advisable that they should raise more of these than is sufficient for their own consumption. In 1831, they exceeded in this way, and were then at a loss to discover how the surplus was to be disposed of. The whole quantity of wheat grown upon the island in that year was estimated at 383,000 bushels, with an excess over the consumption of the preceding year of 70,000 bushels, making in all a stock of 453,000 bushels, while the consumption was not reckoned at more than 250,000, thus leaving a surplus of 253,000 bushels. These difficulties, however, neither apply to wool nor oil, both of which will always find a ready market in the mother country, and to any extent. It is evident, therefore, that, in the meantime, the farmer of Van Dieman's Land must betake himself chiefly to the growing of wool, and the merchant to the trading chiefly in both—in so far at least as regards the position of the country with that of others, its internal commerce being of course a totally different thing. In this colony, we find a much greater disproportion between the exports and imports than in New South Wales; the latter, in 1830, amounted to L.300,000, and the former to L.170,000, leaving a balance against the island of no less than L.130,000. The principal items which compose this amount of exports are—wool, L.48,000; wheat, L.40,000; and oil, L.17,000; but it must be observed, with regard to the wheat, that the comparative largeness of the amount exported this year, was in a great measure owing to an unusual failure of the crops from excessive droughts in New South Wales, throughout the whole of the three or four preceding years. It must farther be observed, on the other hand, that the imports are by no means always adjusted to the real wants of the colony; on the contrary, they often exceed it by two or three years' consumption. By taking this circumstance, then, into account, the actual difference in value between what the colony really wants, and what it has to spare, would not be found nearly so great as it appears to be by the returns of its exports and imports; since the latter is not regulated by demand, but by a spirit of speculation, and that not on the part of the colonists themselves, who know better, but of merchants at home here, who, hearing that 100 puncheons of rum are wanted in the colony, send 1000, and so on in proportion with almost all other things. The consequence has been, with regard to manufactured articles, that they have in many instances sold in Hobart Town for less than the first cost in London, with freight, insurance, commission to agents, &c., all to pay besides. It is true that this will in time cure itself; the thing will by and bye find its level; but, in the meantime, what we have stated is the case.

The colonial revenue for the quarter ending 31st March 1832, amounted in all to L.18,844, 1s. 9½d., and its expenditure to L.14,093, leaving a difference in favour of the former of L.4751. Here, too, as in New South Wales, the principal source of revenue is spirits, licences, &c. Out of the L.18,844, L.10,648 is derived directly or indirectly from spirituous liquors and wines; and of this, again, L.9785 is from duties on spirits alone, imported into the colony, and L.385 from licences to retail it; and in considering this amount of duties, it must be observed, also, that these are not, in most instances, above the one-half that they are here; and that, therefore, it requires double the quantity to produce the same amount of revenue. In the statement from which these items are taken, we observe, among others, in the department of the colonial expenditure, the sum of L.1710, 17s. charged under the head aborigines; thus it would appear, that besides being troublesome neighbours, they are also very expensive ones. The revenue of the colony seems to be gradually, though perhaps not very rapidly, increasing. In 1830, the annual amount was L.65,000, and in 1832, supposing each of the quarters to be as productive as that given above—and there is no reason to conclude that they will prove less—it will amount to L.75,376; thus showing an excess in the year 1830 of L.10,376, or a yearly increase of upwards of L.5000. The expenditure, however, of the colony seems to be keeping pace with its receipts, as in the year just named, the latter exceeded the former by L.20,000; and in 1832, presuming, as in the former case, that the remaining three-quarters will be equal in amount to the first, it will do no more, or rather scarcely so much.

GOVERNMENT AND POPULATION.

Up to the year 1825, Van Dieman's Land was formerly a dependency on the colony of New South Wales, and was then governed by a kind of deputy-governor. All its colonial laws, orders, and regulations, proceeded from the parent colony, and were generally mere counterparts of those promulgated there, without a due consideration, in every case, of their fitness or unfitness for the neighbouring land. In the year above named, however, on an earnest petition from the inhabitants to the home government, the colony was declared free and independent of New South Wales, and amenable only to the mother country. Its internal policy, therefore, is now conducted by a lieutenant-governor, as in the case of the former, endowed with similar authority and similar powers, and an executive and legislative council, the former a sort of privy council, for assisting and advising with the governor on all important matters, and the latter for framing and promulgating colonial laws, and imposing duties. There is also here a chief justice, attorney-general, and all the other appendages of a supreme court of judicature, courts of requests, attorneys, barristers, solicitors, proctors, sheriffs, justices of the peace, and the whole of the paraphernalia of civil and criminal jurisprudence known in this country. There are besides, as in New South Wales, a number of police magistrates, each having a separate and distinct district under his judicial authority; these are, as in the former case, stipendiary. The laws here are the same with those in England, in so far as the circumstances of the colony will admit. The members of all the civil institutions are appointed by the crown, consisting, in the executive council, of four in number, including the governor, and in the legislative of fifteen, also including that officer. The expense of the judicial department amounts to about L.13,000 per annum, and the ecclesiastical to about L.6500. The military and convict establishment are paid by the mother country. The governor's situation is reckoned worth L.5000 per annum, although his net salary is only L.2500; the difference is made up by taking into account various items, such as furnished houses, gardens, farms, servants, horses, cattle, sheep, pigs, poultry, fish, &c.; and a colonial newspaper says, that "five times five thousand pounds may be saved or made during the usual term of governorship." The salary of the governor's private secretary is L.500 per annum. The population of the whole colony, including the convicts, is estimated at 25,000, of which about from 10,000 to 12,000, or nearly one-half of the whole population of the island, are convicts. It is to be observed that this amount of the latter will not be given by taking the numbers which are to be found in each district alone, because to these there fall to be added the convicts in Hobart Town itself, besides the district, amounting there alone to nearly 3000, and the various penal establishments, houses of correction, and chain-gangs, none of which are taken into the account of convicts in any of the districts.

CONVICTS.

We have stated, under the preceding head, that the convict population of Van Dieman's Land amounts altogether to from 10,000 to 12,000; and it might be thought that this was quite enough, if not even an alarming proportion to the free inhabitants, the whole military force in the island not amounting to more than 1000 men; but so far from this being considered the case by the colonists themselves, who ought to be the best judges of the matter, there is just now a much greater demand on the colonial government for assigned servants from that class than can be complied with: so great, indeed, is this demand, that the superintendant of convicts there intimated by public notice (July 9, 1832), "that, from there being upwards of 1000 applications for assigned servants registered in his office, and as there will be no possibility of doing more than supplying the urgent wants of new settlers, the governor has directed it to be notified, that no farther application for convict labour will be received until the existing list of application has been very considerably reduced."

The average expense of transporting each convict to New South Wales or Van Dieman's Land, has been estimated at L.20. Their treatment while on shipboard is such as many an honest man would envy: each convict is allowed three-quarters of a pound of bread every day, a basin of gruel, with butter or sugar, to breakfast, and as much beef, pork, or plum-pudding, as he can eat to dinner, and pea-soup four times a-week, with three or four gills of wine at different times during the same period. Their bedding, clothing, &c., are of the best description, so far as mere comfort goes; and every thing that can be done to secure them in health during the voyage is carefully attended to. On reaching Hobart Town, whither all the convicts intended for Van Dieman's Land are first sent, they are, as in New South Wales, immediately marched to barracks, and thereafter assigned over to settlers, or employed in the government works. Though under a very strict surveillance, and severely punishable for comparatively slight offences, every inducement, consistent with the ends of justice, to amend their lives, is held out to them by government, and, with this view, the whole convict population on the island has been classified. The first are those who, from especial good conduct, are permitted to sleep out of barracks, and are allowed the whole of each Saturday to work for themselves. The second are allowed the latter, but not the former. The third are those employed on the public roads, and are relieved from work every Saturday at noon. The fourth are the refractory, who work in irons, under the sentence of a magistrate. The fifth the incorrigibles: these are also worked in irons, but, as a farther punishment, are kept entirely separate from the other prisoners. The sixth and seventh are those sent to the different penal settlements, where they are again classified by the respective commandants of these establishments. When assigned to a settler, each convict is furnished with a complete suit of slop clothing, which the former is obliged to pay for, at the rate of one guinea for each suit: his master must afterwards furnish him with two suits of slop clothing, three pairs of boots of a particular description, four shirts, and one cap or hat, per annum, with comfortable lodging and medicine, and medical assistance when necessary. In case of illness, the convict is removed to the colonial hospital, or, by his master paying 5s. per annum to the district assistant-surgeon, the services of the latter can be demanded for him at any time, if not at a greater distance than 15 miles from the place of his residence. The convict is also allowed ample rations of flour, meat, &c. Sugar, tea, and tobacco, are at the option of his master, to be given as a reward for or stimulus to industry, these being deemed a full equivalent for the convict's services: he is not allowed to claim any wages in money, or any other shape, from his employer, nor is any convict allowed to acquire any property, either in sheep, cattle, or lands; and what money they may be possessed of on their arrival in the colony is taken from them, and placed in a saving's bank at a rate of five per cent. interest, clear of all deductions, and cannot be withdrawn during the currency of their sentence without the consent of the government. The convict servant must also be furnished by his master with sufficient bedding, a palliass stuffed with wool, two blankets, and a rug, all of a quality equal to those issued from the public stores. Masters are enjoined to make a yearly return of all the convicts in their employment, with an account of the general conduct of each, that the deserving may receive the indulgencies due to them for good conduct; and in the event of that being so remarkable as to entitle them to a ticket of leave, or licence to work for their own benefit, and wherever they please, the master on whose recommendation such an indulgence is granted, is considered as having a peculiar right to be furnished with another convict with the least possible delay, seeing that, to do an act of justice, he deprives himself of a valuable servant. All memorials and petitions of convicts to government, with the exception of those confined to penitentiaries or chain-gangs, are drawn up for them when unable to do so themselves, or to procure another to do it for them, at a reasonable charge; if in town, at the colonial secretary's office, on payment of 1s. 2d. per page, which includes every expense, as materials, trouble, &c.; and, if in the country, at the office of the police magistrate of the district in which they happen to be. In the case of the former, the penitentiary and chain-gang prisoners, who are not supposed to be able to command this sum, they are prepared without any charge or fee whatever by their respective superintendants.

With regard to female convicts, these are either sent to factories, where they are kept at work suited to them, or are also assigned as servants to married settlers, this last being an express condition in their assignment. Their weekly rations are less than those of the men, being eight and a half pounds of flour, five and a quarter pounds of meat, two ounces of tea, half a pound of sugar, two ounces of soap, and one and a half ounce of salt; the indulgence of tea is imperative on the master in the case of females. The bedding to be furnished them by their employer is the same with that furnished to the men. He is also bound to supply them yearly with one cotton gown, two bed-gowns or jackets, three shifts, two flannal petticoats, two stuff do., three pairs of shoes, three calico caps, three pairs of stockings, two neck handkerchiefs, three check aprons, and one bonnet. The bed and bedding in both cases are considered the property of the master, and are retained by him on the discharge of the servant.

BUSH-RANGERS.

These are convicts who have run away from their employment, and, taking to the woods, live by plundering the settlers, whom they often murder as well as rob. The great improvements which have taken place in the police regulations of the island, and the superior footing on which it is now placed to what it was formerly, have now nearly put an entire stop to this desperate trade. At one time, however, it was carried to such a fearful height as threatened the entire ruin of the colony. The most atrocious murders and robberies were daily committed by these desperadoes, who prowled about the country in large gangs, with regular captains at their head. They were generally well armed, and well provided with ammunition, and seldom committed a depredation without adding to it the crime of murder. The most celebrated of these wretches was one Michael Howe, who arrived in the colony from England in the year 1812, under a sentence of seven years' transportation. Soon after his arrival, Howe absconded, and, joining a gang already in the woods, or in the bush, as they prefer saying in the colony, commenced his career as bush-ranger. Being a man of a fierce and relentless disposition, and withal of daring courage, capable of every enormity, and of facing any danger, he was soon chosen leader of the gang with which he had connected himself, and continued in that capacity for nearly six years, the terror of the whole island. At one period of his career, Howe, distrusting the faith of his party, left them, and formed the design of giving himself up to the government, on a chance of mercy being extended to him. On this occasion he wrote to the deputy-governor—Van Dieman's Land being then dependent on New South Wales—stating that he was prepared to surrender himself, provided that an assurance was previously given him of personal safety in the meantime, and that such a favourable representation should afterwards be made to the governor-in-chief as might procure his ultimate pardon. The conditions were immediately agreed to, and the desperado yielded himself quietly to the authorities.

Either a dread, however, of the result, or a longing for the joys of the bush, having come over him, he shortly again absconded, and recommenced, with additional vigour and ferocity, the career of crime which he had so temporarily resigned. Howe was accompanied in all his wanderings by a native girl, who followed his footsteps with the most persevering attachment, sharing his hardships and fatigues, and incurring with him all the dangers of his desperate trade; yet, on one occasion when hard pressed by a party of soldiers, the ruffian suddenly turned round and fired on the unfortunate girl, who, worn out with fatigue, was struggling to keep up with him. Considering her as only an incumbrance in his flight, though intending to have killed her outright, he succeeded only in wounding her slightly. Howe was at length entrapped and killed by some of his own associates: he was enticed into a hut by being told that ammunition was to be had in it. On his entrance, one of the conspirators suddenly discharged a musket at him, but missed him. "Is that your game?" said the desperado, coolly, and he levelled his piece at his antagonist, and fired in his turn, but also missed his object. He now rushed out of the hut, but was instantly pursued by the persons who had allured him in, and, being soon overtaken, a savage combat took place with the butt-ends of muskets, and Howe, after defending himself with great courage, at length fell and expired on the spot, his head being battered to pieces by the blows with which it had been visited. The bush-rangers have had many leaders of note, though none of equal celebrity with Howe. One Peter Geary, a deserter from the 73d regiment, seems to have ranked next to him as a bush-ranger captain; this man also himself committed, and encouraged his gang to commit, the most horrid atrocities. Geary was at length shot by a party of the 40th regiment, after maintaining with his gang a smart engagement with the latter.

These days of bush-ranging are now, however, almost entirely over, both in Van Dieman's Land and the sister colony. Depredations of this kind are but of extremely rare occurrence, and have no longer the sanguinary character which they formerly had, acts of violence being now seldom perpetrated. The establishment of the police magistracy was one of the most effective measures adopted for the extinction of this scourge of the colony, as its local operation laid every part open, as it were, to the light, lessening the coverts of the marauder, or driving him at any rate to a greater distance.

SOCIETY.

It has been said by one writer (Henderson), that the British character in both colonies, New South Wales and Van Dieman's Land, has deteriorated. It may be so; but in both there is still to be found a great deal of highly agreeable, if not highly refined society. In the more remote settlements of the colony, society of any kind is scarce, and indeed this would be found one of the greatest wants of which a well-educated grown-up family would have to complain in locating in the interior; but even this would not certainly be greater, nor even so great, probably, as occurs in the Highlands of Scotland, where many miles of almost inaccessible country often intervene between house and house. There are, besides, a number of boarding-schools and seminaries of various kinds, throughout the colony, and in particular in and about Hobart Town and Launceston, conducted by persons of the highest respectability, and equally well adapted for their purposes, both with regard to accommodation and arrangements, with any similar institutions in the mother country. Though society of any thing like a superior kind is scarce in the interior, and throughout the more remote portions of the various districts, yet it is to be met with. There are now a great number of well-educated persons amongst the settlers in Van Dieman's Land—people of property, who have been accustomed to all the elegancies and refinements usually attained by the better classes here. These are scattered over a great part of the colony, living on their estates in handsome cottages, or more stately edifices, with gardens, parks, lawns, shrubberies, &c. around them, and all the other characteristics of snug genteel English country residences. It has been remarked, too, and with truth, that the latter settlers have brought more money with them than the first; that, in short, there is now a better class going out than went before. Emigrants with L.10,000 or L.12,000 are now by no means uncommon there, and there have been several instances, both from India and England, of fortunes from three to five times that amount having been brought into the island. In Hobart Town the most select society is to be found, and certainly, perhaps, also the worst on the face of the earth. The former, however, is not only select, but, being situated in the very heart of the enemy's country as it were, the very metropolis of roguery, the emporium of petty larceny, and other little peccadilloes, it is hedged in and defended with triple walls of brass. Candidates for admission are examined from head to foot with the most anxious and scrupulous inquiry—they are carefully weighed in the balance, tried, tested, squeezed, and hot-pressed. If they stand all this, they may walk in; if not, they must turn to the right about. An intelligent correspondent, whose letter now lies before us, thus speaks of Hobart Town:—"The town is wonderfully enlarged—fine streets, wharfs, and shops. We have three steamers almost ready for a start, coaches on the various roads, and *lots of private carriages*." It is this last assertion which has induced us to make this quotation here, as it may give some idea of what society is to be expected where these indications of property, wealth, and refinement, are so numerous.

The convicts in this country are under similar surveillance with those in New South Wales, and are not permitted, either by the government or the colonists themselves, to approach the precincts of society. The emancipats, again—those whose term of banishment has expired—though afterwards becoming wealthy, and supporting a good moral character, are, nevertheless, always considered inadmissible to good society; and though there is no objection to the maintaining a mercantile connexion with them, it is rarely allowed to extend further. Several of this class have here, as well as in the sister colony, acquired extensive and valuable property, and many of them have become wealthy by other lawful pursuits, and at this moment one of the finest estates in Van Dieman's Land, comprising 2200 acres, is the property of an emancipated convict.

EMIGRATION.

As in the case of New South Wales, which was the subject of a former paper, the persons most suitable to emigrate to Van Dieman's Land are—farmers, farm-servants, mechanics, labourers, and unmarried females. As the circumstances, therefore, under this head are nearly similar in both cases, we shall adhere to the same classification, but pointing out, as we go along, whatever differences *do* exist as regards the emigrant between the two colonies.

Before proceeding, however, to the details of "emigration," as it refers to the island generally, we shall run over the "proposals" made by the Van Dieman's Land Company to emigrants for their own particular territory, which, as we have elsewhere said, is situated in the north-western part of the island, and comprises altogether about 350,000 acres, including three small islands. This company proposes to let their lands in farms of 50 acres each, or more, in proportion to the capital of the emigrant; and although less will certainly do, it would yet seem that about L.200 would be necessary to commence with a fair prospect of success. The outlay on a farm at the outset is calculated to be somewhat less than L.90; and as it will take some time before any return can be expected, the means of subsistence until then must also be taken into consideration, besides other incidental expenses, so that an emigrant ought not to count on less than probably double this sum being necessary. The first indispensable outlay is thus estimated:—

Eight bullocks, at L.6 each .	L.48	0	0
One cart or dray . . .	15	0	0
Two ploughs	7	0	0
Two pair of harrows . . .	3	10	0
Bullock-chains, bows, and yokes .	3	10	0
Various small implements . .	10	0	0
	L.87	0	0

The company offer many important advantages to their settlers, which those going to other parts of the colony are wholly without. They propose to grub out and cut up the trees of ten acres on each farm at their own expense, leaving to the tenant the trouble only of bringing them together and burning them. They put fences round each farm, the farmer carting the materials, as also those necessary for building a house or cottage, which they will also erect for him, furnishing doors, windows, fastenings, &c.

The rent of their forest lands they propose receiving in produce, giving the first year gratis to the tenant; and of their grass lands they demand but half rent for the first year. They will also have no objection, under particular circumstances, to receive payment in labour, as well as in money or produce.

They farther propose to advance money to tenants, for the purpose of improving their lands, when it shall appear that these improvements are calculated for the general interests of the company, as well as the particular interest of the tenant. Seed-corn will be lent to the tenant, to be repaid out of the first crop; clover and grass-seeds will be supplied to him gratis for his pastures; and timber carriages will be lent him to assist in clearing his finest lands: in short, every encouragement and assistance which can tend at once to place the tenant in a comfortable situation, and promote the interests of the company, will be afforded him; and all their regulations and proposals are justly founded on the principle, that these are inseparable without injury to both. On the whole, this scheme of the Van Dieman's Land Company seems one of the most eligible that has yet been suggested with regard to emigration, whether it be to America or Australia, or any other quarter of the world. One of its best features remains yet to be exhibited, and we cannot do this better than in the language in which it is given in the company's prospectus. It includes, indeed, by far the most important and interesting part of the subject of emigration, so far as the emigrant is personally concerned. "Tenants will have the advantage," say the company, "of knowing, when they leave England, where they are going to; that they *will be received when they land by persons interested in protecting them*, and passing them to their occupancies as speedily as possible, and with little expense to themselves—an advantage which settlers with small capital will know how to appreciate. They will also have the disinterested and valuable advice as to their proceedings, which the company's agents will be enabled to give them before they can have the benefit of their own experience."

These are considerations of the last consequence to the emigrant, and are worth all the others connected with the subject put together. When once settled, and when ready to come to market with his produce, the tenant is promised that he shall at all times have the assistance and advice of the company's agent as to its sale; and the latter will farther be ready, it is said, to make such arrangements for the general body, regarding the sale of produce and markets, as may be beneficial to the whole. Holding out such prospects as these, the Van Dieman's Land Company are now inviting emigration to their territories,* and we think them well worthy the consideration of all those who would seek to improve their condition by migrating to a foreign land.

Without recapitulating, as we think it unnecessary, the description of persons best suited to emigrate to Van Dieman's Land on the ordinary footing, we now proceed to speak of them in the order originally proposed, beginning with the

FARMERS.

From all the accounts which we have of the agricultural state of Van Dieman's Land, it appears that *good* farming, at least until very lately, was not by any means common there; and when we consider how much depends upon a thorough knowledge of that science, and perceive, at the same time, how much has been done in that country with a very slight acquaintance with it, it will be evident how greatly the chances of ultimate success are increased on the part of the emigrant by his being experienced in husbandry before going out. As we have had occasion to remark before, however, the growing of wool will be, or at least ought to be, the principal object of the settler. For a certain proportion of grain, and other agricultural produce, he will always find a ready and remunerating market in the island, say—for wheat, about 5s. 6d. to 5s. 9d. per bushel; but this, in the meantime at least, must be limited, and he cannot count on any other demand than what arises from the immediate wants of the colony itself; he ought to cultivate land, therefore, with this prospect alone in view, and proportion it accordingly. With regard to wool, again, it is otherwise: he cannot have too many sheep, provided he takes care that they are of the right sort. He may grow any quantity of wool, and he will always find a ready sale for it at Hobart Town, or he may ship it to England, if he prefers it, or sees it for his advantage. But let him pay every attention to the breed, and the improvement of his flocks in the quality of their wool, for on this, of course, depends the price which he will receive for it. On this subject we quote the following extract of a letter from a highly respectable settler, dated the 18th July 1832:—"I am happy to say that the settler's prospects are as favourable, indeed more so, than they were some time since. Sheep keep up their price—12s. to 15s. per head, and wool has much advanced. I sold ours this season for 10d. per pound; it is our intention to send it to England for sale after another year. We are getting rid of our coarse flocks, and improving the wool with Saxony rams. I have no doubt, in the course of three years, that the wool in the London market will yield us 2s. per pound." And there is no doubt, that, if due attention is paid to the quality, and to the preparing of the wool for market,† in the washing, sorting, packing, &c., that this price will be realised, for in the London sales of New South Wales and Van Dieman's Land wool for December 1831, the latter brought even then, the better sorts from 1s. 3d. to 2s. 2d. per pound, and the former, some of it, as high as 2s. 11d.; and we have no doubt that the improvements which have since taken place in the cultivation of this article, will entitle it now to still higher prices, provided no unforeseen change for the worse takes place in the wool market. Besides the growing of wool, there is another exceedingly promising source of wealth open to the settler—this is the dairy, which seems to be strangely neglected in the colony, although the demand for this species of produce is great, and the prices even extravagantly high; butter readily bringing 2s. 6d. to 3s. per pound, and colonial cheese 1s. to 1s. 3d. per pound. Yet, with all its vast extent of rich pasturage, and its innumerable flocks and herds, Van Dieman's Land imports both of these articles from New South Wales and the Cape of Good Hope. Indeed, in the former country, there is more than one

* For farther particulars on this subject, we refer the reader to the "Proposals" themselves, published in the form of a pamphlet, by Richardson, 91, Royal Exchange, London, 1833.

† See our article on New South Wales, for a set of "Directions" on this important subject.

person who, wisely devoting themselves to this profitable branch of farm produce, are rapidly realising fortunes. Any person, therefore, going out with a thorough knowledge previously of dairy matters, would assuredly find his account in it. The cattle there are certainly much inferior in general to what they are in this country, and therefore a similar return as to quantity could not be expected, but still that return would be amply sufficient to realise a very handsome yearly profit to the dairyman. The person going out there, or indeed any other who intends grazing cattle, would do well to take with him a quantity of English grass-seeds of various kinds, and particularly Dutch clover, which, when once settled, he should always carry about with him, sprinkling it here and there as he goes over his pasture lands, as the sameness of the grasses in Van Dieman's Land, notwithstanding of their richness, has been found injurious to the health of the cattle. On reaching his destination, he will learn that a little salt also placed in situations where it may be at once kept dry, and be within the reach of his cattle, will be exceedingly beneficial to them.

Land is obtained in this island precisely on the same terms as in New South Wales, viz. either by the purchase of crown lands from the government, or of private property from individuals; the lowest price of the former is 5s. per acre, rising higher in proportion to its value as regards local situation or natural advantages. A deposit of ten per cent. must be paid on making the purchase, and the whole amount in one month thereafter. In the case of private property, it is, of course, impossible to say what the price may be, since that will depend upon circumstances, on which we cannot found any previous presumption; but good land, already under cultivation, may be had here, as in the sister colony, at from 10s. to 15s. per acre; and, as in the case of the Ross Reserve already spoken of, even unlocated crown lands will bring this sum and a good deal more—in one instance nearly double—but these were particularly fine lands, the very pick and choice of the island. There are few other uncultivated tracts that would bring any thing like these prices. The intending agriculturist emigrant must not think of going out to Van Dieman's Land, any more than to New South Wales, without capital; or rather, it is, if possible, still more necessary, or at least a larger amount is necessary in the former than in the latter case, for the expense of clearing and bringing the land into cultivation is greater. A farm of a hundred acres in New South Wales requires, upon an average, an outlay of about L.700 to make it fit for the plough, while in Van Dieman's Land it will cost L.1000, or L.10 per acre. This difference arises from the greater expense of maintaining convicts in the article of clothing in the one colony than the other. In Van Dieman's Land, this item costs the settler from L.7 to L.8 per head, while in New South Wales it will not average more than L.5; this is of course a difference in the price of labour, operating against the Van Dieman's Land settler. Neither the one colony nor the other, then, are places for a ruined man to go to; without being in possession of some capital after he lands there, he can do nothing: he cannot move a single step—no, none—nay, less easily than he could probably do at home. There, at the outset, he will get no credit; no honesty of intention, no integrity of character, will avail him; nothing but the money, and of this, too, he had as well have a pretty round sum, or he had better remain where he is, wherever that may be. Even in the best case, all idea of making a fortune must be abandoned. There is no such thing as fortunes being made, either by agriculture or grazing, in either Van Dieman's Land or New South Wales; but a competency, and a great degree of comfort and independence in circumstances, are readily acquired in both, much more readily than here, by industry and perseverance, when aided at the outset by a little capital; and, indeed, if it be allowed that wealth may assume another shape than that of money, that to have abundance of all the necessaries and comforts of life, with a certainty of your children inheriting, if not forfeited by their own misconduct, all these blessings—if this be wealth, then wealth *is* to be acquired in both Van Dieman's Land and New South Wales; but accumulations of mere money are entirely out of the question.

The following "advice to emigrants," that class of which we are now speaking, viz. farmers, comprises nearly all that can interest him with regard to his situation, and the conduct he ought to pursue after landing in the colony. It is from the Van Dieman's Land Almanack, 1832:—"In several respects, the situation of a newly-arrived emigrant is peculiar. Every action, thought, and word, are for the moment influenced by the spirit of excitement, which is inevitable to all who have left their native land in order to settle in a new and very indistinctly-understood country. With expectations highly raised, a strong feeling of self-consequence, and being keenly alive, too, to whatever is likely to affect the success of the enterprise, the emigrant is apt frequently both to overrate and to underrate difficulties; to form opinions upon light grounds, and afterwards pertinaciously adhere to them; in short, altogether to go wrong, merely for want of having been set right at starting.

One of the chief things to be impressed upon the emigrant, is, that the sooner he reaches his ultimate destination, wherever he purposes this should be, the better will it prove for him. Every shilling expended at intermediate places, every hour passed at hotels or lodging-houses, is an abstraction of capital, which he will bitterly repent before he has lived one year in the colony; for it is idle to conceal from him, that upon his own *frugality* and *industry*, more than upon any other cause whatever, will his success depend; and he should besides be told, that money is of so much more value here than in England, that if he purpose relying upon such aids as are common there, and should thus be led into an outset that is in the least beyond his own resources, or beyond such means as he has immediately at command, independent of any other quarter whatever, he will be preparing the way to his own certain destruction. Once let him be in the hands of the money-lenders, and the rapid manner in which an interest of fifteen to thirty per cent. (which is the least he will find he has to pay) swallows up principal and every thing he has besides, will astonish him. Houses, land, possessions of every sort, all become swept away by the fell hand of the sheriff's officer; and years of anxiety, toil, and deprivation, finish by placing him in a prison. But all this may be avoided by attending to a few plain rules or guides of conduct, upon entering the colony, and among them may be enumerated the following:—

1. Beware of what acquaintances are formed. It sometimes happens that emigrants are thrown, upon arrival, among classes who have formed a jaundiced opinion of every thing around them—of the colony—of its administration—its resources—its general state or condition—and whose chief delight now is in gaining proselytes to their own notions. Whatever information these communicate, will be tinged by the state of their own minds; and, as a general rule, therefore, every thing that so reaches the ear of the emigrant should be received with extreme caution. Equally to be guarded against are another class, or those who always view things in their brightest colours—for a young colony presents of itself a peculiar field for the man of enterprise and speculation; and if these be nourished by too much encouragement, they will bring ruin upon the projector.

2. Beware of becoming a politician, or of belonging to a party—an emigrant should leave all things of this sort in the country to which he has bid adieu. He cannot afford to have his mind or his time divided between what his new avocations demand of him, and such pursuits as these. Delightful as they may be also, they are perfectly out of place in a young colony, the governing principle of whose inhabitants should be, the moral conveyed in the fable of the bundle of sticks.

3. Never forget that you are in a country where, for a few years at least, prudence requires that the veil of oblivion should be drawn over many of the comforts, and still more of the luxuries of life, to which, perhaps, you have been accustomed for many years. Whatever may be your circumstances, things of this sort cannot be indulged in for a time, without departing from those maxims of prudence which have been already inculcated.

4. Be extremely cautious how you are led to make purchases, or forming bargains of any sort. Almost every one you meet will have the best horse, the best cattle, sheep, &c., the island produces, for sale; but let the second best be good enough for you; or rather remember that there is nothing so good that something else may not be found which will equally answer the purpose; or again, that it is better sometimes to be without a thing a week, than to have it one day too soon.

The settler should never forget that his independence—his true comfort—will depend upon his being able to obtain, without money, the greater part of those necessaries of life which money is elsewhere required to purchase. He should aim to produce every thing within himself—to raise all from his own ground. He who does so, although his income may be small, may still be a wealthy man if he be true to himself; but, as before said, much depends upon how he sets out.

A few words will now be added by way of acquainting the emigrant with certain routines that may assist him upon first landing in his search for land. His most important business, generally speaking, is the selection of land—desirableness of the early settlement upon it, of himself and family, has been already mentioned. The piece of information that will prove most useful to him with respect to the selection of land, is, that infinitely more depends upon his own energy than upon any thing else whatever. His first business, after landing in the colony, is to obtain from the survey department a printed form of application; and, having filled it up, and forwarded it to its proper destination, he will soon receive an answer, acquainting him with his excellency the lieutenant-governor's determination upon his case. Presuming this to be favourable, his next step is to fix upon the land he may desire to have; and here, it must be confessed, a most difficult task is before him. He will, no doubt, have been permitted to examine the charts of the island that are in the surveyor's office; but what information do these afford?—what can be learnt from them, even by persons who fancy they know every corner of the colony?—and what, then, do they impart to the newly-arrived emigrant? However, he will, of course, have studied them a little previously to departure for the interior—a measure that is imperative, personal inspection being the only dependence whereon he can reasonably ground any hopes of success. But here, again, obstacles will be his lot at every step. The district-surveyors will be unable, in consequence of the backwardness of the surveys, and other similar causes, to give him half the information, with respect to lands in their immediate neighbourhoods, upon which he had perhaps calculated. Again, it is no easy matter to discriminate, by natural marks, a piece of land which may remain ungranted, from other portions or tracts in the vicinity which may have been selected, although they have remained unimproved; or, again, from those parcels that have been marked off as *reserves*, or for the church, or for future villages, townships, &c. Besides, the person in quest of land has always to expect to be misled by persons who are in the habit of assuming a right to crown land to which they have no pretension, merely because they have found it convenient as a pasturage for their sheep and cattle. In addition to all these, it must not be overlooked that there is really very little good land, except in remote situations, remaining ungranted; so that, upon the whole, the task of searching for it may well be termed difficult and perplexing.

Still the active energetic searcher of land need not despair; but, as before said, much, very much, depends upon himself: in fact, he may be considered either the maker or the marrer of his fortune throughout his whole career in the colony, for it is the vere worst place in the world for the idler, the spendthrift, or the lounger; whilst, on the other hand, it presents ample—although perhaps he may at first consider it slow—encouragement for the man of sober and industrious habits."

The greatest difficulty which the new settler will have to encounter in preparing his land, is from the trees with which he will find it encumbered. To free the land from these is an expensive, tedious, and exceedingly laborious process, but as it of course must be done, it had best be set about with cheerfulness, and [illegible] at with unremitting perseverance. The settler [illegible] now cast his coat, and set fairly to work with his assistants. A great many settlers have contented themselves with cutting the trees a little way above the ground, leaving the stumps and roots to decay of themselves, without grubbing them out entirely, as they ought to be. This is a saving of labour and expense in the first instance, but it will not be found so in the long-run. These stumps take ten or twelve years to decay; and even in the state of decomposition to which they are then reduced, they still require to be taken up, and not having the tree to act as a lever in tearing them from the earth, they are often found more troublesome to root out than the whole tree itself would have been; while in the ground too, they interfere sadly with the operations of both plough and harrow, deform the ridges, interfere with proper draining, rendering it more expensive by making it more circuitous; and as neat and regular husbandry is always the most profitable, and as a crowd of blackened stumps sticking up in a field must entail the reverse, so must the farmer's profits be proportionally lessened, to say nothing of the ungainly appearance which they must present in a cultivated field.

The manner of feeding and rearing cattle is in every respect exactly the same in Van Dieman's Land as in England and Scotland, and their farming is also nearly the same, differing only in so far as a greater degree of heat in summer requires that it should. There is an idea gone abroad, that all the good land in Van Dieman's Land is already located in the possession of settlers, and that there is none there worth having to be had. This is untrue: there are many millions of acres of fertile country there still to dispose of: probably by much the greater part of the best situated lands, in so far as a contiguity to market or to points of embarkation is concerned, are already in the possession of private persons; but there is much valuable ground in the interior unoccupied, particularly a fine newly-discovered tract at the back of Mount Wellington, which will alone afford excellent locations to all who may seek them for some years to come.

MECHANICS.

The demand for this class is equally great here as in New South Wales, and the encouragement the same. Wages from 5s. to 8s. per day; sometimes as high as 10s. for first-rate workmen. Living, however, is considerably higher here than in the sister colony, especially in the article of animal food, as will be seen from the list of prices in the last page of this sheet, and by which it will be perceived that beef and mutton are 5d. to 6d. per lb., and hams the enormous price of 1s. 9d.; while in New South Wales the former does not exceed 4d., and may be bought at 3d. Tea, sugar, &c. are the same price in both places. The encouragement which the government of this country offers to emigrants of this class, viz. an advance of L.20 to married mechanics taking their wives along with them, and for farther particulars regarding which we refer our readers to our sheet on New South Wales, applies equally to Van Dieman's Land as to the former colony. On the whole, New South Wales seems to be the most desirable place of the two for both the mechanic and the labourer, since wages are not higher in Van Dieman's Land than in the former, while provisions are cheaper; besides, the other being the elder country, every thing there is more matured, and placed on a firmer and broader basis; the extent of country is all but unbounded; the population is nearly double to what it is in the former; and, in short, it must always be considered, from these and other circumstances, as the principal colony, notwithstanding it is no longer recognised as such in a political point of view. It is the wealthiest, and, as a necessary consequence of its being the first established, and as being long held as the chief settlement, it is several steps in advance of the other in various important particulars. The description of mechanics most in demand here is much about the same as in New South Wales, viz. coopers, ship and house carpenters, cabinetmakers, joiners, wheelwrights, brickmakers, and sawyers; stone-quarriers, cutters, and masons: all kinds, however, will be made welcome; nor will any be at the smallest loss to find employment; and the liberality of the home government relieves them, until they shall be long enough there to repay it, of one-half of the passage-money for themselves and wives; in other words, they have only to advance L.20 for this purpose, the state advancing the other L.20, the whole amount of passage-money being about L.40 for each married couple.

FARM-SERVANTS AND LABOURERS.

These are also greatly wanted in the colony, and readily obtain employment on the same terms as in New South Wales—the former from L.10 to L.15 per annum, with ample weekly rations of provisions; and the latter 1s. per day, with fully as much bread, meat, &c. as they can consume, and in some instances still better terms may be had; but as the government does not afford assistance to them in any shape, they are left to find their way out as they best can; and there is no other way but by paying L.20 for a passage, a sum which very few indeed of the latter class in particular are able to command; and if burdened with a wife and family, which would considerably more than double this amount, the idea of such going either to Van Dieman's Land or to New South Wales, seems entirely out of the question; that is, the idea of going out as mere labourers, and without any capital. It might be thought that where the want of labour is so much felt, and the demand for it so great as it is in these colonies, that the remuneration would be proportioned to this scarcity and demand; but this is not a necessary consequence, and, in fact, in these very instances does not follow; for this reason, that however much they want labour, they cannot afford to go beyond a certain price for it; and if it cannot be had upon such terms as will make it worth the colonist's while to perform certain work, he must just leave that work undone: this operates seriously against the colony, but is nothing in favour of the labourer, or rather it is ultimately equally injurious to him.

Both the mechanic and labourer should be informed, also, that the colonists pay as little in money to any of their workmen as they possibly can, always stipulating for a portion of their wages being taken in produce. This does not apply so much to their principal towns, such as Sydney, Hobart Town, Launceston, &c.; but in the country it is the universal practice. Money, in short, is an exceedingly scarce commodity in the colony, and its place is as far as possible supplied with the produce of the soil.

UNMARRIED FEMALES.

Free servants of this description are also greatly wanted in Van Dieman's Land. The government bounty offered to these equally applies to both colonies, viz. a gift of L.12, to enable them to pay their passage out, to all between the ages of fifteen and thirty years, who form part of a family about to proceed thither, that is, under the protection of parents or relations; and a similar sum to all unmarried females between the ages of eighteen and thirty, who intend going out alone. In both these cases, certificates of good moral character from the minister of the parish in which the applicant resides, and from a respectable householder, are required, before any female can be admitted as a candidate for this bounty. Printed forms of certificate and applications, both for unmarried females and mechanics, may be had at any emigrant ship-agents in London, Liverpool, or Leith. Farm-servants of this class are particularly wanted; these, and stout active servants of other descriptions, are just now obtaining L.15 per annum of wages.

The preferences given by government to candidates are of three different kinds—the first, to those who go out in company with their families; the next, to those who can make themselves useful in a former's family; and the third, to those who offer to pay a larger proportion than others of the cost of their passage. In the absence of these claims, priority of application is the only guide. The form of application contains blanks, to be filled up—the first, with the name of the applicant; the second, with her age; the third, with the amount she proposes to contribute towards the expense of the voyage; the fourth, the name and address of the minister of the parish in which she resides; and fifth, the name and address of any respectable householder to whom she is known. The female going out upon these terms is in no way bound to the government, but is perfectly free to go where she chooses on landing in the colony, and to follow after whatever employment she thinks fit; she is, in short, in every respect, as free then as she is before leaving Britain.

There is yet another mode by which single women, between the ages of eighteen and thirty, if possessing good health, and good moral character, may get out to the colonies of either New South Wales or Van Dieman's Land, at a small cost. At our sea-ports offers are made, including provisions during the voyage, to take out women of the description above named, on payment of L.6; or if unable to make this advance, on payment of L.3, they coming under an obligation to pay the further sum of L.5 out of their earnings after their arrival in the colony. The difference of the passage money, which is altogether L.18, is in these cases made up by the colonists, and is a free gift; none who avail themselves of it being placed under the smallest restraint in consequence of their acceptance of it.

PASSAGE.

Although, when looking at a map of the world, the distance from this country to Van Dieman's Land and New South Wales seems to be much the same—and, indeed, when compared to the whole space between, it is but as a mere point—yet the actual distance between Hobart Town and Sidney, the capitals of the two colonies, is considerably upwards of 400 miles, the latter being much farther away than the former. On this account the amount of passage-money to Hobart Town is in general several pounds less than to Sidney. For a single man in the cabin, including provisions, it is about L.50 to the former, and L.55 to the latter; and in the steerage about L.21 and L.23; the difference, in short, is about L.5 in the case of a cabin passenger, and from L.2 to L.3 in that of a steerage passenger—in both, the passage-money for a married couple is somewhat less than double. Each passenger is allowed a certain quantity of luggage freight free, generally about half a ton each, although in this particular there is a considerable difference with different ships, some giving more, but a greater number less.

With the prospect of such a long voyage before him, it would be well for the intending emigrant, both for his own sake and that of his fellow-passengers, to make up his mind, before embarking, to put up, as far as he possibly can, with any little disagreeables which may occur during the voyage. He should determine neither to give nor take offence on slight occasions, but keep on good terms with all about him, overlooking little inadvertencies and hasty expressions on the part of his fellow-voyagers. He should rather try how pleasant a companion he can make of a man than quarrel with him because he does not find him so ready-made to his hands. Let this experiment be fairly tried, and it will be found, in nine cases out of ten, that unfavourable appearances or first impressions are not criterions of character. Above all things, keep upon good terms with the captain of the ship. He has it much in his power to make your situation comfortable, or otherwise, during the voyage, and most assuredly you will make very little by placing yourself in an attitude of hostility with regard to him. You will gain nothing by getting upon your high horse, and talking big about what you have a right to say, or to do, or to expect; for though really a disagreeable man, he will take care not to go the length of doing any thing which can bring him within the reach of the law, or regarding which you could have any good hold of him; but how miserable can he not make your situation, and yet keep short of this! How many things can he not do to annoy you, for which, though giving you much unpleasant feeling at the time, you could scarcely afterwards find a name!—annoyances, in fact, which, though painful enough to feel, appear exceedingly trifling in relation. All this, however, may be easily avoided: be at some pains to study the man's character; humour his foibles, if he have any; and be not ready to take offence at any thing he may say or do, though it may not appear to you at the time altogether what it ought to be. By doing this, you will consult your own comfort, and with ninety-nine chances to a hundred in favour of your finding your captain a very honest fellow.

VAN DIEMAN'S LAND PRICES CURRENT—1832-3.

Ale, English, per doz.	L.0	18	0	Meat, beef, per lb. 4d. to	0	0	6

—— stone, do.	0	9	0				

THE COLONIAL GARDEN.

The seasons of the year in these colonies being very different from what they are in this country, we beg to offer the following observations on the proper periods and mode of planting in the kitchen garden, abridged from the Appendix to the work of W. C. Wentworth. The observations apply to New South Wales in particular, but may with a reasonable allowance be also useful as regards Van Dieman's Land:—

Potatoes, for a general winter crop in field or garden, should be planted from the end of January to the end of February, or even the beginning of March, rather than lose the planting; and they will come into use in winter, when cabbages and other vegetables run to seed. The ground should if possible be prepared a month before the planting, and a preference given by the country gardener to new ground, or dry wheat stubble, where the soil is light. The town gardener should keep his ground in a good state by frequent light manuring. In July the ground should be prepared for the summer crop, at which time the winter crop will be fit for digging; in which process every care should be taken to prevent their being bruised; and if possible, they should be dug in cloudy weather, to avoid exposure to the sun, which would rot them; whereas, if carefully preserved, they will keep sound for a length of time; which will be the more desirable, as at this season vegetables are mostly scarce and dear. In August the planting should be made, or even in September, if necessary; and at the end of the latter, or in October, they will require to be hilled and earthed, and well cleansed from weeds, which must also now and then be done as weeds make their appearance. In the choice of seed for this crop, a middle-sized potato should be preferred, without any objection to their being cut, as is the customary mode of planting. In October you may also plant potatoes for a latter crop; and this, though perhaps less abundant than that sown in August or the beginning of September, will nevertheless be sufficiently productive to pay well the expense and labour of planting. The potato is so essential and desirable an article of food, that too much care cannot be bestowed in their culture and preservation; for should other crops fail short, this will afford the grower a certain means of supporting his family.

Carrots and parsnips, for a general crop, may be best sown in December and January. The ground should be dug deep, and broke up very fine. If the soil be light, the seed should be sown on a calm day, and trod in. Carrots and parsnips may also be planted in July, and also in November. They thrive best in an open situation, or a light sandy soil; and after they come up, should be thinned and set out with a small two inch garden hoe.

Cabbages, for a constant supply, may be sown in January, April, May, July, August, October, and early in November, at a time when the ground is in a moist state. The plants sown in April will not run to seed. Care should be taken to set out the plants in a richer and stronger ground than the bed they are taken from; otherwise the crop will be poor. Their first bed should now and then be weeded with the hand in dry weather, and the freshest and strongest plants removed first.

The ground for turnips should be prepared in February, and at the latter end of the month some may be planted, for which purpose gentle showery weather is most favourable. Turnips for a general crop should be sown early in March, and they will be ready for food for sheep in the beginning of May. During their growth they require hoeing once or twice, to thin and keep them clean, if the land be foul. Turnips for table use may be sown at any time between March and September, or the beginning of November, when absolutely necessary.

The seed of cauliflower may be sown at any time between November and February, but best in December. Some sow about the middle of May for a summer crop, and this practice is found to answer.

In March prepare the ground for onions, by breaking it up well, and richly manuring it. At the end of the month, and beginning of April, sow a light crop of onions for immediate use. In April prepare for a general crop, which should be sown at the latter end of the month, or beginning of May, to keep them from going to seed. When they grow to a proper size, which will be from the latter end of October to the beginning of November, they should be carefully laid down, so as not to break the tops; for should the tops be broke, and the wet penetrate, the onions will inevitably spoil. When fit to draw, they should be gathered on a fine dry day, and laid under cover, so as not to be at all exposed to the sun.

The ground should be prepared in March for peas and beans of all kinds, by well working and manuring; and at the end of the month, and in April, they may be sown for a spring crop. Some sow from the beginning of March till the middle of June, as occasion may require. Prepare in August for a later crop; and French beans may be as well sown in October as at any other time.

In Van Dieman's Land, the farmer sows his grain in July, August, and September, which are the spring months; in October he prepares the land for Swedish turnips; in November he gets in his potato and turnip crops; December is the height of his hay harvest; at about the middle of January his wheat harvest commences, and continues through February; in March he pays attention to his fallowing and husbandry; in April he gathers his second crop of potatoes; in May he lays down his English grasses; and in June he continues his ploughing and harrowing. Thus, he has a continual round of pleasurable occupation in his fields—

"Oh! friendly to the best pursuits of man,
Friendly to thought, to virtue, and to peace,
Domestic life in rural leisure passed."

Sold by John Macleod, Glasgow, and all other Booksellers in Scotland, England, and Ireland.—Published once a fortnight. Stereotyped by A. Kirkwood, and printed by Ballantyne & Co. Paul's Work.

CHAMBERS'S
INFORMATION FOR THE PEOPLE.

CONDUCTED BY WILLIAM AND ROBERT CHAMBERS, EDITORS OF THE "EDINBURGH JOURNAL" AND "HISTORICAL NEWSPAPER."

No. 15. PRICE 1½d.

POLITICAL ECONOMY.

POLITICAL ECONOMY is the science which explains the sources and distribution of national wealth. Though a study better fitted perhaps for learned men than for common people, it is yet of more or less importance to every body—for all men have interests which it may teach them to cultivate, and rights which it may teach them to defend. The working classes, in particular, ought to be better informed on this subject than they are in general: it would make them understand the exact nature of their position in the world, the relation which their own interests bear to those of other men, and the means and ways which they ought to take to improve their condition. It has all along been from a want of this knowledge, that labouring people have never as yet had any consistent policy among themselves, wherewith to meet the policy of those who had such knowledge; never as yet have been able to ascertain their true interests, either as individuals or as a class; and thus have grown up at the mercy of mere chance, and are now perhaps far less comfortable and happy than they might otherwise have been. They have hitherto been excusable in a great degree for this ignorance, on account of the science having never been explained, either in terms which they could understand, or in a form which was accessible to them. Such, however, is no longer the case. Here, for a sum of money which even to them is a trifle, and in language which we hope will be within the comprehension of the most unlearned, will be laid before them, all of this branch of human knowledge with which it is of particular importance that they should be acquainted.

CULTIVATION OR NO CULTIVATION.

Originally the surface of the earth was a mere waste, and the men that could live upon its spontaneous fruits were in a most unenviable condition. We see this proved before our own eyes by the state of certain large uncultivated tracts in North America, where there is not above one man for a thousand acres of ground, and even the few who live there by hunting and other rude arts, are exposed to the most dreadful wants, the result of which is frequent cases of starvation.* Human reason informs us, that the design of the Creator in planting mankind upon the earth, was, that they should labour to cultivate it, and live upon the produce. By this means, it is evident that they not only acquire far more comforts as individuals, but enable more to live upon the same space of ground. Two hundred and twenty persons, for instance, live upon every square mile in England, and even a greater number in the Netherlands, while not one man can subsist upon that space of ground in the savage parts of North America. There may be more difficulty in demonstrating that some English workmen are better off than the generality of Indians; for the advantages of the one cannot be exactly balanced against the disadvantages of the other. But it is to be presumed that few rational men would prefer the wild freedom of these savages, accompanied as it is by privations of the severest kind, and which frequently abridge life itself, to the toil of a common labourer or workman, in such a country as England. It is clear, then, that labour was necessary to improve and extend the natural bounties of the earth.

LABOUR.

In one sense, labour has existed from the very beginning—for even to pull a wild apple or hunt down a wild animal requires some exertion. What is here meant, however, is, that regular consistent exertion which produces regular consistent results, and tends to something beyond supplying the necessities of the moment. Labour properly began when the first field was ploughed and the first grain sown; and its utility was first felt, when it was found that the plougher and sower could either live better himself in consequence of the process, or enable others to do so. A step was then taken towards the improvement of natural advantages, and the increase of the species.

This species of labour is called agricultural: it is entitled to the first consideration, because its produce was an article of first-rate necessity, and because the earth, upon which it acted, is the natural source of all things. Another kind of labour is manufacturing. Any operation of the hand, by which a thing in a natural and insufficient state is adapted for the use of man, or rendered more agreeable to him, is an exertion of manufacturing labour. If the first agriculturist made his own plough, or converted the straw of his first crop into a rude bonnet to shelter him from the rays of the sun, he was also a manufacturer.

EXCHANGE.

In the first condition of human labour, every man would have to plough and reap for himself, and also to make with his own hands all the rude articles he required for his personal conveniency. Having plenty of time, he would feel this as no great disadvantage. By and bye, his time would become more valuable, and in order to make as good use of it as possible, he would find it advisable to confine himself to agricultural labour, and purchase those manufactured articles which he required, from a man who, for the same reason, had begun to make the production of such things his exclusive business. Thus, society would become divided into distinct classes, who exchanged labour with each other for the general conveniency, and for the purpose of making each individual more productive.

PROPERTY.

One thing was from the very first necessary, before any labour could be undertaken upon proper principles. It was necessary that where a man sowed, he should be certain he would reap; where he fabricated an article, that he should be certain of having liberty to use it. If he could not calculate pretty safely upon the product of his labour becoming his own property, he would want all motive to exertion, would neither sow nor manufacture necessary articles, and both himself and his fellow-creatures would be deprived of the advantage of his labour. Hence arises the idea of property. At first, as among the North American Indians at the present day, a very faint notion of property would obtain, and perpetual attempts would be made to despoil a neighbour of what he had endeavoured to mark out as his own. By and bye, however, when men began to understand better what was for their general as well as particular interests, men would be permitted to fix themselves upon certain tracts of ground as their own, and would be protected in the enjoyment of them by regulations called laws, which every sensible man would support in the case of a wronged neighbour, in order that they might be supported when it was his turn to be injured. It would be found better that the land should be thus divided among a limited portion of people, while others only lived upon it indirectly, than that there should be no property at all, and, consequently, no labour. Even those who were worst off by this arrangement, were better off than if it had not been formed, for in the one case they could still sell their labour to the man who had property, and thus gain a livelihood, while in the other they would either starve, or be killed in the disputes which would be sure to take place, or, what is most probable, not be called into existence at all. To make it plain how useless is any natural product of the earth, if it be not claimed and guarded by some man as his particular property, let us instance a cherry-tree in a hedge-row, the fruit of which is sure to be seized by wayfarers before it ripens. Better it would be for society to give up this tree by general consent to one of their number, whether *he* had any pretensions to it or not, and thus let it be protected till its fruit ripened, than permit it to remain of no use to any one. The *merits* upon which the first proprietors of the earth contrived to secure what their representatives now enjoy, is a question which all classes of political thinkers seem to think it best not to agitate:† enough it is for our present purpose to show, that property is absolutely necessary, in order that there may be labour, and in order that any of the advantages of labour may be experienced by society at large.

MONEY.

Money is a necessary consequence of exchange. Direct barter is soon found inconvenient, and the cause of loss. The one party does not always want exactly what the other has to give, or only wants a part of it; and before every one gets exactly what he requires, he has to exchange over and over again, by which he loses a part of his time, and probably incurs much expense for carriage. Money, therefore, which saves this inconvenience and loss, appears to have been brought into use almost as early as the very commencement of social transactions among mankind. The labourer accepts of certain coins, or pieces of paper which he knows can be converted into coins, instead of any actual necessary of life which his employer would otherwise have to give him; and with these coins, in minute divisions, he can purchase to a fraction what he requires, without any loss of time. Money, on the other hand, or any of the things which represent it, is of great convenience to those who save a part of their gains; it will keep quite fresh, while many other articles would perish. There has never yet been found any perfect money or representative of value. The metals most commonly used, though the nearest possible approach perhaps to a fixed standard, are yet liable to fluctuations in their own value, by reason that they are themselves articles of merchandise, and are at one period more plentiful than at another. When a nation, however, agrees upon their value, the government (which represents that nation) can give them a sanction by stamping or coining, which obviates a considerable part of the disadvantage.

CAPITAL.

As soon as any thing was produced by labour, above what was necessary for immediate consumption—as soon as the property of the ground could be exchanged for something else, and men became possessed of various articles which facilitated the production of others—capital was in existence. This is a thing of immense importance in political economy. It is evident that, while men could only rear or make what they immediately needed, they were very ill provided. In order to be at all at their ease, it was necessary that they should have something stored up, to serve them in the event of a failure of crops, or of any other deranging circumstance. In order, moreover, that one thing might be made, it was necessary that another (a tool, machine, or other appliance) should previously exist; and the more plentiful the first thing was, the second could be produced so much the more easily, and disposed of at so much the less cost.

Capital is formed of the savings of mankind from the beginning: it is what the reason of man has directed him to lay aside, out of his gains and labours, as a means of gaining and labouring to much greater advantage thenceforward. It is found, like ground property, into which it is convertible, in the hands of a limited number of persons, for all are not so fortunate as to have formed any for themselves, or to have inherited or received any from others who did. When

* This is put beyond question by the Memoirs of John Tanner (who had been thirty years among the Indians), published at New York in 1830.

† It is worthy of remark, that there never has yet been any attempt of the unpropertied classes, in any country, to dispossess their more fortunate brethren. The idea of such a thing seems never to be entertained by more than a few isolated individuals. There have, however, been many wars and movements of the poorer classes against undue privileges assumed by the wealthy.

a man possesses capital, he generally becomes an employer; when he has none, he is generally compelled to be a labourer or workman. The capitalist can apply his possessions to the purchase of a stock in trade, or a set of tools or machines for a manufactory, and thus he is apt to become rather a director of labourers than a labourer; though, in one sense, every man who does any thing to serve his fellow-creatures, is liable to that designation; while every working man, on the other hand, may be termed a capitalist, if he only possesses a spade or a pickaxe, or, what is equivalent, a little instruction in his trade—for all these things are alike the result of a storing up. Capital and labour are in many things, indeed, confounded together; but, in political economy, the latter is generally considered as a bare power of exerting native faculties, while the other is held as that superfluous wealth which has been treasured up by careful men, and is employed in furnishing the materials of labour.

ADVANTAGES OF CAPITAL NOT EXCLUSIVE.

Men who find themselves obliged to labour are very naturally inclined to envy those whom the possession of capital has exempted from that necessity. It could easily be shown, however, that the advantages are not all on *one* side.

Capital obviously produces the following good results: It enables men to buy the raw materials for manufactures in sufficiently large quantities, and to erect and employ machinery, human and mechanical, on a sufficiently extensive scale, to produce goods at a cheap rate, and thus facilitate their sale. Of course, this does good to the labourers, for it extends the bounds of employment. Considering labourers, moreover, as part of the public, they enjoy their fair share of the advantages which that body derives from the employment of capital. If capital lays an extensive railway, or erects a pier or a lighthouse, which reduce the prices at which things can be produced, the labourers, so far as they use the articles so cheapened, are the better of it. Among the uses of capital is that most indispensable one, the storing up of the surplus of a good harvest against the chance of a bad one: the labourers, of course, experience their proper share of the advantages thus attained. Another of its grand uses is the enabling a set of middle-men, merchants and shopkeepers, to buy goods in large quantities from the manufacturers, in order to deal them out in small quantities to those who need them. Without these middle-men, the distribution of goods could not be effected; and without capital, they could not exercise this useful branch of business. Of course, the labourer has his own share of the advantage thus gained. But it is needless to expatiate on this part of our subject. The possession and use of capital is what chiefly distinguishes a civilised from a savage society, and all who belong to the former state must be better off than if they belonged to the latter.*

DIVISION OF EMPLOYMENTS.

As society advances, employments always become more and more divided and subdivided, until each man at length takes only a minute part of an employment which formerly even in its entire state, did not perhaps occupy one man. The advantages aimed at in this, are as follow:—

By division of employments, time is saved. A man carrying on different occupations, in passing from one to another, must change either his position, his place, his tools, or the direction of his mind, and in any case time is lost in the transition. Nor is it alone the time apparently required for the transition that is lost: he does not immediately *get into heart* with his new employment; he saunters and hovers for a while, and the work is perhaps finished before he has attained the full rapidity of execution which it might allow of. The present writer, for instance, has found that he always advanced three times more rapidly, towards the centre and termination of any composition in which he was engaged, than at its commencement.

Greater skill is attained in a small branch of employment, and attained by a briefer period of instruction, than in a more extensive one.

The habit of the body, the muscular system, becomes more powerful when exerted constantly in one direction, than in many.

When an employment is divided, the master can husband the skill and force of his operatives by applying the exact portion requisite for each branch, and no more: whereby the price of production is lessened.

In consequence of divided employments, tools are invented and applied to each, and eventually machines are formed from a combination of these, so as to abbreviate labour in a very great degree, and of course cheapen the articles produced.

It has been customary to give the art of pin-making as a captivating illustration of the advantages of divided labour. Every woman must be sensible, that, if she had to make her own pins, she would hardly have time to do any thing else; hence the advantage of having pins made by one particular set of workmen. If each pin, however, had to be made entirely by one man, and without the use of machinery, he could not sell this article at such a price as to enable any people of ordinary fortune to purchase it; each pin would perhaps cost sixpence. In order that this article may be produced at its present moderate price, it has been found necessary to apply ten different persons, of different degrees of strength and intelligence, to fabricate it. One man is employed in the business of reducing wires to the necessary thinness, by passing them through holes in a steel plate; he will draw and clean about thirty pounds weight in a day. A woman and a girl are then employed in straightening the wire. A man, a woman, and a child, are employed in cutting it into the proper lengths, and giving the point; they can do from thirty-four to thirty-six and a half pounds weight in a day, and earn about seven shillings. The formation of the heads is accomplished by a boy and a man, the former to twist a long spiral wire, and the latter to cut it into the minute portions necessary for one separate head. The fixing of the heads is executed by a woman, by means of a steel die and other processes, and yields one shilling and sixpence for twenty thousand. The tinning of the pin is done by a man and a woman or lad. The papering, which is generally executed by women, we consider a separate process. To make 5546 pins, weighing one pound, occupies, in the different processes, rather more than seven hours and a half; and the total expense of the labour, each person being paid according to his skill and his proportion of the time, is nearly thirteen pence. It is evident, that, if ten persons were not employed, the workmen would lose time in turning from one operation to another, and perhaps have to spend a degree of skill and strength upon particular departments, above what was really required. A man would be doing the work which could be deputed to a boy, and yet require a man's wages, which of course would enhance the price of the article.

Watchmaking presents another striking instance of division of labour. One hundred and one persons in all are employed in forming and preparing the different parts of a watch, and only one of them, the finisher, is instructed in two of the operations. No doubt, as in pin-making, the subdivision of the employment has conduced to facility and cheapness.

QUESTION OF CHEAP PRODUCTION.

It is of importance to observe, that, while these subdivisions produce the effect just stated, the effect also tends to reproduce the subdivisions. If watches were not cheap, and generally accessible, there would be very few sold; consequently, perhaps, there would be no establishment for watch-making where so many as one hundred and one persons could be employed. Twenty persons, perhaps, at the utmost, would be engaged in the whole operation—would, of course, work at comparative disadvantage—and render a greater price indispensable. Unreflecting persons are sometimes heard to say, that it were better things in general were dear than cheap. But it is shown, that, unless we consent to the abstract advantage of the utmost possible cheapness in all things, we abandon the very advantages which the nature of social life holds out to us, want articles which we could otherwise have, and obstruct employment rather than encourage it.

The use of capital is shown here at the same time. If there were not capital or savings to employ one hundred and one men in one place for the production of this small article, it would be much dearer than it is, and not nearly so many men would be employed: in other words, the population would be so much less, or so much the worse off.

CONCENTRATION OF LABOUR.

It is advantageous for the cheap production of articles, that each article should be produced in certain places or districts.

The existence of mines of metal at particular places, renders it necessary that the articles formed from those metals should be respectively produced as near to them as possible, for the saving of carriage. Or, if coal be required in large quantities for the preparation of any kind of goods, a medium may be struck between the locality of the coal and the locality of the material, with a reference to the comparative weight and facilities for conveying each. On the whole, it is of importance that a centre for the issue of the prepared goods should be found as near as possible to the places where the means of preparing them can be obtained cheapest.

The clustering of men of one occupation is not only rendered unavoidable by this governing circumstance, but it is of positive advantage in itself. The competition is the more active where the number in one trade is the greater, and thus the public is apt to be served on the lowest terms, and with all other advantages, in their greatest extent. It is perhaps of still greater service, in as far as it tends to suggest and encourage the invention of useful machinery, and to improve every other mode and practice connected with the business. It is of convenience to the customers, or middle dealers, in as far as it saves them the trouble of moving here and there to considerable distances for a proper and advantageous supply of what they require. It also causes a kind of mart or exchange to be formed, tending to the ascertainment and diffusion of all kinds of information necessary for men engaged in the trade. Finally, it tends to check the unhappy fluctuations of price, which are so often the cause of loss to the capitalist, and the source of misery to the working man.

LARGE FACTORIES.

The advantage of concentrating labour is found in another way, namely, in the erection of large instead of small factories. The more extensive the factory, if all its parts are properly attended to, the more exactly is each man likely to be adapted to his employment—the more likely is it that no part of any man's skill and force is expended amiss or uselessly—and the cheaper does the system of supervision (a very important item) become. Trouble and expense are saved in conveying the various kinds of raw material from one workman to another, and in many instances an expense may be saved upon those officials, of whom one at least is in every case necessary. If *sets* of workmen are required, such as the tens of persons employed in pin-making, the enlargement of the factory may be necessary in order that there may be no imperfect *set*—which would be the cause of a loss. Where one engine or *power* is required, it may serve for a great establishment as well as for a small, and thus cause a very important saving. There may even be an advantage, as Mr Babbage ingeniously shows, in having a factory of such extent, that enough of engines are employed to render the services of an entire, instead of a fractionary man, necessary for keeping them in repair—a regular hired workman being cheaper than one called in occasionally.

In fact, there is no limit to the advantage of large establishments, except the difficulty which a capitalist always finds in getting agents who will turn things to as good account as himself. A master's eye is proverbially advantageous, and it is not good for any man to expend capital much beyond the range of that useful organ. As to the advantage which the public derives from extensive and concentrated systems of production, we are not aware of any limit to it. Every thing that tends to cheapness, as this does, must be of service to them. The workmen, on their part, find its advantage in the same degree, since cheapness increases consumption, and therefore tends either to the increase of their wages, or to the increase of their own number.

MACHINERY.

The question of machinery is one of some delicacy, but it would be improper to omit all notice of it in the present sheet. As the whole progress of things from the beginning has been from *no tools* to *tools*, from *no modes of shortening labour* to *modes of doing so*; and as the community has both been increased in number and improved in comfort by these processes, it would be impossible for any philosophical inquirer not only to deny the advantages of machinery, but to assign any conceivable limits to those advantages. The question, however, has not been ingenuously met by the writers who endeavoured lately to tranquillise the popular mind in the disturbed districts of England. "As well," said they, "fall out with a spade, or any common tool, as with a machine, since they all alike tend to shorten labour: as well might the plough be denounced for preventing the employment of the spade," &c. There is this difference, in our estimation, between the one case and the other, that tools are in a great measure the implements required by individual labourers, before they can work at all; while machines are a combination of tools, dispensing with the men. It is immediately advantageous for the community, and eventually for working men too, that tools should be thus combined, and their users disemployed. But it is not immediately advantageous for *these very men*: on the contrary, it obviously deprives them in the middle of life of all the advantage of their apprenticeship and acquired skill—turns them adrift upon other employments, where there is perhaps no reception for them—and, even if they got employment there, reduces them to the painful and penurious state of learners, in a trade for which their previous habits of body and mind render them, perhaps, very unfit. It is no consolation that the machine which has deprived them of bread offers them a particular necessary or luxury of life at a much lower rate than they ever had it offered to them before; for, without their usual wages, they can buy it at no rate whatever. It is no consolation to them that the public is advantaged just now, and that themselves or their own class will be advantaged afterwards: they cannot but see that the immediate advantage of the public is *their* immediate loss; and as no workman ever has much more than his week's wages to look to, they are brought face to face with starvation, long before their own promised share of the profit can be realised.

It is nevertheless necessary that workmen liable to this misfortune—for such it is to be considered—should

* "When we look at the nature of the accumulated wealth of society, it is easy to see that the poorest member of it who dedicates himself to profitable labour is in a certain sense rich—rich as compared with the unproductive and therefore poor individuals of any uncivilised tribe. The very scaffolding, if we may so express it, of the social structure, and the moral forces by which that structure was reared, and is upheld, are to him riches. To be rich is to possess the means of supplying our wants—to be poor is to be destitute of these means. Riches do not consist only of money and lands, of stores of food and clothing, of machines and tools. The particular knowledge of any art—the general understanding of the laws of nature—the habit of experience of doing any work in the readiest way—the facility of communicating ideas by written language—the enjoyment of institutions conceived in the spirit of social improvement—the use of the general conveniences of civilised life, such as roads—these advantages, which the poorest man in England possesses or may possess, constitute individual property. There are means for the supply of wants, which in themselves are essentially more valuable for obtaining his full share of what is *appropriated*, than if all the productive powers of nature were unappropriated, and if, consequently, these great elements of civilisation did not exist. Society obtains its almost unlimited command over riches by the increase and preservation of knowledge, and by the division of employments, including union of power. In his double capacity of a consumer and producer, the humblest man has the full benefit of these means of wealth—of these great instruments by which the productive power of labour is carried to its highest point."—*Working Man's Companion—Rights of Industry—Capital and Labour*, p. 60.

be made aware of the exact nature of the remote advantages which will accrue from what caused their present distress. The cheapness attained by machinery always tends to increase the consumption to a proportionate extent, not only by bringing the article into powerful competition with other luxuries in our own country (which is not an undivided advantage, since it must diminish employment somewhere else), but by enabling the British merchant to outcheapen the foreign manufacturer. Thus, there are infinitely more people now employed in the cotton manufacture than what there were before the invention of machinery. To go no farther than the piece of literary labour now in the hands of the reader:— It is not long since the paper-making machine lessened to a great extent the number of labourers in the production of that article. Of seventy persons, for instance, in one Mid-Lothian mill, all, except a very few, were in one week paid off; when, being unacquainted with any art or craft, and unable to live on apprentice's wages, almost the whole of these poor men were obliged to become stone-breakers by the wayside. No one can deny the hardship of this case. Yet mark the general result. But for the introduction of the paper-machine, this sheet, containing a full view of a most important subject—the result of much research and reflection—could never have been published. It could not have been published, we mean, at the price of three-halfpence; and had a larger sum been necessary, even so much as a halfpenny, the speculation would have never been thought of, because it would not have held out hope of profit. Thus, it will be observed, at the expense of some immediate suffering to a small class—a suffering which nothing on earth could avert, so long as every man is at liberty to pursue his own interest—the whole of the working men in the empire may be said to have for the first time had presented to them, at a price they could pay, and in terms they could understand, a species of knowledge, the uses of which in benefiting them are altogether beyond calculation.

PROVISIONS AGAINST IT RECOMMENDED TO WORKMEN.

It may also be represented with some force, that the employing classes are not alone responsible for the consequences of abbreviated labour. The *employed* may reasonably be looked to, since they are most nearly concerned, for an exertion of some kind or other, to alleviate what appears to be an unavoidable calamity. By bringing up part of their families to different trades—by storing up a little in Savings Banks or in Friendly Societies, during a period of good employment—by opening their eyes to *coming machinery*, and looking out in time for a retreat—much might be done to soften the calamity, before it arrived. After it does arrive, the proceedings of the workman might in many cases be amended. We hold it not creditable, for instance, to the cotton-weavers in the west of Scotland, that, after their art was destroyed by the power-looms, they should have clung so long to its reduced wages, and persisted in breeding up their children to it, as a means of in some small degree increasing the family resources—thereby entailing certain misery along with existence. It might have surely been expected that where so many more profitable trades were going on around them, they might have more generally contrived to change their employment, and thus, by allocating a small portion of their losses upon their neighbours, put an end to by far the greater part of their distress. Much of what is here blamed may arise from that feeling of attachment which men come naturally to feel towards a particular line of life, and a particular place of residence. But we hold that these feelings are only good to a certain point, and were never meant to interfere with better principles. It may also be represented, that the very condition of a working man implies that he cannot amass any capital, as, when he does so, he is tempted to become an employer or master. But, on the other hand, there is upwards of thirteen millions of workmen's spare earnings in the Funds (through the Savings Banks), which shows that there may be a surplus in wages, which neither is required for immediate support, nor is drawn into mercantile or manufacturing speculation. A working man should take care how he convinces himself that he cannot save. When, from one wage, say twenty shillings, he is reduced to fifteen, does he not still live? Why then might he not have spared, say one shilling off the twenty, and still lived? Even though assured of no mischief from machinery or other accidents in his trade, he should consider that his life, in all probability, will not consist entirely of working years. The evening cometh when no man may work. Upon ordinary chances, there will be a few years at the end of life, during which he will be unable to support himself by labour. Now, it is a sound principle, which cannot be broken without great danger, that every individual man should, if at all possible, *provide for himself throughout the whole of adult life.* It is destructive to all good feeling that he should burden a public establishment; and it is an unfair thing to the succeeding generation, that he should look there for his support. The claim of a child is imperative upon the parent during youth; *that* is no debt, or, if it be, its only fair discharge is in the care taken of the next generation; but the parent has no just or laudable claim upon his own children; it is cruel to enforce such a thing, and it is very uncertain that it will be rendered. So indisposed are men sometimes to attend to their parents in old age, so disposed are they to look after their children only, that we have known instances of the most respectable, and, to appearance, good-natured men, who paid very little or no attention at all to these relatives, leaving them to a style of life bearing no proportion in comfort to their own. We would advise all workmen, if existing circumstances will permit, to trust solely to themselves for provision during old age. It is easy for a man of tolerable resolution to lay by a small weekly sum, which he will not miss at the time; and he may depend upon it, the money will never do him any harm.

PROFITS.

The object of the capitalist is *profit*; that of the workman is *wages*. In common speech, an employer or trader is conceived to aim at profit alone, though he may also exert himself actively. But in reality, every such employer or trader is a workman besides, and in so far as he is so, a part of his gains should be ranked as wages, while only that should be deemed profit, which accrues to him as a remuneration for his disbursement of capital. On the same principle, that part of the gains of any operative which arises from his possessing tools or acquired skill, should be ranked as profit, seeing that it arises from capital, while only that (generally much larger) portion should be considered as wages, which he earns by the actual exercise of his natural strength and ingenuity.

As capital is the result of former industry—the gatherings of either some existing man, or of some deceased person who bequeathed it to him—and may thus be considered as the reward of past self-denial; so is profit the reward of a continued self-denial in the possessor of capital. If a man possesses, for instance, a hundred pounds, which he has it [illegible] to spend in personal indulgences, or to put out to active use, under his own industry and superintendence, or under the industry of another, he will, if he can abstain from spending it, realise a certain addition to it, which falls to be considered as profit. Should he think proper to employ it in setting up a small shop, he may, by the aid of his own industry, and the exertion and display of other good qualities, probably double it before the end of the year. If he prefers letting others exert their industry upon it, he may put it into a bank; in which case, he will only get a per-centage for the liberty of using it, being something much smaller than he would probably acquire the other way, but only so in proportion to the absence of his own labour, and his comparative exemption, in the latter case, from the risks of trade. Either way, it is just the reward which he deserves for his fortitude in abstaining from squandering his hundred pounds. Where the profit is not required for the immediate necessities of the capitalist, it is added to his existing stores, and thus becomes in itself new capital.

It is a law of profits, that they must, at every particular time, be pretty nearly alike in all branches of employment. Capitalists are generally very much alive to the superior advantages which may exist in any particular line of business; and if they see an opportunity of turning their stores to better purpose in one way than another, they instantly desert the present channel, and throw their money into the new one. Competition, of course, soon reduces the advantages of the new line to the general level. There may, it is true, be circumstances which protect the said new line. Other capitalists may find it difficult, from personal considerations, to make a change; or the cost of the change, and loss incurred by it, may exceed the probable profits. The invention of improved processes generally produces an increase of profits; and this superiority continues as long as it is difficult, or inconvenient, or impossible, for other capitalists to take advantage of the improvement. Upon the whole, profits must always bear a reference to the general standard of prosperity for the time: when the country is prosperous, and many articles of consumption are wanted, capital comes more into request, and profits rise; when, on the contrary, there exist more articles than what are immediately needed, capital flags in its activity, and profits sink.

It is impossible to dismiss the subject of profits without alluding to the singular decline which they have experienced within a very few years. It is in the nature of things that profits should decline in proportion as capital becomes larger in amount and more active in operation; and when they decline from no other cause, there is reason for rejoicing rather than regret. Of late years, however, profits have been reduced, not only by this salutary cause, but by another of a very different kind—namely, unfortunate legislative arrangements respecting the currency. This is a subject which it would be difficult to explain to a common mind, and upon which even cultivated thinkers are not altogether agreed. The decline of profits has inevitably produced a decline of wages, and thus the poor man suffers from a cause which it would perhaps require volumes to explain to him—if even volumes could clear up so intricate a subject. It is a striking fact, and should spur on the common people towards general knowledge, that they sometimes suffer, like dumb animals, to the most frightful extent, without knowing the source of their malady, and, consequently, without being able to take the least step towards their own relief. Were they generally enlightened, they might be able to avert or overcome various disasters, which otherwise press severely on them, and cause a trouble to the rest of the community; and it should form an argument of power against those who *fear* the progress of plebeian tuition—that, if thus enlightened, the industrious classes would be less apt than they are to attribute that to the government, which has arisen from causes entirely distinct. No safety, indeed, but in perfect light!

WAGES.

We now come, it may be said, to the kernel of the whole subject. Wages are what the industrious man habitually regards as the motive and object of all his toils. Wages supply him with his own share of the earth's alimentary productions—often too small for his comfort—and give him the means for a dearer purpose still, the gratification of those helpless beings who depend upon him as their sole refuge, guard, and stay. Wages, indeed, have an interest in the eyes of the poor man, which the capitalist can never experience, in almost any degree, respecting the same sum of money. To the employer, a shilling, in one weekly instance, is nothing; to the workman or clerk, it is held as a thing of the last moment—appreciated if gained or added, and deplored when taken away.
