Between these and the great granite range of the Nerepis valley, altered sandstones and slates, diorite, felsite, and cherty quartzite, occur.

It will thus be seen that the band of rocks now under consideration resembles those of Kingston, in the presence of felspathic and greenstone beds, while it differs principally in the abundance of coarse syenite, and syenitic gneiss. The rocks of Oak Point seem to be a connecting link between the two.

To the southwestward of the series last described, and directly opposite the termination of the Kingston peninsula, the nature and relations of the rocks are no longer doubtful. The abundance of pale pink felsites and felspathic quartzites, with beds of interstratified greenstone, at once recalls the rocks of Kingston, and indicates an extension of this series to the westward. Except along the line of the main River, however, their development in this direction is little known, the district being as yet wholly unsettled. Rocks probably forming a part of the same series appear far to the southwest, along the New River, in the County of Charlotte. These will be again referred to.

For the sake of comparison with the descriptions already given upon the eastern side of the River, the following series of observations is introduced, showing the succession of formations along the western side, extending from the granites of the Nerepis to the Suspension Bridge :—

- 1st. From Douglas Mountain nearly to the County line.—Granite.
- 2nd. From the County line to the Douglas Arms.—Altered sandstone, bedded greenstone, syenite, altered slate, cherty and felspathic quartzites.
- 3rd. From Douglas Arms to mouth of Nerepis.
 - a. Grey granitoid beds—syenite and syenitic gneiss, in thick deposits.
 - b. Green altered sandstones.
 - c. (At Nerepis Mills), Greenish and reddish altered slate.—Str. N. 40° E.—Dip V.
 - d. Diorite or greenstone in thick beds.
 - e. (Near mouth of Nerepis), Red slaty conglomerate, reddish sandstone and greenish sandstone or quartzite. These are in thick hardened beds and of coarse materials.
- 4th. From mouth of Nerepis to County line between Saint John and King's.—Felspathic rocks and quartzites, with bedded basalts, similar in every way to those of Kingston.—Str. N. 80° E.—Dip 72° N.
- 5th. Near the County line, and directly opposite similar beds in Kennebeckasis Island, the last named rocks are partly covered with a limited deposit of sub-carboniferous sandstone and conglomerate, red and crumbling, and resting unconformably on the underlying series.
- 6th. From the County line to the Suspension Bridge, the rocks as a whole are chiefly those of the Portland Group. Syenites become more abundant, and a gradual and insensible passage takes place from the rocks of Kingston to those of Portland. No marked transition is apparent, the line of division being probably indicated, and at the same time obscured, by the carboniferous deposits above described.

While the rocks of Kingston have thus been shown to occupy an extensive district, west and north of the Saint John River, along both shores of the Reach, observations in other localities would seem to indicate a corresponding easterly extension.

It has already been stated that, while occupying the entire peninsula from which their name has been derived, these rocks may be traced to the eastward in two diverging ridges, the one terminating at Dickie Mountain, near Norton Station, the other at a short distance below the head of Belleisle Bay. Stretching along the northern side of the latter, and forming the watershed between the tributaries of the Belleisle and Washademoak Rivers, is a ridge of rocks, somewhat variable in composition and of moderate elevation, which, though exhibiting some peculiarities, can with difficulty be distinguished from the deposits of Kingston and the Reach. As the series referred to is an extensive one, occupying the high land from the Saint John River eastward to within a short distance of Butternut Ridge, and as connected observations are here impossible from the abundance of superficial beds, and the gradual encroachments of carboniferous deposits, it will be best to describe its different localities separately.

Bull Moose Hill.—As composing the highest land in the ridge now under consideration, and also as best displaying the peculiarities of the series, if not itself constituting the volcanic vent to which the other deposits of the district owe their origin and character, Bull Moose Hill deserves our earliest attention.

The elevation to which the above name is commonly applied, which, however, is a collection of several hills, rather than a single well defined eminence, is as various in its composition as it is irregular in outline. The rocks which compose its mass are of three principal varieties;—

a. Metamorphic rocks, in part eruptive?—syenite, hypersthenite, basalt, diorite.

b. Sedimentary beds—altered shales and sandstones, highly charged with volcanic products.

c. Carboniferous sandstones and conglomerates, unaltered.

Of the first named beds, the most abundant and most varied outcrops occur a little to the westward of the real Bull Moose Hill, on the farms of Messrs. George and William Northrup. At this locality, to which a detailed description is devoted in the Report of Dr. Gesner, the rocks are exceedingly various in texture, but less so in composition. They may for the most part be described as dioritic or greenstone rocks, (resembling syenite in general aspect and granular crystalline texture, but containing little or no quartz). They are tough, of a whitish colour, speckled with black and greenish-black, and graduate from varieties in which little distinction is apparent (except in colour,) between its constituent minerals, felspar and hornblende, to those in which the texture is very coarse, and the individual crystals large and prominent. Syenite and syenitic gneiss are also present, as well as some varieties of true granite. Some of the syenitic and dioritic beds are well filled with magnetic oxide of iron, constituting the so called “iron ore” described by Dr. Gesner. The latter will be again alluded to.

The *sedimentary* beds of Bull Moose Hill are best exposed along its summit and towards its southeastern side. They consist of grey altered grits, trappean slates, bedded traps, (partly vesicular,) and reddish grey micaceous sandstones. There are also beds which have the appearance of being composed of volcanic ash, and others (though less common,) of compact cryptocrystalline felspar.

On the eastern slope of the hill, at one or two points, are poorly exposed outcrops of green and purple mica slates.

The *carboniferous deposits*, resting unconformably on the older series, occupy principally the southeastern side of the eminence, rising nearly to its summit. They do not require further notice in this connection.

Belleisle Corner and Spragg's Brook.—Between the rocks of Bull Moose Hill and those observed in other portions of the Parish of Springfield, there is but little diversity, although in many parts the latter more nearly resemble the rocks of the Kingston peninsula, than is the case in the above-named eminence. They may be well seen at many points near the head of Belleisle Bay, but especially along the line of Spragg's Brook, near “The

Point," where they consist of interstratified compact and laminated felspars, altered slates, diorite, and syenitic gneiss. Near the source of the last named stream greenish and purplish mica slates, conformably overlaid by thick beds of slaty sandstone, were observed, and differ somewhat from any other rocks seen in this portion of the Parish. They occur along the summit of the high land north of the Belleisle, and near compact dioritic rocks, which seem to be a western prolongation of those of Bull Moose Hill.

In advancing to the eastward from the last named eminence, the same band of dioritic and syenitic rocks, with some true granite, and a small bed of limestone, is found to occupy the axis or centre of the elevated ridge dividing the valleys of Belleisle and Washademoak, as far as and beyond Kierstead Mountain, near Collina Corner. As at Bull Moose Hill, they are flanked on either side by sedimentary beds, consisting of clay and micaceous slates, compact and porphyritic felspars, interstratified with altered slates and grits. They are progressively covered with carboniferous deposits, which finally completely cap them, and at Butternut Ridge form the eastern termination of this elevated district.

In reviewing the characters of the series above described, the most noticeable feature is the almost total absence of red sediments, usually abundant where volcanic phenomena prevail, and here leading to the conviction that most, if not all, the beds alluded to, are not of eruptive but purely metamorphic origin. A few red beds, however, were observed a short distance back of Belleisle Corner, consisting of altered conglomerates associated with green epidotic rocks, and recalling the somewhat similar deposits already noticed near the mouth of the Nerepis, at the foot of the Long Reach. As these red and comparatively soft rocks are confined to the valley of the Saint John or its eastern prolongation, it is possible that the bed of the latter may once have been partly filled with such deposits, which have since been mostly removed by denudation.

There can be little doubt that the entire series of Belleisle rocks is to be grouped with those of the Kingston peninsula, which, indeed, they resemble even more strikingly than the deposits already noticed on the north side of the Reach. There is, however, one locality forming the western termination of the district referred to, in which the rocks differ so materially from anything seen in other portions of the ridge, as to require more particular notice.

Parish of Kars.—On the left bank of the Saint John River, and directly opposite the great granitic band of the Nerepis, occurs a series of bold bluffs confronting the shore, and comprising a variety of rocks for the most part very different from any which occur in this portion of the Province. They are well exposed in the neighbourhood of Tenant's Cove, and consist of the following kinds:—

- a. Altered micaceous slate. Strike E. and W. Dip 80° N.
- b. Porphyry and porphyritic slate.
- c. Chloritic schist, greenish, with veins of epidote and asbestos.
- d. Amygdaloidal slate.

- e. Chloritic schist, with green oval spots of epidote. Strike N. 60° E. Dip 70° N.
- f. Greenish altered grit, with veins of quartz and epidote.
- g. Porphyritic diorite.
- h. Porphyry, (base of compact felspar, crystals yellow and white.)

The above rocks occur in repeated alternations for a considerable distance. The porphyry alluded to is singularly beautiful, and is very similar to rocks of that variety as developed among the altered sediments of the Little River Group, hereafter to be described. Indeed, between the latter and the whole series above given, the resemblance is very striking. The abundance of epidote, the presence of asbestos, the chloritic schist with its oval spots, as well as the porphyry and porphyritic slate, are all features strongly characteristic of the "*Cordaites shales*." One rock only, the porphyritic diorite, resembles the beds of Kingston and Belleisle.

From the singularity of the deposits, and the marked contrast which they exhibit to the beds of Bull Moose Hill and the adjacent district, I was led to make further examinations to determine, if possible, how far these beds extended easterly, and to settle the fact as to whether or not they constitute a portion of a separate group. For this purpose expeditions were made into various parts of the Parish of Kars, but no other outcrops similar to the above were anywhere observed. Along a line of section extending from Jenkin's Cove, in Belleisle Bay, to Rush Hill, in Queen's County, the only rocks noticed were altered slates and flags, bedded basalts, and diorites similar to those of Bull Moose Hill.

AGE OF THE KINGSTON GROUP.—In the absence of fossils (none of which have yet been observed in beds of this group), we have only the general lithological characters and the stratigraphical relations upon which to rely for the determination of this important question. As the conclusions derived from these two independent sources accord exactly, we may consider the position of this formation as established with some degree of certainty.

a. Lithological Characters.—Some hesitation being felt by Mr. Matthew and myself in assigning definite names to the highly metamorphosed rocks of Kingston, Principal Dawson of Montreal, has kindly undertaken, in connection with Professor Hunt of the Canadian Survey, to examine a suite of the more characteristic specimens, and to compare them with the different rocks of Canada and Nova Scotia. The names assigned to the different beds in the foregoing descriptions are based upon the conclusions of these two gentlemen.

In remarking on the general appearance and composition of the specimens submitted to his notice, Professor Dawson observes: "In regard to the probable age of these rocks, Dr. Hunt does not regard them as very like anything he knows in Canada. They are not like the Quebec Group or the Laurentian, our two principal series of metamorphic rocks in Lower Canada.

"In comparing them with Nova Scotia, I have no hesitation in saying that they are *unlike* our Atlantic coast series, which I believe to be Lower Silurian, but that they are very like the rocks of the Cobequid Mountains

and of the inland hills of Eastern Nova Scotia, which I believe to be Middle and Upper Silurian. This is the age to which I would therefore be inclined to refer your rocks, though I would not affirm that they may not include Lower Devonian, which in Nova Scotia are altered with the Upper Silurian.

“I regard your specimens as altered sediments, though some of the felspathic and hornblendic ones may be true Plutonic Rocks.”

b. Stratigraphical Relations.—While the specimens above referred to were in the hands of Dr. Dawson and Professor Hunt, Mr. Matthew, from an examination of the stratigraphical relations of the group, arrived at nearly the same conclusions. They are thus stated by that gentleman:—

“In Professor C. H. Hitchcock’s First Report on the Geology of Maine, the rocks in the eastern part of Washington County in that State, are shown to be, to a great extent, of Upper Silurian age, organic remains of that period* having been found at Pembroke and Lubec. The slates of this district are penetrated and disturbed by large masses of trap rock, and contain deposits of copper as well as iron, while lead ores occur in the associated beds of limestone. This series of strata extends through the Islands of Passamaquoddy Bay to Saint George, where the ores of copper and lead occur in quantity in altered slates and limestone, associated in like manner with trap, and yielding fossils † (brachiopods, &c., not yet examined).

“The metamorphic strata at New River, further east, which appear to overlie these last, as will be shown hereafter, bear a strong resemblance to the Kingston rocks, and are on a line with them. Moreover, the anticlinal fold in the Pre-Silurian beds of Portland appears to be overturned to the north, and in such a case, if a fault exists along the line to the Kennebeckasis River, we would expect to find a younger group of strata on the north, opposite the older rocks of the south side of the river.

“In addition it may be observed that fragments of shale, holding fossil shells of Middle or Upper Silurian aspect, occur in the “drift” or boulder-clay at Saint John, pointing to the existence north of that place, of a group of sediments resembling those of Washington County, Me., and Antigonish, Nova Scotia.

“Their relations to other groups, as well as their appearance when altered, indicate that the Kingston rocks and their associates may be provisionally looked upon as Upper Silurian, though Middle Silurian and Lower Devonian beds may also occur. The only objection to this view is the absence of such hard rocks along the outcrops of the soft Lower Silurian strata in Saint John County, where these latter are covered by deposits of Upper Devonian age. This may be accounted for by denudation subsequent to their deposition, or by supposing an elevation of the older rocks above the sea when those of Kingston were being formed.”

* Determined by Professors W. B. Rogers and E. Billings.

† First made known to me in the summer of 1864, by Mr. Frye, of Saint George.—L. W. B.

TOPOGRAPHICAL FEATURES.—In the peninsula of Kingston the most striking topographical features are the remarkable parallelism of its sides, and the presence of longitudinal ranges of nearly uniform elevation, separated by series of parallel valleys. For over thirty miles its principal mountain chain is perfectly continuous in direction, stretching in picturesque cliffs from Hampton to the Milkish. Between this range and that bordering the southern shore of the Reach, (the latter being lower and less perfectly continuous than that of Clifton,) the land is nowhere high, a circumstance also indicated by the fact that the sub-carboniferous rocks begin to occupy this valley long before they reach the summits of its two bounding chains. To the eastward the whole series is depressed, and gradually dies away, while to the west the height progressively increases, the land growing bolder and higher, until at last it is abruptly terminated in the elevated ridges of the Land's End.

North of the Reach, the series of rocks doubtfully referred to the present group, is even higher and more rugged than those of Kingston. The Devil's Back, and other prominent ridges, are here included.

The westward extension of the Kingston series is so little known, that any attempt to describe its topographical features would be superfluous. The fact that it still remains for the most part in a state of unbroken wilderness, is a sufficient indication of its rough and sterile character.

In Charlotte County the area occupied by the rocks above noticed, and referred to the Kingston Group, is for the most part low; at least there is little variation in its features, and no high ridges appear. The greater portion of the route between Lepreau and Magaguadavic is through a country inconceivably barren, low bare ledges of rock, or extensive sphagnous swamps alone greeting the eye.

AGRICULTURAL CAPABILITIES.—After what has been said, it will be readily perceived that that portion of the Province underlaid by rocks of the Kingston series is not adapted to the purposes of agriculture. The whole group is but scantily covered with soil,—extensive barrens and low sphagnous swamps, or bare elevated ridges, constituting its most common features. This is equally true of the rocks in the Kingston peninsula and of those in Charlotte. Although in each a few more fertile tracts occur, due to the action of existing rivers, or the distribution of the drift, the greater portion of the country occupied by these rocks is hopelessly barren.

USEFUL MINERALS.—While proving thus barren for the purposes of agriculture, the rocks of the Kingston Group are somewhat more promising for the prospects of the miner. At several points they have been found to be metalliferous, and though the localities so far known are not numerous, nor the deposits extensive, it is to be hoped that they will not prove entirely without economical value.

The principal metalliferous locality in the present series is that situated at the foot of Dickie Mountain, near the Fingerboard, Norton. This spot, which was hastily examined in the summer of 1863, and alluded to in

my Report for that year, I have now studied with more care, and some additional facts of interest have been obtained which will be now described.

The following is the succession of rocks passed over in going from Norton Station to Blair's (now Coate's) Mill.

From the Station, along the line of the Belleisle Road, the rocks are sub-carboniferous conglomerates as far as the Mill, (a distance of one mile). In the ravine by the road-side, however, the older series appears a short distance below the Mill, and is as follows:—

1. Foot of Dickie Mountain.—Laminated compact felspathic rocks. Str. N. 62° E. Dip 80° N.W.
2. Dark felspathic quartzite, 100 feet thick.

At the Mill—3. Altered breccia? containing crystals of iron oxide in the flaws and crevices, associated with

4. Felspathic schist (consisting of a grey base with red felspathic blotches.)
5. Altered slates interstratified with the above. Str. N.E. & S.W. Dip 30° N.
6. Red cherty bands, containing crystallized oxide of iron. Str. N. 50° E. Dip 52° N.
7. Thick beds of gneissose mica schist. Strike and dip as before.

8. Dark sandy slate, gneissose mica schist, ferruginous felspar rocks, and altered sandstones.
9. (Separated from the last by 200 feet of soil.) Thick beds of grey bituminous limestone, holding argentiferous galena, and stained with carbonate of copper. The limestone (dipping easterly 4J°) extends some distance to the westward, and holds the galena at a variety of places. It is evidently Sub-Carboniferous, and between Dickie Mountain and Belleisle Corner no rocks of earlier date appear.

The galena-bearing limestone may therefore be considered as situated at or near the base of the Carboniferous, and as the copper which it contains is a secondary product, we must look to the subjacent beds for the original deposit of the ore. In confirmation of this view I found that, lying between the limestone and the rocks above described, are a few outcrops (artificially exposed) of grey ash-coloured quartzite covered on its surface with thick scales of copper glance, the unaltered ore.

The locality is a more interesting one than I had first supposed, and is worthy of further practical exploration. As far as possible, I examined the rock in the vicinity with care, and also over the sides and summits of Dickie Mountain, but found nothing noteworthy additional to what has been stated above.

The relation of the beds of Norton, viz: First, the older series, (partly volcanic), then carboniferous limestone holding secondary ores, and lastly, carboniferous conglomerates, is remarkable, and will be again alluded to in the remarks on the metalliferous localities of Sussex, Quaco, and Shepody.

Besides the locality above described, no deposits of workable extent are known in the Kingston Rocks, either in those which form the peninsula of that name, or the similar beds northward and westward of the Reach, referred to the same series. A few simple minerals, among which may be mentioned chlorite, crystallized epidote, orthoclase, and specular iron, are found at many points, and are characteristic of the group. Iron pyrites is also abundant in several bands of micaceous slates at the Land's End.

In the remarks on the series constituting the high land northward of the Belleisle, reference has been made to the occurrence of two metals, Magnetic Iron at Bull Moose Hill, and Copper Pyrites along the ridge extending thence towards Butternut Ridge. These two localities require a more extended notice.

Iron Ore of Bull Moose Hill.—In the third Report of Dr. Gesner, (p. 51–2) a detailed account is given of the rocks occurring in the Parish of Springfield, and special reference is made to “an enormous deposit” of valuable iron ore, occurring on the farms of Messrs. Northrup and Benson, near Bull Moose Hill, and thence extending easterly and westerly for several miles. The same author moreover asserts his belief, that the bed referred to constitutes “one of the most extensive veins of iron ore in the British Provinces, being sufficient to supply America for thousands of years.”

Having heard some doubts expressed as to the correctness of this assumption, I took pains to re-examine the district referred to, with the object of confirming, if possible, so important a discovery. After as diligent a search, however, as my opportunities permitted, I am compelled to say that the value of this ore, if such it can be called, has been greatly over-rated. It is true that many of the rocks contain a considerable percentage of oxide of iron, but nothing which could properly be described as an ore bed, was anywhere observed.

I have already alluded to this band of rocks, and stated that the latter are probably eruptive, though possibly of metamorphic origin. They comprise many varieties of diorite, some true granite, syenite, and hypersthenite. The rock which contains the ore is partly syenitic and partly dioritic, with perhaps some dolerite, while the ore itself is the magnetic oxide of iron. The latter, a very common associate of the last named mineral, is quite uniformly disseminated through the mass of the rock, and occasionally appears in crystalline grains. As far as examined, however, no true bed or vein was anywhere seen. The description of Dr. Gesner would imply that the ores are titaniferous.

While I am thus compelled to deny the richness of this iron ore, I am equally obliged to discredit the idea of its extended distribution. It is true that the dioritic range in which the iron occurs, extends for many miles to the eastward, but at no locality between Bull Moose Hill and Kierstead Mountain were any facts observed leading to the belief in the existence of beds of valuable ore.

Allusion has been made to the presence of copper in the slates accompanying the dioritic rocks above described. This fact was observed at two localities, not however, very remote from each other. The first is the farm of Michael Gallagher, about five miles west of Collina Corner, and near the Parish line between Springfield and Studholm. The rocks here consist of blueish and greenish micaceous slates, (Str. N. 40-50° E., dip about 50° southerly,) much folded and twisted. The greenish beds hold the copper, which is disseminated through the rock in small veins, comprising both the yellow sulphuret and peacock ore. The metal is not abundant, nor is there any distinct lode, but no explorations have been attempted.

The second locality is evidently continuous with the first, being composed of similar rocks, and similarly situated with reference to the dioritic band. It is on the southern slope of Kierstead Mountain, near the house of J. Chowan, Esquire. The quantity of the metal is even smaller than in that of the first described locality.

MICA SCHIST FORMATION.

The second of the series alluded to as geologically connected with the Silurian rocks, is the extensive formation long known for its valuable mineral deposits, to which the above name may be given, and which is found occupying extensive belts of country in the more central portions of the Province. Lying for the most part outside of the district which has occupied our attention, we propose to dwell but briefly on its characters, and only introduce it here as giving completeness to the geological succession in New Brunswick, and as helping to fill a wide hiatus which would otherwise exist, between the formations already noticed and those which are to follow.

DISTRIBUTION.—The group of rocks to which the above name has been applied, occupies, in the centre of the Province, an area exceeded in extent only by the sandstones and shales of the Coal Measures. Entering the Province from the west in two bands, parallel to and resting upon the granitic rocks of York, they follow the latter in their northeasterly course completely across the Province. To the westward, moreover, the lower band seems to bend around, enclosing the Carboniferous formations, and to rest

along its southern limit on the granites of King's and Charlotte. It terminates abruptly at the Saint John River, in the southern part of the County of Queen's, where the beds are finely exposed in the village of Hampstead. The precise limits of their distribution are too little known to be described minutely.

CHARACTERS.—So far as my opportunities have admitted of their examination, the rocks of this series are remarkably constant in their character and composition. Although largely composed, as implied by the name above given, of micaceous schists, the group includes also extensive districts where argillaceous slates prevail, and, north of the coal basin especially, numerous beds of quartzite. The latter may be well studied at Prince William, above Fredericton, where they are particularly interesting from the valuable ores contained in them, and where also they afford the most satisfactory data upon which to base the question of their age. The quartzite beds in the district alluded to are frequently from four to five feet in thickness, and at the antimony mines form a portion of the walls of the lodes. The strata are usually nearly vertical, and have a general north-easterly strike, but with many sharp foldings; they are at times highly metamorphosed, and largely injected with quartz veins. I have succeeded in tracing beds similar to those of the antimony mines, as far as and beyond the Magundy settlement, while to the northward they rest against a wide belt of granite, being partly covered by rocks of the Coal Measures, which repose upon their upturned edges unconformably.

Between the rocks of Prince William and those of Hampstead, there is one important difference. While in the former quartzites are exceedingly abundant, so much so that over districts of considerable extent little slate can be found, at the latter the beds are almost wholly of the last named material, while the quartzite is nearly or quite absent. The slates of Hampstead are of two kinds. One is finely bedded, hard, and very micaceous, breaking into flat plates; the other is still harder, and very splintery, breaking with a pseudo-columnar fracture. The latter at first sight resembles trap, but in texture and composition is a true slate.

The general strike of the series at Hampstead is about east and west, the dip vertical and irregular. As the beds are conformable, or nearly so, the thickness of the entire series at this place cannot be less than 5,000 feet.

AGE.—The great antiquity of the series now under consideration was early recognised. In the Geological Report of Dr. Gesner, the term *Cambrian* is applied to this belt of rocks, and Dr. Robb in the construction of his map, based in part upon that Report, has adopted the same view of their age. This term *Cambrian*, though now usually discarded in American Geology, implies that the formation so designated occupies a position near or even below the base of the Silurian Series, having been originally applied to the rocks of Wales, and supposed by Murchison to be equivalent to the Huronian rocks of Canada.

To the adoption of the belief in a Pre-Silurian age for this extensive series of clay slates and mica schists, there are several strong objections. Of these the most important and conclusive is the marked resemblance already pointed out, both in character and position, between the Huronian rocks and the lower member of the Coldbrook Group. That the latter should be represented, within an area of eighty or ninety miles, by extensive deposits so unlike as the green volcanic beds near Saint John, and the compact grey slates of Queen's and York Counties, may well be regarded as impossible. We must, therefore, look to some of the vacant places of the geological scale as developed in New Brunswick, for the position which this series may be found to fill, and this position is most probably to be sought near the base of the Silurian Series, where a wide hiatus exists between the Potsdam rocks of Saint John and the Bloomsbury beds of the Upper Devonian. As already stated, this blank is partly filled by the rocks of Kingston, which, according to Dawson, are probably Middle and Upper Silurian, but a wide interval, representing the Lower division of that series (excepting the Potsdam rocks), would still be unaccounted for, and here we may provisionally place the series now in question. It may be further remarked in this connection, that the dissimilarity observed in the two great belts of York and Queen's Counties may really be indicative of their *different* age. The resemblance of the former to the slates and fine sandstones of Saint John is very marked, and it is possible that the two may be identical. The discovery of fossils in this series is therefore to be looked for with much interest.

TOPOGRAPHICAL FEATURES AND AGRICULTURAL CAPABILITIES.—Although elevated considerably above the level of the great coal basin which they surround, the rocks of this series do not rise into any prominent ridges, and usually maintain a nearly uniform level. Being for the most part composed of hard materials, they do not readily yield to atmospheric agencies, and the soils where they occur are, with few exceptions, of a medium quality.

USEFUL MINERALS.—Whatever may be the age of the mica schist formation, its economical importance as a metal-bearing series is yearly becoming more apparent. If, as there is little doubt, the two wide belts referred to this group, which cross the central portion of the Province on either side of the great granitic band of York, are really identical with the similar beds of Queen's, no other formation can compare with it either in extent or in the value of its mineral deposits. In these belts, as pointed out in my Report of 1863, occur the manganesian and auriferous rocks of Gloucester, the immense iron-ore deposits of Carleton, the antimony lodes of Prince William, and the ferruginous slates of Queen's.

These rocks, however, have not been included in the district to which our attention has been devoted, and we have therefore no new facts to offer. I may however state that within the last year operations have been continued at several of the localities above mentioned, and with very general promise of success. At the antimony mines, more particularly, work has been progressing vigorously, a new shaft having been opened and regular operations

entered upon. The quality of the ore now raised is of an excellent description. The following are the results of three analyses made by my brother, Mr. W. W. Bailey, on samples from the newly opened shaft:—

	1st Analysis.	Second.	Third.
Antimony,	68.98	70.1	69.00
Sulphur,	28.86	28.4	27.28
Iron,	.85	.0	.85
Gangue,	.81	1.5	1.50
	<u>99.50</u>	<u>100.0</u>	<u>98.63</u>

GENERAL REMARKS UPON THE AZOIC AND SILURIAN.

In the preceding descriptions of the formations severally referred to the Azoic and Silurian ages, we have confined ourselves to a simple and concise statement of the facts, without attempting to suggest any theories for their explanation. Before passing to the succeeding groups, of the Devonian, Carboniferous and Tertiary Ages, it is necessary to offer some few remarks on the probable origin of the rocks already described, their distribution, disturbances, and, in short, their general history.

A. ORIGIN OF THE BEDS.—In the Portland, Coldbrook, and Saint John Groups, (the formations here ascribed to the Silurian age, and partly perhaps to the Laurentian and Huronian,) we have presented to us rocks referable to three principal varieties of origin—aqueous, volcanic, and organic.

a. *Fragmental Deposits.*—Under this head are included all those formations, of purely aqueous origin, which owe their characters to the influence of moving waters, either the wave-action of a beach, the more powerful erosion of oceanic currents, or the slow and long continued attrition produced by the waves in sheltered bays, or at the bottom of deep seas. Under all these circumstances fragmental deposits are produced; coarse conglomerates and sandstones in the former case, shales and fine-grained slaty beds in the latter.

That a portion of the rocks of the Silurian and Azoic were of the character here described, can hardly be doubted by those familiar with the effects *now* produced by similar agencies on all our shores. The slates of the Portland Group, the sandstones and conglomerates which constitute the upper member of the Coldbrook, as well as the shales and sandstones of Saint John, are but the hardened beds of sand, mud or gravel which formed the bottom or shores of the sea in which they were deposited, and afford unmistakeable evidence of the physical conditions which prevailed in the ages to which they belong.

In the study of the rocks of the Portland Series, for reasons to be stated presently, it is very difficult to draw satisfactory conclusions as to their origin, or to give any adequate idea of the period which produced them. As already remarked, they are of extreme antiquity, and in the course of

subsequent ages have been so altered and disturbed, that few traces of their primitive character are now left to us. That the granites, syenites, gneiss, and mica slates, which constitute the great bulk of the formation, are really fragmental deposits, in other words, that they were once merely accumulations of pebbles, sand and gravel, is partly evidenced by the fact of their repeated alternations, which could only occur in deposits produced by shifting waters, and partly by the gradual transition from one of these beds into another, the former, perhaps, entirely destitute of any marks of stratification, yet passing into beds, which, except in their firmer texture, do not differ from the daily-forming deposits of our shores.

In passing from the highly altered sediments of the Portland Series to the consideration of the Coldbrook Group, which immediately succeeds, the recognition of the presence and mode of origin of its aqueous deposits is much less difficult. Yet even here, owing principally to the effects of volcanic action, the original character of the strata has been greatly altered. Passing over for the moment the consideration of its lower member, we have a succession of deposits, usually, though not invariably, of a somewhat coarse character, comprising rough sandstones, conglomerates, and grits. They are of great thickness, especially in the rear of Quaco, and are usually of a bright red or purple colour, the latter being the result, as observed by Mr. Matthew, of their association with volcanic outbursts. They may have been produced by the action of ocean currents, but it is more probable that they were due to the effects of the waves, beating powerfully upon an exposed coast.

Between the rocks above alluded to as constituting the upper member of the Coldbrook Group, and the deposits which underlie the City of Saint John, the contrast is very marked. While in the former, beds of coarse materials are almost universal, the Saint John Group is, without exception, a collection of the finer sediments. Throughout the limits of its distribution, not one conglomerate or even a grit has been yet observed; while the sandstones which occur interstratified with the slates, are usually of a fine and even texture.

In drawing our conclusions with regard to the origin of the rocks belonging to this group, we are no longer obliged to depend upon purely mineral characters. Evidence of a much more satisfactory nature is here afforded us, evidence which leaves no doubt as to the physical conditions under which these rocks were deposited.

Allusion has already been made to the presence in the Saint John slates of numerous markings, such as worm-burrows, shrinkage-cracks, ripple-marks, and the impressions of drops of rain. All these are faithfully recorded upon the rocks, and are the witnesses left upon the shore by the waves and sun, of the period which produced them. They teach us that that period, in this portion of the continent, was one of shallow waters, or slightly emerged sand-reefs, of coasts exposed to the alternate action of heat and moisture, coasts on which the impressions made by falling showers, or

the movements of marine animals, became hardened in the sun, to be afterwards filled and preserved by the further accumulations of sand and clay.

The evidence afforded by the markings alluded to, coincides with that derived from the organic contents of the beds. Trilobites, the most characteristic fossils, are believed to have inhabited shallow waters. Some of the finer deposits, as suggested by Mr. Matthew, may be of deep-water origin; but even these may have been the result of slow and long continued attrition, in shallow but sheltered bays.

b. Volcanic Accumulations.—These are confined to the lower member of the Coldbrook Group, and are evident in their mineral composition as well as in the alterations which they have produced on adjacent strata. It must not, however, be supposed that the whole vast accumulation of the deposits constituting that member are *purely* igneous in their origin. Though largely composed of matter ejected from volcanic vents, they also contain numerous beds of aqueous origin, and it would seem that the materials discharged by the former had, in most cases, been worked over, and re-assorted by currents of water.

In reflecting upon the enormous thickness and extent of the Coldbrook lavas, one naturally asks the question, From whence did all this material come? After the lapse of so many ages, the question is not an easy one to answer. Successive accumulations have buried and concealed the ancient surface, powerful water-currents have held sway over the entire district, volcanoes of a later age have again altered and disturbed the products formed at the earlier period. Probably many different vents existed; not mere craters like those of modern volcanoes, but extensive fissures, miles in length, whence issued the enormous floods of molten matter, or the showers of ashes, which now constitute the great bulk of the deposits.

We are indebted to Mr. Matthew for the recognition of one at least of these ancient volcanic openings. In his study of the rocks east and northeast of Saint John, that gentleman has recognized, near Dolan's Lake, at the source of the Coldbrook, a ridge of eruptive rocks, such as trap, basalt, hypersthenite, &c., extending for a distance of several miles, and probably indicating one of the principal vents or fissures from which the Coldbrook lavas flowed. In approaching this locality from its southern side, the gradually increasing quantity of volcanic beds, porphyritic and ashy slates, seem to point directly to this spot as their origin. This and other similar vents, now filled with eruptive matter, are indicated upon the map by a bright crimson colour.

c. Beds of Organic Origin.—Under this head are usually included limestones, either with or without fossils, and coal, the former being the result of animal activity, the latter of vegetable accumulation.

The great abundance of limestone beds in the Portland Group has already been pointed out, as well as the fact that they are destitute of fossils. We have then only the general character and association of the beds on which

to base our judgment of their mode of origin. Mr. Matthew has pointed out the abundance of magnesian silicates which they contain, and in suggesting the idea that they are partly dolomitic, believes that they may have been produced by chemical deposition; the entire absence of fossils, notwithstanding the partial metamorphism of the beds, seeming to disprove the theory of organic secretion.

It is, however, to be observed, as remarked by Professor Dana of other portions of the continent, that conditions favourable for the production of precipitated limestones on so vast a scale are not likely to have occurred, while the mere absence of fossils does not necessarily disprove their animal origin, for "the sea which grinds pebbles and sand and makes fine sandstones, may also grind shells and make an impalpable limestone." The same author also suggests that some of the more ancient limestones of America may have been produced by the accumulating shells of minute animals, termed Rhizopods, all traces of which would be destroyed by a slight degree of metamorphism. Such may have been the origin of the Portland Limestones.

The presence of graphitic laminae and thick beds of graphite, interstratified with these limestones, indicates, so far as such remains can do, an origin near the level of the sea. It would seem that the theory of wave action on a coast, where calcareous beds were forming, but where also plant remains might occasionally be deposited, offers the most satisfactory explanation of this difficult problem.

B. METAMORPHISM.—By this term is meant that alteration in aqueous deposits, characteristic of all the more ancient rocks, by which they have lost their original nature, become hardened and solidified, or as in extreme cases, completely re-formed and crystallized.

In the rocks of the Portland Group, especially in those which constitute its lowest beds, this process of alteration has reached its utmost limit. The granites, syenites, &c., which form the greater portion of its bulk, are crystalline rocks, and though probably once like the beds of sandstone, slate and shale of later periods, have now lost all trace of their sedimentary origin, and can with difficulty be distinguished from those which are purely igneous. That the great majority of these granites and syenites are really metamorphic, however, cannot be doubted, as they may readily be traced merging into those of a stratified character, such as gneiss and mica slate.

In the upper beds of the Portland Group, as pointed out by Dr. Dawson and Mr. Matthew, the metamorphism is less extreme. Vegetable accumulations have, however, been changed to graphite, the limestones have lost their colour, and the organic contents of both have been for the most part obliterated. All these changes may have taken place without the existence of distinct volcanoes.

In the Coldbrook Group, metamorphism is still a common feature, especially in the Lower Member, but here it is most apparent in the effects of

volcanic action. There has been, as observed by Mr. Matthew, a *local* metamorphism, whereby the stratification of that member has been almost obliterated.

In the Saint John Group, though the slates and sandstones of which it is composed have been hardened and compacted, the changes here alluded to have been much less prominent. There has been only a *partial* alteration of the beds, most marked near the western limit of the group, and growing gradually less evident as the latter is traced to the eastward. Besides the mere consolidation of the beds, whereby soft shales have been converted into compact semi-crystalline slates, this partial metamorphism is shown in the effects produced upon the fossils of the group. The Trilobites and Brachiopods were probably as abundant in the neighbourhood of Saint John as elsewhere, yet here they are so excessively distorted as to be incapable of recognition. Farther to the east, at Ratcliffe's Stream, they both are abundant and almost as perfect as when originally buried.

C. DISTURBANCES AND FOLDINGS.—To those familiar with the action of river and oceanic currents in forming sedimentary beds, the mere statement of the fact that the series now under discussion are composed of stratified deposits, will be sufficient evidence that these deposits once occupied a horizontal position. That they have now lost this original horizontality is equally apparent to those familiar with the general character of the groups, a fact which is nowhere better displayed than in the slates and sandstones of Saint John, these latter having been violently folded and twisted in every conceivable direction. The same is equally true, though less directly apparent, in the altered rocks of the Portland and Coldbrook Groups.

How far the foldings and displacements which characterize these formations, are the results of disturbances confined to the Azoic and Silurian Ages, or how far they may belong to succeeding epochs, it is very difficult if not impossible to say. That most of them were produced at a much later period is conclusively proved by the fact, that the newer as well as the more ancient beds have been involved in the change referred to, a general parallelism in the direction and inclination of the folds being apparent from the bottom of the Coldbrook Group to the upper member of the Devonian. The upheavals and mountain-making which marked the close of the latter age will best be understood after a more minute description of its several formations. Between the deposits of the Coldbrook Group, however, and the underlying beds, Mr. Matthew has observed evidence of slight unconformability.

That the Portland rocks had undergone some degree of flexion, independently of the disturbances shared by them with the Silurian and Devonian Groups, seems probable from the succession of similar deposits in various portions of the mass. Mr. Matthew has thus recognized one synclinal fold at least, distinct from the great upheaval in which the rocks of this series were affected along with the deposits of later ages, and it is not unlikely

that others may yet be found. One great plication of a similar character is also noticeable in the rocks of Kingston, although in these, as in the Portland Group, it is difficult to trace such alterations of level, from the extreme metamorphism of the beds.

D. LIFE.—The organic remains which the rocks of the Portland and Saint John Groups contain, are entirely of marine origin. Of the former too little is known to draw satisfactory conclusions as to the life of the period, even if such life existed in its earlier beds. In the upper portion of the series, the occurrence of graphite, as well as of obscure plant-remains, indicates the existence of a vegetable, as do possibly the limestones that of an animal, world, but both were probably confined to the ocean, the former consisting only of the lowest Algae, or Sea Weeds, the latter of the humblest Mollusks and Radiates, or even of the lower and systemless Protozoa.

The Coldbrook Epoch has furnished no traces of the organic world. If such ever existed in the beds, they have been destroyed, and all traces of them removed, through the influence of intense volcanic action.

The Saint John Group, on the contrary, affords many and interesting evidences of the peculiar Flora and Fauna of the age. Trilobites among Crustaceans, Brachiopods among the lower Mollusks, and worms, seem to have been the characteristic animal life of the period. They are all *marine*, and therefore indicate that the sea had partial sway over the regions where they now occur. The vegetable fossils, though poorly preserved, also indicate a similar origin.

CONDITION OF THIS PORTION OF THE CONTINENT DURING AND AT THE CLOSE OF THE AZOIC AND SILURIAN AGES.

From the descriptions which have now been given, it will have become apparent, that during the deposition of the various rocks referred to the Azoic and Silurian Ages, a prolonged period of repose prevailed throughout the districts where these rocks occur, broken only by the volcanic activity which marked the epoch of the Coldbrook Group. Ages of great duration, ages only to be measured by the enormous thickness, exceeding thousands of feet, of the stratified deposits belonging to them, must have elapsed between the close of the Azoic, and the period when the Kingston rocks were formed. Through all these vast intervals of time, no evidence exists to show that any violent disturbances broke the general quiet, unless it be the folding of the Portland and Kingston rocks, and even this may have been the result of a later date. Each formation was quietly deposited upon that which preceded it, the almost entire conformability which now marks their succession being conclusive evidence that no period of marked upheaval prevailed between the deposits of one epoch and those of another.

The age and relations of the Kingston rocks, and those of the mica schist formation, are too little known to enable us to speculate with any great

degree of certainty upon the conditions of the periods in which they were produced. That the date of their displacement and upheaval was long subsequent to that of their deposition, there can be little doubt, and it is highly probable that they, like the Saint John and Coldbrook beds, were formed during a period of general quiescence. That they should be unrepresented south of the Portland anticlinal, where a wide hiatus exists between the Potsdam or Primordial and the Upper Devonian Groups, may be due to the fact that this portion of the Province was then above the level of the sea, or else that the beds here formed were removed by denudation. The latter is probably the true explanation, as is evidenced by the fact that the character of the Saint John Group implies a subsidence of the land when its upper beds were formed.

In fine, we may consider the Silurian Age as marked in New Brunswick by a succession of minor oscillations, slight changes of level, producing alternations of different stratified deposits, but with no disturbances or upheavals of great magnitude. In many of these features it stands in marked contrast to those which immediately succeed.

BLOOMSBURY GROUP.

The Bloomsbury Group, like the Coldbrook which it closely resembles, comprises two very different series of sediments, the lower and older being volcanic, while the upper and newer is of aqueous origin. These must be separately considered.

A. VOLCANIC BEDS.—DISTRIBUTION.—The most extensive and typical exposure of the volcanic beds of the present group is furnished by the locality from which their name has been derived, the high hill called Bloomsbury Mountain, near the centre of the Parish of Simonds. This mountain, as described by Mr. Matthew, constitutes the western termination of a ridge of land extending northeasterly in the centre of the County, and appears to represent one of the ancient fissures or volcanic vents, from which, during the Devonian period, were poured forth the lava, ashes, and scoria, which now constitute the lower member of the Bloomsbury Group. The streams of eruptive matter, thus discharged, flowed from the central opening in three directions, northeasterly, westerly, and southwesterly, as indicated by the positions which they now occupy.

The upper limit of the Bloomsbury lava streams, trending to the west, may be traced in a long, though narrow, line of hills, from the head of Black River, below Loch Lomond, to Courtney Bay. Removed by denudation from the latter, the beds of the group re-appear in the southern part of the City of Saint John, and again on the opposite side of the Harbour in the Town of Carleton. They are somewhat increased in bulk in the latter place, but soon disappear to the westward under extensive accumulations of post-pliocene gravels. At Sheldon's Point, however, and Manawagonish,

rocks probably referable to the present group occur, and beyond in the peninsula of Pisarinco, as well as on the Musquash River, and westward towards Lepreau.

The second great belt of Bloomsbury lavas, trending southwesterly, though in much thicker beds than those last described, is comparatively limited in distribution, reaching only from the central vent of Bloomsbury Mountain to the Millicent Lake, in the rear of Mispick. The valley of Black River cuts directly across, and is largely included in the series referred to, and in its upper part forms the line of division between its two members. The thickness of the lower member, as measured by Mr. Matthew, has been approximately stated at 2000 feet.

Of the eastward flow of the Bloomsbury lavas, little is known. Notwithstanding the great thickness of the group near the sources of Black River, it can be traced but a short distance in this direction, being rapidly covered and concealed by the carboniferous deposits in the rear of Quaco.

CHARACTERS.—At Bloomsbury Mountain, where the best exposure has been stated to occur, the following peculiarities have been noticed by Mr. Matthew :—

“The elevation consists of basaltic trap, and is flanked on each side by beds of amygdaloid, trap-ash, and other products of volcanic origin, which also cover the crest of the anticlinal fold for two or three miles west of the hill. The succession of strata is best displayed on the south side of the hill, where they succeed each other in the following order:—Basaltic trap, unstratified, of great thickness; bedded basalt, amygdaloidal porphyry, bedded basalt, hornblendic trap-ash, micaceous quartzite, vesicular trap-ash slate; thickness of the stratified deposits about 3,000 feet. There is also on this slope a volcanic conglomerate, viz., fragments of trap rocks imbedded in trap-ash slate. The quartzite resembles some of the finer beds at West Beach and Black River, and the porphyry is that alluded to in Gesner's third Report, p. 15. The trap-ash slate is in many places full of irregular vesicles, the sides of which are coated with minute crystals of quartz, calcite, and specular iron.”

The remaining portions of the Lower Bloomsbury beds do not differ from those above described, except in the comparative infrequency of unstratified basalt.

B. SEDIMENTARY BEDS.—DISTRIBUTION.—The deposits of the Upper Bloomsbury, of purely aqueous origin, are generally found in bands of varying width, lying parallel to, and immediately above the volcanic deposits of the lower member. They may thus be traced, following the different distribution of the latter, almost throughout its entire extent. The greatest development of the member is along the space between the Black and Mispick Rivers, and towards the foot of Loch Lomond. On the southern shore of the latter red sediments also occur, which have been doubtfully referred to the Coldbrook Group, but may possibly be a continuation of the beds

last described. On the south-eastern side of the Bloomsbury axis, the upper member of the group again appears, but it is here a comparatively thin deposit, and occupies but a very limited area.

Turning to the westward, this member is also but poorly represented, and at Courtney Bay does not exceed a thickness of 150 feet. In Saint John and Carleton, as well as at Sheldon's Point, it is wanting altogether. On the west branch of the Musquash, however, in the village of Ivanhoe, reddish sediments occur, resting upon the Portland series and overlaid by the Dadoxylon sandstone, and therefore belonging to the Upper Bloomsbury, but whether they have any direct connection with the deposits to the east, or are the result of some nearer and independent outburst, it is at present impossible to say.

CHARACTERS.—In lithological characters the upper member of the Bloomsbury Group is very constant, consisting of fine-grained red clay slate and reddish-grey conglomerate. Its thickness has been stated at 500 feet. The rocks of this member, according to Mr. Matthew, constitute a passage from the volcanic beds to the sandstone of the (Little River) group above. As far as known they contain no fossils.

AGE.—The association of the Bloomsbury rocks with the Groups which are to follow, is conclusively proved by the general similarity of their deposits, by their entire conformability, and by the *absence* of such perfect conformability between these and the Primordial (or Saint John) rocks below. As the overlying beds have been shown to be unquestionably of Upper Devonian age, there can be no hesitation in referring the Bloomsbury Group to the same horizon.

Although occupying a large area in Southern New Brunswick, and attaining a great thickness, this group may be a comparatively local one, not directly representing any of the sub-divisions usually adopted in the description of other portions of the Continent.

TOPOGRAPHICAL FEATURES.—Although comparatively limited in their distribution, the two members of the Bloomsbury Group, when present, occupy a prominent topographical position, and confer a very marked character on the scenery and physical features of the districts where they occur. The volcanic member, especially, rises prominently above the general level of the country, and has, more perhaps than any other series, been concerned in the peculiar configuration of the district east and southeast of Saint John.

Reference has already been made to the westward flow of the Bloomsbury lavas, and their separation into two belts near the foot of Loch Lomond, one turning westerly to the Harbour of Saint John, the other in a more southerly direction, towards the mouth of the Mispick. These two belts, now rising into hills of moderate elevation, are really connected through their whole extent, but from the effects of folding and denudation after they had been covered with later deposits, now present the appearance of two diverging ridges, enclosing a valley of triangular shape, narrow at its apex

near the Bloomsbury vent, and widening outward and westward towards the sea. Over the area now occupied by this valley, which, however, had not then been formed, were deposited, during the succeeding Devonian epochs, the sedimentary beds which now constitute the Little River and Mispeck Groups.

AGRICULTURAL CAPABILITIES.—Being of limited and comparatively local distribution, I have had no opportunity of personally examining the fertility of the land underlaid by the Bloomsbury Rocks. Mr. Matthew, however, to whom the group is familiar, describes the district which they occupy as bold, but in general clothed “with a generous forest growth.”

USEFUL MINERALS.—So far as known, the Bloomsbury Group is destitute of metallic ores, or other minerals of economic importance.

LITTLE RIVER GROUP.

In the remarks on the topography of the Bloomsbury Group, it was stated that the two diverging lines of volcanic hills, which represent the course and position of the Bloomsbury lavas, are the bounding ridges of a valley, in which now lie the later beds of the Devonian. The first of the series thus included, resting on and conformable with the underlying beds, is that to which the above name has been applied.

The Little River Group consists of two members, one of coarse and the other of comparatively fine ingredients, termed, from the characteristic fossils which they hold, the Dadoxylon Sandstone and the Cordaite Shales. Though intimately connected, they do not invariably occur together, and for this reason as well as others, will be separately considered.

A.—DADOXYLON SANDSTONE.

DISTRIBUTION.—The lower member of the Little River Group, to which the preceding name has been applied, immediately succeeds and rests upon the upper member of the Bloomsbury. Folded with the latter into a depression or trough, it has been traced by Mr. Matthew in a double curve extending from Manawagonish, west of the Harbour of Saint John, around, and along the southern flank of, Bloomsbury axis, maintaining throughout this district a nearly uniform width.

On the eastern side of Courtney Bay, it first appears near the mouth of Little River, and thence following the line of the Bloomsbury beds below it, extends northerly and easterly towards the head of the Mispeck, being very well exposed at Mount Prospect, about four miles east of the City. Near the sources of the Mispeck the band of these rocks bends slowly around, assumes a southerly direction, and follows the last named stream to within a few miles of its mouth. Again changing its direction, it now flanks the end of the Bloomsbury ridge, and extends in a narrow belt eastwardly as far as the east branch of the Black River. Beyond the latter, as far as known, it rapidly disappears.

To the west of Saint John, besides the locality at Manawagonish, the Dadoxylon Sandstones have been observed by Mr. Matthew and myself on the west branch of the Musquash River, in the village of Ivanhoe, resting upon a deposit of the Upper Bloomsbury and overlaid by Cordaite Shales.

CHARACTERS.—It has already been remarked, when describing the characters of the Bloomsbury Group, that the red deposits, which form its upper member, constitute beds of transition between that group and the one now under consideration.

As indicated by the name it bears, the Dadoxylon Sandstone is chiefly composed of coarse materials, though less so than in the group which immediately preceded it. While the upper beds of the latter consisted chiefly of reddish conglomerates, the present series is composed of a hard grey sandstone, associated, however, with occasional beds of grit and layers of dark grey shale. The transition above alluded to consists, therefore, in a gradually increasing fineness in the sedimentary beds, indicating changes in the physical conditions under which they were deposited.

In lithological characters, the Dadoxylon Sandstone, as described by Mr. Matthew, is remarkably uniform and constant, and has been of great service in the study of the geology of the section now under consideration. But the chief interest which attaches to this deposit, is derived from the abundance and wonderful perfection of the organic relics which it holds, the first undoubted relics of a land vegetation in the long series of formations which have so far occupied our study. A detailed account of these plant remains, and of the localities in which they occur, will be found in a later portion of this Report.

B.—CORDAITE SHALES.

In the consideration of this, the upper member of the Little River Group, we have presented for our study by far the most useful and interesting deposit which occurs in this portion of New Brunswick, if not indeed in the whole Province. Recognizing its economical importance as a rich metalliferous series, it has been one of the special objects of the present survey to ascertain minutely the distribution, age and characters of the rocks composing it, and to mark its limits accurately as the great copper-bearing group of Lower New Brunswick. Although the greater portion of the country occupied by this series is still uncleared, and among the wildest and most rugged in the Province, we have so far succeeded in tracing out its rock formations, that the limits of the latter may now be looked upon as approximately fixed, at the same time that its age and productive metalliferous character are satisfactorily established. As the details of this examination are of great importance, I shall here describe the observations made more minutely than in the case of the preceding groups has been deemed necessary.

DISTRIBUTION.—It will naturally be supposed that, forming as they do two members of a single group, the Dadoxylon Sandstone and Cordaite

Shales should be intimately associated and occur together, and that the distribution of the former should be a general indication of the position of the latter. While, however, this is true as regards that portion of the group occurring in the neighbourhood of Saint John, it has been ascertained that the Dadoxylon sandstones constitute a comparatively local deposit, while the shales which succeed, spread much more widely over extensive districts, both to the east and west.

On the eastern side of the Harbour of Saint John, the shales referred to are first met along the coast near the mouth of the Little River, where they form a narrow band lying between the embouchure of that stream and the promontory of Red Head. The band of rocks thus appearing, though narrow at the coast, widens as it is traced into the interior of the peninsula, and follows approximately the curve already pointed out as marking the distribution of the subjacent sandstone. The line of its outcrop may be readily traced on the geological map, forming a sharp and somewhat irregular curve, extending from Red Head to the Mouth of the Mispick. In the latter portion of the curve, owing principally to a fold in the strata, the rocks occupy a somewhat wider space than is covered in the former.

Terminating on the coast at the locality last mentioned, the Cordaite Shales, now trending southwesterly, seem for the moment to be lost in the waters of the Bay. Like the sandstones which underlie them, however, they follow the curve of the volcanic beds of the Bloomsbury Group, and doubling the promontory which marks the southwestern termination of the latter, reappear along its eastern flank, still resting upon the Dadoxylon Sandstone, and extend in this direction to the mouth of Emerson's Creek. Along this portion of their distribution, however, between the Mispick and Black Rivers, there is a great difference in the character of the group observable, so great a difference, indeed, as to have caused some hesitation in assigning these beds to their true position. They occupy the coast from the point southwest of the Millicent Lake, including Beveridge and Thomson's Coves, as far as the mouth of the Black River. On the eastern side of the latter they extend along the shore to Emerson's Creek, and in the interior to a somewhat greater distance, but from this point are rapidly covered with the carboniferous deposits which extend to Quaco. They reappear, however, northwest of the last named place, and eastward of Tynemouth or Ten Mile Creek, where they rise into a low ridge, consisting chiefly of the conglomerates at the base of the series, and are crossed by all the principal roads leading in this direction.

The same series has also been observed on Vaughan's and Macomber's Brooks, northeast of Quaco, covered as before by carboniferous deposits on its southern slope, and to a less degree on its northern also, where, however, it is succeeded, at a very short distance, by beds of the Lower Coldbrook. Owing to the disturbances and foldings alluded to in the description of the latter, the whole vast mass of the Lower and Upper Bloomsbury, Saint John Slates, and Dadoxylon Sandstones, have mostly disappeared, and we here

find beds even below the base of the Silurian almost side by side with the shales of the Upper Devonian.

From Vaughan's Brook, in the neighbourhood of Quaco, the Upper Member of the group now under consideration begins rapidly to widen, and to the eastward soon attains an enormous development. Higher members than those last described appear at Melvin's Beach, and thence, with the exception of a few isolated carboniferous deposits at Salmon River, Goose Creek, and Martin's Head, extend with a bold and unbroken front along the coast to Point Wolf, at the western limit of Albert County. They thence no longer keep the shore, but, pursuing their normal course, may be traced in a series of bold high ridges as far as Shepody Mountain.

While the southern limit of the group is thus uniform and regular, the line which marks its northern boundary is more difficult of recognition. Owing to one or more immense synclinal folds, the area covered by these rocks is enormously increased, and from the limited space occupied near the sea coast, behind Quaco, now widens until it embraces the whole extent of country south of the Shepody Road. On the latter thoroughfare the rocks of the group were first observed near Wallace's Post Office, in the Parish of Hammond, King's, and near the source of the Great and Little Salmon Rivers. On the last named stream they were found to occupy the whole country southward to the coast. Whether they similarly occupy the entire valley of the former has not been ascertained, the difficulties of descending these rapid and mountainous water-courses, through a country without a settlement, being of too difficult a character to admit of exploring both of the above named streams. The limits of the group in this direction, however, cannot vary far from the outlines as laid down upon the Map.

Following the line of the Shepody Road from the point above mentioned, the rocks of the present group, or "coast series" as it may conveniently be termed, have been distinctly traced to the eastward as far as the high lands back of Hopewell, while deposits, probably referable to the same series, have been observed at a great variety of places both in the County of King's and eastward in that of Albert. These will be severally referred to in the remarks on the characters of the group.

In general, it may be stated that the upper limit of the series is a line extending nearly northerly from the vicinity of Quaco, crossing the Shepody Road near the sources of the Salmon River, thence extending in the same line so as to include a large area in the Parish of Hammond, to near the sources of the Pollet River. It follows the line of the Shepody Road eastward into Albert, and certainly includes all that portion of the latter country which lies southward of that road, between it and the sea; while the character of the metamorphic series which appear to the northward, would seem to indicate even a wider distribution. Like all the older formations in this portion of the Province, the Little River Group is progressively covered to the eastward with carboniferous deposits, which at Shepody Mountain finally cap the subjacent metamorphic beds, and form their well-marked eastern termination.

Before the commencement of the present season's work, our knowledge of the extent of this most important group was limited to the area immediately about Saint John, and eastward to Black River and Gardner's Creek. We have now succeeded in fixing its true limits in this direction, and in giving to it a distribution which, to say the least, is as gratifying as it was unexpected.

But not only have these metalliferous rocks been thus found to occupy such an extensive area to the east; they have also been found to spread widely to the west, and to give promise of valuable discoveries in a region to which, as yet, but little attention has been paid. I refer to portions of the peninsula of Pisarinco, west of Saint John, and to a large district south of the Musquash River, between the Lancaster Mills and Chance Harbour. Their distribution in this direction will be best understood after a description of the characters of the group shall have been given.

CHARACTERS.—In passing from the Lower to the Upper Member of the Little River Group, the transition which we have already pointed out as marking the change from the Upper Bloomsbury beds to the Dadoxylon Sandstone, attains its maximum, the Cordaite Shales, as their name indicates, being chiefly an accumulation of the finer sediments. Such changes from coarse conglomerates to sandstones, and from sandstones to shales or limestones, are of constant occurrence in geological history, and are of the highest importance, indicating as they necessarily do, great physical or geographical changes in the circumstances under which the formations were deposited.

In the group before us the transition from coarse to finer sediments is very gradual, and even in the member we are now considering, though fine slates and shales constitute its most common feature, many of the latter are rough in texture, and there are frequent alternations of coarser beds. Sandstones, quartzites and grits are not of unfrequent occurrence, and in some localities, especially where the upper layers are found, conglomerates appear. As there is much variety in this respect, and as the area covered by this group of rocks is a very large one, it will be necessary to describe the peculiarities of each locality separately.

a. From Little River to Mispeck.—In this portion of the series, the position of which has been already traced, we find the most characteristic and typical exposures of the beds, or at least those which best display the peculiarities of structure and composition, upon which are based the name and associations of the group. At the locality north of Mount Prospect, where the series was originally studied by Mr. Matthew, all the above varieties of rocks occur, viz: grey, greenish and red shales; reddish and grey sandstones, grits, and conglomerates alternating with the shales. In two thirds of the thickness of the latter that gentleman has observed as many as thirty seven distinct alternations with the coarser beds, varying from two to forty feet in thickness, and indicating, as above explained, an equal number of changes

in the direction, force, or depth, of oceanic currents. In the upper third, according to the same authority, the sandstones become redder, and some thick beds of a coarser conglomerate appear.

Near the upper limit of the group, a tendency is again apparent to accumulate deposits of the coarser kinds, the beds thus characterized forming beds of transition to the lower sediments of the Mispeck Group.

From Mispeck to Emerson's Creek.—Allusion has already been made to the occurrence between the above-named localities of a series of highly altered rocks, so different in their composition and characters from those of any other series in this portion of the Province, that much doubt has existed with regard to their true relationships.

The rocks in question, stretching along the coast for a distance of several miles, from Cape Spencer to beyond the embouchure of Black River, consist of a thick series of micaceous slates, imperfectly formed granites, or semi-granitic sandstones, with some volcanic beds, conglomerates, grits and limestones. At Beveridge Cove and West Beach, Mr. Matthew has observed the following succession:—

1st. Red clay slate, and grit, and coarse reddish micaceous slate, resting upon the Dadoxylon Sandstone.

2nd. A thick mass of granulite, and imperfectly formed granite, with beds of trap-ash.

3rd. Grey micaceous slate.

4th. Reddish sandstone and grit, overlaid by coarse conglomerate, holding beds of *haematite*.

5th. Dark grey micaceous slate, and basalt, (stratified?).

A short distance to the eastward, the quasi-granite passes into schist, abounding with volcanic ash beds, and overlaid by similar strata containing several large beds of iron ore. Further east in the same metamorphic series are a number of thick belts of impure limestone much altered, and hard clay slate with copper pyrites.

The limestones may be seen near the entrance to the settlement of Black River, on the Mountain Road from Loch Lomond, and, as described by Mr. Matthew, appear to be on the line of a minor synclinal fold. They are covered by shaly beds, holding imperfect remains of plants (the only plant remains found in this series east of Cape Spencer,) and are tinged of a green colour by the decomposition of the copper pyrites which they hold. Above the shaly beds are heavy accumulations of granitoid sandstones, like those above alluded to in the sectional list, associated with argillo-micaceous slates. The latter would appear to be, with the exception of some traps, the highest beds developed at this locality.

From Emerson's Creek to the region behind Quaco, the Cordaite Shales are chiefly represented by a long low ridge, consisting of heavy beds of red conglomerate and dark red slate, and are continuous with the first member of the series as found at Beveridge Cove. In the western part of the Black

River settlement, they have been observed by Mr. Matthew resting conformably on the Dadoxylon Sandstone, and therefore representing the base of the series. They thence continue to the eastward, but as noticed in the remarks on their distribution, are mostly, if not entirely, covered and obscured by carboniferous deposits. They may be seen on the old road to Quaco, about four miles from that village, and consist of red metamorphic slaty conglomerates.

On Vaughan's and Macomber's Brooks, four miles northeast of Quaco, the same series again appears, still at the base of the Cordaite Shales, and consists of the following rocks, in descending order;

1. Grey conglomerates with angular pebbles.
2. Reddish conglomerate with red slate pebbles, (also red slate?)
3. Pale reddish grey sandstone.
4. Conglomerate, like No. 2.
5. Slaty grit, (dark reddish brown.)

The section is terminated, between four and five miles out, by volcanic rocks of the Lower Coldbrook Group.

Eastern portion of Saint John County, including the Coast and the Little Salmon River.—Although not developed in the immediate neighbourhood of Quaco, the Cordaite Shales begin, from the locality last described, to widen in the limits of their distribution, and soon attain an enormous development, including, as before stated, the whole district along the coast and south of the Shepody Road, far into the County of Albert.

The series first strikes the Bay about seven miles east of Quaco, in high bold ridges, at Melvin's Beach. It here consists of micaceous slates, but exhibits no features of especial interest. Between Melvin's Beach and the mouth of Little Salmon River, no examination has been made, unfavourable weather preventing the carrying out of our designs in this direction. From the observations made on the last stream, however, and along the coast to Point Wolf, it may with much probability be inferred that no essential differences of structure will be here displayed. The observations referred to will now be given.

Little Salmon River.—From the position and course of this stream, taking its origin in the lower part of the Parish of Hammond. (K. C.), and thence running almost due southerly to the coast, it was hoped that its examination would be attended with very important results, and that the entire series of rocks, from the base to the summit of the group, might be passed over in their true succession. It will however be seen that these expectations, owing to a folding of the strata along the course of the river, have been but partly realized.

After reaching the head-waters of the Little Salmon River, where the latter is crossed by the Shepody Road, a division of our party was made, Mr. Matthew undertaking the arduous task of descending the stream above named, while Mr. Hartt and myself examined the district northward to the Parish

of Sussex, and thence eastward along the Shepody Road into the County of Albert.

As descriptive not only of the geology, but also of the topographical features and general aspect of the country occupied by this band of rocks, I here add Mr. Matthew's observations, as graphically given in his own words.

Crossing from Wallace's Post Office on the Shepody Road, three miles over level and undulating land, the river was reached at a bridge, about eight miles above its mouth. "Below the bridge, for the first two miles, the valley is narrow, and shut in by lofty and steep hills from 150 to 200 feet high. The rocks which appear along the sides of the stream are chiefly schistose, becoming coarser in texture as the Upper Falls are approached. At the bridge, and for a mile below it, the bed of the stream is filled with shingle and boulders, though ledges of slate of pale buff, grey, reddish, purplish and greenish colours, appear at intervals, (apparently talcose, though in reality micaceous.)

Near the Falls, beds of greenstone may be seen interstratified with bluish and grey slaty micaceous grits. At this point, the depression through which the river runs is no longer a valley, but becomes a narrow gorge or ravine shut in by precipitous hills, increasing in elevation as the coast is approached, from 250 to 400 feet high. One elevation opposite Carleton's Mill is said to rise to the height of 500 feet.

For six miles the bottom of the gorge is very rough, and the stream is broken by frequent falls, rapids, and eddies. So tortuous does it become, that in many places the bed of the stream and the course of the valley cannot be seen for a distance of more than from two hundred to four hundred feet. At a mile from its mouth, the latter, although still narrow, enlarges and terminates abruptly at the shore of the Bay, between high hills.

For two miles from the Upper Falls, passing the Little Falls, and as far down as the Lower Falls, little else is met than a grey clay slate, frequently tinted with green and blue, and somewhat indurated. For three miles below the Falls, passing the points known as "The Long Eddy" and "Keyhole," the only rocks seen were thick homogeneous beds of cherty or jaspery slate, (variegated with red, purple and grey colours, and sometimes beautifully striped with various shades), except for a short distance, where the stream crossed beds of purplish and greenish slate, holding shining films of chlorite.

Half a mile from the Mill the grey clay slates noticed above, were again met with, and from the Mill to the Bay shore we re-crossed the micaceous slates, grits and conglomerates observed on the upper part of the stream. On the shore, eastward of the entrance, my attention was called to a small quantity of copper ore (associated with much iron pyrites) occurring in the slates at that point, but no regular vein was seen."

From the Head of Little Salmon River to the boundary of Albert County.—
While the examination of the district intersected by the Little Salmon

River was being undertaken, as above described, by Mr. Matthew, observations of a similar character were made by Mr. Hartt and myself on the country lying to the north and northeast of the same stream.

Allusion has previously been made in the remarks on the Coldbrook Group, to a band of volcanic rocks, crossing the Parish line between Sussex and Hammond, and near the Manganese mine of Mr. Davidson. Pursuing a southerly course from that locality, the first rocks of a different character are seen near where the Crow Brook, a branch of the Great Salmon River, crosses the Shepody Road. They consist of pink granites, or semi-granitic altered sandstones, probably not eruptive. From Crow Brook to Sand's Lake, near the Shepody Post Office, the rocks are micaceous slates, pyritiferous gneissoid slate, and slaty grit.

To the eastward of the Shepody Post Office, for a distance of one mile, and thence northward to the vicinity of Pleasant Lake, no marked difference is apparent, until the latter is approached. The first rocks seen are granitic, much like those near Crow Brook, but are here partly gneissoid, and distinctly interstratified with slaty beds. The latter are almost talcose, and much contorted, having, however, a general strike of N. 60° E., and a northerly dip of 45°. The alternation of these two kinds of rocks continues for a distance of several miles.

Turning north along the eastern branch of the Little Salmon River, the same series continues, without, however, the granite beds, to a point about a mile west of the Pleasant Lake, in the Parish of Hammond. At this point the following rocks were observed:—

- 1st. Very compact, dark greenish altered sandstone. Str. N. 75° E. Dip about V.
- 2nd. The above passes, by containing pebbles, into an indistinct conglomerate.
- 3rd. The same as the above, but cherty.
- 4th. Trappean (slightly amygdaloidal) slaty conglomerates.
- 5th. Light grey conglomerate, with dark olive green spots of chlorite.
- 6th. A bed of chert.

From the presence of volcanic beds, it may be inferred that the rocks above enumerated may possibly belong to an eastern prolongation of the Coldbrook Group,* and that the latter here marks the northern limit of the Cordaite Shales. From Pleasant Lake eastward the rocks are again interstratified granitic and gneissose sandstones and slates, as far as the boundary of Albert. From where the latter crosses the Shepody Road to the settlement of Great Salmon River, a distance of about eight miles, the only rocks seen were similar to those above described, viz., micaceous slates, of grey and purple colours, and gneissoid sandstones, succeeded as the Bay is approached, by chloritic and clay slates like those of the Little Salmon River. The latter extend westerly, including the Gordon, Alma, and Williams Copper Mines, as far as, and beyond Point Wolf, being, however, separated from the coast by a narrow belt of carboniferous sandstones and conglomerates.

*It is possible, and even probable, that other outcrops of this and the remaining older groups may yet be observed, within the space here assigned to the Cordaite Shales.

From Martin's Head to Point Wolf.—Having now described the district along and south of the Shepody Road, we must next retrace our steps, and returning to the mouth of the Little Salmon River, examine the series as exposed along the coast.

Between the last named stream and Martin's Head, the rocks of the coast belt line the shore, but exhibit no features of especial interest, with the exception that they hold occasional indications of copper ore. The promontory of Martin's Head is partly composed of the present series, and partly of rocks of a later age. The former rise into hills of considerable elevation on the main land, and again reappear, at the extremity of the point, forming high, bold bluffs, of a peculiarly wild and forbidding aspect. They here consist of red and green micaceous slates, holding numerous quartz veins and seams of specular iron. Calc spar of a fine blood-red colour is also common in the crevices of the rock. Reddish beds predominate near the base of the series, while green epidotic slates are more abundant in the upper parts. The whole group of rocks is much disturbed, and has been raised to its present elevation by eruptive agencies, apparent in the large masses of greenish porphyry and epidote, which are well exposed at the outer extremity of the cliffs. Many of the slates are chloritic, and hold veins of quartz and calc-spar, with small quantities of Sulphuret of Copper. They are occasionally penetrated with trappean dykes, and contain a few small seams or veins of poor asbestus.

From Martin's Head to the Vernon Mine, the distance by water is about three miles. Directly in the rear of the former, the rocks of the coast-belt rise into hills of moderate elevation, and extend along the shore as far as the mouth of Goose Creek. They consist of dull purple, red and green slates, conglomerates and grits, the slates being very hard and compact, and seamed through and through with veins of quartz, from a few inches to as much as four feet in thickness.

At Goose Creek the older metamorphic series is separated from the Bay by a small deposit of Lower Carboniferous age, but again reappears, with the same characters as above, at a point about one mile distant from the Vernon mine, and thence occupies the shore without interruption as far as the harbour of Point Wolf. In this portion of its development, and especially at the mine above named, the beds are much altered and disturbed by igneous ejections, which have not only produced foldings and irregularities, but have also greatly changed their colour and general aspect. Epidote is especially abundant, and dykes of trap penetrate the rocks in all directions.

From Point Wolf the rocks of the coast series were found to extend easterly, occupying the entire district south of the Shepody Road, as far as the village of Hopewell, being, however, separated from the Bay by Carboniferous deposits, as indicated upon the Map. They are similar in every way to those of the Salmon River mines, and at various points (hereafter enumerated) show indications of copper ore. At Hopewell they again approach the sea, and constitute the high land in the rear of the village, being

well exposed along the line of the Crooked Creek, and finally terminate in Shepody Mountain.

From Salmon River to Elgin.—While the rocks of the coast belt have been shown to occupy the whole district south of the Shepody Road, observations at various points would seem to indicate that most of the country north of the latter is also composed principally of beds belonging to the same group.

In the examination of a section extending across from the mouth of the Great Salmon River to Elgin, the only rocks differing from those of the coast belt were observed on either side of the great valley of the Coverdale, and consist of highly altered semi-granitic rocks, approaching protogine. These would seem to form two prominent anticlinal ridges, with the slates and shales of the coast belt resting on their sides. The latter occupy an extensive district in Blackwood Block, (where they contain copper ore), and again in the rear of Elgin and along the Pollet River. They are well exposed between the two Falls of the latter stream, where they consist of clay, chloritic and micaceous slates, with dark blueish and reddish pyritiferous quartzites. These are associated with trappean (?) beds of green epidotic rock, and dykes of felspar porphyry.

Many of the rocks at this locality recall those observed in the neighbourhood of the manganese mines in Sussex, and may with the latter constitute a part of the Lower Coldbrook series. Their resemblance to the coast belt, however, is still more marked, and they have been so represented upon the Map. If the latter be the true view of their relations, the locality is an interesting one, as in that case they seem to represent the metalliferous portion of the group.

The section last described may be considered as comprising the extreme width attained by the Cordaites Shales, a distance of not less than twenty eight miles. It would be extremely interesting to ascertain how far this enormous widening of the series is due to synclinal folds, and how far to an actual thickening of the deposit. It would seem that the reversal of the beds observed by Mr. Matthew on the Little Salmon River extends easterly into Albert, and the syenitic and protogine rocks behind Elgin, and south of the Coverdale, may represent corresponding folds in the upper portion of the district. Owing, however, to the distribution of the drift, which covers all except the southern slopes of the valleys, the only dips observed were on the latter and were northerly.

Prosser Brook and Caledonia Mountain.—From its extreme width along the line from Salmon River to Elgin, the group before us narrows but little as it is traced to the eastward. It undoubtedly occupies the whole of the great central unexplored portion of Albert County, and may be seen at many points around the border of the latter. Here, however, it exhibits some new features worthy of more special notice.

The most ready means of access to the interior of the wild lands referred to, is by a somewhat rough road extending southerly from the Carboniferous

basin, and following the course of what is known as the Prosser Brook, a branch of the Coverdale River. This road and stream penetrate to within a few miles of the central point where the Parish lines of Elgin, Harvey and Hillsborough meet each other, and furnishes a geological section of much interest.

From Elgin to the mouth of the Prosser Brook, the only rocks are sandstones and calcareo-bituminous shales of Lower Carboniferous Age. The latter also extend, for a distance of about two miles, southward of the point where the Prosser Brook forms its junction with the Coverdale. The stream then intersects, and in a narrow and wild gorge passes through, a range of hills, overhanging the road in cliffs certainly as much as 500 feet in height. Along the sides of this gorge, which is about half a mile in length, the rocks are well exposed, and are similar to those observed, and already described, as occurring along the road from New Ireland to Elgin, near the upper part of the Coverdale. They are as follow, the succession being in descending order, and in a southerly direction:—

1. Carboniferous rocks, resting unconformably on
2. Granite and altered pyritous slates, interstratified with trap beds.
3. Altered conglomerate and slate.
4. Syenite and gneiss.
5. Altered felspathic slates.
6. Gneissoid and syenitic beds, the latter holding veins of epidote.
7. Altered shales. Str. E. & W. Dip 80° N.
8. Dark trap or altered slate, forming a bed enclosed by syenite.
9. Gneiss. 10. Dark compact trap. 11. Syenite.

The section is terminated by the last named rock, which forms the northern side of an extensive and apparently fertile valley, running easterly, and from its position evidently continuous with that observed near the sources of the Coverdale. This valley, which is of moderate width, is filled with diluvial detritus, and no outcrops of rocks *in situ* were observed. Crossing to its southern side, however, and nearly opposite the first described gorge, is another somewhat similar, but less bold, into which we were enabled to penetrate but a short distance. We here found a tolerable exposure of Lower Carboniferous shales, holding Ganoid fishes, and in every way similar to those of the Albert mines. The shales probably occupy the greater portion of the valley, and extend in the direction of Baltimore, which is but a few miles distant. Their outcrop, however, is but small, and the high hills, which rise abruptly around them, are evidently composed of metamorphic rocks, similar to those observed in the other portions of Albert County.

Baltimore and Caledonia.—Between the mouth of Prosser Brook and the settlement of Baltimore, in the Parish of Hillsborough, following the line of the road, the only rocks observed are Lower Carboniferous. We may, then, consider this line as marking the northern limit of the Cordaites Shales, if to that series all the deposits above described may be properly referred. Our next observations on the group were made at the last named locality.

Leaving the Baltimore Oil Works, which rest on the Lower Carboniferous bituminous shales, and driving in the direction of Hopewell, the land rapidly rises, and rocks of the older series again appear. They are first seen about a mile above the works, and here consist of hard greenish-grey altered slates, (Str. N. 75° W. Dip 40° N.) The high land thus formed, and which is commonly known as Caledonia Mountain, constitutes an extensive and moderately level table-land, extending to a point within a few miles of the coast, near Shepody. Along the top of this elevated plateau, the rocks are hard compact clay slates, (Str. N. 80° W. Dip 50° N.) extending to a point near the Parish line between Hillsborough and Hopewell, where they are succeeded by exposures of a true granite. The latter is abundant, and extends for some distance, being succeeded by syenite and syenitic gneiss, and subsequently, near the southern border of the plateau, by thick beds of olive-green, purple and grey micaceous slates, which are in every way identical with those of the coast belt. Near this point a quarry has been opened in the slates, which were thought useful for roofing purposes, but so far as they were seen by us, they seemed far too soft and splintery, as well as too irregular, to be of any value for that object.

It will be noticed that there is a marked similarity, both in the character and in the succession of deposits, as observed on Caledonia Mountain, with those already described as occurring near the western boundary of the County, on the road from Salmon River to Elgin. They also resemble the altered series of Prosser Brook, and bear the same relation as the latter to the sub-carboniferous shales which rest upon their flanks. This elevated plateau I believe to be higher even than Shepody Mountain, the height of the latter being usually stated at 1,000 feet.

With the last named eminence we close our descriptions of the easterly districts occupied by this wide spread and most important series. Like all the groups which have preceded, the Cordaite Shales now become covered with carboniferous deposits, and rapidly disappear. On Shepody Mountain they may be seen at the Manganese mines, but only in limited outcrops, being overlaid by the thick conglomerates, which constitute the upper half of the eminence. From the latter the land falls off in all directions towards the sea, and, with the exception of a very remarkable locality, hereafter to be noticed, at Beach Hill, near Dorchester, the "coast belt" is not again seen in this direction.

We have yet to notice the occurrence of the same group in, and to the westward of, the City of Saint John.

Saint John City.—In the remarks on the distribution of the Dadoxylon Sandstone, which it will be remembered forms the lower member of the Little River Group, it was stated that the beds of that division occur near the lower portion of the City, resting upon the slates of the Saint John Group. Reposing upon the latter, and forming the extreme southern limit of the peninsula, are found a few beds of the Cordaite Shales. They do not, however, properly constitute a portion of the City, being below tide level,

and only exposed at low water, in a series of reefs. They are fossiliferous, like the beds east of Courtney Bay, of which they are the continuation, but exhibit no features requiring especial notice.

Carleton.—In crossing to the western side of the Harbour, the rocks of the Little River Group are not immediately apparent, the area intervening between the volcanic Bloomsbury beds and the promontory of Negro Point, being covered with an extensive deposit of post-tertiary clays. A little to the westward, however, at the locality known as Duck Cove, they are again apparent in bluffs upon the shore, resting upon the Dadoxylon Sandstone, and extending in a series of reefs outward below the Bay. It is here that the vegetable remains already alluded to, by which the age of these rocks has been definitely ascertained, are found in the greatest abundance and most thorough preservation. They have been made the subject of special study by Mr. Hartt, who has worked indefatigably in their collection and determination. As the results of this gentleman's labours have never yet been published, it is only just that they should find a place in the present Report, and it is therefore with much pleasure that I here refer the reader to the Appendix, where Mr. Hartt's observations are given in detail.

Pisarinco.—Between the plant-bearing beds of Duck Cove and the peninsula of Pisarinco, the older metamorphic rocks now under consideration, are largely covered and obscured by post-tertiary clays, with marine and river alluvia. The only outcrops yet observed were noticed by Mr. Matthew at Sheldon's Point and Taylor's Island, the peninsula which forms the southern side of Manawagonish Cove. At both of these localities the rocks are chiefly volcanic, with ledges of purple slaty sandstone along the shore, and are probably at the base of the Mispick Group.

In the peninsula of Pisarinco, as previously stated, the rocks of the Portland Group extend from the southern shore of Spruce Lake southward as far as the embouchure of Mill Creek, of which stream they form the northern side, in a low ridge of metamorphic limestone. The southern shore of the same tide-way is composed of a series of very hard grey and black altered slates and shales, succeeded by thick beds of trappean rock, covered in turn by bright green and purple micaceous slates, dipping southerly, and forming the northern side of Pisarinco Cove.

On the southern shore of the latter, hard blueish-green altered slates and trappean beds, the former holding veins of quartz and specular iron, occur, being especially prominent near Negro Head, and thence extending westerly for several miles. They are probably the western continuation of the rocks of Sheldon's Point. The last rocks observed in this direction were upon the shore near the village of Irishtown, and consist of interstratified beds of hard green and red felspathic quartzite, and dark green basalt.

From the descriptions of Dr. Gesner, it would seem probable that on the western side of the peninsula, near the point known as the Black Beach, the Portland limestones re-appear by denudation, and again on the opposite side of Musquash Harbour. It is possible, however, that the latter may be

of Devonian age, and represent the limestones already noticed eastward of Black River.

In the remarks on the distribution of the Portland Group, it was stated that near the foot of Spruce Lake, north of Pisarinco, and on the line of the Saint Andrews road, occurs a limited deposit of bright red coarse conglomerates. As the Portland rocks re-appear to the southward, these conglomerates would seem to be a detached portion of a newer formation, certainly Devonian, of which the remaining portion has been removed by denudation. This is rendered still more evident by facts observed to the westward.

Musquash.—Between Spruce Lake and Knight's Mills, along the Saint Andrews road, no rocks of a later date than the syenites of the Portland Group appear. At the last named locality, however, as previously noticed, occurs a limited exposure of Devonian beds, consisting of Dadoxylon Sandstone resting upon red sandstones and conglomerates of the Upper Bloomsbury. The latter deposits are comparatively thin, while the sandstone beds attain considerable thickness, and may be traced to the westward for a distance of several miles.

Eastward of the last named rocks, and occupying the greater portion of the space included by the bend of the Musquash River, there rises a ridge of moderate height, known in the vicinity as the Diamond Hill. This elevation, which comprises an area of several miles, is composed of broad bare ledges of coarse red conglomerates, resting upon beds of reddish sandstone. The conglomerates hold pebbles of red sandy slate, white quartz, jasper, and black slate (like that of the Upper Portland beds), and are seamed through and through in every direction with veins of white and limpid quartz. In the latter quite large crystals are not infrequent in the crevices, while those of smaller size are so abundant as to have given origin to the name by which the hill is generally known. The beds have a nearly easterly strike, and dip southerly at an angle of thirty degrees. They are evidently of Devonian origin (probably representing the Little River Group), and are similar in kind to those that have already been noticed on the south shore of Spruce Lake.

From Ivanhoe to Chance Harbour.—That the succession of deposits on the western side of the Musquash River might be compared with those already described to the eastward, in the peninsula of Pisarinco, an examination was next made along a line extending from Knight's Mills, near the western limit of the village of Ivanhoe, to the Bay shore at the settlement of Chance Harbour. Along the road which connects these two localities, the following observations were made.

After leaving the Dadoxylon Sandstone along the line of the Saint Andrews road, and turning southward, the first rocks observed are reddish purple sandy slates. These attain a considerable thickness, and are succeeded, at a distance of half a mile, by beds very similar to those of Diamond Hill, viz., coarse reddish purple conglomerates and sandstones,

filled with veins of crystallized quartz, (Str. N. 70—80° E. Dip N.)—These latter beds extend to a point about half way between Musquash and the shore, where the road from the former forks with those which lead respectively to Chance and Dipper Harbours. Following the first of these, the red beds above described are almost immediately succeeded by a dark green sandstone, dark purple porphyritic slate, and dark green sandy shales. Passing the latter, which are comparatively thin, an abrupt change is apparent in the character of the beds. To the red and purple sandstones and conglomerates, succeeds a series, enormously developed, of hard altered semi-granitic sandstones and pink imperfectly formed granites. The latter, like the former, are distinctly stratified, dipping southerly, and are passed over continuously to a point within a short distance of the Bay shore. Though nearly uniform in character, they occasionally hold a few small beds of dark green altered slate.

At a short distance from the shore at Chance Harbour the granitic rocks are succeeded by deposits of altered grey micaceous schists. These attain but little thickness, and the section is suddenly terminated at the shore by a high basaltic hill, rising abruptly to an elevation of over two hundred feet.

In reviewing the general character of the rocks above described, in connection with those already noticed in the peninsula of Pisarinco, the resemblance to what has been observed in the district immediately eastward of Saint John, is very striking, and well worthy of further notice.

On page 59 of the present Report, in some remarks on the characters of the highly altered sediments of West Beach and Black River, a sectional list of deposits is given, as observed by Mr. Matthew. On comparing the latter with the observations above recorded, the similarity in the character and succession of the beds is too obvious to leave any doubt that, in age and relative position, the two are strictly identical. Each member of the series there enumerated has also been observed on the Chance Harbour road, with the exception of the fourth, holding beds of hematite. As, however, no examination has been made of the surrounding country, and as iron is abundant in the beds of Pisarinco, it is not improbable that this most valuable member will be yet discovered in this neighbourhood.

It has also been stated in the same connection, that to the eastward, the quasi-granite of West Beach passes into schist, abounding with volcanic ash-beds, some of the latter containing large beds of iron ore, and still further to the eastward, is succeeded by thick belts of impure limestone much altered, and hard clay slate with copper pyrites.

It would seem that, while in the district between Musquash and Chance Harbour there is a repetition of the deposits near Beveridge Cove, we have in the beds of Pisarinco the volcanic ash-beds above alluded to, and possibly the thick beds of impure limestone, as previously suggested. This comparison is rendered the more striking by the occurrence in both, of numerous seams of Specular Iron, as well as of slates holding thin veins of Copper Pyrites.

It has been stated by Dr. Gesner, that between Mace's Bay and Point Lepreau, the rocks are thick conglomerates, holding pebbles of trap, porphyry, and serpentine, and filled with veins of quartz. These rocks, according to the same authority, extend as far as Dipper Harbour, of which they compose the shores, while about a mile to the northward re-appears "the great limestone formation," with enormous masses of serpentine. There can be little doubt that the conglomerates are the same as those observed on the Chance Harbour Road, which are certainly Devonian, and it is extremely probable that the same age is to be assigned to the limestone beds. It is, however, possible, that the latter may, as suggested in the remarks on the limestones of Pisarinco, be a portion of the Portland Group, exposed by denudation.

All the beds above enumerated, both those of Beveridge Cove, and those of Pisarinco and Chance Harbour, may be considered as certainly Devonian. It is not yet fully ascertained whether they should be referred to the Cordaite Shales, the upper member of the Little River Group, or be considered as portions of the Mispeck Group, altered by volcanic action.

Lepreau.—Before leaving the consideration of the Devonian rocks of the Little River Group, I desire to make a few observations on the character of the deposits at and around the village and harbour of Lepreau.

In the Report of Dr. Gesner (I. 51—53) it is stated, that at the entrance of this harbour, "conglomerates and *new* red sandstones" appear, composing two small islands, while upon the main land, at the falls of the Lepreau River, are other sandstones "intermediate between the new red, and those forming the upper series of the coal measures." Northward of the bridge, the sandstone is again termed "*new red*," and is said to occupy a low, level country. It is still further stated, that on the south side of the entrance the deposits referable to the coal measures appear, extending along the shore of Mace's Bay to "*The Basin*," where they are covered by a coarse conglomerate, and finally by the (new?) red sandstone. The sandstones referred to the Carboniferous Period are stated to contain numerous remains of plants, (including, among others, a *Stigmaria*), while the rocks themselves have been hardened, and crystals of feldspar formed among the particles of sand.

I have had but little opportunity to examine more than a limited portion of the rocks described by Dr. Gesner, but have no hesitation in saying that a portion at least of the above assumptions are totally incorrect. There can be little doubt that a large part, if not the whole, of the deposits referred to, are neither of Carboniferous nor Triassic origin, but really belong to the Devonian Age. This opinion is based upon the following facts:—

a. It has already been shown that Devonian sandstones and conglomerates, of a red colour, occupy the whole district between Musquash and the shore at Chance Harbour. A slight westerly extension of these rocks would include the Harbour of Lepreau.

b. Between Musquash and the Lepreau Village, the only rocks observed, as far as Hanson's Brook, are syenites of the Portland series. Near the latter stream, coarse dull red conglomerates appear, holding ash-like pebbles,

which in turn rest upon bare ridges of trap. These two rocks would seem to represent, respectively, the Lower and Upper Bloomsbury beds. They extend as far as the village, turning, however, near the latter, a little to the northward.

c. The red sandstones of the Lepreau Falls bear no resemblance to either the New Red or Carboniferous beds seen elsewhere on the coast, while they do strongly recall, by their dull purple tint, many of the deposits of the Upper Devonian.

d. The "New Red" system, so far as observed in New Brunswick, is invariably confined to the very edge of the coast, and never extends more than a short distance inland. As the rocks so called are stated by Gesner to be covered by conglomerates, and as the latter are probably continuous with those of the Chance Harbour road, it is reasonable to suppose that both are of Devonian age.

e. The rocks of Saint Andrews, referred by the same authority to the New Red Sandstone and Carboniferous Systems, and described as containing plants, have been shown by Principal Dawson, upon the evidence of the same plants, to be in reality Devonian. Analogy would suggest the same conclusion for the rocks of the Lepreau Basin.

It would, at first sight, appear as if the existence of plants must be taken as positive evidence of the Carboniferous age of the beds which hold them, but when, in the same description, we find that "the small quantity of coal and lignite, has been changed into a kind of anthracite," the impression is almost irresistible, that where the latter occurs the beds are of Devonian age.

It is further stated by Dr. Gesner, that "the strata of conglomerate, extending from Mace's Bay to Point Lepreau, are thick, and composed of pebbles of trap, porphyry, and occasionally serpentine, united by a calcareous cement. They contain numerous veins of calc-spar and quartz, and also afford evidence of the disturbing force communicated to all the formations along the coast." This description applies very well to the conglomerates of Musquash and the Chance Harbour road, while it is very unlike the coastal Carboniferous series. Moreover, the latter part of the description distinctly implies that these beds have undergone flexure with the other (Devonian) formations of the district.

I do not, by the above criticisms, intend to deny that *any* Carboniferous and New Red Sandstone beds occur at this locality. On the contrary, I think it quite possible that *both* may be sparingly represented; but what I do mean to assert is, that a large proportion of the beds above described have not been correctly referred to these formations, but are in reality of Devonian age.

As to the existence of a Carboniferous basin, it is rendered probable by several facts. Among others, it has been stated to me by Mr. Reynolds, of the Lepreau Mills, that he has observed small ($\frac{1}{2}$ inch) outcroppings of coal

in this district, mixed with iron ore, while at New River in Charlotte County, six miles to the westward, Mr. Matthew observed numerous fragments of the same substance scattered over the fields. Upon the latter Mr. Matthew remarks:—"It is difficult to account for their presence here. It is just possible that a thin deposit of carboniferous age may exist under the terrace upon which they are scattered, but it seems more probable that they have come from some part of the Lepreau Basin. This hypothesis would make it necessary to allow the existence of westerly currents during the Terrace Period."

As to the beds of New Red Sandstone, if such really occur in the vicinity of Lepreau, they must occupy very limited areas directly upon the coast. Possibly, as suggested by Gesner, the promontory on which stands the Light House, may be of this age.

AGE OF THE LITTLE RIVER GROUP.—As previously noticed, the study of the fossils contained in the plant-beds of Carleton, has enabled Principal Dawson to refer the strata in connection with them to the Chemung and Portage Groups of the Upper Devonian Series.

TOPOGRAPHICAL FEATURES.—After the details now given of the character and distribution of the Cordaite Shales, it will not be necessary to enter into a minute description of the extensive district which they occupy. It is sufficient to say that the latter is among the wildest and most rugged in the Province, intersected by numerous streams, whose courses for miles occupy the bottoms of deep defiles, and rising along the shore of the Bay of Fundy into cliffs and lofty ridges of great grandeur. An excellent idea of the peculiar scenery may be gathered from the description, already given, of the Little Salmon River. From the mouth of the latter to the Harbour of Point Wolf, the height of the land will average from six to seven hundred feet, and near the Vernon mine rises to a still greater elevation.

AGRICULTURAL CAPABILITIES.—Although not to be considered as producing soils of superior quality, the character of the land overlying the Cordaite Shales cannot be looked upon as so utterly barren as in the case of some of the groups already described. Many portions of the district occupied by these rocks are, indeed, remarkable for their sterility, but, taken as a whole, the land is usually well wooded, and affords, both in the excellent supply of timber and the abundance of water-power, excellent opportunities for the lumbering trade. Few attempts have yet been made to cultivate the land, which is mostly in a wild state, and roads are greatly needed, both for the development of its agricultural and mining capabilities.

USEFUL MINERALS.—*A. DADOXYLON SANDSTONE.*—As far as known, the lower member of the Little River Group is entirely destitute of valuable minerals, and may therefore be dismissed without further consideration.

B. CORDAITE SHALES.—It has already been repeatedly stated that the rocks of this division, constituting the upper member of the group now

under consideration, may be regarded as the great metalliferous series of Southern New Brunswick. Having now offered the proof of their Devonian age, as well as described in detail their characters and distribution, we have only to call attention to the several points at which productive ore-beds have been observed.

The metals which have so far been found in the rocks of this series are iron, copper, and manganese.

a. Iron Ores.—The principal locality for this metal is the district in the vicinity of West Beach and Black River, where several large beds of hematite occur. As they are well known, and were described in my Report of last year, it is not necessary to make further allusion to their character, than to say that one portion of the ore occurs in a coarse reddish-grey conglomerate, the other, two or three miles to the eastward, in beds of trappean and micaceous slates. These rocks have been shown by Mr. Matthew clearly to form a portion of the Cordaite Shales in the Devonian series.

Besides the ore-beds alluded to, iron is abundant in seams and veins through most of the rocks occurring in this district, and it is not improbable that further search would reveal the latter in available quantities.

The only remaining district likely to be productive of this metal is the peninsula of Pisarinco. I have already alluded to the resemblance between the latter and the beds of Beveridge Cove, and stated that specular iron is not uncommon in its southern portion. Were the metal in greater demand, its presence in this region might be looked for with very good prospect of success. The same is true of the district lying to the west of Musquash Harbour, and thence towards the Basin of Lepreau.

b. Copper Ores.—The most important and well known localities of copper, appertaining to this series, are the mines occurring in the eastern portion of Saint John, and western portion of Albert, Counties. In the district alluded to, between Martin's Head and the settlement of Great Salmon River, no less than four distinct attempts have been made to carry on operations, with varying success. These constitute respectively the Vernon, Alma, Gordon, and Williams Mines. The three latter were visited by myself in the summer of 1868, and described in my Report of that year; the former, though also alluded to in the same Report, was not visited until the past season. It may therefore not be out of place to add a few observations, made by Mr. Matthew and myself, upon its present condition.

The Vernon Copper Mines are situated upon the Bay Shore, about three miles eastward of Martin's Head, and about two from the mouth of Goose Creek. The rocks in which operations have been begun are metamorphic beds of the Bay Shore belt, which here rise abruptly from the level of the sea to a height varying from six to eight hundred feet. Their character has already been described. They consist of dull purple and grey micaceous slates, conglomerates, and grits, much injected with igneous matter, and holding veins of quartz, calc-spar and chlorite. They are in every way identical with the rocks of Martin's Head and the region to the westward,

belonging, with the latter, to the Cordaite division of the Little River Group, a formation referable to the Upper Devonian Age.

Since the date of my last Report, operations of a vigorous character have been begun, and a force of about forty men is now constantly employed. At the time of my visit, three adits had been driven near the base of the hill, and preparations were in progress for systematic labour. Owing, however, to the abrupt character of the shore, the want of a suitable harbour, and the difficulty of procuring supplies through the unsettled district above, active operations had been greatly retarded. A road is now being opened to connect the mines with the Shepody Road, and I believe it is the intention of the company to erect a breakwater, whereby the obstacles at present existing may be greatly diminished.

The rocks of the Alma, Williams and Gordon Mines, are in every way similar to those of the Vernon, and, having been described in my previous Report, do not require further notice. All mining operations at these localities have been for the present discontinued.

In addition to the places above described, the following are localities appertaining to the Cordaite Shales, in which the presence of ores of copper has been ascertained:—

a. The shores of the Great Salmon River, Albert County, probably a continuation of the lodes at the Alma and Gordon Mines. *Ore*—Copper glance.

b. On the farm of Andrew M'Farlane, three miles back of Salmon River, Albert, and on road to New Ireland. *Ore*—Peacock copper and yellow sulphuret, in dark slaty grits. No explorations have been made.

c. Near entrance of Little Salmon River, Saint John County.* A small quantity of copper, associated with much iron pyrites, occurring in slate.

d. M'Lachland's farm.* Indications somewhat more promising than at the last named locality.

e. Near Martin's Head, at foot of the hills, on the north side of the marsh connecting the headland with the shore. *Ore*—Erubescite (or Peacock ore.) The specimens seen were of a very rich character. No attempt had been made, at the time of our visit, to ascertain the extent of the deposit, but the locality is a promising one, and deserves further exploration. The facilities for the successful carrying on of mining operations are very superior to those of the Vernon mine, the land being lower, and the shore protected by the promontory of Martin's Head. Indications of copper have also been observed upon the Head itself.

f. Shepody Mountain. Near the Manganese mine of Mr. Steadman, a shaft has been sunk in greenish chloritic slate, to a depth of fifty feet, in search of copper, which is said to occur in veins of quartz. The locality was examined by Mr. Hartt, but no indications of that metal were observed. It has also been stated that *native* copper occurs in quartz veins in the conglomerates of the Manganese mine.

* Observed by Mr. Matthew.

g. Black River Settlement, on the Mountain road from Loch Lomond. *Ore*—Copper pyrites and the green carbonate, in hard clay slate.*

h. Pisarinco. Yellow sulphuret of copper has been found in the altered slates and grits of this peninsula, but not in profitable quantities.

At all the above named localities, the rocks are certainly members of the upper division of the Little River Group. In those which follow, the beds are probably portions of the same series, but, as expressed in the remarks on the characters of this group, their position has not been ascertained with absolute certainty.

i. Blackwood Block, Albert County. I am informed by Mr. Matthew, that in this district, and near the lake which forms the source of one of the branches of the Salmon River, copper has recently been found by Mr. G. F. Keans of Saint John.

The latter gentleman observed some veins, and numerous boulders, of quartz on the hillsides about the lake, as well as felspar, mica, (silvery grey and black) hornblende, actinolite, and chlorite. The copper was observed in a ledge of hard grey metamorphic slate, on the north side of the lake, filling seams in the rock, and is a green carbonate, not the original ore. The accompanying rocks are described as paler and coarser slates, some of the latter having an ash-like aspect (volcanic?), and reddish felsite. All of these rocks are similar to those occurring in the Cordaite Shales, or cupriferous band of the coast. Both of the above-named gentlemen, to whom I am indebted for the facts of its occurrence, regard the locality as a promising one, and deserving of further examination.

This locality is not very distant from the point at which particles of drift gold were observed by myself and others in the summer of 1868. The occurrence of the latter is curious, and difficult of explanation. It can scarcely be supposed that this metal should have come from beds of Devonian age, such as those of the neighbourhood appear to be. Neither are there any rocks of a greater age in this portion of the Province, unless we suppose the re-appearance of the Saint John slates, or some portion of the Coldbrook and Portland Groups. As to the former, as far as observed to the eastward, no approaching alteration, such as is usually found in gold-bearing series, was observed, and eastward of King's County the group itself appears to be entirely wanting. The same is true of the Portland Group, but it is not at all unlikely that beds of the Coldbrook may be represented in this district, and to them we must provisionally look for the origin of this metal. It should, however, be borne in mind, that Dr. Hayes of Boston, has, by analysis, ascertained the presence of gold in the rocks of the Vernon mine, also a part of the series of which the locality at Blackwood is supposed to form a member.

k. Beech Hill, Westmorland. On the south-eastern side of the Memramcook River, in the Parish of Dorchester, and about three miles from Char-

* Observed by Mr. Matthew.

ters' Inn, occurs a very singular metalliferous locality, but recently discovered, and which opens a new field of investigation in a district heretofore supposed to be destitute of metal-bearing rocks.

The precise locality where this discovery was made, is on the land of Joseph Landry, constituting a portion of the settlement known in the vicinity as Beech Hill. The land has been leased from its owners by Mr. Alex. Wright of Salisbury, with whom I paid a visit to the spot during the past season.

In examining the district where the ore occurs, I found that the land immediately surrounding the lode is everywhere covered with rocks of carboniferous age, over the surface of which are scattered innumerable boulders of highly crystalline quartz. The beds from which the latter have been derived are not directly visible, but near the point where they are most abundant, a pit has been sunk to a depth of about five feet, exposing a distinct quartz lode of from four to five feet in thickness. This lode has a course about N. 22° W., a nearly perpendicular dip, and is bounded by regular walls. Only one of the latter was distinctly visible, and consisted of buff-coloured and reddish altered grit or breccia. Covering the latter, as well as a portion of the lode, are an ochreous clayey conglomerate, then a reddish slaty clay, and finally over all some two or three feet of soil. These uppermost deposits have a decidedly carboniferous look, and are destitute of metallic indications.

The ore, which is confined to the quartz lode, is the grey sulphuret, and is scattered through the rock in veins and spots, while, by alteration, it has given a green tinge to much of the associated gangue. A portion of the quartz is distinctly, and at times finely, amethystine, (indicating the presence of manganese). Barytes is also found in the lode, and specimens from the neighbourhood contain a green variety of fluor. There seemed to be an entire absence of calcareous matter.

Hoping that some exposures might be found in the neighbourhood, by which the age of the deposit could be ascertained, I made a careful search, but found no beds *in situ*, with the exception of carboniferous sandstones, shales, and conglomerates, the former holding characteristic plants. Boulders, however, were common, and evidently derived from a metamorphic series, such as gneiss, syenite, mica schist, green and ashy slates.

This locality is certainly an interesting one, and worthy of further exploration. It would seem to imply an easterly prolongation of the metalliferous coast belt, as well as a great thinning out of the carboniferous beds by denudation. It is not unlikely that similar exposures, from which the boulders have been derived, may be discovered in the neighbourhood.

MISPECK GROUP.

DISTRIBUTION.—The deposits of this Group, constituting the newest member of the Upper Devonian Series, occupy, in comparison with the groups already described, a very limited area. So far as certainly known, they may be said to be confined within the narrow district intervening between the Little and Mispeck Rivers, and consequently occupying the centre of the basin already pointed out, as formed by the folding of the Upper Devonian Groups.

They rest immediately upon the beds of the Cordaite Shales, and so nearly resemble the latter as to be not easily distinguished. It is therefore not unlikely that the group may yet be found to have a wider distribution, especially westward of the Saint John River, in the peninsula of Pisarinco.

The Mispeck Group not being included in the field of our summer's labour, the following descriptive remarks are taken from the paper of Mr. Matthew.

CHARACTERS.—"West and north of Mount Prospect, where the Cordaite Shales disappear beneath the stratified gravel which covers the top of that hill, the dip of the beds at the base of this group rapidly diminishes from 30° to 15°, and the strike at the same horizon varies 10°. The lowest member is a coarse reddish conglomerate, having a red slaty paste filled with large subangular fragments of a grey altered rock, like the lower slate of the Coldbrook Group. It also contains fragments of reddish sandstone, and a few pieces of impure slaty limestone. The conglomerate is overlaid by thick beds of purple clay slate, which, by accession of coarser materials, becomes a slaty sandstone and grit filled with white particles. The strata of this group are much thicker on the north than on the south side of the basin. An isolated deposit of red slates, resembling the finer beds of this group, rests against a mass of altered rock, which seems to be a continuation of the Bloomsbury volcanic beds, at Taylor's Island, west of the Harbour of Saint John."

If the beds last alluded to be properly referred, it is very probable that those of Pisarinco, already described, may in part at least appertain to the same group. They have been noticed, however, as forming a portion of the Cordaite Shales. The same is true in part of the district between Musquash and Chance Harbour.

AGE.—The Mispeck Group, as will be seen by the Sections at the close of the Report, constitutes the highest member of the Upper Devonian Series, and is covered unconformably by conglomerates at the base of the Lower Carboniferous Formation. It has not been found to contain any fossils.

TOPOGRAPHICAL FEATURES, AND AGRICULTURAL CAPABILITIES.—Between the districts underlaid by the rocks of the Mispeck Group, and those which belong to the series last described, there is little diversity. No very prominent ridges appear, and the soils, except where the result of diluvial agency, are usually of a very inferior character.

USEFUL MINERALS.—With the exception of slates for roofing purposes, which some beds of this series are capable of furnishing, the Mispeck Group has not been found to contain any minerals of economic importance.

GENERAL REMARKS UPON THE DEVONIAN.

A. ORIGIN OF THE BEDS.—After the minute descriptions which have now been given, it will not be difficult to understand the origin and succession of the several formations, which constitute in Southern New Brunswick the Upper Devonian Series.

Ushered in by a period of intense volcanic activity, which moreover seems to have been renewed at various intervals, and was again prominent near its close, the Upper Devonian age presents a succession of deposits, partly of volcanic and partly of sedimentary origin.

The great bulk of material which now constitutes the lower member of the Bloomsbury Group, consisting of basalt, amygdaloid, trap-ash, and conglomerate, may, in part, have been produced above the level of the sea. From the compact character of its rocks, however, and their association with aqueous sediments, it seems more probable that the eruptive outbursts were, for the most part, sub-marine, or at least under the influence of oceanic currents. The associated beds, while they indicate the presence of moving waters, do not imply that those waters were deep, and we may readily suppose the existence of volcanic vents so near a coast, that materials, discharged from the former, may have fallen into, and been re-assorted by the currents of the latter. The presence of conglomerates with the volcanic rocks confirms this view of their origin.

It is noticeable that the rocks which immediately succeed the eruptive beds are of a bright red colour. It has been remarked by Mr. Matthew, that such association of reddish sediments, with volcanic outbursts, is of almost invariable occurrence, the former appearing to be a consequence of the latter.

Between the lower member of the Bloomsbury and the upper member of the Little River Group, so great is the variety and so constant the alternations in the several beds, that no one description would prove applicable to them all. Many kinds of rocks, conglomerates, sandstones, and shales, occur in oft-repeated succession, and are evidences, as already observed, of as many changes in the physical conditions under which they were deposited. Coarse conglomerates, where they occur, are an indication of rapidly moving currents in shallow waters, or of wave action on exposed shores; sandstones are indicative of more tranquil waters, though still too much disturbed for the accumulation of finer sediments; while slates and shales are composed only of those materials, which, sheltered from the waves and currents, have been slowly reduced to the finest mud. It is in these latter, also, that we most frequently find traces of those organic relics, which, more than any merely mineral characters, give us evidence of the age and origin of the beds which bear them.

In the several groups of the Devonian, all the varieties of rocks above enumerated occur, with the addition of volcanic sediments, which seem to have been produced in varying quantities through the whole age, and some

thick beds of limestone. None of the rocks, with the exception of the last, bear evidence of a deep water origin, while the fossils, so abundant in some portions of the Little River Group, even imply the presence of marshes and dry land. The limestones, as remarked under the observations on the Silurian, may have been the result either of organic secretion or chemical deposition. For the reasons there stated, the former is considered the more probable explanation.

B. DISTURBANCES AND FOLDINGS.—To those at all familiar with the general character and aspect of the district occupied by the Devonian Rocks, it will scarcely be necessary to state that the various formations which these rocks compose, do not now occupy the horizontal position in which they were deposited. They have been violently and powerfully disturbed, uplifted, and pressed into gigantic folds. Where still soft and pliant they have yielded to the pressure, and we find their curved and bending strata giving evidence of the fact; where too firmly consolidated to admit of flexion, they have cracked and broken, giving rise to enormous fissures, not unfrequently filled with the eruptive matter which was the cause of the disturbance.

To form a just idea of the character and amount of these enormous dislocations, it will only be necessary to glance at one or more of the different Sections* appended to this Report. These Sections, which are three in number, are designed to represent the general structure, arrangement and position of the different geological formations in the lower portion of the Province, extending from the County line of Queen's to the Bay of Fundy. They are not merely ideal, but are based upon the results of actual examination, and illustrate, much more clearly than can be done by any verbal description, the general relations and disturbances of the different groups in the districts which they represent. The Key appended to the Sections, together with the numbers indicative of the several groups, and the topographical references, will enable those interested in the subject to readily understand the explanations which follow.

In the examination of the First Section, representing the structure of the district along a line from the granite of Nerepis to the Bay Shore at West Beach, it will be seen that there are three anticlinal axes, (two of great, and another of lesser magnitude,) with four, and perhaps five, corresponding synclinal folds. The former are marked by the position of the Portland Rocks south of Kennebeckasis Bay, and of the Lower Bloomsbury Group, east of the Mispeck, while between the two is seen a smaller anticlinal, and an extensive fault, near Beaver Lake. The two great ridges of the Portland and Bloomsbury Groups thus form the outer limits of a valley, divided however near its centre by the high gravel beds of Mount Prospect, in which are now found in regular succession the Coldbrook, Silurian, and Devonian beds. The latter, but not the former, re-appear again southeast of Bloomsbury Mountain, at West Beach, and Black River.

* Prepared by Mr. Matthew and myself.

In the western portion of the Section no details are given, the extreme metamorphism of the Portland and Kingston Rocks rendering all observations on their inclination very difficult and unreliable. There would seem, however, to be a general northerly dip along the Kennebeckasis and the peninsula of Kingston, while beyond "the Reach" the dip is reversed, and has a southerly direction, the Saint John River occupying the synclinal depression between the two.

It is important to observe that between the Azoic, Silurian, and Devonian Groups, there is a general conformability through all the folds, but that in the Kennebeckasis valley, Carboniferous rocks rest upon the upturned edges of the former.

On comparing the Section just described (A) with that indicated under (B), and which extends along a line nearly parallel to, but eastward of the former, several prominent points of difference will be apparent.

The Portland Group still forms a central anticlinal, and from it, as before, the Coldbrook and Saint John rocks dip southerly. The Bloomsbury beds still occupy the same position (with the Devonian and Carboniferous formations resting on their southern slope), but no longer as an anticlinal; disturbances, upheavals and downthrows having altered the relations of the different groups, and brought to view deposits which, in the previous section, were concealed below the surface. The cause of the changes here alluded to, is evident in the ridge of eruptive syenite north of Negro Lake, which has produced a secondary folding and a dislocation of the adjacent beds. By this folding the Saint John rocks are again exposed, and to the southward re-appear in their natural sequence. The western portion of the section differs from the one first described, only in the gradually increasing prominence of Sub-Carboniferous deposits, which, as before, rest upon the older series unconformably.

In the Third Section, taken along a line still farther to the eastward, the changes already begun in the second section become still more apparent, and several new features are introduced. It will be seen that the great mass of the Lower Bloomsbury Group, before so prominent, is no longer seen, though possibly indicated, in part, by the depression of Nugent Lake, while the Lower Coldbrook beds, wanting in the southern part of the first section, and but slightly visible in the second, are now enormously thick, and constitute the one great anticlinal upon which the other groups repose. The Portland Rocks have entirely disappeared (at Hammond River), and are not again found to the eastward, the place which they before occupied being now filled with the high conglomerate ridges of Upham and Salt Spring Brook. None of the older series are again seen to the north, with the exception of the Kingston Rocks, divided by the valley of the Belleisle, and partly covered with Carboniferous beds.

In the southern portion of the Section (near Quaco), some other changes of great interest will be observed. In addition to the Carboniferous deposits,

which are here represented as at M'Kay's Head, an entirely new series is introduced in the Triassic or New Red Sandstone formation, lying unconformably upon the Carboniferous strata, as these, in turn, are unconformable to the Devonian beds below them. The relations of the different groups are still further complicated by the presence of enormous dykes of eruptive basalt, constituting the bold promontory of Quaco Head, and violently disturbing all the overlying beds, with the exception of the New Red Sandstone. As this portion of the district is particularly interesting, a second, ideal Section (D) has been prepared upon a larger scale, where the relations of the different groups may be seen as viewed from the surface of the Bay. This section will be more fully described in the remarks on the Carboniferous formations of the coast.

In pursuing the investigation of the districts to the eastward of those above represented, the most marked changes are the entire disappearance of the Coldbrook (or Huronian?) Series, near the eastern side of the County of King's, and the enormous widening of the Cordaite Shales. The details of the latter, from the wildness of the district, are too disconnected for the construction of another section parallel to the last; but, as already noticed, there would appear to be one or more synclinal, and corresponding anticlinal folds along the Little Salmon River, and in the central portion of Albert County. Still farther eastward, a section in the valley of the Petitcodiac, would show only Carboniferous deposits, almost completely concealing the older series, at Prosser Brook and Shepody Mountain.

From a comparison of the three Sections above described with the Geological Map, it will at once become apparent that the general direction of the folds is very regular, a little north of east, and approximately parallel to the northern shore of the Bay of Fundy.

This direction coincides with what has been observed in other portions of America, and indicates that the force producing the disturbance, must have acted uniformly over immense districts. What the nature of the force it is difficult to say, but that its power was enormous will be sufficiently evident from the descriptions already given of the effects produced. That it was exerted in a direction from the sea, would also seem to be probable, a fact long since noticed along the entire Atlantic coast, where it is most evident in a general prevalence of easterly dips. In New Brunswick the force has not been sufficient to produce the latter, (as will be seen from the sections,) but the same conclusion would still seem to follow from the occurrence of all the downthrows on the northern sides of the anticlinals, *i. e.* on the side most remote from the ocean.

The most remarkable of these faults and downthrows is that already noticed as occurring near Negro Lake and Ratcliffe's Millstream, south of Loch Lomond, and illustrated in two of the accompanying Sections. By comparison of the position of the different groups represented, it will be seen that the amount of displacement is equal to the entire thickness of the Lower

Coldbrook Group, not less, therefore, than 5,000 feet. Even this, however, would seem to be exceeded by the tremendous fault now indicated by the valley of the Kennebeckasis, if, as is probable, the latter was formed, like the above, at the close of the Devonian Age. Supposing the Kingston rocks to be only Upper Silurian, we still have a downthrow equal in vertical depth to the entire thickness of the latter, added to that of the Lower Silurian, (Huronian?), and part of the Laurentian; for we now find the former, (*i. e.* the rocks of Kingston,) side by side with the limestones and syenites of Portland.

Such were some of the physical changes, which cause the Devonian Age to stand out so prominently in the geological history of this portion of the continent.

C. METAMORPHISM.—It will readily be believed, after a consideration of the enormous power exerted upon the rocks of the Devonian Series, whereby they have been changed in position, and thrown into such gigantic folds, that the mere flexion of the beds was not the sole nor even the principal result produced by these disturbances. The characters of the rocks themselves have undergone a marked alteration, whereby sandstones, conglomerates and shales have been hardened and solidified, and limestones have lost all traces of their organic origin; or it may be the process of alteration has advanced still further, and resulted in a complete crystallization of the beds, the evidence of their original character being thereby obliterated.

We have already had occasion to offer some remarks on the subject of metamorphism, as illustrated in the deposits of the Azoic and Silurian. In the groups now before us, constituting in New Brunswick the Upper Devonian Series, we have this process more fully exemplified in all its stages. These may be most conveniently treated under the three heads of consolidation, partial alteration, and crystallization.

a. Consolidation.—This is the first step in the process of metamorphism, and consists of a simple hardening of the sedimentary beds. All of the Devonian rocks have undergone this change in a greater or less degree, what were formerly deposits of sand or pebbles, becoming hardened into refractory sandstones and grits, while soft and friable shales have been changed into compact and unyielding slates.

Such consolidation is partly the result of heat, and partly of aqueous solutions. The cements most commonly occurring among the Devonian rocks are calcareous and silicious. The great quantity of the latter in particular localities is well illustrated in the eminence known as Diamond Hill, east of Musquash, where the abundance of the quartz, cementing the conglomerates, is truly wonderful. Iron seems also to have been an active and very common agent in producing consolidation, especially in the Little River Group, where the abundance of this metal is shown, not only in the frequency of ferruginous veins, but also in the red tint which characterizes the larger portion of its beds.

b. Partial Alteration.—From the mere consolidation of loose materials to their partial metamorphism, the step is a short one, while the latter in turn passes by insensible stages into a complete crystallization, whereby the characters of the original substance are lost, and new mineral aggregates are produced. This partial metamorphism is best illustrated by the changes thus wrought upon the *organic* contents of the beds, giving rise to distortion of the forms in animal fossils, or a debitemenization of those belonging to the vegetable kingdom. These changes are well marked in some of the beds of the Little River Group, especially in the Dadoxylon Sandstone and the fossiliferous portion of the Cordaite Shales. In the former, the remains of trunks of trees, such as the great Conifer termed *Dadoxylon*, first changed into seams of ordinary coal, have now, as noticed by Mr. Matthew, been converted into anthracite, while in the latter, the ferns and other delicate plants have undergone a still greater alteration, and are now found to have the lustre and character of graphite.

Among other effects produced by partial metamorphism, the most common and the most important are changes in the composition of mineral veins, or alterations in the colour of the enclosing beds. Such changes may be the result of a moderate and gentle heat only, and consist of a simple loss of water and other vaporizable constituents, as when the iron ore termed *Limonite* is converted into *Haematite*, or a more powerful heat may have been necessary, a heat sufficient to produce sublimation, giving rise to the escape of vapours and mineral solutions.

All of the changes here mentioned are common among the rocks of the Devonian Series in New Brunswick, the former in the great variety of colour characteristic of the sedimentary beds, and which is largely due to the presence or absence of combined moisture, the latter in the effects produced where the disturbances have been most active, and igneous ejections most powerful and frequent. The whole coast of the Bay of Fundy, occupied by rocks of this age, is filled with such evidences of partial metamorphism, while at Martin's Head, and about the various Copper mines, they are especially remarkable. Veins of calc-spar, naturally of a pure white colour, have been changed to a rich crimson red, epidotic and chloritic veins penetrate the rocks in all directions, while the accompanying ores themselves have undergone similar alteration, oxide of iron becoming changed into the specular variety, or the dull-coloured sulphurets of copper into glance and peacock ore.

c. Crystallization.—This third and most complete stage in the process of metamorphism, is that by which the original character of stratified deposits is completely destroyed, and the ordinary beds of sand and clay converted into crystalline granite, syenite, and gneiss,—a change already illustrated in the highly-altered deposits of the Azoic Age.

In several of the Devonian groups a similar but more partial alteration has already been pointed out. The semi-crystallized rocks of Black River and Chance Harbour are but imperfectly formed granites, which a very slight

continuance of the metamorphic influences would have converted into compact unstratified beds, not to be distinguished from the similar formations produced by purely igneous agency. The same may also be said of the semi-granitic and protogine rocks, associated with the upper member of the Little River Group, in the County of Albert.

There are, however, extensive districts in various portions of the Province, where the process of crystallization has reached its extreme limit, and where we can no longer directly trace any evidence of sedimentary origin, the deposits of clay and argillaceous sand having become converted into micaceous slates, gneiss, syenite, and true granite.

The districts occupied by these rocks, being among the largest in the Province, require a more extended notice.

DEVONIAN GRANITES.—*a. Distribution.*—The general position and extent of the great granitic belts of the more central portions of the Province, have already been pointed out in the introductory Chapter. Not being directly included in the district examined during the past season, a small portion only of their distribution is represented upon the Map. They are two in number, the general outline and position of which may be described as follows:—

The first, or great central belt, entering the Province from the State of Maine, passes through the Counties of York, Northumberland, and Gloucester, and extends to within a short distance of the Bay of Chaleur, at Bathurst. Its northern limit is a line, starting from the North Lake, near the Monument Brook, on the boundary, passing between the first and second Eel River Lakes, on through the neighbourhood of the Howard Settlement, to the Saint John River, above the Meductic Rapids. Crossing the latter, it trends northeasterly near the head-waters of the Miramichi, and strikes the Nepisiquit River a few miles above the Grand Falls of that stream. The southern boundary is approximately parallel to the northern, crossing the Saint John River four or five miles below the mouth of the Pokiok, but is much more widely separated to the west than to the east, where, near Bathurst, the width of the belt becomes greatly reduced. It will be observed that in the latter direction, as well as at the crossing of the main river, these outlines differ materially from those heretofore represented.*

The second great band of granitic rocks, also entering the Province from the State of Maine, extends from the neighbourhood of Saint Stephen, with some interruption, to the Saint John River, where it is abruptly terminated opposite Spoon Island, below the village of Hampstead. It is here somewhat over a mile in thickness, being partly covered on its northern side by argillaceous and micaceous slates, and on its southern, by the rocks of Kingston.

* For the particulars of the occurrence of this granitic belt, and the associated slate formations at Bathurst, see the Report of last year; also, an Article on the Geology of the Nepisiquit, in the *Canadian Naturalist*.

b. Characters.—In mineral composition the first of the above great series is remarkably variable. It may be well studied at and near the mouth of the Pokiok, where this stream, running through a narrow gorge not more than thirty feet in width, but over a hundred in depth, falls into the River Saint John. The most abundant rock at this locality is a coarse reddish syenite, divided by irregular joints, (to which the course of the stream is due), associated, however, with some true granite, (consisting of quartz, white felspar, and black mica). Much of the latter is very coarsely porphyritic, large crystals of felspar, sometimes two inches in length by one in breadth, composing a large proportion of the rock, and projecting on its weathered surface in grey and white angular blotches. This porphyritic granite is very abundant throughout the central belt of York, and is scattered in boulders over a large portion of the County. In this respect it differs greatly from the other series yet to be described. To the north of the Pokiok, and between that stream and the Shogamoc, the granite contains some beds of gneiss passing into mica slate, while veins of finer grained granite, with others of compact crystalline felspar, occur at various points.

The granites of Queen's County differ from those above described, chiefly in their more compact and even texture. So far as I am aware, they are never coarsely porphyritic, and are more constant in composition. Along their eastern terminus, where they have been extensively quarried, they are true granites, being composed of quartz, light-coloured felspar, and black mica, in nearly equal proportions. They have been described by Gesner as approaching gneiss, but the appearance of stratification, which that author observed, is, I think, due solely to a system of joints, by which all these granites are characterized, and which is of great service in the process of quarrying.

To the westward, along the line of the Douglas Valley, the granites become somewhat coarser, and at Fall Brook hold considerable quantities of *schorl*, or impure black tourmaline.

c. Age.—In series so extensively altered as those now under consideration, the only facts upon which our conclusions can be based, are their stratigraphical relations, and the analogy of adjacent districts.

As to the former, it has already been noticed, that throughout their entire extent the granites of York are flanked on either side by nearly perpendicular series of slates and quartzites, while in the Parish of Prince William, both are covered by rocks of the Lower Coal Measures, which rest upon their upturned edges unconformably. It is therefore evident that the period of upheaval and crystallization in the former, must have been subsequent to the deposition of the mica slates, yet antecedent to the opening of the Carboniferous era. Judging from the phenomena exhibited in other portions of the Province, it seems probable that the Devonian Age, so remarkable for the number and extent of its volcanic outbursts, witnessed also the disturbance which is here referred to. It is, however, possible, that such dis-

turbance may have taken place at an earlier date, or even at several widely separated epochs. The latter supposition would seem to be directly proved by the presence of granite veins passing through the earlier series, and producing a secondary alteration of its constituent minerals.

The above view of the age of the New Brunswick granites, excepting those of the Portland and Kingston Groups, is confirmed by the analogy of Nova Scotia, where, according to Dawson, rocks of this character and age penetrate the formations of the Upper Silurian and Lower Devonian.

d. Topographical Features.—The central granitic band of New Brunswick is for the most part high and rugged, although less so than the formations in the northern portion of the Province, or the southern band of the Nerepis. The latter affords some of the wildest and most lofty scenery in New Brunswick, including Bald Mountain, Douglas Mountain, the Eagle Cliffs, and many other eminences. Over both districts there is little soil beyond that furnished by the "Drift," and the country is in almost all parts an unbroken wilderness.

e. Useful Minerals.—Indications of Tin have been said to occur in the rocks near the mouth of the Pokiok, but after a careful search, I have found nothing to warrant a belief in the existence of metals at this point. Beyond their application for building purposes, for which the granites of Queen's County are admirably adapted, the rocks of these series are without economical value.

CONDITION OF THIS PORTION OF THE CONTINENT DURING AND AT THE CLOSE OF THE DEVONIAN AGE.

It will be remembered that in the remarks on the close of the Silurian Age, it was stated that the character of the rocks then forming in this portion of the Continent, seem to indicate a gradual sinking of the land beneath the sea. The upper beds of the Saint John Group are deep-water formations, while those of Kingston, in many parts at least, also indicate a similar origin. How long this subsidence continued, or whether any portion of the groups was again elevated to form dry land, during the long interval which elapsed before the opening of the Upper Devonian Era, it is impossible from our present data to determine. As, however, the latter epoch approached, it is probable that all those portions of the Province now occupied by the rocks of the Bloomsbury, Little River, and Mispeck Groups, with many others from which these beds have since been removed by denudation, were still covered by the ocean, for the volcanic products of the former indicate an origin under pressure, which could alone have been produced by outflows beneath the sea.

It does not necessarily follow that the waters then covering the land were deep, and as we pass to the upper member of the group, the evidence of strong but shallow currents, producing coarse conglomerates, indicates a gradual period of emergence. During this and the succeeding epochs, a

series of minor oscillations, marked by the alternations of coarser and finer beds, prevailed throughout the course of the Era. As the latter, however, drew slowly to a close, a period of disturbance, upheaval, metamorphism, and mountain-making, began upon a grand scale. The strata previously horizontal, or nearly so, were pressed into gigantic folds, the span of which is sometimes as much as several miles, and the original height not less than 2,000 feet, while at the summit of the folds, where the strain was greatest, dislocations ensued, resulting in the formation of extensive fissures, and the outflow of igneous matter. Accompanying the escape of the latter, began that general process of alteration and metamorphism which, as we have seen, characterizes so large a portion of the deposits belonging to this age. Then, too, the vapors and chemical solutions, filling the cracks and fissures, commenced those changes which have resulted in the formation of mineral veins, which abound in many portions of the districts described, and give to them their economical value.

Before leaving the consideration of the Devonian Age, we may add a few words on its peculiar *Life*, for it is here that we first meet with undoubted indications of a *land* vegetation. It will be remembered that vegetable fossils, of an obscure and doubtful character, have already been noticed as occurring in deposits of a much older date, even as low as the Saint John Group, and the upper beds of the Portland. In all these, however, the remains are too poorly preserved to be easily made out, and are, without exception, *marine* plants, of the very lowest order of organization. In the Upper Devonian sandstones and shales, however, a great advance has been made, in the change from a *marine* to a *terrestrial* vegetation. In place of the low and humble sea-weeds, which represented the entire vegetable world in the earlier periods, we have now to contemplate the Continent as raised in part above the sea, and clothed with Ferns and Conifers.

Among the most remarkable and constant of these plant-remains, is the fossil called the *Dadoxylon*, from which the name of one member of the Little River Group has been derived. This plant (*Dadoxylon Ouangondianum*—*Dawson*,) seems to have been a coniferous tree, of considerable size, some of the trunks, which are common in the sandstone, being as much as a foot or more in diameter. They are sufficiently preserved to show the pith, and, occasionally, even the rings which marked their annual growth.

Besides the pine-like *Dadoxylon*, the sandstones and shales contain the remains of numerous *ferns*, beautifully preserved and of great variety, and with them numerous Calamites, plants closely allied to the *Equisetum* or *Scouring Rush* of our marshes.

Nor are there wanting evidences by which we may judge of the animal as well as the vegetable life which flourished in this portion of North America at that early period. Not the least interesting of the discoveries made in the rocks of the Devonian Series, was the finding by Mr. Hartt of the undoubted traces of an *insect* life, the wings of these animals being, like the Ferns, beautifully preserved in the softer shale. They are by no means so abundant

as the other fossils referred to, but they are quite sufficient to prove the existence of these animals in the Devonian forests, and thus to establish the fact of their introduction upon the globe, at a period earlier by a whole geological age than that which had heretofore been assigned them.

In the disturbances which marked the close of the Devonian Age, most, if not all, of this abundant life became destroyed, and with a few exceptions, all evidence of its existence obliterated.

CARBONIFEROUS AGE.

The Carboniferous Age, or Age of Coal Plants, is usually divided into three Periods—the *Sub-Carboniferous*, when *marine* beds were mostly in process of formation;—the *Carboniferous*, when, over much of the Continent, the land had been sufficiently elevated to form wide-spread plant-sustaining marshes, giving rise to deposits of vegetable matter, now converted into coal;—and the *Permian*, when the sea again covered extensive districts. Of these, the two first mentioned periods only, are believed to be represented in New Brunswick.

A.—SUB-CARBONIFEROUS SERIES.

DISTRIBUTION.—The rocks of the Sub-Carboniferous Period in New Brunswick, like those of the same formation in Nova Scotia, occupy an extensive area, being not only widely spread over a district where no other rocks appear, but also occurring in isolated masses, irregularly distributed among the beds of the older groups, partially filling the depressions produced by the folding of the latter, or even rising along the sides of the ridges, and at times towering above their summits.

The general distribution of the Series will be apparent from a glance at the Map, where the beds comprising it are represented by a bright vermilion colour. As they are much more easy of recognition than the older formations on which they lie, they will not require so minute a description. The following are the principal areas which they occupy:—

1. The Valley of Belleisle Bay, and its extension easterly towards Butter-nut Ridge; also the Valley of the Kennebeckasis, and its extension easterly, along the Petitcodiac, to Moncton. This latter valley, near Norton, unites with that of the Belleisle, the Sub-Carboniferous rocks extending thence through a large portion of King's, Albert, and Westmorland Counties.

2. The Valley of the Petitcodiac, between Moncton and Shepody Bay. This division includes the district about the Albert Mines, with the asphaltic and bituminous shales of Elgin, Hillsborough, Baltimore, Dover, and Dorchester.

3. Detached areas upon or near the Coast. Of these, the principal are the neighbourhood of Gardner's Creek, with the region around Quaco, Martin's Head, Goose Creek, Point Wolf, and Salmon River.

4. The border of the great central Carboniferous Basin.

5. The Lepreau Basin, Charlotte County. The occurrence of Carboniferous rocks at this locality is not certainly known.

6. On the Tobique River, in the County of Victoria, between the Red Rapids and the Blue Mountains.

The above separation into divisions will be found convenient, not only as a geographical classification, but also as associating together deposits most nearly alike in character. These latter will now be more fully described.

CHARACTERS.—1. *Valleys of Kennebeckasis and Belleisle Bay.*—In this portion of their distribution, the rocks of the Subcarboniferous Period, as first pointed out by Mr. Matthew and Dr. Dawson, consist of materials mostly derived from the older metamorphic ranges on which they rest. These materials are usually of a coarse description, and, cemented together, produce a rough conglomerate, usually of a bright reddish-brown colour, with which, however, are associated some finer beds of sandstone and shale. Mr. Matthew thus describes the composition of those which occur in Kennebeckasis Bay:—

“Paste.—Dark red clay or sand, derived from granite,—rarely a gray calcareous mud.

Pebbles.—Imperfectly rounded fragments, one foot or less in diameter, of 1st, Granite or Syenite; 2nd, Metamorphic Limestone; 3d, Mica Slate; 4th, Soft brown sandstone.

These rocks, except the last named, are derived from beds of the Portland Series.” They fill all the upper part of the valley, and have been traced along the line of the river, as far as Apohaqui Station, near Sussex. They also cover, wholly or partially, many of the islands in Kennebeckasis Bay, and though in its lower portion mostly removed by denudation, are still represented in isolated patches, or lengthened strips, along the shore. They constitute the larger portion of Long Island, (where, however, older beds also appear,) and rise into a bold bluff at its eastern end. They form a part of the shores of the Milkish Creek, and are also seen on the southern shore of the Bay, covering most of the district between Boar’s Head and Sandy Point. They even re-appear on the western side of the main river, near the County line between Saint John and King’s, thus indicating that the whole of this great valley was once filled by them.

Between the rocks of the Kennebeckasis and those of Belleisle Bay, there is little diversity, except in the nature of the materials, and the source from which they have been derived. While the former, as before stated, consist mostly of fragments from the Portland Series, the latter are chiefly composed of the felspathic and hornblendic rocks of the Kingston Group. They are also finer in their texture, and hold a few thin beds of soft green and reddish shale. These rocks occupy a large area, and are well exposed, with beds of freestone, south of Belleisle Point, where the main road from Kingston crosses their broad flat surfaces, dipping slightly to the north.

They occupy also the entire valley of the Belleisle River, rising nearly to the summit of Bull Moose Hill, and thence extend to the eastward, along the slopes of the older series, as far as Butternut Ridge. The latter is composed of conglomerates with thick beds of limestone, and is continuous with the series which surrounds the great central coal-field of the Province.

Between the valley of Belleisle Bay and River, and that of the Kennebeckasis, the rocks are mostly of the kind above described. In addition, however, to the ordinary beds of conglomerate, shale, and sandstone, there are also several beds of impure bituminous limestone. These are well exposed at Dickie Mountain, on the northern side, (where the calcareous beds hold lead and copper,) and westward, along "the middle-land" road to Kingston. These limestones rest directly upon the altered rocks of the older groups, and may be considered as representing, at this locality, the lowest beds of the Carboniferous Series.

It has been stated that the Kennebeckasis conglomerates have been traced to the eastward as far as Apohaqui Station, near Sussex. Their outcrops, however, are not continuous, and at Norton they seem to be overlaid by a newer series, consisting of fine-grained grey sandstones, grey and black shales, with some thin beds of reddish calcareous conglomerates. These are well exposed in the railway-cutting east of the Station, and are remarkable for the great number and fine preservation of the ripple marks, and other impressions, on the softer beds. On one large slab, measuring four feet by four, no less than sixteen of these great ripples were counted, each occupying a space of from one to two inches.

At Apohaqui the lower deposits again appear, as well as the upper. The latter were found by Mr. C. R. Matthew to contain beds of bituminous shale, and sandstones with veins of *Albertite*.

It would be impossible, without unduly extending the limits of this Report, to give a detailed account of all the different localities included in the immense district now under consideration. At hundreds of points the Subcarboniferous rocks have been seen and studied by our party, but few facts, requiring special notice here, were observed.

Mr. Matthew has suggested the division of the series into two members, an upper and a lower, approximately equivalent to a similar subdivision of the same series in Nova Scotia. These two members are thus characterized:—

"1. A lower—consisting of coarse red conglomerates, red sandstones, and red shales. Fossils—Algae, and stems of land plants.

"2. An upper—comprising grey sandstones, and grey and brown shales."

To these divisions of Mr. Matthew, it is now necessary to add the occurrence of large beds of limestone and gypsum, as well as salt springs, in connection with the first member above given, or it may be, occupying even a lower horizon, and calcareo-bituminous shales associated with the latter. As these, however, are of economic importance, their consideration is deferred to the section on the useful minerals of the group.

In general, the coarser conglomerates of the lower division are most frequent along the southern margin of the basin, and near the older metamorphic hills, as at Damascus, through much of Upham, Picadilly Mountain, &c.; the fine grey sandstones and shales usually occupy the central portion of the valley, (in the eastern part, though not in the west), and from Sussex seem to cover most of the district as far as the Petitcodiac.

2. *The Valley of the Petitcodiac, between Moncton and Shepody Bay.*—The Subcarboniferous Basin of Albert and Westmorland Counties, continuous with that of the Kennebeckasis on its northern side, is irregularly bounded on the south and west by the metamorphic hills of the Devonian Series. Besides spreading widely over a continuous district, along either shore of the Petitcodiac River, the rocks of this division also partly occupy depressions between the folds of the older series, and gradually disappear among them. As the district is a large one, allusion will be made only to its more important features.

In the formations of the Albert County Valleys, rocks of both the divisions before enumerated are not uncommon. The coarser conglomerates of the lower member are usually found resting directly upon the metamorphic groups below them, and like those of the Kennebeckasis, have derived the great bulk of their materials from these groups. This is especially the case along the Pollet River, near Elgin, where the conglomerate is very coarse, and holds pebbles (some of them 30 x 18 inches in size,) of porphyry, syenite, jasper, protogine, red clay slate, quartzite, epidote, &c. All of these may have been derived from the rocks of the Cordaite Shales, and beds similar to many of them may be seen *in situ*, a short distance above. This is especially true of the porphyry, found penetrating the rocks in numerous dykes, and occurring in the conglomerates as pebbles of great beauty.

These coarser beds are but the eastern prolongation of the similar ones already noticed as common along the line of the Hammond River, and, though not perfectly continuous, re-appear at many points in the Parishes of Hillsborough and Hopewell. As already observed in the remarks on the older series, they progressively cover the latter to the eastward, and finally, at Shepody Mountain, rise above them. In the eastern and central, as in the western portion of the district, they are associated with sandstones and shales, with large and valuable deposits of limestone and gypsum. The precise localities of the latter will be indicated in the remarks on the useful minerals.

Irregularly distributed among the beds above described, are found, not unfrequently, the grey sandstones and shales which constitute the upper member, and at times also, deposits which can with difficulty be distinguished from the ordinary strata of the Coal Measures. But the formations which are most remarkable in the Group before us, and which give to the whole Series its most interesting character, are those to which we have already alluded under the name of *bituminous shales*, including the coal-bearing

beds of the Albert Mines, and the oil-producing strata of Baltimore, as well as those which yield petroleum at Hillsborough and Dover.

In the Acadian Geology of Dr. Dawson, (Chapter x,) there is given a section illustrating the relations of the Subcarboniferous rocks of Nova Scotia to those of New Brunswick, and also a detailed account of the geology of the Albert Mine, with a discussion of the origin and nature of that celebrated deposit. As this work is easily accessible, we do not here propose to enter into a recapitulation of the interesting conclusions therein contained, but only to add a few results of our own observations, upon particular localities in the neighbourhood. These will be more readily understood by reference to the following Table, constructed by Dr. Dawson, and designed to illustrate the succession of deposits, in descending order, between the mouth of the Petitcodiac River and the Albert Mines:—

“ 1. Grey sandstone, often coarse and pebbly, with shales and conglomerate, Hopewell Ferry, &c. These beds perhaps correspond to the great sandstone ledges of Seaman's Quarries, Joggins.

2. Reddish sandstones and shales.

3. Limestone and gypsum.

4. Red sandstone and conglomerate.

5. Grey and dark coloured conglomerate.

6. Calcareo-bituminous shales of the Albert Mines, Hillsborough. These beds appear here to lie at the very base of the lower carboniferous series.” A similar descending succession was also observed to the northward, up the Memramcook River.

To these observations of Dr. Dawson, we would add the following remarks:—

A reference to the Geological Map, at the close of this Report, will show that the Albert Mines occupy a position nearly mid-way between the older metamorphic hills and the Petitcodiac River. These hills, constituting the high table-land of Caledonia, and its eastern spur, Shepody Mountain, have been shown to be probably a portion of the Cordaite Shales of the Upper Devonian Series, penetrated by, or at least containing, large beds of granite and syenite, near their central parts. On the northern side of this metamorphic range, in the settlement of Caledonia, shales of the same age and general character, but more highly charged with bitumen than those of the mines, appear, and seem to be in direct contact with the older beds. They here have an easterly strike, and a northerly dip of about 50°.

A few miles west of Caledonia, near the sources of the Prosser Brook, we have already pointed out the occurrence of bituminous shales, similar to the above, and recognizable by their peculiar fossils. This deposit is in the exact direction of a line connecting the shales of the mines with those of Caledonia, and indicates an extension of the series along the valley already alluded to between the sources of this stream and the Coverdale River. On the northern side, however, of the chain which separates this valley from that of the Petitcodiac, we have again the calcareo-bituminous shales, with their characteristic fossils, (extending westward through Elgin far into the County of King's,) but here no longer resting upon the metamorphic hills,

being separated from the latter by the thick and coarse conglomerates of the Pollet River.

At the last named locality the distribution of the series, which was carefully studied by Mr. Hartt and myself, is nearly as follows, the succession being an ascending one:—

- 1st. Metamorphic rocks of the Upper (Pollet River) Falls.
- 2nd. At the Lower Falls—Coarse conglomerates derived from the above.
- 3rd. Interstratified conglomerates, and hard grey sandstones. (Str. N. 48–50° E. Dip 60° N. W.)
- 4th. Grey sandstones and sandy shales.
- 5th. Bituminous shales—concretionary, and slightly calcareous—containing ganoidal scales. They more nearly resemble the shales of the Albert Mines than those of Caledonia. The strike and dip are irregular, but approximately as follows:—Str. N.—N. 44° E. Dip often vertical, but at times about 60° N. W. At some points a conglomerate is bedded in the shale.
- 6th. Grey sandstones, grits and shales—occupying most of the country between Elgin and Salisbury.

It would seem from these observations that the bituminous shales, though apparently in direct contact with the older series at Baltimore and Prosser Brook, are separated from the latter by conglomerates of great thickness at Elgin Corner, (and the same is true at other points,) these conglomerates, therefore, constituting a lower member. Whether the similar deposits of the Kennebeckasis occupy the same position, is not certainly known; but the relation of the bituminous shales near Norton, evidently a westward prolongation of those at Elgin, to the beds below them, render it probable that such is the case. This view is still further confirmed by the observations made upon the carboniferous districts of the coast, where the coarse conglomerates seem to occupy a similar position.

3. *Coastal Detached Areas.*—The principal localities along the Bay of Fundy, at which Carboniferous deposits have been observed, have been already enumerated. At some of these localities, beds of the Lower Coal Measures, as well as those of the Subcarboniferous Series, occur, and for convenience will be considered in connection.

a. Gardner's Creek and the Region around Quaco.*—“The Carboniferous rocks of Gardner's Creek and vicinity, form a part of the largest of several deposits of this æra, scattered along the southeastern shore of the Province, east of Saint John; now isolated, but evidently marking the former existence of a large area of sediments in the depression filled by the waters of the Bay of Fundy, continuous with the coal formation which bounds its northeastern end; and probably connected also with the Lower Carboniferous (Dawson) of the Kennebeckasis valley, by the depression of land at the mouth of the Saint John River.

“The strata of the district under consideration seem to lie in a series of undulations, nearly parallel to those of the older series of metamorphic

* The following description of the first-named locality is written by Mr. Matthew, from data collected by that gentleman and myself, while spending a few days in that vicinity in the Summer of 1862.

rocks, but having frequently a more northerly direction. These corrugations have been impressed upon the beds, at some period between the close of the Carboniferous and the Triassic epoch; since, as will be shown in the sequel, sediments of the latter age were found reposing upon the upturned edges of the Carboniferous beds.

“ Along the shore, from Emerson’s Creek to Quaco, cliffs of greater or less elevation, present excellent opportunities for studying the varied characters presented by these latter. The strata consist chiefly of sandstones and shales, in frequently alternating beds, varying from a few inches to 20 feet or more in thickness. The prevailing colour is a chocolate red, paler, and often giving place to grey, in the sandstones, but frequently deepening to a dark purplish red in the shales. The sandstones often pass into grit, and more rarely into beds of a hard conglomerate, made up of pebbles derived from the indurated rocks of the metamorphic hills, imbedded in a sandy matrix.

“ A few beds of dark grey shale occur, and, with the finer sandstones, hold plants of several genera and species characteristic of the true Carboniferous formation, usually in an imperfect state of preservation and by no means abundant.

“ Specimens of these fossils were submitted for examination to Dr. Dawson, who remarks upon them as follows:—

‘ In looking over your Gardner’s Creek plants, I find the following:—

Coridaites borassifolia, and *trunk* of same.

Calamites Suckowii.

C. ——— *cannaeformis*.

Megaphyton, (species not determinable.)

Sternbergia.

Cardiocarpon, (several species.)

Lepidophyllum.

Neuropteris, { like *N. Loshii*,
like *N. auriculata*, } too imperfect to be sure of them.

‘ In so far as they tell anything, (and this is not very much,) the specimens are Carboniferous rather than Devonian, and are more like the *Millstone Grit* than any other part of the Carboniferous.

‘ I had almost forgotten to say that the *silicified wood* seems to be coniferous, and may be *Dadoxylon Materiarium*, but is not well enough preserved to be certainly determined.’

“ Westward of Wallace’s Cove, massive beds of a hard conglomerate (of grey and brown colours), derived from the wreck of the Devonian and Silurian rock northward, are brought up by an anticlinal fold in the formation, and constitute the principal mass of the bold promontory known as M’Kay’s Head.

“ A similar deposit may be seen at Quaco and Rogers’ Heads, resting on the flanks of ridges of intrusive trap. Near the Light House at Quaco, it is associated with thick beds of limestone, and for the reasons to be stated presently, Prof. Bailey and myself think both it and the calcareous strata, Lower Carboniferous, the conglomerate probably representing the coarse fragmentary rocks of the Kennebeckasis valley.

“As already intimated, the strata of this coal basin are much folded and otherwise disturbed. Faults, connected with downthrows, were observed at several places; and at Dewar’s, (Gardner’s Creek,) where the beds are curiously folded and bent, an admirable opportunity is afforded, both in the cliff and on the beach, for studying these phenomena. There seems to be an extensive overturned dip at this place, as indicated in the Sketch and Diagonal Section * across the measures, by which the higher members are inverted.”

The region about Quaco, above alluded to in the remarks of Mr. Matthew, is a very complicated one, and deserving of further notice. Subcarboniferous, Carboniferous, New Red Sandstone, and Eruptive Rocks, are all present, and so intimately associated as to be difficult of recognition. The general relation of these different groups will be apparent from the Section (H) illustrative of this locality, and from the following descriptive notes:—

The village of Quaco is situated partly on Carboniferous and partly on Triassic and Diluvial beds. To the west of the settlement, and on either side of the Light House, rise the two bold promontories of eruptive trap, known as Quaco Head and Rogers’ Head, the latter attaining an elevation of over 200 feet. Reposing upon the flanks of the first mentioned ridge, the lowest beds observed are limestones (without fossils), attaining at times a thickness of 25 feet, and covered by a hard and coarse conglomerate, composed of materials derived from the eruptive and calcareous beds below, with some pebbles of manganesian slates, cemented by a fine red sandy paste. These conglomerates are undoubtedly the equivalents of those forming the promontory of M’Kay’s Head, and of others which occur to the eastward, and like them are covered with thick beds of grey conglomerate and sandstone, (holding *Calamites* and trunks of trees,) with some thin beds of calcareous shale, (the latter containing *Cyprides*, *Naiadites*, &c.). All the beds above referred to are full of faults, displacements, and downthrows, a few of which are indicated in the Section. It is in these faults, and among the beds which bound them, that the principal deposits of manganese, formerly mined, occur.

Overlying all the rocks above named, and irregularly filling in all the inequalities produced by the igneous disturbances, are deposits undoubtedly referable to the Triassic Period. The lowest of these deposits, occurring near Quaco Head, and in the rear of the Light House, is a bright red calcareous breccia, holding interstratified beds of manganese. It is unconformable to the underlying strata, being evidently composed in part of materials derived therefrom, and is covered *conformably* by beds of New Red Sandstone, which appear at the Light, and also to the eastward, overlying the trap of the Head, as well as on the shore forming both sides of the Harbour.

In the succession of deposits above enumerated, a number of distinct events are indicated; first, the denudation of some older metamorphic Series,

* See Sections (D and G) at close of the Report.

(probably the Cordaite Shales,) and the production therefrom of the hard conglomerates, associated with thick beds of limestone, which represent the base of the Lower Carboniferous Series; secondly, a slow succession of oscillations near the sea level, of low land growing *Calamites* and trees, and giving rise to the thick beds of sandstone, conglomerate, and shale, with thin seams of coal; thirdly, an upheaval of the trap, causing violent dislocations of the overlying beds, and an alteration of the limestone; and lastly, a period of repose, in which the calcareous breccia and red sandstone strata were deposited in regular succession upon the upturned beds below them. If we take into account the fact that manganese occurs in the superficial deposits of drift, this metal would seem to have belonged successively to no less than *five* distinct geological Periods.

b. Martin's Head, Goose Creek, Point Wolf, and Salmon River.—The remaining coastal Carboniferous areas require but brief notice. At the first of the above named localities, deposits of this age may be seen, filling the space between the Head and the high metamorphic series in the rear. They consist of soft grey sandstones, friable marls and shales, of pale brown, grey, and chocolate colours, and differ from the ordinary type of the coastal Series in their remarkable softness and incoherence. They form a synclinal between the extremity of the Head and the upland, reposing unconformably upon the rocks of the latter, with a southerly dip of 60° . They here hold beds and veins of gypsum, and are overlaid by several well defined marine terraces.

A short distance to the eastward of the last named locality, red and purple conglomerates, and grey slaty calciferous shales are exposed in nearly perpendicular beds, and form the eastern side of the Harbour of Goose Creek. They probably represent the similar beds at M'Kay's Head and Quaco, and afford fine crystals of calc-spar in several varieties.

At Point Wolf, the hard conglomerates representing the base of the Series again appear, but constitute only a few small Islands. Between the latter and the high hills of the metamorphic shore belt, softer conglomerates and sandstones, of red and chocolate colours, are seen dipping northerly, and form the inlet of Herring Cove. They are here covered with thick beds of grey and buff coloured sandstones and shales, shattered and broken in every direction, and filled with enormous pot-holes. It is probable that the lower beds, dipping below the hills, have contained limestone or gypsum like the similar beds at Martin's Head, which, being undermined by the sea, have caused the falling in of the immense superincumbent mass. It is difficult in any other way to explain the broken character of the ground, which in roughness is unequalled in this portion of the Province. As a confirmation of this supposition, I may add that a salt spring issues from the hill upon the Bay Shore.

The Carboniferous Beds of Point Wolf extend to the eastward, through the settlement of Salmon River, and thence to Salisbury Cove. Between the two last named localities, however, the hard conglomerates at the base

of the series again appear, and rise into the bold ridge known as Owl's Head, attaining an elevation of not less than seven hundred feet. They are exceedingly hard, containing pebbles of *quartz*, *epidote*, *jasper*, *calc spar*, *talcose slate*, &c., derived from older series, and are filled with slickenside surfaces. Resting upon them, and forming the northern side of the ridge, are fine-grained grey sandstones and thin conglomerates, the former holding remains of *Sternbergia*, *Calamites*, *Lepidodendra?* *Sigillariae*, *Megaphyta*, &c., with large trunks of undetermined trees. The sandstones at this locality, as also at Quaco, contain numerous thin seams of *coal*, the bitumenized remains of the coal-plants; and attempts have been made to open mines for this substance, but with little or no prospect of success.

Between Salisbury Cove and Hillsborough, the deposits are chiefly those of the upper member above described. Some ridges, however, of conglomerate appear, and constitute the promontory of Cape Enragé, as well as the long islands lying between the latter and Shepody River.

That the deposits of the coastal Carboniferous areas above described contain beds of the Subcarboniferous Series, as well as of the Lower Coal Measures, is regarded as probable by both Mr. Matthew and myself, for the following reasons:—

1st. Heavy beds of hard and coarse conglomerates, such as are seen at M'Kay's Head, Quaco Head, Goose Creek, Point Wolf, and Owl's Head, do not occur in the great central coal basin of the Province, (though this may be due to the absence of protruding ridges, from which these conglomerates might be derived); they probably represent the coarse fragmentary beds of the Kennebeckasis Valley.

2nd. The existence of thick beds of limestone, such as that of Quaco (and Salmon River?). These limestones occupy the same relative position as those of Sussex and Upham.

3rd. The occurrence of *gypsum* at Martin's Head, Salmon River (?), Cape Enragé, and Hopewell; and

4th. The apparent connection of the conglomerates at Owl's Head, with the Lower Carboniferous of Shepody. The finer beds at the same locality, and also west of Quaco, may represent the Millstone Grit of Dawson.

4.—*The border of the great central Carboniferous Basin.*—This division of the Series is a very extensive and varied one, occurring as a narrow belt skirting the Coal Measures around their entire extent.

Starting from the north side of Butternut Ridge, where they gradually coincide with the Series already described of the Belleisle and Sussex Valleys, these rocks may be traced to the westward, along the northern flanks of the Kingston Group, as far as the Saint John River, at Long Island. Crossing the latter, (being nearly opposite on the two sides, not widely separated as heretofore represented,) they extend in a nearly uniform southeasterly direction through the settlement of Inniskillen, to the road between Saint Andrews and Fredericton, south of Brockaway's. Here gradually bending

around, they assume at first a northerly, and then a northeasterly direction, and in the latter course extend, with some irregularity, as far as the Coast of the Bay Chaleur, near Bathurst. The belt is but the outcropping border of a Series, which probably underlies the greater portion of the Carboniferous basin.

Of the extensive district implied in the above description, I have personally examined but a very small fraction. These examinations, however, have been found to possess so many features in common, that the general character of the series is sufficiently established. The latter may be conveniently divided into two Sections, based rather upon the conditions of their origin than their geological relation.

1st. A volcanic series,—the rocks being yellow and reddish-purple quartzose grits and altered slates, associated with thick beds of trap, basalt, and amygdaloid, and altered by them.

2nd. Red calcareous conglomerates, red sandstones, and red shales, (unaltered.)

A. *Hampstead and Rush Hill, Queen's County.*—A general description of the distribution of the different formations at the first of these localities, has already been given in the remarks on the great central granitic band of the Nerepis. In advancing to the north from this granitic axis, after passing a moderately wide belt of nearly vertical mica schists, the latter abruptly give way to a wide-spread series of volcanic and altered rocks, evidently referable to the Subcarboniferous Period. They occupy an area of several miles along the western side of the River, opposite Long Island, and extend to within a short distance of the Otnabog Lake, where they become covered with the ordinary grey rocks of the Coal Measures. It is near their junction with the latter that the best and most typical exposures may be seen, as given in the following Table, the succession being a descending one:—

1. South shore of Otnabog Lake—Grey sandstones, in broad, flat masses, with very slight northerly dip.

2. (At the farm of Mr. Merritt, one mile below)—Basaltic and vesicular trap, with coarse grey amygdaloid, holding *calc spar*, *quartz*, and *heulandite*. The trap slopes gradually to the north, but on the south presents a bold mural face, the general direction of which is N. 60° E. In the valley thus formed are met—

3. At the foot of the cliffs—Buff coloured Carboniferous sandstones.—Dip 40° N.

4. Soft, ochreous, blue and yellow shale, with splintery fracture.

5. (Immediately below the latter)—30 feet of greyish and reddish semi-crystalline limestone, holding numerous fossils.

6. Thick beds of yellowish and reddish altered grit, projecting in pseudo-columnar masses. This is the most abundant and the most remarkable rock of the series. It is of a coarse though uniform texture, and consists of bright glassy particles of sand, perfectly transparent, imbedded in a reddish or yellowish clayey paste. It is quite hard and compact, at times recalling porphyry, but is destitute of a distinctly crystalline character. It passes also insensibly into other beds, which approach more nearly to an ordinary grit. These, with the rocks first mentioned, probably underlie most of the district between Merritt's and the slate of Hampstead, but are largely concealed by diluvial detritus. Many volcanic beds, however, appear, consisting of hard conchoidal basalt, vesicular trap, and amygdaloid.

Directly opposite the section above described, and occupying an equal, if not a greater area, the same series again appears in the Parish of Wickham, the same curiously altered grits being exposed, in broad flat masses, along the river side for several miles. The trap ranges, however, though present, are much less numerous and prominent, while the finer beds and limestones are not immediately apparent. The latter, however, may again be seen a few miles eastward of the river, at Rush Hill, where they resemble in every respect those of Hampstead, in character as well as in the fossils which they hold. They also resemble the limestones of Butternut Ridge, and between the two may be observed at many points along the northern slope of the high land which forms the water-shed between the Washademoak and Belleisle. There is, however, this important difference in the geological position of the series on the two sides of the Saint John River; while on the western these Subcarboniferous rocks repose against vertical mica slates, on the eastern the underlying beds are of the Kingston Group. The nearest rock observed in the neighbourhood of the limestones at Rush Hill, was a coarse-grained diorite, similar in every way to those so abundant in the formations north of the Belleisle.

B. Bald Mountain, York County.—About twenty miles west of Fredericton, and a little to the north of the Saint Andrews Road, near where the latter enters the Harvey Settlement, rises a hill, sloping gradually on its eastern side, but on the western laid bare in a bold mural cliff, known in the neighbourhood by the name of Bald Mountain. This hill, a prominent object in the landscape for miles around, is as curious in its characters and probable origin, as in the isolated position which it holds.

In approaching the eminence from the south, the only rocks observed in the immediate neighbourhood were grey sandstones, &c., similar to those of the central carboniferous district. A short distance to the eastward, however, near the sources of Long's Creek, ledges of red calcareous slaty conglomerate may be seen, dipping westerly, and again at various points in the settlement of Harvey. It would thus appear that Bald Mountain, like the trap beds of Hampstead, occupies a position near the line of junction between the Subcarboniferous Series and the ordinary Coal Measures.

This analogy of relation, taken in connection with the bold and precipitous character of the eminence, would at first sight suggest an eruptive origin, and lead us to expect the presence of basalts and amygdaloids, similar to those so extensively and prominently exposed in the County of Queen's. An examination of the hill itself, however, shows the presence of no such rocks, being entirely composed of sedimentary beds, extremely altered.

These sedimentary rocks may be classified as follows:—

1. Altered purplish slate or claystone, partly amygdaloidal.
2. Dark purple compact felspar, porphyritic with limpid particles of quartz.
3. Altered volcanic grit, also with limpid pebbles of quartz, and undistinguishable from the similar beds of Hampstead and Rush Hill.

The principal mass of the mountain is composed of the altered rock constituting the first of the above divisions. No distinct stratification is apparent, the whole series displaying marks of violent distortion. Many of the rocks exhibit on their weathered surface innumerable zigzag furrows, running in all directions, and giving to the mass the appearance of having been violently compressed while in a still flexible condition; while others are perfectly compact and of extreme hardness.

Neither the second nor the third of the above named divisions were found *in situ* upon the summit of the mountain, but are well exposed on the western flank, and along the Saint Andrews Road, to within a short distance of Harvey. In the latter place, the unaltered red slaty conglomerates appear, and occupy an extensive area.

The details of the two localities above given will suffice as descriptive of a group of rocks largely developed in connection with this division of the Subcarboniferous Series, and which re-appears at many points along the borders of the great central basin. Among other marked localities, I may allude to the district a few miles west of Fredericton, where, on both sides of the Saint John River, we have a re-occurrence of the volcanic beds, in connection with the red sandstones and reddish purple conglomerates, of this formation. The latter may be seen at the Indian Village, resting upon contorted Silurian (?) slates, and again at Sugar Island, in the Saint John River, where they are gypsiferous, and underlie silicious conglomerates, dipping southwesterly at an angle of 90°. At these localities, however, the sedimentary beds are destitute of the highly metamorphic character so remarkable in the rocks of Bald Mountain and Hampstead, while the trap-pean beds are more basaltic. The latter are well exposed along the river-edge of the Keswick Ridge, and opposite the French and Indian Villages. They also re-appear at Spring Hill, and on the opposite side of the river, at Clark's Mountain and the Royal Road.

The following Table will be found to illustrate, in a systematic order, the various localities where observations have been made on the characters and distribution of this most important series, throughout its entire extent. They are partly the result of my own observations, and partly of those of Dr. Robb :—

- a. Parish of Wickham, Rush Hill, &c., Queen's County, described above.
- b. " Hampstead, Merritt's, &c., " " " "
- c. Inniskillen Settlement, Petersville Parish, Queen's County. Porphyritic breccia.
- d. " Brook of Sticks," near Vail's (Brockaway's)—road between Saint Andrews and Fredericton.—Light purple conglomerate, near porphyry, and under grey grits, dipping north. This porphyry is much like the altered slate of Bald Mountain.
- e. Northwest end of Harvey Settlement, near Messiah Brook.—Porphyritic breccia, under grey grits.
- f. Harvey Settlement, main road.—Red conglomerate, near porphyry.
- g. Bald Mountain.—Altered slates and grits, described above.

h. On road from Bald Mountain to Long's Creek, at farm of Nicholas Barker—Dull reddish brown slaty conglomerate.—Pebbles, angular fragments of trap and mica slate; cement, calcareous.

i. Saint John River, at French and Indian Villages.—Red sandstones and conglomerates, with basaltic trap.

j. Sugar Island and Keswick Ridge.—Same as above.

k. Clark's Mountain, Keswick Road. “ “

l. McLeod's Hill, Royal Road.—Vesicular trap and amygdaloid, much like that of Hampstead, exposing to the west a bold front, but sloping gradually to the east. The amygdaloid holds fine quartz crystals and rhombohedral calc spar, but no heulandite.

m. Between Cardigan and Stanley, York County; also, at Tay Creek and Red Rock Settlement.—Red sandstones, resting on metamorphic slates.

n. Three miles below Stanley.—Red marly sandstones, under grey grits, and near clay-stone porphyry; the latter light coloured, with dark purple blotches.

o. Four miles from Boiestown, forming the axis of the Portage between the Nashwaak and Miramichi.—Amygdaloid.

p. Mouth of the Nepisiquit River, near Bathurst.—Light blueish and reddish sandstones and conglomerates, with light blue shales, holding Lignite and Copper Ore.

It will thus be seen that throughout this extensive Series, the association of volcanic outbursts with red and purple sediments is very marked, and shows that the period of igneous activity, so prominent during the Devonian Age, had not yet ceased in the earlier part of the Carboniferous. It is probable that the greater portion of the references made by Dr. Gesner to eruptive rocks along the district occupied by this belt, as well as the similar indications in the geological Map of Dr. Robb, have had their origin in beds belonging to the Group now under consideration.

AGE.—It has already been stated in the Introductory Chapter, that the great series of sediments now described, were originally referred by Dr. Gesner to the New Red Sandstone or Saliferous System of European geologists, but subsequently, on account of its resemblance to similar formations in Nova Scotia, to the Lower Carboniferous Series. Dr. Robb, on the other hand, while supposing that most of these red beds were below the Coal Measures, and possibly Devonian, indicates by the colouring of his Map, that the grey rocks of King's, Albert, and Westmorland Counties, including the bituminous and coal-bearing strata of the Albert Mines, form a part of the same series as the grey sandstones and grits of the great central basin.

That all the beds included in the foregoing descriptions are, unless otherwise stated, properly to be referred to the Lower Carboniferous System of Dawson, is conclusively proved by the following facts:—

a. The stratigraphical relations of the Albert County rocks, already explained, show their position near the base of the Series referred to. This position is confirmed by the evidence of the fossils,* viz:—*Ganoid Fishes*, remains of *Lepidodendron elegans*; *L. corrugatum*, *Cyclopteris Acadica*, and stems of large ferns. These fossils, as well as the character of the beds which

* Observed by Messrs. G. F. and C. R. Matthew in the beds near Norton; also by Mr. Hartt at the Albert Mines, and Elgin.

hold them, render it probable, as first observed by Dr. Dawson, that the latter are contemporaneous with the similar beds of Horton Bluff, in Nova Scotia.

b. That the coarse fragmentary rocks of the Kennebeckasis Valley, and the detached coastal areas, are partly of the same series, but of a lower horizon, has already been shown by their position underneath the bituminous shales of Albert. Associated with the coastal areas, however, are some beds probably referable to the Millstone Grit, and others to the Lower Coal Measures.

c. The limestones, salt-springs, and gypsum, so abundant throughout the series, establish the identity of the latter with the similar Group in Nova Scotia.

d. The limestones referred to, where not too much altered, as at Hammond River, Norton, Butternut Ridge, Rush Hill, and Hampstead, contain characteristic Lower Carboniferous fossils, *Terebratulæ*, *Producti*, *Conulariæ*, &c.

TOPOGRAPHICAL FEATURES.—Among all the geological formations represented in New Brunswick, there are probably none which exhibit such diversity of outline and position, as the rocks of the Subcarboniferous Series. Being composed of a great variety of material, conglomerates, sandstone, shale, limestones, and traps, and therefore very differently affected at different places by denuding and other agencies, the features of each particular district may in general be inferred from the prevailing character of its rocks.

As a rule, the land underlaid by members of this series is comparatively low, yet at times, when the coarser beds appear, hills and ridges of very considerable altitude are found. This is especially the case along the southern margin of the great central valleys of the Kennebeckasis and Petitcodiac, as well as among the isolated areas on the coast. Among the latter, the high conglomerate ridges of M'Kay's Head, Rogers' Head, Owl's Head, and Quaco, are unsurpassed in this portion of the Province for their lofty and rugged grandeur.

Between the ridges and valleys of the Carboniferous, and those of the underlying metamorphic series, there is always this distinction to be observed, that while in the latter the elevations and depressions are the results and indications of great flexures in the beds, the former indicate no disturbance whatever, being merely the result of excavation by running waters. The general course and dimensions of the older valleys are therefore uniform over extensive areas, while those which are due to the eroding power of water, are as irregular as the direction of the currents which produced them. Even where conforming to the general folds of the district, the latter are often connected by transverse valleys, the former never so, unless through the agency of faults, giving new direction to the currents.

Bearing in mind these facts, together with what has already been stated with regard to the character and distribution of the group, it will not be

difficult to understand the more prominent topographical features of the different districts occupied by these rocks.

The most important of these districts, both in an agricultural point of view, and as affording the only easily available line of connection between the eastern portion of the Province and the City and River of Saint John, is the great valley of the Kennebeckasis and Petitcodiac Rivers, sufficiently indicated by the position of the European and North American Railway, which occupies its centre. This valley is too well known to require minute description here.

South of the latter, and approximately parallel in general direction, are the valleys of the Hammond River and its tributary, the Salt Spring Brook. These valleys are bounded and separated from each other by high and frequently precipitous ridges of coarse conglomerate, due entirely to the action of running waters, which have removed the softer shales and sandstones, while the harder beds have been unaffected. These conglomerate ridges, so common in the Parish of Upham, continue to the eastward, where they include Picadilly Mountain and the high lands south of Sussex, and along the Dutch Valley, (being here divided by the transverse depressions of Trout Creek and its branches,) and extend far into the County of Albert. In the latter, however, the conglomerates gradually approach the older series, and conform to their foldings, while the country to the east and south, at and about the Albert Mines and Hillsborough, becomes broken into innumerable minor valleys, too irregular to admit of accurate description.

The only remaining district requiring notice in this connection, is the great border of the central Carboniferous basin, where the presence of eruptive agencies has produced features somewhat different from those found in other portions of the Series. As a whole, this belt of rocks is low, (although more elevated than the beds of the Coal Measures which it surrounds), and only acquires prominence where raised and altered by igneous dykes, as at Bald Mountain, Keswick Ridge, and many other localities.

AGRICULTURAL CAPABILITIES.—While, as has been shown, the districts occupied by the rocks of the Silurian and Devonian ages are for the most part covered by soils of a poor, or very inferior quality, those in which the series now under consideration occurs, are unsurpassed for their value and fertility. Composed for the most part of materials very imperfectly consolidated, they are easily acted upon by atmospheric and aqueous agencies, and readily crumble into rich and productive soils. The presence also of limestone and gypsum, of almost universal distribution through the series, greatly enhances its value, and gives to this division of the geological scale an interest which is scarcely equalled even by its abundant mineral deposits. Hence the great importance of an accurate knowledge as to the distribution and characters of its several members, and of a Map by which their location may be readily ascertained. No other district in the Province, except where alluvial deposits prevail, will compare with that of the Subcarbon-

iferous Series in fertility, and none, therefore, offers so many facilities for settlement. In the southern portion of the Province, this fact, readily recognized by settlers, though unconscious of its cause, has led to the occupation of the greater part of the district, but many fertile tracts still remain uncleared; while along the Tobique River, where similar rocks occur, the advantages of settlement are unsurpassed. The position of these rocks, so far as they occur in the southern Counties, may be readily ascertained from their delineation on the Map. Where limestone and gypsum are indicated, the soil can hardly fail to be of a rich and productive character.

USEFUL MINERALS.—The deposits of economical value belonging to the Subcarboniferous Series, are *Limestones, Gypsum, Salt, Coal, Bituminous Shale* and *Petroleum, Freestones*, and the ores of *Iron, Lead, and Manganese*.

a. Limestone, Salt, and Gypsum.—The mode of occurrence of these three most valuable minerals has already been described in the remarks on the characters of the Series. It only remains to indicate in tabular form the various localities in which they have been found.

LIST OF LOCALITIES CONTAINING SUBCARBONIFEROUS LIMESTONES, SALT SPRINGS, AND GYPSUM.

ALBERT COUNTY.

Demoiselle Brook.—Limestone, gypsiferous sandstone, and gypsum.

Plaster Quarries.—The beds, as observed at this locality by Mr. Hartt, are 60 feet thick. The gypsum is of two varieties, the *Hydrous* and the *Anhydrous* Sulphate, which pass into each other. The latter is usually of a blueish tint and is much seamed by “soft plaster.” It also occurs of a very pure white colour, and quite translucent. The *Hydrous* variety is often equally white, and so soft as to be readily cut with a knife. Reddish brown crystals of *selenite* were observed to occur rarely in the plaster. The latter, with slaty limestone, may be seen outcropping at many points in the neighbourhood. At the time of our visit, extensive operations were in progress, 80 tons being daily transported to the wharf on the Petitcodiac River.

Near Elgin.—Limestone, on farms of James Ayton, and J. Hayward.

Prosser Brook.—Limestone, on farm of Isaiah Steves.

Turtle Creek.—Limestone, on farms of Edward Berry and William Forbes.

KING'S COUNTY.

Butternut Ridge.—Limestone and Gypsum. (Salt Spring, Gesner.)

Hammond River, Parish of Upham.—On road from Quaco to Sussex, at W. Baird's, large bed of gypsum. To the eastward, near Wanamake's Inn, limestone.

Davidson's Manganese Mine.—Limestone;—also at the source of South Branch of Trout Creek.

Mill Stream.—Limestone and Gypsum, at several points between Apohaqui and Butternut Ridge.

Norton.—Limestone, with galena and copper pyrites.

Salt Spring Brook.—Salt Springs, on land of A. Campbell.

Sussex.—Limestone, gypsum, and salt springs.

Springfield.—On middle-land road from Kingston to Belleisle, Limestone.

QUEEN'S COUNTY.

At Merritt's, above Hampstead, limestone.

Rush Hill.—Limestone; a continuation of the same is indicated by boulders along the northern side of the high land in rear of the Belleisle.

SAINT JOHN COUNTY.

Quaco.—Thick beds of limestone, between the Village and Rogers' Head.

Martin's Head.—Gypsum. This deposit was formerly worked, but long since abandoned, except as required for local use.

WESTMORLAND COUNTY.

Parish of Salisbury, on the North River, above Petitcodiac Station.—Limestone, Salt Spring, and Gypsum.

Parish of Sackville.—Gypsum.

To the above may be added the immense limestone and plaster beds of the Tobique River, already noticed as probably referable to the Subcarboniferous Series.

b. Coal and Bituminous Shale.—The only deposits belonging to the Subcarboniferous Series, usually referred to the above head, are the so-called coals of the Albert Mines, near Hillsborough, and the calcareo-bituminous shales or cannel coal of Baltimore. We do not propose here to enter into the vexed question as to the nature and origin of the first named substance, but refer the reader to the Acadian Geology of Dr. Dawson, where will be found a complete history of the remarkable locality in which it occurs, with observations on its character and probable mode of formation.

We may, however, state that, in the opinion both of Mr. Matthew and myself, the Albertite is neither *coal* nor *jet*, but an *oxydized oil*, derived from the decomposition of fish remains, and subsequently changed by chemical action. We base this opinion partly on its geological age, (the discovery by Mr. Hartt, during the past summer, of *Cyclopteris Acadica* and *Lepidodendron elegans* in the shale of the Mines, proving its position as a part of the Lower Carboniferous of Dawson, probably equivalent to the red shales of Gaspereau, Nova Scotia,); partly on the almost complete absence of vegetable remains and underclays, such as abound where all true coal-beds exist; partly on the chemical composition of the substance, and the almost entire non-production of ash, when burned; partly also on its perfectly homogeneous character, wherein it differs from all ordinary varieties of coal; and lastly, upon the mode of occurrence of the deposit itself, which is not like that of a true *bed*, but rather in *veins*, irregularly penetrating not only the enclosing shale, but also layers of sandstone at a great distance from the principal deposit. To these reasons may also be added the fact, that springs containing oil are not uncommon throughout the district in which the Albertite is found.

A more important question than the origin of this coal is that of its *amount*, and the probability or otherwise of its occurrence in different localities from those now under exploration. The determination of this question, however, is beset with many difficulties, due partly to the unsettled state of the country, but chiefly to the very irregular mode of occurrence in the deposit itself. Our labours have been mainly devoted to ascertaining the geographical extent and distribution of the accompanying shales, and their relations to other groups.

Before leaving the vicinity of the original Albert Mines, it may be well to refer to a more recent attempt to obtain this coal, from another locality in the immediate neighbourhood. At a point about half a mile from the principal works, and near the line of the Railway, a shaft* has been sunk to a depth of 200 feet. It passes through a very friable dark red sandstone, with greenish patches, in which also fibrous gypsum occurs abundantly, filling up the cracks and joints. The bituminous shales may be seen at several points near the works, being much folded and full of concretions. Their strike is irregular, and the dip, while at one point only 4° or 5° to N. 55° W. is at another southerly to about the same amount. The coal does not apparently differ from that of the Albert Mines, but I am not informed as to its quantity or mode of occurrence.

In the remarks on the characters of the Subcarboniferous Series, it has been stated that the calcareo-bituminous shales occur at several points to the westward of the original Mines, as at Baltimore, Prosser Brook, and Elgin. It would seem, (as will be apparent from an examination of the Map,) that there are two or more distinct bands of this substance, extending in nearly parallel directions, over a large extent of country.

The first of these belts may be considered as having its centre at the Albert Mines. About six miles to the westward occur the so-called shales or pyro-schists of Baltimore, evidently co-ordinate with those of the former locality, though differing somewhat in appearance and composition. Like the latter, they contain Ganoid fishes and veins of Albertite, irregularly distributed through the mass of the rock. Still advancing westward in the same direction, we reach the head of Prosser Brook, where again the peculiar bituminous shale may be seen near the house of A. Hayward, and is easily recognizable by its peculiar fossils. It here occupies a position at the bottom of a narrow valley in the older metamorphic series, and apparently rests upon the latter. Beyond this point it has not been traced in this direction.

The second belt, occupying a position somewhat north of the latter, extends along the base of the metamorphic hills, and was first observed a few miles east of Elgin, on the land of W. A. Colpitt. It was found at this point to be highly bituminous, and several fossils were detected by Mr. Hartt, among others, the common *ganoid scales*, teeth of a *rhizodont* type, like those of Horton Bluff, in Nova Scotia, and remains of plant-stems, with a fragment of *Lepidodendron elegans*. With the shales occur friable grey calcareous sandstones, and thin layers of fibrous calc spar. The former have a strike about N. 45°—50° E., and a northerly dip of 50°.

In the village of Elgin the bituminous shales again appear, and were traced in a westerly direction for some distance up the branch of the Pollet River. They more nearly resemble the shales of the Albert Mines than those of Baltimore, are often highly calcareous, and contain, besides some obscure fern-stems, numerous large plates of fishes, much like those of Horton Bluff. The general relations of the beds at this locality have already been given.

To the westward of Elgin, and in the eastern part of the Parish of Sussex, a shaft has been sunk in beds of shale, evidently a continuation of those last described, and *Albertite*, in every way similar to that of the first discovered deposit, has been sparingly removed.

* The observations at this locality were made by Mr. Hartt. Since writing the above, I have received a specimen, termed "East Albert Coal," recently discovered about two miles southwest of Hillsborough. It does not, apparently, differ from the ordinary Albertite, and gives new interest to the occurrence of this valuable mineral. The new vein at the surface has, I believe, a thickness of three or four inches, which increases with the depth.

The next point at which deposits of the substance under consideration have been observed, is at Morris', on the South Branch of Trout Creek, and still in the general direction of the deposits already described.

Lastly, calcareo-bituminous shales, as before noticed, occur in the vicinity of Norton, with sandstones, containing veins of Albertite. This is the most extreme westerly point at which beds of this character have been observed.

Returning to our starting point, at the Albert Mines, and going in an easterly direction, the fish bearing shales are again found on the eastern side of the Petitcodiac, in the County of Westmorland, but whether a continuation of either of the above described belts, it is difficult to say. The following are points at which they have been observed:—

- a. Boudrot's Village, Parish of Dorchester. This is in the exact direction of a line connecting Baltimore and Hillsborough.
- b. At White's, near the Ferry, Dorchester.
- c. At J. Robertson's, Memramcook.
- d. Near Ayer's Mill, Dover.

It will thus be seen that of the two belts of coal-bearing shale, the one occupies a position somewhat to the north of the other, and extends with much regularity from Norton Station through Elgin to Dover. The second, approximately parallel, also extends easterly from Prosser Brook through Hillsborough, to the Memramcook River, in Dorchester.

While thus succeeding, beyond our expectations, in the determination of the position and extent of the Albert Shales, we are still without definite facts as to the actual occurrence of workable deposits. When, however, we consider the comparatively slight indications which led to the exploration of the original mine, we may well trust that in a district so large, other beds of equal extent and value will be found. The presence of the mineral itself at such widely separated points, the abundance of fish remains wherever the shale occurs, and the highly bituminous character of the latter, to say nothing of the presence of oil-springs, all tend to confirm this opinion, and to give to this portion of the Province an interest not exceeded by any other.

Petroleum.—In connection with the discussion of the characters and position of the Albert coal, and the oil-yielding strata of Baltimore, it is interesting here to allude to the various points at which the last named substance has been found to exist as a naturally-formed product.

The presence of *petroleum*, or mineral oil, in the Parish of Dorchester, was early recognized by Dr. Robb, Dr. Jackson, and others, but it is only within the last few years that any attempts have been made to open distinct wells. The principal locality at which operations have been begun, is that where the presence of this substance was earliest pointed out, viz: the district lying between the Petitcodiac and Memramcook River, near Dover. The "Westmorland Petroleum Company," incorporated in 1864, have here erected buildings suitable for their undertaking, and have sunk by boring to a depth of over 400 feet. The rocks passed through, as enumerated in a Report to the Company, are as follow, in descending order:—

Blue clay.

Shale.

Soapstone (?).

Blue limestone, full of crevices. Red sandstone.

Shales ———. Depth, 90 feet. Several veins of Oil.

Sandstone and Conglomerate. Depth 120 feet. An excellent show of Oil.

Soapstone (?)

Limestone and Conglomerate, very hard, and with many crevices.

Red Sandstone.

Grey Shales. Depth 207 feet. Evidence of Copper, the tools coming up coated with that metal.

Conglomerates, with Iron and Manganese.

Very hard rock. Depth 300 feet. Struck a vein of salt water. Gas strong and burning on the Sand Pump.

60 feet of Black compact Shale. Small vein of Oil below.

Conglomerates.

Hard rock, } 400 feet. Gas very strong. Struck a vein of salt water
Shales and Sandstone, } and Oil.

Sandstone. 430 feet.

The general character of the rocks enumerated, would seem to imply that the strata passed through belong near the base of the Lower Carboniferous Series, and are similar to what may be observed at the Manganese Mine, on Shepody Mountain. The so-called *Soapstone* is probably a *fire-clay*, such as occurs at the last named locality; while the indications of copper and manganese may be due to secondary ores derived from subjacent metamorphic beds. I have not however seen any specimens of the rocks removed, and am therefore unable to pronounce positively on their character.

At the time of my visit, operations had been temporarily suspended, during the putting down of copper pipes for pumping. I observed, however, the strong escape of gas from the well, bubbling through a mixture of water and oil, and also observed the latter substance floating on the surfaces of springs in the vicinity. I have since been informed, that after the sinking of the pipes, several gallons of oil were removed in a single day's pumping.

Besides the locality above referred to, petroleum has been observed at several other points in this district, sometimes in a liquid form, escaping with the water of springs, at others in an oxydized condition, forming a thick tarry substance, termed *maltha*.

On the western side of the Petitcodiac River, an American Company have undertaken to bore for oil, on Stevens' Brook, near Hillsborough. At the time of the examination of the locality by Mr. Hartt, operations had but just commenced, and pending the arrival of a steam engine, the boring was carried on by hand. The depth then reached was only twenty five feet, the excavation being made in a friable red sandstone. A few feet from the latter, an adit had been driven into the foot of the hill, and had become partially filled with water, on the surface of which a thick mineral oil was floating by bucketsfull.

With the Sandstones of this locality are beds of blueish shale, and compact impure concretionary limestone, with numerous irregular masses of jaspery agate.

The last point at which I have had an opportunity of observing the presence of mineral oil, is the neighbourhood of Elgin Corner in Albert County, where several of the springs were found to be thoroughly impregnated with this substance, so as to be rendered unfit for ordinary use. The most marked of these springs is on the land of David Steves, and but a short distance from where we had already recognized the existence of Albert shales. A gas bubbles constantly from the water, and the latter tastes and smells strongly of petroleum. I did not, however, observe any distinct oily films, though the iridescence due to the latter was sometimes present.

In attempting to arrive at positive conclusions as to the probable quantity and value of Petroleum in Southern New Brunswick, we are immediately met by the uncertainty which still prevails in other portions of America, with regard to the origin and mode of action of oil-wells. In the absence of certain data from which to judge, we may briefly allude to the principal facts which favour a belief in the existence of the latter in the districts above enumerated.

In the first place, the geological age of the formations where these springs occur (already shown to be near the base of the Lower Carboniferous Series), is the same as that of the great oil-regions of Pennsylvania and Ohio.

Secondly, the large quantity of Albertite, if the latter be properly regarded as an altered oil, shows the former existence of this substance in a fluid condition, filling cavities in the disturbed strata. If we suppose the greater part of the oil to have become converted into the so-called *coal*, it is not reasonable to suppose that only a single deposit of the latter exists, and if not, other large beds of Albertite are to be expected, a result as important economically as would be the discovery of oil-wells.

Thirdly, the wide area over which actual indications of petroleum have been observed, goes far to indicate the general presence of the latter. It is no objection to such a belief that but trifling quantities of oil have as yet been obtained at the several localities, for such is often the case, where continued search leads to profitable yields. Indeed, so great is the uncertainty attending the discovery of actual wells, that in the Pennsylvania oil-district, according to Professor Evans,* "it is one chance out of many to strike oil at all, even in neighbourhoods where it exists in abundance." The same author observes that the presence of oil on the surface of water in springs is not a reliable indication of the original well, as currents of the latter may have carried the oil to considerable distances; gas springs on the contrary, and especially the finding of large quantities of imprisoned gas, are regarded as good indications that oil is near.

We leave this interesting subject, with the hope that operations of a sufficiently extended character will be persevered in, until the question shall have been definitely settled, whether or not this valuable substance is to be

* See an Article on the action of Oil Wells in September No. (1864) of Silliman's Journal.

sought for in this portion of America. We may add, that the district about Elgin would seem to be a favourable one for the prosecution of such undertakings.

Freestones, &c.—Among the useful minerals of the Lower Carboniferous Series, the gray sandstones of Albert and Westmorland Counties, so extensively used for building purposes, occupy a prominent place. The principal quarries are the following:—

Albert County.—Mary's Point and Grindstone Island—Albert Stone Quarries.
Cape Demoiselle—M'Kay's and Stuart's Quarries.

Westmorland.—Dorchester Freestone Quarries.
Sackville Parish, Joggins—Westmorland Olive Freestone Quarries.

At all of the above localities, operations of a more or less extended character are carried on, and large quantities of stone are annually exported or employed for local use.

Grindstones, also highly prized, are obtained at most of the above named quarries.

Iron.—This metal, though occasionally found in connection with other ores as a part of the series under consideration, does not occur in sufficient quantity to be of economical value.

Lead.—The principal locality at which this metal occurs in Lower Carboniferous rocks, is the foot of Dickie Mountain, near the Fingerboard, Norton, where limestone of this age holds both lead and copper. As the ores have probably come from the underlying metamorphic beds, they have already been described in connection with the latter. (*See useful Minerals of Kingston Group.*)

Manganese.—This is by far the most abundant ore present in this series, and has been observed at a number of points.

a. In the neighbourhood of Quaco, between the latter and Rogers' Head, the occurrence of manganese has already been pointed out, both as present in Carboniferous rocks and the overlying New Red Sandstone. The metal seems to occupy the line of a fault in the former, and irregular beds and pockets, in a breccia referred to the latter. The largest bed observed was from one to two feet in thickness. The same metal occurs as pebbles in the associated limestone, and with the latter in a coarse conglomerate.

b. On the western slope of Shepody Mountain, in a situation geologically similar to that at Quaco, manganese has been extensively mined, as described in my Report of 1864. Since the date of my first visit, operations have continued with increased vigor, and a new steam engine has been erected for pumping and for removing the ore. The manganese at this locality occurs at the base of the Carboniferous conglomerate, separated from the older metamorphic series (Cordaite Shales) only by a bed of *fire-clay*. The metal occurs in irregular beds near the surface, but farther under the mountain is more evenly distributed. Native copper has been reported as occurring in quartz veins, associated with the conglomerate.

c. The manganese mine of Mr. Davidson, situated at the source of the Hammond River, and upon the Parish line between Hammond and Sussex, was also alluded to in my Report of last year. The locality has since been visited by our party, and the ore has been found, as then described, to occur in semi-metamorphic Carboniferous limestone, containing *Terebratulæ*, and also in "Drift." In the former the metal, of variable thickness, is included between distorted beds of the limestone, and is associated with *Barytes*, *Calc Spar* and *Limonite*, (*hydrous Peroxide of Iron*). The deposit from the drift gravel has been worked out, and operations have been abandoned at both points. Further exploration, however, would be very desirable.

It will be observed that at all the three localities above mentioned, viz., Quaco, Shepody, and Sussex, this ore would seem to occur in the same geological position, near the base of the Lower Carboniferous Series, as will be more apparent from the following comparison:—

Quaco.—First Carboniferous Conglomerate, (with pebbles of the two following):—

Manganese.

Limestone.

Sussex.—Second* Carboniferous Conglomerate.

Manganese and Limestone.

Shepody Mountain.—First (?) Carboniferous Conglomerate.

Manganese.

Limestone and Fire clay.

It may be added that the lead of Norton occupies a similar position, in limestone at the base of the Carboniferous System.

CARBONIFEROUS SERIES.

DISTRIBUTION.—The rocks of the Carboniferous System, irrespective of the great and important Gypsiferous Series last described, occupy, in the more central portions of the Province, a district not exceeded in extent by that of any other formation in New Brunswick. Bounded on every side, except that which faces the Gulf of Saint Lawrence, by the red rocks of the Subcarboniferous Series, the position and outline of the latter, already described, is a general indication of the extent and distribution of the Coal Measures. As but a very small portion of this large area has been included within the field of our labours, it will be sufficient to refer very briefly to its outline and general characters.

Occupying a triangular basin, of which the two principal sides are from one hundred to one hundred and sixty miles in length, the Coal Measures of New Brunswick have their western limit near the Oromocto Lake. From this point as the apex of the triangle, they widen gradually to the eastward, and occupy, on the line of the Saint John River, the entire district between

* The first conglomerate of Hammond River is a thin deposit.

Spring Hill, above Fredericton, and the lower side of Otnabog Lake, in Queen's County. On the eastern side of the river, their outlines are less accurately known, but they have been found to include most of the country near the head-waters of the Miramichi and its tributaries, as well as to the southward along the Washademoak, spreading on the Gulf of Saint Lawrence from New Bandon, Gloucester County, to Shediac, and possibly beyond. The outline of that portion of the series represented in the Map, has been laid down somewhat arbitrarily, except along the Saint John River, where it has been directly observed.

In addition to the region above described, a few detached areas belonging to this series are represented among the Carboniferous districts along the north shore of the Bay of Fundy.

CHARACTERS.—The rocks of the great central coal basin are entirely of sedimentary origin, and graduate from coarse silicious conglomerates and grits, through several varieties of sandstone, to sandy shales. The latter are comparatively rare, and true shales still more so, although the latter constitute beds of some thickness in the more central portions of the district. The most common rocks, especially on the western side of the Saint John, are sandstones, generally silicious, which pass insensibly into grits and very coarse conglomerates, the latter increasing in number towards the border of the basin.

In *colour*, the rocks referred to differ remarkably from those of the series last described. While the latter are almost universally of bright red or reddish brown colours, the rocks of the Coal Measures are almost as universally grey. Reddish beds, however, are not entirely wanting, (as at Grand Lake, and elsewhere,) and at times greenish, yellow, and even pure white sandstones occur. These varieties of colour may in part be due to the presence or absence of plant remains, such as *Calamites*, &c., which are very abundant throughout these rocks.

The materials out of which the conglomerates and sandstones of the Coal Measures have been formed, have not been clearly recognized. In the western part of York County, where only I have had an opportunity of studying them, the pebbles are very generally of pure quartz, jasper, or quartzite, enclosed in a sandy matrix. Boulders of altered slate and diorite are also sometimes seen, and the matrix becomes more felspathic, as if derived from granite. Unlike the Lower Carboniferous rocks, they are seldom calcareous.

AGE.—The precise equivalency of the different members of the great New Brunswick coal-field with those of Nova Scotia, where the succession has been most carefully worked out, is still a matter of some uncertainty. The study of the fossils, collected from various portions of the basin, has led Principal Dawson to observe, that there is a mixture of the Floras of several different horizons, possibly due to the comparatively small thickness of the Carboniferous beds. The plant-remains (*ferns*, &c.), from the region of Grand

Lake, are believed by that author to be on the horizon of the middle coal formation, though tending to the upper, while those collected by Mr. Matthew, from Gardner's Creek, more nearly belong to the Millstone Grit. Descriptions of many of these plants, including the names of all those yet collected in New Brunswick, by Messrs. Hartt, Matthew, and others, may be found in a paper by Dr. Dawson, entitled a "Synopsis of the Flora of the Carboniferous Period."

TOPOGRAPHICAL FEATURES.—In the term *basin*, already frequently applied to the district occupied by the rocks of the Coal Measures, we have the general character of that district sufficiently indicated. Lying in a trough or shallow depression, left by the folding of the older metamorphic series, and nowhere themselves much disturbed from their original horizontal position, the Carboniferous strata occupy a broad expanse of comparatively low and level land, much depressed in some portions of the basin, where lakes of considerable size are found, and rising gently towards the borders. The Saint John River, entering the district a few miles above Fredericton, drains with its tributaries the western and central portions, while the Miramichi, and other streams which flow into the Gulf of Saint Lawrence, perform a similar office for the more eastern parts.

AGRICULTURAL CAPABILITIES.—Compared with the soils of the Lower Carboniferous districts, those of the Counties underlaid by the Coal Measures are generally poor and unproductive. Derived from rocks composed largely of grey sandstone and shale, they are usually themselves grey in colour and light in texture. Where the former prevails, the soil is usually sandy, where the latter, it is as commonly a stiff clay. From the level character of the country, drainage is frequently imperfect, and sphagnous swamps, bogs, or low sandy barrens, are abundant, frequently extending over large areas. Intersected however by several of the principal rivers, which in the spring freshets annually submerge large districts, the amount and quality of the intervale lands is nowhere exceeded in the Province. Excepting where the latter occur, settlements are almost entirely wanting.

For very excellent remarks on the soils of the Coal Measures, as well as upon those of other geological formations in New Brunswick, we may refer the reader to the Agricultural Report of Prof. Johnston.

USEFUL MINERALS.—*Coal.*—The only locality where mining operations have yet been carried on for this mineral, is the region about the Grand Lake, where, however, the beds do not exceed a thickness of twenty inches. Coal has also been reported from a great number of other localities embraced within the district under consideration, but has nowhere been found to exist in profitable quantities.

The absence of this mineral over so wide an extent of country where the rocks are clearly those of the Carboniferous Period, has always excited surprise, and hopes are still entertained that some portions of the district, much

of which is still covered with forest, will yet be found to be productive. If, however, the suspicion of Dr. Dawson should prove to be correct, that only those beds of the Cumberland coal-field are here represented, which under and overlie the workable coals, there is little to be expected.

During the past year, several attempts have been made to obtain this mineral in the settlement of Harvey, near the western limits of the coal-field. A visit to the locality by the writer, has convinced him that the operations begun in this quarter cannot result otherwise than in failure. With a very moderate easterly dip, and at a very short distance from the Subcarboniferous Series, the Coal Measures can here have but little thickness, while their coarse character, and the abundance of conglomerates, are very unfavourable to the existence of coal. The inducements which have led to the search for the latter, are the presence of numerous pieces of this substance contained in the sandstone, but these are only the altered remains of plants, common everywhere in rocks of this age. The few seams which exist never exceed a few inches in thickness.

If any portion of the central basin should prove to be productive, it is most likely to be along its eastern border, in the Counties which front the Gulf of Saint Lawrence. It is, moreover, to be remembered, that the coal occurring in this series is a true caking coal, and bears no relation to the so-called coal of the Albert Mines.

GENERAL REMARKS UPON THE CARBONIFEROUS.

A. ORIGIN OF THE BEDS.—By examining the materials out of which rock-formations have been built, and regarding the greater or less degree of wear undergone by the former before consolidation, we have the key to their whole history. A mass of stone, no matter what its character, broken off by waves or currents from some larger mass, ground and polished by constant attrition, and subsequently heaped up with hundreds of others, which may or may not be like itself, to be with the latter firmly cemented together, and raised far above the ocean in which it was originally formed, is still an unmistakable evidence of the beds from which it came, and tells us at once of the physical changes which the latter have undergone.

In the rocks of the Carboniferous Age, as developed in New Brunswick, the tracing of such evidences is a very easy and a very interesting study. In the Lower Carboniferous Series, more particularly, the conclusions to be drawn from the examination of its various formations, are remarkably striking and instructive.

It will be remembered that in the description of the coarse conglomerates occurring at the base of the series, in the Valley of the Kennebeckasis, along the Hammond River, and among the promontories of the coast, it was stated that the rocks were in each case composed of materials derived from the

older metamorphic hills upon which they rest. That such is in reality the case is plain, for the different pebbles out of which the conglomerate is built, still retain all their original characters, and may be directly compared with the beds from which they came. Many illustrations of this fact have been already given, especially among the formations of Albert County, and along the Bay of Fundy, which have been made principally from the wear of the Upper Devonian Series; but nowhere are they more striking than in the valley of the Kennebeckasis, both for the readiness with which the rocks may be recognized, and the conclusions to which their comparison has led. The conglomerates in the valley referred to, hold numerous pebbles, sometimes as much as a foot in diameter, of syenite, granite, or metamorphic limestone, in every way identical with the same rocks in the Portland Series below them, and evidently derived therefrom. It will, however, be apparent, that as the latter is the oldest group of rocks represented in the Province, and on either side of the principal fold is covered with the later deposits of the Huronian (?), Silurian, and Devonian beds, these must all have been removed before the former could have been exposed, or fragmentary materials be derived therefrom. Hence we are obliged to adopt the conclusion already pointed out by Mr. Matthew, and unmistakably indicated in the character of the beds, that "currents or other agencies of vast force or long continuance, (perhaps both,) held sway over that region at the opening of the Carboniferous age," and that by the eroding power of these currents the superincumbent beds were worn away. Moreover, from the very general occurrence of these conglomerates among the Subcarboniferous rocks of the Lower Counties, we infer that the areas traversed by these currents must have been numerous and wide-spread.

In the rocks of the same series surrounding the great central coal basin, the absence of such coarse conglomerates is very remarkable, and shows that in physical and geographical conditions this portion of the Province differed somewhat from that above described. Here, too, we have a new feature introduced in the presence of volcanic products. That the curiously altered sandstones, claystones, &c. of Hampstead and Harvey, were formed through the influence of igneous action, is evident from their constant association with beds of trap and amygdaloid, having been, with the latter, probably formed beneath the pressure of the sea. Their connection, moreover, with unaltered shales, and limestones abounding with marine animals, prove that they were not all directly affected by these eruptions, but were merely formed of the products to which the latter gave rise.

The abundance of limestones, associated with thick beds of gypsum, throughout the Lower Carboniferous Series, and their intimate relations with the coarse conglomerates of the lower Counties, would seem to indicate, as pointed out among the similar beds of Nova Scotia by Principal Dawson, that deposits of several different kinds may have been in process of formation within comparatively small districts. It is probable that while the waves and powerful currents were building up the coarse conglomerates

along the margins of the older metamorphic ranges, animal life, giving rise to the accumulation of calcareous beds, was abundant in the deeper waters, and layers of fine mud, now hardened into shale, were forming. There were oscillations of level also, and beds of fine or coarse-grained sandstone were made where shales or conglomerates were produced before, each alternation in the character of the rocks being an evidence of some change in the conditions under which they were deposited.

Principal Dawson, in his *Acadian Geology*, has explained the formation of the great gypsum beds of Nova Scotia, on the theory of volcanic action near or in seas tenanted by lime-secreting animals; the former giving rise to streams of sulphuric acid, which, flowing beneath the ordinary sea-water by their greater density, have come in contact with beds of calcareous matter, converting the latter into gypsum. The similar relation of this substance to the beds of marl and limestone with which it occurs, renders it probable that the same explanation may be extended to New Brunswick, where the evidence of intense volcanic activity among the later formations of the Devonian Age, constitutes the most marked feature in that era. It is, however, not a little remarkable in this connection, that though limestones are abundant among the Subcarboniferous rocks of the central basin, where the associated beds have largely been formed from volcanic materials, gypsum is quite absent, no deposits of the latter having been yet observed.

The origin of the calcareo-bituminous shales of Albert County, and their associated beds of liquid and solidified oils, is even more puzzling than that of the gypsum which accompanies them. Their identity in geological age and general character with the shales of Horton Bluff and Gaspereau River in Nova Scotia, would seem to imply a correspondence in their mode of formation, the latter, as shown by Dawson, having been produced by the gradual accumulation of fine mud in waters abundantly tenanted by fish, while upon the neighbouring shores, *Lepidodendra* and other carboniferous trees were growing. Between the two localities,* however, there is one prominent difference, in the absence among the Horton beds of the great deposits of bituminous matter which are so remarkable in the region about Hillsborough, in New Brunswick. If, as we have supposed, the latter are due to the oxydation and hardening of oily matter derived from the decomposition of fish-remains, the deposit may have accumulated in open fissures in a period subsequent to the formation of the shales, producing extensive oil-wells, to be compared with those opened within the last few years in Pennsylvania and Ohio, and indications of which are also abundant in many parts of the district now under consideration. The subject is, however, still wrapped in great obscurity, much of which may be removed when the origin of *liquid* oil-wells shall have been more completely understood.

In all the deposits above referred to, with the possible exception of the Albert Shales, the character and alternation of the different rocks indicate

* The bands of limestone, referred to by Dawson, as distinguishing the beds of Horton Bluff, have been observed by Mr. Hartt and myself among the fish-bearing shales of Elgin.

an origin at or beneath the level of the sea, and also that there was a gradual subsidence of the land when the earlier beds were formed. How great must have been this subsidence is evident, when we consider how elevated were the folds left at the close of the Devonian Age, from which, however, all the upper portions were removed, exposing, as in the Kennebeckasis valley, even the original Azoic rocks, at the very base of the geological series. This subsidence, moreover, was slow and not continuous, for the alternations of coarser with finer beds, and the occasional formation of thin seams of coal, show repeated oscillations near the sea-level.

In passing from the Lower Carboniferous Series to the consideration of the Coal Measures which succeed, the evidence of the rocks still proves the general prevalence of aqueous conditions, and the formation of deposits under the influence of powerful currents. The seas of the epoch, however, were much less deep than in the earlier period, and limestones and gypsum were no longer formed. Conglomerates and coarse sandstones, filled with drift-plants, are the most abundant rocks, and tell us only of gradually emerging sand-reefs, or beds of gravel, subject to constant alteration, and occasionally giving birth to a few straggling plants, or detaining and burying those floating by in the changing currents. Some portions of the basin were indeed above the water, and swamps, in which grew luxuriant forests, prevailed in the more central regions, as at Grand Lake and elsewhere; but those prolonged conditions, so remarkable in the Coal Measures of Nova Scotia, of estuaries and lagoons, extensive forests, and low peaty swamps, giving rise to the accumulations of enormous masses of vegetable matter, now represented by the coal-beds, do not seem to have been present in New Brunswick, where such deposits never exceed a few inches in thickness. It is, however, to be remembered, that even for the formation of a single foot of coal, there must have been, as shown by Bischoff, Dana, and others, an accumulation of vegetable matter at least eight feet in depth, the remaining seven having been subsequently lost by chemical alteration and compression. Future observations may show that these swamp-conditions were more common and abundant than is now thought to have been the case, but a wide distinction will still remain in this respect between the Carboniferous rocks of New Brunswick and those of Nova Scotia.

B. DISTURBANCES AND FOLDINGS.—Like the Azoic, Silurian, and Devonian formations which have preceded them, the rocks of the Carboniferous Age no longer hold their original horizontal position. An examination of the Sections at the close of the Report, already explained as regards the older metamorphic series, will show that while these latter are covered unconformably by the conglomerates, shales and sandstones of the Carboniferous Period, these in turn have themselves been tilted, and pressed into a series of greater and smaller folds. They now stand in positions variously inclined to the horizon, and at times, as already shown in the case of the formations of this age at Gardner's Creek, have been completely overturned. Faults

and fissures abound along the lines of these disturbances, and downthrows have also been observed.

That these upheavals and dislocations were produced in the interval between the close of the Devonian, and the opening of the New Red Sandstone Era, which is to follow, is evident, from the fact that the Carboniferous beds are unconformable to the older metamorphic series, and are composed of materials derived from them, while they in turn have their tilted and denuded edges covered by the deposits of the Triassic seas. There is, however, a general correspondence between the older and the later groups in the direction of the folds, showing that the force, whatever its nature, which produced the disturbances in the earlier periods, was still in action at the close of the Carboniferous.

Besides the *general* flexion and dislocation of the beds above referred to, there were also some local disturbances during the period we are now considering, most evident in the upheaval of the beds by intrusive igneous action. The most remarkable example of such uplifting is furnished in the cliffs of Quaco, where also many other successive events are finely portrayed. A description of this remarkable locality has already been given. (*See Section west of Quaco.*)

Between the Subcarboniferous Series and the rocks of the Coal Measures, there would appear to be much discordance in the amount of their upheaval, and I should not be surprised if decided unconformability should yet be established, the latter, in the central basin, never having so far as I am aware, the high dip found among the Lower Carboniferous beds which underlie them.

METAMORPHISM.—In the remarks upon this subject, at the close of the Devonian Age, it has been stated that three separate and successive stages may be distinguished in this process, viz:—Consolidation, or the mere cementing of loose materials, Partial Alteration, and Complete Metamorphism or Crystallization.

In the Carboniferous formations of New Brunswick, these changes are mostly confined to the first named stage, and more rarely to the second; re-crystallized rocks are almost entirely wanting.

Among the most firmly consolidated beds of this age are the coarse fragmentary deposits near the base of the series, as seen in the valley of Hammond River, and among the headlands of the coast, many of the latter equalling in hardness the older metamorphic groups, from whose wreck they have been built. From these to the soft beds of shale, penetrated by and filled with the remains of plants, there is every variety of gradation.

Of the second stage in the metamorphic process, the beds of this series also afford numerous examples, most prominent, however, in regions characterized by igneous activity. It was probably from partial alteration, produced by eruptive outflows, that the limestones in the cliffs of Quaco lost their colour and their fossils, while similar influences have wrought the

remarkable changes, already noticed, in the sandstones and shales of Hampstead, Harvey, and other localities along the margin of the coal-field. In the latter, the change has at times almost resulted in a re-crystallization of the minerals, the altered beds referred to being with difficulty distinguished from true porphyries.

In this connection, reference may be made to a very curious rock, apparently an altered sandstone, occurring in beds on the Kouchibouguac River, in Kent County, and known among the French as "*Gres a reflets.*" As implied by the latter name, its broken sides, no matter what may be the plane of fracture, exhibit brilliant reflecting surfaces when held at definite angles, although in other positions as rough and destitute of lustre as are ordinary sandstones. The mineral would seem to be the result of partial metamorphism, but I am ignorant as to the precise mode of its occurrence.

CONDITION OF THIS PORTION OF THE CONTINENT DURING AND AT THE CLOSE OF THE CARBONIFEROUS AGE.

In looking back to the general physical and geographical conditions which prevailed in this portion of America, during the progress and at the termination of the Upper Devonian Era, it will be remembered that through the lengthened periods when the different formations of the latter were in progress, the more southern portions of the Province (and probably the northern also,) were still, for the most part, below the level of the sea. They do not, however, appear to have been depressed to any considerable depth, and there were some districts sufficiently elevated to produce plant-sustaining marshes, and others even dry land, covered with a forest vegetation and tenanted by animal life. These, however, were not the prevailing conditions of the period, which was rather one of slow oscillations below the sea-level, accompanied by numerous volcanic outbursts, and a gradual sinking of the land, sufficient to build up by the agency of the waves, strata several thousands of feet in thickness. Towards its close these minor oscillations culminated in grander movements, and an epoch of revolution ensued, during which the beds, previously horizontal, were thrown into gigantic folds, and metamorphism and mountain-making followed the periods of comparative repose.

The ridges formed during this epoch of disturbance, and now represented by the various elevated lines of hills in the lower Counties, constituted at the opening of the Carboniferous Era, the dry land of the period, and against their flanks washed the waves, by whose eroding action the various deposits of the latter group were formed. There were still oscillations, and probably in the earlier portion of the age a somewhat rapid depression of the land, especially near the mouth of the Saint John River, and in the more easterly portions of the Province. The greater part of Saint John and Albert Counties were probably islands, surrounded by coral-building seas, while the Bay of Fundy, already outlined, was bounded on the south by the

Cobequid Hills of Nova Scotia, and was then a wide channel opening freely at both ends to the sea. Over the more central portions of the Province, also, the ocean still prevailed, for we there find limestones, filled with relics of marine life, and this vast bay, a western prolongation of the Gulf of Saint Lawrence, may have been connected with the waters of the Kennebeckasis valley by the great fault at the head of the Long Reach, through which the Saint John River now flows. Around the margin of this bay, and possibly over its entire extent, volcanic outbursts were frequent, and some of the conditions of the earlier Devonian Periods were again witnessed.

In passing from the Lower to the Middle and Upper Carboniferous formations, we find that the same series of minor oscillations were still in progress, but now no longer upon the margins of deep seas, while the general movement was one of elevation rather than depression. The extent of the great basin above alluded to became narrowed by the gradual filling up and raising of its bed, and in place of waters tenanted by marine animals, we have to contemplate the existence of wide-spread inland seas, or shallow fresh water lakes, with extensive marshes, covered with luxuriant vegetation. These swamp-conditions, however, as previously remarked, were of much shorter duration here than in the other great coal-fields of America, and, while the immense accumulations of vegetable matter, now stored in the form of *coal*, were being deposited in the neighbouring Province, New Brunswick passed with comparative rapidity through these elevatory movements, and was added to the permanently dry land of the Continent.

GENERAL REMARKS UPON PALAEOZOIC TIME.

We have now attempted to trace, from the evidence of its rocks and fossils, the gradual formation and growth of this portion of America, and to present a general view of its physical and geographical conditions during the different geological ages, constituting what is known as Palaeozoic Time. Before passing to the consideration of subsequent epochs of growth or alteration, it is interesting to compare the succession of events so far described, with those which characterized other portions of the Continent during the same eras.

The *Silurian Age*, the first of the Palaeozoic Series, does not, so far as known in New Brunswick, seem to have differed very greatly in its characteristics from what has been observed over the greater part of North America. It was an age of almost universal submergence, though to but shallow depths, and in the seas were to be found only the lower forms of animal and vegetable life; Trilobites and Brachiopods characteristic of the former; sea-weeds or marine Algae of the latter. Limestones, however, so abundant among the Lower as well as the Upper Silurian strata over the more central portions

of the Continent, do not seem to have been here represented among the former, although it is not unlikely that such may yet be found among the calcareous and fossiliferous formations in the north of the Province.

Of the *Devonian Age*, which succeeds to that above described, we know in New Brunswick only the later portion. No deposits, unless some part of the Kingston Series, have yet been found to represent the earlier and middle epochs of the era, and we are therefore without data from which to form comparisons with other regions of the continent. The want of these deposits, as stated in an earlier portion of the Report, may be due to the elevation of the land at this time above the level of the sea. In contrasting the formations of *Upper Devonian age*, as found in the Province and elsewhere in America, the most marked point of difference is the very general prevalence of igneous activity in the former, both as evinced in the thick volcanic accumulations of the Bloomsbury epoch, and also later, in those of Little River and Mispeck. As in other portions of the continent, however, dry land of greater or less extent had now succeeded to shallow seas, and there is evidence of a terrestrial vegetation, and of insect life.

In the period of upheaval, folding, and metamorphism, which separated the Devonian from the Carboniferous Age, we see the grandest and most striking of the physical events which mark the geological history of New Brunswick, as well as the feature in which that history is most strongly contrasted with what took place elsewhere on the continent. Throughout the Atlantic coast of America, including the great Appalachian region, where oscillations of level were most frequent during the Palaeozoic ages, this period of revolution did not take place until the close of the Carboniferous. Some slight elevations, accompanied by metamorphic changes, did indeed occur at the close of the Lower Silurian, and the slight unconformability between the rocks of the Saint John and Bloomsbury Groups, may indicate a corresponding oscillation here, but no great period of disturbance and mountain-making prevailed, until after the deposition of the coal beds. The events as observed in New Brunswick more nearly correspond with those of Canada, Maine, and Nova Scotia,* where, as in this Province, the Subcarboniferous rocks cover the upturned edges of Silurian and Devonian strata unconformably.

In the *Carboniferous*, or last of the Palaeozoic Ages, while there were some general points of resemblance between this and other regions of the Continent, there were also some marked differences. From the folding and metamorphism which brought the Devonian Era to a close, the conditions of general level which had hitherto prevailed, and which still continued to prevail, over a large part of North America, had here been succeeded by others of much greater diversity. There were numerous islands, peninsulas, and long narrow strips of land, possibly of considerable elevation, at some periods separated by deep oceanic waters or shallow straits, at others, sur-

* (Logan, C. Hitchcock, Dawson.)

rounded by extensive inland lakes. There were probably rivers of greater or less size, (for the inequalities of the land would naturally produce a flow of water from their sides), and marshes filled with a tropical vegetation. Volcanoes also seem still to have been in active operation, especially in the more central portions of the Province, and may, in part, have produced the oscillations indicated by the alternations of different stratified deposits.

As the Carboniferous Age was closing, and disturbances on a grand scale were affecting other portions of the Continent, similar changes, but in a much smaller degree, were again witnessed here. There were uplifts, foldings, and dislocations, accompanied by a breaking and hardening of the strata, but there was no metamorphism. The rocks are not *crystalline* rocks, and the coal deposits are those of the ordinary bituminous variety, which have not been changed by the action of heat. About the region of Albert County, these dislocations were especially numerous, but whether they were strictly cotemporaneous with the great period of Appalachian revolution or not, is still undetermined.

With the close of the Carboniferous Age, we reach also the termination of one great cycle in geological time. After repeated alternations of submergence and elevation, of wear and restoration, this portion of the continent had become comparatively stable. Oscillations of level did indeed take place at a later date, as they are undoubtedly taking place *now*, but, in general, they were sufficient to affect only the very border of the Province, and a long interval elapsed before the whole was again depressed beneath the sea. The organic world, also, hitherto of a character very unlike that of the present creation, was from this time of a more modern type, most of the ancient or Palaeozoic forms having disappeared.

MESOZOIC TIME.*

From the Palaeozoic rocks, to the description of which the preceding part of this Report has been mainly devoted, we pass to the consideration of another series, which marks the introduction of a new order of things in Geological History—the increase and prevalency of *Reptilian* forms of life, and the assimilation in the type of the vegetation to that which now exists.

These features characterize the great cycle of time, known as the Secondary or Mesozoic Age. Of the three periods into which this age is usually divided, the *Triassic*, *Jurassic*, and *Cretaceous*, the first, or period of the New Red Sandstone, is alone represented in New Brunswick.

NEW RED SANDSTONE OR TRIAS.

DISTRIBUTION.—The occurrence in this Province of deposits of later date than the Carboniferous Era, has long been a disputed question; for, while Dr. Gesner asserted in his Reports, that the sandstones of Saint Andrews—shown to be Devonian,—those of the Kennebeckasis and Petitcodiac Rivers, and certain deposits west of Gardner's Creek—which are Lower Carboniferous,—and the higher strata of Grand Lake, probably Carboniferous,—were all New Red Sandstones, Dr. Robb, on the contrary, was of opinion that no rocks of this age occur on the north side of the Bay of Fundy.

There are, however, three very limited areas on the Bay shore, where deposits of this period do exist. The first is between Gardner's and Ten Mile Creek, one and a half miles long and half a mile wide. The second is at Quaco, where they may be seen in the depressions, east, south and west of Quaco Head. They underlie the village, and probably extend along the shore to the eastern end of the settlement, where we observed them in contact with the older Devonian shales, which form the shore-line thence to Lower Salmon River. They also extend some distance beneath the waters of the Bay, and may thus connect with the first mentioned area. A third outcrop is on the low shore of Salisbury Cove, east of Owl's Head. Here the action of the sea, in removing a covering of sand and gravel, has exposed two patches of Red Sandstone.

CHARACTERS.—The bulk of the Secondary strata at the several localities above enumerated are red sandstones, but at Vaughan's Creek, (Quaco,)

* The remarks upon this division of the geological scale, as well as upon that of Cenozoic Time, which is to follow, are from the pen of Mr. Matthew, that gentleman having kindly undertaken the task of completing this portion of the Report, while I was myself engaged upon that which has preceded. The data upon which these remarks are based are, as far as regards the New Red Sandstone, chiefly from observations made by our party collectively; those upon the Post Tertiary Period are the results of Mr. Matthew's individual studies.

an upper member appears, having an entirely different aspect. It is an incoherent conglomerate, of a grey colour, consisting of sand and round boulders of quartzite, altered slate, &c., derived from the hard sediments of the metamorphic hills northward, being, as Gesner remarks, "conformable" to the red sandstones which constitute the lower member, and "perfectly stratified."

These latter consist chiefly of soft earthy sandstones of a bright red colour; but layers of conglomerate, holding quartz pebbles mixed with fragments of grey and brown sandstone, are common in those at Gardner's Creek. From the coarser beds, and from detritus on the beach at the last named place, were gathered the only organic remains which we observed, viz., fragments of *coniferous wood*. As the majority of these were partly rounded and imbedded with pebbles, they were probably derived from the ruins of the Carboniferous strata, in which, at the distance of a few miles, such fossils may now be seen. One, however, bore no marks of transportation, and of it Dr. Dawson observes—"The fossil wood from the New Red Sandstone, though not well preserved, appears to be coniferous, and to have one row of discs on the cell-walls, in the manner of the mesozoic pines of the genus *Peuce* or *Pinites*."

Many striking instances of oblique lamination were observed at the same locality, and, indeed, this irregular structure characterizes the formation. The influence of currents setting in three or four directions at consecutive periods, can be traced in the few layers represented in the wood-cut F, at the close of the Report.

At Quaco the lower beds are often concretionary or brecciated, while the more easterly deposit at Salisbury Cove, although agreeing in other respects, has but a slight dip (to the E. N. E. 10°), and is of a pale colour. The rocks of the lower or red member can be readily distinguished from the Carboniferous and Lower Carboniferous formations which they accompany, (although frequently confounded with them by Dr. Gesner,) by the irregular thickness and truncation of the layers, by the absence of fine shales and hard massive conglomerates, and in general by their bright red colour.

The general course and inclination of the strata at Quaco and Gardner's Creek are remarkably constant, the dip being to the N. N. E. at angles varying from 25° to 45° , the highest beds at the latter place having the last named inclination. Here too, unless there are extensive downthrows on the south side of the numerous cleavage-planes by which the beds are intersected, the sandstones must attain a considerable thickness—probably 800 feet—seeing that they rise into cliffs 100 feet or more in height, and extend half a mile inland.

AGE.—In an article entitled "Observations on the Geology of Saint John County, N. B.," published in the *Canadian Naturalist*, the Secondary age of the red sandstones east of Gardner's Creek was asserted. This will be evident on inspection of the Section D, where their western edge may be

seen to meet the highly disturbed Carboniferous strata, and also by the Sketch E, of their eastern termination, where the discordance is equally obvious.

These observations have been confirmed by an examination of the red sandstones of Quaco, which rest upon the limestone and conglomerate of the Lower Carboniferous formation unconformably, as may be seen on reference to the Section H, illustrative of this locality. These red sandstones, although intersected by numerous cleavage-planes, are not contorted or folded at any of the places where we have examined them.

From the features presented by the two series at Gardner's Creek and Quaco, we infer that a considerable period of time elapsed, during which the numerous thick beds of sand, gravel, clay, and calcareous mud, now forming the limestones, conglomerates, sandstones and shales of the Lower Carboniferous and Carboniferous formations on the coast, were hardened into stone, the imbedded trees which they contain silicified, and the whole series disturbed, pressed into sharp folds, injected with trap, and entirely removed in some places by denudation, before any sediments of the later or New Red Series were formed. The latter, therefore, can scarcely be older than the Trias. But in their main features, and in their relations to older formations, the red sandstones on the northwest side of the Bay of Fundy, agree with those which add so much to the fertility of Annapolis and Cornwallis Valleys in Nova Scotia, and no doubt mark in this direction the limit of that tidal bay, traversed by strong and variable currents, in which Dr. Dawson supposes the latter to have been deposited.

Loose beds of coarse shingle, which are found at the summit of the series, mark the influence of similar powerful currents and long continued wave-action on an exposed coast, at the *close* of this Period.

TOPOGRAPHICAL FEATURES AND AGRICULTURAL CAPABILITIES.—The sediments of this series, situated as they are upon the southern margin of New Brunswick, and being of such limited extent, can have little influence on the agricultural capabilities of the districts in which they occur. They are soft and yield easily to the waves, whose destructive action rapidly undermines the cliffs, and enlarges fissures in the strata, thus forming "*drongs*" or perpendicular detached masses of rock, and giving rise to some of the most remarkable scenery on the coast.

USEFUL MINERALS.—The only useful mineral known to exist in available quantity in these sandstones, is the oxide of manganese, found at Quaco. The character and mode of occurrence of the latter has already been noticed in another connection.

CENOZOIC TIME.*

Between the epoch of the New Red Sandstone, and the close of the Tertiary Age, a wide gap occurs in the geological record of this part of America. During this interval, extensive accumulations equivalent in age to the Oolite, Chalk, and Tertiary deposits of England, were spread over wide areas of this continent, embracing a large extent of country on both flanks of the Alleghanies, and the great western plains. The Islands of Martha's Vineyard and Nantucket, off the coast of Massachusetts, and certain *lignite* beds of Brandon, Vermont, indicate the eastern limit of these formations, which, if they ever existed here, were swept away by the extensive denudation marking the succeeding period of the "Drift or Newer Pliocene."

The phenomena which distinguish the latter epoch are noticeable in every part of the Province. For wherever the soil is removed, the rock beneath is found to be covered with numerous parallel furrows or grooves, having in general a north and south direction. These marks have been made by stones and fragments of rock, frozen to enormous masses of ice, which, impelled from the north over the surface of the country, have also given to the northern declivities of hills and rocky ledges, a rounded outline.

The accumulations of mingled mud, stones, and fragments of rock, resulting from the breaking down of prominent ledges, and the erosion of the softer beds by this agency, constitute the *boulder-clay*, and form the principal subsoil of the country. They are frequently well exposed by the wasting away of high banks along the sea shore, and occasionally in the river valleys.

At the close of the period last described, the whole Province, excepting perhaps the highest hills, was buried beneath the ocean; but during the next, which was an epoch of emergence, the superficial deposits of the preceding or "Drift Period," were exposed to the action of the waves, and while the coarser material was left on the hill sides and elevated plains, forming gravel flats and sandy terraces, the finer portion was washed away by the waters, and settling from them in depressions of the surface, formed the clay beds which fill valleys in various parts of the Province.

The continual rising of the land, and consequent retrocession of the ocean, would bring one area after another within the influence of the waves, and the sand-banks and flats formed at one period would be cut down and partially swept away in the succeeding; thus giving rise to the terraces met with on the coast and in the interior.

To this cause, viz., the gradual recession of the sea,—we may ascribe the terraces and *high intervalles* of the Saint John River and its tributaries, below

* I may here repeat the statement, that the above remarks are the results of Mr. Matthew's individual observations, and are from his own pen. The views set forth are therefore to be considered as those of that writer only.—L. W. B.

the Grand Falls. For, the rising of the land being at times arrested, the sediment brought down by the river, would settle in the still water of the estuary which then existed at Woodstock and Fredericton, and by a further recession of the sea, a greater impetus being given to the current, the delta would be cut through by the river, and carried further down to form a new flat at a lower level, leaving a skirting of the older deposit rising in a terrace on both sides of the valley. This process, carried on for a lengthened period, would give rise to a series of river terraces, at different heights, in the valley of the Saint John, corresponding to those which border hill-sides along the coast.

The stratified clay and sand of this Epoch contain numerous organic remains of the creatures which inhabited the waters from which they were deposited. Those in the vicinity of Saint John have yielded about fifty species of Mollusca (*shell-fish*), ten Radiata, Bryozoa, and Articulata (*Star-fish, Corals, Barnacles, &c.*), and also three species of Algae (*sea-weeds*); while ten additional species are known to occur in other parts of the Province.

How long the elevation of the land above referred to continued, or to what limit the waters retired, we know not, but it is evident that it extended beyond the present shore of the continent, for, as may be gathered from the observations of Drs. Gesner and Dawson, former land-surfaces, indicated by the presence of stumps of trees, logs, and beds of peat, have been met with in shallow waters along the shore of the Bay of Fundy and Gulf of Saint Lawrence at various points, such as Grand Manan,* Cumberland Basin, and Miramichi; as has also been observed to greater depths on the coasts of Massachusetts, New York, and New Jersey.

At a subsequent period, the land thus elevated began to sink slowly beneath the ocean, and the vegetation which covered it was either swept away, or buried beneath deposits of sand and mud, such as the salt marshes of Albert and Westmorland Counties, and the marshes and *low intervalles* of the lower courses of the Saint John.

This epoch of depression is that in which *we* live. On the coast of New England and the Middle States, the subsidence of the land goes on at the rate of about one foot in the century. Here the rate has not been ascertained, but the process is so slow that the marshes (where indications of the sinking of the land are most readily seen,) are built up by the addition of fine mud settling from the tidal waters of the Bay, so that no appreciable change appears.

There are certain fresh-water and terrestrial deposits, such as *river alluvia, calcareous marls, silicious earths*, and deposits of *peat*, belonging chronologically to both this and the preceding epoch, but which are more conveniently considered in connection with the later; for although they were no doubt in process of accumulation in the more elevated districts at the time that the low land was still submerged beneath the sea, and its surface-

* Also Frye's Island.—L. W. B.

deposits undergoing modifications attending the rising of the land, yet at every locality where fresh-water strata and peat accompany stratified clays and sands of marine origin, they are found to rest upon them, and therefore must have been formed at a later period.

The superficial deposits of the Province may thus be conveniently classified under three heads, indicating as many changes in the relative position of sea and land. These are* :—

The Glacial Period—In part at least an epoch of depression.

Champlain and Terrace Periods—A time of elevation.

Modern Period—A time of depression.

At a future time I hope to be able to give in greater detail an account of phenomena incident to these periods, more especially the *Life* of the second, as indicated by the organic remains in deposits along the southern shores of the Province, (and the application of the latter to Agriculture and the useful arts), to which account these remarks are introductory. Any information which will extend our knowledge of the subject, will be thankfully acknowledged by the writer.

GENERAL SUMMARY. †

In the preceding Report upon the Geology of Southern New Brunswick, the whole series of formations known to exist within that region has been described, and the age of each, so far as known, indicated. In conclusion, the following Table is given, to present in a synoptical form a history of the physical changes which these formations have undergone.

In the *first* column they are separated into three great divisions, based upon the state in which the remains of the vegetation are found. No carbonaceous matter has been observed in the New Red Sandstone, but it is presumed that it will resemble that of the Coal Measures.

The *second* column shows the great physical disturbances resulting from movements in the earth's crust, and furnishes a further means of separation into six or more minor divisions.

In a *third* column, the relative consolidation and alteration of the various formations is shown,—a change from loose layers of gravel, sand or mud, which depends not so much upon age as upon disturbance of the earth's crust, with intrusion of melted matter from beneath, dissemination of vol-

* The classification here given by Mr. Mathew, differs somewhat from that already used in the Tabular View, on Page 13. The latter, as before stated, has been adopted from the Manual of Professor Dana. For further remarks on the succession of the Post Tertiary Epochs, reference may be made to the last named work, also to an Address of Dr. J. W. Dawson, before the Natural History Society of Montreal, published in the Canadian Naturalist.—L. W. B.

† By Mr. Mathew.

canic ashes in the strata, or the deep burial of sediments, where great accumulations are formed. Several stages of change are indicated, *coherence* where the particles in the beds become consolidated; *partial alteration* where the layers are hardened; *great metamorphism* where the rocks are frequently crystalline, but the stratification is not obliterated; and *extreme alteration*, where the evidences of original sedimentary deposition are almost or entirely lost.*

In the *fourth* and *fifth* columns will be found respectively the local names given to the various groups of strata, and to the several formations with which they are known or supposed to correspond.

CLASSIFICATION OF THE SEDIMENTS OF SOUTHERN NEW BRUNSWICK ON PHYSICAL GROUNDS.

State of organic matter.	Disturbances.	Metamorphism.	Local Names.	General Divisions.
Peat.	{ Horizontality not at all, or but slightly disturbed }	Incoherent.	{ Boulder clay, Stratified clay, Gravel, &c. }	{ Newer Pliocene, and Post-Tertiary. }
Bitumen present. Coal of the ordinary character, (soft.)	{ Corrugations absent, not folded with Carboniferous. }	{ Particles slightly or not at all coherent. }	{ New Red Sandstone. }	{ Trias. }
	{ Corrugated, but not involved in the great folds of the older strata. }	Slight or partial.	{ Coal Measures. Albert Shales and Sandstones. Kennebeckasis Conglomerates and Shales. Carboniferous Limestone. }	{ Coal Measures, and Lower Carboniferous. }
All involved in the great corrugations impressed at the close of the Devonian Age. Bitumen absent. Carbonaceous matter converted into anthracite & impure graphite.	{ }	{ Partial, often great, where volcanic sediments prevail. }	{ Mispeck Group. Little River " Bloomsbury " }	{ Upper Devonian. }
		{ Great, not unfrequently extreme. }	{ Rocks of Kingston, Nerepis, and Bellisle. }	{ Middle and Lower Devonian ? Upper and Middle Silurian ? }
		{ }	{ Not recognized. }	{ Upper part of Lower Silurian. }
	{ Undulations anterior to the great folds of the Devonian Period. }	{ Great, but extreme only in volcanic sediments. }	{ St. John Group. Coldbrook " }	{ Primordial Period, (Dana.) Huronian. }
	{ Line of contact with Coldbrook Group undulating. }	{ Great, often extreme. }	{ Portland Group. }	{ Laurentian. }

* For further explanation of the different stages of metamorphism as illustrated in New Brunswick, see the observations on this subject in the general remarks at the close of the Silurian and Devonian Ages.—L. W. B.

CONCLUDING REMARKS.

I cannot allow this Report to be concluded, without expressing to the various gentlemen who have aided in its preparation, my thanks for the services they have so kindly offered. My obligations are more especially due to my fellow-travellers, Messrs. Matthew and Hartt, both for their assistance in the field, and subsequently, in the study of the rocks and fossils collected; to Prof. Dawson, of Montreal, for a revision of some of the more important data, and an examination, in connection with Prof. Hunt, of selections of the metamorphic rocks; and to Prof. Verrill, of Yale College, and Mr. Scudder, of Boston, for valuable contributions. It had been hoped that the papers of the last two gentlemen, (that of the former on "The Mineral deposits of the western border of New Brunswick, and the Geology of Grand Manan," and that of the latter on the Insects of the Devonian Rocks near Saint John,) would have been completed in time for publication with the main body of the Report; but as this has been found impossible, it is intended that they shall appear in the form of Appendices.

In addition to the contributions last named, Mr. Matthew has kindly offered, from the reports of Dr. Gesner, the observations of Prof. Hitchcock in Maine, and data collected by ourselves during the past season, to add a short article on the Geology of Charlotte County; also one on the comparison of the Coast (Devonian) Series with the Metalliferous Rocks of the Eastern Townships of Eastern Canada.

Mr. Hartt will further contribute a Paper "On the Devonian Plant Locality of the Fern Ledges, Lancaster, N. B., with a detailed Section and Notes on the Fossils."

These, with a List of New Mineral Localities and of the Fossils of the Province, will appear as soon as they can be prepared.

APPENDIX A.

ON THE DEVONIAN PLANT LOCALITY OF THE "FERN LEDGES," LANCASTER, NEW BRUNSWICK,

WITH A DETAILED SECTION, AND NOTES ON THE FOSSILS.

BY C. FRED. HARTT, A. M.

The following description of the Devonian plant locality at Lancaster, in the vicinity of Saint John, and the section of the strata, are compiled from notes made during the summers of 1861, '62, and '63, during which I undertook to examine carefully every bed exposed at the locality, and to collect as complete sets as possible of the fossils occurring in each.

Of the several localities for fossil plants in the vicinity of Saint John, the richest and most interesting is that of the "Fern Ledges." These are a series of ledges exposed on the sea shore, between high and low-water mark, at the foot of the properties of Messrs. N. S. Demill and Zebedec Ring, Duck Cove, Lancaster, about a mile west of the town of Carleton. The ledges are formed by the outcropping edges of beds of sandstone and shale, belonging to the Little River Group of Mr. Matthew. These have a strike of about W. 10° N., and a southerly or seaward dip of about 45° . This strike corresponds very nearly to the trend of the shore, along which, rounded and much worn by wave action and buried in sea weed, their edges run like furrows. The shale beds, in which the plants occur, are, on account of their softness, everywhere so worn away by the waves from between the enclosing sandstones, as to be in only a few places accessible.

Only near high-water mark are the ledges of any height, and from these the plant-bearing shale beds are almost entirely removed. The ledges extend along the shore for some 325 paces, with a width of 300 feet, more or less, exposing a thickness of strata of about 150 feet. Numerous faults occur at the locality, the principal of which, on the easternmost side of the most prominent projecting ledge, and whose direction is S. 30° W., is a downthrow of about 50 feet.

Directly in front of the ledges, and about half a mile from the shore, is a series of skerries laid bare at low water, called the "Shag Rocks." I have never visited them, but the beds of which they are composed have an apparent east-westerly strike, and a high dip to the southward. They are probably the upper members of the Cordaite Shales.

Beds of sandstone and shale, similar to those at the Fern Ledges, show themselves on the shore about three quarters of a mile to the westward.

They contain the remains of a few species of plants, identical with those occurring at the "Ledges," but the beds are higher up in the series. This locality, called the "Calamite Ledges," has not been so carefully examined as that to the eastward. I have collected there the following species, nearly all of which are common to the two localities:—

Cordaites Robbii, DAWs.—Extremely abundant in certain layers of black shale, and very finely preserved.

Sphenopteris Hitchcockiana, DAWs.—Abundant in detached pinnules.

Pecopteris discrepans, DAWs.—Apparently rare. Have found but a single pinnule.

Cardiocarpum cornutum, DAWs.—Not infrequent, associated with cordaites, calamites, &c.

Calamites transitionis, GÆPPT.—Abundant.

C. cannaformis, BRONGNT. " "

Annularia acuminata, DAWs.

Pinnularia dispalans, DAWs.—Common.

Psilophyton? glabrum, DAWs.

Stigmaria ficoides, (var.) BRONGNT.—A single specimen with rootlets attached was found by my father, J. W. Hartt, in a bed of sandstone, about half-way up in the section here exposed.

Lepidodendron Gaspianum? DAWs.—Two or three ill preserved specimens of a Lepidodendron, which Dawson has referred with doubt to this species, were collected at this locality by Mr. Matthew and myself.

The sandstone at the Fern Ledges is very compact and hard, and of a grey colour. It contains many plant remains, but usually in a badly preserved state. Thin beds of arenaceous shale, of a fine texture and dark grey colour, becoming black sometimes, or passing into light greenish-grey, are interstratified with the sandstones, and these beds are highly charged with plants, which occur preserved as graphite, every nerve and nervule of a fern leaf being as distinct as in a pencil drawing.

It had been ascertained several years ago, by Gesner, Robb, Dawson, and others, that the beds of the Little River Group were fossiliferous, and ill-preserved plant remains had been observed in the sandstones of the "Ledges." Mr. Matthew, who had previously discovered in the shales at the foot of the City of Saint John, near the Barracks, the plants which Dawson described in his paper on the "Flora of the Precarboniferous, &c.," collected in 1860, at the "Ledges," from one of the exposures of plant bed No. 1, of the following section, some obscure markings which were probably leaves of *Asterophyllites longifolia*, DAWs.; but it was not until May, 1861, that I found that these rocks were richly fossiliferous, and discovered in beds Nos. 1, 2, 3, and 8 (?), a large number of fossil plants, principally ferns, a remarkable Crustacean, *Amphipeltis paradoxus*, SALTER, and a *Spirorbis*. Messrs. Matthew, W. R. Payne, James Hegan, and Lunn, took part in the explorations which were carried on during the summer, Mr. Matthew discovering, among other things, a new species of *Eurypteris*, *E. pulicaris*, SALTER; while Mr. Payne secured a single specimen of a trilobite, still undetermined, the only one the locality has afforded.

These discoveries proved so interesting that Principal Dawson, to whom I communicated them, paid a visit to Saint John, and examined the locality in person. The collections made were put into his hands, and the plants were described in an interesting and valuable paper published in the Quarterly Journal of the Geological Society, entitled, "*On the Flora of the Devonian Period in Northeastern America.*" The number of plants obtained thus far from the Lancaster localities was 36, which, with the three species of Crustacea, the Spirorbis, and the three species of plants previously collected in Saint John by Mr. Matthew, made the number of species of animals and plants ascertained to occur in the Little River Group, 43.

The following summer I spent thirty days at this locality, being rewarded by the discovery of some ten or more new species of plants, principally ferns, and by securing larger and more perfect specimens of many of the species described by Dawson from mere fragments. But the most valuable and entirely unexpected discovery, was that of *remains of insects*, of which five species have been obtained. These specimens are in the hands of my friend, Mr. Scudder of Boston, the well known Entomologist, for description. During the summer, I began the task of examining every bed in the section at this locality, a task not easy to perform, where the tough rocks lying below high water mark and buried in a luxuriant growth of sea weed, are worn away in such a manner as to make it difficult to work them.

In the summer of 1863, I spent eight days at the locality, during which time I finished my section. Several new plants were discovered, together with many quite perfect specimens of several hitherto known only as fragments. Of the latter was a large frond of *Neuropteris polymorpha*, DAWSON.

The Crustaceans *Amphipeltis paradoxus*, SALT., and *Eurypteris pulicaris*, SALT., were described and figured by Salter in the Journal of the Geological Society for February, 1863.

A paper by Mr. Geo. Matthew, entitled "Observations on the Geology of Saint John County, New Brunswick," in which the relations of the Little River Group to the other rocks of the vicinity of Saint John were considered, appeared in the Canadian Naturalist in the preceding year.

The number of species of plants now in my hands for determination, is not far from twenty-five. It is my intention, after having made yet more careful examinations of the rocks of the Little River Group, to describe and figure them in a *Monograph of the Flora and Fauna of the Devonian Period in the vicinity of Saint John*, which paper I hope ere long to have ready for publication.

In the following Section, the measurements were taken along a line crossing the beds at right angles to their strike, from high-water mark near the bathing house stairs, to low-water mark. The rich fossiliferous shale beds, or *plant-beds*, as I shall term them, are numbered from below upwards, for convenience of reference. The thickness and lithological character of these beds vary somewhat in their different exposures. The position of one or two plant-beds appearing elsewhere at this locality, but not observed

on the line of section, is indicated. I have given lists of all the plants, &c., described, which I have collected from each plant-bed, with some remarks on their mode of occurrence, and I have noticed some of the undescribed species.

The following Section begins at the base of the *Dadoxylon* Sandstone beds, at their junction with the trappcan beds of the Bloomsbury Group, which form the high land skirting the shore to the northward, and takes up the overlying beds in ascending order :—

SECTION OF THE LITTLE RIVER GROUP AT THE " FERN LEDGES," LANCASTER, N. B.

Heavy beds of grey sandstone and flags.

Thickness, by estimation, 300 feet.

Dadoxylon Ouangondianum, DAWs.—*Calamites*, &c.

Under this head I have classed all the beds underlying the Plant-bed No. 1, which I am disposed to regard as the lowest of the rich plant-bearing layers, and the base of the Cordaite Shales. These beds occupy the low ground lying between the ridge of the Bloomsbury Group and the shore. They are covered by Drift, and show themselves only in limited outcrops, and in the ledges on the shore. In the western part of the ledges they are thrown forward on the beach by a fault, forming a prominent mass of rock, in the summit of which a fine trunk of *Dadoxylon* is seen imbedded in the sandstone. Recent excavations made in these beds in quarrying stone for building purposes, in the eastern part of the locality, where the rocks are very much broken up by dislocations, have exposed numerous badly preserved impressions of large trunks of this tree.

PLANT BED No. 1.

Thickness 1 foot.

Black arenaceous shale, varying from a fissile sandstone to a semi-papyraceous shale, very fine grained and very fissile, charged most richly with beautifully preserved remains of plants, among which are the following species :—

Calamites transitionis, GÆPPT.—Occasional, in large, erect specimens.

Asterophyllites latifolia, DAWs.—Extremely abundant, often showing ten or twelve whorls of leaves, sometimes with many branches.

A. acicularis, DAWs.—Also very abundant. I have obtained, since the publication of Dawson's paper, some very fine fronds, showing the mode of branching and the strobilus-like termination of the frond.

? *A. longifolia*, BRONGNT.—I have, since the appearance of Dawson's paper, collected a fine suite of specimens of the species which he has referred with some doubt to the above, and strongly suspect it to be a distinct species.

? *A. scutigera*, DAWs.—The curious stems of this species, with their scale-armed nodes, occur abundantly in this bed. The specimen figured in Dawson's paper on the *Flora. Dev. Period*, N. E. America, Pl. xiii. fig. 19, and which he refers to the apex of this species, came from Plant-bed No. 2, in which I have never detected *A. scutigera*. Stems of this *Asterophyllites* are not unfrequently found in the sandstone overlying Bed 1 in the eastern part of the Ledges.

Sphenophyllum antiquum, DAWs.—A single specimen of a *Sphenophyllum*, found in a light coloured shale overlying the bed, has been referred by Dawson to this species.

? *Pecopteris obscura*, LESQX.—Ferns are extremely rare in this bed. Dawson has referred with doubt to this species, a single specimen, the only one I have yet found. It is figured in his paper.

Sphenopteris sp?—A delicate little *Sphenopteris*, occurs very rarely in this bed. It may be *S. marginata*; but my specimens are not sufficiently well preserved to enable me to identify it.

- Cardiocrinum cornutum*, DAWSON.—Rare.
- Psilophyton elegans*, DAWSON.—Occasional.
- I have never detected any trace of *Cordaites Robbii*, DAWSON., in this bed. It is extremely common in the overlying strata.
- Grey sandstones and flags, with occasional ill-preserved plants, *Calamites transitionis*, GÖPPERT., *Cordaites Robbii*, DAWSON.—*Asterophyllites* and *Sternbergia*, 2 feet 6 inches.
- Black arenaceous shales of the same character as those of No. 1, but without fossils so far as I have examined,— 11 inches.
- Compact, flaggy, grey sandstone, with badly preserved plant remains, *Calamites*, &c.,— 2 feet.
- Very soft, dark, lead-coloured shales, much slickensided and charged with fragments of plants. This bed is so soft that the action of the weather and the sea have everywhere denuded it to the level of the beach. 4 feet.
- PLANT BED No. 2. 1 foot.

At the point where the section crosses the bed, and where I first discovered it, it consists of very compact and hard, light lead-coloured, slate-like, arenaceous shale; but the character of the shale varies much in its different exposures, being sometimes very soft and fissile, and of a very black colour. The following is the list of species which it affords:—

Calamites transitionis, GÖPPERT.—Occasionally; never in good specimens.

C. canæformis, BRONGNIER. “ “ “

Asterophyllites acicularis, DAWSON.—Rather rare.

A. latifolia, DAWSON. “ “

A. longifolia, BRONGNIER. “ “

A. parvula, DAWSON.—Whorls of a minute *Asterophyllites*, which may belong to this species, are not infrequent in this bed.

Annularia acuminata, DAWSON.—I have collected a great number of specimens of this species from Bed No. 2, as well as from some of the overlying plant-beds, where it is very much more abundant; but I have found it to occur invariably in detached whorls. The leaves in a whorl are never spread out in the same plane, as in *A. sphenophylloides* for instance, but are always more or less erect, usually spreading slightly. It is a minute species, the leaves being 1.6—1.5 of an inch in length.

Pinnularia dispalans, DAWSON.—Abundant.

Psilophyton elegans, DAWSON.—Quite common, always in fragments, never in good specimens.

P. glabrum, DAWSON.—Flattened stems, with a wavy woody axis, traced in a brighter line of graphite, occur in this bed, but always in fragments. Dawson refers them with doubt to the above genus. They are not uncommon elsewhere at this locality.

Cordaites Robbii, DAWSON.—Extremely abundant, and very fine specimens may be obtained, especially from the upper part of the bed, and rarely specimens showing the base or the apex of the leaf.

Cyclopteris obtusa, LESQUER.—Occurs very abundantly in detached pinnules, rarely with several attached to a rachis. The specimen figured in Dawson's paper, Pl. xv. fig. 33, came from this bed, as also did those of the following:—

Cyclopteris varia, DAWSON.—Rare.

Neuropteris serrulata, DAWSON.—Very rare.

N. polymorpha, DAWSON.—Extremely abundant, never in large fronds.

Sphenopteris Hæninghausii, BRONGNIER.—Quite abundant, often in fine fronds. Is this species specifically identical with the European?

S. marginata, DAWSON.—Abundant, in fine fronds.

S. Hartii, DAWSON.—Very rare. The original specimen came from this bed.

S. Hitchcockiana, DAWSON.—Dawson has suggested that certain minute bodies, which resemble fragments of comminuted leaves, and which are scattered abundantly through the shale of this, as well as some of the other plant-beds, may be the detached pinnules of the above fern. They, however, show no structure, being merely minute rounded or oval patches of graphite, and they have never been found attached to a rachis.

Hymenophyllites Gersdorffii, GÆPPT.—Rather rare. *Hymenophyllites Gersdorffii* is a species occurring in the French coal. I am inclined to doubt whether the New Brunswick species is identical with it.

H. obtusilobus, GÆPPT.—Rare.

H. curtisilobus, DAWSON.—The specimen on which Dawson founded his species, was obtained from this bed.

Pecopteris (Alethopteris) discrepans, DAWSON.—Amongst all the abundance of plants afforded by Bed No. 2, I have detected only one or two pinnules of this fern, which appears first in abundance in Bed No. 3. It is afterwards one of the most common species.

Pecopteris ingens, DAWSON.—Very rare, only two or three fragments of pinnules having been found.

Trichomanites?—Only a single specimen, probably, as Dawson has suggested, only the skeleton of a fern.

Cardiocarpum cornutum DAWSON.—Abundant, and very finely preserved, never attached.

C. obliquum, DAWSON.—Quite abundant, also never attached.

Trigonocarpum racemosum, DAWSON.—Rare.

Eurypteris pulicaris, SALTER.—The occurrence in Bed No. 2 of this minute Crustacean, was first detected by my friend Mr. George Matthew. It is very rare, not more than four or five specimens having been found by Messrs. Matthew, Payne, and myself, at the time of the description of the species by Salter. I have since that time succeeded in collecting nearly twice as many more, some of which appear to belong to a new species.

Amphipeltis paradoxus, SALTER.—The specimen figured in Salter's paper was found by Professor Dawson and myself, in breaking a piece of shale in my cabinet, that came from this bed. Only one other specimen has since been obtained. It consists of two or more of the thoracic segments, and was collected by Mr. Lunn. It is in the collection of the Natural History Society of New Brunswick. In addition to the above species, this bed has afforded the following as yet undescribed:—

Cyclopteris, sp. nov.—A large *Cyclopteris* occurs not unfrequently in Bed No. 2, although rarely in complete pinnules. It bears some resemblance to *Cyclop. ingens*, L. & H. of the Middle Coal Measures of Grand Lake, New Brunswick. I have lately obtained some fine specimens in sufficiently large number to admit of its description.

Neuropteris, sp. nov.—A single specimen collected by Mr. Lunn. Dawson speaks of it as in some points resembling *N. gigantea*, and says—"It is about an inch in length, broadly oval in form, and with thick and persistent and crowded nervures, forking twice."

Sphenopteris, sp. nov.—A specimen of a *Sphenopteris* was discovered in this bed by my friend Mr. James Hegan of St. John. It was forwarded to Prof. Dawson, but proved too imperfect for description. I have since obtained other specimens, which will enable me to describe it.

Spirorbis, sp.?—The leaves of *Cordaites* in the upper part of the bed, are as thickly covered with a little *Spirorbis* as are the fronds of the recent fucoids of the Ledges. The specimens are too poorly preserved for identification.

Trilobites.—Mr. Payne collected a minute trilobite from this bed. The specimen was sent by Professor Dawson to Mr. Salter, but that gentleman has made no mention of it in his paper.

Insect Remains!—In the Summer of 1862 I discovered an organism in Bed No. 2, which at the time I could make nothing of; but which I have since proved to be the wing of an insect. Several weeks after, I found in Bed No. 8 an unequivocal insect's wing. This discovery was followed by that of others, as I shall have occasion hereafter to relate, my father, J. W. Hartt, finding another in this bed.

Compact flaggy sandstone, quite barren.

5 feet 10 inches.

PLANT BED No. 3.

10 inches.

Black and lead-coloured shales, quite compact in upper part, but in lower very crumbling, splitting irregularly, slickensided, often with polished surfaces, and traversed by thin quartz-veins. These shales are so soft that the sea and weather have everywhere denuded them to the level of the beach. There are now no exposures of the bed workable.

The following are the Fossils which occur in it:—

Calamites transitionis, GÆPPT.—Occasionally.

C. canæformis, BRONGNT. “

Asterophyllites latifolia, DAWS.—Very beautiful whorls of this plant are very common here, the whorls, though usually detached, being sometimes found united three or four together.

Annularia acuminata, DAWS.—Common.

Pinnularia dispalans, “ “

Psilophyton elegans, “ Occasionally.

P? glabrum, “ “

Cordaites Robbii, “ Extremely abundant, but not so well preserved as in Bed No. 2. Leaves apt to be preserved as polished bands of graphite, with venation obliterated.

Cyclopteris obtusa, LESQX.—Not very abundant.

Neuropteris polymorpha, DAWS.—In beautiful specimens, common.

Sphenopteris marginata, “ Not common.

S. Hæninghausii, BRONGNT.—Not common.

Pecopteris (Alethopteris) discrepans, DAWS.—It was here that I first discovered this species. It occurs quite abundantly, but always in fragments. It was from specimens taken from this bed that Dawson figured and described the species.

Cardiocarpum cornutum, DAWS.—Quite common.

C. obliquum, DAWS.—Quite common.

Coarse sandstone, full of obscure casts of <i>Sternbergia</i> and <i>Calamites</i> ,	6 feet	6 inches.
Soft shale and fissile sandstone, with <i>Calamites</i> ,	0 “	3½ “
Sandstones,	2 “	3 “
Shale, with obscure remains of plants,	0 “	2½ “
Sandstones, barren so far as examined,	4 “	10 “
Sandstone and shale, with a few <i>Calamites</i> and <i>Cordaites</i> ,	0 “	9 “
Sandstone and coarse shale, with obscure markings,	5 “	10 “
Light greenish, coarse shale, with fern-stems, <i>Cordaites</i> , and obscure markings, <i>Carpolites</i> (?)	0 “	7 “
Sandstones and coarse shales, with badly preserved vegetable remains,	18 “	9 “
PLANT BED No. 4.	1 “	0 “

Coarse shales, affording at the point where the line of section crosses it—

Cordaites Robbii, DAWS.

Calamites transitionis, GÆPPT.

Neuropteris polymorpha, DAWS.

Psilophyton glabrum, “

Pinnularia dispalans, “

I have examined at two different points in the eastern part of this locality, a bed which appears to correspond to this. It is characterized there by a very beautiful *Neuropteris* (sp. nov.) with long linear-lanceolate pinnules decurrent on the rachis, to which they form a broad wing. The pinnules are often four inches in length. This is one of the most beautiful ferns occurring at the locality. Several other new forms are associated with it. Among these is a magnificent *Cardiocarpum*, nearly two inches in diameter.

Sandstone with obscure markings.

9 feet 6 inches.

PLANT BED NO. 5.

6 inches.

Soft, fine-grained, light greenish shale.

Cordaites Robbii, DAWs.—Extremely abundant.

Calamites cannaeformis, BRONGNT.—Found occasionally.

Psilophyton ? *glabrum*, DAWs.

? *Asterophyllites acicularis*, DAWs.

Pecopteris (Alethopteris) discrepans, DAWs.—Quite abundant.

Sphenopteris marginata, “ “

Pecopteris, sp. nov. ?

Hymenophyllites, sp. ?

Neuropteris polymorpha, DAWs.—Very abundant.

Spirorbis occurs in the bed, attached to the leaves of *Cordaites*. I have never detected it in any of the beds higher up.

Compact flaggy sandstones and coarse shales, with a few plants.

8 feet.

PLANT BED NO. 6.

2 feet.

Fine-grained and light coloured shale, with great abundance of *Cordaites Robbii*, and *Calamites transitionis*; above that a layer of coarse shale, with *Cordaites* and stems of plants badly preserved; then a layer of soft, very friable shale, with few fossils; and lastly, a layer of coarse shale of a greenish-grey colour, with—

Pecopteris discrepans, DAWs.—Abundant.

Cordaites Robbii, “ “

Calamites cannaeformis, BRONGNT.

Neuropteris polymorpha, DAWs.

Cardiocarpum cornutum, “

Cardiocarpum obliquum, “

Pecopteris, sp. nov.—Occurs abundantly in some of the overlying beds.

Sandstones and coarse shales, with abundance of plant-remains, principally *Cordaites* and *Calamites*.

5 feet.

PLANT BED NO. 7.

2 feet.

This is one of the richest plant-beds of the section. The shales composing it vary much in character in different exposures. They are for the most part of a grey colour, and compact, like a fine-grained sandstone, though they pass into a light brownish, very fissile, soft shale, and there are some layers of a very black colour.

Cordaites Robbii, DAWs.—Very abundant, and in a beautiful state of preservation.

Calamites transitionis, GÖPPT.—Not abundant as good specimens.

C. cannaeformis, BRONGNT.—Rare.

? *Asterophyllites acicularis*, DAWs.—In very beautiful specimens, very common in certain thin layers. There are two or three other species, occurring also in the overlying beds, which appear to be new.

Annularia acuminata, DAWs.—Extremely plentiful.

Pinnularia dispalans, “ “ “

? *Psilophyton elegans*, DAWs.—I have obtained several specimens of a *Psilophyton*, growing in tufts, and closely resembling this species.

Neuropteris polymorpha, DAWs.—Occasional.

Pecopteris (Alethopteris) discrepans, DAWs.—Abundant, and obtainable in good specimens.

Cyclopteris obtusa, LESQX.—Occasional.

Sphenopteris marginata, DAWs “

? *Hymenophyllites Hildrethi*, LESQX.—Occasional. This delicate little fern, which is very common in the overlying plant-bed, bears a very strong resemblance to *H. Hildrethi*; but it may be new.

Cardiocarpum cornutum, DAWs.—Quite abundant.

C. obliquum, “ “

C. sp. nov.—A very elongated species.

Alethopteris, sp. nov.—A new species allied to *A. Serrula*, LESQX., but distinct.

P. (A.) sp. nov.—A new species, apparently allied to *P. Milioni*, shows fructification?

P. (A.) sp. nov.—A very beautiful species, occurring in very large fronds. Several other plants not yet determined.

Insects.—A single insect's wing was obtained from this bed by my father and myself.

Compact sandstone and coarse shales. (Barren of fossils.) 3 feet.

PLANT BED No. 8. 1 foot 10 inches.

Fine grained, tough, but fissile sandstones, rather coarse shales, often of a greenish cast, and at the top a thin layer of very black shale, very rich in plants. The middle portion does not contain so many plant remains, but the lower is as well stocked as the leaves of a herbarium. The following are the fossils I have collected from it:—

Cordaites Robbii, DAWs.—As usual in great profusion, and in very fine specimens.

C. transitionis, GEPPT.—Occasional.

C. cannaeformis, BRONGT. “

? *Asterophyllites acicularis*, DAWs.—Quite common, together with one or two other species apparently new, which occur also in Bed 7.

Annularia acuminata, DAWs.—Extremely common, especially in certain layers.

Pinnularia dispalans, DAWs.—Abundant.

? *Lycopodites Matthewi*, DAWs.—Rare.

Cyclopteris obtusa, LESQX.

Cyclopteris, sp. nov.

Neuropteris polymorpha, DAWs.—Quite frequent in detached pinnules.

? *Hymenophyllites Hildrethi*, LESQX.—Very common.

Pecopteris (Alethop.) discrepans, DAWs.—This is the most abundant fern in this bed.

It occurs usually in detached pinnules, though not unfrequently in considerable fronds. I have from this bed a frond ten inches long, which I hope to figure.

Pecopteris (Alethop.)—Besides the above, there are three or four other species, new, some of which occur also in Beds 6 and 7.

Cardiocarpum cornutum, DAWs.—Not very common.

C. obliquum, DAWs.—Also, “ “

C. sp. nov.—The elongated species spoken of in the list of fossils given for Bed 7.—Quite common.

Several other species of plants not yet determined.

Insects.—Two species, two specimens. One was obtained by my friend Mr. James Hegan. Mr. Scudder informs me that all the insect remains from this locality are sufficiently well preserved for determination.

Sandstones and coarse shales, with badly preserved *Cordaites Robbii*, DAWs. 26 feet.
C. transitionis, GEPPT., and *Pecopteris (A.) discrepans*, DAWs.

Fine grained, light-greenish shale, with obscure remains. 1 foot.

Sandstone and shales, with *Calamites* and obscure markings. 23 feet.

This brings up the section to those beds which are exposed within a few feet of low-water mark. Owing to the short time during which the rocks are laid bare by the fall of the tide, to their hardness, and to the way in which they are rounded down by the surf, the work of exploring this part of the section is very difficult, and I have not been able to give them a very close examination.

A very rich plant-bed crops out within a short distance of low-water mark on the very eastern margin of the ledges. Its place in the section is somewhere near Bed 8. It is characterised by *Cyclopteris valida*, DAWSON, which appears to be limited to it. The unique specimen figured in Dawson's Paper "On the Flora of the Devonian Period, &c.," Plate xvii. fig. 52, came from this bed. I obtained here a magnificent frond of *Neuropteris polymorpha*, DAWSON, showing its structure finely, and the different forms of the pinnules in different situations on the frond. Many of the species common in the underlying beds are also to be found in this; but I am unable to give a complete list.

Total thickness of the Beds embraced in this Section, 444 feet, 11 inches.
Cambridge, Mass., December, 1864.

Since the above was written, I have received the following letter from Mr. Scudder, relating to the fossil Insect-remains.

*Boston Society of Natural History,
Berkeley, corner of Boylston Street, January 11, 1865.*

MY DEAR MR. HARTT,—I have made as careful an examination as my present circumstances will permit, of your most interesting collection of the fossil remains of insect-wings from Lancaster. There are ten specimens in all, eight of which are reverses of one another, thus reducing the number to six individuals; of these, one, a mere fragment, belongs, I think, to the same species as another of which the more important parts of the wing are preserved, so that we have five species represented among these Devonian Insects, and these remains are all, I suspect, composed of portions of the anterior wing alone. The data being thus fragmentary, the conclusions cannot be quite so satisfactorily determined as we could wish, but we can still discover enough to prove that they are of unwonted interest. Besides the peculiar interest which attaches to them as the *earliest known traces of insect life on the globe*, there is very much in themselves to attract and merit our closest attention.

One of them is a gigantic representative of the family of *Ephemera* among Neuroptera, some three or four times the size of the largest species now living, with which I am acquainted.

Another borrows some striking points of the peculiar wing-structure of the Neuropterous family *Odonata*, and combines with them those of families remote from that, and even belonging to a distinct section of the Neuroptera, exhibiting to our view a synthetic type which combines in one the Pseudoneuroptera and the Neuroptera, and represents a family distinct from any hitherto known.

Other fossil insects, found in carboniferous concretions in Illinois, and described in Silliman's Journal, (N. S. xxxvii, 34), which Professor Dana has kindly allowed me to examine,* also belong to hitherto unrecognized families, exhibiting similar relations to these in-our-day-disconnected Sections of Neuropterous insects; and your third species is a member of still another family of Neuroptera, which finds its natural relations between the two described by Professor Dana.

A fourth, of which only an unimportant fragment was found, would seem to belong to the Neuroptera; but by some peculiarities of the minuter cross-veins, thrown off in the middle of the outer edge of the wing, in a most irregular and unusual manner, suggests no intimate relations with any known family, but must have belonged to a group of large and weak-winged insects.

* The results of this examination will shortly be communicated to Silliman's Journal.

The fifth and last to be mentioned is of very striking interest, because, while it exhibits the peculiar venation which forms the well known tympanum or stridulating apparatus of the male, in the Orthopterous family *Locustariae* (though differing somewhat from that), it also most resembles the Neuroptera in all or nearly all the other peculiarities of its structure, and suggests the presence in the insect-faunæ of those ancient times of a synthetic type, which united the characteristics of the Orthoptera and Neuroptera, in themselves closely allied; this point however requires patient and severe investigation, and only my earliest impressions are here recorded, made however immediately after a close examination into the relations of other fossil insects.

I earnestly hope that this locality, from which these remains were disinterred, may receive a most careful and thorough examination by yourself, who have already shown so much diligence and careful scrutiny in the discovery of such important and easily overlooked remains. Hitherto, the study of fossil insects has been mainly confined to those of much more recent date, and has resulted in shedding comparatively little light upon geological and palæontological questions; but these few remains, coupled with the pair of insects found in Illinois, induce us ardently to anticipate that the future study of fossil insects, drawn from such ancient strata as these, may lead to as brilliant and important results, in the elucidation of geological problems still open, in widening the range of our palæontological horizon, and in our general knowledge of the history of Life on our globe in all its bearings, as have been reached by the study of the remains of animals of a more substantial structure, but which have hitherto been denied to the student of fossil Entomology.

With many thanks to you for the opportunity of an inspection of these relics, to which so strong an interest attaches, and hoping soon to give you a more detailed and satisfactory report,

I remain, very sincerely yours,

SAM. H. SCUDDER.

APPENDIX B.

LIST OF NEW BRUNSWICK FOSSILS.

By C. FRED. HARTT, A. M.

The following list of Fossils comprises all the species ascertained to exist in the Province. A large proportion of these, principally plants, have been accurately determined, thanks to the labours of the distinguished Dr. Dawson, to whom Acadian Geology and Acadian Geologists owe almost everything. The list is of course very incomplete; but it will serve to show what little has been done in the study of the Palæontology and Fossil Botany of New Brunswick, and the extent of the field yet unexplored that invites the researches of the Palæontologist and Fossil Botanist. It has afforded many treasures, and there is promise that the future explorer will not go unrewarded.

The materials for this list were collected from the following sources:—

Dawson's "*Synopsis of the Flora of the Carboniferous Period in Nova Scotia*," in which a number of species of Carboniferous plants from several localities in New Brunswick are given, a few being new.

Dawson's "*Flora of the Devonian Period in N. E. America*," from which was taken the list of described Devonian plants.

The papers of Dawson, Salter, Matthew, and Jackson, relating to the geology or Palæontology of the Province. For the list of *post-tertiary* forms I am largely indebted to my friend Mr. Matthew. The rest of the list is made up from my own notes.

Quite a number of New Brunswick Fossils are mentioned in Gesner's Report, but his determinations are not trustworthy, and I have included none of them in this list.

I. POST TERTIARY.—MARINE CLAYS.

Articulata.

Balanus Hameri, Lawlor's Lake.

B. crenatus, " "

Mollusca.

Pecten Islandicus, Ch. Lawlor's Lake, R. R. Depot, Saint John.

P. tenuistriatus,

Mytilus edulis, Linn. " " " "

Cardium pinnulatum, Con. " " " "

Tellina Grœnlandica, Lawlor's Lake, &c.

T. calcarea, Duck Cove, &c.

- Leda Jacksoni*, Lawlor's Lake.
L. truncata, Duck Cove; Lawlor's Lake; R. R. Depot, Saint John.
Nucula antiqua, " " " " " "
Mya arenaria.
M. truncata, " " " " " "
Aphrodite Groenlandica, Duck Cove, &c.
Cardium Islandicum, *Linn.*
Mesodesma, R. R. Depot.
Saxicava distorta, *Say*.
Lyonsia arenosa, Duck Cove.
Lacuna neritoidea, *Gould*, Duck Cove.
Pandora trilineata, "
Natica clausa, *Sow*, "
Buccinum undatum, *Linn*, Duck Cove.

Bryozoa, several species undetermined, Taylor's Island, Lawlor's Lake, &c.

Radiata.

- Ophiurans, two species, Saint John, Duck Cove.
Toxopneustes drobachensis, (*Echinus granulatus*), Red Head, Lawlor's Lake.

Plants.—Algae, three species, undetermined.—*Manawagonis*.

N. B.—Beside the above Mollusca, there are in Mr. Matthew's hands twenty or thirty additional species, not yet determined.

II. NEW RED SANDSTONE.

For remarks on the only fossil of this age see Report, page 124.

III. CARBONIFEROUS EPOCH.

a. *Upper Coal Formation*.—(*Dawson*).

Plants—Described Species.

Dadoxylon materiarium, *Dawson*, Miramichi.

b. *Middle Coal Formation*.—(*Dawson*).

Animals.

The only animal I have seen from the Middle Coal Formation is a little *Spirotbis*, resembling *S. Carbonarius*, which occurs attached to plants in the roof-shales of the Coal-Seam at Coal Creek, Newcastle, Grand Lake. *Coprolites of Fishes* are found in the same shales.

Plants—Described Species.

- Dadoxylon Acadianum*, *Dawson*, Dorchester.
Calamodendron approximatum, *Brongnt.* Coal Creek, Grand Lake.
Antholites rhabdocarpi, *Dawson*, " " " "
Calamites Suckowii, *Brongnt.* " " " " Gardner's Creek.
C. Cistii, *Brongnt.* " " " " Baie de Chaleur.
C. nodosus, *Schlot.* " " " "
C. canæformis, Gardner's Creek.
Asterophyllites grandis, *Sternberg.* Coal Creek, Grand Lake; Baie de Chaleur.
Annularia galioides, *Zenker*, " " " " "
Sphenophyllum emarginatum, *Brongnt.* " " " " "
S. saxifragifolium, *Sternberg.* Baie de Chaleur.
Cyclopteris (Nephropteris) obliqua, *Brongnt.* Coal Creek, Grand Lake.
C. (? Neuropteris) ingens, *L. & H.* " " " "

- Neuropteris rarinervis*, *Bunbury*, Coal Creek, Grand Lake; Baie de Chaleur.
N. gigantea, *Sternberg*, " " " "
N. Loshii, *Brongnt.* Gardner's Creek? Baie de Chaleur.
N. auriculata, " " " "
Odontopteris Schlotheimii, *Brongnt.* Baie de Chaleur.
Sphenopteris munda, *Dawson*, Coal Creek, Grand Lake.
S. latior, *Dawson*, " " " "

Halonia? sp.? *Dawson*, Coal Creek.

c. Lower Coal Formation.—(*Dawson*.)

Animals.—The Fauna of the Carboniferous limestone in New Brunswick, though rich in species, has not yet been touched by the palæontologist, and all the species are still undetermined. A small collection of my own, from Ocnabog Lake, and a suite of specimens collected at various localities during the past summer by Professor Bailey, will enable me, while preparing a lengthy Monograph of the Carboniferous Limestone fossils of Nova Scotia, to do something towards exploring this new field, and towards settling the age of the Acadian Carboniferous limestone, concerning whose exact equivalency I now entertain some doubt. The majority of the New Brunswick specimens I have had the opportunity of examining, occur also at Windsor, Brookfield, and elsewhere in Nova Scotia. The genera comprise *Productus*, *Terebratula*, *Spirifer*, *Athyris*, *Macrodon*, *Aviculopecten*, *Oronotaria*, *Naticopsis*, *Nautilus*, *Orthoceras*, &c.

The very interesting fish-fauna of the Albert shales is not yet worked up. Dr. C. T. Jackson has named and described a few of the species in his Report on the Albert Coal Mine; but his descriptions are very unscientific and altogether unsatisfactory. His named species are the following:—

- Palæoniscus Alberti*, *Jackson*, Albert Mines.
P. Brownii, *Jackson*, "
P. Cairnsii, *Jackson*, "

IV. DEVONIAN.

a. *Little River Group*.—(Upper Devonian.)*Animals*—Described Species.

The only animal remains described from the Little River Group are the two Crustaceans;—

Amphipeltis paradoxus, *Salter*, Fern Ledges.

Eurypterus pulicaris, *Salter*, “

Undescribed Species.

All the undescribed species belong to the Branch of Articulata, and comprise representatives of its three classes.

Insecta.

Five genera, five species, nov. Fern Ledges.

Vide Letter from Mr. Scudder, Appendix A.

Crustacea.

Eurypterus, sp. nov.? Fern Ledges.

Phillipsia? sp. nov? “ vide Dawson “on the Flora of the Devonian Period in N. E. Amer.” p. 303, Note.

Vermes.

Spirorbis, sp? Fern Ledges.

Plants—Described Species.

Dadoxylon Ouangondianum, *Dawson*, Little River; Point below Barracks, St. John; Fern Ledges, Lancaster.

Sigillaria palpebra, *Dawson*.

Stigmaria ficoides, (var.), *Dawson*, Calamites Ledges, Lancaster.

Calamites transitionis, *Gœppt*. Calamites Ledges, Fern Ledges, Saint John, Little River; Mispeck Bridge on Black River Road.

C. cannaeformis, *Brongnt*. Localities same as preceding.

Asterophyllites acicularis, *Dawson*, Fern Ledges.

A. latifolia, *Dawson*, “

A. scutigera, *Dawson*, “

? *A. longifolia*, *Brongnt*. “

A. parvula, *Dawson*, “ Saint John.

Annularia acuminata, *Dawson*, “ Little River.

Sphenophyllum antiquum, “ Saint John.

Pinnularia dispalans, *Dawson*, “ “ Little Riv. Calamites Ledges.

Lepidodendron Gaspianum, *Dawson*, Calamites Ledges.

Lycopodites Matthewi, *Dawson*, Fern Ledges, Saint John.

Psilophyton elegans, *Dawson*, “

P. glabrum, *Dawson*, “ Calamites Ledges.

Cordaites Robbii, *Dawson*, “ Calamites Ledges; Saint John; Little River; Mispeck River Bridge on Black River Road.

C. angustifolia, *Dawson*, Saint John.

Cyclopteris Jacksoni, *Dawson*, Saint John.

C. obtusa, *Lesq*, Fern Ledges, Little River.

C. varia, *Dawson*, “

C. valida, *Dawson*, “

Neuropteris serrulata, *Dawson*, Fern Ledges.

N. polymorpha, *Dawson*, Fern Ledges; Little River; Calamites Ledges; Saint John; Mispeck.

- Sphenopteris Hœninghausii, *Brongt.* Fern Ledges.
 S. marginata, (*Dawson*,) Fern Ledges.
 S. Hartii, (*Dawson*,) " "
 S. Hitchcockiana, *Dawson*, Fern Ledges, Little River, Calamites Ledges.
 Hymenophyllites Gersdorffii, *Gappt.* Fern Ledges.
 H. obtusilobus, *Gappt.*, " "
 H. curtilobus, *Dawson*, " "
 Pecopteris (Alethopteris) discrepans, *Dawson*, Fern Ledges, Little River, Calamites Ledges, Saint John.
 P. (A.) ingens, *Dawson*, Fern Ledges.
 P. (A.) obscura, *Lesqx.* " "
 Trichomanites? " "
 Cardiocarpum cornutum, *Dawson*, Fern Ledges, Little River, Calamites Ledges.
 C. obliquum, *Dawson*, Fern Ledges.
 Trigonocarpum racemosum, *Dawson*, Fern Ledges.

Undescribed Species.

In addition to the above species, I have in my hands for determination about twenty-five more, the majority of which are new. They belong to the genera *Asterophyllites*, *Cyclopteris*, *Neuropteris*, *Sphenopteris*, *Hymenophyllites*, *Pecopteris*, *Alethopteris*, *Cardiocarpum*.—(Vide Appendix A.)

V. SILURIAN.

a. Primordial.

The fauna of the Primordial in New Brunswick comprises, so far as is now known, about 17 species of Trilobites and Brachiopoda, all of which are new, and will be figured and described in a paper which I have in course of preparation, but whose publication may be delayed for a short time, until further material shall have been collected, so that all the species may be satisfactorily illustrated. (Vide "Preliminary Notice," pp. 30, 31, of this Report.)

The following is the list of the genera, with the number of species in each:—

Paradoxides,	5 sp. nov.	Orthisina,	2 sp. nov.
Conocephalites,	7 "	Discina,	1 "
Agnostus,	1 "	Obollesella,	1 "
Genus nov.	1 "	Lingula,	2 "

The localities are Ratcliffe's Millstream and Coldbrook.

Cambridge, February 14th, 1865.

NOTE.—In the above list by Mr. Hartt, no reference has been made to the rich fossiliferous limestones of Restigouche County, probably for the reason that the numerous remains which they contain, though finely preserved, have not yet received any thorough or careful examination. While, however, this uncertainty exists as to the particular species afforded by the locality, it may not be out of place to mention the names of those genera believed to occur in the beds referred to. They are as follow:—

Favosites (*Gothlandica et basaltica* ?), *Syringopora*, *Cyathophyllum*, *Orthis*, *Strophomena* (*Leptæna depressa et L. euglypta*), *Murchisonia*, *Zaphrentis*, *Cyclolites*, *Atrypa*, *Avicula*, *Litoites*, *Turbinolopsis* and *Stems of Encrinurus*.

A boulder with a finely preserved pygidium of a Trilobite (a species of *Dalmania*), and another covered with the chain-coral (*Helysites*) have been found in the same district, but from what beds they were derived is unknown.

Beside the above-named Silurian fossils, there are in the University collection many other forms from various localities not mentioned in the foregoing list, among others marine shells from the clays of Saint Andrews and Bathurst; *Sigillariae*, *Stigmariæ*, *Calamites*, &c., from various parts of the Coal Field; and obscure plant-remains from the Devonian rocks of Charlotte.—L. W. B.

APPENDIX C.

CUPRIFEROUS ROCKS OF SOUTH-EASTERN NEW BRUNSWICK,

COMPARED WITH THOSE OF THE EASTERN TOWNSHIPS, CANADA.

By GEO. F. MATTHEW, Esquire.

[Read before the Natural History Society of New Brunswick, 4th February 1865.]

There are few readers of the public prints who have not learned of the famous Acton Copper Mines and the Chaudiere gold region of Canada, though perhaps many are not aware of the inexhaustible mineral wealth existing in that part of Lower Canada known as the "Eastern Townships."

Extensive stores of knowledge on this point may be found in the Report on the Geological Survey of Canada (1863). From this work, where the geology of this region is elaborately and systematically detailed, I make some gleanings.

The sediments of the region in question belong principally to the Quebec Group of Canadian geologists, which Mr. Billings has shown to be equivalent to the Calciferous and Chazy formations of New York and Western Canada.

"The lower division of the group appears to be supplied with ores of iron, lead, zinc, copper, nickel, cobalt, chromium, and titanium, as well as with silver and gold. Some of these are known to exist in quantities economically available, and others will hereafter probably be found to be so.

"This portion of the group abounds also, in its more altered portions, in roofing slates, serpentine, soapstone, potstone, whetstone, magnesite and dolomite.

"The country over which the group is distributed is a mining region of much importance.

"What is considered the upper portion of the group, composed of the Sillery sandstones, does not appear to be in any remarkable degree metalliferous, nor is it yet certain whether the more valuable metals abound in the dark shales which are at the base of the group.

"This whole series of rock, however, occupies a place which brings it to the horizon of the upper copper-bearing series of Lake Superior."

In the metalliferous district of the Eastern Townships, the lower division of the group would appear to consist of grey clay slates, with thick beds of felspar rock, which in some places have the appearance of coarse-grained sandstones—succeeding these a great mass of magnesian strata with micaceous slates and sandstones (the most highly metalliferous portion of the group)—and lastly red shales connected with the upper portion of the group (Sillery sandstones). A great part of the copper ores occur in *fahlbands* (or metalliferous layers) in chloritic slates and limestone. The serpentines,

with which ores of magnetic and chromic iron are associated, are said to represent the dolomites, in an altered condition. Owing to their pearly aspect, the micaceous slates of this group have heretofore been looked upon by New England geologists as *talcose* schists or slates, but Dr. T. Sterry Hunt has by analysis found them to consist of a hydrous mica, mingled with silica in a finely divided state, and proposes for rocks of this description the term *nacreous* slates.

Having glanced at some features of the Quebec Group, let me now call attention to certain resemblances in lithological characters presented by the metalliferous strata of the coast series in Southeastern New Brunswick.

In a hurried descent of Little Salmon River and passage along the coast to Point Wolf in Albert County, I was enabled to gain a general idea respecting the character and distribution of the rocks alluded to. Here they cover a greater extent of country than further west, owing to two or more synclinal and corresponding anticlinal folds.* From the Shepody road south to the coast, they occupy a tract of elevated land ten miles wide and thirty in length, covered with wood and uncultivated.

Along the road alluded to gneissoid rocks are associated with the slates, and probably represent the granitoid sandstones found near the base of the series at Black River. Slates with a micaceous or talcoid aspect, together with chloritic slates and grits, come out upon each side of Little Salmon River at and below a bridge about eight miles from the mouth, and reappear with reversed dip along the coast. In the synclinal trough intervening, are grey clay slates or argillites, with beds of diorite, and overlaying these a thick deposit of cherty slates.†

In the lower portion of the series, exposed in cliffs and abrupt hills along the coast, copper ores have been met with at a number of places (specified in the body of the Report,) usually in veins, but sometimes disseminated in lumps or grains, in layers of the slate forming *fahlbands*. The deposit at the mouth of Little Salmon River is of this kind, and the character of one of those at the Vernon mine, which yielded gold to the value of \$22 per ton of ore, seems to indicate that it also is a *fahlband*. A more interesting locality is that at Black River, where the remains of Devonian vegetation are found associated with copper pyrites in the same bed, in a manner similar to a carboniferous deposit at Bathurst, and indicating that the copper had been thrown down from a chemical solution, in the way in which Dr. Hunt supposes the ore beds of the Quebec Group to have originated.

Suspecting that the slates of Black River, called "talcose" by Dr. Gesner, and which I found to be altered equivalents of the argillo-micaceous slates of Mispeck, were really of a different character, I submitted specimens of them to Drs. Dawson and Hunt, who pronounced them to be "micaceous slates."

* One of these folds (anticlinal) at the river alluded to, dips at a large angle to the northeast, and to this fold, or the synclinal northward, is probably due the course of the main stream of Lower Salmon River.

† The position of these, as well as their character, render it probable that the Mispeck Group is represented by these upper rocks, the strata of both districts being marked by beds of igneous origin at the base, and the cherty slates may answer to the fine clay slates of the highest Devonian rocks.

Similar slates, with talcoid laminæ, of various shades from cream-colour to lilac and purple, which agree in outward appearance with the nacreous slates of the Quebec Group, occur on Little Salmon River and along the coast to Point Wolf. In these and the chlorite slates and grits of the same district, the most important ore-beds and veins of copper ore have been found. Specular iron ore is so abundant in some of these slate rocks, as to give them the character of specular schists. Dr. Gesner speaks of great masses of serpentine in connection with the "older slates and limestone" of this region; adding another to the points in which these rocks resemble those of the Quebec Group.

Magnetic and chromic iron ores may be looked for in these ophiolites. Slates suitable for roofing are said to exist in the rocks of the coast series at Shepody.

The principal difference between this formation and the great metalliferous group of Canada, appears to be the greater abundance in the latter of calcareous and magnesian deposits.

The activity of volcanic agencies in Southeastern New Brunswick at the period when the older strata which border the northern shore of the Bay of Fundy were produced, has already been noticed in the preceding Report; and to this cause the promising character of Albert and the eastern part of Saint John County as a field for mining operations, may in part be due.

But while we note the resemblance in the character of the slates and altered (granitoid) sandstones, as well as the cupriferous deposits of the two series, we do not infer that they were formed at the same period, but on the contrary believe that they are separated in time by the vast accumulations of the Middle and Upper Silurian, and Lower Devonian periods.

The grounds upon which this opinion is based may be shortly stated as follows:—

1. The strata of the Black River Settlement and West Beach are known to be Upper Devonian (Cordaite Shales).
2. The conglomerates at the base of these shales have been traced eastward into the high lands which approach the coast beyond Quaco, and at Lower Salmon River.
3. Strata similar to those of West Beach were found along the course of Little Salmon River, and extend thence eastward to Albert County.

An examination of the mineral resources of the country where these rocks occur, will be attended with some difficulty, owing to the almost unbroken forest which covers them. Still, even a partial exploration may result in the discovery of metalliferous deposits at present unknown; and will at least be the means of collecting a fund of information invaluable to those interested in mining operations in that quarter.

APPENDIX D.

NOTES ON THE GEOLOGY OF CHARLOTTE COUNTY.

By GEO. F. MATTHEW, Esq.

(Read before the Natural History Society of New Brunswick, February 3rd, 1865).

At Professor Bailey's request, I have thrown together the following remarks, embodying a few observations made by us in Charlotte County, and some general views on the geology of that portion of the Province.

UPPER [AND MIDDLE?] DEVONIAN.—Besides the strata of this age in south-western Saint John County, described in the body of this Report, and the sandstones of Saint Andrews referred to this age by Dr. Dawson, there are two or three small areas in Charlotte covered by the rocks of this formation.

The first of these is a ridge of conglomerates, &c. extending easterly from L'Etang river, along the coast to Dead Man's Harbour.

The promontory (Point Midjic) on the south side of the entrance to Magaguadavic Harbour, is also (according to information given to Prof. Bailey by Mr. Frye) composed of red Devonian sediments. Several of the smaller islands in Passamaquoddy Bay are of similar origin; and a chain of small islands in the Bay of Fundy, called "The Wolves," are probably of this age, since Dr. Gesner states that they are composed of conglomerate and trap.

Professor Bailey examined the country along the road from Magaguadavic to Saint Andrews. He found the Devonian rocks extending in several parallel ridges, having a northwest course, from Troak's Mountain to the Digdeguash River. Between these points the rocks are all of a trappian character. At the former place are dark coloured claystone-porphry, (with crystals of red felspar) and amygdaloid; while towards the River last mentioned, red compact felspar and syenitic trap prevail.

West of the Digdeguash, purple sandy shales and sandstones are associated with the traps, and were found to extend as far as Chamcook, where the bright red sandstones of Saint Andrews terminate. These have in general a southerly inclination of 20°; but the purple sediments and trap beds to the north and east, usually tilted in the same direction, are more irregular in dip.

UPPER SILURIAN.—A great part of the older rocks of this County are highly altered, and the determination of their age is therefore a perplexing question. The strata noticed under this head may prove to be in part either above or below this horizon.

In remarks on the age of the Kingston rocks, it was stated that in the southeastern part of Washington County, Maine, there is an extensive district occupied by Upper Silurian sediments, having a breadth of about twenty miles. A large part of them are metamorphosed and injected with masses

of trap; but around Cobscook Bay they are less altered, and contain organic remains of Upper Silurian age. This formation, if it extends into New Brunswick, should pass through the islands which separate Passamaquoddy Bay from the Bay of Fundy, and enter Charlotte County at Magaguadavic, L'Etang, and Beaver Harbour.

On some parts of this shore the older series is obscured by the Devonian rocks of later origin, already noticed; but at those points along the coast where the latter do not occur, slates, trap rocks and limestones, similar to those of the Maine shore and Passamaquoddy islands, are found. As the mines and mineral localities of these slates and limestones are described in detail, in the Report presented to the Legislature at its last Session by Prof. Bailey, it is unnecessary for me to allude to them further in this connection.

While at New River last summer, I made an examination of the strata along this stream, from its mouth to a point eight or ten miles inland. The rocks were found to be similar to those observed by Dr. Gesner along the coast from L'Etang to Mace's Bay. They do not agree in all particulars with the formation at Saint George and L'Etang, but may be in part the same series more highly altered. They consist chiefly of schistose gneiss, passing on the one hand into hornblende schist, and on the other into slaty compact felspar, or more rarely into mica schist; altered clay slate, cherty slate, and silicious mica slate, are of less frequent occurrence. At the river's mouth the strata are somewhat chloritic, and towards the interior the stratification of the gneissoid beds becomes more obscure, and ridges or beds of syenite and granite appear. These granitoid rocks are probably altered sandstones and grits, for at a cliff on the east side of the stream, a bed of granite, two or three feet thick, was seen resting upon slate, and overlaid by similar schistose beds obliquely laminated.

The inclination of this series is S. S. E. 40° - 60° . There is a fold in the strata a short distance below the falls, but the thickness of the beds must nevertheless be great.

For seven miles from the coast the country is comparatively level, and is extremely desolate in aspect, being almost entirely destitute of trees, covered in part by peat bogs, and elsewhere by a meagre, sandy and unproductive soil. Further inland a range of hills of the granitoid rocks above alluded to, cut through by this and the neighbouring streams, partially conceals a distant range of mountains.

The gneissoid rocks of New River resemble those of Kingston, but the diorites which abound in the latter are of less frequent occurrence here. If they are really the same formation, as seems probable, the range of hills through which the River passes may correspond to those on the north side of the Reach below Oak Point, while the more distant mountains will be a continuation of the granite eminences which extend across the River from Hampstead above the Reach.

On the northern flank of these mountains there is a belt of arenaceous shale (grauwacke slate of Gesner), usually of grey colours with a tinge of

green or blue. The mica schists observed by Prof. Bailey on the River Saint John at Hampstead, in Queen's County, are probably the same rocks in a more altered state. Eastward of Grand Lake, in the same County, and towards the centre of the great interior coal field, micaceous shales project through the horizontal carboniferous strata. They were examined by my brother (C. R. Matthew) several years ago, who speaks of them as follows:—

“ Three miles above Hughson's Mills on Coal Creek, the Coal Measures overlie unconformably a large deposit of bluish silvery-grey slate and shale; the layers of the former (Coal Measures) horizontal or nearly so; those of the latter dipping S. by E. 50°.

The Coal Measures exposed here consist of—

Slaty grey sandstones,	2' or 3 feet.
Rubby purple shales,	8 or 10 feet.
Grey slaty sandstones,	12 feet.

The upper sandstone contains *Calamites* and *Sternbergia*.”

The discovery of this *Island in the Carboniferous sea* gives countenance to the view now generally entertained, that the Coal Measures in this section of Acadia are of no great thickness.

To the westward these shales probably extend into the wilderness country in the northeastern part of Charlotte. To the southwest they may be represented by the red granite rocks of the Magaguadavic and Digdeguash Rivers, similar red felspar rocks being associated with the Upper Silurian shales in other parts of Acadia, as the high table land in the northern part of Cape Breton, and the elevated mountainous district at the sources of the Tobique, Nepisiguit, and Upsalquitch Rivers. To this band of arenaceous shales we are inclined to refer certain fragments of slate of similar texture and colour, occasionally met with in the drift at Saint John. They yield the following organic remains:—

Chonetes, resembling *C. Nova Scotica*, but having long slender spines at the hinge line; *Clidophorus*; *Cypricardina* or *Orthonota*; *Rhynchonella*(?); *Orthis*; *Leptodomus*(?); *Pterinia* or *Avicula*; *Encrinural joints*; and, on the finer layers, long flexuous impressions, which may be sea-weeds.

LOWER SILURIAN.—A wide belt of slates, admitted by all observers to be of great antiquity, and which will probably prove to be a mining region of much importance, passes through the central part of York County, and the western portion of Charlotte, into the neighbouring State of Maine. Both Drs. Gesner and Robb denominated them Cambrian; but as this term is now restricted to a series of sediments considered by the best English geologists to be equivalent to the Huronian of Canada—a formation known to lie beneath the true Lower Silurian,—it will not be sufficiently accurate, if they should prove to be of the latter age, as we suppose they will. They do not assimilate in physical characters to the known Acadian equivalents of the Cambrian or Huronian series, (see Coldbrook Group in Report), and we found that a collection of rocks of this formation in the University of

New Brunswick, made principally by the late Dr. James Robb, consisted mainly of dark coloured quartzites, and pale green clay slates, the former intercalated with the slates in numerous beds of from one inch to many feet in thickness, thus resembling the strata of the Saint John Group (Lower Silurian,) and differing from the Upper Silurian and [Middle? and] Upper Devonian deposits which have been recognized in this region.

Moreover, the slate formation in question contains beds of glossy plumbaginous schists, which may correspond to the carbonaceous shales of the Saint John group. This latter formation is now known to be equivalent to the Potsdam, together with the Calciferous (and perhaps the Chazy) formations of the New York Geologists, so that we are not inclined to adopt Prof. Hitchcock's surmise, that "it would not be strange if the name Cambrian, which was applied to both these belts of mica-schist in New Brunswick many years ago, and is now generally discarded, should ultimately prove to be their correct appellation." The antimony mines occurring in this series at Prince William, are described in the Report of last year. Molybdenite, a mineral found in loose pieces at Saint Stephen, Fredericton, and Bathurst, has probably been derived from it. We observed no mica-schist in the University Collection from these shales, although their extension into Maine is described by Professor Hitchcock as a mica-schist formation. This gentleman remarks of the mica-schists on the western border, that they extend along the course of the Saint Croix River, from the lower end of the Chepedneck Lakes to a point on the river two and a half miles from Saint Stephen, being there met by the syenite and granite previously described as extending through the country from the Nerepis River. "In the space (along the Saint Croix) just alluded to, there are two synclinal and three anticlinal axes. The low land soils of this district are invariably very good. That of the high lands may be compared to that between Bangor and Charleston." He also adds:—"The finest auriferous belt brought to light the past season, crosses the Saint Croix River above Calais. The rock is a mica-schist full of quartz veins and beds. An examination of these veins near the railroad bridge in Baileyville, showed us several pieces of bright flake gold. The best locality is on the west side of the river, upon some ledges through which a passage for the railroad has been excavated." "Across the river in New Brunswick, upon land of Mr. Bolton, of Saint Stephen, is another locality where gold has been found. Its distance from Sprague's Falls (railroad bridge) cannot be very great, as it is about nine miles northwest from the Calais bridge. The exact locality of the gold is in a plumbaginous slate, very black and greasy. Near it is a large boss of quartz, with sub-veins of quartz running through it; and there are also near by veins of quartz containing pyrites. These two localities are the most promising of any seen by us in the Saint Croix country."

It will be observed that in the alternations of arenaceous and dark coloured clay slates and intercalated quartzites, this formation resembles the gold-bearing series of the Atlantic coast of Nova Scotia, long ago recognized as Lower Silurian by Dr. Dawson.

If both prove to be on the same geological horizon as the Saint John Group, (viz. Potsdam, Calciferous, &c.) our knowledge of the age and relations of the older metamorphic rocks of Acadia will be placed on a firmer basis than heretofore.

NOTE ON THE FOSSILS FROM FRYE'S ISLAND.*

I have made a hasty examination of the specimens forwarded by Mr. Frye, and find that they tend to confirm the views already expressed regarding the age of the rocks in the central and eastern part of Charlotte County.

Owing to the great distortion of many of the forms, and the small amount of material sent, I cannot speak confidently as to the presence of several genera mentioned below.

Dalmania, *Phacops*, *Orthoceras*, 2 sp. (?); *Murchisonia*, 2 sp.; *Loxonema*, *Holopea* (?), *Lucina* (?) or *Anatina* (?), *Avicula* (?), *Leptodomus* (?), *Spirifer*, *Chonetes* (?), *Atrypa*, *Rhynchonella* (?), *Retzia* (?), *Strophomena*, *Orthis*, *Discina*, *Favosites*, *Zaphrentis*, 2 sp.; *Syringopora* (?); and there are also numerous joints of an *Encrinite*.

Among these trilobites, shells and corals, there were no broad-winged Spirifers, and the assemblage of genera seem to me to indicate a Middle or Upper Silurian age, but I am not sufficiently familiar with the organisms of these formations to speak with confidence on this point. The rock in which they occur is a shale alternating with calciferous sandstone and limestone, all very hard and full of joints.

APPENDIX E.

DUNSINANE COAL.†

[Read before the Nat. Hist. Society of N. B. 3rd February 1865.]

The members of this Society are probably familiar with the appearance of this mineral, of which a small quantity has been mined and brought to the City for trial. It is a somewhat impure variety, having layers of bituminous shale intercalated with the coal. In composition it approaches the Springhill coal of Cumberland County, Nova Scotia, as will be seen by the following analysis:—

* See Report, page 39. These fossils reached us at too late a date to allow of their complete determination.

† This seam is on or near land owned by Messrs. Light, Murdock, and Shives.

	Dunsinane.	Springhill.*
Moisture,	1.3	1.8
Volatile combustible matter,	28.9	28.4
Fixed Carbon,	52.9	56.6
Ash,	16.9	13.2
	<hr/> 100.0	<hr/> 100.0

Specific gravity of Dunsinane Coal, 1.466.

As the sample was taken from near the surface, a few per cent. in addition to the "Volatile matter" and "Fixed Carbon," may be secured at the expense of the (chocolate brown) "Ashes," from specimens taken at a greater depth.

The locality from which the mineral comes is under the flank of a hill opposite Piccadilly Mountain, and only half a mile from the European and North American Railroad, and will not be far from a tongue of the "Coal Measures," which is represented on Dr. Robb's Geological Map as entering the valley of the Kennebeckasis from the east. The existence of true *Coal Measures* over the area in question is, however, open to doubt; while the surrounding country resembles in its contour that part of the valley which is covered by the *Lower Carboniferous formation*. Between the layers of the coal from Dunsinane, one meets occasionally with fish scales of the *ganoidal* type, and these, it is well known, are very abundant in the Lower Carboniferous, both of this and the neighbouring Province. The question could probably be determined by an examination of the plants which accompany this coal, and more surely by a properly conducted examination of the place. Our present knowledge of the district would, however, lead us to suppose that it is underlaid by the formation last mentioned, and although this group of strata is usually barren of *workable* coal seams, it is not always so, for in Scotland and on the continent of Europe, large quantities of coal are taken from it every year. A thorough search may reveal deposits of the mineral sufficiently large to be of economic importance, for the character of the sediments in the *Kennebeckasis valley* is not by any means such as to forbid their occurrence. Owing to the settled character of the country, and the excellent facilities for transportation, such coal seams would be a great benefit, both to the districts around and to the manufacturing interest in and about the City.

Saint John, 3rd May, 1864.

G. F. M.

* Acadian Geology.

ADDENDA.

Page 14. In placing the Saint John Group as equivalent to the Potsdam or Primordial and Quebec Groups, the Primordial *Period* (of Dana) is to be understood, including the Calciferous Epoch and possibly a part of the Chazy. That portion of the Saint John Group yielding fossils, is, according to Mr. Hartt, truly Primordial, but in other portions of the group, Calciferous and Chazy beds *may* be represented, establishing the comparison with the Quebec Group of Canada.

Page 27, (5 lines from the bottom.) The Sand Point beds, before supposed to be continuous with those of Long Island, have been ascertained to be distinct, appertaining to the Portland Group.

Page 38. The name "Subcarboniferous Series" in this Report has been used as equivalent to "Lower Carboniferous" or "Lower Coal Formation" of Dawson. The former term is that employed in the "Manual" of Prof. Dana, but I share in the objection which has been urged against the use of the word Subcarboniferous, as implying something of uncertain age, lower than the Carboniferous. Widely different as are the two series in New Brunswick, they are still so intimately connected, especially in Albert and Westmorland Counties, that it is very difficult if not impossible to separate them.

Page 105. *Albert Coal*.—In confirmation of the view here advocated, that the substance called *Albertite* is derived from *bitumen*, and is of Lower Carboniferous age, I am happy to be able to add the testimony of Principal Dawson, who in a letter to myself, after a perusal of the preceding Report, states, that, from his later visits to the locality, he has become convinced of the fact that the deposit is a *vein*. The same distinguished authority, however, inclines to the belief that the bitumen may have been derived from *vegetable* rather than animal matter, and that the former may have existed as a *mucky* mud, carried by streams from swampy districts, and settling in quiet waters. In such *vegetable mud*, he observes, which may be seen at the outlet of swamps, the vegetable matter is always finely comminuted.

Page 126. In the note at the foot of this page it is not intended to convey the idea, that the views set forth as to the succession of events in Cenozoic Time are *entertained only* by Mr. Matthew, but merely that he is here relating his own results, and not those of our party collectively. Other eminent naturalists maintain the same opinions as those here advocated.

CORRIGENDA.

Page 12, line 9, for *is* read *are*.

Pages 17, 19 and 89, for *Sandy Point* read *Sand Point*.

Page 20, for *Queen's Lake* read *Quinn's Lake*.

Page 23, line 9, for *nominally* read *normally*.

Page 23, line 22, for *traps, forming* read *traps and tufa, forming*.

Page 25, (middle) omit the words "*if not wholly*."

Page 101, (17 lines from bottom,) for *were originally referred* read *was originally referred*.

Page 123, line 9, for "*period of the New Red Sandstone is alone represented in New Brunswick,*" read *the period of the New Red Sandstone is alone known to be represented in New Brunswick, although it is possible that Jurassic strata may also exist among the Sandstones now to be described.*

Letter from Professor Bailey to the Honorable the Provincial Secretary.

University of New Brunswick,

Fredericton, 1st May, 1865.

SIR,—I have the honor to lay before you a few Copies of a Report prepared by myself, and entitled “Observations on the Geology of Southern New Brunswick.”

In presenting this Report to be submitted to the House of Assembly, I desire to call your attention to the objects aimed at in its preparation, and to offer a few suggestions as to the advantages to be derived from a further prosecution of the same work.

By a vote of the House of Assembly at the last Session, an appropriation of \$500 was made to defray the expenses of a Geological Survey, of which, as then stated and understood, I was to have the charge. In accordance therefore with directions received from the Government, I was employed from ten to twelve weeks during the Summer of 1864, being assisted in my undertaking by two most talented geologists and natives of the Province, Messrs. G. F. Matthew and C. F. Hartt of St. John, gentlemen whose scientific contributions have earned for them a most enviable reputation among European, as well as American naturalists. The cost of the survey for the time above stated did not exceed the sum of \$300.

The object more especially aimed at by our party has been to thoroughly investigate the geological structure of Southern New Brunswick; to ascertain the exact limits of distribution, the character, thickness, agricultural capabilities, and useful minerals of each formation, represented in the districts studied. While not neglecting the opportunities offered for the discovery of new mineral deposits, (several of which will be found alluded to in our Report,) our aim has been rather to establish which series are metaliferous, and which otherwise, to mark the position and extent of each, and to give such facts and explanations as shall tend to develop the mineral resources of the Province, and be a guide for all future inquiry in this direction. These results will be found embodied in the carefully prepared Map and Sections accompanying the Report, and are fully detailed and explained in the body of the Report itself. Among other important conclusions, the following may be here alluded to:—

1. The determination of the age, character and distribution of the great iron and copper-bearing series of the Bay Shore, of which the Vernon and

other copper mines form a part. This series has been examined with great care, and its value and extent fully established.

2. The age and origin of Albertite, with the distribution of the Albert shales, the occurrence of oil-bearing strata and springs of Petroleum.

3. The discovery, confirmed by undoubted evidence, of the age of the Saint John Group, as equivalent to the great Primordial or Quebec Group of Canadian and American Geologists, a discovery made *solely* by our party, and of which Professor Dana, of Yale College, New Haven, one of the most eminent of living Geologists, in a letter to myself, dated 31st March, 1865, has said, "The discovery is a grand one, full of interest to Europe as well as America."

During the past season, our work was mainly confined to the four Counties of Saint John, King's, Queen's, and Albert. It is our desire to carry on the same observations to the westward, into the County of Charlotte, with a view to the determination of the actual age, extent and value of the metaliferous series which there enter the Province from the State of Maine.

In the pursuit of this object we would be greatly benefited by the assistance of Professor C. H. Hitchcock, Geologist to the State of Maine, Professor Verrill of Yale College, Professor Agassiz of Cambridge, and probably Professor W. B. Rogers, late State Geologist of Virginia.

Should it be thought advisable to entrust to our hands further labor in this direction, we would desire to ask no further appropriation than that necessary to meet the actual expenses of the survey, probably not exceeding the sum of three hundred dollars. Mr. Matthew has signified to me his readiness to accompany me, asking no other compensation than that necessary to ensure him against personal loss.

A work carried on in the manner indicated, would not only be of direct value in the development of the wealth of the Province, but from the circumstance of all specimens collected, being retained *in* the Province, and moreover made directly useful by imparting the information so gained to the youths who attend the Provincial University, would derive a greatly increased interest and value.

I may be permitted to conclude by saying, that our work has been so far accomplished by the assistance and under the direct supervision of Professor Agassiz, Principal Dawson of Montreal, and Professor Hunt of the Geological Survey of Canada, and has met with their warm approval. The same gentlemen would, no doubt, continue to assist any further labors in this direction. From the second named and most distinguished authority, I am permitted to quote the following lines contained in a letter to myself after a perusal of the Report now submitted. Dr. Dawson thus writes:—

"I am *very much pleased* with the systematic and careful manner in which the work is done up, and regard it as by far the most important contribution yet made to the Geology of the interesting and very complicated region to which it refers."

Should any further work be entrusted to our charge, (for which as before stated, we desire no compensation,) I can only assure you that we will endeavour to make it as thorough, as reliable, and as generally useful, as may be in our power.

You would greatly oblige me, Sir, by bringing before the consideration of your associates in the Government, and also before the House of Assembly, in whatever manner you may deem to be proper, the substance of the preceding explanations and proposals.

I have, &c.

(Signed)

L. W. BAILEY,

Prof. Chemistry &c., University New Brunswick.

Hon. A. H. Gillmor, Provincial Secretary.

APPENDIX VIII.

A

PRELIMINARY REPORT

ON THE

GEOLOGY OF NEW BRUNSWICK,

TOGETHER WITH

A SPECIAL REPORT

ON THE DISTRIBUTION OF THE

“QUEBEC GROUP”

IN THE PROVINCE.

BY

HENRY YOULE HIND, M.A., F.R.G.S.

(LATE PROFESSOR OF CHEMISTRY AND GEOLOGY IN THE UNIVERSITY OF TRINITY COLLEGE, TORONTO.)

Author of “Narrative of the Canadian Exploring Expeditions in Rupert’s Land,”
“Explorations in the Interior of the Labrador Peninsula,” &c. &c. &c.

FREDERICTON.

G. E. FRENETY, PRINTER TO THE QUEEN’S MOST EXCELLENT MAJESTY.

1865.

Fredericton, January 16th, 1865.

SIR,

I have the honor to present "A preliminary Report on the Geology of New Brunswick," including a Special Report (Chapters VIII. & IX.) on the probable distribution of the "Quebec Group" within its limits, according to instructions which I had the honor to receive from His Excellency the Administrator of the Government on the 9th July 1864.

With a view to avoid unnecessary recapitulation, I have so arranged the Reports, that the description of the 'Quebec Group' occupy their proper places in a general outline of the Geology of the Province.

In the Introductory Chapter I have given a brief and concise summary of the results of the season's work.

The following Maps accompany the written descriptions :—

I.—A General Geological Map of the Province, showing the probable limits of Formations.

II.—A Plan of the exposed Antimony Veins in Prince William Parish, on the property of the Brunswick Antimony Company.

III.—A Plan of the Letite Copper Mine, (Wheal Louisiana,) showing the structure of the Rocks in the Mascabén Peninsula.

IV.—A Plan of the Vernon Copper Mines, showing the structure of the Rocks on that part of the Coast of the Bay of Fundy.

V.—Section of the Carboniferous Outlier in the Valley of the Tobique.

I have the honor to be,

Your obedient servant,

HENRY Y. HIND.

The Hon. S. L. TILLEY,
Provincial Secretary.

CONTENTS.

INTRODUCTORY CHAPTER. Page ix.

CHAPTER I.

LEADING GEOGRAPHICAL FEATURES OF THE PROVINCE.

Early Political importance of the "Highlands" of New Brunswick—Political importance of a Name—Origin of the name 'Acadia'—The Height of Land, or Highlands of New Brunswick—Elevation of the Highlands—Blue Mountain, view from—A night on Blue Mountain—Section from Miramichi Lake to the Restigouche—Mr. Sandford Fleming's Section—Section on the Royal Road, one hundred miles—Subordinate Mountain Ranges—Section from the Mouth of Goose Creek to Sussex Vale—Coast Section across the Basin occupied by the Carboniferous Rocks—Major Robinson's Survey—The Rivers of New Brunswick—The Saint John—Origin of name—Rise of—The Grand Falls—Height and descent of—General character of—The Restigouche—Early notice of—Mr. Richardson's Description of, to the Mouth of the Patapedia—The Coast Line—Bay of Chaleurs—Miscou Island—The White Whale—The Walrus—Bay of Fundy—The Tides—Depth of the Bay—The Cumberland Basin and Bay Verte Peninsula—Change of Coast Line. 19

CHAPTER II.

GEOLOGICAL SKETCH OF THE PROVINCE.

Nomenclature—Necessity for a uniform nomenclature—Nomenclature adopted by Sir W. E. Logan—The Sedimentary Rocks of New Brunswick—Economic materials they contain—The CENTRAL GRANITE BELT—The age of the Granite—Its character—Localities where it is seen—On the Nipisiguit—At Gulquac Lake—Long Lake Portage—On the South West Miramichi—Does not occur in the form of a continuous broad belt; but in several narrow belts—The Granite on the Saint John, occurs also in narrow belts—On the Frontier—Length and breadth of the Granite axis—Its importance—Geographical and Geological features compared—The Southern Granite Belt—Its mode of occurrence in the Southern Range—On the Magagnadavic—Breadth of the Granite in the Northern Belt—Occurs in Elgin Parish—Origin of the Granite—It is probably an altered Sedimentary Rock—Professor Hunt's views—Upper and Middle Silurian Series—Devonian Rocks—The Carboniferous Series. 39

CHAPTER III.

THE CARBONIFEROUS SERIES.

Area occupied by this Series—Possible extent of the true Coal Measures—Distribution of the Series in New Brunswick—The Central Area—The Tobique Outlier—The Bay of Fundy—On the Restigouche and Bay of Chaleurs—Details of the Eastern Coal Field—The Lower Carboniferous—The BOVAVENTURE Formation—Its Distribution

—The Copper Ores of Bathurst—Origin of—Dependence of their existence on the vegetable matter in the Sandstones—Section near Bathurst—Paucity of life in the Bonaventure formation—Absence of Coal—Improbability of finding extensive deposits of Copper in this Rock—The presence of the Metal depends upon the presence of organic matter—General origin of similar deposits—The TOBIQUE OUTLIER—Description of the Rocks on the Tobique—The Plaster Cliffs—Succession of Rocks in the Tobique Valley—Economic Materials in—The Limestones of the Tobique compared with others in the Province—Comparison between the Tobique Rocks and those of Albert County—Woodstock Conglomerate—Analysis of. 54

CHAPTER IV.

THE CARBONIFEROUS SERIES—(Continued.)

The Central Triangular Area—Dr. Gesner's views—Dr. Robb's views—Mr. Henwood's opinions—Personal examinations—Dana and Dawson's subdivision of Carboniferous Rocks—Section in New Brandon—Lower and Middle Formation—Synopsis of the Flora of the Carboniferous Rocks of New Brunswick—The Flora of the Upper, Middle and Lower Rocks of the Series—Productive Coal Measures on Grand Lake—Probability of Coal being found in New Brunswick—Grand Lake Coal—Quantity raised—Section of Rocks from Oromocto Creek toward the Douglas Hills—True Coal Measures in the Valley of Salmon River—On the Richibucto—True Coal Measures probably extend from Grand Lake to the Gulf—The Valléys of the Kennebecasis and Petitcodiac—Section in Albert County and Westmorland—Section north of Norton Station—Review of what is known respecting the Carboniferous Rocks of New Brunswick—Value of Gypsum and Limestone—Bituminous Shales—Life and Climate during the Carboniferous Period. 69

CHAPTER V.

THE ORIGIN OF ALBERTITE.—THE ALBERT SHALES.

Geological age of the Albert Shales—They lie at the base of the Carboniferous Series—Disturbances in Albert County—Anticlinal and Synclinal axes—Faults—Section from Albert Mine to Cape Demoiselle—At Taylor's Mill Site—At the Big Cape—On the Tramway—At Hillsborough Village—Bituminous Shales—ALBERT SHALES—Area over which they are found—Anticlinal axes in Albert and King's Counties—The Albert Mine—Character of the Mine—Observations in the Mine—Faults and Disturbances—An Overlap—Dr. Robb's and Professor Taylor's views—Dr. C. T. Jackson's views in 1850 and in 1851—Reasons why opinions were discordant—Professor Taylor's comparisons—Professor Bailey's views in 1864—Origin of Albertite—Albertite formerly a liquid—Crushed Albertite—Two periods of injection—Professor Hunt's views with regard to Bitumens—Albertite an inspissated Petroleum—Localities where Albertite is found—It comes originally from underlying Devonian Rocks—United States Commissioner of Agriculture on Albertite—Albert Shales—A source of coal oil—Importance of the Albert Shales—Gas regenerating furnaces—Petroleum Springs in Albert and Westmorland—Conclusions with reference to Albertite—Composition of this substance. 85

CHAPTER VI.

THE DEVONIAN SERIES.

The Valley of the Restigouche—Upper Silurian and Devonian Rocks—Area occupied by the Devonian Rocks in this Valley—Devonian Rocks on the Bay of Fundy—Age of the Rocks—Extent of the Basin—The Devonian Rocks of Saint John—The Flora of the Devonian Rocks—The richness of this Series in Mineral Wealth—Iron Ores—Copper Ores—Origin of Petroleum—Source of the Albertite—Source of the Bituminous or Albert Shales—The Vernon Copper Mines—Origin of Metalliferous Veins—Segregated Veins—Gash Veins—True Veins—Origin of True Veins—Lead Ores—Argentiferous Galena—Erroneous impressions which prevail with respect to the percentage of Silver in Argentiferous Galena—Description of the Vernon Mines near the Mouth of Goose Creek—Description of the Rocks on the Coast—Red Conglomerates, Epidotic Traps and Plumbaginous Slates—Green Conglomerate Slates—General arrangement of the Rocks—Intrusive Traps—Copper-bearing Traps—Newer Traps—The Sedimentary Rocks—Conglomerates and Porphyries—Steatitic Rocks—The Copper Lodes—The Peacock Vein—Fissure occupied by—Width of the Vein—Veinstone, Bitter Spar and Quartz—The Levels—The Green Vein—Occurs in a line of fault—Extension eastward of the Copper-bearing Traps. 111

CHAPTER VII.

THE UPPER AND MIDDLE SILURIAN SERIES.

Their Boundaries in the Northern part of the Province—The upper part of the Series occurs at Cape Bon Ami—On the Upsalquitch River—On the Tobique—On the Saint John—The Middle, on the Bay of Fundy—Section at Cape Bon Ami—Honestones—Fossiliferous Limestones—Upsalquitch Lake—The Grand Falls—The Upsalquitch and Restigouche Rivers—Mountainous character of the Country—Swallow-tailed Butterflies—Wall of Trap—The Drift—Indian Superstition—Upper Silurian Rocks on the Restigouche—On the Upsalquitch—Argillites on the Tobique—Honestones—Uniformity in the Rocks on the Lower Tobique and Upper Upsalquitch—The Saint John—Hydraulic Limestones—The Grand Falls—Description of—The Gorge—Terraces—The Saint John above the Grand Falls to the Province Line—Upper and Middle Silurian Rocks on the Bay of Fundy—The Arisaig Series—Lead Ores on Campo Bello—Frye's Island—The Saint George Peninsula—Wheat Louisiana—Letite—Description of the Mascaben Peninsula—Section on the Peninsula—Trap and Slate Series—Hornblendic Slate—Fractures and Dislocations—The Main Fissure—The Mine—The Windlass Shaft—Subordinate Lodes—Frye's Island—Probably Middle Silurian—Barytes—Uses of—L'Etang—Limestone of. 127

CHAPTER VIII.

THE LOWER SILURIAN SERIES.—THE "QUEBEC GROUP."

The Metalliferous Rocks in Canada and the United States—Sir W. E. Logan's discoveries—THE QUEBEC GROUP—Importance of the Quebec Group—Economic Minerals of the Group—Age of the Group—How brought to the surface—Origin of the Metals it contains—The Quebec Group in NEW BRUNSWICK—Its Northern Boundary—Its prolongation into Maine—Probable breadth of the Quebec Group in New Brunswick—

Influence of the Granitic Belts on these Rocks—Its development on the Nipisiguit—Black Slates on the Nipisiguit and near Dumbarton Station—Copper Ore at the Grand Falls—Golden-hued Micaceous Schists—Feebly Auriferous Copper Ores on the Nipisiguit—Red Shales, with Iron and Manganese and Copper Ores, on the Nipisiguit—On the Campbell River—The Beccaguinic—The Shiktehawk—At Jacksontown, west of the Saint John—Near Boiestown—On the Tattagouche—Folds of the Strata on Campbell River—Probable limit of the Group about the Nictor—Upper Silurian Slates on the Nictor or Little Tobique—Jaspersy Rocks on Campbell River—Red and Green Porphyries on the Serpentine—Ores of Metals on Campbell River—Iron, Manganese, Nickel, Copper, &c.—Diorites—Epidote—GEOGRAPHICAL DESCRIPTION of the Country south of Tobique Lake—Milpagos Lake—Gulquac Lake—Granite Ridges—Beaver Dams—Long Lake—Milnagec Lake—Portage to the Little South West Miramichi Lake—Miramichi Lake, (Little South West)—Granite Boulders—The Magaguadavic to Roix Station—Upper Falls of the Magaguadavic to the Lower Falls—Characteristic Strata belonging to the Quebec Group—GNEISS; ANORTHOSITES; DIORITES; EPIDOSITES; MICA ROCK; MICA SCHISTS; ARGILLITES; DIALLAGE ROCK; HORNBLLENDE ROCK, with GARNETS; MAGNETIC IRON IN DOBORITE; COPPER PYRITES; OPHIOLITES, (Serpentines); STEATITES; CHLORITES; MAGNESITES; DOLOMITES; LIMESTONES; DEPOSITS OF SILICA. 143

CHAPTER IX.

THE QUEBEC GROUP—(Continued.)

Metalliferous Deposits in the Quebec Group of New Brunswick—Iron, Manganese, Copper, Antimony, Nickel, Lead, Zinc, Gold, Silver—Origin of the metallic deposits in this Group—Professor Sterry Hunt's Views—The Woodstock IRON ORES—Description of the Ores—Chemical Composition—Properties of the Iron—The Woodstock Iron Works—Opening for capital and enterprise in the working of these Iron Ores—Their extensive distribution—Their development on the east side of the Saint John—On the Beccaguinic—Their associations with limestones for fluxing, fuel for smelting, labour, and their occurrence in a fine agricultural country—Their occurrence on the Shiktehawk—Three undulations on the east side of the Saint John have brought the ores to the surface—Vast importance of these ores—Native silver in a jasper boulder on the Shiktehawk—MANGANESE AND COPPER ORES—On the Nipisiguit, Tattagouche, Campbell Rivers, Bull's Creek—Saint John—Professor Hunt's views respecting the origin of Copper in the deposits of the Quebec Group—ANTIMONY ORES—The ores of Prince William Parish—Characters of the Dislocations—The Pits—Probable extent and richness of the ore—NICKEL—COPPER—Production and uses of Antimony—LEAD ORES—ZINC ORES—Sequence of the strata in Canada—ISLAND OF ORLEANS SERIES—PHILLIPSBURG SERIES. 160

CHAPTER X.

SURFACE GEOLOGY.

General absence of thick deposits of Boulder Drift in the Province—Local origin of the Boulders—Absence of Laurentian Boulders—In Gaspé—Innumerable multitude of Boulders south of the Granitic Belt—General absence on the northern side—Boulders near Fredericton—Origin and course of these Boulders—The country of Boulders—The Labrador Peninsula—Agents in the distribution of the Boulders—Glacial Ice—

Striations—General direction in this Province—Common over the entire Province—Glacial work—Lake George—Bear Lake—West of Oromocto Lake; down the Magaguadavic—Remarkable formation of the western extremity of the Coal Measures—Oromocto Lake Escarpment—Table of Glacial Striæ in New Brunswick—Progress of a Glacier—Thickness of the glacial mass once covering the Province—Agassiz on the thickness of the ice during the Glacial Period—Dr. Dawson's views—Probable elevation of the Continent during the Glacial Period—Glacial Lakes—Escarpments—Dr. Rink's experience in Greenland—Conditions under which Glaciers are formed—Zones of Moistures—Glacial Zones—Notice of Agassiz's theory of an Ice Cap—Glacial phenomena may be common to all geologic ages—Difference between Sea Coast escarpments and Glacial escarpments—Action of Glacial Rivers—Phenomena of Glacial Rivers in Greenland—Glacial Rivers excavate rocks and form escarpments—Escarpments may be formed at any level—A glacial mass cuts its way into a slope, forming an escarpment continually increasing in elevation—The valley of Lake Ontario excavated by Glaciers—Glacial Striæ show only the last record of the moving mass—Lake Basins and many escarpments show the work they have done—Remodelling of Glacial work—Lake Basins—Origin of certain Lakes in New Brunswick—Valley of the Saint John near Fredericton—BEACHES and TERRACES—Marine Terraces—On the Bay of Fundy—Post Pliocene Marine deposits—Modern elevations and depressions on the coast—Extensive upthrow west of the Saint John—Glacial Lake Terraces—Contour Lines at the Mouth of the Nerepis—Terraces opposite Gagetown—Contour Lines and Terraces near Fredericton—Alluvial Terraces—Boulder Clay in the bed of the Saint John—Sections of the alluvium on the Banks of the Saint John near Fredericton—Table of Drift Islands which have escaped denudation—Terraces of Lake Superior, &c.—Origin of—The GRAND FALLS of SAINT JOHN—Origin of—A Valley of erosion—The Tidal Falls at the mouth of the Saint John—Probably a valley of erosion—Early account of the "Falls"—"Horsebacks"—Action of Rivers on their banks—Influence of the motion of the Earth. 182

CHAPTER XI.

ECONOMIC MATERIALS IN THE DRIFT.

BOG IRON ORE or LIMONITE—Its formation—Its distribution—Importance of the Ore in Canada—The St. Maurice Forges—WAD or BOG MANGANESE—Principal Ores of—Its use in the Arts—Its use as a material for separating Gold from Quartz Sand, or Clays—Its use in the separation of Silver—SHELL MARL—KAOLIN for Pottery—CLAYS for Bricks and Pottery—MOULDING SAND—BLUE PHOSPHATE of IRON—GOLD—Its distribution in Auriferous Drift in Canada—In Glacial Drift—Mode of washing the Drift—The Hydraulic process—The Hydraulic process in California—Experiments on the River du Loup in Canada—Distribution of Gold in the Drift of New Brunswick—I. On the Upper Upsalquitch—II. The Nipisiguit—III. Campbell River and Long Lake—IV. The Serpentine—V. Blue Mountain Brook—VI. The Little South West Miramichi—VII. Springfield—VIII. Between Hopewell and Golden Mountain—IX. Dutch Valley Road—Conclusions—MISCELLANEOUS MATERIALS NOT IN THE DRIFT—Plumbago or Graphite—Dolomites—Origin of—Hydraulic Limestones—Composition of—Properties of—Grindstones—Probable Indian Relics on the Atlantic Coast—Professor Chadbourne's Account—Account in Sewall's Ancient Dominions—Mr. C. H. Hitchcock's Description—Mr. Morse's Account. 213

CHAPTER XII.

THE AGRICULTURAL CAPABILITIES OF CERTAIN DISTRICTS.

NOTES ON THE CLIMATE.

Importance of Limestone—Limestone Rocks produce good Soils—Progress of Settlement in the Laurentian Region of Canada is on the Crystalline Limestones—In New Brunswick the presence of a fine Hardwood Forest indicates the proximity of Limestone—Area of first class Land in the Province—Aids to Agriculture—Manures—Lime—Quantity manufactured in New Brunswick—In Maine—Gypsum—Some Localities where Limestone is found in the Province—Some Localities where Gypsum is found in the Province—Trap debris—Phosphate of Lime—Fish Manures—Its manufacture in France—In Newfoundland—Professor Hunt's descriptions—Manufacture at Gaspé—Value of the Fish Manure manufactured at Gaspé—Importance of the manufacture of Fish Manure on the Gulf Coast.

NOTES ON THE CLIMATE OF NEW BRUNSWICK.—The character of the Winter Season—Comparative Table, showing the mean opening of Rivers, Canals, and Harbours, from St. John to the Straits of Mackinaw—Duration of Navigation on the St. Lawrence, compared with the St. John—Table showing the mean Winter temperature of St. John, Quebec, and Montreal—Table of Annual means of Temperature, &c., at St. John, by G. Murdock—Table of Monthly and Seasonal means of Temperature at St. John, by G. Murdock—Table of mean results at Toronto—Table of minimum and maximum temperatures at Fredericton, by the Rev. Dr. Brooke—Comparative Table, showing the difference between some points in the Climates of St. John and Fredericton, by the late Dr. Robb—Table showing the mean annual temperature of St. John, Fredericton, Quebec, Montreal, and Toronto.

CONCLUSION.—The advantages of a systematic Geological Survey.

APPENDIX.

- I.—ORIGIN of the NAMES of certain RIVERS and PLACES in NEW BRUNSWICK, together with MICMAC and MILICETE names for some COMMON THINGS.
- II.—NAMES of PLACES and RIVERS derived from the ABENAQUIS Language.
- III.—ENUMERATION of the MAMMIFEROUS ANIMALS ascertained to exist in or on the Coasts of NEW BRUNSWICK.
- IV.—ENUMERATION of the BIRDS of NEW BRUNSWICK, with a notice of those which winter in the Province.
- V.—ENUMERATION of the FISHES of NEW BRUNSWICK.
- VI.—Fossiliferous Marine Clays of Maine and the St. Lawrence compared.
- VII.—TABLE showing the Value of the Imports and Exports, being the Produce and Manufacture of the Colony, of MINERALS, ORES, and METALS, manufactured and unmanufactured, during the years 1861, 1862, and 1863.
- VIII.—MINING LICENCES—Rules and Regulations.

INTRODUCTORY CHAPTER.

The Geology of New Brunswick has formed the subject of four Reports by the late Dr. Abraham Gesner, written during the years 1839 to 1842 inclusive, twenty three years having elapsed since the date of Dr. Gesner's last official contribution to our knowledge respecting the Mineral resources of the Province.

In 1849 the late Dr. Robb contributed an admirable resumé of known facts connected with the Geology of New Brunswick to Professor Johnston, who was engaged by the Government during the same year to report on the Soils of the Province, and their capabilities for agricultural purposes. Dr. Robb's communication was accompanied by an excellent Geological Map, compiled, as he himself states, from the Reports of Dr. Gesner, Dr. Jackson's Reports on the Geology of Maine, Sir Charles Lyell's Travels in North America, and his own personal observations and enquiries.

In 1851 Dr. Robb, in conjunction with Professor Taylor, prepared a Report on the "Asphaltum Mine at Hillsborough," which all subsequent experience during the past thirteen years has shown to be a correct exposition, as far as it goes, of the Geology of the Albert Mine.

Dr. Dawson, of McGill College, Montreal, in conjunction with Sir Charles Lyell, has established the true age of the Albert Shales, and in his 'Acadian Geology' a portion of Albert County is especially noticed, and some of the rock formations on the coast of the Bay of Fundy.

Dr. Dawson has subsequently written some very valuable papers on "The Flora of the Carboniferous Period in Nova Scotia," and "The Flora of the Devonian Period in North Eastern America," in which important references are made to New Brunswick rocks.

In August 1863, Mr. G. F. Matthew of Saint John, published in the Canadian Naturalist and Geologist, a most creditable and able Paper, entitled "Observations on the Geology of Saint John County, N. B.,"; and in 1864, Professor Bailey, of the University of New Brunswick, communicated to His Excellency the Lieutenant Governor, a very interesting and well written "Report on the Mines and Minerals of New Brunswick." The same gentleman has also published in the Canadian Naturalist and Geologist for April 1864, a Paper entitled "Notes on the Geology and Botany of New Brunswick,"* with a Map of the country on the course of the rivers between the mouth of the Tobique and the mouth of the Nepisiguit.

These contributions to the Geological bibliography of New Brunswick, have been frequently referred to in the following pages, together with others which are enumerated either in notes of reference or in a list of works consulted, given at the close of the introductory Chapter.

* Read before the Natural History Society of New Brunswick 12th February 1864.

In May 1864, after an interview with Sir W. E. Logan, the Director of the Geological Survey of Canada, I addressed a letter to that eminent Geologist, soliciting his co-operation and that of Professor Hunt and Mr. Billings, in relation to the rocks and fossils of New Brunswick, partly with reference to my contemplated preliminary explorations, and partly in anticipation of any future action that the Government of New Brunswick might be disposed to take with regard to a complete Geological Survey of the Province.

The answer of Sir W. E. Logan, together with my communication to him, are appended,* and no words from my pen are necessary to show the vast advantage which must result to New Brunswick, from having the opinion of Sir William Logan and his associates on the rocks of the Province; but I should not do justice to my own feelings if I were to permit this public opportunity to escape me of expressing a grateful sense, as far as I am concerned, of the disinterested kindness of Sir William Logan, and the gentlemen of the Canadian Geological Survey, or to record my admiration of a zeal for Science alone which induces those gentlemen to undertake a laborious task, for which they ask no other recompense than that which Science herself can give.

In the preparation of my preliminary Report, I have frequently had occasion to scrutinize the labours of the late Dr. Robb; and here I venture to express, not only a very high opinion of the value of the work he has left behind him, but a strong appreciation of his trustworthy observations, and of his scrupulously conscientious record of facts. Through the kindness of his brother, Mr. Charles Robb, of Montreal, I have been permitted to peruse his manuscript notes on the geology of certain portions of the Province. Although many of these were made thirteen to sixteen years ago, and long prior to the important discoveries of the past decade, yet they manifest views, especially in relation to the once vexed question of the nature of Albertite, which he would probably long since have successfully developed, had the Almighty been pleased to have prolonged his life.

It now remains for me to state in general terms the results of the season's operations.

DISTRICTS VISITED.

I commenced my explorations on the 15th June, at Dalhousie; proceeding thence to Campbelltown on the Restigouche, and having engaged Indians there, ascended that river to the mouth of the Upsalquitch, which was traversed to its source, then crossed over to the Nepisiguit, and continued on down stream to Bathurst.

After spending a few days in the vicinity of Bathurst, I travelled across the country to Chatham, and thence to Fredericton.

In a letter addressed to the Provincial Secretary, I communicated some of the results of the exploration up the Upsalquitch and down the Nepisiguit,

* Vide Letters I. and II. at the close of this Chapter.

suggesting at the same time a further exploration of the Quebec Group of rocks which I had ascertained to have a breadth in the district examined of from thirty six to forty miles.*

His Excellency the Administrator of the Government in Council, was pleased to give instructions that the suggested sections across the Quebec Group should be made without delay.

From Fredericton I proceeded to Prince William, thence to Woodstock, and *via* the Shiktehawk and South West Miramichi, to Boiestown.

I then started *via* Woodstock for the Tobique, and having procured Indians and canoes, ascended that river as far as the mouth of the Gulquac, made a portage of twenty miles to Tobique Lake, explored the undescribed and unmapped Gulquac and Millpagos Lakes, and then portaged to Long Lake. Leaving the canoe at the head of that fine sheet of water, I took two Indians and made a portage of eight miles through forests innocent of lumbermen or indeed of "white men" of any description, to the Little South West Miramichi Lake, and descended the river issuing from that lake until I came to sedimentary rocks in place.

Returning to Tobique Lake, I went with "shoed" canoes down Campbell River, ascended the Serpentine as far as practicable, the water being unusually low, and returned to the Nictor or Forks of the Tobique *via* the right hand branch of the river. An ascent was then made up the Little Tobique for a few miles, and subsequently the main river was descended as far as Blue Mountain. Again, taking two Indians, and leaving the canoes in charge of a third, I made a traverse to the summit of Blue Mountain 1650 feet above the sea. The object of this traverse was to ascertain the southern limits here of the Carboniferous Outlier, which has converted the valley of the Tobique into a fertile and beautiful region, capable of sustaining an agricultural population of one hundred thousand souls. Slowly descending the Tobique to its mouth, I then leisurely ascended the Saint John, in canoe, as far as Little Falls, or within ten miles of the Canadian boundary line.

From Little Falls I proceeded to Quebec, thence to Montreal, where an opportunity of again examining the rocks of the Quebec Group in the Geological Museum was embraced. After remaining a week in Canada, I took the steamer from Quebec to Shediac, and from Shediac proceeded to Fredericton.

In October I visited King's County, making a section across Norton and Springfield, also, subsequently across Albert County, and from Hopewell Corners returned *via* Golden Mountain to Sussex Vale, and then proceeded to the Vernon Copper Mines, near the mouth of Goose Creek, on the Bay of Fundy. Returning thence to Fredericton, I spent two days in making up my notes, and then started a second time for the Prince William Antimony deposits, where I made a careful examination of the rocks and mapped the courses of the exposed veins, determining their relation and origin. I then crossed the country through the Harvey Settlement to Dumbarton

* Vide Letters III. and IV. at the close of this Chapter.

Station, on the New Brunswick and Canada Railway, and from this place proceeded to Roix Station, and made a section across the country to Saint George. After visiting the Upper Falls of the Magaguadavic, and making a section to the Lower Falls, I proceeded to the Letite Copper Mines, to which special attention was paid, and the probable origin of the Copper deposits in the Mascabin peninsula discovered, and the probable age of the rocks on Frye's Island; returning to Fredericton *via* Saint John. My last exploration, except in the immediate neighbourhood of Fredericton, was made in November, when the Vernon Mines on the Bay of Fundy were visited a second time, and four days spent on the coast, in an endeavour to trace the origin of the Copper deposits in that promising belt of rocks. This I found to be in certain copper-bearing intrusive traps which have a wide, and probably a very important distribution on that part of the coast.

In this general outline of journeys through the Province, every County of which I have visited except Kent, the lateral excursions from the main routes are not included.

The results of the season's work may be thus briefly expressed.

1. The QUEBEC GROUP, which is the great metalliferous formation of North America, has the following approximate breadths in the subjoined localities:—

1. Five miles from Bathurst,	20 Miles.
2. From Ramsay's Brook, southeasterly,	36 "
3. From near Nictor Lake,	"	...	44 "
4. From the Tobique,	"	...	43 "
5. From the Meduxnekeag,	"	...	38 "
6. On the New Brunswick and Canada Railroad,			24 "

Time has not permitted me to obtain the necessary data, to determine the approximate breadth of this group in the southwestern part of Queen's, Sunbury, or King's County, nor even in the south part of Charlotte County, but of its presence there, valuable evidence is not wanting.

I have paid particular attention to the circumstances under which the Albertite in Albert County has originated, and venture to hope that I have succeeded in showing,—

- 1st. That Albertite is an inspissated Petroleum.
- 2nd. That it has originated from underlying Devonian Rocks probably of the same age as those yielding the vast stores of Petroleum in Canada and the United States.
- 3rd. That there is much probability that this valuable material will be found along the summits of two anticlinal axes (Ridges), one, extending from near Apohaqui Station, through the valley of Sussex Vale, to the County of Westmorland, on a general course N. 80° E., for a distance of fifty miles; the other anticlinal having a course nearly north-east, (magnetic), (N. 48° E.) from a few miles west of Shepody Mountain, through the Albert Mine, to and beyond the Petitcodiac River.

Along the eastern anticlinal the valuable bituminous shales which yield from sixty to ninety gallons of crude oil to the ton occur in great force.

The ascertained existence of the true Coal Measures within the limits of the Province, near and probably east of Grand Lake, is highly important, and a reasonable expectation may now be entertained that workable beds of coal will be found in the areas indicated in the Chapter on the Carboniferous Series.

The view formerly entertained with reference to the granitic belt passing through the Province from the frontier of Maine to the Bay of Chaleurs, a distance of one hundred and fifty miles, must be greatly modified. Instead of its being one broad belt, as represented on the Map constructed by the late Dr. Robb, it consists of a series of very narrow belts, (at least ten in number on the Miramichi,) with schists and metalliferous slates between them. The granite belts are of Devonian age, and it is, probably, not an intrusive rock, but consists of highly altered sedimentary strata, which have been brought to the surface by a series of anticlinal folds, with strata belonging to the Quebec Group on their flanks, and between the numerous narrow belts of which the entire formation is composed.

The same remark applies to much of the granite in Charlotte, King's and Saint John Counties. They are probably sedimentary rocks, highly metamorphosed, but bearing an intimate relation to the less metamorphosed or altered rocks on their flanks.

The copper-bearing Series of Saint George and the Vernon Mines are both important, though of very different geological ages. I have shown in the case of the Saint George Mines, that the probable origin of the copper is a hornblendic schist; but do not wish to be understood to say that the trap rocks of the series are not also copper-bearing. In the Vernon Mines, the copper-bearing traps, which are there intrusive, are the source of the metal, and they extend far beyond the limits of the area examined.

The antimony deposits of Prince William, on the property of the Brunswick Antimony Company, and on a series of Leases held by Mr. Hibbard, of Saint George, and gentlemen associated with him, are valuable; and a rather lengthy description of these deposits, their origin and probable extent, will appear, fully warranted by their prospective value to the Province.

The iron ores of Woodstock have been found to come up on the north side of the main granitic axis, in at least three different belts, extending over thirty miles, and probably, with intermediate breaks, as far as the Bay of Chaleurs. On the Beccaguimec and the Shiktehawk, each belt is associated with limestone beds. They are situated in a splendid agricultural and well timbered country. On the south side of the axis they have been recognized coming to the surface in two belts.

These ores, like the manganese and copper with which they are more or less associated, are true sediments. The copper deposits of Woodstock belong to the same class, and in view of their origin, I am inclined to think that they will be found commercially valuable. The veins which have been

opened by Mr. Stephens, and partially opened by Mr. Connell, are segregations of the metal distributed through the country rock, which is apparently of the same age as the copper-bearing sediments of Canada East. Hence there is a probability that valuable beds will be discovered.

The gold which I have found to exist in the drift over a large portion of the northern Counties, and to a less extent in Saint John and King's Counties, will speak for itself. Too little, however, is yet known of the rocks of the Quebec Group in this Province to warrant the expression of an opinion as to its origin. A comparison with other countries where the same rocks occur, and are known to be auriferous, might apparently form the basis of reasonable conjecture; but gold has been found in quartz veins penetrating both Upper and Lower Silurian Rocks in Canada, and these rocks overlap one another from the Bay of Chaleurs to the Maine Boundary, and far beyond towards the Atlantic Ocean.

Although gold has been found in the drift derived from these rocks, it has not yet, to my knowledge, been discovered in quartz veins penetrating them.

I have much pleasure in expressing my obligations to many gentlemen for their courteous assistance and attention. Among others, to the Hon. John McMillan, of Campbelltown; Mr. Dugald Stewart, and Mr. Barberie, of Dalhousie; Mr. Busted, of Bourdo; Mr. Byers, of the Albert Mine; Mr. Baldwin, of Bathurst; the Hon. Charles Connell, and Dr. Connell, of Woodstock; Mr. Stephens, of Woodstock; Mr. Woodward, of Saint John; Mr. McLellan, of Hopewell Corners; Mr. Frye, of Saint George; the gentlemen in the Crown Land Office; Mr. Wilkinson, of the Board of Works; Mr. Sanford Fleming, C. E.; Mr. Burpee, C. E.; Mr. Murdock, &c., &c.

To Dr. Brooke, of Fredericton, I am much indebted for an excellent series of Meteorological observations, which he has continued uninterruptedly for a period of seventeen years.

No. I.

From Professor Hind to Sir William Logan.

(Copy)

Montreal, May 30th, 1864.

DEAR SIR WILLIAM LOGAN,—I have been commissioned by the Government of New Brunswick to make a preliminary Geological Survey of that Province during the present season, and am now *en route* to commence the work.

As there is every reason to believe that many of the formations in New Brunswick are repetitions of rocks which occur in Canada, and are of considerable economic value, I should be much obliged if you would allow me to send a complete series of whatever specimens I may collect in New Brunswick, to your address at the Museum of the Geological Survey, for comparison by yourself, Dr. Hunt, and Mr. Billings, with Canadian illustrations.

If you, Dr. Hunt, and Mr. Billings, will be so kind as to undertake the examination of what I may be able to send, and to communicate the results to me for the information of the Government of New Brunswick, I should be glad to know whether any expenses would

be attached to the transmission of the specimens, provided they become the property of the Canadian Geological Survey.

There can be no doubt that it would be a matter of great importance to New Brunswick if a complete set of specimens, illustrating the rocks of the Province, were submitted to your inspection and judgment, and I venture to hope that it would also be of advantage to the Museum of the Geological Survey of Canada to possess the specimens for the sake of comparison and study.

I am, very truly, yours,

(Signed)

HENRY Y. HIND.

Sir W. E. Logan, &c. &c. &c.

No. II.

From Sir William Logan to Professor Hind.

(Copy)

Montreal, 30th May, 1864.

MY DEAR SIR,—In reply to your letter of this morning, I beg to say that we should be happy to receive a full collection of New Brunswick specimens, including minerals, rocks, and fossils, the expenses on the transmission of which, if the collection were permanently lodged in our Museum, we would willingly defray.

The possession of such a collection would enable us to institute a comparison between the Geology of Canada and that of her sister Colony, and in some degree to make available our ascertained results in forwarding your investigations and promoting the development of her mineral resources.

The rocks of New Brunswick are only an extension in part of those of Canada, with the addition of the coal formation, and from the descriptions of Robb, Bailey, Hitchcock, and others, as well as a limited personal examination by myself, it appears to me probable that the Quebec Group, which is so important in the Eastern Townships of Canada, for its economic minerals, will be found to have a considerable development in New Brunswick.

The rocks of this Group, I need not inform you, yield, in Canada, ores of Iron, Chromium, Lead, Antimony, Copper, Nickel, Silver, and Gold, with soapstone, potstone, hones, marbles, serpentines, cement stones, building stones, and roofing slates. They are a continuation of the gold-bearing series of Georgia, Carolina, and Virginia, and come up through Maryland, Pennsylvania, New Jersey, New York, and Vermont, into Canada, passing thence into Newfoundland.

By undulations they are repeated in New Brunswick on each side of a Granitic axis, which stretches from Deer Island on the coast of Maine, to Bathurst on the Bay Chaleur, and finally present themselves on the Atlantic Coast of Nova Scotia. It is of course very important to the interests of these Colonies that the limits of the Group should be traced out in them, as much in detail as possible.

In making serviceable in the investigation the experience and practice we have acquired on the Canadian Survey, we should be only carrying out a suggestion which has already been placed before the respective Governments of these Colonies, by the adoption of which the labour of the investigation would be shortened and the cost cheapened, while a unity of design would be given to the whole subject, rendering the results, both economic and scientific, intelligible to the world with much less study than would otherwise be required.

I am, my dear Sir, very truly, yours,

(Signed)

W. E. LOGAN.

Professor Henry Youle Hind, Quebec.

No. III.

From Professor Hind to the Hon. the Provincial Secretary.

Fredericton, July 9th, 1864.

SIR,—I have the honor to inform you that I have just completed a geological exploration up the Upsalquitch River, in the County of Restigouche; also a portion of the country in the County of Gloucester, as far as the Nicadoo River.

The result of that exploration is of sufficient importance to induce me to make known to you, without delay, the character of the rock formations I recognized in position.

The rocks of the country south of the Restigouche, for about 20 miles, belong to the Upper Silurian Series, but south of a point on the Upsalquitch, near Ramsay's Brook, all the way to the Nepisiguit; the Quebec Group of Sir W. E. Logan—a most important series of Lower Silurian Rocks—forms the country.

This Group I also found to exist all the way down the Valley of the Nepisiguit, to within seven miles of Bathurst, and as far west as the Nicadoo River. About two or three miles beyond the Nicadoo, I believe it to be overlaid by the Upper Silurian Series, mentioned as occurring on the lower portion of the Upsalquitch.

The Quebec Group has a breadth of not less than 36 miles between the Upsalquitch and the Nepisiguit, I presume that it extends about ten miles south of the Nepisiguit, until it is covered by the Bonaventure formation, or base of the Carboniferous Series.

The vast economic importance of the Quebec Group is stated in the letter addressed to me by Sir W. E. Logan, of which I had the honor to forward you a copy some days since.

I searched for gold in the drift and alluvial deposits of the Upsalquitch and Nepisiguit, and found minute particles on the upper portion of the Upsalquitch, and unworn and worn fragments of dimensions from one eighth of an inch in diameter, downwards, on the Nepisiguit. The washing process was carried on in a common tin dish.

As there is every probability that the Quebec Group stretches throughout the Province, from Bathurst to the Maine Boundary Line, and beyond, in a northeast and southwest direction, it is of the greatest importance to the interests of this Province that its breadth and general extension should be ascertained without delay, and I venture to suggest that I be instructed by the Government to make two or more Sections across the formation, in order to establish approximately its area.

I have only to remark, further, that the Quebec Group, being the great Metalliferous Rock Series of the American Continent, if found to be, as I suppose, largely developed in New Brunswick, will place the prospective mineral resources of this Province in a very prominent position before the scientific world.

The cost of the exploration I suggest, would be about \$400; it could be accomplished in 50 days, and would, I think, establish the existence of the Quebec Group in New Brunswick, over an area exceeding one million acres.

I have the honor to be, Sir,
Your obedient servant,

HENRY Y. HIND.

The Hon. S. L. Tilley, M. P. P., Provincial Secretary, Fredericton.

*Provincial Secretary's Office,
Fredericton, N. B., 9th July, 1864.*

SIR,—The Administrator of the Government in Council has had under consideration your communication of this day's date, proposing to make two or more Sections across the district of country designated therein, for the purpose of ascertaining the width and extent of the Quebec Group of Rocks;—

And I am instructed to request you to make the proposed examination, and report the results to the Government at as early a date as possible.

I have, &c.

(Signed)

S. L. TILLEY.

PRELIMINARY REPORT.

CHAPTER I.

LEADING GEOGRAPHICAL FEATURES OF THE PROVINCE.

Early Political importance of the "Highlands" of New Brunswick—Political importance of a Name—Origin of the name 'Acadia'—The Height of Land, or Highlands of New Brunswick—Elevation of the Highlands—Blue Mountain, view from—A night on Blue Mountain—Section from Miramichi Lake to the Restigouche—Mr. Sandford Fleming's Section—Section on the Royal Road, one hundred miles—Subordinate Mountain Ranges—Section from the Mouth of Goose Creek to Sussex Vale—Coast Section across the Basin occupied by the Carboniferous Rocks—Major Robinson's Survey—The Rivers of New Brunswick—The Saint John—Origin of name—Rise of—The Grand Falls—Height and descent of—General character of—The Restigouche—Early notice of—Mr. Richardson's Description of, to the Mouth of the Patapedia—The Coast Line—Bay of Chaleurs—Miscou Island—The White Whale—The Walrus—Bay of Fundy—The Tides—Depth of the Bay—The Cumberland Basin and Bay Verte Peninsula—Change of Coast Line.

The geographical features of a country are greatly dependent upon its geological structure. This is especially noticed in New Brunswick, where the mountain ranges lie almost altogether within the limits of the disturbed and ancient sedimentary rocks; the elevated plateaus and gently undulating plains distinguishing nearly the entire area of the comparatively undisturbed strata of the coal field.

For this reason it may be proper to glance briefly at some of the leading geographical features of the Province, limiting the observations made to the chief mountain ranges, the rivers, and the coast line. The introduction of a few historical notices may, in the judgment of many, enhance the interest which prominent physical peculiarities generally command.

EARLY POLITICAL IMPORTANCE OF THE "HIGHLANDS" OF NEW BRUNSWICK.

The highest continuous mountain range, or "axis of maximum elevation," as it is technically termed, between Canada and this Province, with its continuation into the United States, once formed a very important subject of enquiry on the part of the Governments of Great Britain and the United States of America.*

* Report of the British Commissioners to Survey the Territory in dispute between Great Britain and the United States of America, on the North Eastern Boundary of the United States.—Blue Book, 1840.

In the Report of the Royal Commissioners appointed to investigate and report upon the respective claims of Canada and New Brunswick to the Territory ceded to Great Britain by the Treaty of Washington,* the following remarkable passage occurs, which, by the way, has recently received additional strength from the disputes relating to the Straits of San Juan.—“The want of good maps, and correct information as to the topographical and physical character of the country, have been the principal cause of the constantly-recurring disputes which have now for more than half a century occurred in this part of North America, and rendered necessary Commission after Commission for inquiry and research.”

POLITICAL IMPORTANCE OF A NAME.

It appears, however, far more singular, that a mere name, whose origin is still disputed, should have been instrumental in leading to the wars between England and France which terminated in the conquest of Canada.

The misunderstandings which arose in the construction of this expression, “all ACADIE, according to its ancient limits,”—ended in the war of 1756, and the annexation of all the possessions of France in North America to the British Empire.†

The interest in the word ‘*Acadie*,’ has been recently revived under very different circumstances to those which first drew the attention of the entire civilized world to its origin and meaning, and which gave rise to interminable controversies, and finally led to sanguinary wars.

The Province of New Brunswick having formerly been wholly or in part included within the ‘ancient limits of Acadie,’ a glance at the origin of this word may not be out of place in a geographical sketch of the country it once in part represented.

In 1603, the Sieur de Monts received letters patent, in which the word “ACADIE,” or “Cadie,” is first used as the name of the country. His grant is from the “40me degré de latitude jusqu’a 46me,” the 40th degree of latitude to the 46th,‡ thus including that part of New Brunswick which lies south of a line drawn between Fredericton and Bay Verte in the County of Westmorland.

The Boundary Commission consider the origin of the word “Acadie” to be as follows:—

“The obscurity which has been thrown in past times over the territorial extent of Acadie, that country of which De Monts received letters patent in 1603, was occasioned by not attending to the Indian origin of the name, and to the repeated transfer of the name to other parts of the country to which the first settlers afterwards removed. Even before the appointment of De la Roche, in 1598, as Lieutenant-General of the country, including those parts adjacent to the Bay of Fundy, the Bay into which the Saint Croix

* Blue Book, 1851, page 94. † Report of Commissioners on North Eastern Boundary.

‡ *Fastes Chronologiques*, quoted in Report of Commissioners on North Eastern Boundary, 1840.

empties itself was known by the Indians of the Morisset tribe, which still inhabits New Brunswick, by the name *Peskadumquodiah*, from *Peskadum*, Fish, and *Quodiah*, the name of a fish resembling the Cod.*

“The French, according to their usual custom, abbreviated the Indian name, which we sometimes, in the old records, read *Quadiac* and ‘*Cadie*,’ and at length we find it taking the general designation of ‘*Acadie*.’

“The English race have turned the original Indian name into *Passamaquoddy*, and the Indians of the district have long been by them familiarly called *Quoddy* Indians, as by the French they have been called *Les Acadiens*.”

That the word “*CADIE*,” was at one time commonly used, may be inferred from its occurrence in the *Relations of the Jesuits for 1671*.—“*Qui habitent les costes de Cadie et de la Nouvelle Angleterre*.”

Dr. Dawson, in his “*ACADIAN GEOLOGY*,” gives a rather different version of the origin of this historic name:—

“The aboriginal *Micmacs* of *Nova Scotia*, being of a practical turn of mind, were in the habit of bestowing on places the names of the useful articles which could be found in them, affixing to such terms the word *Acadie*, denoting the local abundance of the particular objects to which the names referred. The early French settlers appear to have supposed this common termination to be the proper name of the country, and applied it as the general designation of the region now constituting the *Provinces of Nova Scotia, New Brunswick, and Prince Edward Island*.”

FORMER LIMITS OF ACADIA.

The Jesuit Father, Hierosme Lallemon, writing from *Quebec* in 1659, says “*Acadia* is that part of *New France* which faces the sea, and which extends from *New England* to *Gaspe*, or more correctly to the entrance of the great *River Saint Lawrence*. This extent of country, which is fully 300 leagues, has but one name and one language.”—*Relations des Jesuits, 1659*.

In a Map by *Coronelli*, dated 1689, published at *Paris*, the Peninsula south-east of the *Bay of Fundy* is called “*Acadie*,” whilst the country north of the *Bay of Fundy* and watered by the *Saint John River*, is named “*Etechemins*,” after the Indian tribe whose hunting grounds formerly extended over that part of the Province. Under the French these were frequently separate governments. By the *Treaty of St. Germain* in 1632, “*Canada* and *Acadia* were restored to France.” By the *Treaty of Breda* in 1667, France was left with all her old possessions, as well as by the *Treaty of Ryswick* in 1697. The consequence of these frequent mutations was, that the French possessions east, west, and south of the *Saint John*, were occasionally placed under one and the same jurisdiction, which for the time went by the name of “*Acadie*.”

* The Provincial name of this fish is “*Pollock*,” and it still continues to frequent that Bay.

In 1702 war broke out again, subsequently to which came the Peace of Utrecht, in 1713, when France ceded to England for ever her rights to "all Acadie, according to its ancient limits." The misunderstandings which now arose in the construction of this expression, ended in the war of 1756, and the annexation of all the possessions of France in North America to the British Empire.*

The Abbe Ferland in his "Cours D'Histoire du Canada," states that the origin of this word is unknown, and he enumerates several compound words, being the names of places, of which it forms a part, such as Tracadie, Shubenacadie, Chykabenakdie.†

THE HEIGHT OF LAND OR HIGHLANDS OF NEW BRUNSWICK.

The height of land or "axis of maximum elevation," which formed so long the subject of dispute between the United States and Great Britain, and subsequently between Canada and New Brunswick, may be said to commence within the limits of the Province at the base of Mars Hill, an isolated twin-mountain situated close to the boundary line in the State of Maine, and about five miles from the River Saint John, in the County of Carleton. This conspicuous elevation rises 1650 feet above the sea, and it forms one in a range of numerous peaks which stretch in a northeasterly direction to the Bay of Chaleurs.

This height of land is the south branch of two great chains of highlands which come from the head waters of the Connecticut River. The northern branch lies altogether within the limits of Canada, and was formerly claimed by New Brunswick as its legitimate boundary. The southern branch, springing from the same source, traverses the State of Maine, and entering New Brunswick at Mars Hill,‡ pursues the course towards the Bay of Chaleurs already adverted to. These were the highlands formerly claimed by Canada as the southern boundary of that Province.§ The limits of the two Provinces ultimately agreed upon, do not require any particular description; they may be stated to form a line dividing the disputed territory between the highlands into two nearly equal parts.

ELEVATION OF THE HIGHLANDS.

The average breadth of these Highlands is about forty miles; the elevation of the most prominent peaks and notable points in this rugged region are given below. No Map of New Brunswick yet compiled can afford a correct idea of the geography of the southeastern portion of this Highland Belt. Innumerable lakes, with their connecting rivers, separated by high but narrow hill ranges, occur in the blank space on the Provincial Map, from

* Blue Book, 1840.

§ The area of the territory in dispute between Canada and N. Brunswick was about 10,000 square miles.

the head waters of the South West Miramichi to the Nipisiguit. The sources of some of the most important rivers in the Province are not laid down on this comparatively unexplored region, and there are very many lakes, still haunted by the beaver, seldom visited except by Indians, where even the adventurous lumberman has not yet penetrated, which cover a large area about the head waters of the different branches of the Miramichi, and the tributaries to the Tobique and Nipisiguit. As far, however, as the river courses have been laid down in this wild region, they are accurately delineated in Mr. Wilkinson's Provincial Map; and this Report will furnish the continuation of several important streams into the unmapped wilderness, about the head waters of the Gulquac, the right hand branch of the Tobique, and the Little South West Miramichi.

ASCENT OF BLUE MOUNTAIN.

On the 18th August, accompanied by some Indians, I ascended Blue Mountain on the Tobique, reaching the summit just in time to witness the setting of the sun. The scene was one of rare beauty, and the sky being cloudless during the short summer night, the moon near her full, dawn slowly breaking into daylight without mist or cloud on the mountain tops, the most favourable opportunities were offered and gladly embraced to see this part of the Highlands of New Brunswick under conditions seldom enjoyed.

The first impression produced on glancing at this extraordinary scene, was a sense of extreme isolation in the midst of the vast wilderness of forest which lay like a troubled sea far beneath our feet. The detached peaks of many mountains seemed to occupy but a small part of the wide expanse open to view, while the remote ranges, in themselves extensive and formidable barriers, were reduced to rugged lines bounding comparatively small parts of the distant horizon. Such were the Salmon River Mountains, the Twin Mountains on the Gulquac, Moose Mountain, and Mars Hill, far to the southwest; as well as the bold dividing ridge between Long Lake and a Lake at the head of the Little South West Miramichi; and Bald Mountain to the northeast. Minor peaks and ridges limiting the broad valley of the Tobique, served but to give an irregular character to the great plain they diversified.

The clearings of the pioneer settlers on the Tobique, looked like white specks in a vast ocean of dark green. The contrast between the blue outlines of the mountain ranges to the west after the sun had dipped behind them, and the golden tints swiftly gliding up the sides of ranges lying to the east, was singularly imposing; the peaks of all those sufficiently elevated to catch his last receding rays being simultaneously lit up, and then passing into comparative gloom one by one.

The solemnity of a still and cloudless night on the summit of a high mountain in a wilderness country all can understand, but it is not so simple an effort to people in imagination the splendid valley which Blue Mountain overlooks, and through which the Tobique flows like a narrow thread, with a hundred thousand souls; and yet such, perhaps, even within the lives of some who may glance at these descriptions, is the probable future of this little known but most valuable tributary to the Saint John.*

From this mountain is seen the "lowest point" described by Major Robinson, overlooking the Tobique Valley, having an elevation 1,216 feet above the sea. It is situated eighteen miles from the Tobique, to reach which a descent of 796 feet has to be made. The summit level on the opposite ridge between the Tobique and the Restigouche is 920 feet above the sea, or 500 above the Tobique, at the place where his line of section crosses that river.

From the Three Brooks to the Two Brooks, eighteen miles, the line of proposed Government Great Road from the mouth of the Tobique to the Restigouche, skirts the foot of Sisson's Ridge, "one of the finest stretches of hardwood land in the Province."†

The morning mist rising from the Tobique pointed out its course to the narrows, through which it rushes in a deep gorge before debouching into the Saint John. The whole of the lower part of the valley has once been an inland lake of great extent, and, as will be shown when the Tobique is specially described, high falls probably existed at the spot where the narrows are now situated.

The subjoined Table shows the general character of this region for a distance of 78 miles, being a series of altitudes across the country from Miramichi Lake to the Restigouche, according to Major Robinson's survey.

SECTION FROM MIRAMICHI LAKE TO THE RESTIGOUCHE.

	Height in feet above the Sea.	Distance from Miramichi Lake.
Miramichi Lake,	750	0

Height of land between Salmon River and Grand River,	1115	28½
Restigouche,	435	45

The levels obtained by Sanford Fleming, Esquire, Chief Engineer of the Inter-Colonial Railway, are considerably lower between the Restigouche and Two Brooks, in the Tobique Valley.* They are as follow:—

Between Restigouche and Grand River,	750 feet.
Between Grand River and Salmon River,	1080 "
Between Salmon River and Two Brooks,	840 "

The following Section on the Royal Road between Pickard's Mills on the Saint John to the Grand Falls,† one hundred miles in length, extends from the Carboniferous Rocks, which are distinguished by gentle undulations, across the central granitic belt, passes the head waters of the fertile valleys of the Beccaguimic, Munquart, and Shiktehawk, to the Tobique; thence through a fine country to Grand Falls. These two sections, compared with the one which follows across the Carboniferous Rocks, will show how subordinate are geographical features to geological structure in the surface outline of an extensive region.

* I am indebted to Mr. Fleming for the above altitudes.

† I am indebted to the kindness of John Wilkinson, Esquire, C. E., for the above Section.

SUBORDINATE MOUNTAIN RANGES.

These are two in number, situated in the southern part of the Province, and stretching in a northeast by east direction through the Counties of Charlotte, King's, and Saint John, to Albert and Westmorland. They will be more particularly described in noticing the Geology of these Counties. None of the peaks attain such altitudes as some of those in the Highlands, but the plateau on which they are situated in Saint John County is elevated, so that they do not present such striking outlines as the bolder ranges in the northern part of the Province. A rough section was made in November of the present year from the coast of the Bay of Fundy to Sussex Vale, with an aneroid barometer. The altitudes are subjoined, but they must be regarded as only approximate.

Barometrical Section from the mouth of Goose Creek to Sussex Vale.

	Height in feet above the Sea.
Mouth of Goose Creek,	0
Two miles from Goose Creek,	950
Five miles from do.	1045
Shepody Road,	1083
The Chapel on the road to Sussex Vale,	1140
Altitude of hill range east of last station, (estimated,)	1340
Sussex Vale,	58

The hills west of the Chapel may be 100 feet higher, and from this point the descent to the valley of the Kennebecasis is gradual.

THE BASIN OCCUPIED BY THE CARBONIFEROUS ROCKS.

The level character of many portions of this area is remarkable, and in striking contrast with the disturbed portions of the Province which have been briefly described.

Commencing at Bay Verte in the County of Westmorland, the elevation of the Carboniferous strata above the sea, on the line of Major Robinson's Railway Survey, is 109 feet; the utmost elevation the country attains between this point and Shediac (always on the surveyed line) is 185 feet; there is then a very gradual descent to the Cocagne River, but immediately after passing this stream, the country is broken, rising, before reaching Buctouche River, to 227 feet; near Coal Branch it is 259 feet, and between Harley Road and the Richibucto River the country is nearly level at an elevation of 170 feet above the sea, for a distance of ten miles, and one mile of that distance is absolutely level. There then succeeds a low dome shaped rise and fall from 78 to 277 and 71 feet. Extensive level spruce barrens succeed, which are 21 miles across, terminating at the South West Miramichi, the elevations of these barrens not exceeding 80 feet above the sea. Between the S. W. and N. W. Miramichi, the dividing ridge is 225 feet above the ocean, and in the valley of the N. W. Miramichi another level tract of country occurs for thirty miles, the land rising only from 150 feet to 215 feet in

that long distance. A descent is then made to the Nepisiguit, where the Carboniferous strata terminate. The aggregate distance along the surveyed line, which is nearly straight, being 149 miles over the Carboniferous Series of New Brunswick. The route lies near the coast, varying from one to twenty miles distant; it exhibits, however, a remarkably level tract of country, and shows how few in number and how gentle in action have been the disturbances it has undergone.*

THE RIVERS OF NEW BRUNSWICK.

THE SAINT JOHN.

The River, *par excellence*, of New Brunswick, is the Saint John, called also the Wollastook from its original name in the Miciceta language. On the authority of the Honorable Charles Perley, the word should be spelt Awolstook, and its signification is "the Big River."

One of the earliest historical notices of the River Saint John dates from 1598, when it was called "Riviere de la Grande Baie," or La Baie Francaise, as the Bay of Fundy was formerly designated. This occurs in the letters patent confirming the appointment of the Sieur de la Roche Lieutenant-General au Canada, Hochelaga, Terre-Neuve, Labrador, RIVIERE DE LA GRANDE BAIE (Saint John in the Bay of Fundy), Norembegue (the present State of Maine), et les terres adjacentes. (L'Escarbot). In the admirable Report by the late Dr. Robb, on the Agriculture of the Province, reference is made to the discovery of the Saint John by "Champlain, on Saint John Day, in the year 1604;" and in Monro's New Brunswick, there is a quotation from Haliburton's Nova Scotia, in which the name Saint John is stated to have been given to it because it was discovered on the 24th of June, the day of the Festival of Saint John the Baptist. Mr. Monro says also that this noble river was discovered by De Monts. It is clear from L'Escarbot, that the river was known previously to 1598. But in 1604 Sieur de Monts visited La Riviere de la Grande Baie, and *changed* its name to the Saint Jean.

In the "Relations des Jesuites en Canada," allusion is made to the "Iron Mines on the River Saint John," so far back as 1611;† and in the same

* Major Robinson's Survey.

The line is 630 miles long from Halifax to Quebec.

In passing the valley of the Tartigou River, and the watershed between the Saint Lawrence and the Restigouche, it attains an elevation of 763 feet above the sea.

Between the places where it crosses the Restigouche and Nepisiguit near Bathurst, the utmost height it reaches is 368 feet above tide, and this is the highest point reached in New Brunswick.

In Nova Scotia a ridge near Folly Lake, on the Cobequid hills, is 623 feet.

On a profile of this Survey, there is shown a tract of land absolutely level for a distance of five miles. This is situated on the Stewiacke River in Nova Scotia, 35 miles from Halifax, and 20 from Truro, its altitude is 33 feet above high water at Halifax.

Between Harley road and Richibucto River, for a distance of 8½ miles, the country is nearly level, the actual fall towards Richibucto River being 1 foot in 1504 feet for five miles, level for one mile, and a fall of 1 in 3887 for the remaining distance.

The spruce barrens, with an altitude of 49 feet above the sea, through which the surveyed line passed for 18 miles, is perhaps the most extensive tract of level country in the Province.

† "Si le pays estoit habite ou pourroit profiter de ses mines; car il y en a vue d'argent dans la baie sainte Marie, au rapport du Sieur Champlain, et deux de beau et franc cuire, l'une a l'entree du Port Royal, et l'autre a la baie des Mines. une de fer a la Riviere S. Jean et d'autres autre part."—(Relation de la Nouvelle France. 1611.)

record there is a brief description of the dangers encountered in passing the tidal falls which form so curious and distinguishing a feature at the mouth of this river. In 1652 Father Gabriel Druillettes voyaged to its source; and in 1659 the commerce or system of barter which existed between the Indians of the Saint John River and those of "Rigibouctou," is considered worthy of being mentioned in a letter by Father Lallemant on the Missions of Acadia.

The Indian name of the Saint John, as given on a Map by Father Coronelli, published in 1689, is Ouygondi, and the country through which it flows is represented as belonging to the Etechemins nation.* Dr. Dawson has Ouangonda, evidently of the same origin, and he names a fine Coniferous tree found in the Devonian Sandstone at Saint John, "*Dadoxylon Ouangondianum*."

SOURCES OF THE SAINT JOHN.

The Saint John (South Branch) rises in the State of Maine (Lat. 46.2), 115 miles west of Woodstock, or more accurately, due west of the old Meductic Fort, a few miles below that town. It flows in a northeasterly direction through Maine to beyond the 47th parallel, and forms the boundary line between Maine and New Brunswick from the mouth of the Saint Francis to the Monument, three miles above the Grand Falls. After passing that point its course lies wholly within the Province.

The head of the south branch of the Saint John is 2,158 feet above the ocean. The source of the southwest branch, where the Monument is placed under the treaty of Washington on the boundary between Canada and Maine, is 1808 feet, and its northwest branch (in Canada) comes from an elevation of 2,358. This great river, with a course exceeding 400 miles, does not fall much more than the waters flowing into the Tobique or Nipisiguit, from the ridge (2,092 feet) which divides the valleys of those comparatively small rivers in the highlands of New Brunswick.†

Saint John Lake, on the south branch, is 1,075 feet above the ocean, and where the river first enters the Province, at the mouth of the Saint Francis, its waters are not more than 606 feet above high tide.‡

At the mouth of the Madawaska the general course of the river begins to trend towards the southeast, which is its course to the Grand Falls, 125 miles by the river from Fredericton, after which its waters flow almost due south for about 75 miles, until they again arrive at the same degree of latitude as that from which they started, a journey of more than 300 miles. This course, expressed in very general terms, may be described geologically as follows:—

From its source to the mouth of the Saint Francis it runs *with* the strike of the rocks, and from the mouth of the Saint Francis to the old Meductic Fort it runs diagonally *across* the strike of the rocks.

* Blue Book—North American Boundary.—London, 1840.

† The Boundary Commissioners give the height of the extreme source of the Saint John River above Lake Woolastaguam (Saint John Lake), as only 1,315 feet, but this measurement appears to be on the Portage road between the waters of the Penobscot and the Saint John, and not at the true source of the river or any one of its branches.

‡ Boundary Commission.

The due north Boundary line between Maine and New Brunswick, starting from the source of the Saint Croix River, (Lat. 45.48.8), after traversing the wilderness for $77\frac{1}{2}$ miles, is intersected by the River Saint John $2\frac{1}{2}$ miles west of the Military Post at the Grand Falls.

THE GRAND FALLS.

The exact altitude of the Grand Falls, and their elevation above the sea, has been invested with considerable importance in consequence of the position of this splendid cataract having been adopted by the Boundary Commissioners in 1839-40 as the standard point to which the barometrical altitudes throughout the country, east and west, should be referred. Every effort was made to determine their exact relation to the sea level; yet there exists a very marked discrepancy between the results attained by the Barometer, as hereafter described, and those taken in running the due north line.* On a Map embodying a section of the country on the course of the due north line forming the Boundary between Maine and New Brunswick, published under the authority of the United States Government, the altitude of the Saint John waters at the Monument, three miles above the Grand Falls, is stated to be 419 feet. The British Commissioner makes the summit of the Falls 296 feet 9 inches above the tide at Chapel Bar, a few miles above Fredericton, as follows:—

	Feet. in.
Height of the basin at the foot of the Grand Falls, above the tide at Chapel Bar,	177 3
Perpendicular height of the Grand Falls,	74 0
Descent through Rocky Channel,	45 6
Total,	296 9

“The total height of the bed of the River Saint John above the tide at Chapel Bar, being 296 feet 9 inches.”

As the distance from Fredericton to the Grand Falls is $125\frac{1}{2}$ miles, and the ascent by the river is stated to be only 177 feet 3 inches,† according to the levels taken,‡ this would give a fall per mile of only one foot five inches.

* See succeeding paragraphs for probable explanation.

† These are the levels reported by the Commissioners on the authority of a Surveyor, (*vide Report*.) There is, however, reason to believe that they contain very material errors.

‡ Levels (?) on the River Saint John from Fredericton to the Great Falls—

Riviere du Chute to Tobique,	12.71	765
Tobique to GRAND FALLS,**	21.12	

** From Report of Commissioners.

The Commissioners say, in discussing their observations, "The difference between the two inferences above stated, viz., the greatest height of tide at Chapel Bar in the Bay of Fundy, 81.65 feet,* and at Bathurst in the Bay of Chaleurs, 6.9 feet, is 74.75 feet; and the same calculated by barometrical measurement, amounts to 77 feet, showing a total difference of little more than two feet between the two results."

It is, however, remarkable, that Mr. Graham ascertained the upper basin of the Grand Falls to be 419 feet above tide (probably the tide in Passamaquoddy Bay); the lower Basin to be 303 feet; consequently, the height of the Falls with the descent in the gorge, to be 116 feet; the Commissioners giving the total height of Falls and descent in gorge at 119 feet, in round numbers, a difference which unequal stages of water would readily account for.

The real explanation of this discrepancy has been afforded me by a gentleman occupying a position which entitles him to implicit confidence. The levels taken between Fredericton and the Grand Falls are not accurate. The summit of the Grand Falls is really more than 400 feet (419), ascertained by levelling from Passamaquoddy Bay; and the fall between the foot of the Grand Falls and Fredericton is 298 feet, instead of 177, and the fall per mile two feet four inches, instead of one foot five inches. The true altitude of the upper Basin of the Grand Falls being 419 feet. The levels taken on the Royal Road correspond with this estimate.

After taking the leap of 74 feet, the waters of the Saint John rush through a deep semicircular and very narrow gorge, one mile in length, to the lower Basin, which lies nearly due south of the upper Basin, and in the course which the river would have taken had it continued on uninterruptedly. The distance between the upper and lower Basin is only half a mile on the chord of the arc formed by the gorge. A deep ravine indicates the former valley of the river at a time when its waters flowed at a much higher level than at present. No less than five terraces mark its successive subsidences after the ancient valley in which it flowed was filled up, and partially re-excavated. The probable origin of the Falls will be discussed in a subsequent chapter.

THE SAINT JOHN BELOW THE GRAND FALLS.

Between Fredericton and Chapel Bar, soundings indicate a minimum depth of seven feet during the ordinary summer level; the maximum above Fredericton being 23 feet. At Chapel Bar, the head of tide, there was ten inches of water, with a circuitous channel,† when the river was surveyed, which was at a time when the waters were eighteen inches or two feet below their summer level.

* The Commissioners regarded Chapel Bar, *from its position*, being about 90 miles up and distant from the mouth of the River Saint John, to be equivalent to Cumberland Basin, in respect of the height of tide, which is based on the American Ephemeris for 1839, and appears to be excessive.

† Report of Commissioner for Exploring the River Saint John. Sept. 1838.—Appendix to Journals of Assembly.

The Bars of the Saint John are not permanent, shifting from time to time, the greatest change taking place in spring; and floating ice is considered to be an important agent in producing them. Near Burgoyne's Ferry the depth is 60 feet, and at the foot of Long's Island $2\frac{1}{2}$ feet.

The following Table shows the breadth of the Saint John at different places, the measurements being taken at low water:—

At Fredericton,	$\frac{1}{2}$ mile.
Cliff's Bar,	700 feet.
Nacawic,	475 "
Meductic,	550 "
Bel River,	550 "
Griffith's Island,	730 "
Presque Isle,	560 "
Riviere des Chutes,	420 "

Viewed as a whole, the River Saint John, from the Grand Falls to the Sea, presents peculiarities which will be more appropriately described in the Chapter on the "Surface Geology" of the Province; the remarkable tidal Falls at its mouth, with the great depths above and below them, together with the probable cause which has excavated these profound fissures, can then be fully discussed.

THE RESTIGOUCHE.

The "Restgouch" Indians are mentioned by Father Barthelemy Vimont in the Relations of 1642.—"You will see by the letter addressed to us from Miscou by the R. pere Richard, that we were not mistaken. He says in his letter that the people of the Bay of Chaleur, who are called 'Restgouch,' and others who live still further off, &c. &c."*

The Restigouche (Broad River) drains upwards of 2,000 square miles in Canada and New Brunswick. One of its affluents, the Wagansis, rises within ten miles of the Saint John, and is reached by a portage from the Grand River. Where Major Robinson's central line of Railroad crossed it, not far from the dividing ridge which separates it from Grand River, it is only 435 feet above the sea, and 45 miles from the Tobique.

The historical associations of the Restigouche are very interesting. Near the ancient Petit Rochelle, at the head of tide, a decisive battle was fought between the French under Bourdo and the English under Byron, in July 1760. And on the very pleasant farm of Mr. Busted, many cannon balls are continually found, relics of Petit Rochelle, of the old French forts, and of the battle which took place there.

In 1858 Mr. Richardson, one of the officers of the Geological Survey of Canada, examined the Restigouche from its mouth to the junction of the Patapedia, which forms the boundary line between Canada and New Brunswick. His description, which contains some points of interest, is given below.

* Relation de la Nouvelle France en l'Annee, 1642.

THE RESTIGOUCHE RIVER TO THE MOUTH OF THE PATAPEDIA.

‘About eight miles below the Matapedia the Restigouche meets the tide, and there are about two miles more to the head of the Bay Chaleur. For several miles above the Bay the River is from a mile to half a mile wide, and it is thickly set with low islands forming good meadow land. Above this, to the Matapedia, the breadth becomes contracted to less than half a mile, and in some places a considerable current prevails. From the Matapedia to the Petapedia the distance in a straight line is a little over twenty one miles, in a bearing about S. 65 W; but following the windings of the River, the distance given by the boundary Commissioners is thirty seven miles. About seven miles above the Matapedia, at a great bend to the right, a large tributary joins on the New Brunswick side. It is called the Upsalquitch, and is five chains wide at the mouth. About six miles higher up a tributary not more than ten feet across, called the Brandy Brook, joins on the Canada side, and while the distance by water from the Matapedia is thus thirteen miles, it is only six and a half miles over land. Above this, several other conspicuous bends occur; the bow at Cross Point, which is the most remarkable, is thirty one miles above the Matapedia by the River.

In this curve, the distance by water is two miles, while across the land it appears to be not much over a hundred yards. As far up as Brandy Brook the hills stand somewhat back from the River, and rise with gently sloping sides, well covered with soil to the height of from 300 to 500 feet. Within a short distance of this both sides of the River are settled, but farther up the hills come close upon the River, and often rise up abruptly to heights of from 400 to 600 feet. It is thus only on flats at intervals of several miles, that sites can be obtained for settlement on its banks. The sides of the hills in this part appear to be thinly covered with soil, but farther back the land is said to be capable of cultivation.’

Above the Patapedia the Restigouche is wholly within the Province of New Brunswick. At its mouth the Patapedia is six chains wide, including a small island dividing it into two channels; but above this, the breadth does not exceed about fifty yards.

The upper country drained by this river is described as being valuable as an agricultural region, but little is known of it some distance from the banks of the river; and of its geology, above the Patapedia, we are still entirely without reliable information.

The Nipisiguit, Upsalquitch, Miramichi, Tobique, &c., will be noticed in the geological description of the country, to avoid repetition.

THE COAST LINE.

Seawards, New Brunswick is bounded by the BAY OF CHALEURS, the GULF OF SAINT LAWRENCE, and the BAY OF FUNDY.

The BAY OF CHALEURS, or the “Sea of Fish,”* is reported to be without rock, reef, or shoal. It is twenty five miles wide from Cape Despair to

* Micmac—Eck-e-tuan Ne-ma-a-chi—the “Sea of Fish.”

Miscou Island, and seventy-five miles deep to the mouth of the Restigouche. The northern boundary of the Province follows the south coast of this magnificent Bay, and continues up the Restigouche as far as the Mistouche or Patapedia River.

Miscou Island was once celebrated as the chief seat of the Jesuit Missions on this part of the Gulf coast, comprehending the Indians of Gaspé, Miramichi, and Nipisiguit.* At the mouth of the last named river they had a station in 1645. In 1647 a chapel was built by them near where Bathurst now stands, and constant communication was held with Miscou Island, or, as it was then called, "*Ile de Saint Louis*."†

The "Restgouch" Indians are mentioned in the relation of 1642 as being converted by the Missionaries of Miscou.

It is worthy of note that the white whale which at one time was common in the Bay of Chaleurs, and then deserted it for many years, is beginning to return again, and during the month of June of the present year (1864), I saw some hundreds of these remarkable animals sporting in the brackish waters opposite Dalhousie, near the mouth of the Restigouche.

The white whale (*Beluga borealis*) is found from fourteen to twenty two feet in length. It yields from 100 to 120 gallons of oil, which possesses the valuable property of retaining perfect fluidity at temperatures below zero, and is therefore very valuable for lighthouse purposes. Leather has been manufactured from its skin, which commands a sale at eight shillings the pound. The white whale (erroneously called the white porpoise), is caught in strong fish-pounds, at and near the mouth of the river Ouelle, a tributary of the Lower Saint Lawrence, at the Isle au Coudres, and at Point de Cariole on the north shore of the river. In the fall of the year they assemble, and migrate in a body to their winter quarters in the Gulf or Arctic Sea. They live from April to October in the brackish water of the Lower St. Lawrence, and then proceed slowly down the estuary, accustoming themselves to the salt water. Mr. Tétû, of Ouelle, who has been very successful in capturing the white whale, and in bringing its oil and leather into notice, informed me that he has seen the Saint Lawrence 'white with them;' and he has observed them passing towards the Gulf all day long over a space twelve miles broad.

The Walrus too, was once common on the coast of Miscou Island, and were slain in great numbers by the French about the middle of the 17th century, probably by the employees of the "Royal Company of Miscou." The late Mr. Perley notices an interesting geological fact in connection with the bones of the Walrus on Miscou Island. "On visiting the echouage," he says, "or place where the Walrus were formerly slain in such numbers, a little to the westward of Point Miscou, it was found that the ancient beach is now nearly a quarter of a mile from the sea; a long strip of sand plain, covered with coarse grass and a great abundance of cranberries, at this time

* Spelt by the Jesuits "Nepegigouit," signifying "troubled or rough waters."
 † Relations des Jesuits, 1636.

intervenes between the present sea-beach and the former strand. This strip of recent formation is called the *Grande Plaine*; and the curving shore in its front is called by the fishermen *L'Ance a Grande Plaine*. On examining the ancient shore, near the outer edge of a belt of small spruce and fir trees, the bones of the Walrus which had formerly been slain there, were found imbedded in the sand in large quantities, and in good preservation, some of the skeletons being quite complete."*

The shores on the Gulf coast are generally low, and the indentations at the mouths of rivers wide, penetrating, in the form of narrow bays, many miles into the interior. This results from the soft character of the arenaceous deposits belonging to the carboniferous rocks, which form very nearly the whole of the Gulf coast of New Brunswick.

THE BAY OF FUNDY.

This remarkable body of water, originally called "Baie des Francais," and also "Mer de l'Acadie," exhibits various phenomena especially interesting in a geological point of view. The wonderful tides, so ably described by Dr. Dawson,† have been noticed by most travellers in New Brunswick and Nova Scotia with very different impressions, and some discordant enumerations of "facts." Some time since, the Fredericton Athenæum published a paper drawing attention to several absurd statements relating to the tides of the Bay of Fundy, which were thought to be prejudicial to the interests of the Province.

These statements have appeared in works of acknowledged authority, and in some instances by writers of eminence. Sir John Herschel, in his "Outlines of Astronomy," paragraph 756, says, "At Annapolis, for instance, in the Bay of Fundy, it is said to rise 120 feet;" and Mr. P. H. Gosse, in his delightful volume "The Ocean," does not qualify the assertion with "it is said," but tells us that "the spring tides sometimes rise to the astonishing elevation of 120 feet."—(Introduction to "The Ocean.")

By the permission of Captain Shortland, R. N., the Officer in charge of the Coast Survey, I have been favoured with the following facts relating to the Tides in this remarkable Bay:—

* Report on the Sea and River Fisheries of New Brunswick.

† "The tide-wave that sweeps to the northeast along the Atlantic coast of the United States, entering the funnel-like mouth of the Bay of Fundy, becomes compressed and elevated as the sides of the Bay gradually approach each other, until in the narrower parts the water runs at the rate of six or seven miles per hour, and the vertical rise of the tide amounts to 60 feet or more. In Cobequid and Chignecto Bays, these tides, to an unaccustomed spectator, have rather the aspect of some rare convulsion of nature than an ordinary daily phenomenon. At low tide wide flats of brown mud are seen to extend for miles, as if the sea had altogether retired from its bed; and the distant channel appears as a mere stripe of muddy water. At the commencement of flood, a slight ripple is seen to break over the edge of the flats. It rushes swiftly forward, and covering the lower flats almost instantaneously, gains rapidly on the higher swells of mud, which appear as if they were being dissolved in the turbid waters. At the same time the torrents of red water enter all the channels, creeks and estuaries; surging, whirling and foaming, and often having in its front a white breaking wave, or "bore," which runs steadily forward, meeting and swallowing up the remains of the ebb still breaking down the channels. The mud flats are soon covered, and then, as the stranger sees the water gaining with noiseless and steady rapidity on the steep sides of banks and cliffs, a sense of insecurity creeps over him; as if no limit could be set to the advancing deluge. In a little time, however, he sees that the fiat "hitherto shalt thou come, and no further," has been issued to the great Bay tide; its retreat commences, and the waters rush back as rapidly as they entered."—Acadian Geology, pages 23-24.

	Height of Tide.
Point Lepreau,	25 to 21 feet.
Saint John, (outside of Harbour,)	28 to 22 "
Off Emerson's Creek,	31 to 23 "
Off Quaco,	31 to 21 "
Off Cape Enrage,	41 to 32 "
Mouth of Petitcodiac,	46 to 36 "
Off Apple River, Chignecto Bay,	39 to 29 "
Off Cape D'Ore,	41 to 31 "
Off Noel River, Cobequid Bay,	53 to 31 "
Off Black Rock,	36 to 31 "
Off Port George,	32 to 29 "
Off Brier Island,	22 to 16 "

At the extremities of narrow inlets the tides will exceed the maximum of these altitudes by a few feet.

The levels taken during the construction of the European and North American Railway have established the fact, that the level of high tide at Saint John is 10.70 feet *above* high tide in Shediac Harbour, and the level of the rails on the Shediac wharf is 6.70 feet *below* high water at Saint John.

ORIGIN OF THE BAY OF FUNDY.

The wildest theories have been advanced to account for the origin of the Bay of Fundy.* Although it is the most extensive Gulf on the eastern Coast of America, it is less than any of the great inland fresh water Lakes of the Saint Lawrence Basin. A straight line between Brier Island in Nova Scotia and Quoddy Head would pass through the Grand Manan, (formerly Menano; Relations, 1611,) and with this for its southwestern boundary, the Bay would be nearly as long as Lake Ontario, or about 180 miles. Its width varies from 50 to less than 30 miles, and towards its inner extremity it is divided by the Chignecto Promontory into Chignecto Bay and Bay of Minas, or as it was originally called the Bay of "Mines;" and under this name (Baie des Mines) it is mentioned in the early relations of the Jesuits, and allusions made to the Mines, elsewhere noticed.

Although the surface of the Bay of Fundy may approach that of Lake Ontario, its depth is considerably less, and if the southwestern entrance be excepted, the average depth of the Bay of Fundy will not be half that of Lake Ontario (500 feet or 83 fathoms.) The soundings in the Bay of Fundy, which were kindly permitted to be furnished to me, by Capt. Shortland, R. N., show that between Saint John and Digby, the greatest depth recorded is 43 fathoms, between Quaco and Port George 40, and between Martin's Head and Black Rock 29 fathoms. Near the entrance of Chignecto Bay there is 28 fathoms of water, but within the Minas Channel the lead shows 55, and in the Minas Basin 18 fathoms. Between Grand Manan and Brier Island it is 112 fathoms; but Lake Ontario is 720 feet deep in some places.

* See "Reports on the Sea and River Fisheries of New Brunswick," by M. H. Perley, for notice of these theories.

The Bay of Fundy is really nothing more than a shallow valley of denudation, and is a matter of surprise that, considering the tides to which it is subject, its depth should not be greater. It is probable too that a portion of the Arctic current once flowed through the Bay of Fundy, during a period of submergence of this part of the continent; yet the current does not appear to have materially effected its depth.

The levels on the line of the European and North American Railway, exhibit the singular character of the valley of the Kennebecasis and its prolongation to Shediac Harbour. The dividing ridge is attained 97 miles from Saint John, where the altitude is 161 feet above the highest spring tides at Saint John. The summit, 12 miles from Saint John, is in the valley of the Kennebecasis. During the submergence of the country below the level of 170 feet, the current in this valley must have been at times terrific; we see its effects in the bold escarpments and hills which distinguish the country about Sussex Vale. Borings at Lawlor's Lake showed soft material 100 feet below the present surface, which is 62 feet above high tide. This is, probably, a part of the ancient valley of the Saint John, or a deep indent from the sea.

The distance between the extremity of Cumberland Basin and Bay Verte is eleven miles. The highest land on this narrow isthmus is only 17 feet above the level of the highest tides in Cumberland Basin. This is on the Amherst and Bay Verte Road, four miles from the first Lock of the proposed Canal. Another ridge occurs two miles from Bay Verte, but this is only 14 feet above the high tides of Cumberland Basin, or 36 feet above the highest spring tides in Bay Verte. By the removal of these trifling obstacles the waters of the Bay of Fundy would flow into the Gulf of Saint Lawrence, and Nova Scotia would become an Island. If a ditch were dug to admit of the passage of the waters, they would rapidly widen it to a canal, but when they would cease their work of erosion and destruction, is a problem not easy to answer with present data.

CHANGE OF COAST LINE.

There are strong indications of a change in the relations of the coast to the level of the sea, taking place at the present day in the more northern parts of the Bay of Fundy. At the time of my visit to Albert County in the month of October, (1864,) the tides were unusually high, overflowing many dykes in the broad marshes of Shepody River. Several intelligent farmers and residents expressed the opinion that the tides were rising higher than formerly, or what may be really the case, that the land is slowly sinking.

The same physical change has been observed on a more extended scale in Nova Scotia, and was noticed some years since by Dr. Dawson;* submerged forests having been found by him in Cumberland County. Mr. Bell,† in a paper "on recent movements of the Earth's surface," states on the authority

* Acadian Geology.

† Transactions of the Nova Scotian Institute of Natural Science, 1863.

of Dr. Gilpin, that several hundred acres of dyke land in Annapolis, formerly in cultivation, are now given up to the sea.

In the great Tantamar Marsh, in the County of Westmorland, at its eastern extremity, large trees of different kinds, collections of shells and bones of fishes appear at different depths in the alluvium. On its northern border are patches of forest trees, some of which have been felled by the woodman's axe, but the stumps are now overflowed by the tides.* Relics of the early French settlers and many traces of the aborigines have been dug up at depths of five and ten feet beneath the surface. At Shediac and Bay Verte the gravestones of persons killed by the Indians in 1755, are now reached by the tide at high water, which washes the base of old Fort Moncton, and rises above its causeway.†

Two hundred and fifty years ago, (1612,) the Bay of Chignecto (called Chinictou, also Chignectou by the Jesuits, (1612,) and by Champlain, Baie des Genes,) was celebrated for its marshes or meadows, stretching as far as the eye could see.‡ At that time the Indians of this Bay were said to number from sixty to eighty souls, and to be sedentary on account of the abundance of game.

CHAPTER II.

GEOLOGICAL SKETCH OF THE PROVINCE.

Nomenclature—Necessity for a uniform nomenclature—Nomenclature adopted by Sir W. E. Logan—The Sedimentary Rocks of New Brunswick—Economic materials they contain—The CENTRAL GRANITE BELT—The age of the Granite—Its character—Localities where it is seen—On the Nipisiguit—At Gulquac Lake—Long Lake Portage—On the South West Miramichi—Does not occur in the form of a continuous broad belt; but in several narrow belts—The Granite on the Saint John, occurs also in narrow belts—On the Frontier—Length and breadth of the Granite axis—Its importance—Geographical and Geological features compared—The Southern Granite Belt—Its mode of occurrence in the Southern Range—On the Magaguadavic—Breadth of the Granite in the Northern Belt—Occurs in Elgin Parish—Origin of the Granite—It is probably an altered Sedimentary Rock—Professor Hunt's views—Upper and Middle Silurian Series—Devonian Rocks—The Carboniferous Series.

NOMENCLATURE.

With a view to assist in preserving uniformity in the geological descriptions of British North America, I shall strictly adhere to the nomenclature adopted by the distinguished Chief of the Canadian Geological Survey, Sir W. E. Logan.* It is not, perhaps, generally known in this Province, that Sir Roderick Murchison, Director General of the Geological Survey of the United Kingdom, himself the discoverer and delineator of several great Rock Systems, (Silurian, &c.) has adopted the Canadian name Laurentian, first given by Sir William Logan to an ancient series of sedimentary rocks in Canada, to represent rocks of the same age which Sir Roderick Murchison has found to exist in the north of Scotland and some of the adjacent Islands.†

Mr. Alexander Murray, who is now making a Geological Survey of Newfoundland, will doubtless adopt the same nomenclature, and as the formations in Central British America have already been described in general terms according to the same plan,‡ it will result in a few years that a uniform

* This practice not only suggests itself as due to the exponent of British American Geology, but it is expressly recommended by Sir Roderick Murchison, in a letter with which the writer of this Report was favored by that eminent Geologist.

† "If this most ancient gneiss required a British name, it might indeed with propriety be termed the 'Lewisian System,' seeing that the large island of the Lewis is essentially composed of it, capped here and there by derivative masses of Cambrian conglomerate; but the term 'Laurentian' having been already applied to rocks of this age in North America by our distinguished associate Sir W. Logan, I adhere to that name, the more so as it is derived from a very extensive region of a great British Colony."—*Proceedings of the Geological Society, Nov. 1859.*

‡ Vide Geological Map of the country between Lake Superior and the Elbow of the south branch of the Saskatchewan, by the Author of this Report. "Narrative of the Canadian Expedition," Longman, London, 1860. Also Blue Book, 1860. And Dr. Hector's Map of the country between Lake Superior and the Pacific.—*Geological Society's Journal, Nov. 1861.*

system of colouring can be given to a Map of British North America, with intelligible descriptions; and thus the almost inextricable confusion, to a foreigner at least, which has occurred in the delineations of the Geology of certain States of the American Union, will be avoided. There is no reason whatever, why rocks possessing local peculiarities of structure, composition, fauna or flora, should not receive special names, provided their relation to those great geological divisions of past time, with their well known local subdivisions, which are almost universally accepted, be clearly ascertained and prominently kept in view, in order that a stranger to the geographical position of the part of the country they represent and from which they derive their name, may not be subjected to the trouble and loss of time which a new nomenclature so often involves. Local designations are, indeed, sometimes absolutely necessary, and wholly unobjectionable if they specify peculiarities. But no one can substantially defend their application and use to such an embarrassing degree as now prevails in the different geological descriptions of some American States.

With reference to the nomenclature which has been adopted for the geological formations of Canada, Sir William Logan says—"In the names used we have been desirous of availing ourselves as much as possible of those which have been applied to well established groups of strata elsewhere, with a view of at once facilitating comparisons of equivalent masses, and of rendering homage to those whose labours have aided us in understanding our own rocks." For the subordinate groups of fossiliferous strata the nomenclature of the State of New York has been adopted, because the investigations of the able Geologists who conducted that survey had, in some degree, rendered the nomenclature classic in America; and it is only when a group has not been recognized among the rocks of New York, or when a mass there destitute of organic remains is replaced in Canada by one marked by fossils, that a Canadian name is introduced."*

CLASSIFICATION OF NEW BRUNSWICK ROCKS.

The Sedimentary Rocks of New Brunswick belong to the following Great Divisions:—

I. RECENT and POST PLEISTOCENE.

* * * * *

II. TRIASSIC?

III. CARBONIFEROUS.

IV. DEVONIAN.

Devonian Granite.

V. UPPER SILURIAN.

VI. MIDDLE SILURIAN.

VII. LOWER SILURIAN.

Quebec Group.

The valuable minerals belonging to each Group are as follow, as far as they are known; a special description will be given of the mode of occur-

* Geology of Canada, page 19.

rence of each particular mineral, in the Chapter relating to the Group in which it is found:—

- I. RECENT and POST PLIOCENE.—Manganese; Bog Iron Ores; Ochres; Shell Marl; Kaolin; Clays for Pottery and Bricks; Moulding Sand; Blue Phosphate of Iron; Peat; Gold.
- II. TRIASSIC.
- III. CARBONIFEROUS.—Bituminous Coal; Albertite; Petroleum; Bituminous Shales; Limestones; Gypsum; Firestones; Sandstones; Grindstones; Millstones; Conglomerates; Flagstones; Building stones; Decorative materials; Sandstones for Glass.
- IV. DEVONIAN.—Copper; Roofing Slates; Plumbago.
- V. UPPER SILURIAN.—Limestones; Dolomites; Argillites; Honestones; Hydraulic Cement; Whetstones.
- VI. MIDDLE SILURIAN.—Lead; Sulphate of Baryta; Limestones; Ochres; Copper Ores; Iron Ores.
- VII. LOWER SILURIAN.—Copper; Antimony; Manganese; Iron Ores; Lead; Chromium; Nickel; Zinc; Gold; Potstone; Serpentine; Roofing slates; Marbles.

OUTLINE OF THE DISTRIBUTION OF FORMATIONS.

With exception of the rocks belonging to the Recent, Post Pliocene, and Carboniferous Series, the whole of the formations found in New Brunswick have been very much disturbed, but the direction of the forces which produced the disturbance appears to have been uniform rather than discordant; hence it results that over wide areas the strata are folded and curved with great regularity. This is particularly noticed in the grand belts of the Lower Silurian Series which stretch across the Province from the Saint John to the Bay of Chaleurs, in a northeasterly direction. The general direction of the strike of the rocks in these belts is to the northeast (N. 60 E.), and the dip at a high angle either to the southeast or northwest. These belts occur on both sides of a low range of Granite, stretching from the Atlantic coast of Maine to the Bay of Chaleurs, in either two or more broad or in numerous narrow parallel bands, which have apparently broken through the ancient Silurian Rocks, and determined in a great measure the subsequent geological arrangement of a large part of the Province.

The whole of this range of Granite would at the first blush seem to be of much more recent date than the rocks through which it has apparently crushed its way. It is our guide to the leading features of the Geology of the Province, and before alluding to those rocks which are clearly Sedimentary Strata, it will be advisable to describe the character of the great granitic masses, which have been so instrumental in giving them their present position. It is not necessary to enquire at present whether the thick sheets of Silurian Strata were crushed or squeezed into vast folds before the granite broke through them, it is sufficient for present purposes to consider the relation that rock bears to them, and to ascertain in the first place its Geological Age.

THE CENTRAL GRANITE BELT.

THE AGE OF THE GRANITE.

From near Bathurst, on the Bay of Chaleurs, to the islands in Penobscot Bay, on the Atlantic coast of Maine, a distance in an air line of nearly three hundred miles, there is a series of narrow belts, often joined into one, of so-called Devonian granite; that is, of granite apparently thrust up through the Lower Silurian strata which once covered the greater part of the vast expanse of country with one uniform sheet, at the close of the Devonian period, or just before the Carboniferous epoch commenced its existence.

The age of this granite is known from the simple relation it bears to the red sandstones and conglomerates of the Bonaventure formation near Bathurst, which lies here at the base of the Carboniferous series, and to the Devonian rocks of Gaspé; the nearly horizontal and undisturbed Bonaventure sandstones occupy the depressions and hollows in the granite, filling up every crevice and irregularity just as one may suppose sand, both coarse and fine, to cover with a uniform mantle the bottom of deep lakes, unruffled by streams, tides or winds. It is not to be supposed that the nearly horizontal sandstones of the Bonaventure formation, occupy the hollows in the granite with such perfect fidelity and regularity as the sand at the bottom of a deep and tranquil lake, but they preserve that position which they would take if they were deposited in a comparatively tranquil ocean, of which this granite was the floor. In the eastern townships of Canada intruding masses of this granite intersect the Devonian strata,* hence its age must be posterior to them; and in New Brunswick the base of the Carboniferous overlies it horizontally, filling its hollows, and is consequently newer than the granite, hence the exact age of this intrusive rock, if it be intrusive, is about the close of the Devonian Period.

In the Map prepared by Dr. Robb for Professor Johnston's Report on the Agricultural Resources of New Brunswick, the granite is made to occupy a uniform belt across the Province. Its true position differs from this delineation, in several important particulars. According to the observations I was enabled to make during the past summer, on the Nepisiguit, the source of the Little South West Miramichi, the upper waters of the South West Miramichi, and the Saint John River, its aggregate breadth has been over-estimated, and a correct geographical position has not been assigned to it on any Map I have yet seen.

I crossed the belt at the localities above enumerated, and noted the limits of formations with as much precision as the nature of the country would permit without special research.

GRANITE NEAR THE BAY OF CHALEURS.

The granite is first seen near the coast on Middle River, about a mile and a half west of the Nepisiguit, and an eighth of a mile from the Harbour. It appears on the Nepisiguit at the Rough Waters, three miles from the mouth

* Geology of Canada.

of the river. Rough Waters is a classic spot, the river deriving its name from these rapids, which in the spring and fall are very magnificent. Here the Red Sandstones of the Bonaventure* formation, are seen lying in nearly horizontal layers upon the granite, which reveals itself as the floor of one of the earliest Seas belonging to the Carboniferous age. It is surely worth while to pause here for a few minutes and endeavour to realize what is the true significance of the expression "the floor of one of the earliest Seas belonging to the Carboniferous age." It means that we are gazing upon rock which formed the bottom of an ocean whose waves rolled over where we are now supposed to be standing, before any portion of the vast coal field of New Brunswick, Nova Scotia, and Cape Breton, was begun to be elaborated by the wearing down of already existing rocks; before a single plant had been called into existence, of the countless myriads which lie entombed in the coal deposits of this fourteen thousand feet thick mass of rock, which is called the Eastern Carboniferous area or coal field of America, as distinguished from the Western area, which occurs in Pennsylvania, Ohio, Missouri, and other western States.

If the rocks which have been formed since the ocean first rolled over the granite near Bathurst were removed throughout the eastern Provinces, and land and sea supposed to retain their present level, a considerable portion of New Brunswick, the whole, probably, of Prince Edward Island, and a large part of Nova Scotia and Cape Breton would be beneath the sea. This ancient bed of a former ocean can be seen within a few miles of Fredericton, on the road to Woodstock, where the outlying patch of the horizontal carboniferous sandstones repose on the granite near the Pokiok River.

Some conception of the vast lapse of time involved in these ideas may be formed, when it is considered that in Nova Scotia there are no less than seventy six seams of coal, each with their dirt bed, or bed in which a large portion of the plants forming the coal grew, succeeding one another. Each coal seam and dirt bed indicating a period of repose and the growth of interminable forests, in which insects, such as termites, cockroaches and scorpions wandered, dragon flies, weevils and locusts flew, and where numerous reptiles, all now extinct, luxuriated in the vast swamps and estuaries of the carboniferous period. Each coal seam was succeeded by long ages during which the waters covered the land, until in that vast lapse of time a thickness of no less than 14,750 feet of deposits was accumulated in Nova Scotia alone.

Two and a half miles above Pabineau Falls the granite is covered on the north side of the Nepisiguit with horizontal sandstones. It occurs here in the form of low domes. On the south side of the River the Bonaventure rocks come on the banks a short distance above the Pabineau Falls, which are themselves wholly in the granite, the sandstone flanking them on the south side. The granite is seen again at a point about half a mile above

* The "Bonaventure Formation" is the name given by Sir W. Logan to the base of the Carboniferous Series as it occurs in Canada.

Brandy Brook, where also the sandstones and conglomerates appear as cliffs 20 feet high, and on the east side capping a hill some 80 feet in altitude. The Rough Waters, more than two miles long, flow over granite with the horizontal conglomerates and sandstones filling the hollows between the low domes on each side, so that the breadth of the exposed granite is very small here. At the foot of the Rough Waters there is a felspar dyke containing red crystals of the same mineral.

The character of the granite near Bathurst, differs slightly from the same rock on the Saint John. At Rough Waters it consists of white felspar, black mica, and translucent quartz. On the Saint John, the white felspar crystals are generally much larger, the mica less in quantity, and sometimes difficult to discover.

The granite was not recognized on the Nepisiguit above the Grand Falls. In a Map accompanying a Paper read by Professor Bailey before the Natural History Society of New Brunswick,* and published in the April number of the Canadian Naturalist,† granite is delineated as forming the bed and banks of the river for several miles above the narrows, more than twenty miles from its mouth; and in his "Report on the Mines and Minerals of New Brunswick," it is stated that "Granite ridges appear in situ, and seem to have displaced and been thrust through the other strata. The violent eddies and rapid currents in this portion of the stream make careful observation very difficult."‡ I did not recognize any granite in this vicinity, and on reference to my notes, I find the following:—A quarter of a mile above Nepisiguit Brook greenish silicious schist occurs, with a strike N. 10 E. Dip 70 W.—300 yards below Nepisiguit Brook the same green silicious schist, with the same strike as before; half-mile below the great Bend ferruginous slates, with strike N. 40° E., Dip 75° W., showing disturbance, &c. These rocks will be described under the heading "Quebec Group," in a subsequent Chapter.

The granite probably pursues the course indicated by Professor Bailey, and the ridges of which he speaks may have escaped my observation, notwithstanding that special attention was given to the possible occurrence here of this rock, as represented on the Map constructed by the late Dr. Robb.

GRANITE AT GULQUAC AND LONG LAKE.

The next place where the granite was thought to be in position, but was not actually seen, is at Gulquac Lake, the head of Gulquac River, a sheet of water not laid down on the Provincial Map. In this remote lake there are a large number of huge granite boulders, not much worn; they resemble low domes in the lake, but did not appear to be in place. Since low ridges of a highly metamorphic schist were seen in the northern part of Gulquac Lake, it is probable that the granite is close at hand, and it may therefore be, pro-

* 12th February 1864.

† Notes on the Geology and Botany of New Brunswick, by Professor L. W. Bailey—Canadian Naturalist, April 1861.

‡ Page 10.

visionally, placed in this vicinity. Large boulders of the same rock were also observed in a northeast direction, on the Portage between Long Lake and a lake forming the source of the Little South West Miramichi, not laid down on the Provincial Map. The bed of a stream flowing into Long Lake from the elevated ridge separating this fine sheet of water from Little South West Miramichi Lake was composed of granite debris. The portage, although nine miles long, did not afford any opportunities for observing rocks in position, but large boulders were very numerous, and these almost altogether consist of white granite. To the north and south of these localities the sedimentary rocks are seen in place. Hence it is probable that a granite ridge passes through this portage, and is continuous with one near Gulquac Lake. These positions are about eight miles north of the northern boundary assigned by the late Dr. Robb to the supposed "Cambrian" belt which flanks the granite on either side.

ON THE MIRAMICHI.

On the northwest Branch of the South West Miramichi, low granite domes were seen about a mile and a quarter above the forks. They are succeeded by micaceous schists, with granite domes occasionally penetrating through them. Smooth white granite forms the bed of the river about two miles above the narrows on the South West; the channel of the river itself being full of granite boulders. Opposite Mount Alexander, and about three miles northwest of it, the granite has involved large masses and numerous fragments of schist, leading to the idea that it was in a plastic condition when upheaved. The same remark applies to the granite on the Saint John River, and elsewhere. At a point between Mount Alexander and the elevation on the east side of the river, as shown on the Provincial Map, a micaceous schist was observed in position, which continues for some distance. About a mile below Slate Brook, where a quartzose schist was observed, white granite again forms the bed of the river, but it is quickly succeeded by ferruginous schist. A ridge of granite containing parallel belts of schist, appears again about $1\frac{1}{4}$ mile below Slate Brook, after which no more granite is seen on this river, (the country being slates, &c.) until Snake Brook is reached; here there is a belt of granite about 400 yards broad, succeeded by ferruginous slates or schists. The granite appears again half a mile above "The Sisters," where it is succeeded by silicious slates, interpenetrated with numerous quartz veins. It crops out again, however, a few hundred yards lower down the river, when it is overlaid by a quartzite at the mouth of the Sisters, with a strike S. 60 E., dip S.W. angle 80°. Three quarters of a mile below "the Sisters" the granite appears in the form of low domes, the quartzites resting upon it with a strike N. 80 E., and a northerly dip at a high angle. This is the last anticlinal axis or ridge observed on this river, with the granite coming up in the centre.

It would seem from these observations that the great central granitic axis consists of a series of parallel ridges penetrating Silurian rocks; the ridges

forming a number of anticlinal axes with the sedimentary rocks on each side of them. The breadth of country on this line of section over which the granite was seen in position, is considerably greater than represented in Dr. Robb's Map, from which our ideas of the leading features in the Geology of the Province have been derived hitherto, but it occurs in many narrow, parallel belts or stripes, and not in one uniform mass.

GRANITE ON THE SAINT JOHN.

On the Saint John, a small dome of granite is seen protruding through the horizontal strata of the outlier of Carboniferous rocks about one and a half miles east of Tilley's Hotel. West of the outlier it occurs as far as the Sheogomoc River, two and a half miles from Tilley's, where a micaceous schist or gneiss occurs. The schist contains black mica, it is easily separated by divisional planes at right angles to the strike, which is S. 70 E. Dip 65° S. The laminae of the schist are contorted. At the falls of this river, a little above the bridge, white granite is seen in patches penetrating through and overlying the schist, it can also be seen overlying it in masses farther up the river, and it appears to have come through it in many places, giving to the schist the appearance of holding masses of the granite with sharp edges. About three quarters of a mile above the Sheogomoc, the laminae of the gneiss or schist are beautifully apparent. Granite is again seen forming the bed of a brook a mile and a half from the Sheogomoc, but at Sullivan's Creek the strike of the micaceo-arenaceous rock is S. 10 E., dip 37 E. No more granite was seen on this section. The character of this rock in many parts of the region described, is very porphyritic, containing as it does large and well defined crystals of felspar; some of these crystals are an inch and a half long by half an inch in diameter, but few of them are perfect.

GRANITE ON THE BOUNDARY LINE.

This Belt of granite acquires greater breadth as it approaches the Cheputnecticook Lakes, forming the Boundary between Maine and New Brunswick, but it is probable that it alternates with several belts of schist or gneiss. On the western sides of these lakes, in Maine, which are also called the Eastern Schoodic Lakes, and consist of Cheputnecticook, Grand and North Lake, the granite has been recognized by Mr. C. H. Hitchcock, who supposes the greater part of the western shores of Cheputnecticook Lake; (called by Hitchcock, Chepedneck Lake,) to be occupied by granite. Bold bluffs of White granite were found on the west shore of Grand Lake; but the schists also appeared in place. The east side, however, of Grand Lake, is said to be underlaid by granite, and upon a hill between Grand and North Lakes the junction of the granite with mica schist may be seen.* This range of granite, Mr. Hitchcock suggests, may connect with the granite in Penobscot Bay, on the Atlantic coast. There are many reasons for supposing this conjecture to be correct.

* Second Annual Report upon the Natural History and Geology of the State of Maine, 1863.

The length of the granite axis in New Brunswick is one hundred and sixty five miles, and its aggregate breadth varies from one to twenty three miles.

Throughout the larger portion of its development it consists of a series of narrow parallel bands, with gneiss, or schist or slates between them, so that a very considerable portion of the country lying within the outer narrow bands, is occupied by altered sedimentary rocks, some of which may be valuable for the metalliferous ores they contain, the indications being both numerous and promising.

IMPORTANCE OF THE GRANITE AXIS.

The importance of this granite axis will be better understood when its relation to other rocks is explained. If the reader should place before him the Provincial Map of New Brunswick, or any other good Map embracing part of Canada and the State of Maine, with Nova Scotia, he would recognize certain river valleys, coast lines, and mountain ranges, which maintain a curved course from the southwest towards the northeast, and northeast by east; these are—

- 1st. The Saint Lawrence, pursuing a northeast course from Quebec to Bic Island, (south shore); from Bic Island its direction trends about 15° more to the east.
- 2nd. The Saint John River, from Lake Saint John, pursues a northeasterly course for about 100 miles.
- 3rd. The chain of highlands commencing west of Katahdin in Maine, passes north of Mars Hill to the head waters of the Tobique, and has a northeasterly course. The range then trends more to the east, until it reaches the Bay of Chaleurs.
- 4th. The Atlantic coast of Maine and the parallel coasts of the Bay of Fundy, have a northeasterly direction; Minas Channel and Basin trending more easterly.
- 5th. The Atlantic coast of Nova Scotia, from Cape Sable to Margaret's Bay, has a northeasterly course, it then trends more easterly, running parallel to the Saint Lawrence below Bic Island.

These are apparently geographical coincidences, but when the geological structure of the country is studied it will be seen at a glance that they are the result of some law operating uniformly over wide areas.

In a succeeding Chapter a great metalliferous belt of rocks will be described, which comes up on each side of the central granite axis. These rocks are called the "Quebec Group," by Sir W. Logan, who first discovered their relations in 1860, and has since described them as they occur in Canada and elsewhere.

The Quebec Group consists of an ancient series of strata lying near the base of the Lower Silurian System; they have been brought to the surface in Canada by successive foldings which have caused them to assume the form

of a series of parallel ridges;* these, coming from Lake Champlain, follow the general course of the Saint Lawrence to Gaspé, and thence to Newfoundland.

The granite axis of New Brunswick has *apparently* uplifted and broken through the Quebec Group, (which had been previously squeezed into folds nearly parallel to the course of the axis,) and brought it to the surface on either side of a gently curving line, from the Bay of Penobscot in Maine, to the Bay of Chaleurs in New Brunswick, roughly parallel to the outcrop of the Quebec Group in Canada.

The next upheaval to the south occurs on a similar course, but trending a little more to the east in Charlotte, King's, Queen's, Saint John, and perhaps Albert Counties. In the first three of which, the Quebec Group has probably been recognized.

The last great fold in this direction to be noticed, occurs on the Atlantic coast of Nova Scotia, where the "Gold diggings" are situated in rocks belonging to the Quebec Group.

All of these foldings or plications which have aided in producing mountain ranges are, indirectly, the probable result of the gradual cooling of the earth's crust. The ocean beds too, are continually getting heavier by deposits, for which the wear of the coast and the debris brought down by rivers affords the material. That part of the crust of the earth forming the land is continually getting lighter; hence the beds of the oceans are always sinking as a whole, and the huge cracks which this occasions on the land are in part the origin of the mountain ranges near the coast, where volcanic vents and rents show a connection with that part of the fluid interior not rendered solid by enormous pressure. No volcano is found at a considerable distance from the ocean.†

* The Geological reader will understand that it is the endeavour of the writer to avoid as much as possible the use of technical terms, which are not supposed to be generally understood by the popular reader.

Sir William Logan describes the Quebec Group in the following words:—

"The Quebec Group would thus appear to be a great development of strata about the horizon of the chazy and calciferous formations, which were brought to the surface by an overturn anticlinal fold, with a crack and great dislocation running along its summit, by which the group is made to overlap the Hudson River formation." * * * "A series of such dislocations traverses eastern North America, from Alabama to Canada. They have been described by Professor Rogers in Pennsylvania and Virginia, and by Mr. Safford in Tennessee. The dislocation in question comes upon the boundary of the Province in the neighbourhood of Lake Champlain. From this it proceeds in a gently curving line to Quebec, running nearly parallel with the Philipsburgh and Deschambault anticlinal, and keeping just north of the fortress. It thence skirts the north side of the Island of Orleans, leaving a narrow margin on the Island for the Hudson River shales. From near the end of the Island it keeps under the waters of the St. Lawrence to within about eighty miles of the extremity of Gaspé, where it again comes upon the land, and appears to leave a narrow strip of the Hudson River or the Utica formation on the east."

"On the south side of the line, the Quebec Group seems to be arranged in long narrow synclinal forms, with many overturn dips."—*Geology of Canada*.

† See Herschel and Dana on this subject.

Now will be understood the expression which forms part of the introductory paragraph in the first Chapter of this Report, "The geographical features of a country are greatly dependent upon its geological structure." A tabular comparison between these parallel geographical and geological characteristics will be sufficiently striking.

PARALLEL GEOGRAPHICAL AND GEOLOGICAL FEATURES.

1st Geographical.	The course of the Saint Lawrence.
2nd Geological.	The Quebec group in Canada.
3rd Geographical.	The northeasterly course of the Saint John, and the Highlands of New Brunswick.
4th Geological.	The central series of granite belts, with the Quebec group on each side, stretching from the Atlantic to the Bay of Chaleurs.
5th Geographical and Geological.	The narrow granitic mountain ranges with the Quebec group on their flanks in Charlotte, King's and Queen's, &c.
6th Geographical.	The Atlantic coast of Maine and the Bay of Fundy.
7th Geographical.	The Atlantic coast of Nova Scotia.
8th Geological.	The Quebec group on the Atlantic coast of Nova Scotia.

A glance at the Geological Map will show that the great valleys between the anticlinal axes (ridges) just described, are occupied either by the coal formation and its outliers, or by other formations lying in parallel directions to the main ridges.

THE SOUTHERN GRANITE BELT.

This belt commences on the Atlantic Coast of the State of Maine, east of Penobscot Bay, and pursues its course in a northeasterly direction until it reaches the Boundary line. At or near the Boundary line it is divided into two subordinate belts or ranges, one of which crosses the Saint John at "Granite Quarry," and pursues a course towards Butternut Ridge, the limestone of which it has brought to the surface. The other ridge is seen four miles north of Magaguadavic Village, and crosses the Saint John above the City; it was recognized in position on a branch of the Coverdale (Little River), and probably extends to Shepody Mountain. The age of this Belt is the same as the Central Granitic Range, and it has brought up the Quebec Group of rocks on portions of the north side, and probably also on portions of the south side of the axis it represents.

On the road from Roix Station to the Village of Saint George, the granite has penetrated the schists in veins and patches,—and sometimes the patches of granite enclose masses of the schist. There is also a difficulty in distinguishing between the gneiss and the granite, and the impression produced at the time was that the gneiss gradually passed into a granite.

About ten miles from Magaguadavic Village the white granite was seen to involve pebbles of slate. It is here a very coarse granite, containing much

milky white quartz, and large crystals of white weathering felspar. About three miles farther on the road towards Saint George, the crystals of felspar become pale rose red, and the granite is succeeded by a pale red felspathic schist, with a strike N. 80 E., and a vertical dip.

At the Upper Falls of the Magaguadavic the schist has a general strike N. 80° E., and a dip to the north; it is succeeded by white granite about a mile lower down the road to the Village of Saint George. Here the granite is very coarse, the quartz crystals being very large, though imperfect; the felspar pale flesh coloured, and weathering white, with a little mica. Three miles farther down the road there is a very coarse granitoid gneiss, with apparent strike N. 70 E., dip S.* The colour of the mass is rose red on fresh surfaces; it weathers grey.

The breadth of this granite belt on the Roix Station road and on the Magaguadavic, appears to be about four miles. On Little River, in Elgin Parish, it is seen with the gneiss resting on it.

ORIGIN OF THE GRANITE.

The remarkable manner in which this rock has involved within its mass fragments of schist; the singular minuteness with which veins of granite ramify through the schist, well seen on the Shegomoc River; the parallelism of the alternating belts of schist and granite, and the slight disturbance which has occurred during the upheaval, all tend to establish the view entertained by Mr. C. H. Hitchcock, that these granites, as they occur in Maine, have been originally in a plastic state, due to the combined action of vapour of water and a low degree of heat. It is, however, very probable that the views which may be entertained of their origin point to a more precise link in their history than the mere supposition that they were in a plastic state during the time of their upheaval. They are indeed to be regarded more as metamorphosed or altered sedimentary strata than as intrusive rocks. They have probably been altered in position and belong to the class named by Professor Hunt, "Indigenous Rocks," and there are valid reasons for supposing that much of the granites of New Brunswick consist of altered sedimentary strata, changed by metamorphism into plastic felspathic sandstones and granitoid gneiss, then by a further metamorphism, partly into plastic granite and in part retaining traces of the stages of their metamorphism. Near the Magaguadavic, for instance, it was found impossible to find the line of demarkation between granite and granitoid gneiss, and between granitoid gneiss and true gneiss, so imperceptible were they blended one with the other.

Under these circumstances the granite of the central axis, as well as of the southern range, instead of being the agent by which the rocks were lifted up, would have only partaken of the general movement which affected the whole; a movement which we have seen extended from the Saint Lawrence

* The strike sometimes appears to be N. and S., dip W., but that given in the text is probably correct.

to the Atlantic coast of Nova Scotia, folding the strata in vast waves or undulations, at the close of the Devonian period.*

These grand uplifts must not be confounded with another series of earthquake movements which occurred during the earlier portion of the carboniferous epoch, and which are particularly manifest in the Counties of Albert and Westmorland; nor must they be associated with the subsequent gigantic movements of the earth's crust, called the Appalachian revolution, which extended from Alabama to Newfoundland.

Professor Hunt, of the Canadian Geological Survey, has devoted much attention to this intricate and important subject. His conclusions were advanced some years ago, and more recently embodied in the "Descriptive Catalogue of the Minerals sent by Canada to the International Exhibition for 1862." Subjoined is a valuable extract from that work, as well as one from the "Geology of Canada."†

And in a Chapter on the "Eruptive Rocks," in the Geology of Canada, "The general absence of granite from among these intrusive masses is a fact worthy of notice. * * * The granitic rocks of Shipton and of Saint Joseph on the Chaudiere, appear to be *indigenous* masses, belonging to the strata of the Quebec group; but the higher fossiliferous, formations to the east of the Notre Dame Mountains, are traversed in various places by veins and great masses of intrusive granite, whose characters and distribution have been described on pages 430 and 434.

* In describing the altered Devonian slates westward of the Nictaux River, in Nova Scotia, Dr. Dawson hints at a similar change into granite. "The beds of slate, in running against this great dyke of granite, change in strike from southwest to west, near the junction, and become slightly contorted and altered into gneiss, and filled with granite veins, but in some places they retain traces of their fossils to within 200 yards of the granite. The intrusion of this great mass of granite, without material disturbance of the strike of the slates, conveys the impression that it has melted quietly through the stratified deposits, or that these have been locally crystallized into granite *in situ*."—*Supplementary Chapter to Acadian Geology*.

† "The results of recent geological investigations in various parts of the world, lead to the conclusion that many rocks, formerly regarded as intrusive or exotic, are really sediments, altered *in situ*, or indigenous rocks. Such is the case with many granites, syenites, greenstones, amygdaloids, porphyries, and serpentines; all of which are represented among the altered strata of Canada. These sediments at the time of their metamorphism, were however in such a plastic state, that they were sometimes displaced and forced among the overlying and disrupted strata. It is not improbable that the intrusive granites, which are so abundant among the Devonian rocks to the south and west of the Notre-Dame Mountains, are the equivalents of the feldspathic sandstone and granitoid gneiss of the lower Silurian series. It is worthy of note, that intrusive masses are extremely rare in the Laurentian system, so far as known, except in one small area in the Counties of Grenville and Argenteuil, where a succession of eruptions of dolerite, syenite, and quartziferous porphyry, occurred before the commencement of the Silurian period. In the same way, the great masses of the Lower Silurian mountains are free from intrusive rocks. To the southeast of them, however, occur the Devonian granites just mentioned, and to the northwest, along the valleys of the St. Lawrence and Lake Champlain, are a series of intrusive dolerites, diorites, and trachytes."—*Geology of Canada*, page 669.—See also remarks on the same subject at the commencement of Chap. XX in the same work, by Professor Hunt.

"It is worthy of note, that the intrusive masses on the two sides of the mountain range are, so far as yet observed, entirely distinct in character; and that eruptive rocks are generally wanting among the Notre Dame Mountains, which consist chiefly of stratified rocks. It is also to be remarked, that the intrusive granites at their eastern base, are not unlike, in mineralogical characters, to the indigenous granites of the mountains; thus suggesting the view that these are possibly the source of the intrusive granites which break through the Devonian strata."

PLASTIC CONGLOMERATES.

The former plastic condition of the granites, as shown by the involved masses of schist, calls to mind the remarkable conglomerates in the neighbouring State of Maine, described by Mr. C. H. Hitchcock. The peculiarity of these conglomerates consists in the distortion and curvature of the pebbles they enclose. The pebbles appear as if they had been drawn out, curved and pressed together. Mr. Hitchcock considered that not only have the pebbles been elongated, flattened, and curved, since their consolidation into rock; but also that the elongated pebbles have been changed, by chemical action and prolonged pressure, into the siliceous laminæ of talcose and micaceous schists, while the cement has been converted into mica, the talc of talcose schists, and felspar.

The locality of this conglomerate is Weston and the north border of Washington County, Maine, close to the New Brunswick frontier. In travelling northerly it is first seen above the middle of No. 9, which borders on Grand Lake, one of the Cheputneticook Lakes, through which the boundary line runs. The strike of the conglomerate is N. 8° W. Dip 65° E.

It is argued that the elongation of the pebbles was due to pressure at a time when the rock was in a plastic condition.

The presence of graphite is sufficient proof that a great elevation of temperature has not accompanied the metamorphism of many sediments. A high temperature would have dissipated the carbon of the graphite. The thin sheets of this material which are found in the red and green slates at Woodstock; in the altered or metamorphosed rocks at the mouth of Goose Creek, on the Bay of Fundy; near the City of Saint John, and in the plumbeous slates near the mouth of Musquash River, all of which belong to metamorphic rocks, afford sufficient proof that these strata have not been subjected to any considerable elevation of temperature, sufficient to oxydize the carbon they contain. The intercalation of crystalline sheets between fossiliferous beds, is another proof that heat is not essential in the metamorphosis of rock masses. On Frye's Island, fossiliferous limestone occurs between felspathic schists, and highly crystalline limestones. The opinions which necessarily associate high temperatures with the occurrence of crystalline rocks, or of rocks which have undergone metamorphic action, are now no longer tenable.

OTHER FORMATIONS.

Lying to the north and northwest of the Lower Silurian Rocks, brought to the surface by the granite just described, there are immense deposits of Upper Silurian Rocks, much disturbed in places by intrusive traps; and in other localities, as on the coast of the Bay of Chaleur and on the Restigouche, interstratified with volcanic rocks. This series covers nearly the whole of the Province to the north of the more ancient rocks.

On the coast of the Bay of Fundy there is a great series of Middle and Upper Silurian, and Devonian formations, most of which have been greatly altered by bedded volcanic rocks, and in some instances by intrusive traps.

The remaining portion of the Province, covering an area of about 6,500 square miles, is occupied by Lower, Middle, and Upper Carboniferous Strata. These sedimentary rocks will now be severally described in detail in the following Chapters.

CHAPTER III.

THE CARBONIFEROUS SERIES.

Area occupied by this Series—Possible extent of the true Coal Measures—Distribution of the Series in New Brunswick—The Central Area—The Tobique Outlier—The Bay of Fundy—On the Restigouche and Bay of Chaleurs—Details of the Eastern Coal Field—The Lower Carboniferous—The BONAVENTURE Formation—Its Distribution—The Copper Ores of Bathurst—Origin of—Dependence of their existence on the vegetable matter in the Sandstones—Section near Bathurst—Paucity of life in the Bonaventure formation—Absence of Coal—Improbability of finding extensive deposits of Copper in this Rock—The presence of the Metal depends upon the presence of organic matter—General origin of similar deposits—The TOBIQUE OUTLIER—Description of the Rocks on the Tobique—The Plaster Cliffs—Succession of Rocks in the Tobique Valley—Economic Materials in—The Limestones of the Tobique compared with others in the Province—Comparison between the Tobique Rocks and those of Albert County—Woodstock Conglomerate—Analysis of.

The Great Eastern Coal Field of America, the details of which are given further on, covers a large portion of New Brunswick. The Carboniferous area in this Province is estimated to extend over 6,500 square miles, a considerable part, however, being occupied by the Lower Carboniferous or unproductive Coal Measures. It will be shown in the sequel that recent examinations of the Flora of this Series show that the Middle Carboniferous or true Coal Measures occupy a larger and far more important area than was formerly supposed, and it is by no means improbable that productive seams of coal may be discovered in certain directions which will be described in the proper place.

The several parts of the Province where rocks belonging to the Carboniferous Series are known to exist, will now be briefly noticed, as well as a general outline of the Eastern American Coal Field.

If attention has been given to the description of the great folds or plications of the strata which were noticed in the last Chapter, and were there stated to have been the chief cause of the highlands, in the northwestern and southeastern part of the Province, it will be inferentially seen that a deep Sinus or Bay, like that drained by the Kennebecasis, exists in the direction of the valley of Salmon River, and to a less extent along the valley of the South West Miramichi. It is thought probable that these supposed deep valleys, which would be the result of the folding of the strata, may be filled with Lower and Middle Carboniferous rocks, and covered by the upper portion of the Series. The reasons for this assumption will be amplified further on.

DISTRIBUTION OF THE CARBONIFEROUS SERIES IN NEW BRUNSWICK.

I. The great CENTRAL PLATEAU of triangular form, the apex being at Oromocto Lake, the extremities of the base at Bathurst, and the boundary between New Brunswick and Nova Scotia. The termination of this Plateau at Oromocto Lake is very remarkable. It appears to have been cut off abruptly by glacial ice. Vail's Hotel on the Magaguadavic is 230 feet above the sea, resting on Silurian slates. Rising abruptly from the valley of the river like a wall is seen the western edge of the Carboniferous Series, holding Lake Oromocto just within the rim of the narrow belt of Bonaventure rocks which fringe the Coal Measures. Oromocto Lake is 140 feet above Vail's, or 370 feet above the sea, but this west escarpment of the Coal Measures may be 100 feet higher. (See Chapter on Surface Geology for the probable origin of this escarpment.) The central area occupies a shallow basin containing probably one or two deep Bays, between the northeast granitic belt running through York, Northumberland, and Gloucester, and the northeast by east granitic belt running through King's and Queens, in the direction of Butternut Ridge. Its mean elevation is about 450 feet above the sea. Connected with the central area is a deep sinus or indentation between the two granitic ranges in King's County, extending as far west as the Saint John. The entire development of the central area occupies part of Gloucester, Northumberland, and York, nearly the whole of Sunbury and Queen's, a large part of King's, and the whole of Westmorland, Kent, and a considerable portion of Albert County. An outlying patch covers parts of the Parishes of Prince William, Queensbury, and Dumfries.

II. THE TOBIQUE OUTLIER, extending from the foot of the Red Rapids to one mile and a half above Blue Mountain, a distance of 26 miles in an air line. The breadth of this Outlier is not known on the northwest side, but it probably does not exceed in the aggregate 10 miles. Its northeastern boundary was ascertained in July last to extend $5\frac{1}{2}$ miles up the north Gulquac, measured in a direct line. The area of the Outlier is probably not greater than 180 square miles, or 115,000 acres. The mouth of the Gulquac is 420 feet above the sea, which is about the mean elevation of the Outlier.

III. The Carboniferous Rocks on the BAY of FUNDY, not at present forming a part of the central area. This Outlier extends from Emerson's Creek to Quaco.

IV. Mr. Matthew * describes a small area of Carboniferous Rocks on the east side of Saint John Harbour, in the rear of the plateau at Red Head, terminating in a bold cliff seventy feet high.

V. Dr. Gesner mentions an Outlier of the Carboniferous at Point Lepreau.

VI. On the Restigouche, there are small outliers at Point la Seine, also at Eel River, Huron Island, northwest of the mouth of Jacquet River, and in several places between Jacquet River and Bathurst.

* Observations on the Geology of Saint John County.

All of these now separate areas were at one time probably joined together, forming part of the Great Eastern Coal Field of America, which extends from the south shores of Gaspe in Canada, to the northeastern extremity of Breton Island, including part of Nova Scotia, passes under the Gulf of Saint Lawrence, and reappears on the southwestern extremity of Newfoundland. A portion of the bed of the Atlantic is probably composed of the rocks of this Series.

THE EASTERN COAL FIELDS OF AMERICA.

The following details will afford some idea of the Coal Fields of the Eastern Provinces of British North America—(New Brunswick, Nova Scotia, Newfoundland, and Cape Breton Island.)

General thickness of the Rocks of the Basin.

- | | | |
|---|--------|-------------|
| 1. Upper Coal Series—unproductive, | | 3,300 feet. |
| 2. Middle Coal Series—productive, | | 4,000 “ |
| 3. Lower Carboniferous or Gypsiferous Series, | | 6,000 “ |

I. Central Coal Field of Nova Scotia and New Brunswick.

Area, 6,800 square miles; maximum thickness, 14,570 feet; number of seams of coal, 76; aggregate thickness of coal, 45 feet.

The principal known Coal Beds are at the Joggins in Nova Scotia—3½ and 1½ feet thick.

The Grand Lake seam in New Brunswick is 22 inches thick.

II. Colchester and Hants Coal Field, (N. S.)

Area, 200 square miles; Coal seams, under 18 inches.

III. Pictou Coal Field, (N. S.)

Area, 350 square miles; thickness of main Coal seams, 37½ feet and 22½ feet, separated by 157 feet of strata. A pillar of coal 36 feet high was sent to the London International Exhibition.

IV. Coal Fields of Richmond and Cape Breton.

Area, 350 square miles; productive measures cover 250 square miles; thickness 10,000 feet; contains numerous seams of workable coal, the main seam is 6 feet 9 inches thick.

Valuable Coal seams occur also at Lingan and Bridgport, one of which is nine feet in thickness.

V. Newfoundland Coal Field.

Two small Coal fields exist on this Island. The formation is similar to that of Nova Scotia, and the Lower Carboniferous contain red sandstones, red and green marls and gypsum, like the outlier on the Tobique. The thickest bed of coal is about three feet.*

The base of the Carboniferous Series, as developed in Canada and part of New Brunswick, constitutes the BONAVENTURE formation of Sir W. Logan. It consists of Red Sandstones interstratified with beds of a coarse calcareous conglomerate.† In Gaspé the Bonaventure formation attains its greatest

* The Coal Fields of Great Britain—by Edward Hull, B. A. † Geology of Canada.

development; the thickness of the series is there not less than three thousand feet. The only fossils which have been met with in this formation are certain large plants, converted into coal. It thins out in New Brunswick, although it is found at the rim of the basin throughout its entire development in this Province. But there have existed conditions in the Valley of the Kennebecasis, which may have altered the character of the Bonaventure rocks there to a great degree.

The red sandstones and conglomerates which appear alone in Gaspé and the northern part of the Province, are in Westmorland, Albert and King's Counties, underlaid by a most important mass of bituminous shales whose thickness is probably not less than one thousand feet. These shales have been known in the Province under different designations, such as Caledonia Shales, Bituminous Shales, Albert Shales, Asphaltic Shales, &c. For the sake of uniformity they will be described in this Report as Albert Shales, because it is in these that the Albertite—a name first suggested to Sir Charles Lyell by the late Dr. Robb—of the celebrated Albert mines is chiefly embraced, although the same material is found in all kinds of rock as injected veins, and will be specially described in a succeeding Chapter. While, therefore, in Canada the base of the Carboniferous consists of red sandstones and conglomerates, in the southern part of New Brunswick the highly bituminous ALBERT SHALES form the lowest rock of the Series. On the first page of this Chapter, allusion is made to the deep Sinus or Bay forming the valley of the Kennebecasis, and its eastern prolongation. It is in this Bay that the Albert Shales attain their greatest development.

THE LOWER CARBONIFEROUS.

THE BONAVENTURE FORMATION.

Skirting nearly the entire Carboniferous Series in New Brunswick, the conglomerates and sandstones of this formation may generally be recognized by the marked red colour they impart to the soil which overlies them, as well as by the intensely red aspect of the rock itself.

The occurrence of these rocks in the places represented on the geological map constructed by the late Dr. Robb, is in part hypothetical, much of the country where they are supposed to occur having never been examined, and some parts of it rarely visited, even by the lumberman. But from the marked regularity observed in the distribution of the whole series of rocks under consideration, it is probable that the general delineation of their outcrop is correct.

This formation was seen at Bathurst, by Sir William Logan, and described by him in the Geology of Canada. Here it reposes, nearly horizontally, upon granite of Devonian Age. The strata contain fossil plants, which about a mile above Bathurst, on the Nepisiguit, have been replaced in part by Sulphuret of Copper, which again has become converted into the Carbonate at the surface. This transmutation served as a sufficient foundation

for the formation of the Gloucester Mining Company about 23 years since, but, owing to the irregular distribution of the organic remains * and the consequent uncertainty of the operations, the proprietors were induced to abandon the enterprize. The replacement of vegetable matter by ores of copper is by no means uncommon, and it has been described by Dr. Dawson as occurring to a certain extent in some of the lower beds on the Joggins Coast in Nova Scotia.† It is also stated by Sir William Logan, to occur in the Spanish Pyrenees, near Marc Auton and Hechos, where it has been successfully worked. A combination of coal and grey sulphuret of copper occupying the forms of vegetable remains, in a regular eighteen inch bed, seem there to crop out all around a considerable mountain.

The minerals have been introduced into the beds by water holding salts of copper in solution, in the form probably of blue vitriol or sulphate of copper. In contact with the carbonaceous matter of the fossil plants, the copper salt was deoxidized and deposited as a sulphuret.

SECTION NEAR BATHURST.

The following section of the strata occurs at and near the abandoned mine, on the Nepisiguit:—

Chocolate-red micaceo-arenaceous shale, with casts of shrinkage cracks,	ft. in.	30	0
White quartzose conglomerate, the thickest part of which is two feet, diminishing in one direction to two inches, in the space of 15 yards. The bottom is very white, and contains quartz pebbles, some of which are an inch in diameter,		1	0
Whitish-red argillo-arenaceous shale, forming a passage to the next bed below,		0	6
Whitish-red argillo-arenaceous shale in parallel layers; the bed thins out about 30 yards up the stream. It is charged with the remains of broken plants, some of which are replaced by vitreous sulphuret of copper, coated with a thin covering of green carbonate. Some are in part replaced by the copper ore, and partly converted into coal. Small nodules of the sulphuret of copper also occur, chiefly in the lower part, and traces of nickel are said to have been found in some of them. The greatest thickness of the bed is four feet; its average,		2	0
White quartzose conglomerate, similar to that of the summit. This does not thin out in the distance examined, about 50 yards, ...		4	0
Red Sandstone conglomerate with white quartz pebbles; of which some would weigh three ounces,		6	0
Red Shale,		6	0
Red Sandstone conglomerate, with quartz pebbles, some weighing a pound and a half,†		10	0

* Geology of Canada.

† Acadian Geology.

‡ Geology of Canada.

At Rough Waters the strata are seen lying in a nearly horizontal attitude upon the granite, and filling the inequalities of its surface. They extend up this river as far as two miles below the Second Landing, where they cover up rocks belonging to the Quebec Group, and on the north side of the river they here form cliffs 20 feet high, consisting of brick-red shales and sandstones resting upon a coarse conglomerate. They come on the river again, (the intervening space being occupied by granite,) a short distance above the Pabineau Falls on the south bank, the opposite side and the bed of the river being granite. At Brandy Brook the sandstones and conglomerates are seen in cliffs 20 feet high, and on the east side they appear to form a hill about 80 feet in altitude. The Rough Waters, more than two miles long, flow over granite, but on either side the Bonaventure formation may be recognized reposing horizontally upon it, and filling all depressions. The breadth of the Bonaventure formation on the road to Chatham, from its northwestern boundary near Bathurst, is about 13 miles, including the Harbour of Bathurst, and this is probably the broadest portion in the northern part of the Province, assuming that the limestones and gypsum which overlie the red sandstones and conglomerates are not included in the formation. About $9\frac{1}{2}$ miles from Bathurst, there appears to be an outlier or tongue of the Bonaventure Rocks, as shown by the steep cliffs of Little Bass River, and the red character of the soil.

Between the Nepisiguit and the South West Miramichi, the Bonaventure formation has not been traced, although it is laid down on the Geological Map of the Province accompanying Professor Johnston's Report, and where a section was made down the South West Miramichi this summer, the red rocks of the formation were not seen in position, although boulders were numerous. At the foot of the Island above Campbell, the grey sandstones and conglomerates overlying the red rocks have a very slight southerly dip, and rest on the tilted edges of Silurian Shales. That these strata do, however, extend all the way to Bathurst in the form of a narrow belt, is probable, as they are seen in many places between Campbell and the Saint John; they probably form a narrow belt about two miles broad, but in some places cover a wider area, for on Long's Creek, in the Parish of Kingsclear, they were observed a mile and a half below Essana's Mill, (about four miles from the Saint John), forming a coarse red rock, lying upon Silurian Slates. The pebbles were from six inches downwards in diameter, and the dip is to the south at an angle of 20° . (S. 10° E. angle 20° S.) They appear for some miles on the road to Harvey Settlement, which runs across them diagonally. Near the head of Oromocto Lake, when viewed from Magaguadavic Bridge (at Vail's), the bold cliffs of the denuded face of these rocks present a very fine appearance. In the Valley of the Kennebecasis, and probably in other parts of the southeastern portion of the Province, where they are at the surface, the red conglomerates form the hills. It is a strong rock, and has resisted denuding agencies to a much greater extent than the softer sandstones which overlie it, hence the reasons why it not only marks the limit

of the Carboniferous Series in New Brunswick with singular uniformity, but where it is exposed as a mass it forms imposing elevations or steep bluffs.

The same remark applies to this conglomerate on the Gaspé Shore, where the salient parts of the coast are composed of the conglomerate beds, while the re-entering angles correspond to the softer and less resisting red sandstones. Hence the zigzag line of the coast.*

It was suggested by Dr. Robb that the chief highlands on the Kennebecasis, from Milkish to the bluff, Mount Pisgah in Sussex and Studholm, and many hills on the coast of Charlotte County where outliers occur, were formed of this resisting rock.

LIFE DURING THE BONAVENTURE PERIOD.

The prevailing red colour is probably due to per-oxide of iron in the absence of organic remains; and it has been remarked by Dr. Dawson that the cause of the grey colour of certain sandstones may be traced to the presence of fossil plants, which have destroyed their original red colouring matter, the per-oxide of iron, just as in modern marshes on the Bay of Fundy, vegetable matter gradually converts the red into the grey mud, by de-oxydizing the red oxide of iron.

The period of Geological History embraced by the Bonaventure Formation must have been exceedingly barren in that part of the Continent where the red conglomerates and sandstones were deposited. But a series of strata upwards of 3,000 feet thick, almost destitute of animal or vegetable remains, was the prelude to the wonderful development of life which teemed in the oceans, swamps, and estuaries, of the succeeding age. It is probable, too, that deep secluded bays in the seas of this period, abounded in fish life, and their shores with a great variety and profusion of plants, for the Albert Shales, more than a thousand feet thick, in Hillsborough, which belong to the base of the Lower Carboniferous, are loaded with fish and plant remains, and the red conglomerates and marls surround and overlap them, though their thickness is comparatively insignificant.

NO WORKABLE COAL SEAMS IN THESE ROCKS.

In the Bonaventure Rocks, the paucity of fossil remains, independently of their lying at the base of the Carboniferous Series, would make any search for workable coal seams highly speculative; and although small seams from two to four inches thick have been found in various places, such for instance as in the outlier near Campbellton on the Restigouche, and as alleged, in the Harvey Settlement, (township of Manners-Sutton,) yet in the present state of our knowledge but slight prospects can be held out that remunerative seams will be discovered, or that any other result but disappointment will attend the search for *workable* coal in the strata of the Bonaventure formation *on the rim* of the Carboniferous Series in this Province. (*Vide* end of Chapter IV.)

* Geology of Canada.

In the deep sinus, now the valley of the Kennebecasis, other conditions may prevail, and the Lower Carboniferous there yield workable beds, though the probability is against their occurrence; but it would be premature to express any decided opinion on the subject until the thickness of the formation and its rock characters in that remarkable indent are known. It has been stated on good authority, that there exist not far from Sussex Vale, two seams of coal, separated by a narrow parting of clay, the aggregate thickness of these seams being twenty inches.

In addition to what has been already stated with reference to workable seams of coal in the Lower Carboniferous in America, it may be urged that in Scotland the workable coal deposits belong to the Lower Carboniferous, which there, however, is of considerable thickness, whereas the rocks of the same age in the Valley of the Kennebecasis and eastwards are comparatively thin.

The coal fields of Russia are considered by Sir R. L. Murchison to belong to the Lower Carboniferous period.* But they form an immense series stretching over a vast extent of country, and the greater part of the beds of coal are contained in the Carboniferous Limestone Series, as in the case of Scotland and Ireland.†

At the close of this Chapter a comparison is made between the Rocks of the Tobique Outlier and the Lower Carboniferous in Albert County. It will be there seen that the Albert Shales are supposed to be older than the Red Conglomerate of the Bonaventure formation, and to be at the very base of the Series.

OTHER MINERALS IN THIS FORMATION.

With reference to other minerals, the formation appears to be equally barren. Allusion has already been made to the Copper ores near Bathurst, but as these depend upon the abundance of vegetable matter in the sandstones to fix the salts of copper coming from much older rocks (the Quebec Group), in a state of solution, it is manifest that when the general absence of the de-oxydizing fossil vegetable is shown, the copper ore will not probably be found in quantity sufficient to warrant any large expenditure of capital or skill in search of it, for it will be understood at a glance that springs rich in copper salts might percolate through the sandstones for ages, but not a particle of copper would be arrested as soon as the supply of fossil vegetable matter became exhausted. If layers of vegetable matter, such as seams of impure coal, even three or four inches thick, were to be discovered in these rocks near Bathurst, it would afford some encouragement to trace them towards the locality where the copper ores were found. The clue to the copper ores will be the seams of impure coal—these once found, the metal may be looked for along their outcrop, with some prospect of success.

It is very probable that the substitution of a metallic mass for vegetable or animal matter has taken place to an enormous extent in the

* Russia and the Ural Mountains.

† Hull—Coal Fields of America.

rocks of this Continent. Professor Hunt considers that the evidence presented by the copper deposits of the Quebec Group, (from which those of Bathurst originated), appears to show that not only copper, but iron, manganese, nickel, and chrome, which so often accompany copper throughout the ancient Silurian Rocks, were held in solution by the waters from which the sediments of the period were deposited, and that by the agency of organic matters they were reduced to the condition of a sulphuret, and precipitated with the sediments, either in a finely divided state, or more frequently in small nodules or patches, which became interstratified with the rocks of the series.* Hence it would appear, that the Bathurst Copper Ores are a second reproduction of a series of mutations which may be briefly described as follows:—The waters in which the sediments composing the rocks of the Quebec Group, underlying or surrounding the Bathurst shales and sandstones of the Bonaventure formation, were deposited, held salts of copper in solution, these were reduced by the vegetable matter contained in the ancient ocean and precipitated with the sediment in a solid form, and lay for ages as copper ores. Subsequently by the action of water and air, as the rock was exposed by denudation, a portion of the sulphuret again assumed a soluble form, to be a second time deoxygenized when percolating through the organic matter contained in the shales and sandstones of the Bonaventure Rocks. This interesting and instructive subject will be again noticed in considering the origin of the iron ores of Woodstock, and the antimony of Prince William, &c. &c.

THE TOBIQUE OUTLIER.

The red conglomerate and sandstone of the Bonaventure formation cover horizontally the Silurian slates at an Island about nine miles from the mouth of the Tobique, and at the foot of the Red Rapids a fine section is exposed. The conglomerate holds a large number of green slate pebbles, with a less proportion of rounded and sharp pebbles of quartz. Between the Island and Red Rapids there is a protruding mass of this lower rock. The dips show a series of low undulations which continue to the northeastern extremity of the outlier. At the Island where the red rocks are first seen, the strata lie horizontally; at the foot of the Red Rapids the dip is E. N. E. $< 4^\circ$; half a mile up the stream the dip is W. S. W. at an angle of 5° , and a hundred yards farther on the dip is E. N. E. at about the same angle. There are seams of green shale between the red sandstones and shales or marls just above the head of the first rapid, and near the foot of the second rapid the rock loses its intensely red character and appears of a rusty brown, at times merging into grey. This is probably the limit of the Bonaventure formation, the succeeding rocks being more of the character of grits. These occur at Red Bank, eighteen miles up the river, where the strata are composed of minute angular particles of quartz firmly cemented together and possessing sufficient hardness and grit to make them serviceable as Mill stones.

* Geology of Canada.

Other layers are of sufficient fineness to admit of their being used as grindstones, being composed of fine white quartz grains. Above Three Brooks the bands of sandstone crop out on the bank with a north east dip of three or four degrees, and approaching the mouth of the Wapskehegan boulders of limestone become numerous. The red sandstone is variegated, and in it are found patches of a highly calcareous nature. The fine grained conglomerate of a pinkish colour, which occurs above Red Bank, is the same as that used by the proprietors of the Iron Works at Woodstock, in the construction of the new furnace, but the place where they have obtained their material is some miles further up the River. It has a pinkish cast, like some layers of the sandstone associated with it. It occurs in massive beds, and appears to be composed of angular grains of flint or quartz, with a few pebbles of slate.

Half a mile below the Wapskehegan, the pink sandstones disappear, and are overlaid by alternating red and green bands. The green are hard and calcareous, the red shaly and soft, approaching a red marl in composition.

LIMESTONES.

About a third of a mile above the mouth of the same river, silicious limestone appears in heavy bedded layers interstratified with red shales. A limekiln has been constructed at this spot, but is not now in operation. The limestone is pale sea green in colour, weathering dirty white; it occurs in beds from two to four feet thick, and dips to the east at an angle varying from three to five degrees. On the summit of a hill two hundred yards from the river, and about 120 feet above it, the limestone appears in heavy beds, and of a purer description than on the river, containing far less silicious matter. The rock is fissured at the surface, the crevices being two feet and less in diameter. The lime in a kiln constructed at the summit of the hill, is of good quality. The massive beds are not uniform in colour, being pale sea green streaked with red; patches of red are also not unfrequent. The limestone and shale appear to be about 140 feet in thickness. Half a mile above the outcrop of the limestone, a beautiful hard and white sandstone, with green specks in it, apparently succeeds the limestone. It is interstratified with an intensely red sandstone, dipping underneath the limestone. This must be a recurrence of the measures before described, the river here making a great bend to the north west across the stratification.

GYPSUM.

The celebrated plaster cliffs, about 180 feet high, succeed the limestone. They consist of alternating bands of impure gypsum, greenish and red; red shale, and small seams of fibrous gypsum and amorphous alabaster, which also occurs in small dense masses, sometimes rose tinted, but generally pure white. The green and red varieties exfoliate; the red shales are fissile and underlie the gypsum. A careful measurement of the dip showed that the inclination to the southeast was 11 feet 8 inches in 360 feet of horizontal distance, or about 1 in 31½, or equal to a rise of 170 feet in a mile,

which will give the gypsum a thickness of about 350 feet, if the inclination be maintained. Two hundred and fifty yards below the foregoing measurement, the dip was found to be E. $< 6^\circ$.

About a mile above the plaster cliffs there is a remarkable exposure of tufaceous limestone. The surface is reddened by the debris of superimposed or interstratified red shales, but the limestone bands are four feet in thickness, and are weathered into the most fantastic shapes. The forms of the weathered surfaces assimilate those common in limestone caverns, showing numerous stalactitic prominences on the under side of overhanging bands. The tufaceous masses exhibited the impressions of leaves, roots and fragments of wood, which the calcareous substance has encrusted. The fine but highly silicious gritty conglomerate underlies this limestone, which is the continuation of the massive layers before described, coming up again on a synclinal slope below the gypsum, which appears to occupy the summit of the entire series in the valley of the Tobique.

CONGLOMERATE.

A mile and a quarter beyond the plaster cliffs the fine red quartzose conglomerate again comes into view, the lower beds being a coarse sandstone, the beds at the summit of the exposure a soft red sandstone, with pale yellowish green layers. Salt Brook, which flows into the Tobique a short distance above the plaster cliffs, has a brackish taste and medicinal properties; on examination it was found to contain a small quantity of sulphuretted hydrogen, a considerable percentage of sulphate of magnesia, (Epsom Salts,) to which probably its aperient effects are due, and some common salt. Below Sisson's Brook the country is well fitted for agricultural settlement, it equals the fine expanse of alluvial soil near the O'Dell (Otella) settlement.

Red sandstone again appears above Burnt Land Brook with an easterly dip of 4° . And a quarter of a mile above the brook, the heavy bedded crystalline limestones are seen interstratified with red and green shales. The upper layers are greenish, the lower grey. At Burnt Hill Brook the limestone layers were traced fifty feet above the river, but to a passing traveller, being externally red from the decomposing interstratified red shales, they look like beds of red sandstone; a blow with a hammer, immediately dispels this illusion, and reveals the true calcareous character of the upper layers. There are some fine flats with superb elms in this neighbourhood. Half a mile below the Oxbow a low anticlinal axis occurs, the sandstone dipping west at an angle varying from 3° to 5° . Opposite an Island situated in a part of the river called the Oxbow, the banks show strata of alternating red, green, purple-red, and lavender-blue marls, with much shale of the same colours. It is only seen over a breadth of 20 yards. Three quarters of a mile above the Oxbow, the red sandstone and fine conglomerates come up on the west side of the low synclinal, the dip of the strata being east at a very low angle. About the same distance above the Gulquac,

the pink quartzose sandstone and conglomerate, before described as occurring near Red Bank, again come up, and it is from this locality that the materials for the formation of the Iron Furnace near Woodstock, were obtained. Equally good materials appear to exist nine miles lower down the river. The fine conglomerate occupies the bed of the river here, and on the left bank it is seen at an altitude of 40 feet above the water to be capped by alternating white sandstones, red shales and sandstones, and variegated sandstones, the whole having an altitude of about 100 feet; the strata here are slightly undulating.

Immediately below the Little Gulquac, the red conglomerate is seen overlying thick-bedded grey and pink conglomerates, dipping E., showing another low anticlinal axis; and a short distance higher up the river, red sandstone occurs in horizontal layers, terminating the southwest Carboniferous basin in the Tobique valley. This basin is separated by a few hundred yards of Silurian rocks from another but much smaller outlier, which begins about two miles above the North Gulquac, and extends as far as Irving's Brook, at the foot of Blue Mountain, a distance measured in an air line of about six miles. The upper basin contains only the red conglomerates and sandstones; it is separated on the river from the lower basin by an undulation, of which there are three between Red Rapids and Irving's Brook.

The following Table shows the order of succession in the Tobique Series of the Lower Carboniferous Rocks:—

TOBIQUE SECTION.

- I. Gypsum.
- II. Silicious Limestone.
- III. Red and green calcareous Shales.
- IV. Variegated calcareous Sandstone.
- V. White and pink Grits and Sandstones.
- VI. White Grits.
- VII. Red Conglomerates and Sandstones.

The economic materials found in the above rocks are not unimportant; they contain—

1. Sandstones suitable for building purposes and for Grindstones.
2. Grits well adapted for Millstones.
3. Firestones.
4. Limestones.*
6. Plaster.
7. Ochres of good quality in the alluvial flats of the Islands.
8. Indications of Manganese in the rocks below.

* See analysis of one of these limestones on a succeeding page.

When the older rocks upon which these lower carboniferous strata repose are described, other and more attractive minerals and metals will be enumerated among the natural sources of wealth contained within the beautiful valley of the Tobique. Some of the settlers on the banks of this river report the existence of coal, but no specimens were seen, nor is it in the least degree probable that any productive measures will be found within the limits of this valley. A black gravel, cemented by black oxide of manganese, was noticed on the banks of the river; similar gravels were seen on the South West Miramichi. These are important only as indicating the presence of manganese in the rocks upon which the gravels rest. These are probably the same as those which occur on the Nepisiguit and Tattagouche, where manganese is abundant. The metal has been brought to the surface by springs, and its presence leads to the inference that wad or bog manganese will be found in the valley of the Tobique as it is in similar rocks near Sussex Vale, the origin in both cases being from older rocks below.

THE LIMESTONES OF THE PROVINCE.

The Limestones of the Lower Carboniferous Series appear to be all more or less silicious. Some layers on the Tobique contain too much silica to admit of their being used for building purposes; others on the Kennebecasis are remarkably bituminous; and those which Dr. Gesner called "Lias," but which are really Lower Carboniferous, as in Norton, Sussex Vale, on Hammond River, and at Butternut Ridge, emit a fetid odour when struck with a hammer. Other varieties in the same basin are not sensibly bituminous. In many cases it is evident that the bitumen is of foreign origin, and not produced by the decomposition of marine animals in place.

The following analyses of limestones from these localities where the rocks under review occur, compared with one from the ancient crystalline limestone near Saint John, and another from L'Etang, will illustrate the wide difference which exists between the calcareous deposits of the different formations. The first three are taken from Professor Johnston's Report on the Agricultural Capabilities of New Brunswick, the fourth from Dr. Jackson's Report, the last column is by the writer. It will be observed that the specimen of Tobique limestone is more silicious than any of the others selected from Lower Carboniferous Rocks.

WOODSTOCK CONGLOMERATE.

In the vicinity of the Woodstock Iron Furnaces there is a remarkable outlier of ferruginous conglomerate, with a strike N. 35 E. and dip 50° south-westerly, resting unconformably upon the Lower Silurian Slates, which have a strike north and south, and a westerly dip at a high angle, about 200 yards west of the conglomerates. This conglomerate is stated by Mr. C. H. Hitchcock to occur again at a ferry about nine miles above Woodstock, dipping 25° N.W. Some of the strata are fine-grained, with impressions of rain-drops. A few of the pebbles, according to the same authority, are encased in gypsum, and the conglomerate is considered to be of the same age as the Tobique outlier. Without expressing any opinion as to the age of this rock, the following analysis shows it to have been formed chiefly from the debris of the red ferruginous and manganesian slates which form the source of the ore of the Woodstock Iron Mines. From information obtained on the spot, it appears probable that a considerable area of this conglomerate occurs in Brighton Parish, from which its age may be determined. Near Woodstock it rests upon the Lower Silurian Slates unconformably, but inclined in the

same direction; the underlying slates being tilted at a high angle with a westerly dip, the conglomerate dipping also westerly at an angle of about fifty degrees.

CHAPTER IV.

THE CARBONIFEROUS SERIES.—(Continued.)

The Central Triangular Area—Dr. Gesner's views—Dr. Robb's views—Mr. Henwood's opinions—Personal examinations—Dana and Dawson's subdivision of Carboniferous Rocks—Section in New Brandon—Lower and Middle Formation—Synopsis of the Flora of the Carboniferous Rocks of New Brunswick—The Flora of the Upper, Middle and Lower Rocks of the Series—Productive Coal Measures on Grand Lake—Probability of Coal being found in New Brunswick—Grand Lake Coal—Quantity raised—Section of Rocks from Oromocto Creek toward the Douglas Hills—True Coal Measures in the Valley of Salmon River—On the Richibucto—True Coal Measures probably extend from Grand Lake to the Gulf—The Valleys of the Kennebecasis and Petitcodiac—Section in Albert County and Westmorland—Section north of Norton Station—Review of what is known respecting the Carboniferous Rocks of New Brunswick—Value of Gypsum and Limestone—Bituminous Shales—Life and Climate during the Carboniferous Period.

THE CENTRAL TRIANGULAR AREA.

A very considerable portion of this extensive area must still be regarded as a *terra incognita*. It is chiefly occupied by the "forest primeval," and large districts have not yet been topographically examined, except for timber berths. In the Government Map published in 1859, (Mr. Wilkinson's), which embodies so large an amount of geographical information, there are still left vacant spots which show the paucity of existing knowledge even as to the rivers which drain them. A glance at the Map will enable any one to point to such areas between the upper waters of Salmon River and Washademoak River, in the Parish of Brunswick, the north part of Salisbury, and the northeast part of Waterborough. Nor do many portions of this great basin appear to have been visited by a geologist. Sir William Logan, in 1843, walked * along the coast from Bay Verte to Bathurst, but he did not penetrate the interior. Dr. Gesner has given a highly coloured description of the "Coal Fields" of various Counties, but I find nothing in his delineations which would lead one to suppose that he had made a section across the entire Carboniferous area, so as to determine the sequence of the different formations, and establish the existence or otherwise of the Middle Carboniferous or productive coal measures. Dr. Gesner frequently describes in glowing

* It was in this year (1843) that Sir William Logan made that elaborate section of the Carboniferous Rocks at the Joggins in Nova Scotia, which Dr. Dawson has well described as "a remarkable monument of his industry and powers of observation." It may surprise some of my readers who are not fond of walking, when I state that Sir William Logan, in 1843, *walked* nearly the whole way from the Joggins in Nova Scotia, to the boundary of the Carboniferous Series near Bathurst, for the express purpose of examining the rocks exposed on the road to Canada. In his exploration in Canada he has *walked* probably not less than 25,000 miles, or equal to once round the Earth.

terms the amazing advantages which will result to New Brunswick on account of her immense deposits of coal, but he has not in his Reports pointed out the existence of a single *workable* bed of greater thickness than 22 inches. In the admirable resumé of what was known of the "Coal in New Brunswick in 1849," prepared by Dr. Robb, from his own observations and enquiries and the Reports of Dr. Gesner, the following conclusions are stated:—

"1. That though very many outcrops of common coal, well adapted for blacksmith's use, are known to exist in the country, yet none of them exceed eighteen or twenty inches in thickness.

2. That though the beds of cannel coal reported to exist have a very considerable thickness, they hardly come up to the average standard of purity.

3. That the importance of the beds which are known has been over-stated, while the probability of finding others of greater thickness and improved quality, has been much exaggerated."*

Dr. Gesner did not stand alone in his sanguine views respecting the New Brunswick Coal Field. In the Transactions of the Royal Geological Society of Cornwall (1840), Mr. Henwood observes, that "the beauty and extent of these Coal Measures it is impossible to describe. In fact, we pass over nothing else, from Fredericton, on the Saint John River, to Miramichi, and thence to Bathurst, a distance of at least 150 miles. They consist of various beds of sandstone, shale, and conglomerate, with numerous thin seams of coal, few of which are more than a foot or two in thickness. The whole of this district is particularly rich in fossil flora."

My own examinations of the central area have necessarily been limited, and have, indeed, been confined to the district between Bathurst and Chatham; the neighbourhood of Boiestown; a portion of the country between Boiestown and Fredericton; the neighbourhood of Fredericton and Shediac; the Nerepis Road; Oromocto Road; in the Parishes of Manners-Sutton and Kingsclear; in Albert County; in the townships of Norton, Springfield, and part of Sussex, in King's County; and a few localities where an opportunity of making an observation on the rocks occurred, in journeying from one point to another within the limits of the Carboniferous area.

Under these circumstances, it is scarcely necessary to state that whatever information I may be able to offer respecting this large portion of the Province, relates almost altogether to the rim of the area; and as it is known that the rocks within it have been subjected to gentle undulations, which may have exerted a material influence upon them, it will be readily understood that where so large a portion is unexplored, conclusions respecting it must be in the main hypothetical, without they are based upon scientific data. For the purpose of explaining to the unscientific reader that the occurrence of carboniferous rocks to an immense extent, does not necessarily imply the existence of workable seams of coal, or, indeed, any coal at

* Report by Dr. Robb in Prof. Johnston's Report on the Agricultural Capabilities of New Brunswick.

all, it will be desirable to describe in general terms the opinions of Geologists as to the relation which the coal bearing strata, or coal measures in America, maintain with reference to the great mass of rock groups denominated the Carboniferous Series.

Dana* divides the American Carboniferous Rocks into three periods:—

- I. Subcarboniferous Period.
- II. The Carboniferous Period.
- III. The Permian Period.

These are again subdivided in the following manner, showing the relation of the productive Coal Measures to the other Groups:—

- I. Subcarboniferous Period.
 - a. Upper.
 - b. Lower, with *False Coal Measures*.
- II. Carboniferous.
 - a. Millstone Grit Epoch.
 - b. COAL MEASURE Epoch.
- III. Permian.

Dawson gives the following Synopsis of the Carboniferous Rocks of Nova Scotia:—

UPPER OR NEWER COAL FORMATION.

Greyish and reddish sandstones and shales, with beds of conglomerate, and a few thin beds of limestone and coal, the latter not of economic importance. Thickness, 3000 feet or more.

Characteristic Fossils.—Coniferous wood, Calamites, Ferns, &c.

LOWER OR OLDER COAL FORMATION.

Grey and dark coloured sandstones and shales, with a few reddish and brown beds; valuable beds of coal and ironstone; beds of bituminous limestone, and numerous underlays with *Stigmaria*. Thickness, 4000 feet or more.

Characteristic Fossils.—*Stigmaria*, *Lepidodendron*, *Poacites*, *Calamites*, *Pecopteris*, *Equitsetum*, &c. Erect trees *in situ*; remains of Ganoid Fishes, *Cypris*, *Modiola*, *Spirorbis*, *Unio*, &c. Reptiles, &c.

It is a general law, first noticed by Sir W. E. Logan, that the *Stigmaria Ficoides*, when found in an underlay, always indicates a true seam of coal.

LOWER CARBONIFEROUS OR GYPSIFEROUS FORMATION.

Great thickness of reddish and grey sandstones and shales, especially in upper part; conglomerates, especially in lower part; thick beds of limestone with marine shells and of gypsum. Thickness, 6000 feet or more.

Characteristic Fossils.—*Productus*, *Terebratula*, *Encrinus*, *Madrepores*, and other marine remains in the limestones; Coniferous wood, *Lepidodendron*, *Poacites* or *Cordaites*, &c., in thin shales and sandstones; Fishes and scales of ganoid fish very abundant in the lowest beds; *Trilobites*, *Reptiles*, &c.

* Manual of Geology, by James D. Dana. Philadelphia: Theodore Bliss & Co., 1863. An admirable work, with which all students of Geology should be familiar.

In a recent paper by Dr. Dawson, a more uniform nomenclature has been adopted, and the terms UPPER, MIDDLE, and LOWER COAL FORMATIONS, applied to the divisions of the Carboniferous Series. The "Lower Coal formation" is equivalent to the "SUBCARBONIFEROUS" of Dana; the "MIDDLE COAL FORMATION" is the "COAL MEASURE EPOCH" of Dana, including the marine limestones and the principal coal beds. The "UPPER COAL FORMATION" is applied to that part of the Series over the productive Coal Measures, but this does not include the Permian of Dana.*

All the evidence hitherto obtained with regard to the carboniferous rocks of New Brunswick, tends to show that at and near the rim of the central triangular area, the New Brunswick rocks belong to the Lower Carboniferous formation, and consequently lie below the Productive Coal Measures.

Towards the southeast portion of the area, in the neighbourhood of Grand Lake, the rocks are, according to Dr. Dawson, "on the horizon of the middle coal formation, though tending to the upper." This is an important fact, and with a knowledge of the dip and strike of the rocks, it affords not only a guide as to the direction in which the productive coal measures may be looked for, but it also shows that these productive measures will probably be found within the limits of the Province, the more especially as there is reason to believe in the existence of one or more deep bays or sinuses lying within the triangular area; and it is thought probable that these bays (resembling the Sussex Vale Bay,) may be in part filled with the middle carboniferous or productive coal measures. The origin of these supposed bays has been noticed on page 59.

I shall now proceed to describe what is actually known respecting the Carboniferous Rocks of the Province, and conclude the subject with a few deductions, which may serve to indicate the direction of future enquiry.

COAL FORMATION ON THE BAY OF CHALEURS.

At Salmon Beach, four miles from the entrance to the Harbour of Bathurst, red sandstones belonging probably to the Bonaventure Formation, dip to the northeast, and are succeeded five miles farther on by a succession of greenish-grey or drab sandstones, which also dip in the same direction at a low angle. As far as Point Dumai, 12 miles from Cranberry Cape, these rocks can be seen in the cliffs, which vary from twenty to one hundred feet in altitude, and the thickness of all the beds visible amounts to nearly four hundred feet.

In this section there are two seams of coal within 132 feet of one another, the upper one eight inches and the lower six inches thick. The roof of the upper coal seam consists of a dark bluish-grey argillaceous shale, and contains an abundance of ferns and other plants.†

These were submitted to Dr. Dawson, who considers them to indicate beds of the lower and probably *middle* coal formation. The beds include

some species which, in Nova Scotia, are more characteristic of the upper coal formation. "This apparent mixture," says Dr. Dawson, "of plants of different horizons, may be a consequence of the comparatively small thickness of the New Brunswick coal formation."*

FLORA OF THE NEW BRUNSWICK COAL FORMATIONS.

In a "Synopsis of the Flora of the Carboniferous Period in Nova Scotia," Dr. Dawson enumerates the species which he has recognized, as belonging to the different epochs of the Carboniferous Series in New Brunswick, from specimens sent to him by Sir William Logan, Mr. G. F. Matthew, Mr. C. B. Matthew, and Mr. C. F. Hartt.

The following List shows the relationship of these species to the several epochs of the Series, and the localities from which they were procured.

UPPER COAL FORMATION.—(*Unproductive Coal Measures*.)

1. *Sphenophyllum emarginatum*.—Grand Lake; Baie de Chaleurs.
2. *Sphenophyllum Sacrifragifolium*.—Baie de Chaleurs.

MIDDLE AND UPPER COAL FORMATIONS.

1. *Dadoxylon materiarium*.—Miramichi.*
2. *Alethopseris lonchitica*.—Grand Lake.

MIDDLE COAL FORMATION.—(*Productive Coal Measures*.)

1. *Calamodendron approximatum*.—Coal Creek. One of the most common plants in the beds of bituminous coal.
2. *Antholithes rhabdocarpi*.—Grand Lake.
3. *Calamites Suckowii*.—Grand Lake, Coal Creek.
4. *Calamites Cistii*.—Grand Lake, Baie de Chaleurs, Coal Creek.
5. *Calamites nodosus*.—Grand Lake.
6. *Asterophyllites grandis*.—Grand Lake, Baie de Chaleurs.
7. *Annularia galioides*.—Grand Lake, Baie de Chaleurs.
8. *Cyclopteris obliqua*.—Grand Lake.
9. *Cyclopteris ingens*.—Grand Lake.
10. *Neuropteris rarinervis*.—Grand Lake, Baie de Chaleurs.
11. *Neuropteris gigantea*.—Grand Lake.
12. *Neuropteris Loshii*.—Baie de Chaleurs (?)
13. *Odontopteris Schlotheimii*.—Baie de Chaleurs.
14. *Sphenopteris munda*.—Grand Lake.
15. *Sphenopteris latior*.—Grand Lake.
16. *Sphenopteris gracilis*.—Grand Lake.
17. *Sphenopteris artemisifolia*.—Grand Lake.
18. *Sphenopteris Canadensis*.—Baie de Chaleurs (?)
19. *Sphenopteris obtusiloba* (?)—Baie de Chaleurs.
20. *Alethopteris nervosa*.—Baie de Chaleurs.
21. *Alethopteris Serlii*.—Baie de Chaleurs.
22. *Alethopteris grandis*.—Baie de Chaleurs (?)
23. *Beinertia Goeperti*.—Grand Lake, Baie de Chaleurs.
24. *Palæopteris Hartii*.—Grand Lake.
25. *Lepidodendron Pictoense*.—Grand Lake.
26. *Lepidostrobus squamosus*.—Grand Lake.
27. *Cordaites borassifolia*.—Grand Lake, Baie de Chaleurs.
28. *Cordaites simplex*.—Grand Lake.
29. *Cardiocarpum bisectatum*.—Grand Lake.

LOWER COAL FORMATION.

1. *Cyclopteris Acadica*.—Norton Creek.
2. † *Lepidodendron corrugatum*.—Norton Creek.

* In the neighbourhood of Fredericton, on the Nashwaak, and indeed over a wide area of country, the silicified trunks or fragments more or less complete, of this coniferous tree, are often found.

A fragment of a trunk of this species was found on the hill in the rear of Fredericton, behind the Hon. W. H. Odell's residence. It must have measured thirty inches in circumference when entire. The specimen showed a portion of the corky bark and of the pith, but the mass was silicified.

† "This species is eminently characteristic of the Lower Carboniferous Coal Measures, and has not yet been found in the Middle Coal Formation. Fragments of bark resembling that of this species, occur in the coal formation of Baie de Chaleurs, along with leafy branches of *Lepidodendron*, which resemble those of the species, though I believe distinct."—(Dr. Dawson.)

 PRODUCTIVE COAL MEASURES IN THIS PROVINCE.

From the foregoing list it will appear that in the immediate neighbourhood of Grand Lake, the PRODUCTIVE COAL MEASURES exist, although the flora shows that they are "tending to the upper formation." A great point is gained in having the age of these rocks sufficiently established to afford good ground for the belief that these productive measures may be found within the limits of the Province, in such development as to make them of considerable value.

The supposed thinness of the New Brunswick Coal Field is opposed to the expectation that seams of workable coal will be found to occupy very wide areas, yet the structure of the country has been shown to support the view that in a bay or bays penetrating the Carboniferous area from the east, thicker seams than those which exist at Grand Lake (22 inches) may be sought for with a probability of success.

Before Dr. Dawson had an opportunity of examining the flora from Bay Chaleur and Grand Lake, he expressed an opinion unfavorable* to the existence of the productive measures in the Province, qualifying it, however, with the following words:—"The valuable character of the Albert Coal, however, and the well known fact that coal measures often vary materially in their productiveness, as we trace them from one locality to another, give some ground to hope that a Carboniferous area so extensive as that of New Brunswick, may not ultimately be found to be so unproductive as it now appears to be."

THE GRAND LAKE COAL.

The coal raised at Grand Lake from a twenty two inch seam, has hitherto been brought to market in a hap-hazard sort of way. There is no system whatever in mining it. Any farmer who finds the seam on his land, employs persons to dig out a certain quantity of coal, this is bought up by agents and shipped to Fredericton, Saint John and elsewhere. It sold at Fredericton at \$6½ a chaldron at the commencement of the winter of 1864-5, and it appears that about 5,000 chaldrons were shipped from Grand Lake during the season.† The quality of the coal is good, now that more care is taken to separate the lumps of iron pyrites, with which some portions of the seam abound. An American Company has recently leased a tract of land on Grand Lake, and there is every probability that the supply will now be largely increased. The Blacksmiths of Saint John consider it very well adapted for their purposes, and prefer it to the imported coals. It has very little ash, and in a properly constructed grate it makes an excellent fire.

* "In short, so far as I can learn from my own limited observations, and the Reports of Mr. Gesner and Dr. Robb, they resemble the lowest parts of the Cumberland Coal Measures, or those upper members which overlie the workable coals; as if these alone had been deposited and the productive coal-measures left out."—*Acadian Geology*, 1855.

† I am indebted to Mr. Wetmore of Fredericton, for these facts.

Quantity of Coal raised at Grand Lake.

1828,	66	chaldrons.
1830,	70	"
1833,	138	"
1834,	687	"
1835,	3,537	"
1839,	2,143	"
1864,	5,000	"

Some idea of the amount of coal a persistent seam, easily accessible, is capable of yielding, even though it be only 22 inches thick, may be obtained from the following calculation.

Assuming that a chaldron or thirty six bushels of coal is contained in one cubic yard and a half, (really about $1\frac{1}{2}$,) allowance being made for waste and dressing, it would require at 18 inches thickness of seam, three square yards to supply a chaldron of dressed marketable coal. Each acre would, at this rate, yield sixteen hundred chaldrons, and *every square mile one million and twenty four thousand chaldrons.*

If the Grand Lake seam extends towards Coal Branch, on the Rigibuctou, and appears there with a thickness of 15 inches, as suggested by Dr. Robb, the total mass of coal on a length of 40 miles and a breadth of 15 miles, would amount to the enormous quantity of six hundred million chaldrons.

Some years since borings were made at the Salmon River Mines to the depth of 403 feet. In the section given in Dr. Gesner's Report, nine recurrences of coal are mentioned, all unimportant with the exception of "Bituminous Shale and Coal," eight feet thick at a depth of 250 feet; what this may mean the section affords no clue.

It being established that the productive coal measures exist in the neighbourhood of Grand Lake, it remains to be seen,—

1st. In what direction search must be made to find the area where they are developed to the greatest extent.

2nd. Whether the thickness of the series may not show them to be beyond or on the borders only of that part of the coal basin which is characterized by thick beds of workable coal.

The first of these enquiries can be provisionally answered by reference to known facts. The second is a problem, the solution of which can only be obtained by future investigation.

The following section may be suggestive as to the first enquiry, but it is to be regarded as a mere guide; neither time nor opportunity was available for making any more than cursory observations; a complete series would take as many weeks as days were given to those which follow.

The manuscript notes of Dr. Robb supply numerous observations on the dips and mineral character of the rocks, which will fill vacant spaces in the sections subjoined, or afford valuable hints, but it is a matter of regret that the localities of many cannot be easily identified, as they refer to the farms and houses of private individuals 16 and 17 years ago, and are consequently unavailable.

No. I.

OROMOCTO CREEK TOWARDS DOUGLAS HILLS ON THE NEREPIIS ROAD.

KIND OF ROCK.		LOCALITY.
Lower Carboniferous.	1. Dark red or purplish argillaceous Sandstones, - - - -	Oromocto Creek.
	2. Purplish platy Sandstones, -	Bridge at South Branch.
	3. Grey Grits and Sandstones, -	Brizley's Creek.
	4. Coarse grey Grits, - - - -	14 miles.
Bonaventure Formation.	5. Coarse Conglomerate and grey Grits. - - - -	Height of land.
	6. Red Sandstone & Conglomerates,	A mile south of height of land.
	7. Silurian Slates, - - - -	Brook flowing to Nerepis.

This Section, coupled with other observations, appears to show that on the west side of the Saint John, the Lower Carboniferous or unproductive Coal Measures occupy the country.

From the dips recorded by Dr. Robb, it appears probable that Grand Lake, or part of it, occupies a synclinal axis, the anticlinal running in a north-easterly direction between Grand Lake and Salmon River on the one hand, and Washademoak Lake and River on the other. The direction indicated by these undulations would point to a narrow belt lying between those rivers, in the northern parts of the Parishes of Waterborough, Brunswick, and Salsbury, and the southern part of Harcourt, as the probable range of rocks of the age of the Productive Coal Measures, but whether they contain workable seams of coal of greater magnitude than those already known on Grand Lake, is a question to which no available data can supply a satisfactory answer. The presence of this synclinal axis at Grand Lake gives colour to the probable existence of a deep Bay or Sinus, in the direction of Salmon River, stretching towards the coast, and parallel to the Sussex Vale indentation.

Dr. Gesner suggests that "a sum of money would be well employed, in boring at a judicious site, in the neighbourhood of Gagetown, or on the north side of the Washademoak. The result of such an enterprize would be of the highest importance to the Province, and there could be no doubt of its final success."

With regard to Gagetown, the occurrence there of the same dark red or purplish argillaceous sandstones which are found on the Oromocto, as shown in section I, is opposed to the view expressed by Dr. Gesner, these rocks being, probably, below the productive coal measures.

As the Washademoak, from its mouth to its source, is some sixty miles long, the expression "north" of it is too indefinite to be of any service, although it is to the north of that river, that rocks of the age of the productive measures may be found.

Dr. Robb examined the coal on the Richibucto in 1849. He there found a seam 15 inches thick on Coal Brook. The coal cakes like the Grand Lake coal, and the dip is N. W. 10° . "Judging by the quality and thickness of the seam, it may yet prove to be the same as the one at the head of the Grand Lake, from which the sandstones pass continuously but in an undulating manner."* If the passage between the quotation marks is based on actual observation, it is most important. The rocks at Grand Lake having been shown to belong to the true or productive coal measures, the occurrence of these rocks for a distance of fifty miles, measured diagonally across the strike, follows from Dr. Robb's statement. This tends to show that a considerable area in that part of the Province belongs to the middle or productive coal series.

The mean altitude of the triangular area does not exceed 400 feet above the sea; and although the thickness of the carboniferous strata is not, perhaps, more than 1,000 feet, it has been subjected to gentle disturbances which have caused a number of low anticlinals, as already stated. At the mills, $1\frac{1}{2}$ miles below Fredericton, the reddish-grey sandstones dip northwest at an angle of 9° ; and on the south side of the brook above Smith's bridge, the grey sandstone under conglomerate dips northeast at an angle of 18° .—(Robb). Numerous other examples of undulations might be adduced, but those only possess value in relation to the occurrence of coal, where the age of the rock is known.

THE VALLEYS OF THE KENNEBECASIS AND PETITCODIAC.

I have not recognized any rocks of more recent age than those belonging to the Lower Carboniferous, in the long trough-like indentation which stretches from the Petitcodiac to the Saint John; and although the true coal measures may be represented there, it is not likely that the area occupied by them will be large. Indeed, the supposed extent of country covered by the Carboniferous Series, as depicted on Dr. Robb's map, is much too wide. I crossed it in several places, and found the axis of older rocks running parallel to the Gulf, considerably broader than represented. Golden's mountain, for instance, lies wholly within the metamorphic belt; and the same rocks come within ten miles of Sussex Vale station, on the Dutch Valley road, before they are overlaid by the conglomerates of the Bonaventure formation. In various parts of this area there are rocks which may be included within the productive measures, but if so, they are outliers, and their dimensions must be small.

* Third Report, page 73.

In the Parish of Dorchester, County of Westmorland, the Middle or Productive Coal Measures appear on the Memramcook, forming the north extension of the already celebrated Joggins Measures in Cumberland County, Nova Scotia.

Their relation to the Joggins is seen in the following Section by Dr. Dawson* :—

No. II.

SECTION ON THE MEMRAMCOOK.

- | | |
|---|--|
| I. Upper Coal Measures.— | Upper sandstones and shales of south Joggins. |
| II. Middle Coal Measures.— | Coal Measures of the Joggins, and Millstone Grit or Lower Coal Measures of Dorchester. |
| III. Lower Carboniferous Marine Limestone.— | Limestones, Gypsum and Conglomerate of Dorchester and Petitcodiac. |
| IV. Lower Coal Measures.— | Fine calcareous and highly bituminous shales, with thin beds of sandstone. Abundance of the remains of fishes seen at Petitcodiac River, above Dorchester, Albert Mine, and other localities westward of that place. |

The dislocation alluded to in Chapter V. occurring on the southeast coast of Shepody Bay, in Albert County, is situated in a synclinal fold, and the limestone which appears on Hayward's Brook is there at the surface, the probable upthrow being on the southwest side. The whole series of grey sandstone and red and green marl has been removed by denudation on the south side, and the limestone exposed. Had not this upthrow occurred, it is not improbable that the coal measures would have been found on the entire shore of Shepody Bay, whereas the Lower Coal Measures are only represented. The continuation of Shepody Mountain in a northwesterly direction, brings it to the head waters of the east branch of Turtle River, and here the mountain or rather table land of the older rocks has a mean elevation not less than 1000 feet above the sea, which is maintained to considerably beyond Salmon River, in Hammond Parish. In the ravines and gullies on the mountain side (which in some places resembles an escarpment) the red conglomerate and sandstones of the Bonaventure formation may be seen, while the hills north of the tableland, and in some cases forming part of it as it breaks away to the north, are composed of the grey sandstones and grits.

The middle coal formation may be found with productive measures in the southeastern portion of the County of Westmorland, but, I am not able to add from personal knowledge any new facts to those which have already been published by Dr. Dawson.

* Supplementary Chapter to the Acadian Geology, 1860.

About two miles southeast of Salisbury station, the red sandstones of the Bonaventure formation lie in a nearly horizontal position; and seven miles further on they were also seen to occupy the same position, showing that the disturbances which commence north of Weldon Creek did not extend far in that direction. The gypsum of the series is in position, and has been worked about two miles north of the station.

No. III.

SECTION NORTH OF NORTON STATION.

No higher rock than the red conglomerate covering the limestone, which appears so persistent throughout the lower carboniferous rocks in Albert County and the Tobique outlier, was recognized on this section. The series continues as far as the Bellisle River, where the narrow belt of older rocks appears stretching away towards Butternut Ridge.

The limestone would seem to underlie a considerable portion of the north side of the valley of the Kennebecasis, being occasionally brought to the surface by low undulations. At Butternut Ridge it appears in great force, and according to Dr. Robb it has there been elevated in the form of several ridges running parallel to one another, and having a northeasterly course, which is the direction, as already noticed, of the anticlinal axis, bringing up the older rocks all the way from Saint Stephen, on the boundary line.

Silicious layers also occur in the limestone about seven miles northwest of Norton station, but on the whole it makes a white and strong lime. Some feeble veins of galena are seen in this rock.

REVIEW OF THE CARBONIFEROUS SERIES.

On reviewing what is known respecting the Carboniferous area in New Brunswick, the following conclusions appear to be worthy of acceptance:—

1. The entire rim of the central triangular area, the whole of the Tobique outlier, and the greater portion of the deep indent drained by the Kennebecasis and the upper Petitcodiac Rivers, belong to the base of the Carboniferous Series, and consequently do not contain any workable seams of coal. They abound, however, in limestone and gypsum;* and the deep indent from Hillsborough to Norton contains a valuable deposit, and numerous favourable indications of other deposits of Albertite; also extensive and important beds of a highly bituminous shale, which may become valuable as a source of illuminating oil, and as a gas fuel for re-generating furnaces, and for metallurgical processes.

2. The country about and northeast of Grand Lake, is occupied by the Middle or Productive Coal Measures, but whether they contain workable seams of coal more than 22 inches thick, is a subject of future inquiry. The structure of the country leading to the inference that the productive Coal Measures will be found in force in the valley of Salmon River and the Richibucto.

* There are no less than six large areas of gypsum in Albert County.

3. A portion of the County of Westmorland contains the true Coal Measures, and it is not improbable that workable seams of coal may be found there.

4. What is known of the country near the coast north of Richibucto, leads to the inference that the Upper or unproductive Coal Measures are in place there, and consequently, that the probability of coal being found in workable quantities, is by no means great.

5. The interior of the central area, on a line drawn from the Bend of the Petitcodiac to the mouth of the Renous River, along the dividing Ridge separating the waters flowing into the Saint John from those flowing into the Gulf of Saint Lawrence, is geologically unknown, and no definite conclusions can be drawn respecting it; but, the dip of the rocks and the supposed absence of considerable undulations, with the occurrence of the "Lower Coal Measures tending to the Upper," west of this line, point to the inference that the Upper or unproductive Coal Measures are there in place. On the other hand it may be urged that a fault or dislocation would bring the Middle or productive Coal Measures into place. There is however, no data upon which the existence or non-existence of a fault can be predicted. Hence the position of the central area remains still a *terra incognita*.

6. The borings which have been made at Grand Lake, and at New Bandon, show, if correctly registered (?), that no workable seams of coal exist below those which have been already discovered in those localities, as far as the borings have penetrated.

7. The thinness of the New Brunswick Carboniferous Series almost precludes the hope that what have been termed the "false coal measures," will be found in the Lower Rocks of the basin. In Pennsylvania these rocks (Sub-carboniferous) have a thickness of about 5,000 feet, and they contain, both in the State named and in Virginia, a few thin workable seams of coal. In Montgomery County, Virginia, there is a layer of coal two, to two and a half feet thick in these lower, unproductive measures. But there is no reason to suppose that any rocks of the same age in New Brunswick contain seams of coal which approach that thickness, for with the exception of the Albert Shales, the general aspect of the red sandstones and conglomerates lead to the inference that life was scarce during their formation. It will be borne in mind that in America the productive or non-productive character of the different divisions of the Carboniferous Series is much more determined than in many parts of Europe, and the probability of workable coal being found is tolerably well indicated by the fossils of the rocks.

LIFE DURING THE CARBONIFEROUS PERIOD.

The enormous development of vegetable matter which we are able to recognize in the coal fields throughout the world, affords incontestible proof of the existence of most luxuriant plant life during the Carboniferous epoch; but, until recently, the evidences of the existence of air-breathing animals

has not been so satisfactorily demonstrated. In 1841 Sir W. E. Logan discovered the first reptilian foot prints in the coal fields of Nova Scotia. It was already known that land snails and millipedes fed on the leaves and decaying vegetable matter of the luxuriant forests of that period, that insects flitted through the air, and that the seas teemed with fish and moluscos animals; but air-breathing reptiles were supposed to possess too high an organization to admit of their living in an atmosphere loaded, it was supposed, with poisonous carbonic acid, the chief food of vegetables. It has been the happy result of the long continued investigations of Dr. Dawson, to discover the existence of no less than eight different species of air-breathing land animals, which once swarmed, we may suppose, in the carboniferous marshes and swamps of Nova Scotia.*

CLIMATE OF THE COAL PERIOD.

The climate of the Coal Period has long been a difficulty. Many ingenious theories have been advanced to account for the presence of the Coal Series in the Arctic Regions, containing plants and animals which required a mild climate for their growth and development. The recent researches of Dr. Tyndall on Radiant Heat, have afforded a probable explanation of this phenomenon, which has been ably discussed by Professor Hunt.

The properties of gases with respect to radiant heat are most remarkable. Air scarcely absorbs any sensible quantity of radiant heat, but if air absorbs one ray, carbonic acid will absorb 90 rays; marsh gas, 403; ammonia, 1195; and olefiant, 970. Hence although ammonia is as transparent to light as the air we breathe, it is almost opaque to heat. But if the absorption be estimated at a low tension, that is to say when a small quantity of gas only is present, the difference becomes more apparent and striking. Thus at a tension of one inch, for every individual ray struck down by the air, oxygen, hydrogen, or nitrogen—ammonia strikes down a brigade of heat rays 7,260 strong—olefiant gas a brigade of 7,950, while sulphurous acid destroys 8,800 rays. This property is most important in its bearings upon climate. Aqueous vapor which always exists in the air, absorbs heat with great vigour. Regarding the earth as a source of heat, at least 10 per cent. of its heat is intercepted within ten feet of the surface by the aqueous vapour of the air. The removal, for a single summer night, of the aqueous vapour from the atmosphere which covers England, would be attended by the destruction of every plant which a freezing temperature could kill. The moisture of the air covers the earth as with a blanket at night, and where the air is dry as in the great desert of Sahara and the plains of Thibet, or the deserts of Australia, ice is frequently formed during the night by the direct radiation of the heat of the earth towards the planetary spaces, there being no blanket of aqueous vapour to retain it. So powerful is the effect of aqueous vapour in retaining heat that although the atmosphere contains but one particle of

* Five species of carboniferous reptiles have been found on the continent of Europe, three in Great Britain, and four in the United States.—(Air Breathers of the Coal Period.—Dawson, 1864.)

aqueous vapour to 200 of air on an average, yet that single particle absorbs 80 times as much heat as the 200 particles of air.

Bearing in mind that the atmosphere of the coal period contained an abundance of carbonic acid, from which plants drew their food, and limestones the acid combined with their base, we have at once an explanation of the uniform temperature of the earth. The carbonic acid mingled with the air, aided by aqueous vapour, prevented the heat rays of the sun from returning into space by radiation. The earth was covered as it were with "a dome of glass" which maintained at its surface the requisite temperature to enable plants and animals to live even in the Arctic Regions. The gradual absorption of this protecting shield of carbonic acid slowly but effectually changed the climate of the Arctic and Antarctic Regions, and arrested the growth of vegetation during the epochs succeeding the Carboniferous period.

GEOLOGICAL AGE OF THE ALBERT SHALES.

Two distinguished Geologists have pronounced their opinions upon the geological age of the Albert Shales.* They lie at the base of the Carboniferous Series, as developed in Albert County.† They are calcareo-bituminous shales, containing a great number of fossil fishes in a remarkable condition of preservation, every scale being in place, although the fishes are flattened by pressure; they also have their fins perfectly preserved. Some beautiful specimens are occasionally to be procured by breaking open the layers of shale taken out of the shaft, and are found larger than those which have been described. These fossil fish belong to the same genera with those found in the Joggins coal measures of Nova Scotia. Dr. C. T. Jackson discovered (1851) in the shales perfect stems of *Lepidodendra*, large flag-like leaves of plants, regarded as a species of Palm, stems of a fresh water plant, and numerous fishes, all indicative of the Carboniferous Series.

The Section subjoined is from Dr. Dawson's *Acadian Geology*.

1. Grey sandstone, often coarse and pebbly, with shales and conglomerate; Hopewell Ferry, &c. These beds, perhaps, correspond to the great sandstone ledges of Seaman's Quarries, Joggins. They may be traced through Albert County, to the southwest, for a considerable distance.

* Sir Charles Lyell and Dr. Dawson. Dr. Percival, of New Haven, also agrees with Sir Charles Lyell and Dr. Dawson.—*Acadian Geology*. Dr. Robb was also of opinion that they belonged to the age of the unproductive coal measures.—(Evidence at Trial.)

† *Acadian Geology*, page 196.

2. Reddish sandstones and shales.
3. Limestone and gypsum.
4. Red sandstone and conglomerate.
5. Grey and dark-coloured conglomerate.
6. Calcareo-bituminous shales of the ALBERT MINE, HILLSBOROUGH. These beds appear here to lie at the very base of the Lower Carboniferous Series.

Nos. 3, 4 and 5 of this Section remind us of the succession of rocks in the valley of the Tobique, where the strata are arranged in the following order: 1. Gypsum (the highest rock); 2. Limestone; 3. Sandstones and Conglomerates; 4. Silurian Slates.

In Albert County the gypsum is seen beneath the limestone, and the limestone resting upon the conglomerate. The newest rock here seems to be a light brown conglomerate.

The Joggins, celebrated for their unrivalled display of Carboniferous Rocks, are situated on the Nova Scotia side of Chignecto Bay, a distance of sixteen miles from the Albert Mine. Between these two localities the sequence of the rocks has been traced and described at some length by Dr. Dawson.

The coal measures of the Joggins dip to the southwest, and extend in the direction of the strike across Chignecto Bay to Cape Meranguin, where the lower coal measures appear. On tracing these to the northward, they become vertical and dip to the north, forming an *anticlinal* axis.

At Fort Cumberland the coarse grey sandstones still dip to the north, which continues as far as the east side of the Petitcodiac River. At Hopewell the same sandstones reappear, but with southerly dips, showing that the bed of the Petitcodiac here, or Shepody Bay, occupies a *synclinal* axis. On the west side of the Petitcodiac the rock shows alternating dips which will be noticed in succeeding paragraphs, but on the east side of the Albert Mine the dips are northeasterly, on the west side northwesterly, thus showing at and near the mine an *anticlinal* axis. Hence it appears that a series of disturbances has occurred in this district which may have very materially influenced the present distribution of the Albertite which has given to the Albert Mines so widespread a notoriety.

DISTURBANCES IN ALBERT COUNTY.

If a section be made across the County of Albert, from the Joggins, in Nova Scotia, to the syenite and older slates which form the continuation of the Shepody mountain, in a northwest by north direction, a series of *anticlinal* and *synclinal* axes will be found to run roughly parallel to one another in the following order:—

- I. Chignecto Bay,.....ANTICLINAL.
- II. Shepody Bay,.....SYNCLINAL.
- III. Memramcook, mouth of,.....ANTICLINAL.
(Runs through the Peninsula.)

- IV. South of Cape Demoiselle Road,.....SYNCLINAL.
 V. Taylor's Mill Stream,.....ANTICLINAL.
 VI. Between Albert Mines and School House on
 Cape Demoiselle Road,.....SYNCLINAL.
 VII. ALBERT MINE,.....ANTICLINAL.
 VIII. Northwest of Albert Mine, one half mile.....SYNCLINAL.
 IX. Middle Branch of Weldon Brook.....ANTICLINAL.

Five anticlinal and four synclinal axes appear to have been recognized in a distance of twenty two miles.

The general course of these axes is S.W. and N.E. They correspond in a remarkable manner with the course of the other anticlinals in this Province, which have already been described in preceding Chapters, (page 48.)

FAULTS.

Near the mouth of Danniell's Creek there is a fault and an upthrow on the south side, or a downfall on the north side.

At Big Cape on the Petitcodiac a fault throws the strata ten feet down on the south side.

At the Albert Mines the downfall appears to be wholly on the north side.

LOWER CARBONIFEROUS SERIES AS DEVELOPED IN ALBERT COUNTY.

On Shepody Mountain road, about three miles back from the coast, the grey sandstones overlies slates succeeded by syenite. On the coast at Danniell's Marsh, the sandstone capped by conglomerate has a northerly dip, but on Cape Demoiselle road about 1½ miles from its commencement, the grey sandstones dip south, shewing the existence probably in this neighbourhood of a synclinal axis and fault.

At Hayward's Brook, Red and Green Marls are seen resting on cherty limestone which lies on variegated conglomerate—all dipping S. E. The gypsum is recognized on Wilson's Brook in grand mural cliffs. These magnificent wall like precipices may be from 140 to 180 feet high and a quarter of a mile long. When the western sun shines upon the white and bluish masses of gypsum it affords a dazzling and most striking scene. The upper beds are white, the lower bluish, hard, and with a conchoidal fracture. The cleavage is vertical. The gypsum appears to have an easterly dip, and apparently underlies the conglomerate.

The following is a rough section of the Rocks from the Albert mine down the Cape Demoiselle Road to the Shore.

- I. Bituminous Shales,.....(South of Albert Mine.)
- II. Grey Sandstone and Conglomerates.
- III. Gypsum.....Mill Stream.
- IV. Conglomerate.....Hayward's Brook.
- V. Limestone, (cherty.)
- VI. Green and Red Marls.
- VII. Grey Sandstone.

FAULT, bringing number V. Limestone on the coast. Shepody Bay.

I did not visit the section exposed south of Edgett's, but Dr. Robb states that the house and farm is situated on a small *butte* of red conglomerate or breccia, made up in great part of angular fragments of a greenish slate, quartz, flint slate, porphyry and granite. It is difficult to detect any lines of bedding in it. On the beach near the exposure there is a considerable quantity of iron sand, which may have come from the conglomerate. This rock resembles in many particulars the red conglomerate at the base of the Carboniferous area in the valley of the Tobique. It dips to the south, and is succeeded by red sandstone and grey sandstone, containing calamites.

Dr. Jackson has the following Section at Taylor's Mill Site :—

- I. Coarse Conglomerate.
- II. Grey Limestone.
- III. Gypsum.
- IV. Red Marl.
- V. White Gypsum.

The coarse conglomerate here described is evidently of the same age as that seen by Dr. Robb at Edgett's; it is stated to consist of pebbles of quartz, syenite, green metamorphic slate, trap rock, jasper and carbonate of lime.*

At the Big Cape on the Petitcodiac, the following Section may be seen :—

- I. Red conglomerate, (calcareous.)
- II. Greenish conglomerate.
- III. Reddish Sandstone.
- IV. Red Marl. Paint Rock.
- V. Sandstone.
- VI. Red Marl. Paint Rock.
- VII. Sandstone, (Grindstone grit.)
- VIII. Red Marl. Paint Rock.
- IX. Green Marl.
- X. Grey conglomerate.
- XI. Grey Sandstone.

The grey grit resembles the rocks near Fredericton.

A short distance from the place where the grey conglomerates and sandstones reach the shore there is a fault, which throws the south side down about ten feet. The Red Marls or Paint Rocks as they are locally termed may be useful. The hard and homogeneous bands would make good "red chalk."

East of Edgett's, on the Petitcodiac, (about one mile,) Dr. Robb observed bituminous limestone, forming a bed about 12 feet thick, with cleavage joints filled in places *with bitumen*. Some of the pebbles of the neighbouring conglomerate were also coated with bitumen.

He also records on the opposite side of the Petitcodiac (Dorchester), after leaving the red conglomerate, dark coloured bituminous shales with fossil

* Report on the Albert Coal Mine, by Charles T. Jackson, M. D.

ganoid scales, impure limestones, indurated marl, and a very impure coal. The dip was to the N. W. at an angle of 20° .

On Taylor's Mill Stream, the gypsum is seen in a great variety of hues and qualities. From hard grey massive rock to snow white alabaster it passes through all gradations of colour; from a high toned red to the most delicate shade of salmon. The cliffs at the quarry are from 80 to 100 feet high, and the locality is one well worthy of being visited on account of the singular and romantic appearance of the rocks. The section seen on the tramway to the Post Road is as follows:—

- I. Gypsum.
- II. Variegated Red and Green Marls.
- III. Limestone.
- IV. Conglomerate.

On the road from Edgett's to Steves' Brook, a mile north of Hillsborough, the dip of the rocks on the hill descending towards the brook, is to the north, (south of Hillsborough the dips are to the south), showing that an anticlinal axis is crossed, which is probably the main anticlinal passing through the Albert Shales near the Mines. South of Edgett's the dip is southerly, and north of Hillsborough the following dips were noted in October of the present year:—

Summit of hill in the centre of the village of Hillsborough,									
a coarse conglomerate,	Dip	S. 70°	W.	
Half a mile from centre of village, a fine conglomerate,	"	S. 30°	W.	
Sixty yards further down the hill, a sandstone, with small pebbles in some of the layers,*	"	S. 30°	W.	
Near the foot of the hill, a fine variegated conglomerate,	"	vertical.		
Steves' Ravine—Petroleum Spring,	"	W. $< 65^{\circ}$		
At the falls of Steves' Brook the rocks are composed of alternating red shales and red variegated sandstones, green and red, resting on cherty limestones. One bed of green shale is eight inches thick. The upper sandstones are slightly conglomerate. The mass is capped by a very coarse conglomerate, dipping,		N. W. $< 8^{\circ}$		

This rock appears to have been deposited after the disturbances in this part of the country, and perhaps the same remark may apply to the coarse light brown conglomerate capping the entire series in Albert County.

BITUMINOUS OR ALBERT SHALES.†

At the head of Turtle Creek the strike of these shales is E. and W. and dip N. at an angle of 50° . On the south Dividing Ridge the metamorphic slates are seen with a strike N. 60 E. and dip N. 30 W. at an angle of 54° . The bituminous shales are here observed to rest directly on the slates, and

* This sandstone resembles the freestone of the Tobique. The early settlers were accustomed to use it in the construction of their fireplaces.

† Called locally "Baltimore Shales."

the slates on syenite; these rocks resemble the pebbles in the red conglomerate forming the base of the Carboniferous Series in Albert County, and in other parts of the Province.

The area over which the Bituminous Shales are distributed is very considerable, for they have been recognized in patches from near Dorchester, in Westmorland, to Apohaqui, in King's County, a distance exceeding fifty miles.

A tabular list of localities where they appear at the surface, follows:—

KING'S COUNTY.

I. At Apohaqui, beds of Bituminous shale and seams of Albertite in sandstone. Further up the valley are thick deposits of bituminous shale and limestone.*

II. Ward's Creek.—Brownish bituminous shale or slate, extends for several miles towards Dutch Valley.

ALBERT COUNTY.

III. Baizeley's Farm on Turtle Creek.—Bituminous shales, called locally 'Baltimore Shales,' rest unconformably on metamorphic slates.

IV. Five miles N.W. of the mouth of Shepody River.

V. Frederick's Brook.—Bituminous shales, called locally 'Albert Shales,' and a distinction is popularly supposed to exist between the Albert Shales and the Bituminous or Baltimore Shales, which are here called also 'Brown Coal Shales.'

WESTMORLAND.

VI. Memramcook River—(Bellevaux Village) 4 miles north of Dorchester.—Bituminous Shales.

VII. Opposite the mouth of Stony Creek, near Ayre's.

These shales have been brought to the surface in patches along certain well marked lines of direction in Albert County, and in Albert and King's Counties; the one direction, that in Albert County, running in the same course as the Albert Mine anticlinal, namely, from S.W. to N.E. nearly, (Mag.) the other southwest by west to northeast by east, (N. 80° E. Mag).

Belonging to the first series are the exposures opposite Stony Creek, Westmorland, near the Albert Mine, and five miles northwest of the mouth of Shepody River. The second series, are four miles above Dorchester on the Memramcook, opposite Edgett's, in Dorchester, at Baizley's Farm, at the sources of Turtle River, in Mechanic's Settlement, at Cedar Camp, Ward's Creek, and near the Apohaqui Station.

Here then are two systems of anticlinal axes,—1st. The Albert Mine anticlinal, stretching through the County of Albert in a direction N. 48 E. (Mag.) 2nd. The northeast by east anticlinal, running up the valley of the Kennebecasis and beyond it into Westmorland for more than fifty miles,

* Observations on the Geology of Saint John County, by Mr. G. S. Matthew.—Canadian Naturalist and Geologist, 1863.

with the shales in the centre, and the newer rocks flanking them on either side. Along the entire length of this anticlinal, Albertite has been discovered in one form or another.

THE ALBERT MINE.

It does not appear that anything was known about the occurrence of the mineral called Albertite in the year 1849, when Dr. Robb visited Albert County, in company with Professor Johnston, on a Geological tour, with a view to gather information and collect facts for a Report on the Agricultural Capabilities of the Province.

Under date 26th November, 1849, Dr. Robb writes: * "Dr. Gesner (III. 28) mentions the occurrence of a bed of coal at Frederick's Brook, a branch of Weldon's Creek, &c. &c." * * * "I visited" continues Dr. Robb "this place in October last (1849) and found on the land of Mr. J. Steves, near the head of Frederick's Brook, a good deal of brownish bituminous substance but no coal whatever." * * * "Mr. Steves showed me what had been regarded as coal, but it proved to be mineral pitch or hard bitumen; it had only been found, he said, in small rolled fragments in the surface drift of his fields."

The discovery of the existing Albert Mine was due I have been informed, to the bursting of a mill dam on a branch of Frederick's Brook, which exposed the brilliant and massive veins of Albertite, now the source of the mineral of the Albert Mine. The name "Albertite" was suggested to Sir Charles Lyell by Dr. Robb, at a time when the true nature of the mineral was still a matter of doubt. What was known of the Albert Mines in 1852, at the period of the trial,† is already familiar to the public, and need not here be repeated.

* Professor Johnston's Report.

† Report of a case tried at Albert Circuit in 1852, before His Honor Judge Wilmot, and a special Jury. Abraham Gesner *versus* William Cairns.—Copied from the Judges notes. Saint John, 1853. The scientific evidence advanced during this trial was of a singularly diverse description; it has, however, been paralleled recently in a trial in Great Britain, involving the mineral character of the so-called "Boghead coal."

The points of controversy are well noticed in the subjoined abstract as to the character of the material, taken from the Report above referred to.

Abstract of Points in Charging Jury, as to Character of Material.

I. GEOLOGICAL.

1. *General*.—Position of mines and surrounding strata.
2. *Special*.—1. Internal structure of mine.
2. Structure of mineral.

II. MINERALOGICAL.

- Showing the difference or resemblance between asphaltum and coal in,—1. Density;
2. Fracture; 3. Cleavage; 4. Odour; 5. Electricity; 6. Lustre; Charcoal dust.

III. CHEMICAL.

- Fusibility and Solubility,—1. Positive; Comparative.

At the time of my visit in October, 1864, when I descended the mine in company with the Manager, Mr. Byers, to the depth of about 750 feet, the following was the result of the experience of twelve years in working the mine, and also of my own observations:—

1. A Shaft sunk to the depth of 1000 feet still continues in the Bituminous Shales. This, however, does not afford a clue to their thickness, for they are tilted at high angles.

2. The relation of the Albertite to the adjacent rock is absolutely undefined, sometimes but rarely the strata are parallel to the vein, sometimes and generally inclined to it at a greater or less angle, sometimes they butt end on, and not unfrequently for some hundred feet the strata are inclined at different angles to the vein on opposite sides.

3. Faults or dislocations are several in number, but there appear to be three main or chief dislocations, and the vein in one dislocation actually PASSES BEYOND AND OVERLAPS BY MANY FEET THE VEIN IN ANOTHER DISLOCATION, coming to a wedge shaped termination at the extremity of the overlap where the vein ceases. This fact alone is a proof that the vein is not a bed.

PLAINTIFF'S EVIDENCE.

1. *General.*—An anticlinal axis. A vein not a bed. An injected mass thrown up. Strata distorted. No conglomerate above and below. No parallel strata of coal beds. No roof, no floor, no fire clay, no coal fossils, and lies beneath coal formation.

2. *Special.*—Amorphous. No vegetable structure. No cellular tissue. No lamination, and transmits light.

1. Density—less specific gravity than coal. Specific gravity 109. Asphaltum 100 to 120. Coal 120 to 175. 2. Fracture Conchoidal. 3. No cleavage, which coal has. 4. Odour like asphaltum. 5. Is negatively electric, coal not so. 6. Lustre brighter than coal. 7. No animal charcoal, which coal always has.

It is fusible—melts by heat, and is the same after melted as before—is soluble in coal tar, in turpentine, in naphtha, and in other menstrua.

DEFENDANT'S EVIDENCE.

1. *General.*—No anticlinal axis. Is a bed—not a vein. A deposit, and not an injected mass. Strata are parallel. Has roof, floor, fire clay, and coal fossils, and is just where it ought to be, in the coal series above old red sandstone; and it would be a miracle if a coal bed were not there.

2. *Special.*—Has indications of vegetable structure. Distinct laminations. The evidence of its being amorphous only negative as to a few particles.

Taylor in his cross-examination says, Cuban asphaltum—no shales, no fire clay, no fossils, no iron stone, lime stone, sand stone, or sulphuret of iron.

1. Some specimens of coal less than this. 2. Many kinds of coal conchoidal fracture, and many other substances, as flint, glass, &c. 3. Has distinct lines of cleavage. 4. Odour not at all like asphaltum. 5. Kentucky electric, and some asphaltum not electric. 6. Anthracite coal as lustrous—some pieces. 7. Several pieces of this shew charcoal.

Will not melt by heat without changing its character by throwing off gas. Every known variety of asphaltum melts at not exceeding 250; and after cool can be melted again.

Known asphaltum softens in hot sun.

Sun no effect on this.

When apparently dissolved in coal tar, it is not dissolved, but only held in mechanical suspension.

4. In plans of the different levels which were kindly shown to me by the President of the Company by whom the Mine is now worked, and the originals of which were shown to me by Mr. Byers, these overlaps were visible on a plan of a level 623 feet below the surface.

5. On the plan of the "upper surface lodgement," 306 feet deep, there are shown two breaks or dislocations towards the south; in the second lodgement level, 470 feet deep, there are three dislocations to the north, and at the third level, 623 feet deep, there are three dislocations all to the south, including the overlap above described.

6. These dislocations occur in a horizontal distance of 1700 feet.

7. The Albertite occupies a great fissure already worked out, as I was informed, to the depth of 750 feet. In this fissure there are numerous "horses" or masses of rock which have fallen down. The PLACES FROM WHICH THE "HORSES" FELL, WERE FILLED WITH ALBERTITE, and by comparing "a horse" found below in the fissure with a cavity out of which the Albertite has been excavated above, there can be no doubt that the exact spot the "horse" once occupied can be pointed out.

8. The walls of the fissure correspond with one another,—that is to say, where an indentation is found on one wall, the corresponding protuberance can be discovered a little above or below it on the opposite wall.

9. The fracture does not appear to have been continuous, (or it may be that the fissure has not been traced continuously, and that it may yet be found), for the strata of opposing walls are still joined together in some places, but sharply curved and with a slight downfall to the northwest, the layers of rock arching over from the southeasterly wall to the northwesterly wall, and on this side the arch seems to extend lower than on the opposite or southeast side, as if the strata had been pulled down beyond the level of what may be called the abutment of the arch. Mr. Byers very kindly permitted one of the miners to take out from the roof of the lower level the crown of one of these arches, which is now in my possession.

10. The thickness of the vein varies from 17 feet to 0. thinning out and disappearing altogether in places, as at the overlaps, and minute fissures in the walls of the vein are filled with Albertite, these fissures running in every conceivable direction and at all angles to the main vein.

The evidence now afforded by the Albert Mine appears conclusively to establish the fact that the Albertite occurs in an irregular fissure running in a northeasterly course, of great depth, with a slight downthrow to the northwest; that this fissure occupies the crown of an anticlinal axis, which has been traced from near Shepody Mountain to beyond the Petitcodiac River, a distance of ten miles or more, and that the Albertite has been injected in a liquid or soft state under great pressure, so as not only to fill the fissure, but to force itself into all the minor cracks in the rock subordinate to the main fissure.

DR. ROBB'S AND PROFESSOR TAYLOR'S VIEWS.

So far this is the view in substance entertained by Dr. Robb and some others in 1852, and which all subsequent experience has only tended to confirm, and it is due to the memory of the late Dr. Robb, and his associate the late Richard Taylor, to reproduce their published opinions on the Albertite of Hillsborough. The following Report will show how clearly the views of these gentlemen coincided with those which the experience of twelve years now enables an unprejudiced observer to form:—

JOINT GEOLOGICAL REPORT ON THE ASPHALTE MINE OF HILLSBOROUGH, N. B.,
BY RICHARD C. TAYLOR AND JAMES ROBB.

Dorchester, N. B., 29th May, 1851.

The undersigned having examined the mine at Frederick's Brook, in the Parish of Hillsborough and County of Albert, in the Province of New Brunswick, found the mineral dug therein,—

1. To be placed almost vertically in the ground :
2. To vary from 1 to 14 feet in thickness, while its bounding walls diverge and converge accordingly :
3. To vary in its general course or strike :
4. To have its principal divisional planes always arranged unconformably to the bounding strata on either side—as in the case of the chapapote or asphalte of Cuba :
5. To come in contact with the edges much more frequently than with the planes of the contiguous rocks :
6. To be associated with rocks which for very considerable distances from the mine are highly impregnated with bitumen :
7. To have no proper "roof and floor," and no under clay or other subjacent bed containing *stigmara*, or the ordinary vegetable fossil remains of the coal measures :
8. To give off several lateral ramifications, which both intersect and conform to the shale by which they are bounded :
9. To occur in bituminous, marly, [calcareous] shales, which, at the mine, are much disturbed and contorted.

From the facts above stated *we infer*,—

1. That the mineral mass is not parallel with the surrounding strata or measures, but that it cuts or intersects them :
2. That it is a true vein—occupying a line of dislocation of uncertain extent—and not a stratum conformable to the rocks in which it is contained, in the manner of coal seams :
3. That its origin is posterior to that of the shale wherein it occurs—and that it is not contemporaneous with them :
4. That the position of the vein in the rock, as well as the arrangement of the parts of the vein itself, are decidedly much more analogous to the case of asphalte in other places than to that of coal :
5. That it is asphalte, or a variety of asphalte, and not coal or a variety of coal.

(Signed)

RICHD. C. TAYLOR, *Philadelphia, U. S.*
JAMES ROBB, *Fredericton, N. B.*

The late Professor Taylor, whose experience in all subjects relating to coal was of a most extensive and varied character, drew up the subjoined physical differences between coal and "a true Asphaltum vein," which may be valuable to those who are intending to prosecute the search for veins of Albertite either in King's, Albert, or Westmorland Counties.

PHYSICAL MARKS OF "A TRUE ASPHALTUM VEIN."

1. The absence of lamination in the mass.
2. Its brilliant conchoidal fracture and occasional tendency to assume a columnar structure.
3. The character and configuration of its surface markings.
4. Its small specific gravity; not equaling nor exceeding many of the resins.
5. The general prevailing uniformity in the entire substance or contents of the vein.
6. Its aspect, fracture, divisions, purity, and especially its almost entire freedom from foreign and earthy matters.
7. The absence of all vegetable traces in connection with the material of the vein.
8. The absence of all apparent organization in its composition.
9. Its apparent fused and liquid state originally, and its subsequent consolidation after cooling.
10. The practicable restoration of its characteristic surface markings, and its peculiar conchoidal fracture, after being once more rendered soluble, and again cooled and consolidated.
11. Its not soiling the fingers, in the manner of coal.
12. Its being strongly electric.

PHYSICAL MARKS OF COAL.

1. The lamination of its planes, which show the lines of deposit and develop the progress and mode of accumulation.
2. The rhomboidal subdivision and separation which almost all the unaltered bituminous coal seams exhibit.
3. Its irregular or indefinite cross fracture.
4. Its striated lines of horizontal deposition, as shown equally on all the sides of any portion of the mass.
5. The variable appearance presented by these strata, passing from dull, slaty lines or stripes to others which exhibit a highly brilliant, jet-like lustre, according to the greater or lesser amount of earthy impurities which prevailed at the respective periods of their deposition.
6. Its greater specific gravity; as influenced by the presence or absence of earthy matter.
7. The abundant accompanying traces of its vegetable origin.
8. The occasional presence of other organic forms, in close contiguity.
9. The impossibility to effect a solution of coal in manner of asphaltum.
10. Whereas coal in a modified state, such for instance as anthracite, may still exhibit distinct traces of its original laminations of growth by means of the *azénes* which it leaves after combustion, the original aspect of its fracture, after fusion, can never be again restored, as has been shown to be practicable in relation to asphaltum.

DR. JACKSON'S VIEWS.

Dr. C. T. Jackson, of Boston, figured very prominently in the trial just referred to. The evidence he adduced in 1851,* stands in very unhappy contrast with the opinions he expressed in 1850.

In 1850 Dr. Jackson considered Albertite to be "a very beautiful variety of Asphaltum." "It is jet black, glossy, and free from smut. It breaks with a broad, conchoidal fracture, like obsidian, and presents a brilliant surface. It is a little softer than rock salt, which scratches its surface. Its specific gravity is 1.107. It softens and melts when exposed to heat in close vessels."†

* Report on the Albert Coal Mine.

† Vide Proceedings of the Boston Society of Natural History, April, 1850, p. 279.—Silliman's Journal.—British Colonist, May 2nd, 1850.

In 1851 Dr. Jackson calls the mineral "Albert Coal;" he states that "it is not fusible, hence cannot be used like Asphaltum for cement," * * * "and cannot be sold in the market as Asphaltum without fraud;"—that "it is a highly bituminous coal," and "that it is not Asphaltum."

In 1850 he gives substantial and positive reasons, based on experiments, why it *is* Asphaltum. In 1851 he gives substantial and positive reasons why it *is not* Asphaltum.

From what is now known of the properties of Petroleum, inspissated or hardened under different conditions, a vast number of the conflicting results obtained by Chemists of high reputation during the investigations incident to the celebrated trial, Abraham Gesner *vs.* Halifax Gaslight Company, would have been reconciled. At that day—now half a generation since—the experiments made to determine the character of Albertite were based upon a previous knowledge of the properties of certain materials—if these results were discordant, the material was called *coal*, but if in accord, asphaltum—it did not appear to be thought necessary, under the circumstances, to consider whether inspissated petroleum might not present under different conditions many of the chemical properties of coal, and *vice versa*.

Professor Bailey, Dr. Robb's successor in the University of New Brunswick, has revived in 1864 the idea that Albertite is a highly bituminous coal, but he does not give the slightest clue to the reasons which have induced him to express this opinion so confidently. "At the time" says Professor Bailey, "of the celebrated controversy upon the nature of the Albert coal, this fact was one of much importance.† One party contended that the Albertite was a mere deposit, and hence not coal, but asphalt; the other, that it occurred in true strata of the coal measures, and was therefore really a highly bituminous coal. The latter is, undoubtedly, the correct view; yet Mr. Byers informs me, that while in some portions of the mines the coal is in beds conformable with the natural stratification, in others it is directly at right angles to it."

While the opinion, whether the material be coal or Asphaltum, is immaterial as far as regards the tenure of the property, it is of vast importance as a scientific question, and in view of the interests of the Province. If it were coal, the mode of its occurrence would be directly opposed to the views of Geologists respecting the nature, origin, and disposition of coal, and no sound advice could be given towards prosecuting a search for it in any direction whatsoever. It would be an anomaly, or a geological accident, and as

* Report on the Mines and Minerals of New Brunswick—foot note, page 51.

† Many people appear to be of this impression, and to suppose that if it were shown that this article was anything else but coal, it would endanger the rights of the present owners; this opinion is sufficiently refuted by Mr. Justice Wilmot, who, in his charge, stated—"While I do not consider it important in deciding this case, whether the article be coal or asphaltum, for the reasons I have before mentioned, yet as so much trouble has been taken on either side in reference to this question, I shall ask you to say in your verdict which of the two you consider it." The jury said—"We believe the material to be coal."—Report of the case.

such of little worth beyond its present known development. Viewed as an inspissated petroleum, which it will be shortly shown to be, its origin, position, and distribution, together with its chemical and physical characters, are perfectly in accordance with what would be expected in the present state of our knowledge of this substance, and we obtain without difficulty, by simple observation in the field, certain data to guide us in a search for other deposits of the same material.

ORIGIN OF ALBERTITE.

I shall now endeavour to show,—

- I. That there were two periods of injection of the material which, upon consolidation, produced Albertite.
- II. That Albertite is an inspissated or hardened petroleum.
- III. That its source lies in rocks below the Albert Shales, and probably of Devonian Age.

TWO PERIODS OF INJECTION.

In the Report on the Albert Coal Mine, by Dr. Jackson, allusion is made to the crushed Albertite occurring *in situ* in the mines, and a diagram is given showing the supposed relation to the surrounding rocks. I have not seen any specimens of crushed Albertite (*in situ*) from the Albert Mines, but I have before me numerous specimens from another source, obtained during the present year. They were procured from a vein of Albertite found penetrating the grey sandstones far above the Bituminous Shales, about two miles east of the Albert Mines.* A portion of the sandstone adheres to some of the specimens, and it does not appear to be impregnated with bitumen, apparently a curious and indeed remarkable fact, but one which will be explained when the properties of petroleum are discussed.

These specimens are from a vein three inches thick, and they are composed of two layers of Albertite, one layer slightly crushed, the other uniform and differing in no particular from the best specimen from the Albert Mines. The thickness of each portion is about $1\frac{1}{2}$ inches, and each shows the wall of the vein on the outer side, and the crushed portion shows in places an impression of a former wall, which is faithfully copied on the side of the unaltered or homogeneous portion of the vein. The explanation of the origin of these remarkable specimens, I conceive to be as follows: The crushed portion represents an original vein of Albertite occupying a narrow fissure into which it had been injected from below; a disturbance of the strata, accompanied by a slight downfall, occurred a second time, and the fissure was enlarged or widened, the Albertite occupying it being crushed by the disturbance.

After the fissure had opened a second time, it received a fresh injection of petroleum, which filled all the cavities, cemented the broken fragments of the old vein together, and formed upon solidification the vein as it now

* Lampsey's "New Discovery," 1861.

occurs, namely, with one half crushed, the other homogeneous. Other specimens from the same vein have been wholly formed of the crushed fragments, cemented together during the second injection.

When fractured, it is easy to distinguish between a fragment of the old vein and the new cementing material, there being a difference in the brilliancy of the black and in the nature of the surface. The fragments are also as easily distinguished as the crushed specimens.

Independently of any other evidence, the vein recently discovered would afford sufficient proof that the material with which it is filled was injected from below.

ALBERTITE AN INSPISSATED PETROLEUM.

It has been generally supposed that petroleum is confined to rocks of a certain geological age. Recent enquiries into the occurrence of this remarkable substance, have established the fact that petroleum is not only very widely diffused, but also that it occurs in rocks of almost all geological ages, often, however, in different mineral states or conditions. Naphtha, petroleum, rock oil, asphalt, and mineral pitch, are all forms of bitumen, some being solid and the others fluid at ordinary temperatures.*

At the base of the Lower Silurian rocks in Canada, (the Quebec Group) a black combustible coal-like substance, has been found at Quebec, Orleans Island, Acton, and many other places, in veins and fissures in the limestones, shales, and sandstones, and even in the trap rocks which penetrate them. Sometimes it is found in drops or buttons, at other times it lines fissures, in other cases it fills fissures several inches in diameter, so that it has been mistaken for coal, but it is always confined to veins and fissures in the strata, showing its deposition to have been posterior to the formation of the rocks. At Acton it fills irregular cracks and fissures, and sometimes forms masses of several inches in diameter. It is of a shining black colour, very brittle, breaking into irregular fragments with a conchoidal fracture. It varies considerably in its chemical characters. The volatile matter from a specimen at Quebec equalled 19.5 per cent.; from the Island of Orleans 21.0; from St. Flavien, 15.8; and from another locality, six miles from this, 24.5 per cent. "The resemblance of this substance to the altered insoluble bitumen from the Devonian corals at Bertie, taken in connection with the evidences that it was at once in a liquid state, are such that it can scarcely be doubted that the coaly matters in the Quebec Group have resulted from the slow alteration of liquid bitumen in the fissures of the strata."†

In all succeeding formations bitumens or petroleum exists; thus it is found in other lower Silurian rocks in many parts of Canada, as the Utica Slate for instance, the Birdseye formation, in the Trenton group, and Hudson River formation. In the upper Silurian rocks it is also abundant, but it is

* See an excellent paper on this subject by Prof. Hunt of the Canadian Geological Survey, in the 6th Volume of the "Canadian Naturalist and Geologist," entitled "Notes on the History of Petroleum or Rock Oil," August 1861. Also on the same subject, by the same author, in the "Geology of Canada."

in the Devonian rocks that the most remarkable petroleum springs in Canada have been discovered. It may be here mentioned that some of the petroleum bearing strata are overlaid and underlaid by rock absolutely impermeable to petroleum; this probably arises from their being particularly permeable to water; the petroleum refuses to penetrate a moist rock, but when dried it becomes immediately impregnated with the oily substance.

ORIGIN AND FORMS OF PETROLEUM—PETROLEUM WELLS.

Terrestrial vegetation like that which has largely contributed to the formation of coal, is not essential to the production of petroleum, for it is found in those ancient rocks which do not contain a trace of the remains of land plants or animals. That it is essentially of organic origin there is no reason to doubt, and in many instances it is locally produced, for "the fact that intermediate porous strata of similar mineral characters are destitute of bitumen, shows that this material cannot have been derived from overlying or underlying beds, *but has been generated* by the transformation of organic matters in the strata in which it is met with." * * * * *

"In the great palæozoic basin of North America, bitumen, either in a liquid or solid state, is found in the strata at several different horizons. The forms in which it now occurs depend in great measure upon the presence or absence of atmospheric oxygen, since by oxydation and volatilization the naphtha or petroleum, as we have already explained, becomes slowly changed into asphalt or mineral pitch, which is solid at ordinary temperatures. It would even appear that by a continuance of the same action the bitumen may lose its fusibility and solubility, and become converted into a coal-like matter."*

The wells in which petroleum accumulates, as well as the places where a "spouting" well is struck, lie on the line of an anticlinal axis abounding in fissures, into which the petroleum slowly filters from the surrounding rock, and by the pressure of carburetted hydrogen gas, or of volatile matter which it gives off, it is forced to the surface as soon as a communication is effected with the external air. These fissures are natural reservoirs of petroleum, and in the "oil region" it is quite common for the boring apparatus, on reaching a fissure, to sink suddenly several feet.

When a "flowing well" is said to cease, it is not to be understood that no discharge takes place from the iron pipe inserted into the bore or well; the discharge of petroleum ceases, but salt water, which often accompanies petroleum, takes its place and continues for a long time to flow with but little, if any, diminution of volume.

These fissures are frequently connected together by lateral fissures, so that on sinking in the vicinity of a continuously flowing well a neighbouring fissure may be struck which yields "oil," but at the same time causes an immediate diminution in the flow of some of those situated near it. The

* Notes on the History of Petroleum or Rock Oil, by T. Sterry Hunt, M.A., F.R.S., of the Geological Survey of Canada.

same source of supply has evidently been struck, and additional vent given to the oil, water and gas which occupy the net work of fissures freely communicating with one another. These fissures do not pursue a uniform course, and this circumstance often causes apparent anomalies in the results obtained by sinking wells where certain success would appear to be within reach of the operator.* The incident mentioned in the foot note may find a parallel in Albert County, where an attempt is now being made to strike the vein occupying the fissure at the Albert Mine, in the hope of reaching the same deposit of that valuable material. A line has been drawn through the axis or centre of the levels in the Albert Mine, and trials have been made both northeast and southwest on the course of the levels, but as yet without success. It does not appear that any notice has been taken in selecting the trial spots, of the law which governs the dislocations in the Albert Mine fissure; and it is not improbable that by following the

* Mr. Sandford Fleming, C. E., mentions a curious illustration of this uncertainty which occurred in Enniskillen, C. W. "Some time after the 'Shaw' well flowed so successfully, a second party bored the rock to the same depth about one hundred yards from it, and found a copious discharge of oil, but this second well had the immediate effect of reducing very materially the flow from the 'Shaw' well. When either was plugged up, the other yielded a full discharge; but when both were allowed to flow, each yielded only a partial supply. A third party, owning a small oil lot between the two wells, commenced boring on a line drawn from the one to the other, at the distance of about thirty yards from the 'Shaw' well; he naturally expected to rob both wells, whilst their owners (who by this time had formed a co-partnership,) had every reason to fear his certain success. All parties, however, were doomed to disappointment, as the third well proved an utter failure although the rock was bored to a much greater depth than the other two wells."—Notes on the present condition of the Oil Wells of Enniskillen.—Canadian Journal, May 1863.

In October 1864, there were about 250 Oil Companies in the United States, chiefly in New York and Pennsylvania, whose aggregate capital amounted to \$88,000,000, (Gold at 210.) The Government tax is 20 cents per gallon on refined oil, and 10 cents per gallon on crude. The expenses of getting the oil to market are thus stated in the New York Herald of October 14, 1864:—

Crude oil sold at Story or M'Clintock's farm, October 8, 1864, per barrel	
of 41 gallons,	\$7.00
Cost of barrel or package,	3.25
Cartage to Railroad depot at Franklin or to Titusville,	1.50
Freight to New York,	3.60
	<hr/>
	\$15.35
Rate in New York, October 11, 38 cents per gallon,	\$15.58
Barrel returned,	2.50
	<hr/>
	13.08
	<hr/>
Net profit per barrel,	\$2.27

The same paper states, that the aggregate operations of the 250 Companies represent \$140,000,000. The enormous quantity of petroleum drawn from the deep-seated reservoirs in which it has so long remained hidden, must soon cause a considerable diminution in the supply; many of the most famous wells are even now rapidly diminishing in yield. Hence it appears probable that recourse will again be had to bituminous shales, and then the remarkably rich shales in Albert, King's, and Westmorland Counties, will acquire a value before unthought of.

apparently simple course of making trial pits on the course of the vein, as observed at any one of the levels, many unsuccessful attempts to reach the continuation of the fissure by boring will be made.

The Albertite, wherever observed in position, closely resembles in all important particulars the solid bitumens of the older rocks resulting from the alteration of Petroleum. It occupies fissures in several kinds of rocks on the line of one or more anticlinal axes, into which it has been injected from beneath under considerable pressure, leading to no other conclusion as to its origin, in the present condition of our knowledge of the subject, than that it is an altered or inspissated Petroleum, and that its source lies beneath the rocks whose fissures it now fills.

THE ALBERTITE ORIGINATED FROM UNDERLYING DEVONIAN ROCKS.

The remarkable state of preservation in which the fishes, ferns, lepidodendra and other plants which abound in the Albert Shales, exist, precludes the idea of its origin in that formation. It does not appear probable that the peculiar chemical transformation which caused the organic matter to become converted into petroleum instead of coal would not have extended to the beautifully preserved organic remains which exist so abundantly in the Albert Shales, if the petroleum had originated in these beds. It is much more probable that its source is to be found in the partially metamorphosed rocks, probably of Devonian Age, upon which the Albert Shales repose, and the discovery of Albertite in these partially altered rocks gives a very favourable aspect to this view,* if it does not altogether confirm it.

In Cuba the asphaltum which has been worked for nearly half a century, occurs chiefly in metamorphic slate. The differences between the asphalt of Cuba and Hillsborough are very slight and immaterial according to Professor Taylor, and in some veins it occurs in a compact form, in others it is cellular or spongy, as if this latter character was occasioned by the escape of gas during the process of cooling. The highest part of the deposit is porous, the lower portion, where the pressure has been greater, is compact.

Recently some remarkable discoveries of Bitumens in many different stages, from Petroleum to Albertite, have been made in the West India Islands; this part of America is probably destined to emulate if not to rival Ohio and Pennsylvania in the production of illuminating oils, or material from which illuminating oil can be manufactured.

“We do not know,” says Professor Hunt, “the precise conditions which in certain strata favour the production of petroleum rather than of lignite or coal, but in the fermentation of sugar, to which we may compare the transformations of woody fibre, we find that under different conditions it may yield either alcohol and carbonic acid, or butyric and carbonic acids with hydrogen, and even in certain modified fermentations the acetic, lactic and propionic acids, and the higher alcohols like $C_{10}H_{12}O_2$.”

* It is worthy of notice that Dr. Robb found the pebbles of the oldest conglomerate at the base of the Carboniferous Series in Albert County, cemented together by bitumen.

“These analogies furnish suggestions which may lead to a satisfactory explanation of the peculiar transformation by which, in certain sedimentary strata, organic matters have been converted into bitumen.”*

The altered character of the slates underlying the Lower Carboniferous Series in the deep indent stretching from Dorchester to Sussex, does not militate against the supposition that the rocks to which these slates belong are the source of the petroleum; for it is well known that the metamorphism produced by intrusive rocks such as those which occur in the hill ranges bounding this great valley, is generally confined to within a few yards of the intrusive mass. This has been elsewhere shown to be the case with respect to the granite in Digby, Nova Scotia; and in by far the greater number of cases, the only apparent effect of the igneous rock upon the palæozoic limestones and shales, has been a very local induration.

The Petroleum Springs in Albert and Westmorland, which probably come from the underlying Devonian rocks, show that metamorphic action has not there changed in the least degree the character of the fluid, and these springs are situated at the mouth of the great indent between Butternut Ridge and Shepody Mountain, one of them being within five miles of the Albert Mine, and within a comparatively short distance, less than a mile, of Albertite in place.

If a line be drawn through well known localities where Albertite in position has been discovered, it will be found to be nearly coincident with the north-east by east anticlinal described in preceding paragraphs.

near Apohaqui, in 1862.‡ | |

The “Humbold's Mines,” in Mechanics' Settlement, King's County, have been described by Mr. Simms, Civil and Mining Engineer. This gentleman reports:—“No. 1 shaft; sunk 11 feet; 4 to 6 inches of Albertite found; no shale, but the conglomerate and drift for some distance around is impreg-

* Dr. Sterry Hunt.—Contributions to Lithology.

† The two localities in Westmorland lie on the same course as the Albert Mine, or about N. 30° E. hence they belong probably to one and the same fissure.

nated and cemented together with bitumen. Course of seam N. 80° W. Dip nearly vertical.

"No. 2 and No. 5, a small vein of 'coal,' running east and west, *through metamorphic slate rocks*. A leader of 'coal' is seen about 1½ inch thick, and occasional pockets or nests of 'coal' have been found.

"No. 3, a small seam of 'coal' about one inch thick, in the drift nearly east and west. The drift and gravel here, as in most places worked, being cemented with bituminous matter."

"On the south side of the hill there is a shaft sunk 20 feet in depth. After going down about 14 feet, a seam of coal was discovered. The seam is not of uniform thickness, but occurring in pockets of coal 7 or 8 inches thick, and occasionally nipped between the rocks in some places to about half an inch thickness, but the trace never lost. The course of the seam is N. 80° W. and dips very slightly to the south. About 15 feet from the surface, on the south side of the shaft, a small seam of 'coal' joins, dipping northward, and backed by a rock, apparently the wall rock of the mine. In this shaft, as in all the other places worked, no traces of shale have been found; the whole of the conglomerate is cemented with bitumen."

"At a small opening on the northern side of the same hill a seam of 'coal' is seen about ¾ of an inch in thickness, the course running nearly east and west, and dipping to the south."

In all the other places, with the exception of Mechanics' Settlement, the Albertite has been found in the shales, sandstones, conglomerates, or limestones of the Lower Carboniferous Series. According to Mr. Simms, it also occurs in the underlying metamorphic slates. At the first blush it would appear that the bituminous substance may have entered fissures in the slates from above, as it seems inconsistent with prevailing ideas respecting metamorphism that Albertite could resist the supposed degree of heat seemingly involved, without being dissipated; but it will be shown elsewhere that the condition of the slates is such as not necessarily to have required the aid of a considerable degree of heat to produce the alteration in structure they have undergone, and they do not offer any valid reason why the Albertite should not have its origin in or below them. The Albertite or Asphaltum of Cuba, it will be borne in mind, occurs in metamorphosed slate.

The United States Commissioner of Agriculture in a recent Report, in which he describes the conditions under which Petroleum is obtained in the United States and Canada, advances rather a novel view of the origin of Albertite, or as Dr. Wetherall, of Philadelphia, proposes to call it, "Melan-asphalt."

"Its position," says the Commissioner, "has been misinterpreted by several observers, who have reported it a volcanic injection of bitumen into a fissure of the earth many feet in width, by the force of which large pieces of the wall rock have been torn off and carried forward in the mass. It seems, however, pretty well made out, that it was originally a horizontal bed or lake of Petroleum, hardened and covered up by sand and clay deposits

of carboniferous age, and afterwards upturned, bent over, and fractured, so as to assume its present posture. It is not properly a coal bed, therefore, but a mass of hardened coal oil, which can be, and in fact has been mined like a coal bed, and the product used wholly for making gas."*

The condition of the walls of the fissure, of the crushed Albertite in sandstone, and its occurrence in numerous veins in nearly horizontal conglomerates, and in limestone, and in slate, together with its wide-spread distribution, all tend to disprove the supposition contained in the preceding paragraphs, that a hardened lake of Petroleum had been tilted up on edge.

THE ALBERT OR BALTIMORE SHALES.

These bituminous rocks present many peculiarities. Some specimens which I took from the parent rock near the Albert Mines, resemble a fine calcareous mud stratified in extremely thin layers, each layer being separated by a coating of bitumen; I counted upwards of one hundred of these layers in an inch. The bitumen in the shales differs from Albertite; it ramifies through them in fine reticulating veins. The shales which occur near the Albert Mine, differ from the bituminous shales in which the Albertite is found in this respect, that they appear to be the uppermost beds of the formation, and to contain a much larger amount of bitumen; a ton of these shales would yield, upon distillation, from sixty to ninety gallons of crude oil. They seem to have been formed in a shallow tranquil tidal estuary, into which springs of petroleum were discharging themselves; they were subsequently much folded by pressure, and received an additional supply of bitumen by injection under pressure, hence the minute veins which ramify through fractures filled with Albertite.

It is a significant fact that the bituminous matter which is so abundant in these shales in New Brunswick, is almost entirely wanting in shales of the same geological age and position at Horton in Nova Scotia. The Horton beds contains incalculable numbers of fish; "every surface in some of the shales being thickly scattered over with their bright enamelled scales and sharp conical teeth."†

They must not be mistaken for the "Oil Shale" or "Oil Coal" of the "Fraser Mine" in Nova Scotia, which lies geologically far above the Albert Shales, and occupies a position within the true coal measures; nor with the "earthy bitumens" which are found within the same geological limits. These "oil coals" and "earthy bitumens" of the Coal Measures, are thought by Dr. Dawson, (than whom a better authority on this subject does not, perhaps, exist,) to be "a water-soaked vegetable soil, completely bituminized, and twisted, and sliken-sided, owing to the giving way under pressure of the roots and trunks under which it was interlaced."‡

These shales may yet become a source of considerable wealth to this portion of the Province. They can "make steam," and have been used by Mr. Byers, (experimentally) for that purpose, but the bulk of the ash is an objec-

* Report of U. S. Commissioner of Agriculture.—From the Journal of Board of Arts for U. C.

† Acadian Geology, page 215. ‡ Supplementary Chapter to "Acadian Geology."

tion to their use where coal is cheap. But, as a source of oil for illuminating and other purposes, and as a source of gas fuel, they will become very valuable, as the following statement will show :—

At Collingwood in Canada, oil has been distilled from Bituminous schist which yielded only eight gallons of crude oil to the ton. The cost of the crude oil was stated to be fourteen cents the gallon, when rectified it gave from forty to fifty per cent. of burning oil, and from twenty to twenty-five per cent. of pitch or waste. The remainder being a heavy oil fitted for lubricating purposes.*

The Albert Shales yield from 65 to 90 gallons crude oil per ton, or from 35 to 50 gallons fit for illuminating purposes. The Canadian manufacturers considered that if the discovery of petroleum had not materially lessened the price of burning oil they would have realized handsome profits; it is therefore probable that a shale which yields ten times as large a quantity of oil might be profitable notwithstanding the present enormous yield of petroleum both in the United States and Canada.

GAS FUEL FOR FURNACES.

As a source of gas fuel the Albert Shales will probably acquire very considerable importance. The Regenerative Gas Furnaces, the principle of which was discovered by the Rev. Mr. Stirling of Dundee, in 1817, and described by Faraday in 1862, at the Royal Institution of London, are likely to effect a considerable change in Metallurgical operations, and in all kinds of manufactures requiring an elevated temperature. The regenerative gas furnace has already been applied to a considerable extent in Germany for heating iron, having been worked out there under the direction of Dr. Werner Siemens, who has also contributed essentially to the development of the system. The furnaces at the extensive iron and engine works of M. Borsig, of Berlin, are being remodelled for the adoption of this system of heating, as have also been those at the Imperial factories at Warsaw.

“Another important application of the regenerative gas furnace is as a steel melting furnace, in which the highest degree of heat known in the arts is required, presenting consequently the greatest margin for saving of fuel. This application of the regenerative gas furnace is indeed rapidly extending in Germany, but has not yet practically succeeded in Sheffield, where it was also tried. It is, however, in course of application at the Brades Steel Works, near Birmingham. The arrangement of the reversing valves and the air and gas flues is similar to that in the glass furnace previously described.”

“Other applications of the regenerative gas furnace are being carried out at the present time, among which may be mentioned one to brick and pottery kilns for Mr. Humphrey Chamberlin, near Southampton; for Messrs. Cliff, of Wortley, near Leeds; and for Mr. Cliff, of the Imperial Potteries, Lambeth; also to the heating of gas retorts at the Paris General Gas Works, and at the Chartered Gas Company's Works, London.”†

* Geology of Canada.

† From a Paper by Mr. C. W. Siemens, of London.—Read before the Birmingham Institution of Mechanical Engineers, 1862.

This new application of impure combustibles is of sufficient importance to warrant the introduction here of a Notice of Gas Furnaces by Sir M. Faraday.

ROYAL INSTITUTION OF GREAT BRITAIN.

ON GAS FURNACES, &c.—By Sir M. Faraday, D.C.L., LL.D., F.R.S.—Artizan, Sept. 1862.

Gas has been used to supply heat, even upon a very large scale, in some of the iron blast furnaces, and heat which has done work once has been carried back in part to the place from whence it came to repeat its service; but Mr. Siemens has combined these two points, and successfully applied them in a great variety of cases—as the potter's kiln—the enameller's furnace—the zinc-distilling furnace—the tube welding furnace—the metal-melting furnace—the iron-puddling furnace—and the glass furnace, either for covered or open pots—so as to obtain the highest heat required over any extent of space, with great facility of management, and with great economy (one-half) of fuel. The glass furnace described had an area of 28 feet long and 14 feet wide, and contained eight open pots each holding nearly two tons of material.

The gaseous fuel is obtained by the mutual action of coal, air, and water, at a moderate red heat. A brick chamber, perhaps 6ft. by 12 and about 10ft. high, has one of its end walls converted into a fire grate, *i. e.* about half way down it is solid plate, and for the rest of the distance consists of strong horizontal plate bars where air enters; the whole being at an inclination such as that which the side of a heap of coals would naturally take. Coals are poured, through openings above, upon this combination of wall and grate, and being fired at the undersurface, they burn at the place where the air enters; but as the layer of coal is from 2 to 3ft. thick, various operations go on in those parts of the fuel which cannot burn for want of air. Thus the upper and cooler part of the coal produces a larger body of hydro-carbons; the cinders or coke which are not volatilized, approach, in descending, towards the grate; that part which is nearest the grate burns with the entering air into carbonic acid, and the heat evolved ignites the mass above it, the carbonic acid passing slowly through the ignited carbon, becomes converted into carbonic oxide, and mingles in the upper part of the chamber (or gas producer) with the former hydro-carbons. The water, which is purposely introduced at the bottom of the arrangement, is first vaporized by the heat, and then decomposed by the ignited fuel and rearranged as hydrogen and carbonic oxide; and only the ashes of the coal are removed as solid matter from the chamber at the bottom of the fire-bars.

These mixed gases form the gaseous fuel. The nitrogen which entered with the air at the grate is mingled with them, constituting about a third of the whole volume. The gas rises up a large vertical tube for 12 or 15ft., after which it proceeds horizontally for any required distance, and then descends to the heat-regenerator, through which it passes before it enters the furnaces. A regenerator is a chamber packed with fire-bricks, separated so as to allow of the free passage of air or gas between them. There are four placed under a furnace. The gas ascends through one of these chambers, whilst air ascends through the neighbouring chamber, and both are conducted through passage outlets at one end of the furnace, where mingling they burn, producing the heat due to their chemical action. Passing onwards to the other end of the furnace, they (*i. e.* the combined gases) find precisely similar outlets down which they pass; and traversing the two remaining regenerators from above downwards, heat them intensely, especially the upper part, and so travel on in their cooled state to the shaft or chimney. Now the passages between the four regenerators and the gas and air are supplied with valves and deflecting plates, some of which are like four way-cocks in their action; so that by the use of a lever these regenerators and air-ways, which were carrying off the expended fuel, can in a moment be used for conducting air and gas into the furnace; and those which just before had served to carry air and gas into the furnace now take the burnt fuel away to the stack. It is to be observed, that the intensely heated flame which leaves the furnace for the stack always proceeds downwards through the regenerators, so that the upper part of them is most intensely ignited, keeping back, as it does, the intense heat; and so effectual are they in this action, that the gas which enters the stack to be cast into the air is not usually above 300° F. of heat. On the other hand, the entering gas and air always passes upwards

through the regenerator, so that they attain a temperature equal to white heat before they meet in the furnace, and there add to the carried heat that due to their mutual chemical action. It is considered that when the furnace is in full order, the heat carried forward to be evolved by the chemical action of combustion is about 4000° , whilst that carried back by the regenerators is about 3000° , making an intensity of power which, unless moderated on purpose, would fuse furnace and all exposed to its action.

Thus the regenerators are alternately heated and cooled by the outgoing and entering gas and air, and the time for the alternation is from half an hour to an hour, as observation may indicate. The motive power on the gas is of two kinds—a slight excess of pressure within is kept up from the gas-producer to the bottom of the regenerator to prevent air entering and mingling with the fuel before it is burnt; but from the furnace, downwards through the regenerators, the advance of the heated medium is governed mainly by the draught in the tall stack, or chimney.

Great facility is afforded in the management of these furnaces. If, whilst glass is in the course of manufacture, an intense heat is required, an abundant supply of gas and air is given; when the glass is made, and the condition has to be reduced to working temperature, the quantity of fuel and air is reduced. If the combustion in the furnace is required to be gradual from end to end, the inlets of air and gas are placed more or less apart the one from the other. The gas is lighter than the air; and if a rapid evolution of heat is required as in a short puddling furnace, the mouth of the gas inlet is placed below that of the air inlet; if the reverse is required, as in the long tube-welding furnace, the contrary arrangement is used. Sometimes, as in the enameller's furnace, which is a long muffle, it is requisite that the heat be greater at the door end of the muffle and furnace, because the goods, being put in and taken out at the same end, those which enter last and are withdrawn first, remain, of course, for a shorter time in the heat at that end; and though the fuel and air enters first at one end and then at the other alternately, still the necessary difference of temperature is preserved by the adjustment of the apertures at those ends.

Not merely can the supply of gas and air to the furnace be governed by valves in the passages, but the very manufacture of the gas fuel itself can be diminished, or even stopped, by cutting off the supply of air to the grate of the gas producer; and this is important, inasmuch as there is no gasometer to receive and preserve the aeriform fuel, for it proceeds at once to the furnaces.

Some of the furnaces have their contents open to the fuel and combustion, as in the puddling and metal-melting arrangements; others are enclosed, as in the muffle furnaces and the flint-glass furnaces. Because of the great cleanliness of fuel, some of the glass furnaces, which before had closed pots, now have them open, with great advantage to the working and no detriment to the colour.

The economy in the fuel is esteemed practically as one-half, even when the same kind of coal is used, either directly for the furnace or for the gas producer; but, as in the latter case, the most worthless kind can be employed—such as slack, &c., which can be converted into a clean gaseous fuel at a distance from the place of the furnace, so many advantages seem to present themselves in this part of the arrangement.

It will be seen that the system depends, in a great measure, upon the intermediate production of carbonic oxide from coal instead of the direct production of carbonic acid. Now carbonic oxide is poisonous, and, indeed, both these gases are very deleterious. Carbonic acid must at last go into the atmosphere; but the carbonic oxide ceases to exist at the furnace, its time is short, and whilst existing it is confined on its way from the gas-producer to the furnace, where it becomes carbonic acid. No signs of harm from it have occurred, although its applications have been made in thirty furnaces or more.

The following are some numbers that were used to convey general impressions to the audience. Carbon burnt perfectly into carbonic acid in a gas-producer would evolve about 4000° of heat; but, if burnt into carbonic oxide, it would evolve only 1200° . The carbonic oxide, in its fuel form, carries on with it the 2800° in chemical force, which it evolves when burning in the real furnace with a sufficient supply of air. The remaining 1200° are employed in the gas-producer in distilling hydro-carbons, decomposing water, &c. The whole mixed gaseous fuel can evolve about 4000° in the furnace, to which the regenerator can return about 3000° more.

The use of gas fuel in the smelting of iron ores has been further referred to in the Chapter on the "Quebec Group;" and the employment of the Albert Shales, as a source of gas fuel in the smelting of the Bog Iron ores of the Valley of the Kennebecasis, and more especially of the almost pure magnetic ores of Springfield, suggested, as a promising field for the investment of capital, and the creation of local metallurgical industry.

In a subsequent Chapter the importance of the Albert Shales will appear in a more striking light, when viewed in relation to the manufacture of iron by the process of M. Chenot, who received the Gold Medal at the Paris Exhibition, for his discoveries in the use and application of gas fuel in the smelting of iron ores.

PETROLEUM SPRINGS IN ALBERT AND WESTMORLAND.

Natural petroleum springs have long been known in these Counties. Attempts are now being made to reach the source of supply by boring.

The following information respecting the depth of the borings was obtained from workmen at Steeves' Ravine well, in October of the present year:—

1. The Steves Ravine well.—The petroleum spring here has long been known. The oil occurs on the surface of the water in an excavation under the north bank of the ravine. Its odour and colour reminded me of the petroleum at the Enniskillen wells in Canada. The depth of the well was then, (October 15, 1864,) 186 feet. The sand pump brought up fresh water, and a very little oil.

2. The Dover well, about three miles north of Hillsborough, on the east side of the Petitcodiac, 106 feet down, with a strong flow of fresh water.

3. Cummins Well, Westmorland County, Dorchester Parish, about a mile from the Dover Well, 530 feet down; salt water in the pump, small show of oil.

4. Memramcook, about 140 feet down, very small show of oil.

An idea of the depth to which it will be necessary to bore before oil in remunerative abundance may be expected, will be gathered from the fact that the main shaft of the Albert Mines has already been excavated to the depth of one thousand feet, without a trace of oil being met with. It is not probable therefore, with this splendid test well in view, that the prospectors will be successful at a less depth than 1300 or 1500 feet, and it yet remains to be seen to what extent the Devonian Rocks, the probable source of the oil, are developed in that part of the Province.

The inflammable gas which is copiously evolved near the Albert Mine, and in several places in Albert County, is not necessarily connected with petroleum, as it is proceeds from rocks destitute of bitumen.

CONCLUSIONS WITH REFERENCE TO ALBERTITE.

As the question of an increased supply of Albertite is one of very considerable moment to the Province, it may not be an unnecessary recapitulation to state briefly and in order the conclusions which have been advanced in preceeding pages.

It is submitted that it has been shown—

1st. That the Albertite wherever it has been found in situ, occupies fissures produced by dislocations in the rocky strata, or exists as a cementing material in conglomerates, or occurs as an integral part of the rock, as in the Albert Shales.

2nd. That the Albertite, under all circumstances, has been injected from below.

3rd. That there were at least two periods of injection.

4th. That when it occupies fissures, these are on the lines of anticlinal axes.

5th. That it is an inspissated or altered petroleum.

6th. That its source lies beneath the Albert Shales, or in other words beneath the Lower Carboniferous Series.

7th. That it is consequently of Devonian or prior origin, and proceeds probably from rocks of the same age as those which yield the Petroleum of Pennsylvania, Ohio, and Canada.

8th. That it may with confidence be anticipated that a search made in accordance with the views which have been expressed respecting its origin, will result in valuable deposits being found over an extensive area between Dorchester in Westmorland and Norton in King's Counties; but this search must be continued along the lines of anticlinal axes which have been shown to exist within the limits specified.

The quantity of Albertite raised since the opening of the Mine in Albert County, is estimated to be about 170,000 tons. At \$10 a ton (the minimum price at which I was informed it has been sold,) this would amount to one million seven hundred thousand dollars.

CHAPTER VI.

THE DEVONIAN SERIES.

The Valley of the Restigouche—Upper Silurian and Devonian Rocks—Area occupied by the Devonian Rocks in this Valley—Devonian Rocks on the Bay of Fundy—Age of the Rocks—Extent of the Basin—The Devonian Rocks of Saint John—The Flora of the Devonian Rocks—The richness of this Series in Mineral Wealth—Iron Ores—Copper Ores—Origin of Petroleum—Source of the Albertite—Source of the Bituminous or Albert Shales—The Vernon Copper Mines—Origin of Metalliferous Veins—Segregated Veins—Gash Veins—True Veins—Origin of True Veins—Lead Ores—Argentiferous Galena—Erroneous impressions which prevail with respect to the percentage of Silver in Argentiferous Galena—Description of the Vernon Mines near the Mouth of Goose Creek—Description of the Rocks on the Coast—Red Conglomerates, Epidotic Traps and Plumbaginous Slates—Green Conglomerate Slates—General arrangement of the Rocks—Intrusive Traps—Copper-bearing Traps—Newer Traps—The Sedimentary Rocks—Conglomerates and Porphyries—Steatitic Rocks—The Copper Lodes—The Peacock Vein—Fissure occupied by—Width of the Vein—Veinstone, Bitter Spar and Quartz—The Levels—The Green Vein—Occurs in a line of fault—Extension eastward of the Copper-bearing Traps.

The Restigouche forms for some miles the boundary between Canada and New Brunswick, and has been examined by the officers of the Geological Survey of Canada. The rocks in this valley, from the mouth of the Matapeedia downwards, constitute a trough or basin in which the lower rocks belong to the Gaspé Limestones and are of Upper Silurian age, the upper rocks (sandstones and conglomerates) of Devonian age. Intrusive traps are very abundant in this neighbourhood, and have exercised a marked influence upon the present distribution of the sedimentary Rocks.

The Sugar-loaf, 750 feet high, near Campbeltown, is of trap which forms the greater part of the area between this hill and the Restigouche. On the River bank the Devonian conglomerate appears, and at Mission Point there is a sandstone which probably belongs to the same formation. Between Shaw's Brook and Point la Lime, intrusive traps composed of red felspar and black mica are interstratified with the conglomerate which runs along the beach to Point la Lime. Below this point there is a thin seam of carbonaceous shale associated with the conglomerate, with a bed of clay beneath it, which has led to the delusive hope that coal might be found in that vicinity. The same seam is again seen at Point Pin Sec resting on the clay bed, and overlaid by a mass of trap which has changed it to a hard black stone. A conglomerate bed again occurs further on in an easterly direction, from beneath which there appears, near Point Peuplier, a red slate which

the Indians use for the manufacture of their pipes. The rocks seen along the shore towards Dalhousie are nearly all trap.* These conglomerates must not be mistaken for the small outlier of the Carboniferous Series, (Bonaventure formation) near Point la Lime on the south side of the Campbelltown road.

The siliceous conglomerates on the Restigouche resemble, in many places, a modern beach or ridge, whose pebbles are strongly cemented together. It occurs in beds a few feet in thickness, underlaid by shale and sandstone in which few pebbles are visible. In Campbelltown, near the residence of the Hon. John McMillan, a silicious rock crops out in shaly layers, which resembles the siliceous layers in the Section at Cape Bon Ami, described on a subsequent page.

The area here occupied by the Devonian rocks does not probably exceed five and twenty square miles, the greater portion of the valley of the Restigouche in New Brunswick, belonging to the Upper Silurian Series.

DEVONIAN ROCKS ON THE COAST OF THE BAY OF FUNDY.

The remains of a great basin formerly occupied by Devonian rocks are found on the coasts of the Bay of Fundy. Commencing in the State of Maine in the towns of Lubec, Perry, and Robbinstown, there is a narrow belt of Devonian Sandstones on the coast, forming the rim of the basin. It passes thence to Saint Andrews, and is stated by Hitchcock† to appear occasionally in the southwest part of the Province on Spruce Island, Indian Island, Friendship Folly, &c. On the western borders of Boyden Lake in Perry and Charlotte townships, (Me.) "this rock has undergone a change, being converted into silicious slates and trappean rocks." The dip is here northerly from 25 to 30 degrees. The same rocks were thought to have been seen on Bliss Island in November last, also a very small outlying patch on Frye's Island.

From near Point Lepreau, Devonian Rocks appear to form the coast as far as Emerson's Creek, when they are overlaid by Carboniferous Strata. In the rear of these they form a narrow belt which comes on the coast again in the neighbourhood of Salmon River. From near Mousheer's River to Point Wolf, rocks of this age occupy the coast, and a small patch occurs near the mouth of Upper Salmon River.

Mr. G. F. Matthew, of Saint John, has given an elaborate description of the Devonian Rocks in the neighbourhood of that City.‡

Mr. Matthew also describes a probable series of Devonian Rocks on the north side of the Kennebecasis. "They may be the equivalent of the volcanic sediments described above (Bloomsbury Group—Lower Devonian); but their outcrop is so straight for a distance of thirty miles, that they may prove to be part of an older series brought up by a fault."

* Geology of Canada. † Geology of Maine, Scientific Survey, Vol. I. 1861.

‡ Observations on the Geology of Saint John County, by G. F. Matthew—Canadian Naturalist and Geologist, August 1863.

On the southeast side of the Bay of Fundy, in Nova Scotia, Devonian Rocks occur on the Nictau River, Moose River, Bear River, and thence to the extremity of the Peninsula.* They are overlaid near the coast by New Red Sandstone.

The conclusions deduced from these facts are as follows:—

1. A basin of Devonian Rocks, chiefly of the age of the Chemung and Portage Group of the New York Survey, occupies a large area now covered in great part by the waters of the Bay of Fundy.

2. The rim of this Basin is seen in the coast townships of Maine from Lubec to Robbinston, on many points and islands of New Brunswick from Saint Andrews to Lepreau, and near the coast from a short distance east of Lepreau to Saint John, and on the north side of the Kennebecasis, to where it is overlaid by Lower Carboniferous Rocks. The southwestern rim of this basin is recognized in Nova Scotia from near Minas Basin to the extremity of the Peninsula. (Lower Devonian.)

3. The Carboniferous Series in the Valley of the Upper Kennebecasis, and Petitcodiac, are probably underlaid by these Devonian Rocks, and the Bay of Fundy is in great part excavated in them, or in the superimposed Carboniferous Series. [See Chapter I.—Bay of Fundy.]

FLORA OF THE DEVONIAN SERIES.

The Devonian Rocks of the New Brunswick Basin are especially interesting on account of their well developed Flora.

Dr. Dawson has bestowed on specimens collected from different localities much attention, which has been productive of very valuable results.

The rocks which occur at Saint John he describes generally as the Saint John Series.†

The fossiliferous portion of the Saint John Series,‡ says Dr. Dawson, presents the richest known flora of the Devonian Period ever discovered. It far excels in number of genera and species the Lower Carboniferous flora as it exists in British America, and is comparable with that of the middle Coal Measures, from which, however, it differs very remarkably in the relative development of different genera, as well as in the species representing these genera.

“It is only just to observe, that the completeness of the following list is due to the industrious labours of an association of young gentlemen at Saint John, who, under the guidance of Messrs. Matthew and Hartt, have diligently explored every accessible spot within some distance of the city and have liberally placed their collections at my disposal for the purposes of this paper.”

* Supplementary Chapter to “Acadian Geology.”

MINERAL WEALTH OF THIS SERIES IN NEW BRUNSWICK.

The Devonian Series in New Brunswick is apparently rich in mineral wealth as far as it has been examined. In it are contained the important and extensive beds of iron ore at West Beach, described by Mr. Mathew

in a paper read before the Natural History Society. The widely distributed deposits of copper ore at and in the neighbourhood of the Vernon Mines, near Goose Creek, are in this series, and it is very probable that rocks belonging to it underlie a considerable portion of Albert County and King's County, and from these rocks the petroleum, now in an inspissated or altered condition forming Albertite, has originated, as well as the Petroleum Springs which have been noticed in another place, (page 108.) Rocks of the same age, but without having undergone metamorphism, are the sources of the Petroleum in Canada, and in Pennsylvania.

The Bituminous or Albert Shales in the valleys of the Kennebecasis and Petitcodiac, have also derived their bitumen in great part from these rocks. Under these circumstances a careful examination of this important series might lead to more valuable results than those which have been briefly adverted to.

The Vernon Copper Mines are now being worked energetically, and as they promise to become a source of wealth to the Province, and the rocks in which they are situated shew indications of valuable copper deposits both east and west of these Mines, a minute description of them and their geological relations, may be attended with advantage. The examination was made during the month of November in the present year.

As a preliminary to this description it will be advisable to make a few observations on metallic veins and the circumstances under which veins of different kinds originate.

ORIGIN OF METALLIC VEINS.

In expressing an opinion on the commercial value of any metalliferous deposit, it is essential to bear in mind various facts and conditions which experience has shown to be inseparable from mining operations. It is therefore proposed to glance briefly at the known laws which appear to regulate the distribution of veins and masses of ore in both stratified and unstratified rocks.

In rocks of sedimentary origin, metalliferous deposits when they occur in masses, are evidently of the same or nearly the same age as the strata in which they are found. As for instance the clay-iron stone deposits of the coal formations, the beds of hæmatite at Woodstock, &c. (see Chapter IX.), and it is in this form that iron and manganese are frequently found, whereas other metals, including also iron and manganese often occur in unstratified rocks. Some of the mountain masses of iron ore in the Laurentian Series of Canada belong to the stratified deposits, although there are eruptive masses of ore on Lake Superior and in Missouri. The form in which metalliferous deposits occur in the unstratified and often in metamorphosed rocks is that of mineral veins, which are of three kinds, segregated, gash and true veins.*

* See Professor J. D. Whitney on "the Occurrence of Metalliferous Ores."—Geological Survey of Wisconsin.

“Segregated veins, which are peculiar to altered crystalline, stratified or metamorphic rocks are usually parallel with the stratification, and not to be depended on in depth. Gash-veins may cross the formation at any angle, but are limited to one particular group of strata and are peculiar to the unaltered sedimentary rocks. True veins are aggregations of mineral matter, accompanied by metalliferous ores, within a crevice or fissure, which had its origin in some deep seated cause, and which may be presumed to extend for an indefinite distance downwards.”*

True veins are supposed to have originated in faults, and may be indefinitely deep; gash veins probably originated in fissures produced by shrinkage, and are liable to give out on passing into another set of beds. True veins exhibit, first, persistence and depth; second, a peculiar gangue or veinstone forming the bulk of the vein, and often consisting of quartz, bitter spar, calcite, and heavy spar; third, a disposition of the mineral substances of which the vein is composed symmetrically, in parallel layers on the wall, with their chrystalline faces turned inwards and towards the centre of the lode or vein; fourth, well defined walls or sides of the vein, often polished or slickensided; fifth, they are usually independent of the stratification, and the vein stone changes frequently as they enter different strata.

The most productive deposits of Lead Ores appear to occur in Lower Silurian Rocks, or in Carboniferous Limestone. In Spain, and in the Western States, the lead districts are in Lower Silurian Rocks, in England in the Mountain Limestone. Both lead and zinc occur in heavy masses in unaltered rocks, but this is not the case with other metals. When lead occurs in the older chrystalline rocks, it is usually argentiferous and is worked for the silver it yields, and as a general rule the more chrystalline a rock is the more silver will lead ores found in it contain. When lead and zinc occur in the unaltered stratified rocks the deposits are usually irregular and cannot be relied on, but when they occur as true veins they are generally permanent.

ARGENTIFEROUS LEAD ORES.

The lead ores in New England are generally rich in silver, but they occur in such hard rocks and in so small quantities, that although the veins are frequently large and well defined they have not thus far been found capable of being wrought with profit.†

The ore at Warren, in New Hampshire, contains from 60 to 70 ounces to the ton of 2,000 lbs., and in Europe eight ounces of silver to the ton can be profitably separated.

It is a great mistake, however, to suppose that lead ores are necessarily argentiferous. The Galena of the Upper Mississippi Valley scarcely contains more than a trace of silver; and when we hear of lead ore containing “a good percentage of silver,” we must receive the information with due allowance for looseness of expression, or with a suspicion that a want of correct information on the subject is far more probable than “a good per-

* Professor J. D. Whitney.—Geology of Wisconsin.

† Ibid.

centage of silver.' A moment's reflection will show the absurdity of statements to the effect that certain lead ores contain three, two, or even one per cent. of silver. It has been already stated that eight ounces to the ton of ore pays for extraction in Europe. A ton contains 2,000 lbs., and eight ounces troy is two thirds of a pound. One pound in 2,000 lbs. would be exactly one twentieth per cent., and eight ounces to the ton is one thirtieth per cent. One per cent. of silver in lead ore would be 240 ounces to the ton, but as eight ounces pays for extracting, some idea may be formed of the value of a lead mine containing one per cent. of silver to the ton of ore.

THE VERNON MINES.

The Vernon Copper Mines, of which a description will now be given, are situated about two miles east of the mouth of Goose Creek, in the County of Saint John, near Martin's Head. The cliffs here are very precipitous, and the summit level or edge of the plateau is 660 feet above the sea.

DESCRIPTION OF THE ROCKS.

General Arrangement and Character.

The strike of the rocks on this part of the coast being nearly east and west magnetic, and the variation of the compass 20° west, a line of section at right angles to the strike would pass from Jim's Brook, (a small stream which tumbles over a ledge of rocks into the Bay of Fundy, $1\frac{1}{2}$ miles from Goose Creek,) where it crosses the road to the Vernon Copper Mines, down its valley towards Mackerel Cove. For the purpose of representing the actual strike and dip of the rocks as they appear on the coast and in the valley of Jim's Brook, it will be necessary to diverge a few degrees to the west, and then to the east of a straight line at right angles to the strike.

At Mackerel Cove * red slates have a southerly dip, ($S. 20^{\circ} W.$), for a few yards, and are succeeded by conglomerates and plumbaginous slates with a vertical dip, then by green, grey and black plumbaginous slates with a dip to the north, thus showing an anticlinal axis. About eleven years ago attempts were made to discover coal in the plumbaginous slates of Mackerel Cove, and a drift was made for a space of 90 feet horizontally, but of course without success, the rocks on this part of the coast being some thousand feet below the true coal measures. A red arenaceous conglomerate on the north side of the axis exhibits beautiful plumbaginous surfaces, hard, glistening, and intensely black. It is succeeded by green slates which gradually merge into a Diorite containing much epidote. These are followed by a few yards of an intensely red sandstone with slaty cleavage, which gradually becomes a fine conglomerate. A broad belt of Epidotic Trap now forms the coast for between two or three hundred yards; this trap appears again at the Point east of the mine, and probably at succeeding points on the coast in the same direction. The entire series of red, plumbaginous, and green slates just noticed, were thought to be recognized on Goose Creek, at the Mill-dam, and above it. They probably cross the peninsula in successive

* Mackerel Cove is about one mile east of the mouth of Goose Creek.

belts, between Mackerel Cove and Goose Creek. In a ravine near the Mill-dam, the plumbaginous slates have already attracted attention, and although it would be an absurd waste of labour and means to repeat the Mackerel Cove enterprise in search of coal, in what are probably Devonian Rocks, yet an impure plumbago might be obtained of questionable value.

The broad belt of Epidotic Trap has a very important bearing upon the geological structure of the coast for some miles to the east, and it will be noticed in subsequent paragraphs. Succeeding this trap is a very coarse red conglomerate dipping to the south. The beach is strewn with its debris and it shows much metamorphic action, the pebbles it contains being extremely hard and capable of receiving a fine polish. It is probable that some layers of this conglomerate, those near the trap, would afford an excellent material for the manufacture of ornamental tables, vases, &c. A narrow trap dyke succeeds the conglomerate, and is followed by slates and fine conglomerates as far as Jim's Brook, dipping to the north, showing another anticlinal axis or fold. About one hundred yards to the east of the brook and a little out of the line of section, the continuation of the last anticlinal noticed is well seen on the coast. A bright green sheet of trap comes up through the centre of the anticlinal, and is newer than another series of trap dykes, which are of a darker green, ferruginous and copper bearing.

Continuing up Jim's Brook on the line of section, reddish-grey conglomerates form the precipitous cliff down which Jim's Brook plunges for 228 feet. A trap dyke occurs here, which where it joins the slates, abounds in copper pyrites. This is called the Brook vein. The course of the brook changes after passing the trap, and runs in a deep gully for a distance of about 160 yards, in a northeasterly direction, over red and green conglomerates, dipping north; here the course changes again with another trap dyke, and continues for 300 yards in a direction N. 20° E., passing over beautiful green slates and two or three narrow belts of trap. These green slates are probably the same band which were found in excavating a cellar on the summit of the hill 350 yards from the coast. They are porphyritic, unctuous, and soft, being succeeded by still more altered and very hard slates. Some layers of the green slates have a compact texture and clean fracture; they would make good roofing slates if the mass of the rock retains the characters of some of the ledges exposed in the brook. The same slates cross the road to Goose Creek, due west of the Brook. Here they weather of a yellowish white colour, and would not attract attention without fresh fractures were exposed.

THE ROCKS ON THE COAST.

Returning to the coast east of Jim's Brook, red conglomerates highly metamorphosed are seen forming a sharp anticlinal. The conglomerates are jaspery and very hard; the bright green trap coming up through the crown of the anticlinal has already been noticed. Grey and reddish conglomerates dipping north, now occupy the coast, with occasional exposures

of trap as far as the Point of rocks where a great mass of Epidotic Trap forms a well defined land mark, about 250 yards east of the main or Peacock vein. The several exposures of trap in this space are probably parts of a sheet which runs nearly parallel to the coast, and has resisted the action of the sea. The point upon which the house and store of the Vernon Mining Company is built is part of this sheet, the slates being found in its rear. Near Azor's Beach there is an anticlinal axis with porphyritic greenish slates on each side and a trap dyke between, the course of the slates being N. 70° E.

The general arrangement of the rocks north of the broad belt of Epidotic Trap which has been described as occurring near Mackerel Cove, at the Point of rocks and east of Azor's Beach, appears to be that of the north side of great anticlinal fold, the belt of Epidotic Trap, coming up from below and occupying the crown; the south side having been washed away by the sea. Minor undulations occur at Mackerel Cove, 300 yards west of Jim's Brook, 100 yards east of the same place, and about 150 yards west of Azor's Beach. The north side of this fold has been subjected to one or more cracks or dislocations, one being occupied by the Peacock vein, and another probably lying on a course nearly parallel to it and forming the valley of Jim's Brook, the Peacock vein being anticlinal and Jim's Brook synclinal. There is also, probably, a great fault, whose northern boundary is marked by the "Green vein."

INTRUSIVE TRAPS.

Epidotic Trap.

The general course of the Trap dykes is from east to west. The broad belt of Epidotic Trap on the coast is perhaps 200 yards in width. It forms the first point and some hundred yards of the coast east of Mackerel Cove. It has a rather coarse red conglomerate on one side and a fine red conglomerate on the other. It is next seen in force at the Point of rocks, east of the house, with reddish conglomerate behind it at an altitude of 72 feet, and again near Azor's Beach.

Copper Bearing Trap.

In the rear of this great belt there is a series of narrow bands of intrusive trap which come up through the conglomerates and slates nearly at right angles to their dip. These are the COPPER BEARING TRAPS of this part of the coast.

The first band containing copper pyrites was seen at an altitude of 198 feet above the sea, 70 yards east of the Twin Pillars (east of the Epidotic trap near Azor's Beach). Its course would bring it out on the coast about 320 yards (estimated) east of the Point of rocks, where it was seen backed by yellowish green porphyritic slates dipping north. Two other narrow bands of a similar trap cross out on the coast between it and the Point of rocks, but no copper was seen in them. It is probable that the most westerly of these bands appears just in the rear of the Epidotic trap at the Point

of rocks, where the distinction between the two kinds of trap is visible one being very epidotic, the other highly ferruginous and containing no epidote.

North of the Point of rocks another band of trap, 20 feet broad, is visible at an altitude of 229 feet. The fine conglomerates with slaty cleavage, are seen on both sides of this band, and are very porphyritic close to the trap. At an altitude of 350 feet, also about due north of the Point of rocks, there is a wall of trap having a course S. 70 E. and dipping S. at an angle of 78°. This is probably the same copper-bearing dyke which appears at the main pit of the "green vein," and also to the west of it in the gully between it and the upper pit of the green vein, and near the upper pit itself. The next copper-bearing trap of this Series, where the metal has been found, occurs at the Brook vein. Several other belts of trap running apparently parallel to those described may be seen in Jim's Brook, where the strata are exposed, and traces of copper were found in some of them. These copper bearing traps appears to form a set of rudely parallel sheets which come up through the conglomerates and slates, nearly at right angles to their stratification. The sheets face the coast line, and incline towards it at an angle, where observed, of about 78° S. The intrusive character of these traps is well exemplified east of the Point of rocks, where large masses of the conglomerates are seen involved in their mass, and their relation to the copper ores found in the veins is not difficult to trace.

NECESSITY FOR ASCERTAINING THE SOURCE OF THE METAL.

It is important to ascertain the true origin of the metal, as the future profitable working of the copper ores on this part of the coast materially depends upon a recognition and appreciation of this fact. In Canada "the distribution of copper through the rocks of the Quebec Group is very general, and seems to indicate that this metal was almost every where present in the waters from which these strata were deposited."* In a portion of the Acton Mine,† to which the Vernon Mine has been compared, but to which it bears no resemblance, except in the vein stone, "occasionally the variegated and vitreous sulphurets form the cement of a conglomerate rock, enclosing masses and grains of chert and of limestone." * * * "Sometimes the ores, as at Acton and Upton, are in the dolomites, or as in Ascott, in a chloritic limestone, while in many other localities they are found in micaceous or chloritic slates, or in steatite."‡

The reticulating veins of carbonate of lime which form so marked an object in the perpendicular cliffs of dark coloured calcareous slate near the mouth of Goose Creek contain copper ores, but these were probably derived from the trap injections which are so numerous in that vicinity. No copper has been found in the conglomerate of the Vernon property remote from a trap dyke, and specimens which have been analyzed appear free from a trace

* Geology of Canada, Prof. Hunt.

† These Mines occur in the "Quebec Group" of rock near the base of the Lower Silurian, the Vernon Mines are in rocks probably not older than the Devonian Epoch.

‡ Geology of Canada.

of the metal. The ores found in the upper portion of the Peacock vein, near the green vein, appear at the first glance to be wholly in the slaty conglomerate, but on a more minute examination, small calcareous and quartz veins are found, with layers of steatite in which the ores are contained. All the evidence so far gathered, tends to show that the trap is the chief source of the metal on this part of the coast.

NEWER TRAPS.

Narrow bands of a bright green trap which sometimes becomes a beautiful diorite, cut the older traps which have just been described near Jim's Brook. They occur here with the stratification, at the subordinate fold or anticlinal. At the same spot a band about two feet broad is seen at an altitude of about 250 feet above the sea, and may be traced to the gully near the Peacock vein, where it appears at a greater elevation. No copper has yet been found in these newer traps, and as they have only been recognized in the form of a few narrow dykes it is probable that they are not important.

An observer viewing this part of the coast from the sea, or even when making a superficial examination on the beach, would probably be misled not only as to the true relation of the traps and the conglomerates, but also as to the nature of the conglomerates themselves. The bold promontories caused by the hard epidotic trap appear at the first blush to run into the interior nearly at right angles to the coast, and it is only when the sedimentary rocks are seen in position in their rear, that the disposition of the broad but irregularly worn belt which produces them becomes apparent. So also with reference to the parallel bands of copper bearing trap, whose worn edges sometimes come on the coast; they must be examined in all their associations to discover the relation they bear to the sedimentary masses they penetrate.

SPECIAL CHARACTER OF THE SEDIMENTARY ROCKS.

The conglomerates vary from a very coarse pudding stone, best seen near Mackerel Cove, to a fine red, or greenish-grey schistose conglomerate in which the pebbles are nearly of the same colour as the matrix, small and few in number, but water-worn and pretty uniformly distributed. The coarse conglomerate, when altered by proximity to the traps dykes, is a very beautiful rock, and many rounded boulders on the beach which have originally come from high up the cliffs east of Mackerel Cove, would be valuable in the hands of a Lapidary. The fine red and green conglomerates, best seen high up the hill at the rear of the Peacock vein, are very magnesian, and in the vicinity of trap dykes remarkably porphyritic, containing crystals of yellowish felspar, and the enclosed pebbles are also porphyritic. The coarse conglomerate first described holds large pebbles of the porphyritic variety, showing not only that it is newer but that there has been no overlap on this disturbed part of the coast. The green slates on Jim's Brook may hereafter become valuable, as well as the fine red arenaceous rock near the black plumbaginous slates, for building and ornamental purposes. In the

paste of all the fine conglomerates, magnesia appears to be a characteristic element, and the surfaces of most of them are very unctuous. The yellowish-green and brownish-red magnesian schists which appear to overlies the conglomerates or are interstratified with them, are fissile, very unctuous, glisten on fresh surfaces, and are porphyritic. Many of these layers which at first glance resemble a fine volcanic ash, show a conglomerate structure upon examination; holding small water-worn porphyritic pebbles. Some of the layers are, however, so steatitic that they resemble a fissile porphyrite soapstone; they can be cut with a knife, scratched with the nail, and yield when crushed under water a very fine, almost impalpable powder, and it is not improbable that by proper manipulation an excellent polishing powder could be cheaply manufactured from them. In the green or rather variegated variety (purple and green) of these metamorphosed schists or fissile slates, the magnesian portion resembles impure talc, it is lustrous, silvery, semi-transparent, and is not sensibly affected by dilute acid. These schists effervesce very feebly when immersed in an acid, in some specimens no effervescence can be recognized. Minute patches of chlorite occur in the green variety, but no copper has been detected in specimens taken remote from a lode or trap dyke, but copper has been seen in considerable and important proportions in these schists near a trap dyke.

THE COPPER LODES.

These are five in number and may be distinguished as follows:—

- 1st.—The Peacock Vein.
- 2nd.—The Green Vein.
- 3rd.—The Spur Vein.
- 4th.—The Brook Vein.
- 5th.—The Copper bearing Trap east of the Point of rocks.

1. The Peacock vein is a true vein occupying an irregular fissure produced by a crack and dislocation, with the downfall on the northwest side.

2. The Green vein is also a vein occupying a crack on a probable line of fault running N. 65 W., or nearly at right angles to the Peacock vein.

3. The Spur vein lies in a continuation of a fault whose northern boundary is marked by the Green vein.

4. The Brook vein occurs adjacent to one of the copper bearing sheets of Trap, but it has not been opened sufficiently far to admit of any opinion being expressed respecting its productiveness; but reasoning from what has been elsewhere observed here, it is a valuable vein.

5. The copper bearing Trap east of the Point of rocks is a valuable indication and guide for future investigation.

THE PEACOCK VEIN.

The manner in which the Peacock vein has originated may be explained in the following way. The first movement to which the strata were subjected, was such as to give them a northerly dip of 15 or 20 degrees. An irregular

crack then occurred in a general horizontal direction N. 35° E., the strike of the slaty conglomerates being about E. and W. The downward direction of this crack was about 55° N. W. The crack represents then a thin irregular fissure subsequently filled with vein stone and ore, and forming a sheet which has a general strike N. 35° E., and a dip 55° N. W. The conglomerates on the west side of the crack have been made by this dislocation to dip 20° or 25° northwesterly, and on the east side of the crack they dip from 7° to 10° northeasterly, the downfall is on the western side. Suppose, for illustration, that a number of broad sheets of a slightly elastic substance were piled one on the other, and that then they were raised on one side so as to lie at an angle of 20 degrees to the horizon. The extremities being firmly fixed so that they should not move relatively to one another, we can conceive a force from beneath, or pressure at each extremity to bend them in the form of an arch. It is probable that they would crack about the centre of the arch; but if the force were not applied at right angles to their length, they would certainly crack in some other direction. It is easy to conceive that a force from below or a lateral force might be so applied that the sheets should crack at any desirable angle, supposing their structure to be tolerably uniform, and it is also easy to conceive that this crack could be made to take a sloping direction from the uppermost to the lowest sheet, by varying the direction of the pressure. The stratified conglomerates have been subjected to this kind of force, probably a lateral one which acted in a direction near, at right angles to this crack, or from about southeast to northwest, or, as is perhaps equally probable, the crack occupied by the Peacock vein is a *subordinate lateral fracture* connected with the great undulation which first tilted the conglomerate slates and schists in a northerly direction.— (See page 119.) Whatever may have been the primary cause, we find the Peacock vein occupying a fissure, having a general course N. 35° E., and dipping at an angle of 55° in a northwesterly direction. This thin sheet is cut obliquely by several sheets of copper bearing trap.

The traps are supposed to be the original seat of the copper ore, and the Peacock vein was supplied with its copper from them, or from the source which gave it to the traps. Hence it is in the vicinity of these trap-dykes that the richest deposits of copper are to be looked for. It consequently becomes a question of primary importance to ascertain the easiest method of reaching these copper bearing traps where they intersect the Peacock vein.

If the direction of this vein were uniform, as well as that of the intrusive traps, it would be but a simple problem relating to the intersection of plane surfaces under different angles, but since both vein and traps vary in their courses by some degrees, an approximation can only be arrived at, but the general relation having been described, the details in particular cases can be worked out with difficulty.

The vein when it has been fully exposed varies in width from 1½ feet to 7 feet. Its course is uniformly N. 35° E. as seen on the denuded slope of the hill, to a few feet above the upper level, or about 120 feet above the sea. It

then trends to the east and crosses the stairs at an altitude of 209 feet, after which it pursues a course N. 60 E, on the side of the hill, and intersects the Green vein at an altitude of 389 feet above high tide. It has not been traced beyond this point, probably on account of a fault which will be described hereafter.

THE VEIN STONE.

The vein stone consists chiefly of Bitter or Pearl Spar, a crystallized dolomite, composed of the carbonates of lime and magnesia; it is also interseamed with quartz. The Bitter Spar is often white, but sometimes rose coloured, owing to the presence of oxide of iron. The quartz is generally white and translucent, but sometimes rose coloured with the same material. Patches of chlorite occur in some parts of the vein, but generally, as exhibited at the levels, it is a massive seam of the dolomite, although crystals of calcite or calcareous spar are sometimes found. Bitter spar occurs in the copper bearing quartz veins at the Bruce Mines, Lake Huron. It there forms a wall of dolomite from a few inches to two feet in thickness. At the Vernon Mines the dolomite forms a solid wall or sheet fully 19 inches in thickness at the entrance of the upper level. It is remarkable that while the country rock contains abundance of magnesia, carbonate of lime scarcely enters sensibly into the composition of some of the red and greenish conglomerates through which the vein passes. In the copper mining district of Lower Canada the ores are very frequently met with in a gangue of Bitter spar and quartz.

COURSE OF THE LEVELS.

The crack occupied by the vein is very irregular, as will be seen by the following ascertained courses in driving the upper and middle levels:—

Upper Level,	103 feet above the sea.
N. and S.	23 " "
N. 85 E.	21 " "
N. 10 E.	40 " "
Middle Level,	69 feet above the sea.
N. 10 E.	24 " "
N. 20 W.	20 " "

By continuing the upper level on the same course, it is probable that a sheet of copper bearing trap will soon be reached, when a highly remunerative mass of the ore may be expected. In the neighbourhood of trap dykes this vein will be worked with the greatest success.

As already stated at an altitude of about 209 feet above the sea, the course of the exposed vein is N. 60° E. About 80 feet east of the steps on the course of the vein, the conglomerates dip N. W. by N., but at a distance of 280 feet east, they dip N. E. shewing the continuation of the crack and dislocation, although the vein is difficult to trace here. It is, however, well seen 300 feet east of the steps, and 286 feet above the sea; the eastern extremity of the wharf, bearing S. 30 W. There is near here a depression of

several feet on a wooded plateau which may mark the site of a slide which has thrown the vein a little out of its original course and produced a jog, the altitude of the deepest portion of this depression is 360 feet above high tide. After crossing the depression the Peacock Vein shews well in the conglomerate, with leaves or seams of soft chlorite, but with little vein-stone. As it appears on the surface of a precipice here, it seems to run with the stratification. A few rods further on, in a northeasterly direction, the Peacock vein ought to cross the Green vein, but the actual point of junction is covered with debris and the north side is apparently shifted by the fault. This point, which is one of considerable importance, is situated (389 feet above the sea) in the first gully east of the House, and about mid way between the Upper and Lower Pit of the Green vein. It will, however, first have to pass through one of the sheets of trap which run with a general easterly and westerly course, and which is here seen to crop out just below the upper level of the Green vein.

THE GREEN VEIN AND SPUR VEIN.

This is the name given to a vein which occupies a fissure running N. 65 W. or nearly at right angles to the Peacock vein, and dipping S. $< 65^\circ$. The Green vein on this course should cross the road leading to the head of the steps at an altitude of 453 feet above the sea, and about 300 feet from the head of the steps; but, on account of the rock being deeply covered with debris and clothed with forest growth, its course was not traced above the upper pit 409 feet above high tide, but it probably trends to the west and is seen again at the Spur vein. The strike of the slaty conglomerate on the north side of the fissure is about East and West, the dip north, on the south side the strata are much fractured, and this occurs both at the upper and lower pit, 40 feet lower down and 120 feet in a southeasterly direction, on the face of the steep hill. It suggests the idea that the Green vein may occupy a crack about 5 feet broad, produced by a surface slide of comparatively recent origin. This view is apparently sustained by the occurrence of a narrow valley or depression, before noticed, on the hill side some 10 feet deep, a little below the Green vein, (300 feet above the sea) and a few rods south west of the upper Pit, running in the same general direction as the Green vein.

On the other hand the Green vein may occupy a line of fault.

In support of this view it may be urged—1st. That the north walls of the Green vein are slickensided, so are also the walls of the disturbed masses on the south side.

2nd. The ore both at the upper and lower pit occurs between an irregularly arranged mass of shattered rock filling the fissure, with a thin wall of trap having a course S. 85° E. or nearly east and west, south of it, and a few feet below the lower pit there is a strong sheet of trap, of which a thickness of 14 feet are visible running east and west; the upper portion of this sheet has been worn away, but it still projects a little in the Gully.

3rd. The valley or depression on the hill side to the southwest of the Green vein, has a direction corresponding to the fissure in which the Green vein is seated, and a very slight change in its course would carry it to the Spur vein west of the summit of the steps, where the rocks on *the south side* are folded or corrugated by pressure.

4th. There is a considerable proportion of quartz in the vein stone, and some excellent copper pyrites and grey copper, together with scales of specular iron near the trap.

5th. The occurrence of a fault here would account for the abrupt termination of the Peacock vein, which must be sought for more to the westward, and it would explain the origin of the valley without the supposition of a slide.

In the absence of more facts to establish the character of the Green vein, which the state of the hill side, covered by debris, moss, and forest growth, rendered it impossible then to procure, it can only be asserted at present that the impressions produced by what is already known, strongly tend to confirm the view that this vein occurs in a line of fault; that this fault, after passing the axis of the lower anticlinal occupied by the Peacock vein, trends more to the west and is seen again at the Spur vein, which is most probably the continuation of the Green vein.

The descriptions which have just been given of the general structure of the coast in this part of the Bay of Fundy, will suffice to show that no difficulties are likely to supervene in working the copper ores, which appear to have a wide-spread distribution, and to accompany, in fact, the copper-bearing traps their development here. Specimens of purple ore have been taken from veins near trap dykes, some miles to the east of Goose Creek, which promise remarkably well.

CHAPTER VII.

THE UPPER AND MIDDLE SILURIAN SERIES.

Their Boundaries in the Northern part of the Province—The upper part of the Series occurs at Cape Bon Ami—On the Upsalquitch River—On the Tobique—On the Saint John—The Middle, on the Bay of Fundy—Section at Cape Bon Ami—Honestones—Fossiliferous Limestones—Upsalquitch Lake—The Grand Falls—The Upsalquitch and Restigouche Rivers—Mountainous character of the Country—Swallow-tailed Butterflies—Wall of Trap—The Drift—Indian Superstition—Upper Silurian Rocks on the Restigouche—On the Upsalquitch—Argillites on the Tobique—Honestones—Uniformity in the Rocks on the Lower Tobique and Upper Upsalquitch—The Saint John—Hydraulic Limestones—The Grand Falls—Description of—The Gorge—Terraces—The Saint John above the Grand Falls to the Province Line—Upper and Middle Silurian Rocks on the Bay of Fundy—The Arisaig Series—Lead Ores on Campo Bello—Frye's Island—The Saint George Peninsula—Wheal Louisiana—Letite—Description of the Mascaben Peninsula—Section on the Peninsula—Trap and Slate Series—Hornblendic Slate—Fractures and Dislocations—The Main Fissure—The Mine—The Windlass Shaft—Subordinate Lodes—Frye's Island—Probably Middle Silurian—Barytes—Uses of—L'Etang—Limestone of.

A very considerable part of the Province is covered by rocks belonging to the Upper Silurian Series. It forms by far the largest portion of the area included within the Counties of Restigouche and Victoria.

On the Bay of Chaleur the boundary between the Upper and Lower Silurian may be provisionally placed close to Medisco River. It was seen as supposed, on the Upsalquitch at the Portage at Ramsay's Brook, near where a green conglomerate holding red and green slate pebbles forms the falls over which the river plunges. The boundary of this formation was next seen on the Tobique, about five miles from its mouth. Again between the Little and Big Shiktehawk, where a similar conglomerate was recognized, and finally near the North Branch of the Meduxnekeag. Between this point and the Bay of Chaleur, its outcrop, with the exception of a deep indent on the Saint John between Presquile and the Tobique, appears to form a curve roughly parallel to the outcrop of the Devonian Granite described in Chapter II.

The whole of the northern part of the Province not occupied by small Devonian or Carboniferous outliers already noticed, or by intrusive rocks, is supposed to be of Upper Silurian Age. It is, however, probable that Devonian outliers will be found on the upper waters of the Restigouche, in continuation of belts of rocks of similar age known to exist in the State of Maine.

The following brief descriptions of the Upper Silurian Series, as they occur at five points remote from one another, will serve to convey an idea of the great variety and in some cases of the economic value of different members of these extensive and important deposits:—

- I. Cape Bon Ami, near Dalhousie.
- II. The Upsalquitch River and Restigouche.
- III. The Tobique River.
- IV. The Saint John River.
- V. Letite on the Bay of Fundy.

I.—CAPE BON AMI, NEAR DALHOUSIE.

Near Dalhousie, in the vicinity of Mr. Dugald Stuart's fishing station, there is a beautiful series of Traps, trap ash, calcareous slates, and highly fossiliferous limestone, interstratified with one another. Proceeding from south to north, the section exposed may be roughly represented as follows:—

1. Trap.
2. Calcareous Shales.
3. Trap.
4. Calcareous Shales.
5. Trap.
6. Fossiliferous Calcareous Shales.
7. Trap.
8. Highly Fossiliferous Limestone.
- * 9. Trap.

On Mr. Barberie's Farm the calcareous (2) shales occupy the valley, resting on the trap to the southwest at an angle of about 45°. The trap overlaying these (3) is soft and weathers easily, crumbling into a fine earth which is used as a top dressing by the farmers of the neighbourhood. Veins of carbonate of lime and also of quartz ramify through the trap, which in some places is merely a volcanic ash, and shows a more or less distinct stratified arrangement.

No. 4 partakes of a shaly character, some layers are sufficiently hard and fine as to be adapted for honestones. It weathers buff and pale yellow.

No. 5 resembles a vesicula lava, hard, black in colour, but weathering red.

No. 6 consists of highly fossiliferous shales and limestones containing *Favosites Gothlandica*; *Strophomena rhomboidales*, &c. &c. Many layers are fissile and shaly, weathering buff; others are hard and silicious. It is from this layer probably, or its continuation, mentioned in the next paragraph, that the honestones and scythestones, exhibited by Mr. Barberie at the Provincial Exhibition for 1851, were taken. There are several layers here admirably fitted for the manufacture of these stones on a very extensive scale, and the quality is excellent.

* This Series is placed in the above form for the sake of comparison with another Series of about the same age on the south coast of the Province, (Letite.)

No. 7 is a massive trap. On this part of the coast a belt of very hard calcareous shale crops out on the shore, and is covered by high tide. It is succeeded by a conglomerate 14 feet thick, capped by honestone 36 feet thick, and followed by the heavy bedded trap, it is probably a continuation of No. 6, but separated from it by the waves of the sea having worn through the mass to the overlying trap.

No. 8 is a highly fossiliferous limestone reposing on No. 7, filling the hollows. In and near the little stream which flows through the fishing house belonging to Mr. Dugald Stewart, the fossils are very numerous, and many of them in an excellent state of preservation. Among them are—

Favosites	Gothlandica,
“	polymorpha,
“	basaltica,
Strophomena	rhomboidalis,
“	punctulifera,
Calymene	Blumenbachii,
Atrypa	reticularis,

with fragments of orthoceras, together with several species of orthis, spirifera, &c. A slab obtained by the writer and shown at the Provincial Exhibition, contained all of the above species, besides others.

No. 9. A highly ferruginous trap occurs as far as the point of Cape Bon Ami.

II.—THE UPSALQUITCH.

Geographical Features.

Upsalquitch Lake, about two miles long by half a mile broad, forms the source of the River of the same name. It is a beautiful sheet of water surrounded by high conical mountains. The dividing Ridge which separates its waters from those flowing into the Nipisiguit is 1,508 above the sea. One of the conical mountains near this lake has an altitude of 2186 feet,* and another, half a mile west of the lake, an elevation of 1,707 feet. The Little Portage stream, between the Upsalquitch and Nipisiguit, is more than 1000 feet above the sea, (1034) but the Lake itself is only 750 feet higher than the same level. Some idea of the nature of the Grand Falls, which occur within eight miles of the Lake, may be obtained, when a comparison is made between the height of the River at Ramsay's Portage, where the Falls terminate, and the head of the Falls. At Ramsay's Portage the river is 271 feet above the sea; at the head of the Falls it is approximately 700 feet about six miles below Upsalquitch Lake. Hence, in a distance of about 1½ mile, the river is precipitated more than 420 feet. The cascades, some of which are very beautiful, are not marked down on the map, but what are called the "Great Falls" are placed near Borland's Brook, not far from the mouth of the river. Up these Falls there is no difficulty in dragging a canoe, they do not descend more than four or five feet.

* Boundary Commissioners Report.

The general course of the Upsalquitch is northwest, its length is about 44 miles, and it receives numerous important tributaries draining a large but mountainous tract of country. Two miles east of Ramsay's Camp, where the river is 271 feet above the sea, the hills are elevated 1048 feet, and a peak five miles east of the same place is 1432 feet, while within a few miles of the mouth of the river the Squaw's Cap rises 2000 feet above the ocean.

On the shores of Lake Upsalquitch innumerable swallow-tail butterflies were seen, and when clustered groups of from thirty to fifty were disturbed, the cause of their congregating so closely together was found to be a decaying fish bone.

Large areas of cultivable land in the immediate valley of the river cease near the junction of the northwest branch. Where the east branch comes in, a huge wall of trap some 300 feet high and many hundred yards broad forms striking scenery, and some distance above this place the river runs rapidly from side to side of a narrow valley between walls of the same intrusive rock. On Ramsay's brook there is a considerable area of good land, as well as on the nine mile Portage leading to Upsalquitch Lake, where the maple is found in small groves and interspersed with other forest growth.

The drift retains its coarse and apparently horizontal character for about 15 miles up the Upsalquitch, it then begins to show signs of a rearrangement of its materials, with layers of sand and gravel, but no large boulders. Above Ferguson's Brook it forms banks sometimes 30 feet high, and consists of coarse gravel reposing on fine sand not always horizontally disposed. At the Grand Falls the drift contains boulders of local rocks with a considerable quantity of sand, and at the outlet of the lake quartz fragments not much water-worn, are very numerous in the bed of the stream; they vary from half an inch to a foot in diameter, and masses of white quartz two feet in diameter are not unfrequent.

In walking up this stream I observed one of the Micmac Indians take a little crawfish and place it carefully on the bank, about two feet above the then level of the water. On enquiry, he stated that his object was to "get a freshet," so that we might go down the Nipisiguit without difficulty. "The little 'crab' would bring it, and make the water rise just as high as he pleased." He remarked that this was an old Micmac superstition, "and a very good one."

GEOLOGICAL FEATURES.

Mr. Richardson, of the Canadian Geological Survey, examined the Restigouche in 1857, from the mouth of the Patapedia to the Bay of Chaleurs. Allusion has been made in a previous Chapter to the existence of a small narrow basin of Devonian Rocks from the Matapedia downwards. Above this river the rocks belong to the Upper Silurian Series, (Gaspé Limestones). At the mouth of the Patapedia greenish arenaceous slates and sandstones, according to Mr. Richardson, appear to have a dip up the river, and to

underlie the thin bedded limestones and dark grey shales beyond; they can be traced down the Restigouche to Cross Point, a distance of about four miles, where the beds associated with them are calcareous, and hold fossils consisting of fragments of trilobites and bivalve shells, but too much broken to be identified. The sandstones attain the neck of Cross Point, while the thin bedded limestones above them occur at the north part of the turn in the river. To this point the strike and the general valley of the river run about northeast; lower down they turn together, and the sandstones and their associated dark grey calcareous shales are every now and then seen for seven miles in a bearing nearly east. Here the river separates from them, and while they appear to continue in a pretty straight course to the junction of the Upsalquitch, the Restigouche makes a turn to the northeastward on the thin bedded limestones to Brandy Brook, and returns upon them south-eastward to the sandstones at the Upsalquitch. From the Upsalquitch the Restigouche appears to flow on the thin bedded black limestones to the mouth of the Matapedia.

Calcareous shales, and slates with trap, appear occasionally on the Upsalquitch banks as far as Little Falls, where a beautiful section is exposed, in which there appears to be a silicious band, overlying contorted shales; these are underlaid by 40 feet of an ash-coloured crystalline mass forming the falls, and weathering light brown when exposed to running water. This overlies some 80 feet of fissile dark-coloured ferruginous shales, and 25 feet of a cream-coloured rock; of these last two there are four repetitions, the dip of the whole being south at an angle of 80°. Dark calcareous slates, with red silicious bands, are continually repeated for some miles up the river. There is a considerable development of Trap both above and below the Ox-bow, near Meadow Brook, where green and red argillites appear, which are quickly followed by highly fossiliferous limestone, holding numerous specimens of the chain coral, (*Catenipora escharoides*.)

Above Ramsay's Brook, and near the mouth of Hutchinson Brook, red slates appear in place, with a change in the strike; and on the portage just above, a well characterized conglomerate, supposed to belong to the Quebec Group, appears to mark the boundary of the Upper Silurian on the Upsalquitch.

III.—THE TOBIQUE.

The Rocks as developed about half a mile above the Narrows are both geologically interesting and economically important. They are provisionally placed among the Upper Silurian Series, the lower rocks appearing to come into place about five miles from the mouth of the river.

Above the Narrows there is a beautiful Series of red, sea green, and bluish black argillites with a calcareous band holding fossils, (*favosites Gothlandica*.)

There is also a silicious band of very fine texture admirably adapted for the manufacture of honestones. The argillites can be easily worked, and it is probable that the green variety, which is a beautiful material, may

become of economic importance. This rock weathers buff-yellow. The strike of the whole Series is from N. 50 to 60 E. and the dip northwesterly. It will not escape the attention of the reader that red and green argillites, with a fossiliferous calcareous band holding the chain coral, have been described as occurring near Ramsay's Brook on the Upsalquitch; the occurrence of the same rocks near the mouth of the Tobique, at a distance of about 80 miles in an air line, shows remarkable uniformity in the distribution of the Upper Silurian Series here, the strike being such as, if prolonged, would carry the Tobique argillites to the Upsalquitch.

IV.—THE SAINT JOHN.

The calcareous clay slates apparently belonging to this series, cross the Saint John with a strike N. 5° E. below Butternut creek. They consist of alternating bands of slate and limestone, the latter varying from one half to four inches in thickness. About one mile above Florenceville, on the east side of the River, they appear on the line of strike, but in proceeding up the Shiktehawk Portage road for 3½ miles, a hard quartzose schist with a strike N. 35 E., is followed by a conglomerate containing black, blue, and red slate pebbles. This is thought to belong to the lower rocks, and thus to mark the southern limit of the Upper Silurian Series.

On many parts of the Saint John between this place and the Grand Falls, the ribboned calcareous slates make their appearance, with a prevailing strike varying from N. 30° to 35° E., and so they continue with occasional local variation of strike due to trap dykes or dislocations, all the way to within half a mile of the Grand Falls. Many of the narrow limestone bands in this distance appear suitable for the manufacture of Hydraulic Lime. At the Grand Falls the spectacle presented by these calcareous slates is singularly imposing, not only on account of the grandeur of the scenery but geologically, in view of the remarkable foldings in the strata which the great gorge reveals.

GEOLOGICAL FEATURES OF THE GRAND FALLS.

When the Saint John flowed at a higher level the course of the stream was in a nearly straight line from the upper to the lower Basin. This is marked by a deep ravine which runs with a slight curve nearly across the peninsula now formed by the semicircular channel pursued by the torrent in its course through the gorge. The distance from the upper to the lower Basin is half a mile in a straight line, and the difference in level 120 feet. But in making this descent the waters of the Saint John plunge perpendicularly 74 feet, and then rush and foam through a rocky channel a mile long with a descent of 46 feet before they reach the quiet basin below.

The walls of this chasm, which vary from 80 to 150 feet in altitude, are on an average 250 feet apart, but in many places much less; they present most beautiful illustrations of lateral pressure folding massive rocks as if they were the leaves of a book. The strike of the rocks varies from E. and W. to N. 40 E. The thick calcareous bands, with their associated bands of slate,

are twisted and contorted without perceptible fracture in the most striking manner. Numerous potholes of gigantic dimensions attest to the power of continually rolling stones confined within a limited space. This is well exemplified in a small whirlpool which has been locally designated the coffee-mill, into which sticks of timber are drawn at certain stages of water, and where never ceasing attrition soon rounds their extremities into hemispheres. During the time of my visit the water was 35 feet below the level to which stranded timber showed it rises during the freshets of spring.

The gorge is surrounded by a series of terraces four or five in number, which follow its sinuosities. The probable origin of these terraces, and of the present gorge, is discussed in Chapter X. The calcareous slates were not observed to present any other features worthy of special notice, beyond those already enumerated, but it is probable that an attentive study of their structure in this singularly favourable locality would reveal many interesting facts.

COUNTRY ABOVE THE GRAND FALLS.

Above the Grand Falls the country changes its character, particularly near the river banks, which are not only considerably lower, but show blue clay in horizontal layers. Above the mouth of the Siegas fine blue clay is seen to be overlaid by gravel and sand in banks 40 feet high, 30 of which are of clay.

Between the two Islands above the mouth of the Siegas, the ribboned calcareous slates similar to those at the Grand Falls were recognized with a strike N. 70° E. Half a mile below Saint Basil, the slates were of a dark blue colour with the same strike, and opposite Saint Basil there is a small area of beautiful ice polished rock, of similar character.

The Rocks of the Saint John from Little Falls to the Siegas, and from Little Falls to the Saint Francis, have been described by Sir W. Logan, under the heading, "Rocks of the Walloostook or Saint John River, and some of its tributaries." In the Chapter entitled "Distribution of the Gaspé Series,"* the following description will be found:—

"About half a mile down the Madawaska, where the rock comes close upon the river, the same grey greenish-weathering slate is seen, with thin light coloured slightly calcareous bands marking the bedding. The exposures on the river, all the way to Little Falls, at its junction with the Saint John, are not numerous. They consist pretty uniformly of the same slates and sandstones as before, the slates greatly predominating, and occasionally holding a small amount of calcareous matter. At Little Falls the color of the rock is grey internally, weathering generally to a dull obscure olive-green, sometimes so dark as to give it a chloritic aspect. The slate, which is micaceous, is interstratified with occasional hard compact bands, cleaving with difficulty, and possessed of sufficient grit to entitle them to the name of sandstones.

* Geology of Canada, page 426.

“Slates and sandstones, similar to those at Little Falls, are seen farther down on the Saint John near its tributary the Squesibish; where there is a transverse exposure of 200 or 300 yards. Here the slate internally grey, weathers greenish and is interstratified with bands of feebly calcareous sandstones, some of which are from four to twelve inches thick. The bedding is well displayed at this place, and a few contortions in the stratification are visible.

“Still lower down, and about a mile and a quarter above the mouth of another tributary, the Shiguash, a band of coarse conglomerate which crosses the road bears a strong resemblance to that of Black Point on Lake Temiscouata, and holds a great amount of large pebbles and small boulders of black limestone weathering to an ash grey. Some of the calcareous boulders are themselves of a conglomerate character, holding pebbles of a stratified rock, while their matrix includes organic remains. With the calcareous portions of this conglomerate band are mingled others of black jasper and of chalcedonic quartz, with these were observed several pebbles of a blackish green serpentine. The matrix is a hard calcareous sandstone, with grains of white and colored quartz; it is grey internally, and weathers to a yellowish tinge. Vertical beds of the conglomerate running N. 30° E. alternate with beds of sandstone similar in character to the matrix. A breadth of seventy five yards is visible, giving a thickness of 225 feet. As the strata above and below are concealed, the volume may be greater, particularly to the southeast, where the ground rises in a small hill for a quarter of a mile. At this distance the conglomerates are followed by calcareous slates, which at first are interstratified with a few bands of sandstone, resembling that associated with the conglomerate, but, farther on, display strongly calcareous beds, weathering to rotten stone.

“Sometimes the slates, without being themselves calcareous, are interstratified with slightly calcareous sandstones. These alternations are occasionally visible for about 500 yards, between which and the Shiguash, there are no exposures on the road. The examination in this vicinity has not been carried farther.

COUNTRY ABOVE LITTLE FALLS.

“Rocks similar to those of the lower part of the Madawaska and the Squesibish, prevail along the Saint John as far as the Saint Francis, and even to the Black River, twenty miles higher. Both the slates and the sandstones are in general micaceous, and occasionally calcareous. On the Saint Francis no traces have been found of Black Point conglomerates, or of the Jasper rocks of Pointe aux Trembles; nor have we been successful in meeting with the fossiliferous limestones of Mount Wissick, though the distance from Temiscouata is scarcely more than twenty two miles. The lowest exposure belonging to the Quebec Group on this river, consists of a coarse greenish chloritic sandstone, associated with green slates. It occurs just to the north of the Province line, at the foot of a lake called by the Indians Woilenabégeg; below this the country appears to consist chiefly of clay slate. The

most calcareous ridge met with, occurs about three miles above another lake, which is called by the Indians Battewichecageg. The rocks of this ridge, however, shew no fossils, and they do not hold a sufficient quantity of carbonate of lime as to entitle them to the name of limestones. A mountain on the northeast side of this lake displays some strong beds of sandstone, associated with bluish black or dark grey slates, both slightly micaceous, but the sandstones alone are somewhat calcareous. Similar micaceous sandstones sometimes holding a little carbonate of lime, prevail to the mouth of the lake.

“On the Black River, twenty miles above the Saint Francis, there occur the same grey micaceous slates and sandstones, occasionally calcareous. The sandstones weather greenish, and, where washed by the water, acquire a slightly reddish tinge. Large angular blocks of a calcareous conglomerate are occasionally met with; but the rock *in situ* does not occur below the Province line. Both below and half a mile above this line, calcareous slates occur, with black or dark grey coarse limestone bands; and half a mile above this there is seen a conglomerate, of which three exposures occur in a breadth of 300 yards. It holds boulders of a fine silicious conglomerate and of grey quartzite, with blackish vitreous quartz grains, and fragments of green slate. The matrix appears to be composed of this green rock in a comminuted state, with a fine grey slate.

“The fact that this conglomerate itself contains pebbles of an older conglomerate rock, resembling some portions of the Sillery series connects it with the conglomerates of Black Point on Lake Temiscouata, and with that near the Shiguash; which last encloses pebbles of serpentine. These characters suggest the probability that all these conglomerates may be newer than the Quebec Group, the sandstones of which were seen between three and four hundred yards farther up the Black River. They were examined for a distance of about a mile and a quarter, and resemble those of the Sillery series; being greenish, massive, and coarse grained with scales of mica and of graphite, and interstratified with occasional bands of red slate.”*

UPPER AND MIDDLE SILURIAN ROCKS ON THE BAY OF FUNDY.

There are not many localities on the Bay of Fundy where the presence of the Upper Silurian Series is not involved in some degree of doubt. It is, however, probable that the well known development of these rocks on and near the coast of Maine in Cutler, Pembroke, Trescoll, and Lubec, continues at intervals on the coast as far as Lepreau Harbour, and then striking inland, stretches in the form of a narrow inland belt, toward the County of Albert.

In some parts of their development in the Bay of Fundy they are overlaid by outlying patches of the Devonian Series, as at Saint Andrews and on the Mascaban Peninsula, but of their continuity for more than one hundred and twenty miles there appears much probability.

* Geology of Canada.

In the Mascaban Peninsula (Saint George) they are interstratified with traps, and much altered, but on some of the adjacent Islands the limestones belonging to the series are fossiliferous. The trappean series is largely developed westward, in Maine, and it points to a succession of volcanic disturbances alternating with periods of repose, which must have continued through long ages with remarkable uniformity. These rocks are supposed to be the equivalents of the Arisaig Series of Dr. Dawson in Nova Scotia, or the Lower Helderberg of the New York Survey.

The Upper or Middle Silurian rocks on the Bay of Fundy, particularly those which may be styled the Trappean Series, appear highly promising in a metalliferous aspect. In Maine, on the New Brunswick Frontier, they are stated now to yield remunerative returns of lead where mines have been opened; and on the Island of Campo Bello, which is of the same geological age, there appear to be some valuable indications of the same mineral. On Frye's Island, which will be noticed more at length in the sequel, lead ores occur in two places. On the Mascaban peninsula, also called Saint George's peninsula, but better known by the name Letite, copper ores are abundant, so that a special notice of the Letite Mines will not be considered out of place, as it is not improbable that what is there supposed to be a copper-bearing trap, has a wider distribution than is generally imagined by those who have interested themselves in copper mining on the peninsula, and in its neighbourhood.

The name of the mine which will now be described, is the Wheal Louisiana, and as the study of the manner in which the metalliferous lodes are distributed, may serve as a sort of guide to other and similar enterprises, for which there is abundant room and apparently encouraging prospects, more details will be introduced here than would otherwise be considered to lie within the limits of a preliminary Report.

WHEAL LOUISIANA—LETITE.

General Geological Features.

The whole of the Mascaban Peninsula appears to have been subjected to a series of intermittent disturbances, which have not only changed in some degree the relative original position of sedimentary strata but have also altered their character. These disturbances are of a three-fold description, each of which will require a special notice on account of its bearings upon the metalliferous deposits which are largely distributed in a more or less concentrated form throughout the peninsula and neighbouring islands.

The mineral composition and sedimentary nature of the rocks establish the fact, that successive periods of repose were each succeeded by violent volcanic action at some distance from the strata under review. These consist of alternations of stratified talcose, chloritic, and clay slates, and bedded traps or greenstones. Intrusive diorites also occur in this neighbourhood, but while the bedded traps alternate with the clay-slates, the intrusive traps cut them at a low angle, but these intrusions, which are few in number, do

not appear to have exerted here much influence upon the rocks of the peninsula. Some idea of the uniformity with which the periods of disturbance and comparative repose took place, may be inferred from the following section across the strata within a space not exceeding a mile in horizontal distance. It was roughly measured along the road and obliquely to the stratification. This section is given at length in order to point out another set of disturbances which are important in their bearings upon the disposition of the mineral veins found in this neighbourhood, and the mode in which they were filled, wholly or in part.

Section roughly measured along the road to the Wheel Louisiana.

Kind of Rock.	Breadth.		Remarks.

HORNBLENDIC ROCK,	23 "	"	
Slates,	31 "	Dip Southwest.	
Slates and Trap bands } interstratified,	40 "	"	

Here we find, in a distance of about 1,300 yards, some fifteen alternations of slates and Trap,* with at least four anticlinal axes. It is probable that an exact survey would discover more alternations and perhaps more foldings; but the foregoing rough section is sufficiently near the truth to show

* Compare with Cape Bon Ami, near Dalhousie.

the extraordinary disturbances to which the rocks on this part of the coast have been subjected.

MINERAL CHARACTERS OF THE STRATA.

The slates vary much in their composition, they are generally laminated, with even fracture, but they are also frequently conglomerate and porphyritic, holding pebbles and fragments of trap, and sometimes they appear to consist of consolidated volcanic ash, and they are also occasionally talcose, chloritic, and magnesian. Vast beds of hornblendic schist also occur in the series, and in one of these the main lode of the Wheal Louisiana is in part situated.

This Hornblendic Schist presents itself in several different but closely allied forms. Sometimes it appears in one and the same belt as almost entirely composed of hornblende, then of hornblende and quartz, and again of hornblende crystals in a felspar paste, (Diorite,) the felspar weathering white and the hornblende standing out in large greenish black crystals. A considerable quantity of copper ore, and also specks of native copper, are diffused throughout the schist, and this rock may be a valuable source of the copper ore accumulated in the veins which intersect the series. The Diorites or greenstones of Lake Huron afford in abundance the ores of copper, and analysis shows the diffusion throughout the rock of the metals which are accumulated in the veins.* In and near the fissure to which allusion will soon be made, a thin bed of Actinolite occurs.

As will be observed from the foregoing section, the strike of the slates is not uniform, but there is a prevailing strike of about N. 70° E., which may be accepted as the general strike of the series, and this is also the strike of the rocks on Frye's Islands where the disturbances have not been so great.

Fractures and Dislocations.

At Wheal Louisiana the rocks have been upheaved and an anticlinal axis produced. A crack runs along the crown of the anticlinal, and taking a general course N. 55 E. it passes out of the Hornblendic Schist into the adjacent slates and traps, pursuing a slightly meandering course. A downfall or dislocation has taken place along the west side of this crack and thus produced a permanent fissure which is the seat of the main Lode of the Mine.

This fissure can be traced without any difficulty for some hundreds of yards southwesterly beyond the property of the Company. In Key's shaft, which intersects it, it is seen at the extremity of the first level 84 feet below the surface to form an open crack some fifteen feet high by two feet wide. It is also seen at the lower level 125 feet deep, where the part unoccupied by the lode is several inches in diameter. It is worthy of note that the fissure here is in the chloritic and talcose slates, having apparently passed out of the Hornblendic Schist, and, as it has been suggested that this

* Geology of Canada, page 595.

Schist is *one* of the sources of the Copper ores, it may prove to be a rule here that as long as the fissure is found in the Hornblendic Schist it will be productive, when it passes into the slates it may contain cavities which have never been filled with a metalliferous gangue. This fissure has evidently resulted from the following causes:—1st. The upheaval of the strata and the occurrence of a crack along the crown of the arch produced by the upheaval.

2nd. The downfall of the west half of the arched and fractured strata through many feet of space.

3rd. The walls of the fractured strata not coinciding after the downfall, produced a fissure of greater or less capacity in different parts of its horizontal and vertical extension, and of great depth.

The fissure has been partly or altogether filled with materials derived from the rocks in which it occurs. Some of its cavities, those in the hornblendic schist, have already been found full of copper ore, other cavities are lined with quartz crystals, carbonate of lime, bitter spar, and amorphous steatitic layers, also in places they are spangled over with crystals of sulphuret of copper, but still preserve a vacant space in which no metalliferous gangue has yet been deposited. The vein, where the fissure is filled, consists of quartz, calc and bitter spar, the quartz predominating; with patches of chlorite and aggregations of copper ore mixed with mundic and magnetic iron pyrites.

The surfaces of the rock coming together during the downfall are slickensided, and fragments of the mother rock or country are found embodied in the gangue. Small patches of native copper are sometimes seen to adhere strongly to the wall after the lode has been removed. This, however, has only been seen in the Hornblendic Schist, the lode coming from the smooth wall of the fissure in the rock with a clean surface. The subordinate transverse fissures, common under such circumstances, were also recognized, and these, so far as they occur in the Hornblendic Schist, may be productive of ore.

THE MINE.

Key's Shaft.

Key's Shaft has already been sunk to a depth of 125 feet. The upper level is 84 feet below the surface, and has been driven 47 feet in an easterly direction (E. 7° N.) In this level part of the fissure which carries the main lode is struck and is distinctly visible, forming the crack already described, some fifteen feet high, and from two to three wide. The lower levels have been driven at a depth of 125 feet, 43 feet in an easterly direction (E. 7° N.), and 36 feet on a southwesterly course—(W. 28° S. for 24 feet, and W. 22° S. for 12 feet). A jog throwing the lode six feet to the north here occurs, this may arise from unevenness in the line of fracture, the crack passing into a softer rock, or from some other cause changing slightly its course. The east wall of the lode in the western drift is trap, it soon, however, passes into the chloritic slate which presents slickensided surfaces

with patches of chlorite. It is also worthy of note that the crack seems to have had a westerly slope for 84 feet, then it becomes vertical and so continues to the bottom of the shaft. The character of the gangue in the upper level differs in some slight but important particulars from the gangue in the lower drift. The quartz in the upper level for instance is very hard, in the lower level it becomes more friable and easily worked. The mundic (iron pyrites) increases in quantity on descending; chloritic slates with patches of chlorite are more confirmed in the lower levels, and the general aspect of the lode acquires a promising metalliferous character. Magnetic pyrites (pyrrhotine) occurs in abundance both in the upper and lower levels. Copper ore (pyrites) has not been found in large quantity in Key's Shaft, but from the improving character of the lode and the conditions under which it has been deposited, it is very probable that on sinking deeper the ore will be found to increase in quantity. It would be advisable to ascertain the precise position of the shaft with reference to the Hornblendic Schist. If it should be found that on sinking deeper on the line of the fissure, it approaches this rock, the prospects from this shaft will be still more favourable. The great obstacle to encounter will be water, and in order to drain this shaft, if deepened to 300 feet or more, a ten horse power steam engine will be required.

The Windlass Shaft.

This shaft which has not been sunk more than 16 or 18 feet, is situated directly on the crack as it appears at the surface. The crack here is wholly within the Hornblendic Schist, through which the copper, as already stated, appears to be more or less disseminated. Thin radiating leaves of native copper appear on the wall of the lode, and minute particles can be detected in the Hornblendic Schist itself. The crack here has a northwesterly dip, but it appears to leave this rock and pass into the slates and trap towards Key's Shaft, on approaching which the slates are much curved with a southerly dip, but when they arrive within 60 yards northwest of it, they dip northward.

Several barrels of excellent copper ore were taken out of the Windlass Shaft, which is at present nothing more than the lode removed from the crack. By following the course of this lode, which is the course of the crack both vertically and horizontally, it is probable that valuable "pockets," similar to the one already found, will be reached.

SUBORDINATE LODES.

Crossing the fissure at different angles there are numerous subordinate lodes holding more or less copper ore, but it has not yet been determined which are the older, nor is it known whether some of the lodes may not occupy transverse fractures. Of these lodes, six in number appear to cross the fissure within about 160 yards north of the main or Key's shaft. In consequence, however, of the slight meanderings to which they are subjected, it is impossible to state with any degree of precision the points of intersec-

tion, until an exact topographical survey of this area is made, and the courses of the quartzose lodes as they appear on the surface laid down correctly. It will be seen that where these lodes intersect the crack and line of dislocation, valuable deposits of copper ore may be looked for, and it is also apparent, on the supposition that the Hornblendic Schist carries the ore, that where the lodes intersect that rock they will be found to be rich in the metal.

FRYE'S ISLAND.

Frye's Island (called on the Admiralty Chart Cailiff Island) lying south-east of Mascaban Peninsula, is remarkably interesting in its geological aspect. Some of its limestones and grits on the eastern side are fossiliferous, containing *Favosites gothlandica*, &c. On the western side the limestone is crystalline. The lead veins have not yet been sufficiently explored or opened to enable an opinion to be expressed on their probable productiveness, but the minerals with which they are associated, fluor spar and sulphate of Baryta, the fine ochres on the walls of a trap dyke, the singular mode in which masses of quartz have accumulated over the smooth denuded surface of the limestone itself, and the fossiliferous character of some portions of the belt, all invest this Island with peculiar interest. It is a matter of regret that certain fossils which were collected there, together with specimens of the rocks, have not yet been forwarded.

Passing nearly through the centre of the narrow part of the Island there is a very peculiar Diorite, apparently running with the strike of the rock, but differing from any observed on Mascaban Peninsula. The interest of this locality is not diminished by what were supposed to be (at a distance) outliers of Red Devonian rocks, forming Bliss Island, also a small patch of the same red rock resting unconformably upon those of Frye's Island.

The absence of the specimens alluded to in a previous paragraph, militates against the use of copious notes taken during a day's ramble over the Island at the close of last October, the more particularly as the discovery of certain fossils creates a suspicion that the age of the rocks on Frye's Island may belong to the Middle rather than the Upper Silurian.

SULPHATE OF BARYTA.

The heavy spar or sulphate of baryta on Frye's Island is likely to become commercially valuable, the facilities for obtaining the material and for exportation being unusually good.

This mineral is extensively employed in the arts as a paint, both by itself and for mixing with other pigments as an adulteration, for which purpose it is fitted by its great weight. It enters into the composition of the cheaper kinds of white lead paint; sometimes, it is said, to the extent of seventy five or eighty per cent. For this purpose the native sulphate of baryta is crushed, and if necessary, boiled with dilute muriatic or sulphuric acid to remove any metallic oxide which may discolor it, after which, it is ground to a fine powder; an artificial sulphate of baryta is also manufactured by precipitation, and is sold under the name of 'permanent white' or 'blanc fixe.'

This is prepared from the native sulphate by igniting it with charcoal, by which a sulphuret of barium is formed; this, by the addition of muriatic acid, is converted into chloride of barium, from which the sulphate is precipitated by sulphuric acid, the pigment thus obtained is much finer than that prepared by simply grinding the mineral. It is used as a water color, and also in the manufacture of paper hangings, for giving a peculiar glossy surface. In 1861, about two tons a week of the precipitated sulphate of baryta were prepared by this process in South Lancashire. The consumption of the ground sulphate of baryta is very considerable. Many years since, about 4,000 tons of the mineral were sold annually in the United States, of which 1,500 tons were imported from England, and the remainder obtained from various parts of the country.*

L'ETANG LIMESTONE.

The limestone at L'Etang appears to be remarkably pure. After burning 100 parts yield 54.30 parts of quicklime.† When it is considered that 100 parts of pure carbonate of lime yield 56.4 of lime and 43.6 of carbonic acid, (Berzelius) the purity of the L'Etang lime is worthy of note, but it should be borne in mind that the analysis was only for practical purposes, and must not be regarded as chemically correct. On page 66 a Table of analyses of certain limestones is given, from which an idea of its purity when compared with other limestones in the Province may be obtained.

* Prof. Hunt, in 'Geology of Canada.'

† From a Comparative Table in "Geology of Maine," 1861.

CHAPTER VIII.

THE LOWER SILURIAN SERIES—THE QUEBEC GROUP.

The Metalliferous Rocks in Canada and the United States—Sir W. E. Logan's discoveries—THE QUEBEC GROUP—Importance of the Quebec Group—Economic Minerals of the Group—Age of the Group—How brought to the surface—Origin of the Metals it contains—The Quebec Group in NEW BRUNSWICK—Its Northern Boundary—Its prolongation into MAINE—Probable Breadth of the Quebec Group in New Brunswick—Influence of the Granitic Belts on these Rocks—Its development on the Nipisiguit—Black Slates on the Nipisiguit and near Dumbarton Station—Copper Ore at the Grand Falls—Golden-hued Micaceous Schists—Feebly Auriferous Copper Ores on the Nipisiguit—Red Shales, with Iron and Manganese and Copper Ores, on the Nipisiguit—On the Campbell River—The Beccaguimic—The Shiktehawk—At Jacksontown, west of the Saint John—Near Boiestown—On the Tattagouche—Folds of the Strata on Campbell River—Probable limit of the Group about the Nictor—Upper Silurian Slates on the Nictor or Little Tobique—Jaspersy Rocks on Campbell River—Red and Green Porphyries on the Serpentine—Ores of Metals on Campbell River—Iron, Manganese, Nickel, Copper, &c.—Diorites—Epidote—GEOGRAPHICAL DESCRIPTION of the Country south of Tobique Lake—Milpagos Lake—Gulquac Lake—Granite Ridges—Beaver Dams—Long Lake—Milnagec Lake—Portage to the Little South West Miramichi Lake—Miramichi Lake, (Little South West)—Granite Boulders—The Magaguadavic to Roix Station—Upper Falls of the Magaguadavic to the Lower Falls—Characteristic Strata belonging to the Quebec Group—GNEISS; ANORTHO-SITES; DIORITES; EPIDOSITES; MICA ROCK; MICA SCHISTS; ARGILLITES; DIAL-LAGE ROCK; HORNBLLENDE ROCK, with GARNETS; MAGNETIC IRON IN DOLORITE; COPPER PYRITES; OPHIOLITES, (Serpentines); STEATITES; CHLORITES; MAG- NESITES; DOLOMITES; LIMESTONES; DEPOSITS of SILICA.

In Canada and in various States of the Union there have been discovered, from time to time, sedimentary rocks exceedingly rich in metalliferous wealth. The shores and islands of Lake Superior, and the northern shores of Lake Huron, have long been remarkable for their enormous deposits of copper.* The immense aggregations of ores of the same metal in Eastern Tennessee, and in Lower Canada, † are contained in rocks of the same geo-

* In 1861 the mines of Lake Superior yielded 7,500 tons of metal, being about twelve times greater than in 1851.

† Notwithstanding the enormous deposits of copper in many parts of Canada, it is only very recently that attention has been directed to this branch of mineral wealth. The following Table shows the Export of Ores and Copper from Canada since 1850 :—

Year.	Ores, Tons.	Copper, Tons.	Official Value.
1850,	272	62.44	\$36,583
1851,	1,349	122.80	86,756
1852,	598	24.92	32,420

logical age, though known by different names. The vast lead deposits of Missouri,* associated with zinc, cobalt, nickel and copper, have long been known to belong to the most ancient sedimentary rocks; and from similar deposits the gold of the Appalachian range, from Virginia to Georgia, has been originally derived, as well as in Nova Scotia.

Sir William Logan was the first to show, in 1860, that all these different metal bearing rocks, some of which are more than a thousand miles apart, belonged to one and the same formation; and because this formation was well developed near Quebec, and first studied and understood there, Sir William named it the "Quebec Group."

THE QUEBEC GROUP.

Not only is the "Quebec Group"† the great metalliferous formation of North America, but its remarkable thickness and complexity, (7000 feet, or one mile and a third) coupled with the extraordinary manner in which it was deposited and brought to the surface, all unite to make it one of the most interesting and important formations of the entire geological series, with, perhaps, the single exception of the coal measures.

Its iron, copper, nickel, cobalt, antimony, lead, zinc, chromium, arsenic, titanium, silver and gold, which are all known to exist in remunerative quantities in this vast rock series, give it a special value which no other possesses, a value greatly increased by the association with these ores of metals, of serpentines,‡ roofing slates, soapstones, potstones,§ whetstones, magnesites,|| dolomites and building stones.

This great formation stretches from Gaspé to Alabama, then sweeps round through Kansas to Lake Superior where it reappears without any diminution of volume. Its age is that of the Chazy, Calciferous, and part of the Potsdam formations of the New York Survey, and it occupies a position near the base of the Lower Silurian System.

Table of Copper Exports continued.

Year.	Ores, Tons.	Copper, Tons.	Official Value.
1853,	1,639	61.60	94,325
1854,	1,731	—	103,328
1855,	1,708	1.96	91,627
1856,	1,106	—	82,834
1857,	2,869	3.36	240,942
1858,	2,158	2.24	191,949
1859,	3,403	61.	340,686
1860,	6,095	16.	465,525
1861,	7,364	18.	440,130

* In 1860 Missouri produced 4,164 tons of ore, valued at \$356,660.

† The Taconic System of Emmons appears to consist of the Potsdam and Quebec Groups.

‡ A rock composed of silica or flint and magnesia, (silica, 43.6, magnesia, 43.4, water, 13.0,) soft enough to be scratched with a knife; colour, generally different shades of green. The Serpentines of the Quebec Group almost always contain oxides of nickel and chrome.

§ A dark or grey-green impure talc with an unctuous feel. || Carbonate of magnesia.

It has been brought to the surface in the United States, Canada, New Brunswick, Nova Scotia, and Newfoundland, by a series of undulations, or parallel folds, originating probably from lateral pressure coming in a southeasterly direction, similar to that which has given rise to the Appalachian chain of mountains, (See Chapter II.) These folds have broken through the upper crust, and exposed the surface of the Quebec Group.* To the southeast of the great fault (upthrow) in Canada, &c. which brought the Quebec Group to the surface, there is no evidence of Lower Silurian strata higher than those belonging to this group.† The same may be said of New Brunswick, as far as is known of its rock formations.

ORIGIN OF THE METALS OF THE QUEBEC GROUP.

‡ “The metals of the Quebec Group seem to have been originally brought to the surface in watery solution, from which we conceive them to have been separated by the reducing agency of organic matter in the form of sulphurets, or in the native state, and mingled with the contemporaneous sediments, where they occur in beds, in disseminated grains forming *fahlbands*, or as at Acton, are the cementing material of conglomerates. During the subsequent metamorphism of the strata these metallic matters being taken into solution by alkaline carbonates or sulphurets, have been redeposited in fissures in the metalliferous strata, forming veins, or ascending to higher beds, have given rise to metalliferous veins in strata not themselves metalliferous. Such we conceive to be in a few words the theory of metallic deposits; they belong to a period when the primal sediments were yet impregnated with metallic compounds which were soluble in the permeating waters. The metals of the sedimentary rocks are now however for the greater part in the form of insoluble sulphurets, so that we have only traces of them in a few mineral springs, which serve to show the agencies once at work in the sediments and waters of the earth’s crust. The present occurrence of these metals in waters which are alkaline from the presence of carbonate of soda, is as we have elsewhere pointed out, of great significance when taken in connection with the metalliferous character of certain dolomites, which as we have shown, probably owe their origin to the action of similar alkaline springs upon basins of sea water.

“The intervention of intense heat, sublimation and similar hypotheses to explain the origin of metallic ores, we conceive to be uncalled for. The solvent powers of solutions of alkaline carbonates, chlorids and sulphurets at elevated temperatures, taken in connection with the notions above enunciated, and with De Senarmont’s and Daubrée’s beautiful experiments on the crystallization of certain mineral species in the moist way, will suffice to form the basis of a satisfactory theory of metallic deposits.”

* For a description of the phenomena attending the formation of and subsequent foldings and bringing to the surface of the Quebec Group, the reader is referred to the “Geology of Canada,” pages 296 and 233.

† Prof. Hunt—On some points in American Geology. ‡ Ibid.

THE QUEBEC GROUP IN NEW BRUNSWICK.

The supposed northern boundary of this formation within the limits of the Province, commences near the Medisco River on the Bay Chaleurs. The strike of the rocks would carry them to Ramsay's Brook on the Upsalquitch, and thence towards the head waters of the Tobique to the north of Nictau Lake.

A few miles from the mouth of the Tobique there are a series of silicious slates which appear to underlie unconformably a series of Upper Silurian argillites, green, red, and blue-black, and holding *Favosites gothlandica*. The strike of these silicious slates would carry them to the north of Nictau Lake, and this line prolonged in a southwesterly direction is supposed to form a rude but continuous curve, (see p. 127, Chap. VII.) which may provisionally represent the northern boundary of the Quebec Group, which has been brought to the surface simultaneously with the granite axis of Devonian age described in Chapter II.

The continuation of this boundary takes a southerly course and is supposed to cross the Shiktehawk about $3\frac{1}{2}$ miles from its mouth, where a conglomerate occurs, described in Chapter VI. It crosses the Saint John below Presquile, and taking a southwesterly course it enters the State of Maine near the forks of the Meduxnekeag, pursuing its course towards the Atlantic Ocean on the north flank of the granitic axis, where it is represented on Mr. C. H. Hitchcock's Map of Maine as a belt of mica schist. On the south east side of this axis the Quebec Group is again brought to the surface, its eastern boundary being in great measure covered up by the Bonaventure formation or base of the carboniferous series, which in many places reposes upon it horizontally or nearly so. Until further investigations establish the contrary, all the sedimentary rocks, with the exception of the carboniferous, north of the granitic axis which comes in from the State of Maine at Saint Stephens, and proceeds in an easterly direction through Queen's County to and beyond the Saint John, may be considered as belonging to this group, although it is not improbable that there is a narrow belt of middle silurian rocks, on the northeast flank of the carboniferous series a few miles due west of Fredericton. The rocks on the north side of this last named axis, described by Hitchcock as mica schist, in its prolongation through Maine to the Atlantic Ocean, most probably belong to the Quebec Group.

The breadth of this group of rocks measured at right angles to the strike within the limits of the boundaries just described, will be approximately as follows, after deducting the granite axis:—

1. Five miles from Bathurst,	20 miles.
2. From Ramsay's Brook, southeasterly,	36 "
3. From near the Nictau	"	44 "
4. From the Tobique,	"	43 "
5. From the Maduxnekeag,	"	38 "
6. On the New Brunswick and Canada R. R.,	25 "

It has been already stated that this granite axis (Chap. II.) is really composed of numerous narrow belts, which come up between the schists of the Quebec Group, also that it has a much more northerly extension than represented by Dr. Gesner. On the South West Miramichi, there are no less than ten distinctly parallel granite belts, with belts of slate and schist between them. It is clear that this arrangement of the granite and slates may exercise a very important influence upon the rocks now under review, as it not only extends the area over which they may be found, but the metamorphic action exhibited by the granite may have effected a material change in the composition and crystalline arrangement of some of the strata.

THE QUEBEC GROUP ON THE NIPISIGUIT.

The rocks of this Group on the Nipisiguit have undergone more or less metamorphism. Between the Upsalquitch and Nipisiguit, they occur in the form of highly laminated talcose and micaceous schists, splitting easily into thin leaves on weathered surfaces; they are unctuous, ferruginous, some layers abounding in yellow mica, other chloritic, and others presenting a rich golden colour (micaceous,) when freshly broken. They are interpenetrated with quartz veins, and show also bunches of quartz. The same schist occurs just below the Devil's Elbow on the Nipisiguit, and appears at intervals more or less talcose and chloritic, from the 59th to the 47th mile from the mouth of the river. Green schists are seen near the mouth of 44 mile creek, and are succeeded by beautiful purple-red slates, supposed to derive their colour from manganese and iron ore, which are here associated together in the same manner as at Jacksontown, near Woodstock, and on the Tattagouche, where also copper ores occur. The pale sea green slates which come into place above and below nine mile brook are extremely beautiful, and superior in most particulars to the beautiful argillites of Upper Silurian age near the mouth of the Tobique.

Six miles further down the stream red slates appear in the form of mural precipices. These have the same strike as the purple-red slates just described. About a mile and a half above the Grand Falls, near an island, there is a narrow belt of intensely black slates, which present a slightly corrugated surface when split with the cleavage planes; these black slates resemble in every particular similar black slates, described further on, seen near the Dumbarton Station of the New Brunswick and Canada Railroad. The last named position of these slates shows them to be on the southeast side of the granite axis, although they have a northerly dip. The occurrence of these black slates at points so remote from one another (150 miles) is valuable, as affording additional proof to others which will be mentioned in the sequel, that these rocks of the Quebec Group are persistent throughout the breadth of the Province.

The black slates are succeeded by a highly silicious rock, which at the Grand Falls was seen to contain specks of sulphuret of copper, and to be of a more slaty character. The slates just below the Falls are porphyritic, but

a cursory examination failed to detect in them any traces of copper. The anticlinal folds are very numerous down the whole extent of the River, until the granite appears in place.

Below the Falls, and close to the first Salmon Pool there is a belt of glistening talcose-micaceous schist, with an easterly dip (50°), which, when fresh surfaces are exposed and wetted, is of a brilliant and lustrous golden color, glistening in the sunlight with various hues, many of which are the rainbow colors produced by the decomposition of light. The rock is very beautiful, but extremely fragile. It is noticed here, because a rock possessing precisely similar characteristics occurs on the road between Fredericton and Woodstock, near Sullivan's Creek, with an easterly dip. At the Grand Falls, on the Nipisiguit, this rock occurs on the southeast side of the axis, as far as it is known there; on the Saint John it is found on the northwest side.

Four miles above Pabineau Falls sulphuret of copper mixed with iron pyrites is found in green slates, which appear to be a repetition of those already described. This ore at the surface is feebly auriferous. Some specimens have yielded a trace of gold.

The fissile micaceous schist described as occurring on the portage between the Upsalquitch and Nipisiguit, and for some miles down that River, appears again in Millpagos Lake, a beautiful sheet of water not shewn on the Provincial Map, situated at the head of the Gulquac River, about a mile due south of Gulquac Lake, which is also about a mile due south of Tobique or Trowser's Lake. In this remote Lake, which lies at the northern base of the same granitic ridge separating Long Lake from Little S. W. Miramichi Lake, the micaceous schist has a strike S. 70° E., dip W.

There still remains one more well marked rock on the Nipisiguit, which has been traced even with greater persistency than the black slates, the golden hued talcose-micaceous schists, or the fissile grey micaceous schists. This is the red slate with its bands of iron and manganese ores. On the Nipisiguit, red slates, similar to those which are found near Woodstock, are seen a little above Nine Mile Brook, about 31 miles from the mouth of the River. The River runs in the strike of the rock here, and the purple-red slates which occur five miles higher up the stream, are repetitions of the red slates, more deeply colored with manganese than iron. Indeed, it may be said that for a distance of six miles the River appears to flow on or close to the belt of red slates, with their iron and manganese ores. Ferruginous rocks, similar to these red slates were seen on the Quaquabs or Campbell River where they are much metamorphosed, but it is on the Beccaguimic, the Shiktehawk, and at Jacksontown that they occur in force. Those at Jacksontown are already well known, but those on the Beccaguimic and Shiktehawk have not yet been described. They are found in two broad belts, about a mile apart, and loaded with iron ores on the Beccaguimic. A more particular description will be given when noticing the Jacksontown, (Woodstock) iron ores. These slates again occur on the south side of the axis, within 10 miles of Boiestown.

The Tattagouche Rocks are probably repetitions of the same strata; they contain copper in addition to iron and manganese, but copper also occurs in Diorite within a few miles of Woodstock, belonging to the same series, and opened some years since by Mr. Stephens.

THE QUEBEC GROUP ON THE CAMPBELL AND SERPENTINE RIVERS.

Green porphyritic slates on Campbell River, resembling those of the Nipisiguit, are underlaid by quartzite; the same was observed on the Miramichi. About seven miles below the Tobique Lake, near a precipice 70 feet high, called Bull's Eye Rock, true gneiss was observed with the strike S. 60° E., it was followed by green ferruginous slate, which was again succeeded by a highly quartzose rock, by green porphyritic slates and by red slates. Many of the strata on this river so closely resembling those of Nipisiguit and Miramichi, leave scarcely any room for doubt that they all belong to the same series. The foldings of the rocks on Campbell River, near its junction with the Serpentine, are very striking. They are seen to form grand curves in the high banks of the river, which exceed 200 feet. The tops of these curves have been removed by denudation, probably glacial action, but the fine sweep of the strata can by a slight effort of the imagination be continued for more than a mile down the river, which exposes a beautiful section. A conglomerate similar to that seen on the Shiktehawk and on the Upsalquitch, is distributed in masses in the bed of the river about two miles above the junction of the Serpentine and Campbell River. This fact coupled with the occurrence of Banded slates, about a mile from the Nictor, similar to those seen on the Saint John, and which are supposed to belong to the Upper Silurian Series, creates the suspicion that the limit of the Quebec Group in this vicinity may be a short distance to the northwest of the Tobique, below the Nictor or Forks. The Diorites which occur between the Forks and Blue Mountain Brook, are supposed to be for the most part altered sedimentary deposits belonging to the Quebec Group. An exploration for a few miles up the Little Tobique River, rather tended to confirm this view, the slates there being calcareous, ferruginous, and banded like some of the Upper Silurian Slates seen on the Saint John. Hence the limit of this formation is provisionally shown on the map as indicated above.

About two miles above the mouth of Campbell River, on the left side of the river, there is a red jaspery rock with slaty cleavage, which may come on the river higher up in several places, as boulders both of the red and green variety were noticed in the stream, but the rock was hidden from view by drift. On the Serpentine, (right hand branch of the Tobique), below the Forks, there are excellent roofing slates; and at the Falls an exceedingly tough, green and red porphyry, whose surfaces, when ice polished, are remarkably beautiful.

The mountains of this part of the Serpentine are high, and the banks precipitous, sometimes appearing as bold precipices three or four hundred feet above the water level. The sands of this river are auriferous, but the

particles of gold are very fine and the sand itself occurs in very small quantity. This river, however, as well as the Campbell, and the country between it and Blue Mountain, and northeast of Long Lake is exceedingly interesting and promising. Traces of copper were seen on Campbell River in trap, as well as iron, manganese, copper, antimony and nickel. It is not improbable that the iron and manganese may be associated with the red jaspery rock, which was thought to be metamorphosed red slate; the antimony and nickel, probably belong to a lower rock of the series, whose representative is found at the Prince William Antimony Mines, and on the other side of the granitic axis, a few miles north of Woodstock, where I was shown specimens both of antimony and manganese which were stated to have been obtained in the neighbourhood, but the finder, as I was informed, refused to name the locality until he had secured the land.

Throughout the whole of this region great beds and probably intrusive masses of Diorite are common. Some of these contain seams of green coloured epidote which have been mistaken for copper. In one locality above Blue Mountain on the Tobique, there are several traces of "prospecting" operations, which the Indians told me were undertaken some years since by persons from Saint John who expected to find "a copper mine." The Diorites in this neighbourhood contain traces of copper, but the operations seem to have been directed towards the veins of epidote.

Before glancing at the rocks on the section between the Tobique and the little South West Miramichi, it will be necessary to give a brief geographical description of a portion of the country which has not been surveyed or laid down on the Provincial Map. This area is situated south and southeast of the Tobique Lake and Long Lake.

GEOGRAPHICAL DESCRIPTION.

Milpagos Lake.

At the southern extremity of Tobique Lake there is a low portage, about one mile and a half long, leading into Milpagos Lake. This ridge is not more than 80 feet in altitude, and the course of the portage is S. S. W. A narrow stream flows from Milpagos Lake into Tobique Lake. The meaning of the word Milpagos is "a lake with many arms," an expression which scarcely characterizes this sheet of water. Its greatest breadth is not more than 300 yards, and its length is about a mile. At its southwestern extremity it receives a small tributary which flows through a lake a mile farther south, and is the true source of the right hand branch of the Tobique River. The dividing ridge south of Milpagos Lake is probably continuous with the ridge separating Long Lake from Little South West Miramichi Lake, and the Gulquac Lake from streams flowing into the Miramichi. The hills on the east side are from 300 to 400 feet above the lake, which at its upper extremity is very shallow and fringed with a broad belt of rushes, the breeding places of numerous families of ducks, and still the abode of many beaver. A greenish-grey chloritic and micaceous schist, with a strike S. 70° E. and

dip W. at a high angle, forms a narrow ridge in this Lake. It resembles in some particulars the schist on the Upsalquitch Portage. The mountains in view are all in the form of long, low, narrow domes.

Gulquac Lake.

The portage to Gulquac Lake commences in the first open expanse of Milpagos Lake, and pursues a W. N. W. course for not more than one third of a mile, leading into a fine open sheet of water, three quarters of a mile long by half a mile broad, surrounded by a low swampy tamarac and spruce country. The pitcher plant was observed growing luxuriantly in the deep moss fringing this part of Gulquac Lake. A narrow portage, about 200 yards broad, leads into the main portion of Gulquac Lake, which is about two miles long and three quarters of a mile broad, on a due south course. The hills on the west side are from 250 to 300 feet high; on the east side the country is low.

From the number of granite boulders not much worn in the middle and towards the upper extremity of Gulquac Lake, it appears probable that ridges in this vicinity are composed of this rock. The Lake terminates in an extensive marsh lying at the base of the dividing ridge before mentioned. Its outlet leading into Gulquac River, is situated at the southwest extremity, and is closed by a beaver dam seventy yards long, 16 inches high on the Lake side, and two feet six inches on the River side; the waters of this Lake find their outlet during the summer months through the interstices at the upper portion of the dam, in the spring and fall they flow over it. The dam must be very old, as alders three inches in diameter have grown all across it, and their roots have no doubt added to its stability. It is composed of spruce branches, trunks of small trees, mud and stones; a fringe of stones from one inch to six inches in diameter being deposited on the Lake side. The dam is 2 feet broad at the top, 4 feet at the Lake surface, and six feet broad at the River surface. One part of the dam was strengthened with a large pine tree, which had evidently been blown into the Lake, and floated to its place by the beavers. The roots and branches were gnawed off close to the trunk, the marks of the teeth being clearly visible. The length of the tree was 33 feet, its diameter at the butt 20 inches, at the other extremity 12 inches.

Some of the houses were of large dimensions, the height of one being 10 feet, and breadth 16 feet. Two entrances were noticed under the water, and two covered up entrances 3 feet above the present water level, also two at the present level of the water. Near the house was a large heap of freshly cut willow branches, the commencement of their winter store of food, and at some little distance on the marshy ground the remains of last winter's store were visible. During the afternoon some of the beaver were seen feeding in the Lake, diving down among the water lilies, and bringing up portions of the roots. One was shot in the act of feeding in the deep water of the Lake, holding the water lily root between his four paws, and keeping his

body in an upright position with his broad webbed hind feet. Several other beaver dams and houses were seen during this exploration, but none in which the wonderful instinct of this little animal was manifested in so marked a degree as in Gulquac Lake.

It was observed that the canoe might steal towards a beaver to within 30 or 40 yards, when feeding in the Lake, provided the approach were made in perfect silence, even though the animal was advancing at the same time. But the least noise, even the click of the trigger, was sufficient to cause them to dive instantly. The Indians with me remarked, that although the hearing of the beaver is perfect, his eyesight is very deficient, an observation which former experience leads me to suppose is correct. Although we did not deviate from our course for the purpose of hunting, or make any delay beyond what was required in effecting the portage from Milpagos Lake to Gulquac Lake, (half an hour,) the voyage through the last named piece of water yielded us one beaver, one mink, one muskrat, five ducks, four partridges, and a dozen and a half of trout, besides a passing glimpse of a cariboo, a bear, and several tracks of moose.

Long Lake.

Returning to Tobique Lake, we crossed over to Long Lake. The beach at the beginning of the portage is composed altogether of white granite debris; the portage which is $2\frac{1}{2}$ miles long, passes through a swampy piece of ground to a beautiful bay in Long Lake.

This fine sheet of water is about seven and a half miles long, and two broad, but as it is laid down on Mr. Wilkinson's map, it requires no special description. It reminded me of lakes on the canoe route between Lake Superior and Red River. Proceeding to the head of Long Lake, we ascended a small river flowing over granite debris for the distance of a mile, passing the mouth of a small stream which comes from Milnagec Lake. Milnagec, which signifies "Full of Islands," is the name given to one of the feeders of Long Lake. It is situated about three miles W.S.W. of the head of Long Lake, and is stated by the Indians to be about 3 miles long and $1\frac{1}{2}$ broad. The numerous Islands it contains have been the origin of its name.

Little South West Miramichi Lake.

Leaving our canoe on the bank of the stream $1\frac{1}{2}$ mile from the head of Long Lake, we commenced a portage to Miramichi Lake, the head of the little southwest branch of that river, on the south side of the dividing ridge. The portage follows an old Indian path, over a low mountain, which may be 500 feet above the level of Long Lake. The forest is composed of spruce and birch. Three miles from the north end of the portage the path crosses a mountain stream flowing into Long Lake, and at about $4\frac{1}{2}$ miles the summit level is attained which is probably 600 feet above Long Lake. The ascent is gradual, and the plateau covered with a very fine forest of spruce and birch. The descent to Miramichi Lake is also very gradual and through a very fine forest. The whole length of this portage is about $8\frac{1}{2}$ miles. No

rock was seen in position, but numerous unworn white granite boulders render it probable that this dividing ridge is granitic. A few unworn boulders of schist, much twisted and contorted, appear on the south side of this ridge, shewing the presence of belts of that rock running probably parallel with the granite as observed on the South West Miramichi. Arrived on the shores of Miramichi Lake the Indians began to construct a spruce bark canoe, which was finished and afloat in eight hours. Although it was only the 12th of August we were anxious to see if moose would respond to a call. Hardly believing that at this early period of the year any response would be made, and perhaps overcome with the fatigue of the portage, both the Indians and myself fell asleep on the beach, but were suddenly awakened by the splash and plunge of a moose which had answered the call, and approached through the shallow waters of the lake to within twenty yards of where we lay, when warned by a lull or change in the wind which enabled him to scent a suspicious object, he turned round and dashed away into the gloom before we had time to fire.

The head of Little South West Miramichi Lake is very shallow, and much grown up with rushes and water lilies. The main body is about two miles broad and two and a half long. It contains at least fourteen islands, all of them of white granite. The outlet of the lake forms the beginning of the Little South West Miramichi, a river which here is full of micaceous schist boulders and ridges of the same rock, resembling the schist of the Upsalquitch portage. At the rapids close to the Lake, we caught numbers of fine trout, weighing from two and a half to four pounds each. Leaving the Indians to fish, I walked a mile or so down the stream, but finding it choked with boulders, and the ledges of micaceous schist continuing without change, the examination of the river was not pursued any further. Besides the trout mentioned above, large chub are numerous in the lake; we shot several duck, and on the portage a dozen partridge, and saw numerous moose, cariboo, and bear tracks. From these observations it will be inferred that the tract of country described, is still rich in game, the lumberer not having yet reached either Long Lake Portage or the country about Milpogos and Gulquac Lakes. There is, moreover, a large vacant space on the Provincial Map, east of the area described, which the Indians allege has not yet been visited by "white men."

THE MAGAGUADAVIC AT VAIL'S TO ROIX STATION.

From the Magaguadavic to the Dumbarton Station of the New Brunswick and Canada Railroad, the Lower Silurian rocks appear at long intervals apart, the road generally lying through a low and uncleared country, but in the neighbourhood of the Station, they have a strike S. 60 E. with a dip to the N. E. at an angle of 40°. They present themselves here in the form of ferruginous schist beautifully laminated. About three quarters of a mile north of the Dumbarton Station, there are some immense unworn masses of a silicious schist, enclosing crystals of iron pyrites, and resembling in

every particular a schist seen on the South West Miramichi. (See page 45, for a description of the South West Miramichi.) Many of these boulders protrude from a gravelly drift, and they appear to form part of a series of glacial moraines subsequently covered with river drift. On the west side of the Digdewash, about one mile above the Station, a remarkable schistose porphyritic rock occurs, with a strike S. 65 E., and dip N. E. at an angle of 80°. It overlays a blue talcose schist with a N. E. dip. This schist contains highly ferruginous bands with layers of hæmatite. It is followed by black slates which appear in place some distance to the west of the Station, but boulders from these slates were seen in great profusion over the summit and sides of the hills a little to the southwest. These black slates differ, as already stated, in no observed particular from similar slates seen on the Nipisiguit. The occurrence of ferruginous slates with layers of hæmatite above them, is also an exact counterpart of part of the Nipisiguit Series. Immediately in front of the Station the slates are much seamed with quartz layers, and quartz veins form a network between the layers. About five miles from Dumbarton ferruginous slates with bands of black slates were seen to form an anticlinal axis, and near Roix Road Station the blue slates, weathering grey, have a strike S. 50° W., with a vertical dip. It is also worthy of remark that near the Roix Road Station boulders of a conglomerate similar to that which occurs on the Shiktehawk were noticed. These boulders contain fragments of red, green, and black slate, emerald green silicious pebbles, a few quartz and jasper pebbles. Their occurrence here shows probably the proximity of the upper member of the Quebec Group; with these conglomerate boulders were also seen masses which were thought to be from a glauconite schist.

UPPER FALLS OF THE MAGAGUADAVIC TO THE LOWER FALLS.

Near the Upper Falls of the Magaguadavic, about eight miles north of the village of Saint George, a gneissoid schist, interpenetrated with reticulating veins of quartz was seen dipping north at a high angle, and the white granite of Devonian age on which it rested was recognized in position about a mile further down the stream. The granite here forms high cliffs facing the east, some of these escarpments are from 400 to 500 feet high, and from their summits a very extensive and beautiful view is obtained. Part of Lake Utopia with its islands is seen to the east, and Mount Pleasant, estimated at upwards of 1300 feet in altitude, is clearly distinguishable some twenty five miles to the north. The valley of the Magaguadavic lies at the feet of the spectator, while to the south the village of Saint George, backed by the hills lying between it and the sea, appears in delightful contrast to the nearer range of granite hills, from any one of whose summits the different objects enumerated may be observed. The granite is exceedingly coarse, the crystals of quartz being more than two lines in diameter, the felspar, though weathering white, has a pinkish tinge which increases on progressing southward until the rock viewed from a distance looks rose-red. In all particulars

except the occasional occurrence of large crystals of white weathering felspar an inch and more long, the granite resembles the central range. When within about four miles of the village of Saint George, the rock assumes a gneissoid character with a strike nearly east and west, (N. 70 E.) and a dip to the south; it is in fact a porphyritic gneiss, in which the felspar predominates and the mica exists in very small quantity, the quartz crystals continuing large and well defined. The breadth of the granite probably does not exceed here three and a half miles. About two miles from Saint George, a Diorite succeeds the gneiss passing into a homogeneous slate. A mile north from Saint George the red felspathic schist, which appears for a long distance as a more or less precipitous escarpment on the road to Saint Stephen, here forms a magnificent "bluff." The rock is very strong, and seen from the road is a striking object. Its general colour is rose-red. And where partly covered with green moss and grey lichens it presents at a distance a picture of singular beauty, especially when lit up by the rays of the sun after a shower of rain. The contrast of the colours is so remarkable that this rock would form a favourite study for an artist in any country. The schist itself is not less interesting; it has an east and west strike and dips to the south; its upper portion is porphyritic and is probably a diorite. An intrusive green diorite appears on the southern exposure, but it was not traced to the summit. From this rock Lake Utopia is plainly seen, being not more than two miles from it. These green and red diorites resemble those on the Tobique and Campbell Rivers, and would probably form excellent materials for decorative arts. Some portions of the rock which had been submitted to glacial action, and the polished surfaces preserved by a thin coating of sand, were especially beautiful, deep red crystals being imbedded in a light green or rose-red matrix.

FALLS OF THE MAGAGUADAVIC.

At the Falls of the Magaguadavic the slates have a general strike east and west with a southerly dip, but they have been subjected to some disturbance. The slates are succeeded by bedded diorites which from their hardness have arrested the retreat of the falls. Before the falls had reached the pool their retrocession must have been very rapid, as they then fell over fissile blue-black slates which appear just opposite the pool or basin below the mass of bedded Diorite over which the waters of the lower part of the falls plunge. These black slates have a strike nearly due east and west (N. 75° E.) with a northerly dip. They are first corrugated and very hard near to the Diorite, but they soon become fissile and expose large plane surfaces, and some bands are apparently fitted not only for roofing purposes but also for writing slates. The first band of slates is about 200 yards broad, this is succeeded by about 300 yards of Diorite, as exposed on the river bank; the slates then come in again with the same strike but a southerly dip, showing an anticlinal axis here. They are also blacker than before, and when wet appear intensely black; they present a rough surface when freshly fractured, like

the black slates of the Nipisiguit and the black slates near Dumbarton. As both of these slates probably belong to that part of the Lower Silurian Series which is known as the Quebec Group, the resemblance of the black slates of the Magaguadavic to them is remarkable and suggestive. The lower bands of black slates easily break into rhombs, are ferruginous, and sometimes expose many square feet of plane surface with that peculiar roughness which distinguishes the black slates of the Nipisiguit.

CHARACTERISTIC STRATA BELONGING TO THE QUEBEC GROUP.

The great economic value of this series of rocks makes it desirable to supply as full a descriptive account of the strata which compose it as the limits of the present Report will permit. As the series in New Brunswick is merely a repetition of what has been carefully studied in Canada, it will be desirable to incorporate the results of many years study of the mineral characters of these rocks by Professor Hunt.

GNEISS.—Great masses of orthoclase gneiss * are met with in this series. They are generally fine-grained, and are more quartzose than those of the Laurentian system; with which the practiced observer will never confound them. The coarse-grained and porphyritic reddish and white varieties are never met with, and the gneiss is generally of pale greyish or greenish hues. In some cases, great portions of it are so destitute of marks of stratification, that but for their relations to the adjacent beds, they might be taken for intrusive masses. The mica is generally white or greyish, and in small quantity.

Often found reposing on the granite in New Brunswick.

ANORTHOHITE.—Rocks composed of triclinic feldspars, and representing the anorthosites † of the Laurentian system, are common in this series; they are, however, never coarsely crystalline, and are often compact. In some cases the feldspar approaches to albite or to oligoclase in composition. Through an intermixture of hornblende, these rocks pass into diorite. ‡

DIORITE.—In the diorites of this series, the feldspar is sometimes the predominant element. One from Oxford was found, by analysis, to consist of sixty-four parts of albite, and thirty-six of hornblende; another contained seventy-four parts of a feldspar, which was near albite in composition, but contained as much potash as soda. Others of these diorites exhibit a predominance of hornblende, often mingled with a chloritic mineral, and constitute veritable greenstones; which, however, appear to be in all cases sedimentary rocks. They are frequently so finely granular as to appear at first sight homogeneous, while at others they are rather coarsely crystalline, or sometimes porphyritic, from the presence of large feldspar crystals—*Common throughout the group in New Brunswick.*

EPIDOSITE (EPIDOTE AND QUARTZ).—Epidote is a characteristic mineral of great portions of this series. Sometimes it forms with quartz, a fine-grained compact rock, which is found in thick beds in the Shickshock Mountains. At others, the epidote is disseminated in nodules, in a fine grained silicious rock, which often becomes chloritic or argillaceous.—*Common on the Upper Tobique.*

* ORTHOCLASE gneiss—Potash Feldspar gneiss.

† Anorthosite—A Lime Feldspar Rock.

‡ Diorite.—A Rock composed chiefly of feldspar and hornblende,

MICA-ROCK.—This soft grey schistose rock, a bed of which has been wrought as a variety of potstone, has nearly the composition of a hydrous mica, with only three per cent of alkalis, and fifty-one per cent of silica.—*Nipisiquit, Saint John River.*

MICA-SCHIST.—These mica-schists are very variable in their nature, and often highly quartzose; not unfrequently they have the aspect of what are called talcose slates, without, however, containing any magnesia, and owe their peculiar characters to a mica like that of the preceding rock, or to pholerite or pyrophyllite. Pholerite is sometimes found in a pure state, in fissures in the sandstones of this series; and pyrophyllite forms beds, resembling steatite, in the same formation in the southern United States; where it also occurs crystallized with quartz.

Localities.—*Devil's Elbow on the Nipisiquit, Saint John River, Upsalquitch Lake, Milpagos Lake.*

ARGILLITE.—The argillaceous rocks of this series present many varieties, from roofing-slates, and talcoid and plumbaginous shales, to others which are more or less chloritic or micaceous. Some specimens are remarkable from containing small oval masses of regular outline, consisting of orthoclase and quartz. Their exterior portion is generally of feldspar, the centre being filled with quartz; but sometimes the one or the other is wanting, and the kernels consist of quartz or of feldspar only. These oval masses, which are from one-eighth to one-half an inch in length, have their greater diameters parallel. The rock might be called an amygdaloid. Some portions of these argillites are penetrated by small veins with quartz, chlorite, and bitter-spar, intersecting these slates. *Compare the Red States in next Chapter.*

Localities.—*Valley of Shiktehawk, of Beccaguimic, Jacksontown, on Campbell River, on the Nipisiquit, on the Upsalquitch, on the South West Miramichi.*

IRON-SCHIST OR ITABIRITE.—Great beds of a rock made of scales of specular iron, with quartz and chlorite, are met with in the altered Silurian strata. They are sometimes rich iron ores, and at other times contain but small portions of the metallic oxyd. The specular schists often include a portion of titanitic acid, which is occasionally seen in the form of rutile or of sphene, crystallized in veins, sometimes with feldspar. These rocks are apparently identical with the itabirite of Brazil.

Localities.—*On the Upper South West Miramichi, Campbell River.*

DIALLAGES ROCK.—Diallage is abundant, not only as a component of some ophiolites, but sometimes forming a rock, either by itself, or with a little mixture of an amorphous mineral, which approaches to pyrosclerite in its composition.

CHLORITOID-SCHIST.—Chloritoid is abundant in the quartzose mica-schists in this series.

HORNBLÉNDE ROCK, WITH GARNETS.—Beds of black crystalline hornblende rock, including small crystals of red garnet, occur with the serpentines of Mount Albert. In many other parts, hornblende in the form of actinolite, or a tough, fibrous variety allied to it, forms beds of great thickness.

MAGNETIC IRON IN DOLOMITE.—Magnetic iron ore is often found in these rocks, in irregular beds or masses in Serpentine.

COPPER PYRITES.—Copper is abundantly distributed in this formation. The ores are met with in quartzose, argillaceous, micaceous, and chloritic slates, in limestones, and in dolomites. The copper in these strata seems to have been a contemporaneous deposit from aqueous solutions. *Tattagouche—Nipisiquit, four miles above Pabineau Falls—At the Grand Falls—Campbell River—Woodstock.*

OPHIOLITE (SERPENTINE.)—Under the name of ophiolite we include those rocks which have serpentine for their base. The normal ophiolites are nearly pure serpentine, while some are mixtures of serpentine and carbonate of lime (calcareous ophiolites,) and others dolomitic and magnesian ophiolites; containing respectively dolomite and carbonate of magnesia, often in large proportions. All of these varieties are met with in Canada, or in the adjacent State of Vermont. These compound ophiolites are sometimes porphyritic from the presence of diallage (the Italian gabbro). At other times, they have the aspect of conglomerates, exhibiting rounded or angular masses of pure serpentine of various sizes, imbedded in a dolomitic paste, itself more or less coloured by intermingled serpentine. A magnesian ophiolite from Vermont has a gneissoid structure, due to the arrangement of the crystalline magnesite spar, with lamellæ of talc, apparently marking planes of stratification. The ophiolite of Mount Albert is marked with red and green bands, which have the aspect of sedimentary layers; and the relations of the ophiolite throughout this series, where its outcrop has been followed for hundreds of miles, are always those of an interstratified deposit, and never of an eruptive rock. It occurs with dolomite, magnesite, steatite, diorite and argillite, with each one of which it has been found in contact, and it seems sometimes to replace the other magnesian rocks. Its beds vary from a few yards to several hundred feet in thickness. The colours of these ophiolites are of various shades of green; generally much darker than those of the Laurentian series. A red colour sometimes occurs in patches and bands, or pervades the whole mass; this, in some cases, at least, is due to an intermixture of red hematite. Foliated and fibrous varieties (baltimorite and chrysotile) are frequently found in veins in these ophiolites. Chromic iron is also a characteristic mineral, in grains, or in interstratified beds or lenticular masses, often of large size. Magnetic iron occurs in these ophiolites, both in grains and beds, sometimes with ilmenite.

The analysis of the serpentine of these ophiolites show them to contain from seven to ten per cent. of protoxyd of iron, to which they owe their colour, besides small portions of oxyds of chrome and nickel. These two metals often occur in the magnesian rocks of this series, in the form of chromic iron and sulphuret of nickel; but are in many cases present as integral portions of the silicate. This is true, not only of the serpentines, but of the diallage and actinolite rocks, and many of the dolomites and magnesian rocks. It would seem that chrome and nickel were constant accompaniments of the magnesian deposits of the present series. We have also detected these metals in the ophiolites of California, of Portsoy in Scotland, Cornwall, the Vosges Mountains, Mount Rosa and Corsica; while they are wanting in the Laurentian ophiolites of Canada, and in specimens of serpentine from Norway, supposed to be of the same formation.

STEATITE.—Talc slates or schistose varieties of steatite are not unfrequent. These are sometimes nearly pure talc, and at others mingled with hornblende, in the form of actinolite or with bitter spar.

CHLORITE, (POTSTONE.)—Sometimes beds of pure compact chlorite are met with in these rocks.

MAGNESITE.

DOLOMITES.—LIMESTONES.—Dolomites, or magnesian limestones, are abundant in this series, and frequently accompany the ophiolites or serpentines into the composition of which they often enter. These dolomites are generally ferruginous, often containing eight or ten per cent. of carbonate of iron, and sometimes as much carbonate of manganese. They are often mingled with a portion of clay, or of silicious sand, and very frequently

become conglomerates, enclosing pebbles or rounded masses of pure limestone, and more rarely of sandstone, shale, or dolomite, in a paste of ferruginous red-weathering magnesian limestone. In some cases, these rocks have the composition of a true dolomite, in which the oxyds of iron and manganese replace a portion of magnesia. In others, the quantity of lime is not equivalent to the other protoxyd bases, and we have a passage to the magnesites already described; which are rocks consisting of carbonates of magnesia and iron, with little or no carbonate of lime. The foreign minerals of these rocks are few in number; chlorite, talc, hornblende, pyroxene and brown garnet are sometimes met with, and a green chromiferous mica, probably allied to fuchsite, occurs in small scales, both in the magnesites and in the dolomites. With the ferruginous dolomites, are often interstratified beds of pure limestone, which frequently enclose concretionary fibrous masses, made up of concentric layers, like the recent deposits of travertine from calcareous waters.

The conditions under which these dolomites and pure limestones are associated, are such as to leave no doubt that they have been contemporaneous deposits and to forbid the notion of the formation of dolomite by any subsequent alteration of the limestones.—[See Geological Reports of Canada for 1857 and 1858.]

DEPOSITS OF SILICA.—Deposits of silica, which are evidently of chemical origin, and which assume the form of hornstone or jasper, as they include more or less argillaceous or ferruginous matter, are not unfrequent among the mechanical sediments of this series. The two specimens of sandstone from the unaltered strata of the Quebec Group at St. Nicholas, are supposed to represent the granitic gneiss of the altered portions of the same formation. The cement in some of these sandstones, is a feldspathic matter, rich in potash; and the analysis of the rock, as a whole, gives a composition identical with the mixture of quartz, orthoclase, and mica, which constitutes this gneiss. The metamorphism of these aluminous rocks consists then, simply in the crystallization of the silicates of alumina and alkali in the sediments, a reaction which has taken place at no very elevated temperature; the alkaline silicates and carbonates, by which the waters of these sediments are impregnated, aiding the process. At the same time, the reactions between the silicious and argillaceous matters, and the earthy carbonates, in the presence of these alkaline solutions give rise to chlorite, and epidote.*

* Professor Sterry Hunt.—Descriptive Catalogue of a collection of the Economic Minerals of Canada, and of its Crystalline Rocks,—1862.

CHAPTER IX.

THE QUEBEC GROUP.—(Continued.)

Metalliferous Deposits in the Quebec Group of New Brunswick—Iron, Manganese, Copper, Antimony, Nickel, Lead, Zinc, Gold, Silver—Origin of the metallic deposits in this Group—Professor Sterry Hunt's Views—The Woodstock IRON ORES—Description of the Ores—Chemical Composition—Properties of the Iron—The Woodstock Iron Works—Opening for capital and enterprise in the working of these Iron Ores—Their extensive distribution—Their development on the east side of the Saint John—On the Beccaguimic—Their associations with limestones for fluxing, fuel for smelting, labour, and their occurrence in a fine agricultural country—Their occurrence on the Shiktehawk—Three undulations on the east side of the Saint John have brought the ores to the surface—Vast importance of these ores—Native silver in a jasper boulder on the Shiktehawk—MANGANESE AND COPPER ORES—On the Nipisiguit, Tattagouche, Campbell Rivers, Bull's Creek—Saint John—Professor Hunt's views respecting the origin of Copper in the deposits of the Quebec Group—ANTIMONY ORES—The ores of Prince William Parish—Characters of the Dislocations—The Pits—Probable extent and richness of the ore—NICKEL—COPPER—Production and uses of Antimony—LEAD ORES—ZINC ORES—Sequence of the strata in Canada—ISLAND OF ORLEANS SERIES—PHILLIPSBURG SERIES.

METALLIFEROUS DEPOSITS AND METALS IN THE ROCKS SUPPOSED TO BELONG TO THE QUEBEC GROUP IN NEW BRUNSWICK.

I. IRON ; II. MANGANESE ; III. COPPER ; IV. ANTIMONY ; V. NICKEL, VI. LEAD ; VII. ZINC ; VIII. GOLD ; IX. SILVER.

The manner in which the metals of this Group have originated is of much importance in attempting to form an estimate of the commercial value of any deposit. It has been shown in the preceding Chapter, according to Professor Sterry Hunt, who has paid especial attention to this subject, and the results of whose investigations form some of the most important contributions to Chemical Geology which have yet been given to the scientific world, that the metals seem to have been originally brought to the surface in watery solution, from which he considers them to have been separated by the reducing agency of organic matter in the form of sulphurets, or in the native state and mingled with the contemporaneous sediments, where they occur in beds, or in disseminated grains forming *fahlbands*, or, as at Acton, are the cementing material of conglomerates.

During the subsequent metamorphism of the strata, these metallic matters being taken into solution by alkaline carbonates or sulphurets, have been redeposited in fissures in the metalliferous strata, forming veins, or ascending to higher beds have given rise to metalliferous veins in strata not them-

selves metalliferous. The intervention of intense heat, sublimation and similar hypothesis to explain the origin of metallic ores, Professor Hunt conceives to be uncalled for.*

THE WOODSTOCK IRON ORES.

These ores are vast sedimentary deposits many feet in thickness, interstratified with red and green argillites, or with calcareo-magnesian slates, of a red or green, or mottled red and green colour. The ores vary in composition, being both red and black, the black is sometimes feebly magnetic, but it derives its colour more from the presence of manganese than from the black magnetic oxide. The red ore is an impure hæmatite, containing besides the peroxide of iron, some carbonate of the protoxide, and from one to six per cent. of manganese; it is often seamed with thin layers of graphite. The most characteristic of the earthy admixtures, are from two to five per cent. of magnesia, and from .064 to nearly two per cent. of phosphoric acid. The mean of eight analyses gave 32 68-100ths per cent. of iron from the ores worked at the furnaces. Some of the samples yielded as high as 48 per cent. of metallic iron, others as low as 19 per cent.; 32 per cent. appears to be about the general average as shewn in the accompanying Tables, when the extremes are thrown out and the mean of the remaining six analyses is taken.

The slaty ores are often concretionary,† showing layers of small circular or elliptical spaces regularly distributed in lines parallel to the stratification.

* On some points in American Geology. American Journal of Science, May 1861.

† Compare with "Argillite," page 157.

‡ This Table was kindly given to me by Norris Best, Esquire, one of the proprietors of the Woodstock Iron Works. The analyses were made in England by chemists of known reputation.

CHARACTER OF THE IRON.

The iron produced at the Woodstock Iron Company's Furnaces is of a very superior quality. Its colour is silver-grey; its density is equal to that of some varieties of the best hammered iron; it makes excellent steel, and possesses great toughness or resisting power.

The resistance in tons per square inch of—

Yorkshire Iron, is.....	24.50 tons.
Derbyshire “	20.25 “
Shropshire “	22.50 “
Staffordshire “	20.00 “
Woodstock “	24.80 “

The presence of phosphoric acid in iron without manganese, renders the metal “cold-short,” that is, brittle when cold; but if the metal be alloyed with manganese, the two foreign elements combined appear to give it a high degree of ductility; manganese alone is not thought to improve the quality of the iron. It has been suggested that the Woodstock iron owes its great resisting power to the large quantity of carbon it contains; this view, however, is not in accordance with the experiments at Shoeburyness. The iron plates which contained the largest amount of carbon were the most easily fractured, a large percentage of carbon (0.23) causing brittleness. The composition of the plates* which afforded the greatest resistance to concussion, with regard to foreign substances, was as follows:—

	Carbon.	Sulphur.	Phosphorous.	Silicon.	Manganese.
A.....	0.01636	0.104	0.106	0.122	0.28
B.....	0.03272	0.121	0.173	0.160	0.029
D.....	0.0436	0.118	0.228	0.174	0.250

A comparatively large amount of Carbon gives strength to resist tension and compression, but not concussion or the force of impact.†

While, however, the quality of the Woodstock iron is no doubt excellent, it seems probable that the estimation in which it is held by the Proprietors of the Works is a little too exalted, if the following statement in Professor Bailey's Report correctly expresses their opinions:—“The proprietors,” says Professor Bailey, “believe the iron thus wrought to be superior to Swedish, Russian and East Indian pig iron, and draw their conclusions from the fact that one cubic inch of the Woodstock metal will weigh at least 22 per cent. more than either of the above, and is something like 26 per cent. heavier than the most of the Scotch brands.”‡

* The hammered plates manufactured at the Thames Iron Works are made in the following manner:—“Scrap iron of the best description is carefully selected and cleaned, piled, hammered into a bloom, and then rolled into bars 6 inches broad, and 1 inch thick; these bars are cut up, piled, and again hammered into a slab; several of these slabs are put together, heated and hammered to the form required, and this process being repeated, the plate goes on gradually increasing to the length required.”

† Fairbairn.

‡ Report on the Mines and Minerals of New Brunswick, page 58.

1. The specific gravity of common Scotch Iron, varies from 6.9 to 7.1.
2. That of pure iron is 7.8.
3. Of the best razor tempered steel 7.84.
4. Rolled and hammered iron 7.9.

An increase in weight equal to 26 per cent. would make the specific gravity of the Woodstock iron 8.82, or higher than that of copper, (assuming the specific gravity of the "Scotch brands" to be 7.0), and about 12½ per cent. higher than the best razor tempered steel. As this specific gravity for iron of any description manufactured or unmanufactured is wholly unprecedented, we may suppose that the above estimate is too high.

CAPACITY OF THE WOODSTOCK IRON WORKS.

The capacity of these works, with one furnace in operation (and one in process of erection), is stated to be six tons and a quarter of iron a day; the furnace continues in blast for about twenty-four weeks, six weeks being required for the necessary half yearly repairs, so that the actual producing time is about 48 weeks in a year, this would give, at 50 tons a week, the product of one furnace, about 2,150 tons per annum. Each of the British Iron Clad Frigates require from 800 to 1,050 tons of iron for plates, so that the two furnaces, which may be supposed to be in operation in the early part of 1865, would not be able to supply more than enough iron per annum to cover four first class frigates. At this rate it would take two or three generations to remodel the British Navy. Whenever the demand is made, however, and there is a demand for far more than can be supplied, there is ore and fuel enough for fifty furnaces; for on the east side of the River Saint John, the country is still an unbroken forest, except on the borders of the streams. Hitherto, the entire product of the one furnace in operation would be sufficient only to protect two frigates per annum, we must therefore receive the statement that "the British Government uses chiefly the Woodstock iron for the manufacture of the plates,"—*cum grano salis*.*

No doubt it would be extensively used in the British and some foreign navies, if enough iron could be obtained with sufficient despatch. There is a splendid opening for the employment of capital in this direction, and ore and fuel in abundance for many years to come. The whole question is one of very considerable interest and will bear the strictest scrutiny.†

* C. H. Hitchcock—Second Annual Report upon the Natural History and Geology of the State of Maine, 1862, page 414.

† In a Report presented to the Woodstock Athenæum, February 11th, 1862, it is said— "The following statistics regarding the present works, and the extent of the iron beds have been kindly furnished by Mr. Norris Best, Manager of the Charcoal Iron Works at Upper Woodstock. The quantity of wood required for the operations of these works in 1864 is estimated at 12,000 cords, which will strip say 400 acres. Evidently with this consumption annually added to that necessary for the ordinary purposes of the County, wood must go up in price, and the expense of producing Charcoal Iron must be increased. But the present works furnish a very considerable addition to the business of the County, and would provide an item in Railway traffic of no small importance. The estimated production of pig iron for 1864 is 2,750 tons, employing at the mines and about the

DISTRIBUTION OF THE ORES.

The red and green slates with which this ore is interstratified are very widely distributed, as already stated, in a northeasterly direction, extending in fact as far as the Nipisiguit, a distance of more than one hundred and twenty miles. It is probable that owing to local disturbances there will be large breaks in these deposits, and the ores may not be found equally rich throughout the distribution of the red and green slates, but they are known to occur in inexhaustible quantities on the east side of the Saint John, where they appear in probably greater force than at Jacksontown, on the west side of the river, from which the Woodstock Iron Works are supplied.

The first Iron Ore Bed on the east side of the Saint John, seen this summer, was on the farm belonging to Mr. B. Thomas, No. 1, on the south side of the Beccaguimic. This is probably the same bed or one of the series which occurs at Jacksontown. The ore as it appears on the surface of the ground is very black, containing apparently a considerable proportion of Manganese. The red slates with hematite were observed in position with a strike N. 60° E. or from N. 50° E. to N. 60° E. The red and green slates have here a breadth of about one quarter of a mile, the dip is vertical where observed. The iron ore was seen to occupy more or less of 90 yards in this vertical section.

Two miles and three quarters from the Saint John, and within half a mile of the Beccaguimic, the red slates cross the road.

On the road to the Limekilns at Pole Hill, which is marked on Mr. Wilkinson's Map, red slates, which are probably another undulation of the same beds, cross the road about 250 yards from the Beccaguimic road.

On Mr. William Clark's lot, through which the Pole Hill road passes,

furnace and works seventy five men. Twelve teams, with their drivers, find constant employment in hauling the ore, while to cut the wood requires say one hundred and fifty men for twelve weeks; and to haul it some sixty teams and their drivers for the same length of time. The down freight of the pig iron for 1864 is estimated at \$5,500. During the winter the iron, in order to keep up a regular supply for the English market, has to be hauled on sleds to the Houlton Road Terminus of the Saint Andrews Railway, a distance of nine miles, thence sent by Railway to Saint Andrews; and from that place shipped by schooner to Saint John; and every ton thus transported from Woodstock to Saint John, costs one dollar and twenty five cents additional. With a Railway communication between Woodstock and Saint John, the iron could be sent for two dollars throughout the year, and thus on one half the quantity produced there would be a saving in transport within the Province of one dollar and a quarter per ton. The up freight for the Works is estimated for 1864 at \$4,500. Thus for 1864, from the works of the Iron Company alone, the proposed Railway would receive a traffic at present worth \$10,000.

Mr. Best states to your Committee that if there were continuous Railway communication from Saint John to Woodstock, so that mineral coal could be delivered at the works at a rate of 1½ cents per ton per mile, it could be used profitably for iron smelting in this County; and that every description of iron, whether for the varied uses to which malleable iron is put, or for castings, could be produced in Carleton County and sent to Saint John at a price so low as to compete successively with English and Scotch irons. In fact, the result would be that three fourths of the importation of British and Foreign iron would cease."

about $5\frac{1}{2}$ miles from the River Saint John, the red slates with black iron ore are seen in places on the west side of the road. These are, most probably, the Jacksontown beds brought to the surface by a third undulation.

A broad band of limestone deeply creviced, occurs within a mile to the southeast of these iron deposits. It is from this source that the lime for smelting purposes at the Woodstock Iron Works is obtained.

Limestone is said to be found also on Lot N, belonging to W. O. Clarke, on Gin Brook, this is probably the same bed as the one just noticed, brought to the surface by the same undulation which revealed the presence of the first belt of iron ore noticed on the Beccaguimic. The order being—

- I. Red and green slates with iron and Manganese ores...Beccaguimic.
- II. Limestone.....Gin Brook.
- III. Red and green slates with iron and Manganese ores...Cooke Lot.
- IV. Limestone.....Pole Hill.

A band of black iron ore crosses the Portage Road on the Upper Shiktehawk, about $7\frac{1}{2}$ miles from the River Saint John; it has a strike N. 60° E. dip N. E. The red slates with which it is associated are near at hand, crossing the portage road a short distance in advance. The quantity of ore on this road is very considerable, but persons familiar with the country state that two or three hundred yards in the woods south of the road, the iron ores are much more abundant, and two miles from the same locality there is abundance of limestone.

The new settlement of Glassville must be situated on or near a band of these slates, for though not seen in position the debris was recognised at the bend of the North West Branch of the South West Miramichi.

IMPORTANCE OF THESE IRON ORES.

It appears clearly established that on the east side of the Saint John there are not less than three undulations which have brought up the red and green slates with their iron ores and associated beds of limestone. These immense deposits of ore occur in a country possessing an excellent agricultural soil, a splendid forest of birch, beach, spruce, and maple, and limestone in abundance. It will not fail to be noticed that these are elements of local industry belonging to the highest class. For the ore yields an iron of very superior quality, which has been thoroughly tested in the United States and in England, and if it be considered advisable to smelt it on the spot there is abundance of timber for fuel, lime for fluxing, labour for collecting the ore and preparing the fuel, and an excellent agricultural country as the basis of the whole industrial system. Now that this iron has met with so much favour in England, it is not improbable that it may yet be profitable to export the best quality of ore from those beds which are near to the Saint John. Under any circumstances it is probable that in a short time the abundance of fuel, either as coal, or gas from the highly bituminous shales of Sussex Vale, both of which are cheaply procurable in the lower portion of the river,*

* See Chapter VI. for a description of gas furnaces.

will render the construction of gas furnaces for obtaining iron of a very superior quality a matter of pecuniary advantage and provincial importance.

Red slates were seen on the southeast side of the axis, within ten miles of Boiestown on the Miramichi, but they were not specially examined for iron ores. Higher up the river the rocks are very ferruginous, but no details can be given respecting them.

FUEL AND ORE.

In Derbyshire (England,) the following is the proportion of ore and fuel consumed, and metal produced:—

Ore,	2 tons 12 cwt.
Mineral coal,	2 "
Metal produced,	1 "

In Staffordshire:—

Ore,	2 tons 7 cwt.
Mineral coal,	2 " 8 "
Metal produced,	1 "

In Dordogne, (France):—

Ore,	2 tons 7 cwt.
Charcoal,	1 " 3 "
Metal produced,	1 "

Woodstock, N. B.:—

Ore,	3 tons 6 cwt.
Charcoal,	126 bushels.
Metal produced,	1 ton.

This estimate is based on the statement kindly made by one of the proprietors, Mr. Norris Best, in a letter addressed to me under date 11th February 1865.

Mr. Best states that the average proportion of materials used during the past year has been as subjoined:—

Ore,	1180 lbs.
Limestone,	50 "
Charcoal,	20 bushels.

The average yield of the ores is assumed to be 30 per cent. of pure metal. (See Table of Analyses, page 161.)

Then 1,180 lbs. of ore will yield 354 lbs. of metal, or one ton of 2,240 lbs. will require 3.33 tons of ore, and 126 bushels of charcoal, which at seven cents a bushel, the price Mr. Best states he is paying on the 11th February, will cost \$8.82, which is the actual cost of fuel, per ton, according to above data.

At Dordogne, the cost of charcoal for the production of one ton of iron is at the least \$11.60 cents; and in France, generally, the average price of charcoal would raise the cost of every ton of iron to \$14.80 for charcoal fuel alone.

For the further conversion of cast iron into wrought iron, there is required in England about one ton and one third of cast iron, and from two to two and a half tons of mineral coal are consumed, while the same amount of the cast iron of the Dordogne requires to convert it into a ton of wrought iron, one ton and a half of charcoal. In England, a ton of wrought iron requires about five tons of mineral coal for its fabrication. In France, a little over three tons of wood charcoal at \$11.60 a ton, the minimum price of charcoal there.

It is clear that the price of charcoal in the vicinity of Woodstock will rise in the course of a few years, and then the question of a supply of fuel for smelting purposes will have to be vigorously met, or as in Canada, it will be necessary to move the furnaces where ore and fuel are still abundant, without the construction of a Railway enables coal to be delivered at a rate sufficiently low to admit of its being used for smelting purposes. But there are other parts of the Province where ores of iron and fuel exist in abundance together, and where gas fuel can be employed with advantage.

M. CHENOT'S PROCESS WITH GAS FUEL.

In 1857, Professor Hunt called attention to the new metallurgical processes of the late Adrien Chenot, which attracted in a particular manner the attention of the Jury of the Palace of Industry at Paris in 1855, who awarded to the inventor the Gold Medal of Honour. M. Chenot there exhibited a series of specimens serving to illustrate the processes which bear his name, and which have been the result of extraordinary labours on his part, continued through twenty five years.

M. Chenot employs gas fuel, generated from the poorest description of coal, or from any source capable of producing carbonic oxide. One mode of forming this gas fuel has already been described in a previous Chapter, in a notice of the regenerating gas furnace, page 106. According to Professor Hunt, the methods invented by the late Adrien Chenot for the reduction of iron ores and the fabrication of wrought iron and steel, constituted in the opinion of one eminently fitted to judge the case (M. Leplay of the Imperial School of Mines,) the most important metallurgical discovery of the age.

It can not fail to strike every unprejudiced reader that these facts are of the utmost importance to the manufacturing industry of this Province. It has been shown that in the valley of the Kennebecasis, and eastwards towards Westmorland there is a great development of Albert Shales, eminently adapted for the manufacture of gas fuel; iron ores are abundant in the same valley, either in the form of bog ores or nearly pure magnetic ores in Springfield; under such conditions there is no reason why New Brunswick should not soon become an exporter rather than an importer of iron in all its multifarious forms.

The processes of M. Chenot are now (1857) being applied to the fabrication of steel at Clichy near Paris. The iron ore is imported from Spain, and notwithstanding the cost of its transport, and the high price of fuel and labour in the vicinity of the Metropolis, it appears from the data furnished

by M. Chenot to the Jury at the Paris Exhibition, that steel is manufactured by him at Clichy at a cost which is not more than one fourth that of the steel manufactured in the same vicinity from the iron imported from Sweden. Near Bilboa, in Spain, at the works of Villalonga & Co., they are enabled to fabricate the metallic sponge at a cost of 200 francs, or \$40 the ton, and the best quality of cast steel at 500 francs, or \$100 the ton of 1000 kilograms, (2,200 lbs. avoirdupois) notwithstanding the high price of fuel. M. Chenot stated to Professor Hunt that the conversion of the ore to the condition of sponge is effected with little more than its own weight of charcoal.

THE SWEDISH GAS FURNACES.

The subject of gas furnaces in which any kind of fuel may be used, and for which, as already stated, the rich bituminous Albert shales are particularly adapted, has engaged the attention of the most prominent iron manufacturers in England, France, Sweden, and Prussia. In the United States the abundance and cheapness of mineral fuel has hitherto prevented attention being directed to this important improvement in metallurgical arts, and indeed in all those departments of industry which require very elevated temperatures. The Swedish gas furnace uses peat as the fuel, models of their improvements were exhibited at the International Exhibition in 1862. *The old furnace so commonly used for smelting iron ores, and the reverberatory furnace are really nothing more than clumsy and imperfect gas furnaces, where an enormous amount of heat is allowed to escape and more than twice as much fuel is used as the operation requires.* The following short description of the Swedish gas furnace may be acceptable, and when considered in connection with the brief details given respecting M. Chenot's process, and the Regenerative gas furnace of Mr. Siemens, described on page 106, the wide field open for industry in this Province will not fail to attract the attention of thinking men, the more especially when it is remembered that a nation's industry and manufacturing status is measured by its production of iron.

Improved Furnaces.—"In the Swedish department specimens of iron were exhibited made with peat as fuel; and in the Italian department steel was shown made in a gas-puddling furnace with the same fuel. The furnace in which peat is thus made available for metallurgical purposes, although not easily described without diagrams, is still so well worthy the attention of those interested in economizing fuel, that we make the attempt to render its structure intelligible to the general reader. We must assume, in the first place, that he is acquainted with the form and action of a common reverberatory furnace such as may be seen in operation in many parts of the country. Instead of the usual fire-place, there is what is called the "gas generator." This consists of a circular chamber of fire-brick several feet deep, and two or three feet in diameter, closed at the bottom, and having a hopper at the top, through which fuel is supplied. This chamber, at a certain height from the bottom, is in direct connection with the body of the furnace, so that flame may issue as freely from it as from the fire-

place of an ordinary reverberatory furnace. In the sides of the generator, at a certain distance from the top, is a series of three or four small, round holes on the same level, and at some distance lower down is another similar series of round holes. These holes are for the passage of the air intended to support combustion in the interior of the generator, which is blown in either by a fan or some other convenient blowing-machine. Now, when the generator is full of incandescent fuel, and air is injected through the lateral holes, carbonic oxide gas is copiously produced and passes into the furnace, as there is no other place of egress, the hopper at the top being supposed to be shut. As it escapes from the generator, it is met with a current of heated air, or, as it technically termed, "hot blast," which is injected downwards from the roof of the furnace at or near its junction with the generator, either in several jets or one continuous sheet. The carbonic oxide while still hot is thus burnt, and the heat developed is sufficiently intense even to melt wrought iron by the hundred weight. The air which supplies the generator is also previously heated; and in the Swedish furnaces the apparatus for heating the blast consists of a series of cast-iron pipes fixed at the lower part of the stack. Hence only the waste heat of the furnace is employed for this purpose. It is usual to place a hollow cylinder of iron round the generator, so as to leave a closed space between its internal surface and the exterior of the generator; and into this space the hot blast is introduced, whence it passes through the two rows of holes previously described into the interior of the generator. The atmosphere of such a furnace can be rendered either reducing or oxidizing at will by regulating the amount of blast. At the bottom of the generator is a door, by means of which the ashes or clinker from the fuel may be withdrawn."*

PROBABLE CAUSE OF THE SUPERIORITY OF THE WOODSTOCK IRON.

Different ores of iron make very different kinds of steel, notwithstanding the most careful manipulation and scrupulous attention to the manufacturing process in all its stages. Until M. Chenot had investigated the subject, it was but very imperfectly understood, and the difference in the steel and iron produced was frequently stated to be due to the presence of some foreign body such as manganese or phosphorous, or silicon or excess of carbon. According to M. Chenot the nature of the ore has much more to do with the quality of the metal than the mode of treatment, and the *steel producing capacity* of any iron is MEASURED BY THE QUANTITY OF CARBON which it can absorb before losing its malleability and degenerating into cast iron.

The iron of Sweden and the Ural Mountains, after taking up six per cent. of carbon, yields a metal which is still malleable, while that of Elba with four per cent. becomes brittle and approaches cast iron in its properties. The ores of Sweden and the Ural are famous for the excellent quality of their steel; the ores of Elba yield a very superior iron, but are unfit for the fabrication of steel.

* Annual of Scientific Discovery, 1863.

It is a highly important fact that the Woodstock ores, which contain a considerable proportion of manganese, phosphorous, and silicious matter, should produce an excellent iron capable of being made into excellent steel, and we may, in the absence of definite experiment, conclude that it derives these valuable properties from the large amount of carbon it is capable of combining with, without degenerating into cast iron.

Hence, even should the price of charcoal rise considerably higher than it now is in the vicinity of the works, the remarkable quality of the ores will still yield a remunerative return; and it will become a question of simple arithmetical calculation whether it will be most economical to bring the ores to the fuel or the fuel to the ores.

MANGANESE.

The diffusion of the black oxide of manganese through the ferruginous beds which have just been described, will appear upon an examination of the table of analyses on page 161. Some of the ores it will be observed contained nearly seven per cent. of this metal, and from a cursory examination it appears not improbable that beds of ferruginous manganese may be found associated with the iron ores. On the South West Miramichi, the presence of manganese is indicated in several places by beds of black gravel in which the cementing material is the black oxide of this metal. Specimens of manganese were shown to me which were said to have been taken from beds on the east side of the Saint John, about 13 miles above Woodstock. On the Tattagouche, the black oxide of this metal is tolerably abundant, and the purple slates on the Nipisiguit show that the area over which it may be looked for with probable success is large and not inaccessible. Considerable quantities of manganese were formerly exported from the Tattagouche Mines. The development of these and several other mineral deposits in the Province is due to the energy and zeal of Mr. Stephens, of Woodstock.

COPPER ORES.

Judging from the wide dissemination of Copper ores in the Quebec Group of Canada, it appears at the first blush singular, that more extensive deposits of this metal should not have been discovered in rocks of the same age in New Brunswick; yet, when it is considered that the copper ores of Lower Canada have only recently been worked on a large scale, it is not surprising that a similar sparsely peopled area in New Brunswick, by far the greater portion, indeed, being still a thickly wooded wilderness, should have given but very little evidence of the presence of the metal in remunerative abundance. It is unfortunate that all the works which have been undertaken for the extraction of Copper in the rocks of the Quebec Group in this Province should have been temporarily abandoned.

Here, as in Canada East, the copper appears to have been originally deposited with the sedimentary rock in which it is found, being afterwards segregated in veins or bunches, or remaining diffused throughout the country rock.

On the Tattagouche the original matrix of copper appears to be the red slates, which also carry the iron and manganese ores; at the Falls of the Nipisiguit it is a porphyry; and lower down the river, some four miles above the Pabineau Falls, copper ores occur in green slates. On Campbell River they are contained in a diorite; at Jacksontown, the red and green argillites sometimes shows ores of copper. On Bull's Creek, they occur in a diorite, also in a green talcose schist, at Bedell's Cove, near Woodstock, the mother rock was not seen,* but the copper is associated with much iron pyrites. On the east side of the river, on Mr. Connell's farm, small quantities of sulphuret and purple copper have been found in a vein of iron pyrites penetrating a green silicious rock interstratified with green talcose and ferruginous slates.

In the neighbourhood of Woodstock copper ores appear to be widely disseminated, and from the appearance of the ores obtained from Mr. Stevens' mine on Bull's Creek, at Bedell Cove, and at Mr. Connell's vein, it seems probable that remunerative deposits will be found in that vicinity. But in order to form an opinion as to their commercial value, the rocks of that neighbourhood must be carefully studied in connection with the supposed origin of the copper deposits in these ancient sediments. (See page 145.)

CHANGES AT THE SURFACE OF A VEIN.

The change which is often observed to have taken place at the surface of metalliferous deposits is sometimes very considerable, and may penetrate to a great depth. In other instances the vein stone is harder than the country rock, and has resisted the decomposing influence of the atmosphere and water.

Among numerous illustrations which have come under my notice during the past season in this Province, the following are perhaps the best illustrations:—

I. The Antimony lodes of Prince William; these in most cases are persistent, and the lodes are stronger than the country rock, they have resisted decomposing influences, and stand out from the surface in the form of ridges.

II. The beautiful ochres on Frye's Island indicate a complete and deep decomposition of the veins, the influence of decomposing agents has penetrated many feet into the lodes.

III. Some of the copper lodes at the Vernon mines have been much decomposed, what is there termed the green vein shows decomposition to a considerable depth, the resulting ore is the green carbonate. It changes gradually to the sulphuret, and at a depth of 25 or 30 feet will probably disappear altogether, giving place to the sulphuret.

IV. The copper ores in the green slates above the Pabineau Falls on the Nipisiguit are replaced to a considerable extent by "gossan," but it is probable that at the depth of a few feet the gossan will gradually give place to copper pyrites. The same remark applies to some ores near Woodstock.

* These last named localities have been opened by Mr. Stephens of Woodstock.

The explanation of these changes is simple. Copper pyrites is composed of sulphide of copper and sulphide of iron, (two parts copper, one part sulphur, associated with two parts iron and three parts sulphur.) By contact with air and moisture, the copper pyrites is decomposed, the iron remains behind as an impure hydrous oxide or gossan. The copper is frequently removed from the surface by water after having been converted into the soluble sulphate, the sulphuric acid being derived from the oxidation of the sulphuret of iron, the original ore. At depths remote from atmospheric influences the copper pyrites remains intact, hence the reason why lodes which show much gossan at the surface gradually change in character, yielding more and more copper ore, until the gossan is altogether replaced by the original ore of the lode.

THE ANTIMONY DEPOSITS OF PRINCE WILLIAM.

The most important deposits of this metal are in Prince William Parish. It has been stated that this ore also exists on the north west side of the granitic axis, about thirteen miles from Woodstock, but nothing is known of the extent of this deposit. Fine specimens of ore have been presented to me from a vein near Canterbury Station, on the Saint Andrews Railway, but the precise locality where the ores occur was not given.

From a trial survey which was made some years since as far as the Pokiok, for a Railway from Fredericton to Woodstock, it appears that the elevation of the Prince William deposits above the sea is about 460 feet. The survey crossed the road leading to Lake George, a short distance from them, at an elevation of 477.97 feet. The greatest altitude over which the Survey passed between Lake George and the Mines being 490 feet. Lake George is 442 feet above the sea, and about 400 feet above the Saint John River, where the ore is shipped.

As these deposits of Antimony are very remarkable and give promise not only of remunerative results to the present lessees, but of important advantages to the Province, leading to the expenditure of capital and the profitable employment of labour, I have given special attention to them, and have endeavoured to supply as full a description of the works now in operation, of the results which have already been obtained, and of the prospects in view, as the limits of a preliminary Report would permit.

The development of these deposits has been almost altogether confined, latterly, to the operations of the Brunswick Antimony Company, the works on a neighbouring lease, owned, I was informed, by Messrs. Hibbard & Co. of Saint George, having been for some time suspended, but for what reason I could not learn, certainly not on account of the paucity of the mineral on their property, as a cursory examination satisfied me of its existence over wide areas.

In the vicinity of the Antimony Mines in Prince William, the rock is a magnesian slate, interpenetrated with quartz veins. The roof or hanging wall of the lodes is frequently highly magnesian and contains thin layers of

steatite or impure silicate of magnesia. The strike of the foot wall and occasionally of the roof wall does not coincide with the course of the vein as a general rule, although there are instances showing parallelism. The rock has been subjected to a series of dislocations, one set running roughly parallel to one another, the other set cutting the first at a small angle, but some time must elapse before a sufficient area of rock surface will be exposed to determine the general direction and relation of these dislocations with precision; but it is probable, however, that one set has a course of N. 50° W. and another set a course 10 to 20 S. which most nearly coincides with the prevailing strike of the rock. The cracks and dislocations to which reference is now made, are of the utmost importance in forming a judgment respecting the capabilities of these antimony deposits, for *the antimony lodes occupy the fissures caused by the dislocations.*

CHARACTER OF THE DISLOCATIONS.

It will be seen by an inspection of the diagrams which accompany this Report, that even with the very imperfect explanations which have as yet been made, the course of one dislocation can be traced without any difficulty for more than five hundred yards, and if it should result that what are now set down provisionally as parallel dislocations, are in fact continuous, the ascertained length will exceed five times that distance, or considerably more than a mile.

In Pit No. 1 there are apparently two veins inclined towards one another at a low angle, dipping N. E. and separated by a mass of rock, which is probably a slip or "horse" as it is technically termed.

The so called "roof vein" in this Pit is a thin sheet of antimony ore and quartz of unknown length and depth. Its thickness varies from a few inches to more than two feet. It dips to the N. E., and it changes its course in the space of twenty feet from S. 50 E. to S. 75 E. The so called "floor vein" in this shaft dips in the same direction at an angle of 55°, and meets or joins on the roof vein 68 feet below the surface, measured along the incline. Here the veins at the point of junction have respectively a thickness of one foot five inches and two feet, with a magnificent show of sulphuret of antimony, mixed with 'metallic antimony,' in parallel streaks from two to six inches in thickness. These two veins may be described as two sheets of rich metalliferous quartz filling two fissures which join together at a depth of nearly 70 feet on the incline below the surface, continue as separate sheets for an unknown horizontal distance in a southeasterly direction, but form one sheet at the present depth of the mine of unknown extent downwards, and but one sheet in a westerly direction where they have been traced for forty feet, five feet below the surface.

The dip of the 'roof vein' rock is 53° easterly, of the 'floor vein' rock 60° westerly, thus showing an *anticlinal axis* and a *downfall*.

The slickensided appearance of the surfaces shows the pressure to which the rock has been subjected during its displacement. It is also worthy of

note, especially in relation to the origin of these veins, that not unfrequently rounded and angular pebbles are found in the ore. On breaking open masses I have succeeded in obtaining pebbles which appeared to belong to the country rock, and "horses" are by no means uncommon. These facts are important so far as they tend to show that the fissure in which the vein is segregated is probably of great depth and of very considerable horizontal extension. Above the roof vein there is a layer of steatite about two inches thick, it accompanies the vein all the way down to the bottom of the shaft.

The sheet of ore in the upper vein varies from four inches to two feet in thickness, and consists of sulphuret of antimony seamed with quartz, but masses or seams of the sulphuret, with a little 'metallic antimony,' occur in the vein from two inches to seven inches in thickness, sometimes also expanding into bunches eighteen inches in diameter. The country rock in this shaft is a silicious magnesian slate, the magnesian character preponderating in places so as to form an impure steatite, especially immediately above the vein rock.

Patches of Chlorite are seen in the quartz, which is also coloured red in spots by the decomposition of Iron pyrites. Minute veins of antimony penetrate the country rock as well as small quartz veins, and occasionally streaks of the brilliant oxy-sulphuret appear in small lateral fissures.

PIT No. II.

The fissures occupied by the veins opened at Pit No. II. intersect one another in two places. At the point of junction of the main vein and a transverse vein the shaft has been sunk 34 feet on the incline, which is at an angle of 45° to the N. E. But owing to the approach of winter, and a desire to increase the works in shaft No. 1, the miners had been withdrawn from it, and at the time of my visit it was full of water.

The veins, however, being covered with a sandy drift to a depth not exceeding three feet are easily exposed, and were seen for 100 yards on the main lode and sixty yards on the transverse lode. The antimony in these lodes varies from half an inch to 26 inches in thickness, and is a tolerably pure sulphuret.

PIT No. III.

At the third opening, or "Pit No. III," which, according to the mining Captain, is 490 yards from Pit No. I, the strike of the vein is N. 55 W. with a N. E. dip, at an angle of 35° . Here the conditions under which this lode has been made visible to the eye are most remarkable, and constitute a very singular and probably a very unusual feature in mining locations, south or east of Lakes Huron and Superior. Upon the removal of the shallow surface covering of loam or sandy clay, the country rock, together with the huge quartz veins which mark the lines of fracture and dislocations have been striated and polished by glacial action. The soft magnesian and chloritic slate is deeply scored with parallel or slightly divergent grooves, and the hard quartzose antimony veins are polished on the surfaces which have come in contact with the slowly moving glacial mass. For many miles

around this neighbourhood the same glacial markings are visible. I have no doubt that Lake Saint George itself with the flat valley to the south of it, is a memento of the wonderful excavating power of glacial ice. The grinding down and polishing of the surface of the country, coupled with the almost entire absence of drift here, at least to a greater depth than from three to six feet, will enable the practical miner to trace out without difficulty the lines of dislocation and the antimony veins occupying them. Their position on the surface may then be laid down with perfect accuracy on a chart or map of the several properties, by any qualified land surveyor. None of the dislocations, as far as they have been exposed, appear to have been so affected by subsequent disturbances as to make the recovery of a vein, if lost, a matter of much difficulty or expense, and if a vein should be lost the plan will be to go at once to the surface, clean it from drift, and endeavour by aid of the glacial polishing to discover the extent and direction of the "jog."

The vein at the 3rd Shaft is very quartzose, and a considerable proportion of iron pyrites was observed here, which discolours the rock at the surface. Reticulating veins of quartz penetrate it, together with minute veins of antimony. The thickness of the lode varies from two to three feet, and some fine antimony ore was taken out in a blast during my visit, which dislodged a mass 22 inches in thickness, at a depth of 24 feet on the incline.

A "horse" is plainly visible occupying a portion of the fissure to the east of the pit, and the quartz is seen to surround it. The "horse," which is the country rock, must have fallen into the fissure before the metalliferous quartz was introduced. Another instructive and valuable fact is observed at this shaft. As the vertical strata approach the lode at the bottom of the shaft they are curved to the southeast, showing a movement in that direction from the northwest. The rock surfaces are slickensided by pressure. Immediately over the vein the soft impure steatite is visible from half an inch to two inches in thickness; it contains fragments of slate, and is overlaid by a crushed portion of the rock of variable thickness, from three to twelve inches; this is succeeded by the tilted edges of the magnesian slate. These observations show the prevalence of a lateral force acting subsequently to the filling up of the veins, and are worthy of being recorded, as the influence of this force may have operated more energetically at other localities, and occasioned faults or minor dislocations which might not be apparent or easily worked out without this guide.

Probable extent and richness of the Ore.

The reader who is familiar with the origin of dislocations in strata, will be at no loss to understand that the fissures which have resulted from them may be of very great vertical depth and extend over long horizontal distances. The cause, however, may on the other hand be local, and although the depth of the fissure may be great, its horizontal prolongation might possibly not extend over many hundred yards. In the present case the number, breadth and parallelism of the fissures, coupled with the fact that

veins of ore have been discovered in one prevailing direction for considerably more than a mile, afford sufficient evidence of the great extent of the antimony bearing veins in the area to which this report refers. Their depth too, the axis being anticlinal, with a downfall, doubtless extends through the Lower Silurian rocks in which they are situated, and these may be here, as elsewhere, of very considerable thickness, as the following observations show. About half a mile east of the mines a green talcose conglomerate holding black slate pebbles appears in position, this is thought to be one of the upper members of the Quebec Group. The talcose and chloritic slates in which the antimony veins occur appear to underlie this conglomerate, and as the entire series of which the Group is composed has been recognized during the past summer on the southeast side of the great fold which brought them to the surface, it is probable that the thickness of the series below the antimony slates is still several thousand feet. That this question is one possessing considerable interest, in connection with the probable duration of the antimony deposits in this vicinity, becomes manifest upon a review of the rapidity with which mining operations conducted on a large scale penetrate the rocks vertically. The Albert Mines for instance, though of recent origin, have worked out the Albertite on a horizontal distance of 1700 for a depth of 750 feet, and the new shaft now nearly completed will bring Albertite from a depth of one thousand feet.

With respect to the quality of the ore, it may be stated with confidence that it improves as the workings descend. The most common form in which it has been obtained until very recently was that of Stibnite or Grey Antimony Ore,* but in Pit No. 1, at a depth of 60 feet, there was found to be a considerable admixture of 'metallic antimony' with the sulphuret. This native antimony has a brilliant metallic lustre with the characteristic tin-white streak. It occurs in the lamellar form and gives a peculiarly brilliant appearance to the mass. It has been found in a vein fully six inches in diameter, in which the native metal was mixed with the sulphuret with a very small proportion of quartz. It is remarkable that the deposit of antimony recently discovered in the Quebec Group of rocks in the township of Ham, Canada East, should also occur chiefly as lamellar native antimony.

NICKEL AND COPPER.

Associated with these antimony ores are small quantities of the green silicate of nickel, and on the surface the green carbonate of copper. Ores of nickel in small quantities are very common in the rocks of the Quebec Group, especially in the magnesian slates.

The production and uses of Antimony.

The quantity of this metal produced from American mines is extremely small. The recently discovered ores in Australia, although of great extent and richness, are too far from the markets of the world to exercise any influence upon them.

* Composed of Antimony 74: Sulphur 26 in 100 parts.

The importations of antimony into Great Britain * during the years 1855 and 1856, the latest accessible returns were as follows:—

	1855.	1856.
Ores,	623 tons.	1,750 tons.
Crude,	639 cwts.	3,121 cwts.
Regulus,	11 “	1,004 “

Its uses in the arts are rapidly increasing, and it has been long employed in the manufacture of fine pewter, Britannia metal, type metal, stereotype metal, music plates, machinery bearings, particularly in cases of continuous revolution, as in the shafts of screw steamers, &c. It is also used for hardening bullets and shot, and to a small extent for medicinal purposes, &c. &c.

Now that an abundant supply of this metal can be obtained at a small cost from the deposits of antimony in this Province, it is probable that many new uses may soon be discovered.

FAVOURABLE CIRCUMSTANCES CONNECTED WITH THE DISTRIBUTION OF THE ORES.

The circumstances attending these deposits of antimony are singularly favorable towards their development. It may be advantageous to enumerate the most striking; they are—

1st. The geological position of the ores, or in other words their occurrence in the metal bearing group of North America.

2nd. Their occurrence on lines of fracture and dislocation, proving the veins to be ‘true veins’ of unknown vertical depth and horizontal extension.

3rd. The purity of the grey antimony ore and its gradual passage into lamellar native antimony as the veins deepen.

4th. The accessibility and the ease with which they may be reached from the seaboard.

The term regulus signifying “the little King,” was first applied to antimony from the facility with which that metal alloyed with Gold. The alchemists had great hopes that antimony would lead them to the discovery of the philosophers’ stone. The name is now applied to other metals in an impure state. Among the most important alloys of antimony are—

1. Two parts sulphide of antimony with one of iron, forming what was once called Martial Regulus. This alloy possesses magnetic properties.

2. Antimony and zinc—a hard brittle alloy.

3. 1 antimony, 10 tin forms a ductile compound.

4. 12 tin, 1 antimony, with a little copper, forms a fine pewter.

5. Type metal—4 parts lead, 1 part antimony, or 3 lead, 1 antimony.

6. Britannia metal—100 tin, 8 antimony, 2 bismuth, 2 copper.

The specific gravity of antimony is 6.7; it melts at about 840°, or at a dull red heat; the sulphuret has generally a specific gravity of about 4.96.

* Antimony was formerly mined extensively in Great Britain, but during the present century little has been produced. The grey ore from which commerce is supplied comes from Hungary and Borneo. Cornwall formerly produced a considerable quantity of the ore. Native antimony occurs in Canada East, Sweden, the Hartz Mountains in Germany, Dauphiny, Mexico, and, as recently ascertained, in New Brunswick.

LEAD ORES.

Galæna is not uncommon in this Group of Rocks, but no instance, to my knowledge, has been recorded where a vein occurs within the limits of the northeastern belt which promises remunerative results. There is a vein at the foot of Bradley's Island, on the Tobique, but it is not promising, so far as it has been exposed. It is not yet known what may be the precise age of the rocks in Hammond and Upham, where a large vein of Galæna has been traced continuously for about three miles, but the rocks are probably Middle or Lower Silurian, and if the latter, they will belong to the Quebec Group. In Canada, lead ores from this group, have yielded 32 ounces of silver to the ton, equal to five tenths per cent. Eight ounces of silver to one ton of lead ore will pay for extraction in England; this ore, therefore, might perhaps be profitably exported if it occurs in sufficient quantity—other lead ores in Canada, like similar ores in the United States, have yielded little or no silver. (See page 116.)

ZINC ORES.

Zinc Blende or Sulphuret of Zinc occurs in Prince William Parish. A vein in a gangue of quartz may be seen below the road in a gully on Marshall's farm, where an attempt has been made to blast the rocks in search of gold. No special examination has been made of this deposit with a view to see if it possesses economic value, but the impression produced by the specimens obtained was not favourable.

GOLD.

Mr. C. H. Hitchcock reports the existence of an auriferous belt which crosses the Saint Croix River above Calais. This is a part of the southern belt of the Quebec Group. The rock is a mica schist full of quartz veins and beds. Several pieces of bright flake gold were found in these veins near the Railroad bridge at Baileyville. On the New Brunswick side of this river, upon land belonging to Mr. Boulton of Saint Stephen, gold has been found in a black plumbaginous slate. The occurrence of gold in drift in many parts of the Province will be noticed in the next Chapter.

SILVER.

The boulders of jasper conglomerate which occur on the Saint John above Presquile, and are numerous on the Shiktehawk road, probably come originally from the northeast of the Shiktehawk. This rock promises well; but although the jasper rocks were noticed on Campbell River, and a jasper conglomerate on Blue Mountain, no rocks have been seen in place which approach the beauty of some of the boulders noticed on the Shiktehawk Portage. In one of these boulders a small fragment of native silver was seen, which appeared to form part of a vein running through the mass. The specimen (six inches in diameter) was unfortunately left on a birch stump not far from the Glassville Settlement, on the road to the north west branch of the Miramichi.

SECTIONS OF THE GROUP, SHOWING THE GENERAL ARRANGEMENT OF THE STRATA.

The importance of this great group of rocks will render acceptable a brief description of the order and sequence of the strata of which it is composed, as they occur in Canada.

The following is a section of the strata on the Island of Orleans* :—

SEQUENCE OF THE STRATA OF THE QUEBEC GROUP ON THE ISLAND OF ORLEANS.

1. Green calcareo-magnesian shales, weathering to a yellowish or reddish brown, interstratified with thin bands of purplish grey argillaceous shale. Some of the magnesian shales are nearly grass green, and the surfaces of most of the green beds are marked with fucoid-like forms of purplish grey; the green shales hold about twenty per cent of dolomite. The mass is strong, and offers considerable resistance to wearing influences,	} LEVIS FORMATION. MAGNESIAN SHALES.	100
2. Grey argillaceous shale, much softer than the magnesian shale,		100
3. Grey limestone conglomerate; the rounded masses are chiefly of grey limestone; the matrix in many parts weathers to a brownish color, and is probably dolomitic, fossils occur, some of them replaced by silica, but those as yet obtained in this locality are too obscure to be determined; the land in some parts appears to break into lenticular patches,	} DOLOMITIC CONGLOMERATES.	10
4. Green yellow weathering calcareo magnesian shale, with grey argillaceous bands of the same character as 1,		100
5. Grey soft argillaceous shales,		200
6. Yellowish-grey dolomites, weathering orange brown. It holds occasional masses of ash grey limestones, and in some parts of its thickness a multitude of pebbles of quartz as large as peas, and becomes towards the top a dolomitic sandstone,		70
7. Grey, fine, soft, argillaceous shale, with compound graptolites (<i>Phyllograptus typus</i>) about thirty feet from the summit,	} GRAPTOLITIC SHALES.	170
8. Grey limestone conglomerate; the matrix in some parts weathers to a reddish-brown, being dolomitic, and contains a large concretion of carbonate of lime in concentric fibrous layers like travertine. The land holds fossils in some places,		35
9. Grey, fine, soft, shale, with occasional bands of sandstone weathering brownish, none of them over six inches; the bands increase in number towards the top,		500
10. Olive-green argillaceous shale, striped with purplish-grey bands,		400
11. Olive-green arenaceous shale, with disseminated soft grains of a green mineral resembling glauconite, and approaching it in composition. In the upper part of the deposit, the shale contains so much grit as to become almost a sandstone; and within 100 feet of the top, it assumes a red colour, in one or two bands,	} GLAUCONITE BEDS.	400
12. Yellowish-white limestone conglomerate; matrix assumes a dolomitic aspect in some parts; the rounded masses or boulders are occasionally one or two feet in diameter, and some parts of the beds hold fossils,		10
13. Grey, drab-weathering sandstones, in general slightly calcareous, interstratified with grey argillaceous shales; some of the sandstone beds towards the bottom are three or four feet thick, and }	GREY SANDSTONES.	

* From the Geology of Canada—Sir W. E. Logan.

	hold occasional calcareous pebbles. The sandstone becomes thinner ascending, and then the shales prevail; but these become by degrees, more and more arenaceous, and a band or two, about 200 feet from the top, assumes a red colour,	400	
14.	Grey limestone conglomerate; the matrix weathering to a brown in some parts is probably dolomitic,	80	
15.	Grey drab-weathering sandstones and shales, the sandstones slightly calcareous,	300	
16.	Dark grey and green shales, with thin bands of quartzite, and occasional thicker beds of drab-weathering sandstone, some of them being lenticular masses; the dark shales appear in some parts to pass into black,	900	DARK SHALES AND QUARTZITES.
17.	Red and green shales, the red prevailing, interstratified with occasional thin layers of grey, hard sandstone or quartzite, and a few of grey hard limestone; some of the bands of shale are deeper red than the general mass, approaching the maroon colour. Towards the top of the equivalents of these shales at Cape Rouge, occur a small <i>lingula</i> and <i>Obolella pretiosa</i> ; the thickness of the deposit is from 1,500 feet to	1000	
			5,025 feet.

PHILLIPSBURG SERIES IN ASCENDING ORDER.*

A. *

1.	Dark gray and yellowish-white dolomites, weathering grey and yellowish-brown,	Feet. 400	
2.	White and dove-grey pure compact limestones,	100	
3.	Reddish-grey brown-weathering dolomites, and black dolomites, with some thin-bedded limestones,	200	
		—	700

B.

1.	White and dove-grey pure limestones, with some yellowish weathering magnesian bands,	120	
2.	Dark grey and black limestones, some of the beds magnesian,	120	
3.	Dark bluish-grey thin bedded nodular limestones with thin layers of bluish-grey slate, probably magnesian; the surfaces of some of beds weathering into a red or yellow ochreous arenaceous earth,	150	
4.	Black slaty thin bedded nodular limestones, with two or three thick beds of purer limestones towards the base,	300	
5.	Black limestones, some of them massive, weathering bluish-grey, interstratified towards the bottom with black and dark grey yellow-weathering magnesian beds,	350	
		—	1,040

C.

1. Black and dark grey pure compact limestones, weathering lead-grey with a few bands of dove-grey. The beds are all massive, and afford abundance of a few species of testaceæ; the whole of which appear to have the peculiarities of being large-sized and thick-shelled, and occurring in numerous isolated patches, which vary in diameter from about three to ten feet. The fossils are several

* The details of Divisions A and B are given on pages 275, 279, of the Geology of Canada. Phillipsburg is in Canada East near the northern extremity of Lake Champlain.

- underscribed species of *Murchisonia* and *Pleurotomaria*, *Eccilomphalus Canadensis*, *E. intortus*, *E. spiralis*, several undescribed species of *Ophileta*, *Maclurea ponderosa*, several undescribed species of *Othoceras* and one of *Nautilus*. Toward the base, *Maclurea ponderosa* seems to be somewhat smaller than in the upper part of the deposit, and towards the top one or two beds appear to be of a partially conglomerate character, 150
2. Black slates or possibly thin bedded limestones, with a few thicker beds towards the top; the mass is altogether very imperfectly seen, 170

320

D.

1. Black limestone conglomerate, composed chiefly of the ruins of the thick bedded limestones of division C. The enclosed masses vary in size from pieces of an inch in diameter, to blocks containing between fifty and sixty cubic feet, and are cemented together by a calcareo-magnesian paste. Of this, however, from the closeness with which the masses are packed together, there is but a very small quantity. The limestones are generally close grained, and black or dark in color, but there are mingled with them a few scattered blocks of a lighter colored yellow, weathering dolomite, some of them a foot in diameter. Many of the masses of limestone contain fossils, and the species are almost wholly confined to those already stated as characterising the parent beds C 1. There appears to be at least two principal bands of this conglomerate, each varying in thickness in different parts from about 50 to 100 feet. There is an interval between them of from 100 to 150 feet occupied by black slates holding round masses of limestone, which converts parts of the mass varying in thickness from ten to twenty feet into slaty conglomerates. In some parts, either the interval between the main two bands of conglomerates increases considerably, or there is a third band with similar slates intervening between it and the second. The whole is continued in a thickness of from 250 to 300 } CONGLOMERATES
2. Black and greenish argillaceous slates, probably interstratified with occasional thin calcareous bands, and thin lenticular patches of limestone conglomerate, as well as more important bands of yellow-weathering dolomitic slates. The whole is terminated by a band of black limestone conglomerate, similar in character and thickness (from 50 to 100 feet) to those already mentioned, and containing *Maclurea ponderosa* in one of the few places in which the band has been seen. This whole mass of strata is very imperfectly exposed, and much uncertainty exists as to its true general character. Its thickness may be from 750 to 1000 } CONGLOMERATES
3. Grey and black striped slates, some parts of which are calcareous, and weather slightly brownish. They are interstratified with occasional thin beds of black limestone, weathering lead-grey, as well as many strong and solid beds of brown weathering magnesian limestone, and brown weathering slates, some of the latter are marked by an abundance of fucoids resembling *Buthotrephis flexuosa* of Emmons. Occasional beds of sandstone, from one to three feet in thickness, are met with. About the middle of the mass, there has in one place been observed a bed of limestone conglomerate from five to ten feet thick, and other similar ones may occur in different parts of the vertical thickness, 1500 } DOLOMITIC SLATES.

The general absence of deep deposits of clays, sands, and gravel, in other words of Drift, appears to be a prevailing feature in the surface Geology of the Province. On the upper Saint John, above the Grand Falls, there are banks of alluvial clays and sands exceeding fifty feet in thickness, and opposite Salmon River immense deposits of coarse gravel form the cliff like

banks; so also on the Upsalquitch, extensive deposits of coarse gravel interstratified with fine sand are numerous, and the same features are observed on the Saint John nearly all the way to its mouth; these, however, are all of more recent origin than the true boulder formation, although it is probable that they consist in part of remodelled drift. Even on the dividing ridge between the waters of the Upsalquitch and Nipisiguit, the drift appears to be of local origin, and has been, on the portage at least, re-arranged, showing three or more distinct terraces. Nearly all the boulders observed during the past summer were of local origin, or could be traced to rocks in position some few miles to the north; and it may, with some degree of confidence be stated, that very few, if any, boulders deriving their origin from the Laurentian rocks of Canada have been seen during the past summer, even on the higher levels and in the most northern Counties of the Province, without an exception be made of the country about the upper Saint John near the Province line. In the Gaspé peninsula no foreign boulders have as yet been observed in the boulder formation; which there appears to be altogether composed of the debris of the rocks of the country.* This may arise from two causes,—1st. The direction of the ice flow, and subsequently of the drift currents;—2nd. The distance from the northern rocks taken in connection with the direction of the ice flow.

It must not be inferred from the foregoing remarks that boulders are generally absent in the Province, the contrary is really the case, but they are nearly all, if not altogether, of local origin; that is to say, the parent rock from which the boulders originated may almost invariably be found a few miles in a northerly direction from the spot where they lie.

THE BOULDERS SOUTH OF THE GRANITE.

Any one who has travelled on the southern edge of the numerous narrow granitic belts which stretch from the Atlantic coast of Maine to the Bay of Chaleurs, can scarcely fail to have been struck with the vast multitude of granitic boulders which cover the country for some miles in a southerly direction. But if he travel on the northern side of the belt, he will rarely find one granitic boulder. So also when descending some of the rivers, especially those which flow in a general direction from north to south, such as the different branches of the Miramichi, the number and magnitude of the boulders in the beds of those streams when passing through and a little beyond the granitic region, are truly astonishing. In the rear of Fredericton, the southwest side of the plateau and even part of the sides of the valley, are strewed with a multitude of boulders, these are chiefly derived from the sandstones of the Carboniferous rocks, but there are some trap boulders from the trap range in Douglas Parish, some red conglomerate boulders, from the Bonaventure formation on the north side of the River, and also a few of Silurian slate, and a few of white granite. All of these boulders, with the exception of some of the sandstones, must have crossed the valley of the

* Geology of Canada, page 929.

River Saint John, travelling in the direction of the valley of the Nashwaaksis, as will presently be shewn.

These boulders have been brought to their present position by glacial ice. It was formerly very generally supposed that floating ice was the chief instrument in the transportation of boulders, and that glacial ice played but a very small part in these wide spread phenomena, but proof upon proof has accumulated that floating ice is utterly incompetent to effect a tithe of the vast mechanical work apparently inseparable from those conditions always accompanying the true boulder drift.* That water and floating ice have played a great part in distributing the loose materials, previously disengaged by glaciers, over different parts of the globe there can be no question, but the first active agent was glacial ice, and subsequently water, or water and floating ice may have assisted in spreading the debris accumulated by the glacial masses.

CURRENTS INCOMPETENT TO PRODUCE LARGE BOULDERS.

Erratics or Boulders have been frequently adduced as evidence of the influence of currents, assisted by atmospheric agencies. Their rounded appearance has been attributed to weathering, or the attrition caused by running water, or the waves of the sea on a beach.†

It is well known that rounded boulders which would weigh *many hundred tons* are by no means uncommon. These are generally observed to be rounded or worn on all sides, showing that every part of them has been exposed to the grinding force. Sometimes the boulders are observed to be striated or scratched on one side only, thus affording sufficient proof of their origin. No one has ever seen torrents in our rivers sufficiently powerful to move boulders two or three feet in diameter—a *debacle* might cause motion for a short distance. But boulders *in glacial ice* can be seen at any time, not only in Greenland but in many glacial regions, and the actual process of rounding by attrition may be observed.

Mr. T. W. Taylor in his paper on the "*Fjords of South Greenland*,"‡ tells us that "the glaciers bring down with them boulders, sand, and much fine clay, the result of attrition; the *boulders are always rounded*, owing to the severe abrasion they have undergone by being transported over the rocks below, whilst under the enormous pressure of the vast thickness of continental ice."

Another important point connected with boulders is, that rounded masses are frequently to be met with in vast multitudes within a few miles of the parent rock and to the south of it, even when the parent rock is a low

* Under the term "true Boulder Drift" is meant the unmodified drift, that is to say Boulder Drift which has not been re-arranged since it was first deposited, whether by glacial ice or water, or both.

† Boulders of native copper have been found in the Lake Superior region; of copper pyrites in New Brunswick, and boulders of hæmatite and black magnetic oxide of iron of large dimensions are by no means uncommon.

‡ Proceedings of the Royal Geological Society, January 28, 1861.

glaciated ridge, scarcely rising above the general level of the country. This is observed south of a considerable part of the Granitic Belts of New Brunswick. It has been already remarked that all the boulders, and they are legion, of New Brunswick, are of local origin; it may be that on the Gulf Coast a few Laurentian erratics have been brought by ice, but in the interior those rocks are not represented even by erratics. All the large river valleys leading into the Atlantic, from New Brunswick and Maine, are probably in part due to glacial action; for glacial striæ and moraines have been observed in most of them, following the course of the valleys near the sea.

THE COUNTRY OF BOULDERS.

The country *par excellence* of Boulders, is the Labrador Peninsula. During an exploration of part of its interior in 1861, I had an opportunity of observing the extraordinary number and magnitude of erratics in the valley of the Moisie River and some of its tributaries, as far north as the south edge of the table-land of the Labrador Peninsula (lat. $51^{\circ} 50' N.$, long. $66^{\circ} W.$), and about 110 miles due north of the Gulf of Saint Lawrence. Boulders of large dimensions, 10 to 20 feet in diameter, began to be numerous at the Mountain Portage, 1460 feet above the sea, and 60 miles in an air-line from the mouth of the Moisie River. They were perched upon the summits of peaks estimated to be 1500 feet above the point of view, or nearly 3000 feet above the sea-level, and were observed to occupy the edges of cliffs, to be scattered over the slopes of mountain-ranges, and to be massed in great numbers in the intervening valleys.

At the "Burnt Portage" on the northeast branch of the Moisie, nearly 100 miles in an air-line from the Gulf of Saint Lawrence, and 1850 feet above the ocean, the low gneissoid hills for many miles round were seen to be strewed with erratics wherever a lodgment for them could be found. The valleys (one to two miles broad) were not only floored with them, but they lay there in tiers, three or more deep. Close to the banks of the rivers and lakes near the "Burnt Portage," where the mosses and lichens have been destroyed by fire, very coarse sand conceals the rocks beneath, but on ascending an eminence away from the immediate banks of the river the true character of the country becomes apparent. At the base of the gneissoid hills which limit the valley of the east branch (about three miles broad) at this point, they are observed to lie two or three deep, and although of large dimensions, that is from 5 to 20 feet in diameter, they are nearly all ice worn, with rounded edges, and generally polished or smoothed. These accumulations of erratics frequently form tongues, or spots, at the termination of small projecting promontories in the hill-ranges. I have several times counted three tiers of these travelled rocks where the mosses, which once covered them with a uniform mantle of green, had been burnt; and occasionally, before reaching the sandy area which is sometimes found on the banks of the river, I have been in danger of slipping through the crevices between the boulders, which were concealed by mosses, a foot and

more deep, both before and after passing through the "Burnt Country," which has a length of about 30 miles where I crossed it. I extract the following note from my Journal of the appearance of these travelled rocks in the "Burnt Country":—

'Huge blocks of gneiss and labradorite lie in the channel of the river, or on the gneissoid domes which here and there pierce the sandy tract through which the river flows. On the summit of the mountains, and along the crest of the hill-ranges, about a mile off on either side, they seem as if they had been dropped like hail. It is not difficult to see that many of these rock-fragments are of local origin, but others have evidently travelled far, on account of their smooth out-line. From a gneissoid dome, I see that they are piled to a considerable height between hills 300 and 400 feet high; and from the comparatively sharp edges of many around me, the parent rock cannot be far distant.'

THE GLACIATED REGION ABOUT CARIBOO LAKE.

On all sides of Cariboo Lake, 110 miles, in an air-line from the Gulf, and 1870 feet above it, a conflagration had swept away trees, grasses, and mosses, with the exception of a point of forest which came down to the water's edge and formed the western limit of the living woods. The long lines of enormous unworn boulders, or fragments of rocks, skirting the east branch of the Moisie at this point were no doubt lateral glacial moraines. The coarse sand in the broad valley of the river was blown into low dunes, and the surrounding hills were covered with millions of erratics. No glacial striæ were observed here, but the gneissoid hills were rounded and smoothed at their summit; and the flanks were frequently seen to present a rough surface, as if they had recently been exposed by land-slides, which were often observed, and the cause which produced them, namely frozen waterfalls.

No clay or gravel was seen after passing the mouth of Cold-water River, 40 miles from the Gulf, and 320 feet above it. The soil, where trees grew, was always shallow as far as observed; and although a very luxuriant vegetation existed in secluded valleys, yet it appeared to depend upon the presence of labradorite-rock or a very coarse gneissoid rock, in which flesh coloured felspar was the prevailing ingredient.

BOULDERS IN OTHER PARTS OF THE PENINSULA.

Observers in other parts of the Labrador Peninsula have recorded the vast profusion in which erratics are distributed over its surface. There is one observer, however, well known in another branch of science, who has left a most interesting record of his journey in the Mistassinni country, between the Saint Lawrence, at the mouth of the Saguenay, and Rupert's River, in Hudson's Bay. Andre Michaux, the distinguished botanist, traversed the country between the Saint Lawrence and Hudson's Bay in 1792. He passed through Lake Mistassinni; and in his manuscript notes, which were first printed in 1861, for private circulation, at Quebec, a brief description of the journey is given.—"The whole Mistassinni country," says Michaux, "is

cut up by thousands of lakes, and covered with enormous rocks, piled one on the top of the other, which are often carpeted with large lichens of a black colour, and which increases the sombre aspect of these desert and almost uninhabitable regions. It is in the spaces between the rocks that one finds a few pines (*Pinus rupestris*,) which attain an altitude of three feet; and even at this small height showed signs of decay."

The remarkable absence of erratics in the Moisie, until an altitude of about 1000 feet above the sea is attained, may be explained by the supposition that they have been carried away by icebergs and coast-ice during a period of submergence, to the extent of about 1000 feet. I am not aware that any traces of marine shells or marine drift have been recognized north of the Labrador Peninsula, at a greater elevation than 1000 or 1100 feet. In the valley of the Saint Lawrence marine drift has not been observed higher than 600 feet above the sea. Glacial striæ were seen on the "gneiss-terraces" at the "Level Portage," 700 to 1000 feet above the sea. The sloping sides of these terraces are polished and furrowed by glacial action. Grooves half an inch deep, and an inch or more broad, go down slope and over level continuously. It is on the edge of the highest terrace here that the first large boulders were observed.

The entire absence of clay, and the extraordinary profusion of both worn and rugged masses of rock piled one above the other in the valley of the east branch of the Moisie as we approached the table-land, led me to attribute their origin to local glacial action, as well as the excavation of a large part of the great valley in which the river flows. Its tributary, the Cold-water River, flows in the strike of the rocks through a gorge 2000 feet deep, excavated in the comparatively soft labradorite of the Labrador series.

The descriptions which have recently been published* of different parts of the Labrador Peninsula not visited by me, favour the supposition that the origin of the surface features of the areas described may be due to glacial action, similar to that observed in the valley of the Moisie River.

SIR RODERICK MURCHISON ON GLACIAL ACTION.

The reader who is not familiar with the rapid progress which has been made during late years in SURFACE GEOLOGY, will do well to read the following extract from Sir Roderick Murchison's address, in which some of the geological influences ice is capable of exerting, are graphically described:—

"Our knowledge respecting the snow and ice clad region of Greenland† has been from time to time largely increased by the communications of our foreign member Dr. Rink. It is in part through his memoirs, as published in our volumes, that geologists have been enabled to reason upon what they believe to have been the former glacial condition of Scotland, and other tracts in Northern Europe, during a period antecedent to the creation of man. Independently, however, of any acquaintance with the condition of

* See 'Explorations in the Interior of Labrador Peninsula,' by the Author. Longmans, 1863.

† Greenland as it is.—Northern Europe as it was.—From the Anniversary Address of Sir R. Murchison to the Royal Geographical Society, May 25, 1863.

Greenland, as explanatory of ancient phenomena, my illustrious friend Agassiz, in the year 1840, boldly applied to the larger part of the northern hemisphere, and specially to Scotland, the doctrine which he had derived from a study of the effects produced by glaciers in the Alps. Wherever he found that the hardest rocks of North Britain had been ground down, polished, and striated by lines and furrows in the same manner as that by which the rocks beneath or on the side of existing glaciers are affected, there he contended solid ice had once advanced from the mountains to the sea-shore. This view, though supported vigorously by my dear friend and eminent master, the late Dr. Buckland, met at first with much opposition, though of late years it has been well upheld by much good evidence, patiently worked out by Professor Ramsay and various authors; and in the last years particularly by Mr. Jamieson of Ellon in Aberdeenshire, and by Mr. Archibald Geikie, of the Geological Survey. Now that the direct analogy of Greenland has been prominently brought forward, the bold theory of the great Swiss naturalist, who founded it on his knowledge of the Alps, has, to his great honour, been well sustained. Though once a sceptic as to a former spread of snow and ice over a large portion of Scotland, I have for some time been a firm believer in the application to that country of this portion of the theory of Agassiz.

“The manner in which the snow of the mountains descending and first forming “névé,” the solid glaciers which advance to the shores of Greenland, and the mode in which huge masses of these glaciers are broken off and are launched into the sea, have been described by other authors, but by none more clearly than by Dr. Rink, whose long residence in Greenland has naturally given him favourable opportunities for observation. In his last memoir Dr. Rink has shown us, that though little water is apparent on the surface of the ice, yet that every glacier is a frozen mountain-river, which is greatly aided in its descent to the sea by a volume of water (about a sixth part of the whole icy mass), which flows either in interstices of the ice, or between the warmer subsoil and the thick cover of ice which prevents congelation. The proofs of the issue of large quantities of water from beneath the lofty ice-cliffs are seen by the issue of springs of fresh water, which rise like whirlpools at the external edge of the ice; and that some terrestrial living things are brought out in these agitated masses is proved by myriads of sea-birds being seen to hover over them, to obtain food in the brackish and muddy water.

“The occurrence of an unfrozen lake at a certain distance inland in one of the great glaciers, and the occasional sinking of its water, is accompanied by a corresponding rise of the springs in the sea, and the rise of its water by their diminution. At first sight I thought it possible that this existing phenomenon might in some degree serve, though by no means entirely, to explain the manner in which Mr. Jamieson, adopting the theory of Agassiz, has recently accounted for the so-called Parallel Roads of Glen Roy;* the

* See Quarterly Journal Geological Society, vol. xix. (1863.)

lake on whose edges these terraces are supposed to have been formed having been held up by a glacier, the successive shrinkings of which let off at intervals the water from higher to lower levels. But looking to the Greenland case as the result of occasional and frequent openings of channels for the water, I see nothing in it which will account for the gravel terraces of Glen Roy at separate and distinct heights. In our Highland example, I believe with Agassiz and Jamieson, that the lacustrine waters were held up by a glacier; yet, knowing that each gravel terrace on their shores could only have been formed in tranquil periods, the distinct separation of the one from the other is to me a clear proof that sudden movements of the subsoil and rapid change of climate occasioned paroxysmal dislodgments of these icy barriers. In this way the successive subsidences due to the sudden collapse and removal of large portions of glaciers will as well account for the distinct separation of terraces which were accumulated during periods of quiescence, as the successive upheavels of the sea-shore (as I shall presently show) explain to us clearly how the heaps and terraces of gravel with sea-shells, which occur at different altitudes around the British Isles, were produced. * * * * *

“But to return to the consideration of that glacial condition of the surface which geologists are pretty generally agreed upon as having been that which immediately preceded the creation of the human race. Believing, as I now do, that snow and ice formerly covered, during the whole year, my native Highlands, as well as the mountainous parts of England, Wales,* and Ireland, and, further, that glaciers descended from the higher grounds into the adjacent valleys and to the sea-board, transporting into the sea-bottom great blocks as well as enormous accumulations of clay and sand with striated fragments of rocks, constituting the “till” of Scottish geologists,† I must impress upon you that, in adopting this view, you do not embrace the largest portion of the operations of transport which took place in the glacial period. For, when the ancient glaciers advanced to the seas of that glacial epoch, they must (as is now taking place on the shores of Greenland) have launched from their cliffs huge icebergs, which were floated away by the prevailing currents, often to vast distances before they were melted. So in the present day numerous icebergs are wafted for hundreds of miles to warmer and southern seas, in which they disappear, and strew the surface of the sea-bottom with the blocks and pebbles with which they were loaded, to be mixed up with marine shells, sand, and mud.”

ACTION OF GLACIAL ICE.

Whenever the loose covering of clay and sand is swept off the solid rock throughout the whole extent of this Province, glacial striæ are visible, in

* On this subject Professor Ramsay's excellent and original Papers should be consulted; particularly the general reader should peruse his Essay on the 'Old Glaciers of Switzerland and North Wales,' in the 1st volume of 'Peaks, Passes, and Glaciers,' and also published as a separate volume.

† See the very clear and able illustration of this subject, with a map shewing the various directions followed by the old glaciers, in the book entitled, 'On the Phenomena of the Glacial Drift of Scotland,' by Archibald Geikie. Glasgow, 1863.

other words, the rocks are seen to be polished, striated and sometimes deeply grooved. These striations are observed at all altitudes, but they have been obliterated over wide areas by atmospheric influences. During the past summer I saw them on the summit of Blue Mountain, 1650 feet above the sea. There, small surfaces of a very hard metamorphosed conglomerate are beautifully polished and striated. They abound throughout the slate region of the Province, the slate receiving with ease and retaining with much persistency the markings produced by the slowly moving glacial mass.

The general direction of these striæ is N. 10° W., but there are often two sets to be seen, differing in direction by two or three degrees. The best place within a few miles of Fredericton for examining these striæ under very singular circumstances, is in Prince William Parish, at and near the antimony mines. On the road to the mines leading from the main post road the striæ are beautifully retained on the polished surface of a hard silicious slate. The country in that vicinity has been ground away and removed by ice to a vertical depth of some hundred feet, as has indeed, a considerable portion of, if not the whole, of the Province.

In Prince William, however, an observer can not only see the "tracks" of the glacial mass graven on the rocks, but he can also see the work it has accomplished in excavating Lake George. He can trace the course of the glaciers far beyond Lake George (442 feet above tide) and Bear Lake; see it in imagination sweeping past the edge of the Plateau of the Carboniferous series, which it has worn away to a *mes*escarpment west of Oromocto Lake, and as a glacial stream passing down the valley of the Magaguadavic to the sea.

The western extremity of the Coal Measures holds up Lake Oromocto. It has been denuded away by lateral glacial action towards the west, until we have the remarkable spectacle presented of a bold escarpment facing the west, holding up a Lake containing 10,000 acres, and 115 feet above the valley it overlooks. Lake Oromocto is 370 feet above the sea, the escarpment which overlooks the Magaguadavic is 394 feet, and the River itself flowing at the base of the escarpment is 256 feet above the same level.

GENERAL DIRECTION OF THE ICE FLOW IN NEW BRUNSWICK.

The polishing of some of the harder rocks is extremely beautiful, and shows that the action of the ice slowly moving over it must have continued for an exceedingly long period of time. It is not to be supposed that the ice had uniformly one direction, on the contrary, its direction may have varied through an entire quadrant under different conditions. When we look at glacial striæ we see only the last record of the moving mass, the last impression of its presence, but in what direction it moved, or with what effect at any period before the graving of its last striations, we can only conjecture.

In the following Table are given the direction and locality of some of these glacial striæ.

Table showing the Direction of Glacial Striæ in New Brunswick.*

No.	Kind of Rock.	Locality.	Height above the Sea.	Direction.
1	Grey Grits,	Fredericton,	About 350 feet,	N. 10° W.

27	Grits,	Opposite Fredericton,	" 350 "	N. 10° W.

An inspection of the preceding Table, although it is very imperfect, will show that the direction of the moving mass of ice was generally nearly due north and south. As the glaciers approached the sea they accommodated themselves to the sinuosities of the valleys through which they made their escape, and produced striations in different directions. At a greater elevation and more inland, what were on the sea shore mere ice-streams, would be in the interior a uniform or broad glacial mass. Suppose for instance that a mass of ice several hundred feet thick, like that which now covers in part the surface of Greenland, † once extended over the entire surface and

* Some of these observations were recorded by the late Dr. Rebb.

† Between Fredericton and Hanwell, very numerous and uniformly N. 10° W.

‡ "To have a correct idea of the glacier accumulation in Greenland, we must imagine a narrow continent of ice flanked on its seaward side by a number of Islands, and in every other direction lost to vision in one continuous and boundless plain. Through the spaces between these apparent Islands, the enormous glacial accumulations slowly seek their passage to the sea, and send off an annual tribute to encumber, to cool, and to dilute the waters of the adjoining ocean. The average height or depth of the ice at its free edge in these intervals or valleys between the projecting points of coast is 1200 or 1500 feet, of which about one eighth or 150 feet will be above the water. In some of the valleys, however, the depth is upwards of 2400 feet. These phenomena can be seen at the present day in Baffin's Bay and Davis' Straits." "As we advance northwards along the coast

flanks of the granitic highland range to the north and northeast of the Saint John; during its slow movement towards the sea it would not only bring with it the materials it tore off the rocks over which it was passing, but it would also score and polish the rocks themselves. At that period the valley of the Saint John was probably, but not necessarily, filled with drift; the glacial mass passed over it towards the sea, scratching and polishing the rocks during its slow but irresistible journey; approaching the sea it would probably split into tongues, chiefly on account of its moving eccentrically, and thus covering a larger area owing to the figure of the earth; and by reason of climate these tongues would reach the sea as ice rivers, in process of time excavating for themselves deeper and deeper channels, which ultimately became "Fiords" or deep bays where the glaciers "calved," to use the term commonly employed in Greenland, and gave off their icebergs. An inland glacier having, as it were, once established itself in any determinate geographical position, would in process of time, assisted by its own glacial river, wear out a lake basin.*

PROBABLE THICKNESS OF THE GLACIAL COVERING.

Some idea of the former enormous thickness of the glacial mass which once covered a considerable portion, if not the whole of the Province, may be gleaned from the occurrence of those beautifully polished metamorphic conglomerates at the summit of Blue Mountains in the Tobique valley, 1640 feet above the sea. This would involve a glacial mass certainly not less than 2000 feet in thickness; but as there is no doubt that far more elevated mountain summits in the highlands are grooved and polished, it would be very unwise to attempt to fix a limit to the thickness of the glacial mass which once covered the Province from such data.

If we turn our eyes southwards, we find Mount Washington, which is over 6000 feet high, marked with glacial striæ nearly to its summit, the rough unpolished surface of its crown, covered with loose fragments, alone remaining unscored, showing that during the glacial epoch its summit was just raised above the surrounding ocean of ice.†

"In this region," says Agassiz, "the thickness of the sheet can not have been much less than six thousand feet;" and in another place in the same article—"In short, the ice of the great glacial period in America moved over the continent as one continuous sheet, over-riding nearly all the inequalities of the surface."‡

of west Greenland, and thus diminish the annual mean temperature both of the sea and of the atmosphere, we find the glacier approaches nearer and nearer the coast line, until in Melville Bay, latitude 75°, it presents to the sea one continuous wall of ice, unbroken by land, for a space of probably seventy or eighty miles."—Dr. Sutherland, *on the Geological and Glacial Phenomena of the Coast of Davis' Strait and Baffin's Bay*.—Proceedings of the Geological Society, 1853.

* See Professor Ramsay's paper "On the Glacial Origin of Lakes."—Journal of the Geological Society, August, 1862.

† Agassiz in the July number, (1864) of the Atlantic Monthly.

‡ Ice-Period in America.—by Louis Agassiz.—Atlantic Monthly, July 1861. page 58.

If these are the conclusions advocated by Agassiz, in relation to America generally, north of the 44th parallel, we may accept as a very modest deduction the entombment of all the mountains in the Highlands of the Province under one glacial pall.

Dr. Dawson, the able and distinguished President of McGill College, Montreal, whose writings and authority have so frequently been quoted in this Report, does not agree with the views of glacialists as now understood. Dr. Dawson urges as a chief objection to the striation of a portion of the Saint Lawrence Valley—1st. "That the direction of the striation was from the ocean toward the interior, against the slope of the Saint Lawrence Valley;" and 2nd. When speaking of the supposed excavation of the great Lakes by means of ice, he says, "Glaciers could not have effected it; for even if the climatal conditions for these were admitted, there is no height of land to give them momentum."

"But," says Dr. Dawson, "if we suppose the land submerged so that the Arctic current flowing from the northeast should pour over the Laurentian rocks on the north side of Lake Superior and Lake Huron, it would necessarily cut out of the softer Silurian strata just such basins, drifting their materials to the southwest."* This conclusion is far from being borne out by the existing Lake Basins. An Arctic current could not have occasioned the vast subaqueous escarpments which exist on the north side of the Indian Peninsula and its Island prolongations in Lake Huron. There are three hundred feet of water close to many parts of the shore in that portion of the lake, a depth equal to that of the Bay of Fundy, notwithstanding its wonderful tides and never-ceasing currents. The vast depths of the great Canadian Lakes, from 700 to 1000 feet, surrounded by unbroken rocky rims, which hold their waters up, is another potent argument against the existence of currents, especially an arctic one, which is, comparatively speaking, a surface current, the warmer heavier water (39.5°) necessarily seeking the greatest depth and the colder current flowing over it. The geographical position of the axes of the great Lakes, which would be that of the current, is of itself a grave objection to the views urged by Dr. Dawson.

AN ELEVATION OF THE CONTINENT ALONE REQUIRED.

There can be no doubt that a submergence (which probably did not exceed 600 feet in this latitude) would account for some of the phenomena under review, but an ELEVATION of the northern portion of the continent, to the extent of as many hundred feet as some geologists suppose submergence to have taken place in thousands of feet, would explain all the glacial phenomena under consideration, as well as many others for which the hypothesis of submergence alone is wholly inadequate, such as the formation of elevated but local beaches and terraces, the formation of great escarpments increasing continually in altitude towards the west, the excavation of Lake Basins, &c.

* Proceedings at the Annual Meeting of the Natural History Society of Montreal, 1864.—"The President's Address."

This elevation would require to be of the same character as that which is now actually taking place in Sweden, and indeed on a small scale on the Atlantic coast of New Brunswick, Nova Scotia and the United States. A gradual elevation of the northern part of the continent, for a few feet in latitude 35° N., a hundred feet in latitude 40° N., 200 feet in latitude 45° N., 500 feet in latitude 50° N., and 1000 feet in latitude 65 or 70° N., would give the required slope.* The advocates of the Iceberg theory do not hesitate to assume that the continent was submerged to the extent of from 4,000 to 5,000 feet, in order to account for the scratches and Drift on Mount Washington and in the Catskills, yet a comparatively small elevation in the manner indicated above, would not only remove the difficulties with regard to slope, but it would also avoid the necessity for an assumption of which there is no real evidence in the way of Fossil remains, beyond a depression not exceeding in the valley of the Saint Lawrence six hundred feet.†

FORMATIONS OF ESCARPMENTS.

Most of the difficulties attending the formation of elevated beaches of small horizontal extent, at elevations varying from 900 to 1750 feet above the sea, disappear when viewed in connection with glacial Lakes. And that great enigma, the enormous parallel escarpments from 300 to 1000 feet high, and

* An elevation of this see-saw character has actually taken place within certain limits as shewn by marine shells. In Lake Champlain these are found at an elevation of about 400 feet, at Montreal 470 feet, and in the Arctic Regions they have been discovered at an elevation of nearly 1000 feet, on Cornwallis and Beechy Islands.

† In a recent Report on the Geological Survey of the State of Wisconsin by the distinguished American geologists, Professors James Hall and J. D. Whitney, the remarkable view is advanced by the latter, that there is an area of more than 3000 square miles in extent (long. 90° W. lat. $42^{\circ} 50'$ N.) which has never been overflowed since the Upper Silurian epoch. Mr. Whitney says:—"If we consider the magnitude and universality of the drift-deposits in the Northern United States, and especially in Northern Wisconsin, we shall be more astonished to learn that throughout nearly the whole Lead-region, and over a considerable extent of territory to the north of it, no trace of transported materials, boulders, or drift can be found; and what is more curious, to the east, south, and west, the limit of the productive Lead-region is almost exactly the limit of the area thus marked by the absence of Drift."

The conclusions to which Mr. Whitney has been led by the study of this driftless region are briefly as follow:—

1. That since the Upper Silurian period this portion of Wisconsin has not been submerged, and that its surface has, consequently, never been covered by Drift.
2. That the denudation it has undergone has been effected by the simple agency of rain and frost.
3. That a large portion of the superficial detritus of the West must have had its origin in the subærial destruction of the rocks, the soluble portion of them having been gradually removed by the percolating water.
4. The entire absence of terraces indicates that the region in question has not been submerged in recent times. No organic remains other than those belonging to palæozoic times, except those of land animals and plants, have been found in the Lead-region.

On the railway between Milwaukee (Lake Michigan) and Prairie du Chien on the Mississippi, there is no point which rises higher than 950 feet above the sea-level; and the towns of Galena, Menomonee, and Dunlieth, in the Lead-region, are below the level of Lake Michigan.

from 300 to 3000 feet above the sea, and many hundred miles long, without any evidence of beaches on their slopes, appears best susceptible of explanation, by supposing them to be the result of glacial rivers wearing away the soft material of the stratified rocks in advance of the glacial mass, and simultaneously levelling the plains of the base of the escarpments. On the shores of the Bay of Fundy there are immense escarpments, but they contain in every sheltered nook ancient beaches to indicate their origin. Glacial escarpments have not, necessarily, any beaches or terraces showing the presence of a sea washing their shores.

In 1860* I described the remarkable parallelism which exists between great escarpments in America north of the 40th parallel of latitude.

1st. The Niagara escarpment.

2nd. The Riding, Duck, and Porcupine Hill escarpment, west of Lake Winnipeg.

3rd. The escarpment of the Grand Coteau de Missouri.

These are all roughly parallel to one another, and are many hundred miles in length. The lowest, the Niagara, varies from 600 feet to 1300 feet above the sea; the second, west of Lake Winnipeg, from 1600 feet to 2000; the third, the Grand Coteau de Missouri, from 2000 to 3000 feet and more above the ocean. They have all easterly, northeasterly, or northerly aspects, in relatively different parts of their lengths, and appear to have a common origin. If it can be shown conclusively, as Mr. Whitney believes, that the driftless area in Wisconsin has never been overflowed, these escarpments, as well as those of their great outliers in the "far West," can only be due to the same agent which excavated the basins of the great American Lakes, and we may look upon the symmetrical escarpments of the Grand Coteau de Missouri, the Riding Mountain and its prolongations, and portions of the Niagara escarpments, as the result of the action of glacial rivers undermining and washing away the soft strata of the sedimentary rocks, and excavating *in advance* of the glacial mass itself. They may represent different and closely succeeding glacial periods (the Missouri escarpment being older than that of the Riding Mountain,) with, however, a distinct geological interval between them. The close proximity of the isothermal curves in these latitudes to the general direction of the escarpments of the Grand Coteau and Riding Mountain is a very interesting and important feature in connexion with the cause which produced them.†

CONDITIONS UNDER WHICH GLACIERS ARE FORMED.

It is well known that glaciers can only be formed where there is a sufficiently low mean annual temperature and an abundance of moisture. On the shores of South Greenland there is, comparatively, a large annual precipitation, estimated by Dr. Rink at 12 inches per annum, and supplying

* See 'Narrative of the Canadian Exploring Expeditions of 1857 and 1858,' volume ii, page 206, for a notice of these escarpments.

† From a Paper by the Author, read before the Geological Society of London, February 1861. (vide Proceedings for February.)

a vast glacier stretching continuously from the shore, inland. Advancing further up the Straits beyond the region of moisture, the region of glaciers, according to Captain Sir L. M. Clintock, is left behind. No icebergs were seen in the Archipelago of Barrow Straits; with high land and abundance of moisture there is an abundance of icebergs, but in the Archipelago of Barrow Straits, with a drier atmosphere, icebergs are not seen.*

It follows from these observations that a zone of moisture during the glacial epoch would in the north temperate regions be a zone of glaciers, and the boundary of these glaciers would necessarily follow an isothermal line. May not the escarpments described on a preceding page, represent a boundary of a zone of moisture, and the isothermal line which limited the ice masses? and may it not be ultimately shown that the glacial phenomena of the North American Continent have been limited at different periods to certain zones, which were zones of elevation and moisture, and that there is no necessity for conceiving with Agassiz that a continental cap of ice covered both poles, possessing the enormous thickness he assigns to it? Upon this view it does not appear to be improbable that glacial phenomena may be recognized in many preceding geological ages of the world; and the huge rounded boulders in some of the ancient conglomerates, belonging even to the Palæozoic Series, awaken the suspicion that glacial zones existed in those remote periods?

THE VALLEY OF LAKE ONTARIO.

The objection urged by Dr. Dawson, that the glacial mass would have to move up the slope of the Saint Lawrence Valley to explain, on the glacial hypothesis, the origin of the south west striations there, loses its force upon the legitimate assumption of a gradually increasing elevation of this part of the continent towards the north, and while this hypothesis accounts equally well with the iceberg theory for the distribution of the Montreal trap in the valley of the Genessee, and the dispersion of boulders throughout all parts of the Valley of the Saint Lawrence, as shown by Dr. Bigsby, † it affords at the same time a probable explanation of the original formation of the Niagara escarpment, especially of that elevated portion which constitutes the northern flank of the Blue Mountains, which is not less than 1400 feet above the sea level, and is nevertheless continuous with, and a part of, the escarpment to the east. That portion of this long wall of rock, (which stretches from the middle of the State of New York to Lake Superior), lying within the basin of Lake Ontario, has no doubt been greatly remodelled by the ocean during the subsequent period of subsidence to the extent of about 600 feet, but it seems probable that the Blue Mountain escarpment of Lake Huron, whose base is not less than 800 or 900 feet above the sea, should be the result, like the Riding Mountain and the Grand Coteau de Missouri, of the vast hydraulic power of Glacial Rivers.

* Discussion on Captain M. F. Maury's Paper on the Physical Geography of the sea.—Proc. of the Royal Geo. Soc. Nov. 26, 1860.

† Vide Dr. Bigsby, on Canadian Erratics.—Proceedings of the Geological Society—1851.

We thus connect all the phenomena of Striated rocks, Lake Basins, Escarpments, Inland Beaches, "Horsebacks," the formation and partial distribution of Boulders, and the unstratified Drift, with one and the same cause, simultaneously producing these varied manifestations of its power and evidence of its work.

GLACIAL RIVERS AND LAKES.

The great glacial mass which covers a large part of Greenland has its rivers, which are never frozen, uninterruptedly issuing from beneath the glacial covering and pouring their waters into the sea, both during summer and winter. The vast mass of ice appears to act as a clog to the earth, so as to prevent its heat from being radiated into space. Hence, even in Greenland, the bottom of the glacier is apparently constantly thawing, owing to the heat of the earth, and the glacial rivers convey the products of the "thaw" under the ice to the sea.

Dr. Rink, who has resided many years in Greenland, as stated in a preceding extract, and studied glacial phenomena in its grandest development as it now exists, calculates the yearly amount of precipitation on Greenland in the form of snow and rain, at twelve inches, and that of the outpour of ice by its glaciers at two inches. He considers that only a small part of the remaining ten inches is disposed of by evaporation, and argues that the remainder must be carried to the sea in the form of sub-glacial rivers. He shows that copious springs of fresh water boil up through the sea in front of the glaciers that advance into it, and states that their positions are conspicuously pointed out by flocks of sea birds, which invariably hover over them in evident search of some food, whatever it may be, which they always find there.

Dr. Rink also specifies a Lake adjacent to the outfall of a glacier into the sea, which has an irregularly intermittent rise and fall. Whenever it rises the sea springs disappear; when it sinks they burst out afresh, showing a direct connection between the springs and a sub-glacial river. Arguing from what has been observed in the Alps, he concludes that an amount of glacier water equivalent to 10 inches precipitation on the whole surface of Greenland, is no extravagant hypothesis, and he accounts for its presence partly by the transmission of terrestrial heat to the lowest layer of the ice, and partly from the fact that the summer heats are conveyed into the body of the glacier, while the winter cold never reaches it. The heat melts the surface snow into water, which percolates the ice, while the cold penetrates a very inconsiderable portion of the glacier, whose thickness exceeds 2000 feet.*

The Glacial rivers, which flow continually from the continental mass of Greenland ice, and are the inseparable attendants of all glaciers wherever situated, enable us to see how an ice-stream advancing against a precipice

* On the discharge of the water from the interior of Greenland, through springs underneath the ice, by Dr. H. Rink of Greenland.—Proceedings of the Royal Geographical Society, February 23, 1863.

of soft rock will, by means of its river, undermine and carry away the debris laterally, and in advance of itself. It is like a gigantic hydraulic engine constantly playing against the wall-like surface of the rock, and sweeping off the abraded materials in a river flowing at its base. According to this view an escarpment can be formed at any level; it requires only two conditions,—1st. A slowly moving glacial mass; 2nd. *A rising slope.* We can conceive that the glacier does not ascend the slope, but it cuts away the rock in front of it by means of its rivers, and forms an escarpment continually increasing in elevation. Hence it appears probable that the greater portion of the valley of Lake Ontario, together with the valley of the Saint Lawrence, quite independently of the area occupied by the Lake Basin itself, was cut out by glacial ice acting in the manner just described. Glacial striæ it must be observed show only the last record of the receding masses, but we must look to Drift, to Terraces, to Lake Basins, to Boulders, and to Escarpments, for the work which they have accomplished.

The clean-swept floor of the level country at the foot of the great escarpments in the far West, also indicates the boundary of vast glaciers, which left their dirt-beds on the prairie country, even as far as the south branch of the Saskatchewan, where I observed the forced arrangement of slabs in *unstratified clay* in 1858.

The greater portion of this work was completed during the glacial period, when the land was elevated many hundred feet above its present level. Towards the close of the glacial period, and perhaps one of the agents which brought it to a close, occurred the gradual subsidence of the continent to a maximum extent of 600 feet in the latitude of Canada. During its subsidence and subsequent emergence, much of the work of the glacial period was remodelled, and some of it obliterated, the ocean having left traces of its own work in the form of marine and river beaches, and in the redistribution of many erratics, and the deposition of marine clays and sands within certain limits. These marine clays exist in Maine and New Brunswick to the ascertained height of 200 feet, but in the valley of the Saint Lawrence they have a much greater elevation.

The theory which has so long obtained a certain degree of popularity, that icebergs driven by oceanic currents, and grating upon the floor of the sea, grooved and scratched the rocks against which they impinged, has not received any additional strength from the announcement recently made by Captain Maury respecting ocean currents. "These currents," says that distinguished geographer of the seas, "are the most capricious things; they not only sometimes cease to run, but they occasionally turn and run backwards." He cited the Gulf Stream, which the officers of Her Majesty's Ships in sailing between Halifax and Bermuda, had observed actually running to the southward and westward.* The Gulf Stream is very capricious, and its northeasterly course is the resultant of a vast number of changes.

* Ocean Currents on the northeast coast of South America—By J. A. Mann, Esq.—Captain Maury on a discussion of the above Paper.—Read before the Royal Geographical Society, January 12. 1863.

The uniform constancy in the general direction of glacial striæ, where local causes have not operated, strengthen the suspicion that inconstant currents bearing floating ice can have had little to do with their origin.

THE SPITZBERGEN GLACIER.

The great Glacier of Spitzbergen described by Mr. Lamont * has a seaward face from 30 to 32 English miles, and protrudes in three great sweeping areas for at least five miles beyond the coast line. It has a precipitous and inaccessible cliff of ice all along its face, varying from 20 to 100 feet in height. It has of course no visible terminal moraine above water, but Mr. Lamont suggests that it may have some connection with an extensive submarine bank which lies opposite the whole length of the front of the Glacier, and extends for 15 or 20 miles to sea. The soundings on this bank may average fifteen fathoms, with a bottom of blueish clay. Several Glaciers on Spitzbergen were observed to be pushing before them vast heaps of mud and stones, and the bank just described was probably a submarine moraine. Its vast extent, the circumstances under which it is being produced under our eyes, consisting, as it no doubt does, partly of true glacial and partly of remodelled Drift, is suggestive as to operations of retreating or advancing glaciers in ages past.

LAKE BASINS.

There can be little doubt that nearly all the Lake basins in New Brunswick and Maine, like those of Canada, have been excavated by means of glaciers. Sir W. E. Logan has shown that the rock which is most characteristic of the innumerable lake depressions in the Laurentian region of Canada, is the comparatively soft chrySTALLINE limestone, and there is every probability that the main erosive force has been glacial action. Prof. A. C. Ramsay, the local director of the Geological Survey of England, has shown that all the large lakes of Europe have been produced by the action of great glaciers, which by their slow grinding motion formed those depressions in the rocky strata which are now the basins of the lakes.†

It will be observed on an inspection of Mr. Wilkinson's excellent map of New Brunswick and Maine, that the lakes have a general uniform direction from north to south, or from northeast to southwest. There is a tendency among those which belong to the north and south class, to trend a few degrees to the east, this is also observed in the great Fiords on the coast through which the ice found its way to the sea.

The remarkable parallelism between Loch Lomond, Kennebecasis Bay, the Long Reach, with its continuation to Belle Isle Bay, Washademoak Lake, and Grand Lake, all point to glacial action, guided probably by previously existing valleys formed by anticlinal or synclinal folds, these lying in a course not far removed from the general course of the glacial

* Seasons with the Sea-Horses—by James Lamont, Esq. F. G. S.

† Proceedings of the Geological Society.

mass. It has not unfrequently happened that when a glacier entered an ancient valley, it followed the course of that valley as long as it did not deviate many degrees from its original direction, but if the valley deviated more than a certain number of degrees, the glacier left it, and pursued its course up hill and down dale without regard to obstacles not sufficiently formidable to divert it from the line of maximum descent. Hence we frequently find striæ leaving a valley and passing up the southern bank; this is especially the case near Fredericton, where the glacial masses have slowly progressed southwards in the direction indicated by the valley of the Nashwaak, pushed across the Saint John, then partially filled with drift clays, and thence over the plateau to the sea. They have been to a certain extent the cause of the gently sloping banks of the river here, which though they rise to the height of 400 feet above the level of its waters as it now exists, yet their elevation is attained after a long and uniform slope, broken only by terraces which mark the slow subsidence of the river or lake estuary during the period of the partial re-excavation of the valley. These terraces will be noticed in the proper place.

Glacial striæ are frequently observed to run under the waters of existing seas and lakes; in Lake Ontario, for instance, and on the Atlantic coast of Maine and the Bay of Fundy. They have even been observed to run under the waters of the ocean below low water mark. All of these phenomena belong to the close of the glacial period, after the uniform grinding down of the whole country, the formation of the great escarpments, and the excavation of the vast and deep Lakes of the Saint Lawrence Basin. They are among the last records of glacial action.

LIFE IN NORTHERN SEAS.

A strong argument in favor of the glacial origin of the unmodified drift is the absence of fossils. In England fossils, although much broken, are frequently found in the drift, but this shows that the glaciers which originated it terminated in fiords where marine life was abundant as it now is in the Greenland fiords; there, the vast masses of ice which are yearly given off do not appear to interfere with animal life. The northern seas abound with microscopic organisms, and Sir Leopold M'Clintock brought up several small star fishes from a depth of 1260 fathoms or 7560 feet, the nearest land being Iceland, which was 250 miles distant. In the iceberg region the sounding lead also showed abundance of marine life on the sea bottoms which could not fail to be occasionally disturbed by the grounding of icebergs.

TERRACES AND BEACHES.

There are three kinds of Terraces in various parts of the Province, differing from each other as to their origin, viz:—

- 1st. Marine Terraces or Ancient Coast Margins.
- 2nd. Glacial Lake Terraces.
- 3rd. River Bank Terraces.

The terraces on the coast of the Bay of Fundy, consisting of marls holding marine plants and shells, belong to the first class; the symmetrical terraces near Upsalquitch Lake are illustrations of the second, and the beautiful and singularly regular series visible on the St. John from the head of the Long Reach to the Grand Falls, are very imposing instances of river valley terraces.

MARINE TERRACES OR ANCIENT SEA MARGINS.

The estuaries of some of the smaller rivers on the Bay of Fundy, where they have been sheltered from denuding agencies, show well defined sea margins. A third of a mile up Goose Creek the following measurements were roughly taken with an aneroid barometer in November last. Although the altitudes of the several beaches may not be quite correct, yet they are sufficiently near the truth to establish their relations, and to point to certain results inseparable from them; their presence shows the difference between a precipitous coast line and a glacial escarpment.

These beaches have been produced during the slow emergence of the continent after the Glacial epoch. It is not improbable that at the same time, most of the terraces on the banks of the rivers in the interior, lower than 500 feet above the sea, were occasioned by the same cause; in other words by simple drainage. We have only to conceive the valley of the river forming an estuary, and the estuary converted into a river as the land rose.

On the Atlantic coast of New Brunswick and Maine fossiliferous marine clays are found on the shores of most land-locked bays, and sometimes far up the broad valleys of rivers. They belong to the period when some of the lower river terraces were formed, and show the limits of tidal waters during that epoch. They are evidently of the same geological age as the deposits in the valley of the Saint Lawrence and Lake Champlain, (post-pliocene of Lyell,) and many of the fossils they contain are identical with living species. Mr. Hitchcock has shown that out of seventy species enumerated as being found in Maine, and eighty three in the Saint Lawrence valley, twenty five are common to both deposits. Beds of Marl containing marine shells have been found above the Falls of the Saint John near the

* About one-third of a mile from the sea.

mouth of the river, on the shores of Grand Bay, the Kennebecasis, Belleisle, and on the side of the main stream near the Reach, (Gesner.) On the coast these marl and clay beds are very numerous, occurring in all sheltered places, and from 10 to 40 feet above the highest tides. The beds of sand, gravel, clay, and marl, on the banks of the Saint John above Gagetown, consisting of remodelled drift, all appear to be of fresh water origin.

MODERN ELEVATIONS AND DEPRESSIONS OF THE COAST.

Near Point Blakeland, Bayfield notices on his chart of Miramichi Bay, a "Peat bank 10 feet high." Also near Grandoon Island, "cliffs of sandstone 15 feet, covered with Peat."

The soundings taken by Bayfield during 1848, in Miramichi inner Bay, show $2\frac{3}{4}$ and 3 fathoms where four and five fathoms are recorded on the old charts constructed by order of the Admiralty, previous to 1780, and published in that year by J. F. W. des Barres.

The Marsh inside of Hucklebury Island, Bayfield describes as filled with Eel grass and nearly dry at low water; the chart of 1780 shows three and two fathoms of water.

Buctouche Harbour exhibits also great changes. The channel is very much diminished both in breadth and depth since 1780, the depth being about one half. These changes may be due in part to the debris brought down by the rivers, but there is ground for belief that the land is slowly rising north of Buctouche. The walrus bones on Miscou Island, alluded to on page 34, show a gradual elevation of that part of the coast, so also does the Harbour of Bathurst.

EXTENSIVE UPTHROW TO THE WEST OF THE SAINT JOHN.

The elevations and depressions which have just been noticed sink into insignificance when compared with a bold vertical movement of a considerable portion of the Province, which appears to have taken place long previous to the Glacial epoch. The known details of this movement are not sufficiently numerous to permit a general description of its effects to be drawn up, but they are susceptible of being traced over a wide area, so that some ideas may be gathered respecting its nature, which may serve as a guide for future enquiry.

The breaks in the continuity of the narrow belts of the Bonaventure rocks where they cross the Saint John in the Parish of Kingsclear and in the Parish of Hampstead, point to an important elevation of the whole of the Carboniferous rocks west of the Saint John. The sudden termination of the "granite" on the same river, according to Gesner, occurs at the Quarries. The granite and the slate are described as being cut off at the broad point of land between Belle Isle Bay and the Washademoak, and they are there, on the east side of the river, replaced by "trap."

The limits of this raised district are undefined to the west, but there appears to have been an upthrow of great extent, which may exercise an important influence on the geology of the country over which it prevailed.

The action of glacial ice has ground down to a uniform level the rocky strata on both sides of the Saint John, but data may be obtained by careful measurements about ten miles above Fredericton and a few miles below Gagetown, to determine the exact vertical limit of this remarkable upheaval.

GLACIAL LAKE TERRACES.

On page 188 a brief description from the pen of Sir Roderick Murchison is given of what are called by geologists, Glacial Lakes. The terraces already described as occurring near Upsalquitch Lake, on the Portage to the Nipisiguit, are most probably illustrations of this remarkable phenomenon.

The interior of the American Continent affords magnificent examples of Glacial Lake Terraces. At or near the head waters of the St. Lawrence, in the neighbourhood of Great Dog Lake, west of Lake Superior, a succession of these terraces are passed over having elevations above the sea of 945, 1109, 1197, 1398, 1417 and 1435 feet respectively. They appear on the sides of an immense sandbank and are several miles in length.

RIVER TERRACES.

In the following brief description of some of the most prominent river terraces in this Province, it should be borne in mind that the valley of the Saint John was excavated ages before the Glacial or Drift period. It was probably enlarged in certain parts during the glacial period, particularly near Fredericton, and in part filled with drift during the subsequent submergence, and re-excavated during the period of emergence with the formation of the terraces. Some of these terraces will now be noticed, previously to considering the question relating to the probable origin of the Grand Falls.

TERRACES AT THE MOUTH OF THE NEREPIIS.

At the mouth of the Nerepis the contour lines of 50, 100, 150, 200, and 250 feet are parallel to one another, so also, as high as 300 feet, at Belleisle Bay, opposite Hog Island.

TERRACES OPPOSITE GAGETOWN.

The terraces opposite Gagetown, although not precisely represented by the contour lines of Captain Owen's Survey, are remarkably symmetrical, being parallel to one another at the most abrupt turns. They are represented at the following altitudes, all of which contour lines are roughly parallel to one another, and distant as follows:—

No.	Altitude.	Distance from one another.
1	20	0 yards.
2	50	110 "
3	100	180 "
4	150	260 "
5	200	330 "
6	250	385 "
7	300	330 "
8	350	400 "
Summit,	380 feet,	297 "

The elevation of 380 is attained in one mile and 60 yards. These contour lines are on the Jemseg River. Peters' Hill, in the flat or intervale opposite the town, is 57 feet high, it has escaped the denuding forces which re-excavated the valley.

TERRACES AT FREDERICTON.

The contour line of 50 feet above low water, showing the dimensions of the alluvial terrace upon which Fredericton is built, has a greatest breadth on the continuation of York Street of six furlongs, or three quarters of a mile; on Church Street, it is five furlongs, and opposite Government House the distance is the same. Opposite Kingsclear the contour line of 300 feet is 550 yards from the bank of the river, on the Poor House road it is 2,475 yards, and in the rear of Morrison's saw mill 770 yards.

The following table shows the distances of the contour lines given below, on the Poor House road, from the edge of the river, together with the altitude of the Terraces, as nearly as they can be distinguished.

ON THE POOR HOUSE ROAD.	Contour Line. Altitude.	Distance.
1	20 feet.	660 yards.

Beside the upper terraces at Fredericton, which belong to the close of the Drift Period, and were formed during the gradual emergence of the country from beneath the ocean, there are several ALLUVIAL terraces in the great flat on which the city is built, which may be called respectively the Cathedral Terrace, the Burying Ground Terrace, and the Race Course Terrace.

The breadth of the Saint John, opposite York Street, is 825 yards; at low water its greatest depth is 19 feet, just in the middle of the river opposite the Market house; but there are several sections above and below, where the depth at low water does not exceed 15 feet, and a little higher than the Government House, the greatest depth recorded is nine feet, close to the south bank. On the opposite side of the river, (the continuation of York Street,) the contour line of 20 feet in 587 yards from the edge of low water, that of 50 feet, 440 yards, and of 100 feet, 620 yards. The valley of the river at an altitude of 100 feet above low water is about 2,990 yards broad, and at the summit level it is probably not less than four miles.

The bed of the River Saint John consists in many places of blue clay, which may be regarded as unaltered Glacial Drift. It is an extremely interesting problem to ascertain whether the boulders, slates or pebbles in the blue clay of the Saint John, have the arrangement which they would assume if they had dropped through water in the ordinary mode of deposition, or whether they have a forced arrangement, different from that which they would assume if water and floating ice had been instrumental in their distribution. In other words, it is desirable to ascertain whether any part of the blue or even yellow clay exhibits any evidence that it has once constituted the Dirt Band of a glacial mass, similar to some of the blue clay on the shores of Lake Ontario, which I described in 1855.

The Forced Arrangement of Blocks of Limestone, &c., in Boulder-Clay.

(From a Paper by the Author, read before the Geological Society of London, January 1864.)

The forced arrangement of blocks of limestone, slabs of shale, and boulders of the Laurentian rocks, in the Blue Clay at Toronto, formed the subject of a paper which I read before the Canadian Institute seven years ago. A minute description of this arrangement was published in my Report of the Assiniboine and Saskatchewan Exploring Expedition in 1859, to illustrate a similar arrangement of blocks of limestone and gneissoid rocks in the clay on the south branch of the Saskatchewan observed in 1858.

I concluded the description of this remarkable arrangement with the following hint at their origin:—"May not the plastic and irresistible agent which picked up the materials composing the Blue Clay, and then melting, left them in their present position, have been largely instrumental in excavating the basins of the great Canadian lakes."*

And, in 1860, in a "Narrative of the Canadian Expeditions," I remarked, "The widespread phenomena exhibiting the greater or less action of ice, such as grooved, polished, and embossed rocks, *the excavation of the deep lakes of the St. Lawrence basin*, the forced arrangement of drift, the ploughing-up of large areas, and the extraordinary amount of denudation *at different levels*, without the evidence of beaches, all point to the action of glacial ice previous to the operations of floating ice in the grand phenomena of the Drift."†

The following Sections show some of the peculiarities of the Saint John River alluvium.

† Narrative of the Canadian Expeditions of 1857 and 1858, vol. ii. p. 254. Longman's 1860.

‡ Fredericton, Lat. 45° 57' 18.7" N. Long. 66° 38' W. is situated on an extensive "intervale" or flat, whose river edge is about 15 feet above the water in November. The character of the valley here is given in the text. It is 66 miles by road from Saint John, and 84 by water.

§ Dr. Robb.

The depth of the drift near the College is stated by Dr. Robb to be about 35 feet. The thickness of these deposits on the northeast side of the river appears to be considerably less than on the southeast side. Some of the wells on the Keswick are sunk through 7 feet fine gravel, 16 feet blue clay, and 4 feet coarse gravel resting on slates. In a well on a farm in the rear of Fredericton the rocks penetrated were as follows:—

Loose soil and sand,	2 feet 8 inches.
Yellow clay,	14 "
Dark clay,	4 "
Boulders and coarse gravel,	2 "

And in another well on the hill above the University—

Soil and sandy earth,	3 feet 3 inches.
Clay with small boulders and gravel,	7 "
Sandstone of the Carboniferous Series.*					

The depth of the blue clay forming the bed of the river is at least 60 feet.

TERRACES AT THE GRAND FALLS.

If we examine a plan of the Grand Falls after laying down the contour lines showing the different terraces, we can not fail to be struck with the following apparent facts:—

That previously to the glacial period the Saint John River pursued a straight course down the deep ravine to the west of the Portage road, possibly over falls. That this ravine extends from a little above the upper basin very nearly to the lower. It is apparently the former valley of the Saint John, now partially filled with drift.

The height of the upper basin above the level of the sea being 419 feet, it is clear that when the continent was submerged below that depth, the Saint John above the falls flowed directly into the ocean. During that period not only was the old channel partially filled up, but the glacial drift was rearranged over the tract of country near where the falls now are, and elsewhere. When the land began to rise again, the upper portion of the Saint John above the falls was a lake estuary in direct communication with the sea; the continued rising of the land converted this lake estuary into a river, which found its outlet, not by its old filled up channel, but by the course of the uppermost terrace, of which there are four, and all of which, be it observed, appear on Little or Falls River, showing that this Little River also cut its way through the rearranged drift. As the land rose, these terraces became successively developed in the ordinary process of drainage, until the river had re-excavated its ancient bed below the level of the ledge of rocks, when falls commenced and have existed since the Saint John cut out a channel for itself. The new falls began at the lower basin, near where, probably, the ancient falls once existed; the course of the excavated ravine

* In sinking a well near Bathurst, the workmen came to blue clay at a depth of 25 feet, some 200 feet above the sea. The blue clay, which was probably glacial drift, contained a very considerable quantity of bright iron pyrites. On Bull Creek, Woodstock, near the Saint John, there is a fine cliff of stratified yellow clay 60 feet above the stream.

was determined by the terraces, which, according to natural laws, the river had previously formed in the ordinary process of drainage. It is the terraces then which have determined the course of the gorge, not the gorge the formation and contour of the terraces. The gorge is simply a valley of erosion due to the action of running water, guided by a previously existing valley, and formed in the same manner and under similar circumstances as the gorge of the Tobique, or as the gorge of the Falls of Niagara. These valleys of erosion are every where to be seen, and water is competent to execute far more imposing monuments of its power, without calling in the aid of paroxysmal action, convulsions, or earthquakes.

The question will suggest itself to the reader, "why did not the Saint John follow its old channel direct from the upper to the lower basin." It is not difficult to frame a satisfactory answer to this question. The Glacial Drift now forming prominent hills near the falls, was once an unbroken barrier, holding up the lake-like estuary which at that remote period existed above the Grand Falls, and whose work is seen in the beautifully stratified fresh water marls, sands, and clays, on the banks of the river far above the Falls. The lowest point in this Drift barrier was on the course of the highest terrace, and this course was necessarily selected by the drainage waters of the estuary. Subsequently to the assumption of this new passage to the sea, the drift in the old valley has been gradually removed by the ordinary process of sub-aerial denudation, so as to mark its former existence by a depression of unmistakable origin.

DRIFT ISLANDS WHICH HAVE ESCAPED DENUDATION.

Islands on the Banks and Intervale (Flats.)

1. Island on the east bank opposite Robinson's Island, altitude of highest contour line, 150 feet.
2. Island in Gagetown Flats, altitude 51 feet.
3. Islands in Flats just above the mouth of Tenant's Cove.
 - (a.) On east flat, altitude 50 feet, with an escarpment to the southeast.
 - (b.) On west flats, altitude 350 and 380 feet, with escarpments to the southeast and northeast.
4. Island on Promontory, 250 feet high.
5. Island on east bank below Oak Point, 400 feet, with several Islands on west bank, 300 feet; escarpments on the river are common both a few miles above and below Oak Point and the mouth of the St. John, with terraces in the rear.

Terraces.

1. Terraces at Fredericton.
Terraces opposite Gagetown.
2. On the Jemseg.
3. Round Oaknabog Lake and opposite Long Island, highest contour line 400 feet. Distance from river $\frac{1}{4}$ of a mile.
4. Terraces have altitude of 400 feet north-west of Tenant's Cove, with an escarpment 400 feet high facing the east.
5. Terraces near the mouth of Belle Isle Bay have altitude of 350 feet.

Note.—Comparatively low terraces are numerous on the upper St. John. They are well seen at the mouth of the Tobique, and at Woodstock; they are also numerous on the Miramichi.

The foregoing Tables note some remarkable points on the River Saint John, between Fredericton and the sea, showing terraces, islands in the valley, and islands on the banks, which have partially escaped the denuding forces which excavated the bed of the river.

THE FALLS AT THE MOUTH OF THE SAINT JOHN.

The remarkable gorge in which these are situated is stated to be something more than a valley of erosion, although the gorges of the Magaguadavic, the Tattagcuhe, the Nicadoo, the Nipisiguit, the Upsalquitch, the Tobique, and numerous others belong to this class. With the exception, if it be one, of the gorge at the mouth of the Saint John, I have not seen any single instance in the Province which could not be explained by the action of ice and water, or generally, by erosion. On the supposition that the gorge of the Saint John at its mouth has been produced by a violent separation of the rock, (for it has been alleged that the salient and re-entering parts of the sides of this crack can be seen, and if the walls were brought together they would "fit,") it must be a crack or fissure, and if it be a crack which has allowed the waters of the Saint John to pass through their present channel, it will necessarily be of great depth, and in consequence of the strong currents to which it is subjected its depth will be constantly increasing. Soundings do not favour this view, for while the depth of water, according to Captain Owen's Survey, is 100, 114, 140, and even 160 feet between Navy Island and St. John, it does not exceed 87 feet in the Narrows above, and at the Split Rock it is not more than 119 feet in depth. At the Tidal Falls * the depth varies from 8 to 20 and 22 feet between the Mill and the Island; while in the small basin south of the Falls, 126 feet is recorded, and in the large basin above them, it varies from 122 to 204 feet deep, on a nearly due north and south course. The depth is also considerable opposite Indiantown, 195 feet being recorded; and in Grand Bay the depth continues great, varying from 104 to 130 feet.

These facts are certainly opposed to the view that the present outlet of the Saint John is the result of an earthquake fracture, but they favor the view that it is a valley of erosion, excavated subsequently to the Glacial Drift Period.

Nor has much change taken place within the last 254 years; for in the Relations of the Jesuits for the year 1611, there is an account of the voyage of le Sieur de Biencourt up the river, in which allusion is made, in the quaint old French spoken at that day, to the 'frightful difficulties' at the mouth of the Saint John. †

* In some parts of the Long Reach a depth of 126 feet is attained, but in general, soundings show a uniform depth of 70 feet for a long distance.

† La riviere de S. Jean est au Norouest de Port Royal, y ayant entre-deux la Baye Francoise, large de 14 lieus. L'entree de ces: riviere est fort estroite et tres dangereuse; car il faut passer au milieu de deux roches, desquelles l'une jette sur l'autre le courant de marea, estat entre deux aussi viate qu'un traict. Apres les roches suit un affreux et horrible precipice, lequel si vous ne passez a propos et quand il est comble doucement, de cent mille barques un poil n'eschapperoit pas, que corps et biens tout ne perist."

Between St. John and Portland there is a narrow and deep valley now occupied by a church, manufactories, and dwelling houses. In this valley, and above strata of clay, there are marl beds containing shells and decomposed sea weeds, identical with those still inhabiting the shores of the harbour. These beds are about 18 feet above the level of the sea, which at some former period surrounded the site of the city.*

The falls of the Saint John at its mouth are not "falls" in the ordinary acceptation of the term; they result from the narrow and shallow outlet through which the tide, which rises with great rapidity and to an altitude of 28 feet, has to pass. The outlet is not sufficiently broad or deep to admit the tidal waters with their rise, hence a fall inwards is produced during the flow; at the ebb, the tide recedes faster than the outlet of the river can admit of the escape of the waters accumulated within the inner basin, hence a fall outwards. Twice every day the waters are at a level on both sides of the gorge, and for half an hour or so these singular tidal falls are passable for vessels. A former outlet of the Saint John exists to the east of the City.

The following are instructions for going through the falls, which apply, we believe, to no other "falls" in the world:—

"The falls are level, or it is still water at about three and a half hours on the flood, and about two and a half on the ebb, so that they are passable four times in twenty four hours, about ten or fifteen minutes at each time. No other rule can be given, as much depends on the floods in the River Saint John, and the time of high water or full sea, which is often hastened by high southerly winds. For a few days in the spring of the year, the height of the water in the River Saint John renders the passage of the falls extremely difficult."

"HORSEBACKS."

The 'Horsebacks,' which are numerous in this Province, and consist of long raised beaches of gravel with boulders, were probably formed by glacial lakes; that is, they were washed up by lakes in the interior of a glacial mass, on those portions of the coast of the glacial lake which came in contact with the rocks over which the ice was moving. Hence the reason why these 'Horsebacks,' like the detached beaches of similar glacial lake origin, have only a certain limited length and terminate abruptly. There is a 'Horseback' near the Saint Andrews and Quebec Railroad, at M'Adam's Station, about 5 miles long. There are others on the Saint John above Woodstock, and elsewhere in the Province; and it may be that the barrier formerly existing at the Grand Falls was a 'Horseback.'

ACTION OF RIVERS ON THEIR BANKS.

Some years ago it was asserted that all rivers flowing from the north to the south had a tendency to wear away the right bank, and cut their beds in the rock to the right of their course, in preference, as it were, to the left.

* Dr Gesner—Proceedings of the Geological Society, April 1861

This subject has been investigated generally, with relation to the motion of Fluids and Solids relative to the Earth's surface, by Mr. W. Ferrel,* assistant in the Nautical Almanac Office at Washington. To those who are curious in such matters, it may be interesting to know that such great Flats as those of Fredericton, Gagetown, and elsewhere on the Saint John River, have probably been partly produced according to a general law which governs the motions of bodies on the earth's surface, and which may be thus briefly expressed:—

“In whatever direction a body moves on the surface of the earth, it is always deflected to the right in the northern hemisphere, and to the left in the southern hemisphere.”

The motions of the atmosphere are materially influenced by this law, so are those of the ocean, but to a far less extent. The general eastward motion of the water of the northern part of the Atlantic, called the Gulf Stream, and the consequent depression of the water next the coast of North America, is the cause of the Greenland current.

The Gulf Stream flowing north is deflected towards the east, the Greenland current flowing south is deflected towards the west, hence they are preserved separate from one another as if divided by a wall.

When a railway train moves in a straight line at the rate of 40 miles an hour, at the parallel of 45° , the lateral pressure tending to throw it off the track, if it runs due north and south, is about one five thousandth part of its weight; if it moves from north to south, the lateral pressure is to the west, if from south to north, it is towards the east.

The equation deduced by Mr. Ferrel, by which the solution of problems similar to that just noticed may be determined, is as follows:—

Let v be the velocity of a body moving in any direction; F the deflecting force perpendicular to this direction; n the lineal velocity at the equator, equal to 1523.2 feet in a second; then $n = .000072924 =$ angular velocity of the earth's rotation, r being the radius of the earth. Let $O =$ the polar distance in arc, and $g =$ gravity, or 32.2 feet. Then it is shown that $F = \frac{2v \cos. O}{289 n} \times g$

In the case of a railway train moving at the rate of 40 miles an hour, v will equal 60 nearly at the parallel of 45° , and $F = \frac{1}{5183} g$ or the lateral pressure is equal to $\frac{1}{5183}$ of the weight of the train.

By making the necessary substitution in the case of a river flowing at the rate of one, two or three miles an hour, an approximation to the lateral force it exerts on its westerly bank, if it moves from north to south, will be obtained. The same equation may be applied by the curious to ascertain the lateral pressure of glaciers, which, although their movements are excessively slow, must, on account of their enormous weight, exert some lateral pressure, which may or may not be insignificant or immaterial, but it will always be a tendency to move *to the west* in the northern hemisphere.

* The American Journal of Science and Arts, January 1861.

If a glacier move at the rate of one foot per day, it will move $\frac{1}{86400}$ part of a foot in a second.

Putting this as the value of v in the equation—

$$F = \frac{2v \cos. O}{289n} \times g$$

where $n = .000072924 =$ the angular velocity of the earth's rotation, we have

$$F = \frac{1}{2,189,459,200} \text{ of its weight.}$$

Hence a glacier, in order to exercise a lateral pressure of 100 pounds due to the earth's rotation, must weigh upwards of 100 millions tons, if the equation can be considered applicable in this case.

ARTESIAN WELLS.

In some parts of the valley of the Saint John, the unbroken continuity of the blue clay would render the construction of Artesian wells, on the flats or intervalles, an inexpensive and easy mode of obtaining a constant supply of PURE WATER. If the water should fail to reach the surface on sinking through the blue clay to the probable layer of boulders below it, the dips of the sandstones belonging to the Carboniferous Series would generally ensure a supply; but it is yet a question which experiment alone can determine, whether borings for three or four hundred feet in the sandstones would not tap sheets of brine, or at least sheets of brackish water. The probability of obtaining a bountiful supply of fresh water within the limits of the Carboniferous basin, depends upon the locality; for these rocks have been subjected to gentle undulations, although their general dip is to the southeast at a low angle. There are, however, wide areas in which an Artesian well not more than 300 feet deep, and frequently far less, would pour forth a constant supply many feet above its outlet.

H. Hitchcock's Description—Mr. Morse's Account.

The Minerals of economic value found in the Drift are of considerable importance. They are **BOG IRON ORE**; **WAD or BOG MANGANESE**; **OCHRES**; **SHELL MARL**; **CLAYS for POTTERY**; **SILICIOUS INFUSORIAL EARTH or POLISHING POWDER**; impure **KAOLIN** for the manufacture of superior articles of pottery; **BLUE PHOSPHATE of IRON** for pigment; **GOLD**, &c. These are generally found in the re-arranged Drift or Alluvium; also in the alluvial deposits in the valleys of rivers.

The most important metal found in the older or Glacial Drift is gold, derived from Palæozoic Rocks, partly by their decay and partly by the grinding process of glacial ice. The precious metal is also found in the re-arranged glacial drift or alluvium.

BOG IRON ORE or LIMONITE—OCHRES.

The formation of this substance may be described as follows:—Water charged with organic matter, the result of the decay of vegetable substances, permeates ferruginous sediments or drift containing iron sand, and reduces the peroxide of iron to the state of protoxide which is soluble in water, and is brought to the surface by springs either as a carbonate of the protoxide of iron, or in combination with vegetables acids, (crenic, geic, and humic.) In contact with air these protosalts of iron absorb oxygen, the metal is rendered insoluble and is precipitated from the solution of the carbonate as a hydrated sesquioxide, or from the organic solution, as a compound of this oxide with the vegetable acid. While the purer limonites are nothing more

than the hydrous sesquioxide of iron, the bog ores consist of variable mixtures of this with the organic compound, and some of the ochres are probably this combination in a nearly pure state.* The same process brings the manganese to the surface which is so frequently found associated with bog iron ores.

Dr. Gesner enumerates many localities where bog iron ores occur, some of these may become valuable for admixture with other ores of iron, or alone; the iron produced from them being generally of very superior quality. In view, however, of the enormous extent and excellent quality of the Woodstock ores, and the occurrence of excellent magnetic ores, noticed elsewhere, it is not very probable that the bog iron ores, without they are favorably situated, will be sought after for some years to come, although this variety has long been used in Canada.

“The Radnor Forges have within a few years been erected at Batiscan, in the Seigniorship of Cap de la Madeleine, and are supplied with ore and charcoal from this and the adjoining Seigniorship of Champlain. The crude ore is brought to the furnace, partly by the workmen of the Company, and partly by the farmers on whose land it is found. It is washed to free it from adhering earth, and then yields from forty to fifty per cent. of metal; about 2000 tons of cast iron being now produced annually from between 4000 and 5000 tons of ore. The number of workmen employed at the Radnor Forges varies from 200 to 400; a great many hands being required at certain seasons, to dig up and bring in the ore, and to prepare and transport the charcoal.

“The chief manufacture of the Company has, of late, been cast-iron wheels for railway cars, for which the metal appears well adapted. A pair of car-wheels, with an axle, of this manufacture, were sent by Messrs. Larue & Co. the proprietors of the Forges, to the International Exhibition of 1862, which were said to have run 150,000 miles. Wrought iron is also made at this establishment; and a rolling-mill has recently been erected here, which furnishes iron for the manufacture of scythes, and nail-rod iron.”†

WAD OR BOG MANGANESE.

The application of Manganese to many manufacturing purposes, particularly those connected with bleaching and dyeing operations, is decidedly on the increase, and it is not improbable that a considerable demand for the oxide of this metal will grow out of its recent employment in the generation of nascent chlorine for the extraction of gold from auriferous rocks. This metal is rather extensively diffused in New Brunswick; and a special notice of its present application in the arts, with a brief description of Mr. Calvert's process for extracting gold, in view of its prospective value, will probably be acceptable.

The principal Ores of Manganese are—

1st. The grey or black peroxide, sometimes called grey manganese ore, and also *pyrolusite*. It contains 63.3 manganese, and 36.7 oxygen, in 100 parts.

* *Geology of Canada.*

† *Ibid.*

2nd. Wad or Bog Manganese, or the hydrated peroxide. It differs, when pure, from the grey peroxide, in containing one atom of water.

In 1858 there were imported into Great Britain and Ireland, 24,171 tons of manganese, worth £193,368 sterling.

Manganese is now being largely used by the calico printer, and for the manufacture of bleaching powder; but it is the new application of the ores of this substance, in the production of nascent chlorine for the extraction of gold, that seems to promise the most rapid increase in the demand. The following process is due to Mr. F. C. Calvert, of Manchester, who communicated the results of his researches in a paper entitled "New Method of Extracting Gold from Auriferous Ores":—

"At the present time when the auriferous ores of Great Britain are attracting public attention, it may be advantageous to persons interested in gold-mining, to be made acquainted with a new and simple method of extracting gold from such ores, which presents the advantages of not only dispensing with the costly use of mercury, but of also extracting the silver and copper which the ore may contain. Further, it may be stated that the process can be profitably adopted in cases where the amount of gold is small, and the expense of mercury consequently too great. Without entering here into all the details of the numerous (about one hundred) experiments which I made some years since, before I finally arrived at the new method of extracting gold, which I have now the honor of communicating, allow me to state a few facts which are necessary to give a complete view of the subject. If 2.2 parts of pure and finely divided gold, obtained by the reduction of a salt of that metal, be added to 100 parts of pure sand, and placed in a bottle with a saturated solution of chlorine gas for 24 hours, only 0.5 of gold is dissolved. If the same experiment be repeated, but instead of chlorine water, a mixture of chlorine water and hydrochloric acid be used, 0.6 of gold is dissolved. If, instead of employing hydrochloric acid and chlorine gas, a mixture of sand, reduced gold, and peroxide of manganese, with hydrochloric acid, are placed in a bottle, 1.4 of gold is dissolved; so that it would appear that, under the influence of nascent chlorine, the gold is more readily dissolved than when the same gas is mixed in solution with hydrochloric acid, previously to being placed in contact with the auriferous sand. Still these processes leave a great deal to be desired in a commercial point of view, as more than a third of the gold remains undissolved. The same results are obtained if the chlorine gas be generated by another method, viz., by adding to the auriferous sand a mixture of chloride of sodium, sulphuric acid, and peroxide of manganese. Being convinced, therefore, that nascent chlorine gas was a fit and proper agent for cheaply extracting gold from ores, and that it was probably only necessary to modify the method of operating, I allowed the mixture of hydrochloric acid and peroxide of manganese, or of sulphuric acid, peroxide of manganese, and chloride of sodium, to remain for twelve hours in contact with the auriferous sand; and, then, instead of washing-out the solution of gold, I added a

small quantity of water, which removed a part of the acting agent, and this was made to percolate several times through the sand; by which method I succeeded in extracting from the sand, within a fraction the whole of the gold. I then repeated the last experiments with natural auriferous quartz, and easily extracted the two ounces of gold per ton which it contained. I therefore propose the following plan for extracting the gold on a commercial scale:—The finely-reduced auriferous quartz should be intimately mixed with about one per cent. of peroxide of manganese; and if common salt be used this material should be added at the same time as the manganese, in the proportion of three parts of salt to two of manganese. The whole should be then introduced into closed vats, having false bottoms, upon which is laid a quantity of small branches covered with straw, so as to prevent the reduced quartz from filling the holes in the false bottom. Muriatic acid should then be added if manganese alone is used, and diluted sulphuric acid if manganese and salt have been employed; and, after having left the whole in contact for twelve hours, water should be added so as to fill-up the whole space between the false and true bottoms with fluid. This fluid should then be pumped-up and allowed to percolate through the mass; and after this has been done several times, the fluid should be run off into separate vats for extracting the gold and copper it may contain. To effect this, old iron is placed in it to precipitate the copper; and after this has been removed, the liquor is heated to drive away the excess of free chlorine, and a concentrated solution of sulphate of protoxide of iron, or green copperas, must be added, which, acting on the gold-solution, will precipitate the gold in a metallic form. By this method, both gold and copper are obtained in a marketable condition. If silver is present in the ore, a slight modification in the process will enable the operator to obtain this metal also. It is simply necessary to generate the chlorine of the vitriol, manganese, and chloride of sodium process, taking care to use an excess of salt, that is, six parts instead of three, as above directed. The purpose of this chloride of sodium being to hold in solution any chloride of silver that may have been formed by the action of chlorine on the silver-ore, and to extract the metal, the following alteration in the mode of precipitation is necessary. Blades of copper must be placed in the metallic solution, to throw down the silver in a metallic form, then blades of iron to throw down the copper, the gold being then extracted as previously directed. I think the advantages of this process are, 1st, cheapness; 2nd, absence of injury to the health of the persons employed; 3rd, that not only is the metallic gold in the ore extracted (as is done by mercury), but it attacks and dissolves all gold which may be present in a combined state, besides enabling the miner also to extract what silver and copper the ore may contain.”

Manganese deposits have long since been worked on the flanks of Shepody Mountain in Albert County; near Sussex Vale; at Quaco; and at the Tat-tagouche Mines in the County of Gloucester.

Wad or Bog Manganese is frequently found in the overlying drift in the neighbourhood of such deposits, having been brought to the surface in the same way as the iron of ochres, and some limonites or bog iron ores.

The total yield of the Nova Scotia gold fields for the quarter ended Dec. 31st, 1864, is officially stated to be 5,456 oz. 9 dwt. 5 gr., being in advance of any previous quarter. The total yield for the year 1864 is 20,022 oz. 13 dwt. 13 gr., against 14,000 oz. 14 dwt. 17 gr. for 1863.—The employment of manganese in separating the gold from the crushed quartz rock, will probably cause a rapid increase to take place in the production of the precious metal.

SHELL MARL.

This substance is extensively distributed in marshes, lakes and ponds throughout the Upper Silurian region in the northern part of the Province. It is a nearly pure carbonate of lime, and is valuable as a manure, as well as for the manufacture of lime. It originates from springs highly charged with the bi-carbonate, a soluble salt of lime; this becomes converted into the insoluble carbonate or chalk as soon as it reaches the air. Land shells abound in such waters, in consequence of their containing the necessary material with which small molluscous animals construct their habitations; hence it usually bears the name of shell marl, although the marl would not be one atom less in quantity if the shell-builders did not exist. These small creatures are numerous there, because the conditions for their increase are in the highest degree favourable.

KAOLIN FOR POTTERY.

Throughout the granitic region in the County of Charlotte, and particularly on the flanks of the felspathic range which runs through that County, there are several ponds and lakes which contain a whitish mud, composed altogether of impure kaolin. From personal experience, I am not aware of any very considerable deposit, but I have been informed on excellent local authority, that this material exists in great abundance, and in a comparatively pure state, in the form of an impalpable mud, covering the bottom of a lake lying within the limits of the felspar region in Charlotte County. As this is not only very probable, but of some economic importance, the more especially as efforts are now being made in St. John to establish extensive pottery works of the better sort, it is desirable that such deposits should become publicly known, and use made of them.

CLAY FOR BRICKS AND POTTEBY, MOULDING SAND, &c.

When voyaging up the Saint John River in canoe during the past summer, the remarkable deposits of fine blue and yellow clays which appear in the form of high banks some miles above the Grand Falls, seemed to merit attention. The quantity is unlimited, and the quality of some of the layers appeared to be excellent. Other bands are too calcareous, and others too ochreous to serve for the manufacture of bricks or pottery. Layers of fine sand, suitable for moulding sand, are common on the Saint John, and an

immense deposit was seen below Tibbits' Brook, near the mouth of the Tobique, and also in patches lower down the river, and about 20 miles above the Grand Falls, where fine clays suitable for pottery and bricks are abundant.

BLUE PHOSPHATE OF IRON—PIGMENT.

This beautiful mineral is found in considerable quantities in the alluvial clay-banks just alluded to, about 25 miles above the Grand Falls, near the mouth of Green River. The bank here is remarkable, and is worthy of a more minute examination that could be devoted to it. Being situated not far from the thickly settled Parish of Saint Basil, it may become a valuable source of industry to the Acadian settlers on the river banks. The whole of the alluvial terraces of this part of the Saint John, particularly on the east side, are rich in clays, sands, ochres, and blue phosphate of iron.

GOLD.

The interest which is naturally attached to rocks containing the precious metal, or to drift clays and sands throughout which it is distributed, may render an account of the manner in which gold is found in either form acceptable to the general reader, and with this view the following abbreviations from the "Geology of Canada" are subjoined:—

'The existence of gold in the sands of the Chaudière valley was first made known by Lieutenant, now General Baddeley, R. E., in 1835; and within the last twelve years repeated examinations have shown that the precious metal is not confined to that region, but exists in the superficial deposits of a wide region on the south side of the Saint Lawrence extending from the Saint Francis to the Etchemin River, and from the first line of hills on the northwest to the province line on the southeast. The source of the gold appears to be the crystalline schists of the Notre Dame range; and the materials derived from their disintegration, not only constitute the superficial material among the hills of this range, but are spread over a considerable area to the south of them. These same gold-bearing rocks may be traced south-westwardly, along the great Appalachian chain to the southern States of the Union, and are supposed to belong for the most part to the Quebec group. Native gold has however been found in small grains with galena, blende, and pyrites, in a well defined quartz vein, cutting slates which are supposed to be of Upper Silurian age, at the rapids of Saint Francis, on the Chaudière.* In Leeds, at Nutbrown's shaft, masses of native gold of several pennyweights are found with copper-glance and specular iron ore, in a vein of bitter-spar; and small grains of the metal have also been found imbedded

* In 1862, another quartz vein was opened about 100 yards from the last, and has yielded fine specimens of native gold, associated with arsenical pyrites. In 1863, native gold was discovered in a quartz vein with vitreous copper ore, at what is called the Chaudière copper mine, in the rear part of the seigniorie of Saint Giles. An assay of this quartz by Dr. Hayes of Boston yielded only $\frac{6}{10}$ pennyweights of gold to the ton. Gold has also recently been found in a vein at the Halifax copper mines, by George Piercc, Esquire, and an assay of the vein-stone from this place gave about the same proportion of the precious metal as the quartz from Saint Giles. Traces of gold have also been found in a decomposing pyrites from Moulton Hill in Ascot, and it has recently been met with in Ditton.

in a white garnet-rock described elsewhere.* These latter localities belong to the rocks of the Quebec group, but the precious metal has rarely been found in place, and the working of it in Canada has been confined to the superficial deposits of clay, sand, and gravel already mentioned. The occasional occurrence in these of pieces of gold partially imbedded in quartz, shows that it was derived, in part at least, from beds or veins of this mineral, which are common among the talcoid slates of the region. The observations among the gold-bearing rocks of the Southern States seem to show that the precious metal was originally deposited in the beds of various sedimentary rocks, such as slates, quartzites, and limestones, and that by a subsequent process it has been, in some instances, accumulated in the veins which intersect these rocks. The formation of these veins would seem, from the one above described at Saint Francis, to be subsequent to the Silurian period. The same considerations apply to the copper and lead ores of the Eastern Townships.'

MANNER IN WHICH THE GOLD IS DISTRIBUTED.

'The gold is found very generally disseminated throughout the diluvial deposits over the region already designated in Canada, and is not confined to the river beds; the action which distributed the gravel over the surface being anterior to the formation of the present water-courses. When, by the process of washing, the heavier portions of the auriferous gravel have been brought together, they are found to contain abundance of black ferruginous ores, consisting of magnetic iron, hematite, both specular and compact, chromic iron and ilmenite; with occasional grains of garnet, rutile, and more rarely zircon and corundum. The gold is in grains, sometimes angular, but more often rounded, and varying in size from masses of half a pound weight to a fine dust, which last is separated by amalgamation from the black iron-sand.

Mention is made in the Geology of Canada, (pages 518, 520,) of a quartz vein at Saint Francis, on the Chaudière; where small grains of native gold have been found imbedded in quartz, together with argentiferous galena, and sulphurets of zinc and iron, both containing gold, and with arsenical pyrites; much larger specimens of gold have since been found in quartz, about one hundred yards from the locality just mentioned. It is probable that this, and similar quartz veins, may be wrought with profit; but the gold hitherto obtained from this region has been from the superficial deposits of clay, sand and gravel which abound there, and appear to be derived from the breaking up of the rocks that contain the gold-bearing veins. These deposits probably belong in part to the *ancient glacial drift*, or boulder formation, and in part to newer stratified clays and gravels, which consist of the materials of this, modified and arranged by the subsequent action of water. On the Magog River, above Sherbrooke, particles of gold occur in a hard-

* This rock occurs with serpentine on the river Guillaume, the most northern tributary of the right bank of the Chaudière in Vaudreuil. The next one, being in the southern part of Saint Joseph, is named on Bouchette's map the Rivière des Plantes.

bound gravel, 156 feet above the level of Saint Francis, near by. On the Famine River, there is met with an extensive deposit of clay, every where overlaid by sand and gravel. Along the banks of the river, a stratum of the oxyds of iron and manganese, in some parts six or eight inches thick, is seen near the top of the gravel, filling interstices among pebbles of the rocks of the region. Gold is found in this overlying gravel, as well as in the clay beneath; both of which deposits appear to belong to the modified drift. It is met with in similar conditions throughout the banks of stratified material on the Metgermet, which attain a height of fifty feet above the bed of the river. Gold also occurs still more abundantly in the recent alluvions found in the beds and along the flats of the streams which traverse this region, and in time of floods wash down the clay and sand from their banks, depositing the heavier portions along their course. In this way the gold is often caught in the fissures of the clay-slates, which frequently form the underlying rock, and are rich in alluvial gold.

The auriferous drift of Eastern Canada is spread over a wide area on the south side of the Saint Lawrence, including the hill-country belonging to the Notre Dame range, and extending thence south and east to the boundary of the Province. These wide limits are assigned, inasmuch as although gold has not been everywhere found in this region, the same mineralogical characters are met with throughout; and, in its continuation southward, in Plymouth and elsewhere in Vermont, considerable quantities of gold have been obtained from the alluvial deposits.

It would appear from the facts here given that the quantity of gold in the valley of the Chaudière is such as would be remunerative to skilled labour, and should encourage the outlay of capital. There is no reason for supposing that the proportion of the precious metal to be found along the Saint Francis, the Etchemin, and their various tributaries, is less considerable than that of the Chaudière.

THE HYDRAULIC METHOD.

What is called the hydraulic method of washing such deposits is adopted on a great scale in California, and to some extent in the States of Georgia and North Carolina. "In this method, the force of a jet of water, with great pressure, is made available both for excavating and washing the auriferous earth. The water, issuing in a continuous stream, with great force, from a large hose-pipe like that of a fire-engine, is directed against the base of a bank of earth and gravel, and tears it away. The bank is rapidly undermined, the gravel is loosened, violently rolled together, and cleansed from any adhering particles of gold; while the fine sand and clay are carried off by the water. In this manner hundreds of tons of earth and gravel may be removed, and all the gold which they contain liberated and secured, with greater ease and expedition than ten tons could be excavated and washed in the old way. All the earth and gravel of a deposit is moved, washed, and carried off through long sluices by the water, leaving the gold

behind. Square acres of earth on the hill-sides may thus be swept away into the hollows, without the aid of a pick or a shovel in excavation. Water performs all the labor, moving and washing the earth in one operation; while in excavating by hand, the two processes are of necessity entirely distinct. The value of this method, and the yield of gold by it, as compared with the older one, can hardly be estimated. The water acts constantly, with uniform effect, and can be brought to bear upon almost any point, where it would be difficult for men to work. It is especially effective in a region covered by trees, where the tangled roots would greatly retard the labor of workmen. In such places, the stream of water washes out the earth from below, and tree after tree falls before the current, any gold which may have adhered to the roots being washed away. With a pressure of sixty feet, and a pipe from one and a half to two inches aperture, over a thousand bushels of earth can be washed out from a bank in a day. Earth which contains only one twenty-fifth part of a grain of gold, equal to one fifth of a cent in value to the bushel, may be profitably washed by this method; and any earth or gravel which will pay the expense of washing in the old way, gives enormous profits by the new process. To wash successfully in this way requires a plentiful supply of water, at an elevation of fifty to ninety feet above the bed-rock, and a rapid slope or descent from the base of the bank of earth to be washed, so that the waste waters will run off through the sluices, bearing with it gravel, sand, and the suspended clay."

The above description has been copied from a report on the gold mines of Georgia, by Mr. William P. Blake, who has carefully studied this method of mining in California, and by whose recommendation it has been introduced into the Southern States. He tells us that in the case of a deposit in North Carolina, where ten men were required, for thirty-five days, to dig the earth with pick and shovel, and wash it in sluices, two men, with a single jet of water, would accomplish the same work in a week. The great economy of this method is manifest from the fact that many old deposits in the river-beds, the gravel of which had been already washed by hand, have been again washed with profit by the hydraulic method. He tells us that in California the whole art of working the diluvial gold-deposits was revolutionized by this new method. The auriferous earth, lying on hills, and at some distance above the level of the water-courses, would, in the ordinary methods be excavated by hand, and brought to the water; but by the present system, the water is brought by aqueducts to the gold-deposits, and whole square miles, which were before inaccessible, have yielded up their precious metal. It sometimes happens, from the irregular distribution of the gold in the diluvium in California, that the upper portions of a deposit do not contain gold enough to be washed by the ordinary methods; and would thus have to be removed, at a considerable expense, in order to reach the richer portions below. By the hydraulic method however, the cost of cutting away and excavating is so trifling, that there is scarcely any bank of earth which will not pay the expense of washing down, in order to reach the richer deposits of gold beneath.

The aqueducts or canals for the mining districts of California are seldom constructed by the gold-workers themselves, but by capitalists, who rent the water to the miners. The cost of one of these canals, carrying the waters of a branch of the Yuba River to Nevada County, was estimated at a million of dollars; and another one, thirty miles in length, running to the same district, cost \$500,000. The assessed value of these various canals in 1857, was stated to be over four millions of dollars, of which value one half was in the single county of Eldorado. The Bear River and Auburn Canal is sixty miles in length, three feet deep, and four wide at the top, and cost in all \$1,600,000; notwithstanding which, the water-rents were so great that it is stated to have paid a yearly dividend of twenty per cent.; while other similar canals paid from three to five and six per cent., and even more, monthly. The price of the water was fixed at so much the inch, for each day of eight or ten hours. This price was at first about three dollars, but by competition it has now been greatly reduced.

CAPITAL REQUIRED IN GOLD MINING.

From the foregoing statements, it will be seen that the great riches which have of late years been drawn from the gold mines of California, have not been obtained without the expenditure of large amounts of money and engineering skill. This last is especially exhibited in the construction of these great canals, and the application of the hydraulic method to the washing of auriferous deposits which were unavailable by the ordinary modes of working, on account of their distance from water-courses, or by reason of the small quantity of gold which they contain.

In order to judge of the applicability of this method of washing to our own auriferous deposits, a simple calculation based upon the experiments upon the Riviere du Loup will be of use. It has been shown that the washing of the ground over an area of one acre, and with an average depth of two feet, equal to 87,120 cubic feet, gave in round numbers, about 5000 pennyweights of gold, or one and thirty-eight hundredths grains to the cubic foot; which is equal to one and three-quarters grains of gold to the bushel. Now, according to Mr. Blake, earth containing one forty-fourth part of this amount, or one twenty-fifth of a grain of gold, can be profitably washed by the hydraulic method; while the labor of two men, with a proper jet of water, suffices to wash one thousand bushels in a day; which, in a deposit like that of Riviere du Loup, would contain about seventy-three pennyweights of gold. It is probable however that a certain portion of the finer gold dust, which is collected in the ordinary process, would be lost in working on the larger scale. It has already been shown that the gold in Canada is not confined to the gravel of the river channels, and the alluvial flats; but it is found on the Metgermet and Saint Francis Rivers, at from fifty to a hundred and fifty feet above their beds; and although its proportion were to be many times less than in the gravel of the Riviere du Loup, these thick deposits, which extend over great areas, might be profitably worked by the hydraulic method. The fall in most of the tributaries of the Chau-

diere and of the Saint Francis, throughout the auriferous region, is such that it would not be difficult to secure a supply of water with a sufficient head, without a very great expenditure in the construction of canals; and it may reasonably be expected that before long the deposits of gold-bearing earth, which are so widely spread over the southeastern Canada, will be made economically available.*

GOLD WASHINGS IN RUSSIA.

Formerly the Russian mines were celebrated throughout the world for their productiveness. They are principally drift and alluvial washings, and the quantity yielded by the clays, sands and gravel does not generally exceed one grain of gold for 60 lbs. of earth, but sometimes the yield rises to double that average, but never exceeds it. The washings on the River du Loup yielded one and thirty eight hundredths of a grain of gold to the cubic foot of soil, hence it is probable that from this comparison, the Canadian Drift would be amply remunerative if the hydraulic method were employed, and as the Drift extends into this Province on the upper Saint John, it may be worth while to examine the glacial deposits there. Gold has been found in the drift over a large area in the valley of the Saint John, which runs through the State of Maine. Its source is probably the Quebec Group of rocks just north of the Boundary Line, or it may be that the auriferous quartz veins in the Upper Silurian Rocks have largely contributed to the productive clays in that region.

GOLD IN NEW BRUNSWICK.

In this Province there is a large area occupied by auriferous drift, but in consequence of its shallowness, it appears probable that it will not be found so rich as in Canada East, in those localities which are supposed to lie nearest the source of the gold. An exception to this may, perhaps, be found in the upper Saint John, whose waters are in direct communication with the source of the auriferous drift of Canada East.†

In this Province drift gold has been found in the following localities during the past Summer.

I.—*The Upper Upsalquitch.*

The drift on the shores of Upsalquitch Lake is feebly auriferous. The adjective is used in order to express what the writer himself ascertained, but it may be quite inapplicable when applied to the experience of more prospectors in this region. Very fine particles of gold were obtained by washing the

* Notes on the gold of Eastern Canada, being a reprint of portions of various Reports of the Geological Survey of Canada from 1845 to 1863.

† "It is not supposed that the limits of the auriferous district have been ascertained, but that it very probably extends much farther to the northeast, and attains the valley of the River Saint John; while to the southwest it is known to reach Vermont, and to be traceable at intervals through the United States, even it is said as far as Mexico. In its breadth, however, it does not appear to cross the range of mountains with which it runs parallel, and no traces of it have been met with on their northwestern flank."—(Geology of Canada, Report 1851.)

alluvial soil in a brook near an old lumberer's camp, about a quarter of a mile from the Lake. But the experiment was not considered decisive; the only means of digging were furnished by a large hunter's knife, and the only means of washing by a tin plate. Very fine black sand was obtained in considerable abundance. In order to make a fair trial of this part of the country, the drift should be taken from the surface of the rock on which it rests, and at least ten bushels of it thoroughly and carefully washed, as the gold will most probably be, like the sand, exceedingly fine. There is a very large proportion of quartz debris in the river where it issues from the lake; some of the larger fragments were broken and carefully examined, but without success.

II.—*The Nipisiquit.*

On the lower Nipisiquit, near the Grand Falls, I collected the sand and gravel which had been lodged in crevices on the side of a steep declivity down which a small stream sends a thin column of water in the spring and fall. I washed about one gallon of the sand and found several small grains, two filaments, and some very fine gold. If the gold, as I suppose, originates in the Quebec Group of rocks, the breadth of the series here north of the Grand Falls would not be more than three or four miles in the direction of the glacial grooves; thirty miles up the river it would be at least 18 miles broad in the direction of the glacial grooves, but there I made no attempt to wash for gold; had I been aware of its existence in the drift near the Grand Falls, I should certainly not have omitted to give the drift about the Indian Falls a fair trial.

III.—*Campbell River and Long Lake.*

I washed the alluvial drift on this river near the mouth of Long Lake fork, and found much black sand, with a few particles of gold.

IV.—*Long Lake Dividing Ridge.*

The sands in the bed of a small river leading from the height of land into Long Lake looked very promising, I washed two pans but found neither black sand nor gold; but the drift clay on the dividing ridge between the Long Lake waters and the Little S. W. Miramichi is auriferous. This, however, is essentially a granite boulder country; the substratum in the valleys being composed of huge boulders through which the small streams of water flow for miles without appearing at the surface.

V.—*The Serpentine.*

There is very little drift on this river; and the rocky banks below Campbell River are between 500 and 600 feet high for several miles down. The drift above the rise of the river is auriferous, but the alluvial drift gave no gold.

VI.—*Blue Mountain Brook.*

In a valley on the north side of Blue Mountain, near a Beaver dam, a quart of clay gave several small specks of gold. There being, however, no water conveniently situated for washing near at hand, I instructed an Indian

to carry a tin can holding about one and a half gallons of earth until we came to water; the earth yielded several scales and grains of gold about one eighth of an inch in diameter. It was taken from as low a level in the almost dry valley of the brook as possible, and the stones were picked out. This is perhaps the most favourable specimen of auriferous drift I have met with in the Province, but it does not equal drift which I have washed on the River du Loup in Canada.

VII.—*The Little South West Miramichi.*

The drift from this river is feebly auriferous. The gold is very fine, as well as the black sand. Alluvial clay was taken from the immediate bank of the river, and may have been thoroughly washed by river action. The drift on the side of the hill showed more black sand, and perhaps a few more very fine particles of gold; but on the whole the washings were not encouraging.

VIII.—*Springfield, seven miles northwest of Norton Station.*

The gravel from a small brook in Springfield gave an unusually large quantity of the black sand, much of which consisted of the black magnetic oxide; there were also scales of specular iron, and two or three very small particles of gold. The large proportion of the iron sand is explained by the existence in this vicinity of an important bed of the magnetic oxide, the boulders of which are numerous throughout this part of the country.

IX.—*Between Hopewell and Golden Mountain.*

Two trials hastily made during very rainy weather late in the fall, showed that the Drift of this part of the country is slightly auriferous; but these trials are not considered sufficient or satisfactory.

X.—*Dutch Valley Road.*

Some fragments of iron pyrites taken from a vein penetrating an altered schistose rock on the road from Sussex Vale up the Dutch Valley to the Shepody Road, yielded traces of gold. I was subsequently shown some specimens of iron pyrites in which gold could be distinctly seen with the unassisted eye, which it was stated came from the same locality.

Conclusions.

Upon a review of the few attempts, properly conducted, which I have been able to make during the past summer in relation to the auriferous character of the Drift clays which cover certain portions of the country, the following conclusions appear to be just:—

1st. Experience shows that certain Drift clays in the Province are auriferous; but

2nd. No sufficient proof has yet been obtained to show that these Drift clays are so rich in the precious metal, as to make the working of them a promising speculation; and

3rd. Sufficient trials have not yet been made to admit of any definite opinion being expressed in relation to them, but enough is known to render a further and a systematic examination very desirable.

With capital to erect and conduct hydraulic operations to wash the Drift, there can be no doubt whatever that the clays in some localities would amply remunerate the outlay, but for the ordinary operation of sluicing on a small scale, considered in relation to the geographical position of these clays, their remoteness from any source of supply, it would require more exact information than is at present available to warrant the expression of a favourable opinion. At the same time the fact must be taken into consideration and kept constantly in view, that the examinations were made only in the superficial deposits of clay, whereas coarse gold from its great specific gravity is found in the lower stratum and generally on or close to rock upon which the clays rest. These lower clays have in no single instance been reached, neither time nor labour being at my command to enable me to examine them. While therefore the ascertained presence of Gold in the upper Drift, is not yet, by itself, worthy of being regarded of much importance, as a source of the precious metal; it is of very considerable importance as showing—

1st. The probability that the lower and unmodified clays, constituting the original Glacial Drift, will be found remunerative when worked by the hydraulic process.

2nd. That the origin of the Drift establishes the fact that gold bearing rocks exist within the limits of the Province over wide areas, to the north of the localities where the fine gold in the superficial Drift has been discovered; and

3rd. That these gold bearing rocks probably lie within the limits of the Lower Silurian Series, and especially of that portion which has been described as the Quebec Group.*

The recent official Report of the Inspector of the Chaudiere District, (November 30th 1864,) Major de Bellefeuille, gives an encouraging account of gold discoveries in Canada. The labours of an average of 250 men extended over 116 days, were estimated to yield \$116,000.

"As I remarked above," says the Inspector, "if the unfavourable weather the miners experienced in September and October be taken into consideration; also the small space from which that amount was extracted, viz: about three square *arpents*, it cannot but prove the immense wealth of this gold-bearing region. The success with which the few miners still remaining here meet, is but another proof of gold in this part of the Province; it's only a few days ago that one man took out, in one day, nine ounces, and the day previous, the same person had found a nugget of five ounces; that amount was found in a claim that had been, as they believed, well worked. Corroborating thereby what I heretofore mentioned, how imperfectly the mining was carried on."

* On the River du Loup in Lower Canada, Upper Silurian Rocks, penetrated by quartz veins, are supposed to be one source of the gold of that valley, and of the Chaudiere. Upper Silurian Rocks cover nearly the whole of the Province north of the Quebec Group, but it is not known whether they are penetrated by quartz veins.

The positive existence of gold in quartz veins penetrating the Upper Silurian Rocks over a wide extent of country, gives especial value to a large area in New Brunswick, north of the Quebec Group, where altered Upper Silurian Rocks occur.

"Quartz veins are to be found everywhere from the village of St. Francois to the boundary line. Gold has been detected in almost every vein; there is one particularly in the upper part of the first concession, not very far from the Gilbert line, produced by assay, viz: 22 dollars of silver and 15 dollars of gold per ton. This was taken from the surface,—the width of the vein being six feet,—and stripped to the length of 40 feet. Another very promising vein running northeast, intercepted by numerous small veins running due east and west, exists opposite the church of St. Francois on the eastern side of the village. It is supposed to cross the river and continue on the western side of the River Chaudiere.

"In the vicinity of the Famine, quartz has also been found. The mouth of the Du Loup has also brought out innumerable small veins running parallel to each other, in which gold has been found. On the Mill Stream and at the Grand Coulee, both tributaries of River Du Loup, quartz has been assayed, and found to contain gold.

"About the Metgermette and the Oliva, fine quartz is also to be met with. Not very distant from those two rivers, quartz was found on the Du Loup, which having been assayed gives 8 dwts. to the ton; this was also taken from the surface. Between the Portage and Kempt streams, tributaries of the Du Loup, two large veins are observed, they also contain gold. A short distance from the Monument River, a beautiful vein of quartz is to be seen from which gold has been extracted, by merely breaking the surface of the quartz with a hammer; the same results were obtained by Professor Hind,—I believe it was about the Metgermette—by merely crushing it with a stone.

"Quartz veins are to be opened and worked next spring at the village of St. Francois; the Devil's Rapids, where a crushing mill is to be erected. On the Oliva or Metgermette, there is another mill to be constructed. On the highlands of the Du Loup, and I believe on the Kempt stream, veins will be worked and that with profit. From the opinion I have heard expressed by several Professors of Geology, who have visited the mines, and particularly the quartz lodes during the season, I cannot but prognosticate great results to the country by the opening up of such lodes, and by the proper development of the mines which lay buried in this extensive and rich region. There is not the least doubt as to the presence of gold, and that in large quantities."

The quartz vein alluded to by the Inspector as having been found to contain gold by the writer of this Report, is situated on the Du Loup, near to the Metgermette, which river it probably crosses. A description of this vein, and of the mode in which the gold was obtained, together with a particular account of the auriferous character of an area containing 6,600 acres on the Du Loup, and embracing part of the Metgermette, is contained in a Report by the writer, on the River du Loup Mining Company's property.* The statements embodied in the above extracts from Major de Bellefeuille's Report, appear to show that gold is generally distributed in the quartz veins of the UPPER SILURIAN Rocks on the Du Loup. Rocks of this age occurring in New Brunswick, north of the Quebec Group, (see Chapter VII.) suggest the possibility of similar auriferous areas being found in this Province.

* Boston, 1861. Report on the River du Loup Mining Company's location, by Henry Y. Hind.

MISCELLANEOUS MATERIALS NOT IN THE DRIFT.

PLUMBAGO OR GRAPHITE.

The occurrence of Plumbago or Graphite in many localities in this Province, coupled with the valuable process invented by Mr. Brockendon for purifying and preparing this material, make it desirable that attention should be directed to known deposits in New Brunswick. Although graphite or plumbago is widely distributed in small quantities, the following localities are worthy of special notice: Portland, Hammond River, Four miles north of Saint Stephen, Dorchester, Mackerel Cove, Goose Creek. Plumbago is known under the names of Graphite, Black Lead, and Carburet of Iron. Black lead pencils were in use in 1565. At one time £100,000 sterling was realized from the Borrowdale mine in Cumberland (England) in one year, the Cumberland plumbago selling at 45 shillings a pound. This source of supply is now nearly exhausted. Norway, Finland, Ceylon, the East Indies, Bohemia, and Canada, all furnish more or less of this material. The price of which has diminished on account of the discovery of a process by Mr. Brockendon by which impure varieties can be purified. Mr. Brockendon conceived the idea of solidifying the powder by pressure, without the intervention of any foreign adhesive substance, such as glue or gums.

The presence of air between the particles of plumbago proved in the first instance a fatal objection, the apparatus employed in the compression breaking at each attempt. By exhausting the air from the powder previously introduced into paper cylinders, under the receiver of an air pump, it was found that when subsequently submitted, without exposure to the atmosphere, to a heavy pressure, perfect adhesion of the particles took place, and a mass of plumbago or graphite was produced equal in beauty and solidity to the native minerals of Cumberland.

Ordinary plumbago is too impure to be submitted to this process without preparation. It is essential for the success of the operation that the foreign substances should be eliminated.

Mr. Brodie effects this by submitting the plumbago in coarse powder in an iron vessel to twice its weight of common sulphuric acid, and seven per cent. of chlorate of potash, and he heats the whole over a water bath until chloric oxide ceases to be evolved. By this means the compounds of iron, lime, and alumina present, are rendered for the most part soluble, and the subsequent addition of a little fluoride of sodium to the acid mixture, will decompose any silicates which may remain and volatilize the silica present. The mass is now washed with abundance of water, dried and heated to redness. This last operation causes the grains of plumbago to exfoliate, and the mass swells up in a surprising manner, and is reduced to a state of very minute division. It is then levigated, and obtained in a state of great purity, ready to be compressed by the method of Brokendon.*

* Vide Ure's Dictionary of Arts, Manufactures, and Mines. Last Edition.

Besides its use for the manufacture of pencils, this finely divided plumbago is advantageously employed for the glazing of gunpowder, and for the preparation of a paint.

DOLOMITES.

Dolomite is a mineral which in its purest state is composed of equivalent weights of carbonate of lime and carbonate of magnesia, these being in the proportions of 50 to 42, or in 100 parts of 54.35 of carbonate of lime, and 45.65 of carbonate of magnesia. This compound is distinguished from carbonate of lime by its greater density (which is from 2.85 to 2.90), and by its somewhat superior hardness. It is also much less readily attacked by acids than carbonate of lime, and at ordinary temperatures does not perceptibly effervesce with nitric or muriatic acids, unless reduced to powder. When calcined it gives a mixture of lime and magnesia, which is said to yield a stronger mortar than ordinary lime, but which slakes slowly and with but little evolution of heat.

A portion of the magnesia in dolomite is often replaced by protoxyd of iron, and more rarely by oxide of manganese. The dolomites containing carbonate of iron are generally yellowish or reddish on their weathered surfaces, from the change of a portion of the iron into hydrated peroxide, and those containing carbonate of manganese become brownish-black on the exterior from a similar cause.

Crystallized dolomites occur in veins and cavities in various rocks, and have received the names of *bitter-spar* and *pearl-spar*, the latter in allusion to the pearly lustre of the faces of the rhombohedron, which are generally curved.

Bitter Spar form the chief part of the vein stone of the Vernon Copper Mines.*

Dolomites may be produced by the mutual decomposition of bicarbonate of lime and sulphate of magnesia, yielding gypsum and bicarbonate of magnesia, which are successively deposited by evaporation. Hence the constant association of magnesian rocks with stratified gypsums. When bi-carbonate of lime which is abundant in sea water, is precipitated as a carbonate and mingled with carbonate of magnesia, they give rise to a double carbonate which constitutes dolomite.

HYDRAULIC CEMENTS.

The thin bands of limestone which occur in great profusion throughout the Upper Silurian Series as developed on the Saint John above Presqu'île, and also many of the thin layers in the lower rocks near Woodstock, would yield a good hydraulic cement. The properties of this material are dependent upon an admixture of clay with the lime, and artificial compounds can be frequently prepared and used to a large extent.

* For an excellent description of the origin, distribution, and characters of dolomites, the reader is referred to an article by Professor Sterry Hunt, in the Report of the Geological Survey of Canada for the year 1857. Also, page 217 of the Report for 1858, where the origin of dolomites is discussed.

The Hydraulic cement employed in the construction of the Victoria Bridge consists of,—

Lime,	58.55
Magnesia,	2.20
Silica,	29.88
Alumina and oxide of iron,	12.70
Sulphate of Lime,	1.58
							99.91

This cement was found to set in from ten to fifteen minutes after mixing, with disengagement of heat.

Artificial mixtures are prepared by mingling carbonate of lime with clay and calcining the mixture; when natural admixtures of clay and lime occur, they are more advantageously employed than those prepared by artificial means, probably on account of the intimate mixture of the materials of which they are composed.

When a limestone contains ten or fifteen per cent. of clay, it becomes an hydraulic limestone; when the clay amounts to one third of the lime the mixture yields a mortar which hardens almost immediately under water. Dolomites and magnesian limestones generally yield with clay an equally good hydraulic cement.

GRINDSTONES.

The falling off in the manufacture of grindstones in the Province is remarkable. The number produced in 1851 was 58,849, against 42,476 in 1861, being a decrease of 16,373. This decrease has taken place in the County of Westmorland, which produced 33,080 less in number in 1851 than in 1861. In Gloucester an increase of 6,898 is recorded in the Census Tables.

PROBABLE INDIAN RELICS ON THE ATLANTIC COAST.

On various parts of the Atlantic Coast, and more especially on the coast of Maine, heaps of shells, interstratified with charcoal, and commingled with bones of existing animals have been discovered and described from time to time. The interesting discussions which have taken place in Europe respecting the antiquity of man in connection with the remarkable discoveries of his handy work in nearly all European countries, of an age far more remote than has generally been assigned to his existence on earth, invest with much interest whatever may tend to throw light upon this difficult but fascinating subject.

Relics of Indians, evidently of very great antiquity have been found at Newcastle, Trenton, Damariscotta, Goose Island, and many other places in Maine, and with less confirmation, on various parts of the coast of New Brunswick, in Charlotte County.

A few years since, Professor Chadborne of Bowdoin College, published, in the transactions of the Maine Historical Society, an account of a visit to the beds of oyster shells at Damariscotta. He considered them to afford

indubitable evidence that the beds had been made by men. He drew the inference from the position of the piles of shells, the deposit beneath them, the arrangement of the shells in piles, the frequent occurrence of charcoal mixed with the shells even to the bottom, from the fact that fires had evidently been built among them near the bottom, turning a portion of them to lime, which is mingled with the charcoal, and finally, from the mixture of other animal remains, as common clams (*Mya arenaria*), thick shelled clams (*Venus mercenaria*), fragments of the bones of birds, the bones of beavers, with their teeth, and sturgeons plates.

The shells occur in small piles 10 or 15 feet in diameter, and apparently two or three feet deep. The deposit under the shells differs in no respect from the land in the immediate neighbourhood. The shells are entirely distinct from the soil and seem to have been thrown together in a heap. Fires appear to have been occasionally built upon the heaps, fragments of charcoal being numerous in layers.

In "Sewall's Ancient Dominions," a still more circumstantial account is given of similar deposits upon Sayers's Island. Here they are estimated to cover in the aggregate ten acres of soil, consisting of the debris of the bony skeleton of "man, beast, fish, and fowl," in every stage of decomposition from the dusty outline of crumbling earth crushed bones, to perfect skulls, joints, and teeth, in good preservation. The remains of *Mya edulis* or the common clam constitute the great deposit on Sawyer's Island.

Mr. C. H. Hitchcock states that two species of oyster occur in the Newcastle beds, *Ostrea borealis* and *O. Virginiana*. The latter shell, according to Mr. Hitchcock, has not been found living upon the coast of Maine, although it is thought to occur on Prince Edward's Island. The *O. borealis* is very rare upon the Maine coast, and the shell found in the Newcastle beds is *Venus Mercenaria* or the quahog, a scarce shell now upon the coast. It is supposed that those species are now nearly extinct, where they were once very abundant, and served as a chief source of food for the Indians.

In Casco Bay numerous piles of the Indian shell remains are found on many of the Islands; also about Mount Desert, they are common in small piles or heaps along the coast. At Trenton, one of the heaps is six feet thick.*

Two years since Mr. Morse gave an account to the Portland Natural History Society, of some excavations he had made at Goose Island, Casco Bay, in deposits of shells of *Mya arenaria* probably made by the Indians. Beneath the whole deposit and two feet from the surface of the shells, he came upon stones which rested in the old ground surface, under which, he found species of land shells not now living on the island, or of rare occurrence; among them were a few specimens of *Helix multidentata* hitherto rarely found in the interior of the State.

* 1st Report of the Geology of Maine.

NOTE ON THE ANTIMONY DEPOSITS IN PRINCE WILLIAM PARISH.

In a resumé of the favourable circumstances connected with the distribution of the ores of antimony in Prince William Parish, attention was drawn to "their occurrence on lines of fracture and dislocation, proving the veins to be 'true veins' of unknown vertical depth and horizontal extension," also, to "the purity of the grey antimony ore and its gradual passage into lamellar native antimony as the veins deepen." A recent excursion to the Mines of the Brunswick Antimony Company (March 1865), made for the purpose of ascertaining how far the progress of operations during the winter months had attested the correctness of the conclusions arrived at in November 1864, or might lead to modifications in the views then expressed, enables me to add some interesting facts in relation to the character of the fractures or dislocation in which the veins are seated, and to point out an important distinction in the kind of ore found in each vein.

In November last Pit No. 1 had been sunk to the depth of 68 feet, and the so-called "floor vein" and "roof vein" were described as joining together and forming one sheet at that depth. The miners have now reached a depth of 94 feet on the incline, and have made four Drifts, three to the west—No. 1, 20 feet; No. 2, 20 feet; No. 3, 40 feet; and one to the east (16 feet).

The deepening of the pit has revealed the following remarkable peculiarities:—

The two veins, instead of merging or blending into one vein at the depth of 68 feet, are seen to preserve a confluent course downwards at an angle of about 43 degrees. They do not blend together, there being a distinct line of demarkation between them, and on blasting or splitting off the "floor vein," it separates from the "roof vein" with a clean surface, having apparently a perfect cast of a former slickensided wall, which is reproduced on the lower surface of the "roof vein." Between the two veins there are occasionally thin stellar or radiating chrysaline forms of brilliant ore, probably native antimony.

The confluent veins were seen at a depth of 94 feet, to be respectively 16 inches and 8 inches in thickness, but the lower or "floor vein" varies much.

The "roof vein" is a decided conglomerate, holding, as stated in this Report, fragments of the country rock; the "floor vein" appear to be quite homogenous, and contains only the ore with quartz.

The ore in the roof, or conglomerate vein, consists now almost altogether of the sulphuret of antimony, with quartz and carbonate of lime. The ore in the floor, or homogeneous vein, contains the sulphuret mixed with lamellar native antimony and a little quartz.

This observation will probably establish the following facts:—

1st. The intersecting dislocations described in the Report and shown on the plan are of different ages.

2nd. The roof or conglomerate vein is the newest.

3rd. The distinction between the ores is a characteristic one and will be maintained.

When the snow which now covers the surface melts, there will be no difficulty in ascertaining positively which is the older vein; it will be found to be intersected or cut at the surface by the newer vein, and the glacial polishing of the rock will make this important enquiry easily and speedily clear to the miners.

The geological reader will understand at once the reason why the roof vein is supposed to be the newer; its conglomerate character, coupled with the cast of a former slickensided wall on the upper surface of the lower vein being the evidence upon which the supposition is for the present based.

The practical importance of this difference in the veins becomes manifest when the nature of the ores they carry is taken into consideration. The old vein, according to past experience at the mines of the Company, carries a homogeneous mass of rich sulphuret mixed with native antimony.

The newer vein, besides being of a conglomerate character, containing pebbles of the country rock, carries the sulphuret only, or with very little native antimony, it is of great thickness, but when compared with the older vein the ore is impure.

The ore in the old vein appears to be largely distributed in "pockets." The Drifts show that it thins out and expands again in the course of a few yards.

The origin of these veins of different ages is as follows:—The older vein occupies fissures formed by a fracture and downfall in the strata; after these fissures were filled with ore and vein stone, a second disturbance produced a second and larger fracture where seen, which in some places, following the line of greater weakness, occurs on the course of the old vein. Into this second fissure the fragments of the country rock fell from time to time during the process of filling, which probably occurred under different conditions to those which prevailed during the filling of the older or first fissure, hence the difference in the quality of the ore.

The importance of this distinction in the veins becomes the more apparent when the area over which they have been traced is taken into consideration. It will probably be most advantageous to concentrate labour on the old veins, and the observations here described will enable them to be easily found.

NOTE ON THE SALT SPRINGS OF SUSSEX AND UPHAM.

The manufacture of Salt is frequently a very valuable field for private enterprise, and in many countries a lucrative source of revenue to Government. In the State of New York, the celebrated Onondaga Salt Springs have reached an astonishing development within the last few years. The amount of salt inspected in 1861, on the Onondaga Salt Springs Reservation, in and adjacent to the City of Syracuse, N. Y., was 7,200,391 bushels, being equivalent to 1,440,000 barrels, of 280 lbs. each. The duties collected by

the State amounted to \$72,003, although the duty is only one cent a bushel. The disbursements for the support of the Salt Springs amounted to \$45,000, and the dividend paid to the lessors of the salt vats reached 20 per cent. per annum. The salt trade of Syracuse is already enormous. This important article constitutes a large share of the return freight to the boats on the Erie Canal, and the vessels engaged on the great lakes in the transportation of grain and other western productions. The quantity of salt shipped from the Reservation, not forty miles from Oswego, amounted in 1858 to four hundred and twenty millions of pounds, or equal to the load of four thousand canal boats, with cargoes from fifty to one hundred tons. This quantity would ballast one thousand four hundred sailing vessels, with one hundred and fifty tons each. Canada obtains much of her salt from importations *via* the Saint Lawrence from Britain, but there is ample field and opportunity for manufacturing salt within her own boundaries. The shores of the Bay of Chaleurs and Gulf coast would probably afford many favourable localities for the establishment of salines; the heat of our summers of New Brunswick, which may be compared to those of the south of France, would produce a very rapid evaporation, while the severe frosts of the winters might be turned to account for the concentration of the water by freezing, as is practised in Northern Russia.

The value of the imported salt in this Province exceeded in 1862, twenty-one thousand dollars.

The Salines on the Gulf coast will probably attract attention in a few years, but at present the natural Brine Springs in the Parishes of Sussex and Upham, deserve more attention than they have yet received.

It is an important fact that some of the salt bearing strata in the State of Michigan are of the same geological age as the limestones, shales and conglomerates belonging to the lower carboniferous in the valley of the Kennebecasis and Petitcodiac.

The "Napoleon Sandstone" of Michigan is one source of the vast supply of salt which is now being manufactured in that State.

The position of this rock in Michigan, according to Winchell, is as follows :

1. Carboniferous Limestone,	66 feet.
2. Michigan Salt Group,	184 "
3. Napoleon Group,	123 "
(d.) Shaly micaceous sandstone,	15
(c.) Napoleon sandstone, highly saliferous in many localities,	78
(b.) Shaly, micaceous sandstone,	15
(a.) Clay and shale, more than	15
4. Marshall Group,	173 "

Above the Michigan Salt Group (2), and the Napoleon Group (3), there are a series of strata called the "Parma Sandstone," which also furnish brine springs. These rocks lie just beneath the coal-measures.

The occurrence in the Parishes of Sussex and Upham of natural Brine Springs, from which salt has been manufactured, viewed in connection

with the circumstance that the rocks in these Parishes are of the same geological age as the salt bearing rocks in Michigan, renders it probable that the source of the brine would be reached by boring, and a copious supply of rich workable brine obtained. The depth to which the strata would have to be penetrated would not be an obstacle, and there is always a probability that if borings should be made to an extent of 1000 feet, not brine springs only, but petroleum might be reached in part of Sussex and an adjoining Parish.

The following notice of the Michigan Salt Works will be found interesting:—

THE MICHIGAN WORKS.*

“The existence of salt springs in the lower peninsula of Michigan has been known from the time of its earliest settlement, and when in 1836 the State was admitted into the Union, the privilege was granted her of selecting 72 sections of salt spring lands. In the following year she organized a geological survey, principally for the purpose of ascertaining the number and distribution of the salt springs in the State. This survey led to erroneous conclusions, and the borings for salt which followed these conclusions were unsuccessful.

In 1859 a second survey was commenced and this led to the discovery and announcement, for the first time, that below the carboniferous limestone of Michigan occurs a series, 180 feet thick, of argillaceous shales, clays, magnesian limestones, and beds of gypsum; and that here is truly the origin of the brine. The strike of the outcropping edges of these strata describes an irregular circle, inclosing all the central portion of the State. The Michigan salt group of rocks underlies 17,000 square miles, in the form of a vast reservoir, constituting the most magnificent saliferous basin on the continent. The edges are sufficiently elevated to prevent the efflux of water which finds its way into it, and hence the saline particles have never been washed away. Beneath this series of shales is a porous sandstone—the Napoleon sandstone—which, within the circumference of the basin, becomes saturated with brine from above. From the nature of the case, it is evident that the strongest brine must accumulate in the deepest part of the basin.

Under this more intelligent guidance new borings were commenced and a well at East Saginaw reached the solid rock at the depth of 92 feet, and after passing through the coal measures, with their terminal and initial sandstones, pierced the carboniferous limestone, and found the Michigan salt group of strata 169 feet thick and eminently saliferous. In the Napoleon sandstone beneath, 109 feet thick, the reservoir of the brine was struck, and a supply, abundant in quantity, and of 90° strength, was obtained at almost exactly the point which geology had predicted. This well was 669 feet deep, terminating near the middle of the sandstone. Another was subsequently bored, 806 feet deep, extending through the sandstone and penetrating the underlying shales 64 feet.

This decided success was attained early in 1860. By July of that year a “block” had been erected and boiling commenced. Before the close of the year 4,000 barrels of salt had been manufactured, and no less than four other companies had commenced boring at different points along the river.

The following analysis will exhibit the strength and purity of Saginaw brines in comparison with those of other salt-producing regions:—

Other constituents	0.127	0.220	0.013	—	—
Total solid matter in } 100 parts	24.170	22.017	21.140	18.540	9,209

As pure saturated brine has a specific gravity of 1.205, and contains 25.7 per cent of saline matter, it appears that the Saginaw brines approximate remarkably near to saturation.

The following Table exhibits further comparisons:—

Localities.	Weight of one gal. of brine.	Solid matter in one gal.	Pure salt in one gal.	Gals. required for 1 bushel salt.
Saginaw City,	lbs. 9.858	2.38	1.90	29
East Saginaw	9.775	2.15	1.75	32
Bay City	9.716	1.95	1.82	31
Syracuse	9.541	1.76	1.68	33
Kanawha	9.464	0.94	0.75	75

An intelligent writer in *Hunt's Merchants' Magazine* for September, to whom we are indebted for these interesting facts, states:—

It is now but two years since the first salt was manufactured in Saginaw valley; yet it is estimated that in this time the value of real estate has increased to the extent of three and a half millions of dollars in the Counties of Bay and Saginaw. At Carrolton, grounds suitable for salt lots, which, two years ago were bought at \$20 an acre, are now held at \$300 and \$400 per acre. At Saginaw city, salt lands have risen from \$30 to \$200 and \$300 an acre, Wood lands, from one to eight miles west and north of Saginaw city, which, as late as 1861, sold for \$15 and \$20 per acre, are now selling for \$40 and \$45 per acre. At Bay city, the increased valuation has been similar. And this is but the first impression of the creation of this new branch of industry in what is generally regarded as a Michigan wilderness."

CHAPTER XII.

THE AGRICULTURAL CAPABILITIES OF CERTAIN DISTRICTS.

NOTES ON THE CLIMATE.

Importance of Limestone—Limestone Rocks produce good Soils—Progress of Settlement in the Laurentian Region of Canada is on the Crystalline Limestones—In New Brunswick the presence of a fine Hardwood Forest indicates the proximity of Limestone—Area of first class Land in the Province—Aids to Agriculture—Manures—Lime—Quantity manufactured in New Brunswick—In Maine—Gypsum—Some Localities where Limestone is found in the Province—Some Localities where Gypsum is found in the Province—Trap debris—Phosphate of Lime—Fish Manures—Its manufacture in France—In Newfoundland—Professor Hunt's descriptions—Manufacture at Gaspe—Value of the Fish Manure manufactured at Gaspe—Importance of the manufacture of Fish Manure on the Gulf Coast.

Murdock—Table of Monthly and Seasonal means of Temperature at St. John, by G. Murdock—Table of mean results at Toronto—Table of minimum and maximum temperatures at Fredericton, by the Rev. Dr. Brooke—Comparative Table, showing the difference between some points in the Climates of St. John and Fredericton, by the late Dr. Robb—Table showing the mean annual temperature of St. John, Fredericton, Quebec, Montreal, and Toronto.

CONCLUSION.—The advantages of a systematic Geological Survey.

Intimately connected with the rock formations on which they rest, or which lie to the north of the area under review, are the soils which constitute the foundation of its agricultural capabilities.

It has been shown in a previous Chapter that the drift which covers the Province, as a general rule, has been derived from the grinding down of the rocks it covers more or less deeply. Hence when we find the drift shallow, and yet the land supporting a vigorous forest, we may in this Province infer that LIMESTONE lies to the north or underneath. Hence it is that on the Shiktehawk and Beccaguimec Rivers, where the drift is shallow, the vegetation is very luxuriant, in consequence of the limestone bands which accompany the red ferruginous and manganesian slates which form the most prominent rocks in the valleys of these rivers.

The progress of settlement in the great wilderness far in the rear of the Saint Lawrence and Lake Ontario, is a singular and most suggestive illustration of the value and importance of limestone rocks; for the settlements

invariably follow the limestone, guided by the forest growth which it supports. This, of course, occurs only where the drift clays are shallow, and the surface soil has originated close by.

So in New Brunswick, the presence of a rich forest of hardwood throughout the vast area covered by the Lower and Upper Silurian rocks, will probably indicate the presence of limestone underneath or close at hand, and may yet prove an invaluable guide in the search for metalliferous deposits associated with the limestones, throughout the great unpeopled wilderness east of the Saint John, and south and north of the Tobique.

AREA OF SUPERIOR LAND.

The area of first rate upland soil within the limits of the Province was estimated by Professor Johnston to be about one million acres; it is satisfactory to know that further experience suggests the idea that this estimate is too low, and that in the then almost inaccessible river valleys, respecting which Professor Johnston could obtain no information, sixteen years since, without undertaking a journey through an unbroken wilderness, there is an available area of upland soil of a quality which will increase his estimate by at least one half, and an area of intervale and valley land which may be reasonably assumed not less than 3,000,000 acres, instead of 1,050,000, as estimated by Professor Johnston.

The same author estimates the second rate upland to have an area of about 6,900,000, and he considers the soil to be inferior to the preceding, but still "very good in quality."

The naked flats distinguished as bogs, heaths, barrens, cariboo plains, are regarded as occupying 5,000,000, and "not to be considered absolutely irreclaimable, but to be unfit for present culture or for settlement, until much larger progress has been made in the general improvement of the Province;" although many will be induced to concur to a certain extent in this view, yet it must be borne in mind that the experience obtained in Lower Canada shows that by drainage and a year's tillage, many of the bogs, heaths and barrens can be made most productive pasture lands, but the circumstances of location must be favourable to the first preliminary step, drainage.

MANURES.

Among the aids to agriculture which Geology is able to point out, are manures. In this Province husbandry is still in a rather backward condition, yet attention is occasionally devoted to the application of those mineral substances which *assist* farm yard manure in its operations, or supply materials in which the soil is deficient, or act by their presence alone.

LIME.

Lime is used in some Parishes, but only to a small extent. There can be no question that its application on many soils would be attended with immediate benefits. Where lime is not available, the shell marl described on page 217, might be advantageously used.

SOME LOCALITIES WHERE LIMESTONE ROCKS OCCUR IN THE PROVINCE.

SAINT JOHN COUNTY.—Several belts of crystalline limestone at and above the Suspension Bridge over the Saint John, near the mouth of the river. Limestone, sometimes beautifully laminated, very free from silicious and other impurities. Some belts stretch far to the northeast by east passing through Portland, forming part of the hill to the north of the Railway, and cropping out on the road to Hammond River. The graphite or plumbago in this range of limestone show that its metamorphism has not been accomplished by any considerable elevation of temperature, otherwise the graphite would have been oxidized. (See page 52.) An analysis of this limestone is given on page 66. Age, Silurian.

Quaco.—Carboniferous limestone.

Martin's Head.—Carboniferous limestone.

ALBERT COUNTY.—Four outcrops close to the gypsum which the limestone overlies, and in some localities underlies. **LOWER CARBONIFEROUS.**

WESTMORLAND COUNTY.—On the Memramcook, above Dorchester; the continuation of Butternut Ridge; near the gypsum; north of Anagance. **LOWER CARBONIFEROUS.**

QUEEN'S COUNTY.—South of Oknabog Lake, one mile. Strike of rock S. W. on the west side of the River Saint John. On the east side, E. N. E. to N. E. for several miles. Crystalline and fossiliferous. **LOWER CARBONIFEROUS.** In Wickham and Hampstead long narrow belts, northeast by east.

KING'S COUNTY.—Near the gypsum on Salmon River, and on Hammond River in Upham. In Norton, near the Railway Station, and seven miles northwest of it. In various parts of the valley of the Kennebecasis. At Butternut Ridge, in several narrow ridges. (See Analysis.) **LOWER CARBONIFEROUS.**

RESTIGOUCHE COUNTY.—Abundant on the Coast, from Dalhousie to Belle-dune Point. On the Restigouche, black limestones. **UPPER SILURIAN.**

VICTORIA COUNTY.—Numerous narrow bands in the Upper Silurian slates which occupy the greater portion of this County. On the Tobique, underlying the gypsum. (See Analysis, page 66.) **LOWER CARBONIFEROUS.**

CHARLOTTE COUNTY, FRYE'S ISLAND.—Crystalline limestone of very superior quality continues to L'Etang, and thence northeast by east. (See Analysis page 66.) Limekilns at L'Etang, also on Frye's Island. **SILURIAN.**

CARLETON COUNTY.—Numerous narrow bands near and below Presqu'île. Broad belts on the Beccaguimic, and south of the Shiktehawk. Numerous narrow bands interstratified with slaty layers are seen on the Saint John River at Sippral's, Victoria Corner. On north fork of Bull's Creek, Richmond Parish. **LOWER SILURIAN.**

Limestone beds appear to prevail all through the Lower Carboniferous indent, drained by the Kennebecasis. They are not unfrequently associated with the valuable mineral gypsum, which, however, is not so widely dis-

tributed as the limestone, and occurs only in the Lower Carboniferous Series in New Brunswick.

In 1851 there were 35,599 casks of lime burnt in the Province; in 1861, the number of casks was 42,965, showing an increase of 7,366. Sunbury has hitherto produced no lime. Albert, Kent, Queen's, and York, all of which burnt a small quantity of lime in 1851, according to the census of 1861 yielded none. The increase in Saint John County was more than the aggregate increase of the Province, being 7,690 casks, against 7,366. In the adjoining State of Maine 400,000 casks of lime were burned in one Township alone in the year 1836, and 700,000 casks were even then estimated as the total produce of all the kilns in the State. This quantity is now exceeded by the amount thrown into the market annually from one locality alone. No better limestone for the manufacture of lime exists any where than in Charlotte County, and in the neighbourhood of Saint John.

In the Town of Rockland, Maine, about one million casks of lime are annually manufactured. One hundred sail of small vessels are employed in fetching wood for that purpose from the eastward, and it takes eighty sail of coasters to carry the lime to market. The lime of Rockland, before the war, was consumed all along the Atlantic Coast, from Calais to Texas.*

SOME LOCALITIES WHERE GYPSUM IS FOUND IN THE PROVINCE.

ALBERT COUNTY.—In at least six localities in the Parish of Hillsborough, forming the half of a circle, commencing a third of a mile west of Edgett's and appearing a little to the south of the road to the Albert Mines in three patches. Again south of the Mines, and in magnificent mural cliffs on Grass' Mill Stream, Shepody River, and Harvey Parish, on the bank.

WESTMORLAND.—Shepody Bay; on North River; near Anagance; about two miles north of Salsbury Station.

SAINT JOHN.—Near Martin's Head.

KING'S.—In Upham Parish; two patches on Salmon River, just above Smith's Creek, and below it; On Studholm's Mill Stream; north of Butter-nut Ridge.

VICTORIA.—Mouth of Wapskyhegan; on the Tobique, cliffs of impure Gypsum 130 feet high, (p. 63.)

The increase in the quantity of tons of gypsum produced in 1861, when compared with amount brought into the market in 1851, is 6,585 tons; the relative quantities being—

1851,	5,465 tons.
1861,	12,050 "
Increase,								6,585 "

To this must be added 1,000 barrels ground gypsum and 10,000 barrels calcined gypsum in 1861.

*Letter from Alden Ulmer, Inspector, to Prof. C. H. Hitchcock.—First Report on the Geology of Maine.

The debris of Trap Rocks which are not of a very ferruginous character is also found useful in localities where it is easily accessible, such as near Dalhousie.

PHOSPHATE OF LIME.

Phosphate of Lime or Apatite has not been found in sufficient quantity to render it commercially available.

FISH MANURES.

Among the most promising adjuncts to farm-yard manure, which should of course always form the groundwork of what is now called good husbandry, Fish Manures appear likely to secure a prominent place.

Professor Hunt has given special attention to the subject, and in an excellent article on Fish Manures published in the Report of Progress for 1857,* he discusses the questions relating to the manufacture of Fish Manures on the Gulf Coast.

“The use of fish as a manure has long been known ; on the shores of Scotland, Cornwall, Brittany, some parts of the United States, and on our own sea-coasts, the offal from fisheries, as well as certain bony fishes of little value for food, are applied to the soil with great benefit. The idea of converting these materials into a portable manure was however I believe first carried into effect in France by Mr. Demolon, who seven or eight years since erected establishments for this object on the coast of Brittany and in Newfoundland. For the details of this manufacture I am indebted to the *Chimie Industrielle* of Payen. Concarneau, in the department of Finisterre, is a small town whose inhabitants are employed in fishing for sardines, and it is the refuse of this fishery which is employed in the manufacture of manure. The offal is placed in large coppers and heated by steam until thoroughly cooked, after which it is submitted to pressure, which extracts the water and oil. The pressed mass is then rasped, dried in a current of hot air, and ground to powder. 100 parts of the recent offal yield on an average 22 parts of the powder, besides from 2 to 2½ parts of oil. The manufactory of Concarneau employs six men and ten boys, and is able to work up daily eighteen or twenty tons of fish, and produce from four to five tons of the powdered manure.

“ This manure contains, according to an average of several analyses, 80.0 per cent. of organic matters, and 14.1 per cent. of phosphates of lime and magnesia, besides some common salt, a little carbonate of lime, small portions of sulphate and carbonate of ammonia, and only 1.0 per cent. of water. The nitrogen of this manure, which is almost wholly in the form of organic matters, corresponds to 14.5 per cent. of ammonia, and we may estimate the phosphoric acid, which is here present in an insoluble form, at 7.0 per cent. If we calculate the value of this manure according to the rules above laid down, we shall have as follows for 100 pounds:—

Ammonia,—14½ pounds, at 14 cents,	\$2.03	} \$2.34½
Phosphoric Acid,—7 pounds at 4½ cents,	0.31½	

* Canadian Geological Survey.

This is equal to \$47 the ton of 2,000 pounds; the manufactured product of Concarneau, however, according to Payen, is sold in the nearest shipping ports at 20 francs the 100 kilogrammes, (equal to 220 pounds,) which, counting the franc at \$0.20, is equivalent only to \$1.81 the 100 pounds, or a little over \$37 the ton. This however was in 1854, since which time the price of manures has probably increased.

“ Mr. Demolon in company with his brother, has also, according to Payen, erected a large establishment for the manufacture of this manure on the coast of Newfoundland, at Kerpon, near the eastern entrance of the Strait of Bellisle, in a harbour which is greatly resorted to by the vessels engaged in the cod-fishery. This manufactory, now in successful operation, is able to produce 8,000 or 10,000 tons of manure annually. Payen estimates the total yearly produce of the cod-fisheries to be equal to about 1,500,000 tons of fresh fish; of this, one-half is refuse, and is thrown into the sea or left to decay on the shore, while if treated by the process of Demolon, it would yield more than 150,000 tons of manure nearly equal in value to the guano of the Peruvian Islands, which now furnish annually from 300,000 to 400,000 tons. If to the manure which might be obtained from the cod-fish of the Lower Provinces, we add that of many other great fisheries, we are surprised at the immense resources for agriculture now neglected, which may be drawn at a little expense from the sea, and even from the otherwise worthless refuse of another industry. To this may be added vast quantities of other fish, which at other seasons and on some coasts are so abundant that they are even taken for the express purpose of spreading upon the adjacent lands, and which would greatly extend the resources of this new manufacture. The oil, whose extraction is made an object of economic importance in the fabrication of manure from sardines in France, exists in but very small quantities in the cod, but in the herring it equals 10 per cent. of the recent fish, and in some other species rises to 3.0 and 4.0 per cent.

“ Mr. Duncan Bruce of Gaspe, has lately been endeavouring to introduce the manufacture of fish-manure into Canada; but he has conceived the idea of combining the fish-offal with a large amount of calcined shale, under the impression that the manure thus prepared will have the effect of driving away insects from the plants to which it is applied. He employs a black bituminous shale from Port Daniel, and distilling this at a red heat, passes the disengaged vapours into a vat containing the fish, which by a gentle and continued heat, have been reduced to a pulpy mass. The calcined shale is then ground to powder and mingled with the fish, and the whole dried. Experiments made with this manure appear to have given very satisfactory results, and it is said to have had the effect of driving away insects when applied to growing crops, a result which may be due to the small amount of bituminous matter in the products of the distillation of the shale, rather than to the admixture of the calcined residue. Coal-tar is known to be an efficient agent for the destruction of insects, and in a recent number of the *Journal, Le Cosmos*, it is stated that simply painting the wood-work of the

inside of green-houses with coal-tar has the effect of expelling from them all noxious insects. Mr. Bruce caused several analyses of this shale to be made by Dr. Reid of New York, from which it appears that different specimens contain from 2.0 to 26.0 per cent. of carbonate of lime, besides from 1.4 to 2.0 per cent. of gypsum, 2.0 per cent. of iron pyrites, and from 4.5 to 6.7 per cent. of carbon remaining after distillation. The amount of volatile matter, described by Dr. Reid as consisting of water, naphtha and ammonia, was found by him in two different samples to equal only 3.5 per cent., of which a large proportion is probably water.

“ I have examined two specimens of manure prepared by Mr. Bruce from the fish commonly known as the menhadden (*Alosa menhadden*). No. 1 was made with the Port Daniel shale, as before described; while for No. 2, this was replaced by a mixture of clay and saw-dust, which was distilled like the shale, the volatile products being added to the decomposing fish. The oil which rose to the surface of the liquid mass had been separated from the second preparation, but remained mingled with the first. Both of these specimens were in the form of a black granular mass, moist, cohering under pressure, and having a very fishy odour.

ANALYSIS OF EARTHY MATTERS.

	I.	II.
Phosphoric acid,	3.40	3.99
Sulphuric acid,	2.16	.15
Lime,	5.90	4.44
Magnesia,	1.20	1.15
Ammonia,	3.76	2.60

“ If we calculate the value of the first specimen according to the rules already laid down, we have as follows for 100 pounds:—

Phosphoric acid, 3 4-10 pounds at 4½ cents, ...	\$0.153
Ammonia, 3¼ pounds at 14 cents,	0.525
	<u>\$0.678</u>

“ At 68 cents the 100 pounds, this manure would be worth \$13.60 the ton. The sulphuric acid is of small value, corresponding to 80 pounds of plaster of Paris to the ton, and we do not take it into the calculation. The somewhat larger amount of phosphoric acid in the second specimen, is probably derived in part from the ashes of the saw-dust, and in part from the clay. The value of this manure would be \$10.88 the ton.

“ In order to arrive at the real value of the animal portion of this manure, after the removal of the oil, we may suppose, since Dr. Reid obtained from the shales from 4.5 to 7.6 per cent. of fixed carbon, that with the 56.2 parts of calcined residue, there were originally 3.7 parts of carbon derived from the shales. This deducted from 23.7 parts leaves 20.0 of nitrogenized animal matter in 100 parts of the manure, yielding 3.76 parts or 18.8 per cent. of ammonia. This matter consists chiefly of muscular and gelatinous tissues, and Payen obtained from the dried muscle of the codfish, 16.8 per cent. of

nitrogen, equal to 20.4 of ammonia. The 3.4 parts of phosphoric acid in the manure will correspond to 7.4 of bone-phosphate, and if to this we add for moisture, impurities, etc., 2.6 parts, = 30.0 in all, we should have for 100 pounds of the fish when free from oil and dried, the following quantities of ammonia and phosphoric acid:—

Ammonia,—12½ pounds at 14 cents,	\$1.75
Phosphoric acid,—11½ pounds at 4½ cents,	0.51
				\$2.26

“The matter thus prepared would have a value of \$45.20 the ton, agreeing closely with that which we have calculated for the manure manufactured from sardines in France, in which the quantity of ammonia is somewhat greater, and the phosphoric acid less, giving it a value of \$47 the ton.

“Professor George H. Cook of New Jersey, in an analysis of the menhadden, obtained from 100 parts of the dried fish, 16.7 parts of oil, besides 61.6 of azotized matters yielding 9.28 parts of ammonia, and 21.7 of inorganic matters, etc., containing 7.78 of phosphoric acid.* If we deduct the oil we shall have for 100 parts of the fish, according to this analysis, 11.2 of ammonia, and 9.3 of phosphoric acid.

“By comparing these figures with the results calculated for the animal portion of Mr. Bruce’s manures, we find:—

		Ammonia.	Phosphoric acid.
Manure from sardines, (Payen,)	14.5	7.0	
Dried menhadden (Cooke,)	11.2	9.3	
Manure by Mr. Bruce,	3.75	3.4	
Do. do. (excluding shale,)	12.5	11.3	

The proportion of phosphates is of course greater in the more bony fishes. In the manure of Mr. Bruce there are doubtless small amounts of phosphoric acid and ammonia, derived from the shale and the products of its distillation; but these do not however warrant the introduction of an inert material which reduces more than two-thirds the commercial value of the manure. The results which we have given clearly show that by the application of a process similar to that now applied in France and in Newfoundland, which consists in cooking the fish, pressing it to extract the oil and water, drying by artificial heat, and grinding it to powder, it is easy to prepare a concentrated portable manure, whose value, as a source of phosphoric acid and ammonia, will be in round numbers, about \$40 the ton.

“We can scarcely doubt that by the application of this process a new source of profit may be found in the fisheries of the Gulf, which will not only render us independent of foreign guano, now brought into the Province to some extent, but will enable us to export large quantities of a most valuable concentrated manure, at prices which will be found remunerative.”

* Report of the Geological Survey of New Jersey for 1856, p. 63.

NOTES ON THE CLIMATE OF NEW BRUNSWICK.

The suitability of the climate of any district for agricultural purposes is sufficiently indicated in old settlements by the crops raised with success. But this criterion does not necessarily convey correct ideas regarding the extremes of heat and cold, or the durations of the seasons. Throughout the settled portions of the valley of the Saint John Indian corn is grown, and wherever this crop ripens well a fair estimate of the character of the summer climate can be formed. The vegetables exhibited at the Provincial Exhibition show how admirably the summer temperature and rain are suited for the cultivation of root crops and common culinary vegetables, the fruits attested also the favourable character of the climate for their growth and proper development. These facts, however, tell nothing respecting the intensity of winter cold, the duration of the winter season, and the length of time during the year which can be given to outdoor operations. A long cold winter operates injuriously upon farming industry in so far as it compels stock to be housed and fed for a longer period than in a milder climate; but how far this may militate against the progress of husbandry in a district or Province, is not generally understood, and its supposed drawbacks are frequently very much overrated.

COAST AND INTERIOR CLIMATES COMPARED.

It has been shown by Albert Gallatin,* that on this continent inland places, remote from the sea, and under the same degree of latitude, have severer winters and hotter summers than those on the Atlantic coast. The same law appears to obtain in Europe.

Albert Gallatin compares Fort Snelling on the Mississippi, in lat. $44^{\circ} 53'$, and Eastport (Maine), lat. $44^{\circ} 44'$, with the following results:—

	Fort Snelling.	Eastport.
Mean annual temperature,	45.83	42.95
“ Winter “	15.95	22.95
“ Summer, “	72.75	62.10
Mean temperature of the coldest month, ...	13.58	20.68
“ “ of the hottest month, ...	75.47	64.55
Coldest day in the year,	—26	—13
Hottest day in the year,	93	91
Range between hottest and coldest day, ...	119	104

THE CHARACTER OF THE WINTER SEASON.

The River St. Lawrence is generally frozen between Quebec and Montreal every winter, and when there is no ice-bridge at Quebec, the communication between the two cities is open for steamers, generally on the 24th of April.

* Hale's Indians of North West America.

When there is an ice-bridge opposite the great fortress, the river is closed until the 27th of the same month. During a period of twenty years, from 1833 to 1855, the St. Lawrence has been frozen across at or near Quebec nine times without retarding the opening of the navigation for more than three days.

FREEZING OF CANALS AND RIVERS.

The following Table shows how far the seasons, from the Bay of Fundy to Lake Superior, affect navigation by the opening and closing of the Rivers and Canals* :—

	Opens.	Closes.	Average period closed in days.
1, The Straits of Mackinaw,	April 14,	December 6,	129
2, Port of Hamilton,	" 1,	" 28,	94
3, " Buffalo,	" 14,	" 14,	121
4, " Oswego,	March 20,	—	—
5, " Montreal,	April 20,	" 11,	130
6, " Quebec,	" 29,	November 24,	156
7, " Bic,	March 16,	December 19,	87
8, Erie Canal,	April 28,	" 7,	142
9, Welland Canal,	" 8,	" 12,	117
10, Cornwall Canal,	" 25,	" 8,	138
11, Lachine,	" 28,	" 8,	141
12, St. Lawrence River between Lake Ontario, Montreal, and Lachine,	" 26,	" 7,	140
13, St. Lawrence between Montreal and Quebec,	" 24,	" 10,	135
14, The St. John at Fredericton,	" 19,	November 26,	144
15, The Kennebec, Maine,	" 6,	—	—

The geographical course of the Saint John, running from north to south, causes it to freeze earlier, or become choked with ice sooner than the Saint Lawrence, at Montreal, which runs from west to east.

PERIODS OF NAVIGATION.

The duration of the period when Navigation is closed, deduced from the foregoing Table, is as follows :—

	Days.
Quebec,	156
Fredericton,	144
Erie Canal,	142
Cornwall Canal,	141
Saint Lawrence River,	140

The Navigation of the Saint Lawrence for sea going vessels is of course dependent upon the opening and closing of the River at Quebec; hence the Saint John is really open 12 days longer than the Saint Lawrence.

* The first 13 localities are deduced from an average of 10 years. The Saint John, from an average of 28 years, and the Kennebec for 75 years.—Vide Appendix to the Journals of the House of Assembly, Canada, 1853.

Table showing the mean winter temperature of Toronto, Montreal, Quebec, and Saint John, for 1853-4, 1854-5, 1855-6 :—

			<i>Mean Winter Temperature.</i>		
			1853-4.	1854-5.	1855-6.
Saint John,	18.72	21.46	19.88
Quebec,	11.03	13.37	12.75
Montreal,	13.22	12.15	13.96
Toronto,	23.3	21.06	19.6

From this Table it will be seen that the winter temperature of Saint John and Toronto are not unlike as regards intensity of cold.* They are both considerably warmer than either Montreal or Quebec; and if we select a station beyond the influence of the great lakes, yet within the limits of the peninsula of western Canada, we find the extremes of temperature exceed those of Saint John, and that the climate approaches that of Fredericton.

Stratford, at the junction of the Grand Trunk Railway, and Buffalo and Lake Huron Railway, is 1182 feet above the sea, and from its position in relation to the great lakes and its altitude, its climate may be compared with that of Fredericton, although it is two degrees and three quarters further south than the Capital of New Brunswick.

He who is disposed to grumble at the intensity of the cold in New Brunswick and Canada, let him read a generous and truthful article on this subject in Chambers' Edinburgh Journal, (January 1863,) in which some of the charms of the North American winter are portrayed, and some of its drawbacks drawn with a Painter's skill; yet the impression which remains is rather in favor of the cheery side, and the only change one would wish for in our winters here, when comparing them with the same season of the year in many other parts of the temperate zone, is that they were just a little shorter.

METEOROLOGY OF SAINT JOHN.

The following Tables by MR. G. MURDOCH, of Saint John, contain much valuable information respecting the climate on the coast of the Bay of Fundy.

They embody the condensed results of a series of Tables published, in part, in the Agricultural Report for the last season, and when compared with an elaborate Table for Toronto on the succeeding page, a fair idea of the difference between the climates of those distant Cities may be gathered.

* Smithsonian Report, 1860.

TABLE of Annual Means and Extremes of Temperature, with the dates when the latter occurred; also of Precipitation, Clouding, Wind and Thunder Storms, for the years 1861-2-3-4; from observations made at St. John, N. B., lat. 45° 16' 42" N., long. 66° 3' 45" W., height above sea, 135 feet, by G. MURDOCH.*

MINIMUM AND MAXIMUM TEMPERATURES AT FREDERICTON.

The Reverend Dr. Brooke, of Fredericton, has kindly furnished me with a condensed summary of meteorological observations taken by him daily at Fredericton for a period of seventeen years, or from 1847 to 1864 inclusive. These tables contain the monthly maximum and minimum temperatures, the mean temperatures at 7 a. m. and 2 p. m. The days on which the highest and lowest temperatures occurred, and the number of rainy, snowy, and cloudy days in each month. The extreme length of these tables necessarily forbids their being printed here in full, but some interesting extracts from them follow.

Table showing the lowest and highest temperatures recorded at Fredericton between 1848 and 1864 inclusive:—*

	Minimum Temperature.	Max. Temp. during the year.		Minimum Temperature.	Max. Temp. during the year.
1848,	February 28, —16	86	1857,	January 24, —30	86
1849,	" 14, —26	100	1858,	February 23, —14	90
1850,	" 7, —25	94	1859,	January 12, —30	88
1851,	" 9, —22	82	1860,	February 2, —22	88
1852,	January 20, —14	92	1861,	" 8, —27	90
1853,	" 28, —24	94	1862,	" 11, —16	80
1854,	" 10, —34	92	1863,	" 4, —20	95
1855,	February 7, —30	93	1854,	" 19, —30	90
1856,	January 2, —22	98			

On the 29th Dec. 1854, the unusually low temperature of 30 below zero was recorded; and on the 12th July 1849, the thermometer rose to 100 degrees.

The minimum temperatures in the above tables are frequently exceeded in Canada, east of Kingston. At Montreal "cold terms" are not unusual, and sometimes they well deserve the name which has been applied to them.

Dr. Brooke's register shows that on the 29th December 1854, the thermometer at Fredericton fell to 30 below zero, but at Montreal on the 22nd and 23rd December of the same year it fell to 36 below zero, and from 8 a. m. on the 22nd to 10 p. m. on the 23rd, it ranged from — 8.1 to — 36.

Again on the 9th, 10th, and 11th January 1859, the thermometer did not rise above zero during a period of 124 hours, 30 minutes, or more than five days. Mercury froze in the open air; and the mean temperature of the 9th was—27°8; the 10th—29°0; and the 11th—28°. At Fredericton the minimum temperature was 30 below zero, which occurred on the 12th Jan'y.

At Quebec in the winter of 1853 and 4, the thermometer sank below the freezing point 189 nights, or rather more than half the year. There were during that winter 2 days in November in which it fell below zero; 7 in December; 20 in January; 17 in February; and 4 in March, making a total of 50 days during the winter upon which the thermometer was registered below zero.† Although the Saint Lawrence broke up on the 24th April, the ice did not pass out of the Saint Charles until the 5th May.

* These observations have not been reduced.

† Transactions of the Literary and Historical Society of Quebec, January 1855.

CONCLUSION.

THE ADVANTAGES OF A SYSTEMATIC GEOLOGICAL SURVEY.

In 1855 a Select Committee of the Canadian House of Assembly reported on the Geological Survey of Canada. During the investigation, a large number of witnesses were examined, with a view not only to arrive at a knowledge of the benefits resulting to the public from the survey, but also to ascertain the degree of estimation in which the labours of Sir William Logan, (then Mr. Logan) were held in abroad, and the prospective advantages which might reasonably be anticipated from the prosecution of the work on a considerably enlarged scale.

In their Report, the Committee state “the importance of an accurate Geological acquaintance with the country is so universally acknowledged, that it is unnecessary to do more than point out some portions of the evidence which show the immediate practical result; but as an apparent misapprehension exists in some quarters as to the objects of such a national undertaking, your Committee may be pardoned for making some additional observations.

* Fredericton 58 miles inland N.W. of Saint John, Latitude 45° 57' 30" N., Longitude 66° 36' W.

† From Dr. Robb's Agricultural Report.

‡ The means for Saint John are the result of Mr. Murdoch's observations.

§ The means for Fredericton are the result of eight year's observations, but they have not been reduced. It is probable that the mean is about half a degree too high.

|| Transactions Lit. and Hist. Society of Quebec, January 1855.

“The discovery of valuable economic materials speaks for itself, although, even here it may be doubted whether the relative importance of the minerals indicated is always justly appreciated, whether the crystalline limestones of the Laurentian Series have not been of more real value than some discoveries of a far more imposing character. But where the outline of some formation of no very obvious economic use is accurately traced for many miles, when minute and laborious investigations are carried on of the undulations, contortions and disturbances of other strata, with exact measures of their thickness and dip, and when the greatest attention is paid to the fossils they contain, some people are apt to think that the Geologist might be more usefully employed. They draw a distinction between practical utility and scientific interest. The ultimate object, however, of all science is practical utility; IT IS ONLY A SYSTEMATIC, instead of a DESULTORY SEARCH for valuable facts.

“The discovery of some useful material at a particular point would be an isolated fact, though, perhaps, of great importance to that locality; but combined with a correct scientific knowledge of the geology of the country, it would be not only available over an extensive region, but would be the contribution of a valuable truth to the whole world.”

Mr. Hall, of Albany, a gentleman of world-wide reputation, author, among other valuable works, of the “Geology of the First District of the State of New York,” and of those magnificent volumes devoted to the Palæontology of the entire State, submitted in evidence that a sound basis of scientific investigation is of the highest importance in leading to practical results. Mr. Hall said that he conceived that no practical or economic results of great value are likely to arise except those based upon scientific investigations. The great lead-bearing formation of the States of Wisconsin, Illinois, and Iowa was instanced. For many years a serious misapprehension existed in regard to the true position of the lead-bearing rock; and only so late as 1850 was it determined, by a proper examination of its organic remains, that instead of its being in the Niagara group, as formerly supposed, it belongs to a much lower series of rocks, viz., a Lower Silurian Limestone. This erroneous impression gave rise to fruitless searches for Lead ore in the Niagara limestone, which this late information will discourage. There are at this time multitudes of practical miners, who know at once, by the occurrence of certain Fossils, the presence of the Lead-bearing rock, and who would never think of searching for Lead ore in any rock where these Fossils do not exist.

During fifty years previous to the commencement of the Survey in the State of New York, *not less than one million dollars had been expended in abortive search for coal*, where a well-informed Geologist would have at once pronounced the undertaking useless, and certain to prove a failure.

During the last Session of the Canadian Parliament, (1863-4,) a further appropriation of \$20,000 a year for five years was made for the continuation of the survey of that Province, such being the estimation in which this great national work is held in Canada.

A survey of New Brunswick should comprehend—

1. An accurate description, accompanied by a Map, of the limits of each formation, according to the plan already adopted by Sir William Logan, which is now well known in Europe and the United States. "UNITY OF DESIGN would render the results, both economic and scientific, intelligible to the world, with much less study than would otherwise be required." (See Sir William Logan's Letter, page xv, also Remarks on Nomenclature, pages 39 and 40.)

2. An examination of the mineral resources of each formation, showing their distribution and the probable extent to which they may be commercially valuable.

3. A collection of all the minerals found in the Province, with specimens of the rocks in which they occur, and illustrations, when practicable, of their uses in the arts, with a view to the formation of a Provincial Museum, in which all the minerals and fossils of the Province should be scientifically arranged and classified, and the localities where the rock which contains them mapped.

4. The publication of an Annual Report describing the year's operations, and particularizing the nature, extent, and probable commercial value of the minerals in the area examined.

On page xii of the Introductory Chapter, a brief notice is given of some of the results of a preliminary survey during the past year. It has been established that the great metalliferous belt of North America (the Quebec Group) occupies an area of upwards of four thousand square miles, or more than two and a half million acres. In the words of Sir William Logan,* "the rocks of this Group yield in Canada, ores of iron, chromium, lead, antimony, copper, nickel, silver and gold, with soapstone, potstone, hones, marbles, serpentines, cement stones, building stones, and roofing slates." The Chapters in this Report devoted to the Group (Chap. VIII. and IX.) as it occurs in New Brunswick, show that with the single exception of chromium, ALL OF THESE METALS and ECONOMIC MATERIALS have been found within its limits in this Province, and some of them to a far greater extent than they have been recognized in Canada. (ANTIMONY, the WOODSTOCK IRON ORES, MANGANESE). Hence it follows that a careful and systematic examination of this vast rock series promises very valuable results.

The ORIGIN OF ALBERTITE has been described, (Chapter V.) and the probability of its being found in workable quantities over a horizontal distance of fifty miles in one direction, and from ten to fifteen miles in another direction, pointed out.

The distribution of the highly bituminous ALBERT SHALES, and their value as a source of gas fuel for smelting and manufacturing purposes generally, is also noticed at some length in Chapter V., and it is of considerable importance that the area they occupy, their thickness and the extent to which they are available for the purposes described should be accurately determined.

* See Letter No. II. page xv.

The probable existence of workable beds of COAL, besides the Grand Lake seam is shown in the Chapters on the Carboniferous Series, (Chap. III. and IV.) As fossil fuel, whether in the form of coal or rich Bituminous Shales, lies at the foundation of modern progress, the existence of workable deposits in New Brunswick is of the highest importance. Canada, although more than twelve times the area of New Brunswick, possesses no deposits of coal, and no bituminous shales which can approach the richness of the Albert Shales, and no workable seams of Albertite.

The development of the COPPER-BEARING TRAPS on the shores of the Bay of Fundy is also a valuable subject of enquiry. These traps are noticed at length in Chapter VI.

Among apparently minor claims for a complete scientific survey of the Province, are the distribution of its LIMESTONES, the HYDRAULIC CEMENTS, materials for the manufacture of BRICKS and POTTERY, FIRE CLAYS, PLUMBAGO, MARBLES, SERPENTINES, ROOFING SLATES, WHETSTONES, HONES, GRINDSTONES, MILLSTONES, GYPSUM, SULPHATE OF BARYTA, SANDSTONE for GLASS, MOULDING SAND, all of which it will be seen by reference to the index, occur within the limits of the Province, and some of them in great abundance and of excellent quality.

The SOURCE OF THE GOLD in the Drift Clays of the Province is an important subject of enquiry, which has received additional interest from the recent confirmation of further discoveries of gold in quartz veins of Upper Silurian age in Canada, over wide areas on the River du Loup, and generally in the Valley of the Chaudiere and elsewhere. (Chapter XI.) The large area of country occupied by the Quebec Group in New Brunswick, would lead to the inference that the chief source of the gold is to be sought for in the rocks of this Group; but since altered Upper Silurian Rocks also occupy a considerable portion of the northern Counties, it is not improbable that these may have contributed to the auriferous Drift.

Lastly, in order to secure the introduction of Capital into the Province, and the establishment of manufacturing industry on a secure basis, it is absolutely essential that capitalists abroad should have some security for their investments.

The experience of many years sufficiently establishes the fact that unless plans for the development of metalliferous deposits, or for the working of economic materials, be based upon scientific research, showing "the reason why," it is only indulging in a fruitless expectation to suppose that foreign capitalists, or indeed any well-informed or reasonably cautious man, who has not an opportunity of judging for himself, will give them either countenance or support.

APPENDIX.

- I.—ORIGIN of the NAMES of certain RIVERS and PLACES in NEW BRUNSWICK, together with MICMAC and MILICETE names for some COMMON THINGS.
- II.—NAMES of PLACES and RIVERS derived from the ABENAQUIS Language.
- III.—ENUMERATION of the MAMMIFEROUS ANIMALS ascertained to exist in or on the Coasts of NEW BRUNSWICK.
- IV.—ENUMERATION of the BIRDS of NEW BRUNSWICK, with a notice of those which winter in the Province.
- V.—ENUMERATION of the FISHES of NEW BRUNSWICK.
- VI.—Fossiliferous Marine Clays of Maine and the St. Lawrence compared.
- VII.—TABLE showing the Value of the Imports and Exports, being the Produce and Manufacture of the Colony, of MINERALS, ORES, and METALS, manufactured and unmanufactured, during the years 1861, 1862, and 1863.
- VIII.—MINING LICENCES—Rules and Regulations.

No. I.

ORIGIN OF THE NAMES OF CERTAIN RIVERS AND PLACES IN NEW BRUNSWICK.

{Hale's Vocabularies—Transactions of the Am. Ethnological Society—Relations of the Jesuits.}

The importance of understanding the origin of names assigned to a country, district, river, or place, is fully illustrated in the brief history which has been given at the commencement of the First Chapter, of the consequences which followed misapprehensions concerning the word "Acadia." In a historical point of view, names of places are always, or at least very frequently, suggestive, hence their origin and meaning is interesting. So many of the Rivers and Mountains of this Province still retain their original Indian appellations, that it is almost a part of a liberal education to be familiar with their meaning, and yet there are few who give more than a passing thought to this subject.

As means for obtaining a correct list of Indian names of places in New Brunswick are rapidly diminishing, the following is an attempt to arrange such as are known, with a view to their correction by competent authorities, and to fix indelibly the true meaning of Indian terms, before the only source from which we can obtain correct information passes away.

1. RISTIGOUCHE—Miacmac, mentioned in the Relations of the Jesuits for 1642, and spelt "Restgouch." It signifies Broad River.
2. TITTIGOUCHE—Fairy River, (Robert Cooney). POKEMOUCHE; BUC-TOUCHE—Fire River; MISTOUCHE.
3. NIPISIGUIT—Probably Milicete, (Etchemins). (The Micmac word for water is chabuguan, and for river chibuk). Mentioned in the Relations, and spelt "Nepigigouit." It means Rough Waters.
4. MIRAMICHI—Mentioned in Relations for 1646 & 1659—Happy Retreat (?).
5. MISCOU.—Mentioned in Relations for 1685, &c. Formerly called "Isle de Saint Louis."
6. CHEDABOUCTOU, (near Miramichi)—Father de Lionne died here. Relations, 1661. (Bouctou—Fire).

7. ASTICOU—A Micmac Chief. Relations, 1611.
8. KADESQUIT—A part of Acadia where La Saussaye had projected an establishment. Relations, 1611.
9. MENANO—Grand Manan. Relations, 1611.
10. RIGIBOUCTOU—River of Fire, Bay of. Relations, 1646.
“ River. Relations, 1659.
11. As early as 1611, it was remarked by the writer of the “Relation de la Nouvelle France,”* that no trace remained of the origin of the words Norembegue, (the present State of Maine,) Acadia, (the country of the Souriquois or Micmacs,) and Canada.
12. UPSALQUITCH, (pronounced Ab-sat-quitche)—“The River that runs out small.” Micmac.
13. TABOUSINTAC—The place where two reside. (Cor.)
14. MAGUADAVIC—River of Hills.
15. NAGOTQUO—Tobique River, (Milicete). Absegaguit nagotquo-sis quispem—Little Tobique Lake. Quis-pam-sis—Little Lake.
16. SAINT CROIX, (Island). Relations, 1611. Residence of de Monts on the coast of Norembegue.
17. RIVER SAINT CROIX. Relations, 1611. Schoodic.
18. AUTMOINS—Name of the Micmac Conjuror. MANITOUSIN—Ojibway.
19. ETCHEMINS (canoe-men), originally ETEMINQUOIS—Milicete. The hunting ground of the Etchemins extended from the River Saint John to the Kennebec in 1611. Relations, 1611. AMALEATES or the MANEUS tribe—now Milicetes. Paris Documents, 1736. In Canadian Documents spelt Amalците.
20. THE SAINT JOHN—Called by L’Escarbot “the River of the Great Bay,” 1598; by Champlain, Saint John, 1604; by the Etchemins or Milicetes, “Awollastook” or the “Big River”; by the Abenakis, “Loshtook” or the “Long River”; also Onygoudy.
21. “CADIE.”—“A Map of North America, contained in the NOVUS ORBIS of De Laet, published in 1633, distributes the country into the following divisions, commencing on the north: New France, CADIE, Norumbega, (comprising the territory between the Saint Croix and the Kennebec,) New England, New Netherland, Virginia, and Florida.”
—(Collection of the Maine Historical Society, Vol. II.)

The number of Micmacs or Souriquois was estimated at from 3,000 to 3,500 in 1611, by the Jesuit Missionaries. They spoke highly of the characters of the Souriquois and Etchemins—(Micmacs and Milicetes.) The number of Indians in this Province, according to the last census, was 1212, (625 males and 587 females).

* Relations, 1611—page 2.

MICMAC AND MILICETE NAMES FOR SOME COMMON THINGS.

	Micmac.	Etchemins or Milicete.		Micmac.	Etchemins or Milicete.
Man	tchinem	oskitap	Snow	wastouh	warst
Woman	epit	apet	Earth	keshwajowuyaw	takomiqu
Father	nutch (my)	mataqus	River	chibuk	sepe
Mother	kich	nikos	Stone	kundau	panapsqu
Son	unquece	n'kos	Tree	neeppeeesh	apas
Daughter	untouse	n'sous	Meat		wiyos
Head	unidgik	nencagan	Dog	lemuch	lumose
Hair			Beaver		quanbeadt
Ear	hadougan	chalkse	Bear		mowene
Eye	pouogul	n'siscol	Bird	tchipahit	cipsis
Nose	uchickun	nitou	Fish	hemeteh	n'mays
Mouth		neswone	Great	mechkilk	nukamkiqu
Tongue	willenonk	nyllal	Cold	tekayo	nedanbedatsi
Teeth	uabidul		White	uabeg	wapiyo
Hand	kpiten	petin	Black	m'katuey	muk saiwayo
Fingers	cloegan		Red	megoueg	maiquaik
Feet	ukkuat	n'sit	I	nil	nel

Rain	ikfashak	suklan	Ten	ptolu	neqdensk

In 1855, "A Primer for young children, applicable to the Indian language as spoken by the Mee-lee-see Tribe in New Brunswick," collected and arranged by Mr. John Stephens, was published in Fredericton, under the patronage of the Honorable Mrs. Manners-Sutton.

The spelling of some of the words differs slightly from some of those in the vocabulary given above, others are identical, and others again, wholly diverse.

The Rev. S. T. Rand, Missionary to the Micmac Indians in Nova Scotia, has compiled a "First Reading Book," in Micmac, which was published in London in 1854, with phonetic abbreviations, and in the phonetic type of Fred. Pitman. The "Reader" contains 40 pages duodecimo. It is beautifully printed in large type on excellent paper. In 1853 the Gospel of Saint Mathew was also printed "fonetically in Mikmak." The words given by the Rev. Mr. Rand to represent certain objects, differ occasionally from those in the short vocabulary above.

No. II.

NAMES OF PLACES AND RIVERS DERIVED FROM THE ABENAQUIS LANGUAGE.

The language of the Abenakis resembles in many particulars that of the Milicete tribe, and the names of some places in New Brunswick, and in the eastern and northern part of Maine, are derived from the language spoken by this tribe.

The Abenakis proper, occupied the country between the Penobscot and Piscataqua rivers. Subjoined are some of their words which have become incorporated as it were with the English of the present day, so far as relates to names of places.*

AROOSTOOK.—Smooth river. Enters the Saint John above the Tobique.

ALLAGASH.—Bark camp. A hunting camp of the Indians on the lake.

ABENAQUIS.—East land men.

CASCO.—The Heron; also place of victory.

CHEPUTNATICOOK.—Saint Croix River, and Lakes.

KENDUSKEAG.—The place of Eels. Ossekeag; Passekeag.

KABASSAKEAG.—The place of Sturgeon.

MONAHAN.—Island. (Manan.)

MEGANTIC.

METAWAMKEAG.—A river with a smooth gravelly bottom.

MADUCTIC.—Falls of the Saint John.

MADUSNEKEAG.—Tributary to the Saint John at Woodstock.

MILLINOKET.—A lake with many Islands in it. (MILNAGEC.)

MOOSEBEC.—Straits of a River.

NORUMBEGUA.—Maine. Also MAVOSHEN or MAVOOSHEN, in Halkuyt's Voyages.

NICKETOW or NECCOTOH.—Where two streams meet. The forks.

OUY-GOUDY.—The Saint John.

PASCODUMQUOKEAG.—From Pascodum (pollock,) oquen (catch 'em many,) keag (land.)

PASSAMAQUODDY.—Pos (great,) asquam (water,) aquoddie (pollock.)

Mr. C. E. Potter states in the Collections of the Maine Historical Society, that "AQUODDIE" has been Frenchified or corrupted into Acadia, Cadia or Cadie, and applied to the shore of the Bay of Fundy. It is an Indian word meaning a fish. See page 21 Chap. I. Mr. G. Folsom states that "the Bay of Passamaquoddy" is on the French maps named Pesmo-cadie.—(Collections of Maine Historical Society, Vol. II.)

QUISQUAMAGO.—High carrying place.

SCHOODIC.—The place where water rushes.

KENNEBEC.—A snake.

KENNEBECCASIS.—A little snake.

* Collections of the Maine Historical Society, Vol. IV.

KEERSAGE.—A high place ; the same as Ktaadn or Katahdin.

NAUMKEAG.—From Namaas (fish,) kik or keag (a house, land, or place.)

A fishing place.

NEQUAMKIKE.—Nee (my,) asquam (water,) kike (place.)

PENOBSCOT.—Penapse (stone,) auke (place.) Penobsquis.

SABASTICOOK.—Sebastis was an Indian corruption of the French, Jean Baptiste. The Indians formerly pronounced the words as they do at the present day *Che-battis*. Affixing the syllable cook, which signifies place, the word becomes Che-bat-tis-cook or really Jean-Baptiste's place, and hence Sabasticook.—(C. E. Potter.)

No. III.

ENUMERATION OF THE MAMMIFEROUS ANIMALS KNOWN TO EXIST IN NEW BRUNSWICK.

The following List is framed on the same plan as the one published in the Transactions of the Portland Natural History Society. It has been carefully revised by Mr. J. P. Sills of Fredericton, whose forest and field acquaintance with the mammiferous animals and birds of New Brunswick, as well as those of Great Britain, confers a special value on the information he has kindly communicated. The Portland Society's List is retained in its original form, as it is possible that some of the animals, not at present recognized, may yet be found to exist within the limits of the Province. The species not known to occur in New Brunswick are marked with a star, (*) those found in the Province or in the waters of the coast, and not enumerated in the Portland Society's List, are printed in italics. One mark thus, † indicates that the animal changes its colour during winter ; two marks, thus, †† show that it sleeps during the winter season.

CHEIROPTERA.

- †† *Vespertilio Carolinensis*, Geof., Common Brown Bat.
- V. subulatus*, Gm., Little Brown Bat.
- * *V. Noveboracensis*, Say., New York Bat.

INSECTIVORA.

- * *Sorex Forsteri*, Rich., Forster's Shrew.
- * *S. Richardsoni*, Bachm., Richardson's Shrew.
- * *S. platyrhinus*, Wagner, Eared Shrew.
- * *S. Thompsoni*, Baird, Thompson's Shrew.
- * *Blarina talpoides*, Gray, Mole Shrew.
- B. brevicauda*, Gray, Short-tailed Shrew.
- †† *Scalops aquaticus*, Cuv., Common Mole.
- Condylura cristata*, Ill., Star-nosed Mole.

CARNIVORA.

- Felis concolor*, Linn., Panther, Catamount, Indian Devil.
Lynx rufus, Raf., Wild Cat.
L. Canadensis, Raf., Loup-cervier.
Canis occidentalis, Rich., Gray Wolf.
Vulpes fulvus, Rich., Red Fox.
V. fulvus, var. *argentatus*, Silver Fox, Black Fox.
* *V. Virginianus*, Rich., Gray Fox.
† *Mustela Pennantii*, Erxl., Fisher, Black Cat.
† *M. Americana*, Turton, Pine Marten, Sable.
* *Putorius Cicognanii*, Bonap., Small Brown Weasel.
† *P. Richardsonii*, Bonap., Little Ermine.
P. Noveboracensis, DeKay, Ermine.
† *P. vison*, Rich., Brown Mink.
P. nigrescens, Aud. and Bach., Little Black Mink.
Lutra Canadensis, Sab., American Otter.
†† *Mephitis mephitis*, Baird, Skunk.
Procyon lotor, Storr, Raccoon.
Ursus Americanus, Pallas, Black Bear.
Phoca vitulina, Linn., Common Seal.
Stenmatopus cristatus, Gm., Hooded Seal.
Phoca Groenlandica, Harp Seal.
* *Trichechus rosmarus*, Linn., Morse or Walrus.

RODENTIA.

- * *Sciurus Carolinensis*, Gm., Gray Squirrel.
S. Carolinensis, Gm., var. *nigra*, Black Squirrel.
S. Hudsonius, Pallas, Red Squirrel.
Pteromys volucella, Cuv.?, Flying Squirrel.
* *P. Hudsonius*, Fischer, Northern Flying Squirrel.
Tamias striatus, Baird, Chipmunk, or Ground Squirrel.
†† *Areomys monax*, Gm. Woodchuck.
Castor Canadensis, Kuhl., Beaver.
* *Jaculus Hudsonius*, Wagner, Jumping Mouse.
Mus decumanus, Pallas, Brown Rat. (Introduced.)
M. rattus, Linn., Black Rat. (Introduced.)
M. musculus, Linn., Common Mouse. (Introduced.)
Hesperomys leucopus, Wagner, White-footed Mouse.
* *H. myoides*, Baird, Hamster Mouse.
* *Arvicola Gapperi*, Vigors, Redbacked Mouse.
A. riparia, Ord., Bank Mouse.
Fiber zibethicus, Cuv., Muskrat.
Erethizon dorsatus, F. Cuv., Porcupine.
Lepus Americanus, Erxl., White Hare.
* *L. sylvaticus*, Bach, Gray Rabbit.

RUMINANTIA.

- Alce Americanus*, Jardine, Moose.
Rangifer caribou, Aud. and Bach. Woodland Caribou.
Cervus Virginianus, Boddaert, Virginian Deer.

CETACEA.

- Balæna mysticetus*, Linn., Right Whale.
Physeter macrocephalus, Lacep., Sperm Whale.
Beluga borealis, White Whale.
Rorqualus rostratus, Fabr., Beaked Rorqual.
R. borealis, Knox, Northern Rorqual.
Globicephalus melas, Lesson, Black Fish.
Phocæna communis, Cuv., Porpoise.
P. orca, Fabr. Grampus.

No. IV.

ENUMERATION OF THE BIRDS KNOWN TO VISIT NEW BRUNSWICK.

This enumeration is framed on the same plan as the List published in the Transactions of the Portland Natural History Society. It has been revised by Mr. J. P. Sills of Fredericton. The birds not known to visit the Province have a star placed before them, thus, (*) those species which are not named in the Portland Society's List, but have been recognized in New Brunswick, are printed in italics.

INSESSORES.

- Falco anatum*, Bp., Duck Hawk.
F. columbarius, Linn., Pigeon Hawk.
F. Islandicus, Sabine, Jer Falcon.
F. sparverius, Linn., Sparrow Hawk.
Astur atricapillus, Wilson, Goshawk.
Accipiter Cooperii, Bp., Sharp-shinned Hawk.
Buteo borealis, Vieill., Red-tailed Hawk.
 * *B. lineatus*, Jardine, Red-shouldered Hawk.
B. Pennsylvanicus, Bp., Broad-winged Hawk.
 * *Archibuteo lagopus*, Gray, Rough-legged Hawk.
A. sancti-johannis, Gray, Black Hawk.
Circus Hudsonius, Vieill., Marsh Hawk.
 * *Aquila Canadensis*, Cassin, Golden Eagle.
Haliaeetus leucocephalus, Savigny, Bald Eagle.
Pandion Carolinensis, Bp., Fish Hawk.
 _____ *North American Kite*. [Probably a new species.]
Strix pratincola, Bp., Barn Owl.
Bubo Virginianus, Bp., Great Horned Owl.
Scops asio, Bp., Mottled Owl. Screech Owl.
 * *Otus Wilsonianus*, Lesson, Long-eared Owl.
 * *Brachyotus Cassinii*, Brewer, Short-eared Owl. *Small Barred Owl*.
 * *Syrnium cinereum*, Aud., Great Gray Owl.
S. nebulosum, Gray, Barred Owl.
Nyctale Richardsoni, Bp., Sparrow Owl.

- N. Acadica*, Bp. Saw-whet Owl.
Nyctea nivea, Gray, Snowy Owl.
Surnia ulula, Bp., Hawk Owl.
Coccygus Americanus, Bp., Yellow-billed Cuckoo.
C. erythrophthalmus, Bp., Black-billed Cuckoo.
Picus villosus, Linn., Hairy Woodpecker.
P. pubescens, Linn., Downy Woodpecker.
Picoides arcticus, Gray, Black-backed Three-toed Woodpecker.
* *P. hirsutus*, Gray, Banded Three-toed Woodpecker.
Sphyrapicus varius, Baird, Yellow-bellied Woodpecker.
Hylatomus pileatus, Baird, Black Woodcock.
Melanerpes erythrocephalus, Sw., Red-headed Woodpecker.
Picus Canadensis, Canada Woodpecker.
P. Phillipsii, Phillips' Woodpecker.
P. Martinæ, Maria's Woodpecker.
P. querulus, Red-cockaded Woodpecker.
P. Auduboni, Audubon's Woodpecker.
P. ruber, Red-breasted Woodpecker.
Colaptes auratus, Sw., Flicker.
Trochilus colubris, Linn., Ruby throated Humming bird.
Chætura pelasgia, Steph., Chimney Swallow.
Antrostomus vociferus, Bp., Whip-poor-will.
Chordeiles popetue, Baird, Night Hawk.
Ceryle alcyon, Boie, Belted Kingfisher.
Tyrannus Carolinensis, Baird, King bird.
* *Myiarchus crinitus*, Cab., Great-crested Flycatcher.
Sayornis fuscus, Baird, Pewee.
Contopus borealis, Baird, Olive-sided Flycatcher.
* *C. virens*, Cab. Wood Pewee.
Empidonax minimus, Baird, Least Flycatcher.
Turdus mustelinus, Gm., Wood Thrush.
* *T. Pallasi*. Cab., Hermit Thrush.
* *T. fuscescens*, Steph., Wilson's Thrush.
* *T. Swainsonii*, Cab., Olive-backed Thrush.
T. migratorius, Linn., Robin.
Sialia sialis, Baird, Blue bird.
Regulus calendula, Licht., Ruby-crowned Wren. Common Wren.
R. satrapa, Licht., Golden-crested Wren.
Anthus Ludovicianus, Licht, Tit Lark.
Mniotilta varia, Vieill, Black and White Creeper.
Geothlypis trichas, Cab., Maryland Yellow-throat.
* *Helmintherus vermivorus*, Bp., Worm-eating Warbler.
* *Helminthopaga chrysoptera*, Baird, Golden-winged Warbler.
* *H. ruficapilla*, Baird, Nashville Warbler.
* *Seiurus aurocapillus*, Sw., Golden-crowned Thrush.
* *S. noveboracensis*, Nutt., Water Thrush.
Dendroica virens, Baird, Black-throated Green Warbler.
* *D. coronata*, Gray, Yellow Rump Warbler.

- D. Blackburniæ, Baird, Blackburnian Warbler.
 * D. castanea, Baird, Bay-breasted Warbler.
 D. pinus, Baird, Pine-creeping Warbler.
 * D. Pennsylvanica, Baird, Chestnut-sided Warbler.
 D. striata, Baird, Black Poll Warbler.
 D. æstiva, Baird, Yellow Warbler.
 D. maculosa, Baird, Black and Yellow Warbler.
 D. tigrina, Baird, Cape May Warbler.
 D. palmarum, Baird, Yellow Red Poll.
Silvia pensilis, Yellow-throated Wood Warbler.
Silvia autumnus, Autumnal Warbler.
Silvia nigrescens, Black-throated Gray Wood Warbler.
Helinaia Swainsonii, Swainson's Swamp Warbler.
 Myiodiocetes pusillus, Bp., Green Black-cap Flycatcher.
 M. Canadensis, Aud., Canada Flycatcher.
 Setophaga ruticilla, Sw., Redstart.
 Pyrranga rubra, Vieill, Scarlet Tanager.
 Hirundo horreorum, Barton, Barn Swallow.
 H. lunifrons, Say, Cliff Swallow.
 H. bicolor, Vieill, White-bellied Swallow.
 Cotyle riparia, Boie, Bank Swallow.
 Progne purpurea, Boie, Purple Martin.
 Ampelis garrulus, Linn., Wax Wing.
 A. cedrorum, Baird, Cedar bird.
 Collyrio borealis, Baird, Great Northern Shrike.
 * Vireo olivaceus, Vieill, Red-eyed Fly-catcher.
 * V. gilvus, Bp., Warbling Fly-catcher.
 * V. noveboracensis, Bp., White-eyed Vireo.
Vireo Flavifrons, Yellow-throated Fly-catcher.
 * Mimus Carolinensis, Gray, Cat bird.
 * Harporhynchus rufus, Cab., Brown Thrush.
 * Cistothorus palustris, Cab., Long-billed Marsh Wren
 C. stellaris, Cab., Short-billed Marsh Wren.
 Troglodytes Americanus, Aud., Wood Wren.
 T. hyemalis, Vieill., Winter Wren.
 * Certhia Americana, Bp., American Creeper.
Certhia familiaris, Brown Creeper.
 Sitta Carolinensis, Gm., White-bellied Nuthatch.
 S. Canadensis, Linn., Red-bellied Nuthatch.
 Parus atricapillus, Linn., Chickadee; Black-cap Titmouse.
Parus Carolinensis, Carolina Titmouse.
 P. Hudsonicus, Forst., Hudsonian Titmouse.
 * Eremophila cornuta, Boie., Sky Lark.
 Pinicola Canadensis, Cab., Pine Grosbeak.
 Carpodacus purpureus, Gray, Purple Finch.
Fringilla atricapilla.
Black and Yellow crowned Finch.
 Chrysomitris tristis, Bp., Yellow bird.

- C. pinus*, Bp., Pine Finch.
Curvirostra Americana, Wils., Red Crossbill.
C. leucoptera, Wils., White-winged Crossbill.
Aegiothus linaria, Cab., Lesser Red Poll.
Plectrophanes nivalis, Meyer, Snow Bunting.
P. Lapponicus, Selby, Lapland Longspur.
 * *Passerculus Savanna*, Bp., Savannah Sparrow.
 Vireo Bartrami, Bartram's Greenlet.
 Icteria virida, Yellow-breasted Chat.
 * *Poœcetes Gramineus*, Baird, Grass Finch.
Coturniculus passerinus, Bp., Yellow-winged Sparrow.
Zonotrichia leucophrys, Linn., White-crowned Sparrow.
Z. albicollis, Bp., White-throated Sparrow.
Junco Hyemalis, Sclat., Snow Bird.
Spizella monticola, Baird, Tree Sparrow.
S. pusilla, Bp., Field Sparrow.
S. socialis, Bp., Chipping Sparrow.
Melospiza melodia, Baird, Song Sparrow.
M. palustris, Baird, Swamp Sparrow.
Passerella iliaca, Sw., Fox-colored Sparrow.
Guiraca Ludoviciana, Sw., Rose-breasted Grosbeak.
G. cœrulea, Sw., Blue Grosbeak.
 * *Cyanospiza cyanea*, Baird, Indigo Bird.
 * *Pipilo erythrophthalmus*, Vieill., Ground Robin; Towhee.
Dolichonyx oryzivorus, Sw., Bobolink, Rice Bird.
Molothrus pecoris, Sw., Cow Bird.
Agelaius phœniceus, Vieill., Swamp Blackbird; Red-winged Blackbird.
Sturnella magna, Sw., Meadow Lark.
Icterus spurius, Bp., Orchard Oriole.
I. Baltimore, Daudin, Baltimore Oriole.
 * *Scolecophagus ferrugineus*, Sw., Rusty Blackbird.
Quiscalus versicolor, Vieill, Crow Blackbird.
Corvus carnivorus, Bartram, American Raven.
C. Americanus, Aud., Crow.
Cyanura cristata, Sw., Blue Jay.
Perisoreus Canadensis, Bp., Canada Jay.
Ectopistes migratoria, Sw., Wild Pigeon, (*Passenger*).
Zenaidura Carolinensis, Bp., Common Dove.

RASORES.

- Tetrao Canadensis*, Linn, Spruce Partridge.
Bonasa umbellus, Steph., Ruffed Grouse, or Partridge, (*Pheasant*).
 * *Lagopus albus*, Aud., White Ptarmigan.
Ortyx Virginianus, Bp., Quail.

GALLATORES.

- Ardea herodias*, Linn., Great Blue Heron.
 * *Ardetta exilis*, Gray, Least Bittern.
Botaurus lentiginosus, Steph., Bittern.

- * *Butorides virescens*, Bp., Green Heron.
- * *Nyctiardea Gardeni*, Baird, Night Heron.
Ardea Occidentalis, Great White Heron.
- Charadrius Virginicus*, Borck, Golden Plover.
- * *Aegialitis vociferous*, Cassin, Killdeer.
- * *A. semipalmatus*, Cab., Semipalmated Plover.
A. melodus, Cab., Piping Plover.
- * *Squatarola Helvetica*, Cuv., Black-bellied Plover.
- * *Streptilas interpres*, Ill., Turnstone.
Philohela minor, Gray, American Woodcock.
Gallinago Wilsonii, Bp. Wilson's Snipe.
Macrorhamphus griseus, Leach, Red-breasted Snipe.
Tringa canutus, Linn., Gray Back.
T. maritima, Brunnich, Purple Sandpiper.
T. subarquata, Temm., Curlew Sandpiper.
T. alpina, Cassin, Red-backed Sandpiper.
- * *T. maculata*, Vieill., Jack Snipe.
T. Wilsonii, Nuttall, Least Sandpiper.
Calidris arenaria, Ill., Sanderling.
Ereunetes petrificatus, Ill., Semi-palmated Sandpiper.
- * *Symphemia semipalmata*, Hartlaub., Willet.
- * *Gambetta melanoleuca*, Bp., Tell-tale; Stone Snipe.
G. flavipes, Bp., Yellow Legs.
- * *Ryacophilus solitarius*, Bp., Solitary Sandpiper.
Tringoides macularius, Gray, Spotted Sandpiper.
Tringa Pectoralis, Pectoral Sandpiper.
- * *Philomachus pugnax*, Gray, Ruff.
- † *Limosa Hudsonica*, Sw., Hudson Godwit.
Numenius longirostris, Wilson, Long-billed Curlew.
N. Hudsonicus, Latham, Hudsonian Curlew.
- * *N. borealis*, Latham, Esquimaux Curlew.
- * *Porzana Carolina*, Vieill, Common Rail.
- * *Fulica Americana*, Gm., Coot.

NATATORES.

- Anser hypoboreus*, Pallas, Snow Goose.
- Bernicla Canadensis*, Boie, Canada Goose.
- B. brenta*, Steph., Brant.
- * *Anas boschas*, Linn., Mallard.
A. obscura, Gm., Black Duck.
Dafila acuta, Jenyns, Sprig-tail; Pin-tail.
Nettion Carolinensis, Baird, Green-winged Teal.
Querquedula discors, Steph., Blue-winged Teal.
- * *Spatula clypeata*, Boie, Shoveller.
Chauleeasmus streperus, Gray, Gadwall.
Mareca Americana, Steph, Baldpate; American Widgeon.
Aix sponsa, Boie, Summer Duck.
- * *Fulix marila*, Baird, Big Black-head, Scaup Duck.
F. collaris, Baird, Ring-necked Duck.

- Bucephala Americana*, Baird, Golden Eye.
 * *B. albeola*, Baird, Butter Ball.
Histrionicus torquatus, Bp., Harlequin Duck.
 * *Harelda glacialis*, Leach, South Southerly.
Melanetta velvetina, Baird, Velvet Duck.
 * *Oidemia Americana*, Swains, Scoter.
Somateria mollissima, Leach, Eider Duck.
 * *Erismatura rubida*, Bp., Ruddy Duck.
Fuligula perspicillata, Surf Duck.
Mergus Americanus, Cassin, Sheldrake.
M. serrator, Linn., Red-breasted Merganser.
Lophodytes cucullatus, Reich., Hooded Merganser.
Sula bassana, Briss., Common Gannet; Solan Goose.
Graculus Carbo, Gray, Common Cormorant.
Thalassidroma Leachii, Temm., Leach's Petrel.
T. pelagica, Bp., Mother Carey's Chicken.
Puffinus major, Fabor, Greater Sheerwater.
P. anglorum, Temm., Mank's Sheerwater.
 * *Stercorarius pomarinus*, Temm., Pomarine Skua.
S. parasiticus, Temm., Arctic Skua.
Larus marinus, Linn., Great Black-backed Gull.
L. argentatus, Brunn., Herring Gull.
L. Delawarensis, Ord, Ring-billed Gull.
Chroicocephalus atricilla, Linn., Laughing Gull.
C. Philadelphia, Lawrence, Bonaparte's Gull.
Rissa tridactyla, Bp., Kittiwake Gull.
Sterna Wilsoni, Bp., Wilson's Tern.
S. macroura, Naum., Arctic Tern.
Colymbus torquatus, Brunn., Loon; Northern Diver.
C. septentrionalis, Linn., Red-throated Diver.
Prodiopsis griseigena, Gray, Red-necked Grebe.
P. cornutus, Latham, Horned Grebe.
Podilymbus podiceps, Lawrence, The Pie-billed Grebe; Carolina Grebe.
Alca torda, Linn., Razor-billed Auk.
Mormon artica, Ill., Puffin.
Uria grylle, Latham, Black Guillemot.
U. ringvia, Briinn., Murre.
Mergulus alle, Vieill., Sea Dove; Dove Kie.
Pelicanus Americanus, White Pelican.
Larus Sabini, Fork-tailed Gull.
Larus eburneus, Ivory Gull.
Larus leucopterus, White-winged Silvery Gull.
Lestris Pomarine, Pomarine jager.
Procellaria glacialis, Common Fulmar.
Puffinus cinereus, Wandering Sheerwater.

WINTER BIRDS.

The following species may be found in the Province during the winter season :—

1. All the Owls, with the exception of the Snowy Owl.
2. All the Woodpeckers, with the exception of the Golden and Gray.
3. Grosbeak, Nuthatch, and Titmouse, two species each.
4. Crossbill, two species; Snow Bunting, two species; Snow Birds, only seen in winter.
5. Chipping Sparrow, remained all winter (1864-5)—a very rare occurrence.
6. A Field Sparrow was also seen by Mr. Sills, at Lake Yoho, on the 20th January, 1865. Very rare occurrence.
7. Moose Bird, or Whiskey Jack.
8. Crow.
9. Blue Jay.
10. Spruce Partridge.
11. Birch Partridge.
12. Ring Necked Duck.
13. Red Linnet, retaining its colour summer and winter.

Twenty-eight species in all.

NORTH AMERICAN KITE.

Description of a Kite not recognized in Audubon's "*Birds of America*," killed in Cardigan, York County :—

Length of body,	10 inches.
" tail,	7 "
Legs (from body),	7 "
Extended wings,	34 "
Expanded foot,	3 "
Beak,	1 "

Head very small; colour of body pale chestnut; back and wings very dark brown; back of tail, brown-gray; tips of wings, do.; legs, bright yellow; beak, blue and small; weight, very light; floats rather than flies; lives on mice and small birds.

No. V.

ENUMERATION OF THE FISHES OF NEW BRUNSWICK.

[From the Reports of the late M. H. Perley, Esq.]

I. *The Perch Family.*

- 1 The American yellow Perch,.....*Perca Flavescens.*
- 2 The Striped Basse,.....*Labrax Lineatus.*
- 3 The White Perch,.....*Labrax pallidus.*
- 4 The common Pond Fish,*Pomotis vulgaris.*

II. *The hard-cheeked Family, (Sculpin.)*

- 1 The common Bullhead,*Cottus Virginianus.*
- 2 The Greenland Bullhead, " *Grœnlandicus.*
- 3 The two-spined Stickleback,*Gasterosteus biaculeatus.*
- 4 The Norway Haddock,*Sebastes Norvegicus.*

III. *The Mackerel Family.*

- 1 The Spring Mackerel,*Scomber vernalis.*
- 2 The Fall Mackerel,*Scomber grex.*
- 3 The Tunny, or Albicore.....*Thynnus vulgaris.*
- 4 The Sword Fish,.....*Xiphias gladius.*

IV. *The Goby Family.*

- 1 The Wolf Fish,*Anarrhicas lupus.*

V. *Fishes with wrists in their pectoral fins.*

- 1 The American Angler,*Lophius Americanus.*

VI. *The Wrasse, or Fock Fish Family.*

- 1 The Sea Perch, or Cunner,*Otenolabrus ceruleus.*
- 2 The Tautog, or Black Fish,*Tautoga Americana.*

VII. *The Carp Family.*

- 1 The common Sucker,.....*Catostomus communis.*
- 2 The yellow Shiner,.....*Leuciscus chrysoleucas.*
- 3 The Roach, or Red-fin, " *cornutus.*
- 4 The Roach Dace, " *pulchellus.*
- 5 The shining Dace, or Shiner, " *argenteus.*
- 6 The Chub, " *cephalus.*
- 7 The Brook Minnow, " *atronsus.*
- 8 The striped Killifish,.....*Fundulus fasciatus.*

VIII. *The Sheat-fish Family.*

- 1 The common Cat-fish,.....*Pimelodus catus.*

IX. *The Salmon Family.*

- 1 The Brook Trout,*Salmo fontinalis.*
- 2 The Great Gray Trout, " *ferox.*
- 3 The Salmon Trout, (White Sea Trout,)... " *trutta.*
- 4 The Salmon, " *salar.*
- 5 The Smelt,*Osmerus viridescens.*
- 6 The Capelin.*Mallotus villosus.*
- 7 The White Fish, (Gizzard Fish.).....*Coregonus albus.*

X. *The Herring Family.*

- 1 The common American Herring, *Clupea elongata.*
- 2 The Britt, " *minima.*
- 3 The Shad, *Alosa sapidissima.*
- 4 The Alewife, or Gaspereaux, " *tyrannus.*
- 5 The Mossbonker, " *menhaden.*
- 6 The Shad Herring, " *mattowaca.*

XI. *The Cod Family.*

- 1 The Bank Cod, *Morrhua vulgaris.*
- 2 The American Cod, " *Americanus.*
- 3 The Tomcod, " *pruinosa.*
- 4 The Haddock, or Hake, " *eglefinus.*
- 5 The Hake, *Phycis Americanus.*
- 6 The Silver Hake, *Merluccius albidus.*
- 7 The Pollack, *Merlangus carbonarius.*
- 8 The Torsk, or Cusk, *Brosmius vulgaris.*
- 9 The Fresh Water Cusk, *Lota maculosa.*

XII. *The Flat-fish Family.*

- 1 The Halibut, *Hippoglossus vulgaris.*
- 2 The common Flounder, *Platessa plana.*
- 3 The Sand Flounder, " *pusilla.*
- 4 The Fleuk, " *limanda.*

XIII. *The Lump-fish Family.*

- 1 The Lump-fish, *Lumpus vulgaris.*

XIV. *The Eel Family.*

- 1 The common Eel, *Anguilla vulgaris.*
- 2 The Sea Eel, " *oceanica.*
- 3 The American Sand-launce, *Ammodytes Americanus.*

XV. *The Sturgeon Family.*

- 1 The Sharp-nosed Sturgeon, *Accipenser oxyrinchus.*

XVI. *The Shark Family.*

- 1 The Thresher Shark, *Carcharias vulpes.*
- 2 The Basking Shark, *Selachus maximus.*
- 3 The Dog Fish, *Spinax acanthias.*

XVII. *The Ray Family.*

- 1 The Skate, *Raia levis.*
- 2 The Hedge-Hog Ray, " *erinaceus.*

XVIII. *The Lamprey Family.*

- 1 The Lamprey, *Petromyzon Americanus.*

In all eighteen families, comprising forty genera, and sixty-two species of Fish.

No. VI.

FOSSILIFEROUS MARINE CLAYS OF MAINE AND THE SAINT LAWRENCE COMPARED.

[From Notes on the Geology of Maine, by C. H. Hitchcock, Esq.—Proceedings of the Portland Natural History Society.]

The occurrence of fossiliferous Marine Clays on the coast of New Brunswick is noticed in the Chapter on SURFACE GEOLOGY, page 201. The following table drawn up by Mr. C. H. Hitchcock, from materials supplied by Mr. Fuller, and the published list of Dr. Dawson, will be valuable to the Geologist in this Province. The age of the clays is that part of the Post Pliocene period which belongs to the Terrace epoch.

The occurrence of coarse drift over stratified clays containing fossils at Portland, Brunswick, Bangor, &c., appears to show that a temporary local extension or increase of existing glaciers took place towards the close of the glacial period, or perhaps a change in the location of an ice-stream, owing to the filling up of a fiord with debris, as now occurs in Greenland.—(See Mr. Taylor's paper quoted, page 184.)

MAINE SPECIES.

VERTEBRATA.

- Vertebrae of Whales, two species.
- Specimens of fish in concretions, possibly the same as one of the St. Lawrence species.
- Scales of large fish, such as the Rays.
- Teeth of shark, *Carcharias*.

ARTICULATA.

- Cancer irroratus*, Say.
- Hyas coarctata*, Leach.
- Bernhardus streblonyx*, Dana.
- †*Cytheridea Mulleri*.
- Bairdia?
- Nereis*.
- †*Spirorbis spirillum*, Lam.
- Balanus balanoides*, Linn.
- †*B. crenatus*.

MOLLUSCA.

- Terebratulina septentrionalis*, Couth, (Dawson.)
- Ostrea borealis*, Lam., (Mighels.)
- †*Pecten Islandicus*, Ch.
- P. similis*? Laskey.
- Nucula antiqua*, Migh.
- †*Yoldia pygmæa*? Muenst.
- †*Leda Portlandica*, Hitch.
- Yoldia limatula*, Say.
- Leda tenuisulcata*, Couth., (*Nucula Jacksoni*.)

ST. LAWRENCE SPECIES

VERTEBRATA.

- A. *Delphinus*, (Cetacean).
- Mallotus villosus*.
- Cyclopterus lumpus*.
- Remains of a Seal.

ARTICULATA.

- †*Balanus crenatus*.
- B. *Hameri*, Ascanius.
- B. *porcatus*, Dacosta.
- †*Cytheridea Mulleri*.
- Spirorbis sinistrorsa*.
- †*S. spirillum*.
- Serpula vermicularis*.

MOLLUSCA.

- Rynchonella psittacea*, Gm.
- †*Pecten Islandicus*, Ch.
- Leda minuta*, Moll.
- †*L. Portlandica*, Hitch.
- †*Yoldia pygmæa*, Muenst.
- Crenella glandula*, Tott.

E. squamosa.
 †*Biloculina ringens*, D'Orb.

PLANTS.

- Populus balsamifera*, Linn.
Potentilla Norvegica, Linn.
Thuja occidentalis, Linn.
 Algæ.

“The specimens among the mollusca marked with an asterisk are littoral species, or those which live on the shore between high and low water mark: the rest are deep water species. Seventy species are enumerated in the list above as belonging to Maine, and eighty-three as found in the St. Lawrence valley. Twenty-five species, marked with daggers, are common to both deposits.

“It is a curious fact, that in the collections of the Canadian Geological Survey, the group of shells obtained by Bell and Richardson in dredging on the north coast of Gaspé, in about 60 fathoms, is almost precisely that of the shells grouped in these clays about Portland.”

No. VIII.**MINING LICENCE.**

NEW BRUNSWICK TO-WIT:

By His Excellency The Honourable Arthur Hamilton Gordon, C. M. G. Licutenant Governor and Commander-in-Chief of the Province of New Brunswick, &c. &c. &c.

To all to whom these presents shall come :

Whereas

in this Province, has applied for Licence to dig and raise Coal and other Minerals from the Land hereinafter mentioned, having represented that the owner thereof

Now know ye, that in pursuance of authority contained in the Act 18th Victoria, Chapter 76, entitled "An Act Relating to Mines and Minerals," Licence is hereby granted to the said

Heirs, Executors, Administrators and Assigns, for the period of years from the date of these Presents, to dig and raise Coal and other Minerals from that tract of Land situated

Subject always to the Rules and Regulations hereunto annexed, and the payment of the Rent or Royalty at the times, and in the manner therein mentioned, provided nevertheless that the Licence herein granted, shall only continue during the existence of the legal title or interest to dig Coal and other Minerals therefrom of the said or Heirs, Executors, Administrators and assigns.

Surveyor General.

Given under my hand and Seal at Fredericton, the day of
in the year of our Lord one thousand eight hundred and

By His Excellency's Command.

GRANTED LANDS.**RULES AND REGULATIONS.**

1st. Every Mining Licence to be exempted from payment of Royalty for three years from its date.

2nd. The Rent or Royalty upon Coal to be one shilling per chaldron, (with the exception of that to be raised from lands formerly under lease to Berton, Maynard, and Scyphers, where the rate is to be two shillings per chaldron). Upon Shale sixpence per chaldron, and upon all Metallic Ores except Gold and Silver $2\frac{1}{2}$ per cent. upon the value thereof when raised or dug.

3rd. On payment of a fee of five dollars, Licence to be granted to the owner of the soil, or his assignee, for Coal or Shale for a period not exceeding twenty-five years, and for other minerals for a period not exceeding fifty years.

4th. The Rent or Royalty to be paid quarterly on the first day of February, May, August and November in each year after the third, to the Receiver General, or an agent for that purpose to be appointed by the Lieutenant Governor. The statements on which such payments are to be made to be on oath.

CROWN LANDS.

MINING REGULATIONS.

1st. That the right of Mining within a tract of one square mile, for the term of twenty-five years, be put up at a fixed rent of one shilling per chaldron on Coal, and five per cent. on the value of all other minerals raised, to be paid quarterly, on the first day of January, April, July, and October, in each year, to the Receiver General, or an agent for that purpose to be appointed by the Government.

2nd. That the upset preference price paid on each lot be five pounds.

3rd. That the preference money be paid and the ground selected within one hour after the time of sale, after which other lots will be offered, if required, in like manner.

4th. That if the lessee shall not actually raise Coal or other mineral to the value of one hundred pounds from his ground, within any one year after the first, during the continuance of his lease, the same shall become forfeited.

5th. That the lease contains a clause of renewal, or that the Government may resume and take the improvements at a valuation to be made by arbitrators mutually chosen by the Surveyor General for the time being, and by the lessee or his assigns.

APPENDIX IX.

REPORT

ON

THE MILITIA

OF

THE PROVINCE OF NEW BRUNSWICK,

FOR THE YEAR ENDING 31ST OCTOBER 1864.

WITH A MILITIA LIST.

LAID BEFORE THE LEGISLATURE
BY COMMAND OF HIS EXCELLENCY THE LIEUTENANT GOVERNOR.

FREDERICTON.

G. E. FENETY, PRINTER TO THE QUEEN'S MOST EXCELLENT MAJESTY.

1865.

REPORT
UPON THE MILITIA OF NEW BRUNSWICK,
FOR THE YEAR ENDING 31st OCTOBER 1864.

MAY IT PLEASE YOUR EXCELLENCY,

In accordance with Your Excellency's commands, I have the honor to submit the Annual Report on the Militia of the Province of New Brunswick.

As I only assumed the duties of Adjutant General on the 20th of August, my Report must necessarily be brief.

Pursuing the system adopted by my predecessor, Lieut. Colonel Crowder, I shall commence with the Volunteers, or Class A of the Active Militia. This body now consists of Cavalry, Artillery, Engineers, and Infantry, and numbers 1,717 officers and men.

CLASS A.

CAVALRY.

This consists of three Troops, one in York County, and two in King's.

The York County Troop is attached to the First Battalion of York County Militia, and its members are uniformed as Hussars. They receive no money allowance from Government, and have no regular drills. The other two Troops are mounted Infantry, armed with the Long Enfield Rifle. They would be very useful in carrying despatches;—keeping up communication between two columns;—feeling the way in front of a force;—and, (when dismounted), in skirmishing as Infantry. The material, both men and horses, is good; but much and consecutive drill is required to make them really efficient. There is great difficulty in devising any adjustment by which so cumbersome and easily injured a weapon as the Long Enfield Rifle can be safely carried on horseback.

ARTILLERY.

This force consists of seven Batteries of Foot Artillery; six of which are in Saint John and one in Fredericton. As a rule the Batteries are well drilled and uniformed, but their organization is defective and the armament useless. No Battery has more than two Guns, most of which are three pounders, a description of Gun which, at no time effective, is now quite out of date. In addition, they are armed with the Long Enfield Rifle. This fine Corps requires a thorough re-organization; though well drilled, it would be certain destruction for them to take the field in their present condition. To be really of use the Batteries ought to be diminished in number and their strength

increased; the Field Pieces returned, and the Regiment drilled as Garrison Artillery, so as to enable them to man the heavy Guns mounted, or to be mounted, on the Forts protecting Saint John.

The nature of the country, as far as I have seen it, is such, that there are very few places where the best Cavalry and Artillery would not be at the mercy of a small body of bold and intelligent Riflemen; and, indeed, few where a strong Battalion of Infantry could advance any distance in line.

ENGINEERS.

There is one Company of Engineers in the Province, at Saint John. They are a fine body of men, and fairly drilled as Infantry; but they have as yet had no instruction in their own special duties, the tracing and throwing up of Field works.

INFANTRY.

The Volunteer Infantry consists of twenty one Companies, six of which compose the Saint John Volunteer Battalion, the remaining fifteen being independent Companies. I need not repeat the very judicious remarks of Lieut. Colonel Crowder on the organization of Volunteers, to be found in his Report for 1862, but merely state that I perfectly concur in his opinion, that Volunteer Companies ought not to be raised except in Towns, or thickly peopled districts.

What I have to remark myself is, that Volunteers are too apt to neglect drill, and commence their musketry practice at once, the latter being much more interesting but not more useful than the former; that when formed into a Battalion, Companies have still a great tendency to consider themselves independent Corps; and that Officers are not strict enough in enforcing rules and orders, besides being in some instances remiss in obeying those which they themselves receive. The latter observation, however, must not be considered as being of by any means general application. Volunteers are also apt to forget that they enjoy more privileges than are granted to their brethren at home. They get cloth for uniform, arms, and ammunition, free of expense; each Company receives \$80 a year in money; and every individual volunteer is exempt from taxes to a considerable amount. One of the proposals of the late Militia Commission will, I think, if adopted, be attended with favourable results, viz. that the allowance made to Volunteers should be a capitation grant, and only issued to those Companies whose members have actually attended drill a certain specified number of times annually.

At present a Company composed of 43 men gets as much as one of 75; no specified number of drills is required by law to be performed, and while some Companies drill twice a week, others drill only once, and some not once a month. The average attendance generally is only about one-fourth of the nominal strength, although I had the pleasure of bringing a Battery to Your Excellency's notice, where the average attendance was 47, two Drills in the week. I too often find that when the Drill Instructor leaves, the drill

ceases, or nearly so; and it is a matter of surprise to me, that Volunteers do not endeavour to qualify themselves as drill instructors, which many of them are capable of doing. With Your Excellency's concurrence, I have commenced trying to educate some Volunteers for this purpose, by attaching them occasionally to the 15th Regiment. Should the Camp of Instruction, as proposed by the Militia Commission, be carried out, it will be of great value in providing men, not only drilled themselves, but capable of imparting instruction to others; and I would suggest that, after the Camp, a certain number of Volunteers should be allowed to remain and endeavour to qualify themselves for Certificates, as is the custom in Canada.

Though a considerable amount of ammunition is expended, yet no endeavours have been made to give any musketry instruction, much of which ought to be imparted before a single shot is fired. Judging distance drill and practice, a most important branch of Rifle instruction, has never been even attempted in New Brunswick. Rifle instruction, however, is a thing which must be continuous, the men under instruction must devote their whole time to it, and this might advantageously be commenced after the Camp; a certificate granted to those who prove themselves competent, accompanied by a gratuity, and thus a beginning made towards instructing the whole of the Militia.

The fact of Major Willis and myself having both obtained first class certificates at the School of Musketry at Hythe, affords every facility for carrying this out.

In mentioning the above facts, I beg to draw Your Excellency's notice to the limited time at my disposal for attending to the proper duties of my office, viz. the drill, discipline, and official correspondence of the Militia and Volunteers of the Province. The correspondence and returns alone give full employment, and Your Excellency is aware that in consequence of new Battalions having been formed, and I am happy to say, the increasing interest taken by Colonels of Militia, in rendering their officers competent to discharge the duties of their rank, my labours in this branch have recently been increased very considerably. But besides this, I have charge of and am responsible for the whole of the Government Stores; not a round of ammunition nor a single button can be disposed of without my cognizance, and without my keeping an account of it.

The consumption of stores of all kinds is increasing, and the amount of arms, clothing, saddlery and ammunition is such, that a man might be profitably employed constantly in keeping them in order. Much valuable property has been suffered to become useless from want of proper care, and a great deal more has been allowed to pass out of the hands of the Government. Quite lately, Your Excellency is aware, a respectable Firm in this City informed me that a considerable quantity of Government Stores was in their warehouse, including, amongst other articles, barrels of boots, two or three hundred uniforms, &c.; the boots have never been used, and are believed to be twenty or thirty years old. No record of these articles ap-

peared in my books; and my present List, though I have used every endeavour to make it correct, is, I believe, far from being so. I would respectfully recommend that the Militia Stores, both here and at Saint John, should undergo a thorough and searching examination; that a quantity of perfectly useless articles should be condemned and sold, or otherwise disposed of; and that there should be a central Store House, under the charge of a paid officer, to whom should be intrusted the purchase, care and issue of all Military Stores. In Canada the Superintendent of Militia Stores is a Lieut. Colonel, assisted by seven Storekeepers, ranking as Captains.

By entering into contracts with large Firms in England, the Canadian Government is enabled to furnish every article of Militia equipments at a much lower rate than can be hoped for here. With Your Excellency's permission I have ordered a small quantity of officers' swords, belts, sashes, &c., from England; and though I shall be able to sell them at a considerably cheaper rate than that at which an officer could procure them for himself, I shall not be able to dispose of them as cheaply as they can do in Canada. As Your Excellency is aware, my whole time is at the disposal of the Province, but I think my time might be employed with more advantage, were the Store Department placed under other management.

CLASSES B. & C.

The next Branch of the Provincial Force I have to notice, is the Militia Proper, or Classes B and C of the Active Militia. Including the Sea Fencibles, there are 18 Regiments in the Province, divided into 37 Battalions. These Battalions contain all the male inhabitants of the Province, (except Class A, and certain exempts,) between the ages of 18 and 45, but the total numbers reported to me were, Class B, 16,730; Class C, 16,059; together 32,789 men. I need not draw Your Excellency's attention to the inadequacy of the Militia Law which is just expiring; in fact its provisions, when enforced, only deprived the country of the work of the men for a day, without giving any corresponding advantage in a military point, although it is doubtless of some utility, that the Regiments should be occasionally mustered for enrolment and parade. However, the Law, whilst in force, ought to have been obeyed, and I regret to have to report to you that eight Battalions did not muster at all, and that in some others no care was taken to ascertain the number of absentees, or to punish them. Many Commanding Officers, however, conscientiously imposed the fines required by law. The result of this state of things is, that while one man is punished for not obeying the law, his neighbour is not even called upon to do so; and unnecessary odium must be thrown on those officers who discharge the duty which by law devolves upon them. By Your Excellency's command I inspected two Battalions of Militia at their annual Muster, and am happy to state that I found much less confusion and insubordination than I had been led to expect. The officers were in uniform, and had evidently been carefully drilled. One of the Regiments, since divided, had about 1,400 men on

parade, a number which, even when composed of well drilled soldiers, it is much beyond the power of one man to command effectively.

Your Excellency has formed three new Battalions during the last year, but there are several still remaining that might with advantage be divided.

I have the satisfaction of informing Your Excellency, that latterly many officers commanding Militia Regiments have evinced great zeal and perseverance in endeavouring to make their officers acquainted with their duty. In several Battalions the officers are all provided with uniforms, and turn out for drill in larger numbers than some Volunteer Companies. The officers of the undermentioned Battalions are regularly drilled, and from most of them I receive regular monthly returns;—

1st Battalion York County Militia.
 1st Battalion Saint John City Light Infantry.
 2nd do. do. do.
 Saint John City Rifles.
 2nd Battalion Saint John County Militia.
 1st Battalion Charlotte County Militia.
 Restigouche Militia.
 1st Battalion Gloucester Militia.
 3rd Battalion King's County Militia.
 1st Battalion Carleton County Militia.
 2nd do. do. do.

and three others, viz:—

2nd Battalion King's County Militia,
 1st Battalion Northumberland County Militia,
 Albert County Militia,

have intimated their intention of commencing drill. Your Excellency has authorized me to issue arms and accoutrements to such Battalions as may wish to learn to use them, and the Drill Sergeants in the service of the Province are directed to give their services whenever they can be available. The conduct of the Lieutenant Colonels of the above Regiments, and that of the Officers who have so laudably seconded their endeavours, merits Your Excellency's marked approbation, and entitles them to receive the thanks of the Province. They have shown how much can be effected by willingness and perseverance, even under a defective law, and without pecuniary assistance.

SEDENTARY MILITIA.

The only remaining Class is the Sedentary Militia, comprising all male inhabitants, with the same exceptions as Classes B and C, between 45 and 60. These are attached to the Battalions in whose districts they reside, but are not called upon to attend muster. Few Battalions have made a return of them, and these do not seem to have been made with much attempt at accuracy. The whole number returned to me is only 6,188.

In concluding these brief remarks, I have to observe that the long time which the Militia was suffered to remain in abeyance, renders it no easy task to revive it. There is much good feeling, and much susceptibility of receiving instruction; and I am convinced that the method proposed by the Commission assembled lately by Your Excellency's orders, is the very best for imparting a leaven of discipline and military spirit throughout the Province. The first year will necessarily be the most difficult and the most expensive; but when we see what is being done in Canada and in Nova Scotia, and consider that the money voted for Militia purposes is all spent in the Province, I am in hopes that the Legislature will enable Your Excellency to carry out a plan which, in words used at the meeting of the Militia Commission, will secure the "maximum of efficiency with the minimum of expense."

I have seen no country where nature has done more for its defence than in this Province. The great amount of waste land, the consequent scarcity of supplies, the impenetrable woods, and the numerous rivers and streams, provide New Brunswick with fortifications, as effective as inexpensive.—From this remark I of course except frontier or seaboard towns, which would be likely to bear the brunt of an invasion; but for the remainder of the Province, determined men in small bodies have every natural facility for keeping an army at bay. I believe that at few, if at any places in the country, could 10,000 men in time of peace escape starvation, were previous arrangements not made for their provision. An invading army would, therefore, have to draw its supplies from the seacoast or the frontier, and every mile it got farther into the interior, would make this a matter of greater difficulty. Your Excellency may remember that during the Crimean War, the difficulty of transit of stores lay in the last six miles between Balaklava and the front, not in the 3000 miles between Balaklava and England, and yet the whole road was in our possession.

From the denseness of the woods an army would have to keep to the high roads, or rivers, so that the point of attack would be known to a certainty. Most of the high roads are so narrow that I do not think more than two guns or twenty file of infantry could march abreast. The offensive force of an army is proportionate, for the time, to the front it can show, and in places where this cannot be increased, the depth of the column is only a source of weakness. To illustrate this, say that 5000 men, not opposed in any way, are advancing from Saint Stephen to Fredericton. They would have to convey their supplies along with them, and would, at a low estimate, take four days for their march, if the roads were at all heavy. But suppose that the country had been evacuated by the inhabitants, the bridges broken down, and a few trees felled on the road; they would then probably take a fortnight. If, in addition, at every good position on the road, such as those where a bridge had been broken down, they encountered an earth work, flanked by an abatis of felled trees, with a couple of guns firing grape, and one hundred Riflemen all in concealed and safe positions, the date of their

arrival would become a matter of very considerable doubt. Similar obstructions might be repeated at every stream, or naturally strong position; and even if the invading force pushed their way, the bye roads, which I notice are usually at right angles to the main roads, would be a valuable means of cutting off supplies and harassing their rear. I doubt much if a General of any prudence would wish to be entrusted with the command of such an undertaking. The rivers could be easily rendered useless to an enemy by sinking vessels at the shallows, or placing booms across their course, and by placing at those points a few guns and some riflemen. Your Excellency is aware how long the war in New Zealand has lasted, although carried on between semi-savages and our best troops. Defence is always easier than attack, and more especially is this the case in a country like New Brunswick. I find from the Report of Colonel Fordyce and Lieut. Colonel Crealock, that they recommended a corp of lumberers should be raised and armed with axes and revolvers. In the event of war, such a force would be an absolute necessity; and if there is a Camp of Instruction, the formation of the nucleus of the corps would be advantageous and economical.

I have the honor to annex a statement of the Accounts of the Militia Service from 1st November 1863 to 31st October 1864, by which Your Excellency will observe that the total sum drawn for Militia purposes during that period amounted to \$10,000.63, while during the same time, \$1,444.92 recovered from Officers of the Militia for ammunition and other stores furnished to them, were repaid into the Treasury by the Adjutant General.

On the 31st October a balance of \$389.19 was due to the Adjutant General, which would make the expenditure for the year amount to \$8,944.90. No debts were due by the Department; on the contrary, about \$400 is still due from Militia Officers for articles supplied to them, and stores to a considerable amount remain on hand. Several sums were however paid for Military purposes, in addition to the foregoing, which do not appear in my Accounts.

All of which is respectfully submitted.

T. ANDERSON, *Lieutenant Colonel,*
Adjutant General of Militia.

T. ANDERSON, *Lieut. Colonel,*
Adjutant General of Militia.

INSPECTION REPORT

OF THE VOLUNTEER COMPANIES OF THE

NEW BRUNSWICK MILITIA,

1864.

MAY IT PLEASE YOUR EXCELLENCY,

I have the honor to submit to Your Excellency the following Report of the Inspection of the Volunteer Companies of the Militia during the Year 1864.

CAVALRY.

Captain Saunders's Troop.

This Troop was inspected on the 16th November. It is well mounted, and the arms and accoutrements are in fair order. The men want more drill, and should be drilled more frequently together; but this, from the large district the Troop extends over, is difficult to manage. A Drill Sergeant has since been with them for some time.

Captain Saunders, Lieutenant Earle.

Captain Fairweather's Troop.

This Troop was inspected by Your Excellency in December. The attendance was very small; men and horses looked well, but drill is much wanted. This Troop gets no Government allowance.

ARTILLERY.

Five Batteries of this Regiment were inspected at Saint John on the 22nd September. I had every reason to be satisfied with their appearance and drill; an opinion in which the late Capt. Morris, Royal Artillery, coincided.

Captain Thomson's Battery was not present, but it has since been successfully reorganized.

Captain Pick's Battery received Your Excellency's thanks for its soldier-like behaviour in camp; and its attendance at drill is highly creditable, as likewise that of the Battery commanded by Captain Farmer.

Lieut. Colonel Foster,	Major Melick,	Captain and Adjutant Mount.
Capt. Pick,		Lieuts. Sneden,
“ B. L. Peters,		“ Thomas,
“ M. H. Peters,		“ Wetmore,
“ T. M. Lachlan.		“ M. Cordock,
“ R. Farmer.		“ Lansdown,
		“ Murray,
		“ Curard.
		“ Underhill.

Captain Berton's Battery, Fredericton.

This Battery was inspected by Your Excellency on the 9th November. The attendance was good, and Captain Berton drilled his Battery well, though from the confined space in which they were paraded, they did not appear to full advantage.

Captain Berton, Lieutenant Peters.

ENGINEERS.

This Company was inspected on the 17th November. The attendance was good; Captain Boyd and his officers are active and efficient. The Company is well drilled, and for the most part uniformed. The arms are in good order.

Captain Boyd, Lieuts. Parks and Munroe.

INFANTRY.

SAINT JOHN VOLUNTEER BATTALION.

Five Companies of this Battalion were inspected on the 20th September in the Barrack Square, Saint John, under the command of Captain and Adjutant (now Major) Ray, in the absence of a Senior Officer.

The Battalion made a very good appearance, and a few Battalion movements were fairly performed. The Companies were then drilled separately, and acquitted themselves well. Captain Ray deserves credit for the manner in which he commanded, I believe, for the first time. Captain Macshane's Company was not present, but it has since been reorganized, and its attendance at drill is much above the average of that of Volunteer Companies.

Cpts. Ray, (<i>Adjutant.</i>)	Lieuts. Scovil,
“ Thurgar,	“ Dunlop,
“ Millett.	“ Godard,
“ Hall,	“ Sullivan,
“ Burpee,	“ Nicholson,
“ Robinson.	Ensigns Campbell,
	“ Berton,
	“ Murphy.

FIRST BATTALION YORK COUNTY MILITIA.

Captain Simonds's Company.

This Company was inspected by Your Excellency November 8th, in the Barrack Square. The attendance was fair; arms, accoutrements, &c., in good order. The Company drilled remarkably well. Captain (now Major) Simonds is an excellent officer, and his subalterns and non-commissioned officers are efficient and zealous.

Captain Simonds, Lieut. Wilson, Ensign Carter.

Captain Marsh's Company.

The Company has been recently reorganized, and the attendance at the inspection by Your Excellency in December was very poor, being insufficient to enable many Company movements to be executed. It is, however, very fairly drilled, and possesses some smart non-commissioned officers.

Captain Marsh, Lieut. M'Causland, Ensign Davies.

INSPECTION REPORT
OF THE VOLUNTEER COMPANIES OF THE
NEW BRUNSWICK MILITIA,
1864.

MAY IT PLEASE YOUR EXCELLENCY,

I have the honor to submit to Your Excellency the following Report of the Inspection of the Volunteer Companies of the Militia during the Year 1864.

CAVALRY.

Captain Saunders's Troop.

OFFICERS.

Captain Saunders, Lieutenant Earle.

This Troop was inspected on the 16th November. It is well mounted, and the arms and accoutrements are in fair order. The men want more drill, and should be drilled more frequently together; but this, from the size of the district from which the members of the Troop are drawn, is difficult to manage. A Drill Sergeant has been with them for some time since the inspection.

Captain Fairweather's Troop.

OFFICERS.

Captain Fairweather.

This Troop was inspected by Your Excellency in December. The attendance was very small; both men and horses, however, looked well, but drill is much wanted. This Troop gets no Government allowance.

ARTILLERY.

OFFICERS.

Lieut. Colonel Foster,
Major Melick,
Capt. and Adj. Mount,
Capts. Berton,
" Pick,
" B. L. Peters,
" M. H. Peters,
" T. M'Lachlan,
" R. Farmer.

Lieuts. Sneden,
" Thomas,
" Wetmore,
" Peters,
" M'Cordock,
" Lansdown,
" Murray,
" Cunard,
" Underhill.

Five Batteries of this Regiment were inspected at Saint John on the 22nd September. I had every reason to be satisfied with their appearance and drill; as was also the late Capt. Morris, Royal Artillery, who, upon Your Excellency's desire, attended at the inspection.

Captain Thomson's Battery was not present, but it has since been successfully reorganized.

Captain Pick's Battery received Your Excellency's thanks for its soldier-like behaviour in camp at Mount Fordham; and its attendance at drill is highly creditable, as is likewise that of the Battery commanded by Captain Farmer.

Captain Berton's Battery was inspected at Fredericton by Your Excellency on the 9th November. The attendance was good, and Captain Berton drilled his Battery well, though from the confined space in which they were paraded, they did not appear to full advantage.

ENGINEERS.

OFFICERS.

Captain Boyd, Lieut. Parks, Lieut. Munro.

This Company was inspected on the 17th November. The attendance was good; Captain Boyd and his officers are active and efficient. The Company is well drilled, and for the most part uniformed. The arms are in good order.

INFANTRY.

SAINT JOHN VOLUNTEER BATTALION.

OFFICERS.

Lieut. Colonel Crookshank,	Lieuts. Scovil,
Major Ray,	“ Dunlop,
Capt. Macshane,	“ Godard,
“ Thurgar, (<i>Adjutant</i>),	“ Sullivan,
“ Millett,	“ Nicholson,
“ Hall,	Ensigns Campbell,
“ Burpee,	“ Berton,
“ Robinson.	“ Murphy.

Five Companies of this Battalion were inspected on the 20th September in the Barrack Square, Saint John, under the command of Captain and Adjutant (now Major) Ray, in the absence of a Senior Officer.

The Battalion made a very good appearance, and a few Battalion movements were fairly performed. The Companies were then drilled separately, and acquitted themselves well. Captain Ray deserves credit for the manner in which he commanded, I believe, for the first time.

FIRST BATTALION YORK COUNTY MILITIA.

Captain Simonds's Company.

OFFICERS.

Captain Simonds, Lieut. Wilson, Ensign Carter.

This Company was inspected by Your Excellency November 8th, in the Barrack Square. The attendance was fair; arms, accoutrements, &c., in good order. The Company drilled remarkably well. Captain (now Major)

Simonds is an excellent officer, and his subalterns and non-commissioned officers are efficient and zealous.

Captain Marsh's Company.

OFFICERS.

Captain Marsh, Lieut. M'Causland, Ensign Davies.

The Company has been recently reorganized, and the attendance at the Inspection by Your Excellency in December was very poor, being insufficient to enable many Company movements to be executed. It is, however, very fairly drilled, and possesses some smart non-commissioned officers.

SUNBURY COUNTY MILITIA.

Capt. Bailey's Company.

OFFICERS.

Captain Bailey, Lieut. Robert Wilmot, Ensign Patrick Coleman.

This Company, commanded by Captain Bailey, was inspected by Your Excellency on November 3rd. The attendance was fair, but much drill is required by this Company.

Captain Bailey seems to want self-confidence, but he is attentive and correct in his returns.

FIRST BATTALION CHARLOTTE COUNTY MILITIA.

Major Whitlock's Company.

OFFICERS.

Major Whitlock, Ensign Stevenson.

The two Companies of Volunteers attached to this Battalion were inspected at Saint Andrews on the 16th September.

Major Whitlock's Company turned out pretty well, and drilled tolerably; the arms were in fair order.

Captain Sandford's Company.

OFFICERS.

Captain Sandford, Lieut. M'Vey, Lieut. Lochary.

Captain Sandford's Company presented an unsatisfactory appearance both in numbers and drill.

Both these Companies have since been disbanded.

SECOND BATTALION CHARLOTTE COUNTY MILITIA.

Lieut. Colonel Wetmore and Captain Smith's Companies.

OFFICERS.

Lieut. Colonel Wetmore, Captain Smith,
Lieut. Bogue, Ensign James O'Brien.

These two Companies were inspected at Saint George on the 17th September.

They are both fairly drilled, but did not appear to advantage on account of the inspection taking place on the high road.

The arms were in very good order, and the men among the finest I have seen in the Province. Colonel Wetmore has erected a block-house, and purchased two four-pounder guns at his own expense, and is about to train some of his men to work them.

FOURTH BATTALION CHARLOTTE COUNTY MILITIA.

Captain Inches's Company.

OFFICERS.

Captain Inches, Ensign Gregg.

This Company, commanded by Captain (now Major) Inches, was inspected at Saint Stephen on the 15th September.

It is one of the best Companies in the Province. Both Major Inches and Ensign Gregg (since retired) proved themselves competent officers, and the men were thoroughly drilled, and very steady in the ranks. The only remark I had to make was that I wished the Company had been stronger.

Some of the belts in possession of this Company are too old, and ought to be exchanged for new ones.

Captain M'Adam's Company.

OFFICERS.

Captain M'Adam, Lieut. Murchie.

This Company was in the course of reorganization. I inspected the arms and found them in good order.

Captain M'Adam has gone to considerable expense in building a spacious drill room.

FIRST BATTALION NORTHUMBERLAND COUNTY MILITIA.

Captain Russell's Company.

OFFICERS.

Captain Russell, Lieut. Ferguson, Ensign Snowball.

This Company was inspected on 19th October. This is an excellent Company. The attendance was large, the two officers present were well acquainted with their duty, and the manner in which the men drilled, and the condition of the arms, were quite satisfactory. I regret that the state of the weather prevented me seeing this Company out of doors.

RESTIGOUCHE COUNTY MILITIA.

Captain Smith's Company.

OFFICERS.

Captain Smith, Ensign W. M. Caldwell.

This Company, commanded by Captain Smith, was inspected at Dalhousie on the 24th October. The attendance and drill were good, and the arms in fair order.

The drill ground was, from its unevenness, not very well adapted for manœuvres, and some of the members were unpunctual in turning out.

FIRST BATTALION GLOUCESTER COUNTY MILITIA.

Captain Desbrisay's Company.

OFFICERS.

Captain Desbrisay, Lieut. Miller, Ensign Meehan.

This Company was inspected at Bathurst on the 22nd October. The attendance was large, and the arms in fair order. I, however, felt myself obliged to make some strong remarks on the unsteadiness and deficiency in drill manifested by this Company, but at the time I was not aware that it had only been recently formed, and had had the advantage of a Drill Instructor for a very short time. I am happy to state that my observations were taken in good part, and that I have received favourable reports of the increasing efficiency of this Company. A Drill Instructor was sent to Bathurst shortly after the inspection.

SECOND BATTALION KING'S COUNTY MILITIA.

Captain Beer's Company.

OFFICERS.

Captain Beer, Lieut. Thomson, Ensign Arnold.

This Company was inspected at Sussex on the 16th November, but the state of the weather obliged the inspection to take place under cover, consequently there was little room to move about.

The drill and state of the arms were satisfactory, and Captain Beer is an active and intelligent officer, but discipline might with advantage be more strictly enforced.

FIRST BATTALION CARLETON COUNTY MILITIA.

Captain Strickland's Company.

OFFICERS.

Captain Strickland, Lieut. Baird, Ensign Boyer.

This Company was inspected at Woodstock on the 5th November. It is a very good Company, though not so strong as could be wished. I was given to understand that this arose, not from want of spirit amongst the men, but from the prohibition of some of their employers. The inspection had unfortunately to be conducted under cover, on account of the weather. The drill and state of arms were quite satisfactory. Captain Strickland is an excellent and zealous officer, and his subalterns only require practice and self-confidence to become his equals in this respect.

FIRST BATTALION SAINT JOHN COUNTY MILITIA.

OFFICERS.

Lieutenant Rynd, Ensign Tinor.

This Company was not inspected, as drill had been given up for some time. It has since, however, been revived under the command of Lieutenant Rynd.

REPORT ON THE MILITIA.

SECOND BATTALION CARLETON COUNTY MILITIA.

Captain Adams's Company.

OFFICERS.

Captain Adams, Lieutenant Burt, Ensign Barrett.

The Company attached to this Battalion was also not inspected, as, being composed chiefly of lumbermen, most of its members were absent in the woods.

This comprises the whole of the Volunteer Companies in the Province; and I have the satisfaction of informing Your Excellency that I have not received a single complaint against the Drill Instructors employed, but that on the contrary, from my own inspection, and the reports of others, I have every reason to be satisfied with their intelligence and good conduct.

All of which is respectfully submitted to Your Excellency.

T. ANDERSON, *Lieut. Colonel,*
Adjutant General of Militia.

REPORT ON THE MILITIA.

RETURN OF THE MILITIA AND VOLUNTEERS OF THE PROVINCE OF NEW BRUNSWICK, 1864.

MILITIA LIST

FOR THE

PROVINCE OF NEW BRUNSWICK.

In the List of Regiments, the Field Officers have the date of their last Regimental appointments annexed to their names, their Militia Rank being specified in the List of Field Officers. Other Officers will have their Militia Rank opposite their names; the seniority in the Regiment being indicated by the order of their names in each rank.

GENERAL ORDER.

HORSE GUARDS, S. W., London,
16th August, 1864.

Relative Rank.
1—(1864).

His Royal Highness the Field Marshal Commanding-in-Chief has received Her Majesty's commands to promulgate to the Army the following regulation, which has been decided on, in concurrence with the Secretary of State for War, viz :—

The order, as contained in Her Majesty's Book of Regulations, for the relative rank of the Officers of the Army and Royal Marines, with those of the Militia, Yeomanry, and Volunteers, shall be held applicable also to Officers of Colonial Militia, Yeomanry, and Volunteer Corps, which have been, or may hereafter be, raised by the Legislature of the Colonies, with the sanction of Her Majesty the Queen, during the period of their embodiment and service with Her Majesty's Regular Forces.

By Command of His Royal Highness

The Field Marshal Commanding-in-Chief.

A. H. HORSFORD,
Deputy Adjutant General.

An asterisk (*) prefixed to a name, denotes an Officer of Volunteers.

Although every care has been taken to make this List correct, yet there are, no doubt, several errors. Officers are desired to intimate such to the Adjutant General.

It has been found impossible in all cases to ascertain with accuracy the date of the formation of the different Battalions. Information on this head is requested.

STAFF

OF THE MILITIA FORCES OF THE PROVINCE OF NEW BRUNSWICK.

COMMANDER IN CHIEF,

His Excellency The Honorable Arthur H. Gordon, C. M. G., (late Lieut. Colonel 2nd Aberdeenshire Rifles,) 14th September 1861.

Captain Harry Moody, (Oxford Militia,) Aide-de-Camp, 26th October 1861.

Lieut. Colonel Charles Drury, Provincial Aide-de-Camp, 26th October 1861.

Captain B. L. Peters, N. B. Artillery, do. 5th January 1864.

Lieut. Colonel Thomas Anderson, (late Capt. 78th Highlanders,) Adjutant General, and Inspecting Field Officer Western District, 20th August 1864.

Major Charles C. Pye, (late Capt. 63rd Foot,) Deputy Adjutant General, 1st Jan. 1862.

Major Cuthbert Willis, (late Lieut. 15th Foot,) Inspecting Field Officer Eastern District, 9th November 1864.

Lieut. Colonel William B. Robinson, (late Major 3rd West India Regt.) Queen's New Brunswick Rangers, Quarter Master General, 8th June 1863.

Lieut. Colonel William T. Baird, 1st Battalion Carleton County Militia, Deputy Quarter Master General, 8th June 1863.

Lieut. Colonel The Honorable Lemuel A. Wilmot, 1st Battalion York County Militia, Judge Advocate General, 6th August 1834.

FIELD OFFICERS.

REPORT OF THE MILITIA COMMISSION.

At a Meeting summoned by direction of His Excellency the Commander in Chief, and held at Government House, Fredericton, on the 3rd January 1865, and continued upon the 4th and 5th January, at which the following Officers of the New Brunswick Militia were present—

His Excellency the Commander in Chief.

Lieut. Colonel Thurgar, Saint John City Rifles.
 “ Hon. J. H. Gray, Queen’s New Brunswick Rangers.
 “ Hon. John Robertson, Saint John City Light Infantry.
 “ Hon. L. A. Wilmot, First Battalion York County Militia.
 “ Foster, New Brunswick Regiment of Artillery.
 “ Baird, D. Q. M. G., First Battalion Carleton County Militia.
 “ Otty, Third Battalion King’s County Militia.
 “ D. Wetmore, Second Battalion Charlotte County Militia.
 “ R. W. Crookshank, Saint John Volunteer Battalion.
 Captain Simonds, First Battalion York County Militia.
 “ Saunders, New Brunswick Yeomanry Cavalry.

The Adjutant General of Militia.

The following Resolutions were, after debate, unanimously agreed to:—

1. Moved by Lieut. Colonel Hon. L. A. Wilmot—

That the establishment of a Camp of Instruction, composed of a Company from each Battalion in the Province, composed of Volunteers or of men drawn by ballot, for a period of 28 days in each year, would be of permanent benefit to the Militia Force of this Province.

2. Moved by Lieut. Colonel Hon. L. A. Wilmot—

That, in the opinion of this meeting, the remainder of the Militia Force should be called out for — days drill and one day inspection in each year, and to embrace all the male inhabitants between the ages of — and —.

Moved—That the first blank be filled up with the word *three*.

That the second blank be filled up with the word *sixteen*.

That the third blank be filled up with the word *sixty*.

3. Moved by Lieut. Colonel Hon. J. H. Gray—

That it is desirable that the proposed Camp of Instruction should be composed of a Company from each Battalion in this Province, [36 in number] made up to the following strength:—

1 Captain.
 2 Subalterns.
 1 Bugler.
 60 Rank and file.

Total, $64 \times 36 = 2204$

And that the Staff of such Camp should consist of—

1 Commandant, 1 Major of Brigade, 1 Staff Officer, 1 Surgeon.

4. Moved by Lieut. Colonel Hon. John Robertson—

That it is desirable that the Camp (if of the size contemplated) should be divided into three Battalions, to each of which should be appointed—

1 Lieut. Colonel, 2 Majors, 1 Adjutant.

That it is further desirable that the non-commissioned officers and men should receive — cents per diem and their rations, and that the officers should receive the pay and allowances of the corresponding ranks in Her Majesty's Service, and that the Camp should be under the same discipline as that applied to the Militia of Great Britain.

5. Moved by Lieut. Colonel J. V. Thurgar—

That, though this meeting considers the scheme thus laid down as the very least that is required by the exigencies of the case, they are of opinion that the Commander in Chief should be empowered to diminish the number of men to be assembled annually at the Camp of Instruction, and the number of days for which they are encamped, proportionately to the sum appropriated for the purpose by the Legislature; provided always, that such diminution in the number of men does not exceed one half, nor reduce the time below 20 days.

6. Moved by Lieut. Colonel Foster—

That it is desirable that all persons exempt by law from Militia Service, should pay annually the sum of two dollars.

7. Moved by Captain Simonds—

That it is desirable that all Aliens, after a residence of two months in the Province, should pay annually the sum of four dollars for Militia purposes.

8. Moved by Captain Saunders—

That it is desirable that persons drawn for service in the Camp of Instruction should be permitted to furnish substitutes, (under regulations to be hereafter defined,) provided that such substitutes are enrolled members of the Militia in the same Battalion District.

9. Moved by Lieut. Colonel Hon. J. H. Gray—

That it is desirable that non-commissioned officers and men of the Militia omitting to attend the muster and inspection of their respective Battalions, as provided by law, should be liable to a fine of \$— per day;

and that Officers of the Militia omitting to attend in proper uniform be liable to a fine of four times the amount imposed upon non-commissioned officers and privates;—

And that it is further desirable that the above fines be paid in to the Battalion Fund.

Moved by Lieut. Col. Thurgar—That the blank be filled with the word *two*.

10. Moved by Lieut. Colonel R. W. Crookshank--

That it is desirable that all exemptions and fines not specially applied to particular purposes, and all fees for Commissions, be paid to the Adjutant General, to constitute a Militia Fund to be applied to the support of the Militia.

11. Moved by Lieut. Colonel Hon. John Robertson—

That it is desirable that the New Brunswick Regiment of Artillery, and other Corps of Volunteers authorized by the Commander in Chief, shall receive a capitation grant of — dollars a head for every man attending 30 drills during the year, (of which 24 shall be Company and 6 Battalion drills,) in lieu of the allowance now granted.

12. Moved by Lieut. Colonel Wetmore—

That the Oath of Allegiance should, in the opinion of this meeting, be taken by every officer and man belonging to the Militia Force of this Province into whose possession arms shall be entrusted for Militia purposes.

13. Moved by Lieut. Colonel Otty—

That it is the opinion of this meeting that the annual muster of the Militia Force of the Province should not take place until after the Camp of Instruction be dismissed; that a Drill Instructor for each Company, to be selected by the Adjutant General from the most efficient men in Camp, should be appointed to drill the Companies of the respective Battalions from which they may have been taken; and that each Instructor producing a certificate from his Commanding Officer that he has discharged his duty satisfactorily, should be entitled to receive the sum of —.

14. Moved by Lieut. Colonel Baird—

That Sections 36 to 43 inclusive of the Militia Law of Nova Scotia, which have reference to the preservation of subordination at Militia musters, be recommended for embodiment in the Law to be proposed for this Province.

DRESS REGULATIONS.

Fredericton, 7th April, 1863.

The following Dress Regulations for the New Brunswick Regiment of Artillery and for the Engineers, are published by direction of His Excellency the Commander in Chief.

NEW BRUNSWICK REGIMENT OF ARTILLERY.

OFFICERS.

Distinction of Rank.

Colonel, crown and star.	{	Collar laced all round with gold lace inside the gold cord.
Lieut. Colonel, star.		Chevron of flat gold lace, one inch and a half wide, with three rows of small gold braid outside of chevron, two rows figured and centre one plain, eleven inches deep.
Major, star.		Collar laced round the top with gold lace within the gold cord.
Captain, crown and star.		Sleeve ornament, Austrian knot of round gold cord, traced in and out with small gold braid, eight inches deep and figured for Captains, seven inches deep and plain for Lieutenants.
Lieutenant, crown.		

The collar badge to be in silver embroidery.

JACKET—Blue, single breasted, scarlet collar, trimmed according to rank. Gold Russia braid round the Jacket, with figure of 8 at each back seam. Royal gold cord all round the collar. Sleeves trimmed according to rank; holes and buttons down front one inch and three quarters apart; two buttons on each sleeve; lining white. Field Officers to wear Tunics of Royal Artillery pattern.

BUTTONS—Gilt ball buttons with three guns and crown.

CAP—Royal Artillery pattern, dark blue cloth, with band of gold lace one inch and seven tenths wide. A convex gold button and ornament of gold braid on the crown. One inch and three-tenths of cloth to show above the gold band.

TROUSERS—Dark blue cloth, with a scarlet stripe one inch and three quarters wide down the outward seams. Booted with leather for mounted duties.

POUCH—Black patent leather, six inches and three quarters long, two inches and three quarters deep, and one inch and a half wide; outside leaf eight inches deep, six inches and seven-eighths wide at back, and seven inches and three quarters in front, rounded at the ends and wavy; gilt device, gun; buckle, ring and stud, with leaf at each end.

POUCH BELT—White patent leather, two inches wide.

SWORD—Royal Artillery Regulation, with steel scabbard. The sword knot to be a gold line with an acorn.

SWORD BELT—White patent leather, one inch and seven-tenths wide, with slings and without swivels, to be worn under the jacket. Plate, gilt; device, the Royal Arms encircled with a wreath of the rose, shamrock, and thistle, surmounted by a crown.

STOCK—Black silk.

GLOVES—White leather.

SPURS—Yellow metal, crane neck, two inches long for Field Officers. Steel of same pattern for Adjutants and Field Batteries.

Staff Officers will wear the dress laid down for Regimental Officers of corresponding rank.

NON-COMMISSIONED OFFICERS AND GUNNERS.

JACKET—The same as the undress jacket of the Royal Artillery. The badges of Non-Commissioned Officers will be the same as those upon the tunic in the Royal Artillery.

TROUSERS—Same as Royal Artillery.

CAP—The same shape as that of Royal Artillery. Blue cloth, with red band one inch and three quarters wide. Red button on the crown. Chin strap, black patent leather, to be worn under the chin. Sergeants will wear a gold band, and convex gilt button on the crown.

WAIST AND POUCH BELTS—Buff, pipeclayed. Waist belt to be worn over the jacket. Plate, brass, with same device as previously described for the Officers. Sergeants will wear slings to the waist belt, and sword the same as for Royal Artillery.

POUCH—Black leather, same pattern as for Royal Artillery.

STOCK—Black leather.

The Artillery, being furnished with the Long Enfield Rifle and Infantry accoutrements, will, when performing certain duties, be required to wear the latter instead of the Artillery accoutrements above described.

It will be optional for Officers to provide themselves with the blue undress coat, and with dress trowsers and belts, according to the Royal Artillery pattern.

ENGINEERS.

OFFICERS.

COAT—Patrol jacket, similar to that of the Infantry, with blue velvet facings, and edged with blue velvet. Collar edged with yellow silk cord. Sleeve ornament, Austrian knot of round back yellow silk cord, traced in and out with small silk braid eight inches deep and figured for Captains, seven inches deep and plain for Lieutenants. No shoulder cord.

BUTTONS—Bronze. Device—a crown, encircled by a garter containing the words “New Brunswick Engineers.”

CAP—Same as the Infantry.

TROUSERS—Same as the Artillery.

POUCH—Black patent leather, with Royal Arms in bronze on outside leaf. Box, five inches long, two inches and a half deep, and one inch and a half wide.

POUCH BELT—Russia leather, two inches and a half wide. Buckle, tip and slide, bronze and engraved.

SWORD AND SWORD KNOT—Regulation for Royal Engineers.

SWORD BELT—Russia leather, one inch and a half wide, to be worn over the coat. Plate, the same as for Infantry.

GLOVES AND STOCK—Same as for Artillery.

NON-COMMISSIONED OFFICERS AND SAPPERS.

COAT—Similar to that described for Officers, but with blue cloth edging round the Coat and no badges. Square yellow worsted cord on edge of collar. Sleeve ornament, knot of square yellow worsted cord, seven inches deep. Shoulder strap, scarlet cloth, with blue cloth edging. Chevrons, yellow silk braid on blue velvet ground, to be worn on both arms.

TROUSERS—Same as Artillery.

CAP—Same as Officers. Badge, a bronze grenade.

INFANTRY.

Frederickton, 24th February, 1863.

The following Dress Regulations for the Infantry of the New Brunswick Militia, are published by direction of His Excellency the Commander in Chief.

OFFICERS.

COAT—Patrol jacket, scarlet, single breasted, eight buttons in front at equal distances from neck to waist. Collar and cuffs of the Battalion facing—the collar turn over and fastened with hook and eye at neck; the cuffs pointed and five inches in height. The skirt nine inches deep below the sword belt, and with slits at the side according to the pattern. The coat, collar, and cuffs, edged with white cloth a quarter of an inch wide, and the skirts lined with white. On the left shoulder a crimson silk cord with a button to retain the sash. An outside pocket on the left breast.

The Field Officers to wear the usual badges in *gold* at each end of the collar; and a Colonel and Lieut. Colonel to be distinguished by a *gold* crown, a Major by a *gold* star, at the point of each cuff. The other Officers to wear badges in silver upon the collar only.

BUTTONS—Bronze, according to the sealed pattern, that upon the shoulder being small.

CAP—Black cloth without peak, and made according to the approved pattern, which admits of being turned down over the ears as a protection in winter. Red cloth binding, two thirds of an inch deep, and red piping round the crown. The badge in front to be a *gold* crown for Field Officers, a *silver* one for other Officers.

TROUSERS—Dark cloth or homespun, of one uniform colour and material for each Battalion, with a scarlet welt, quarter inch broad, down the outward seam.

SASH—Regulation crimson silk, the ends of the fringe not to hang below the skirt. To be worn diagonally over the left shoulder.

SWORD—Infantry Regulation, with steel scabbard; brass scabbard for Field Officers. The sword knot to be a crimson and gold strap, with acorn head.

SWORD BELT—Regulation, of enamelled white leather, to be worn over the coat. The clasp to be of bronze according to approved pattern. Both it and the buttons may be procured from Messrs. Fermin, 153 Strand, London, or in the Province.

GLOVES—White leather.

SPURS—Yellow metal, crane neck, two inches long for Field Officers. Steel of same pattern for Adjutants.

Regimental Staff Officers, excepting the Adjutant, will be distinguished by black leather swords belts, and will not wear the sash.

SERGEANTS AND RANK AND FILE.

COAT—Similar to that of the Officers, but without badges and with no white edging upon any part. The edges of the coat and facings will be finished by an inner seam. The shoulder straps (and chevrons for Non-Commissioned Officers) to be similar to those in Her Majesty's Infantry. The Battalion is to be marked by the colour of the facing, the County by a number upon the straps.

TROUSERS AND CAP—Similar to those of the Officers, excepting that upon the cap the badge will be a bronze bugle.

His Excellency the Commander in Chief desires that, from the present date, Officers commanding Battalions and Companies, will not procure any new uniforms, excepting of the above described pattern. In cases, however, where special application may be made, and where it may appear desirable, His Excellency will permit one Company in each Battalion to retain a distinctive uniform.

The coats, made from the cloth given by the Provincial Government, can be procured only from the person whose tender may be accepted. They will be made in three sizes, and probably in very few cases will any alteration be found necessary.

Should Officers desire cloth of a finer texture *for their own uniform*, they will adhere strictly to the above regulations in having it made up.

It will be optional for Officers to provide themselves with an undress uniform. In those cases the forage cap and blue frock coat, as worn in Her Majesty's Infantry, will be adopted: the buttons, bronze of the sealed pattern: and the badge for cap, the same as that already described.

Fredericton, 15th April, 1863.

Captains of Volunteer Companies of Militia who wish to receive Uniforms for the Companies under their command, are requested to make application at the Office of the Adjutant General.

On approval of the application, a pattern cap and one coat of each size will be forwarded to the Captain, who will then send in a Requisition for the number of each size required by his men. These will be supplied as soon as practicable. Caps can be furnished by Mr. Whittaker, Prince William Street, Saint John; but, should they be procured elsewhere, they must be made strictly according to the prescribed pattern.

The coat, buttons, bugles for caps, and other articles supplied from Head Quarters, will be charged against Captains of Companies, and are to be paid for immediately upon application for the amount.

The Militia of each County will be distinguished by a number upon the shoulder strap, and Battalions by their facings. All First Battalions will wear *Royal* facings, all Second *sky blue*, all Third *yellow*, and all Fourth *white*. Thus the County of a Volunteer in uniform will be immediately known by his number, the Battalion by his facing.

The Counties will be numbered in the following order, in accordance with the precedent furnished by the Militia List of 1851, where such is the successive arrangement of the Regiments:—

York,.....	1	Sunbury,.....	7	Gloucester,.....	13
St. John City Lt. Infantry,	2	Charlotte,	8	Kent,.....	14
St. John City Rifles,.....	3	Westmorland,	9	King's,	15
St. John Sea Fencibles,...	4	Albert,.....	10	Queen's,	16
St. John County,.....	5	Northumberland,	11	Carleton,.....	17
Queen's N. B. Rangers,...	6	Restigouche,.....	12	Victoria,	18

By Command.

THOMAS M. CROWDER, *Lt. Col., Adj. Gen.*

REGULATIONS FOR THE DRILL INSTRUCTORS.

Fredericton, 13th January, 1863.

I.—To take charge of the Rifles and Accoutrements of the Company or Companies to which they are attached, under the direction of the Officer or Officers commanding those Companies; to instruct each Member of the Corps minutely how to clean his Rifle and Accoutrements, and how to keep them in order; to see that the Rifles always are clean; instantly to report to Head Quarters any damage to or neglect of the Arms, &c., and to send through the commanding Officer a monthly certificate as to their condition.

II.—To be at the disposition of the Officer or Officers commanding Companies to which they are attached, and of other Officers of the Militia who may wish to acquire a knowledge of drill, at all reasonable hours, for purposes of instruction: *minutely* to adhere to the *latest* edition of the Field Exercise, and on all possible occasions to give Position and Aiming Drill for a few minutes. For this latter purpose small bull's eyes should be painted on the walls of the Drill-room.

III.—Invariably to dress in a suitable and soldier-like manner. Should it be difficult to adhere to regular uniform during the Winter months, the forage cap at any rate is to be worn, with such addition of covering for the ears, &c. as may be necessary, but on no account are the Drill Instructors to appear in ordinary civilian's attire.

IV.—At all times to treat Officers with proper respect, never failing to salute any one, in uniform or not, whom they know to be an Officer, whether of Her Majesty's Regular Services, of the Militia, or Volunteers.

By Command.

THOMAS M. CROWDER, *Lt Col., Adj. Gen.*

EXTRACTS FROM MILITIA GENERAL ORDERS.

Government Allowance to Volunteer Companies.

Fredericton, 26th August, 1862.

In accordance with Section 13 of the new Militia Act, each Company of Volunteers accepted up to this date will receive the sum of forty dollars to aid in defraying the expense of an Armory, and to serve as an allowance for keeping the Arms and Accoutrements in repair. Consequently any charge with reference to the repair of Arms and Accoutrements now issued will always be made against the Officer commanding the Company.

In every case where a Drill-room is provided by the Company, the Officer commanding will receive the sum of eighty dollars instead of forty.

Each of the Drill Sergeants distributed through the Province is at all hours to be at the direction of the Officer commanding the Company to which he is attached, not only for public but also for private drills.

Application for the approval of a Volunteer Company.

Fredericton, 21st October, 1862.

His Excellency the Commander in Chief desires to remind Officers raising Volunteer Companies, that when a Muster Roll is forwarded to the Office of the Adjutant General for approval, it must contain the signatures of three Officers and at least forty privates, with ages annexed.

A copy of Bye Laws should also be enclosed, for which a general guide was published in the Militia Orders of the 4th February, 1862.

1863.

No. 2.

Companies will be dissolved should their attendance at drill be unsatisfactory.

His Excellency the Commander in Chief learns with regret from the Monthly Progress Returns, that the members of several of the Volunteer Companies of Militia are extremely remiss in their attendance at drill. His Excellency wishes to remind Officers commanding Companies, that the minimum number of a Volunteer Company, as fixed by the Militia Law, is forty, excluding Officers; that it is intended that this number should not only exist on paper, but in fact, and that it is unfair to the more efficient Corps that the Provincial allowance should be granted to such Companies.

Should there not be an improvement in this respect, His Excellency will feel it his duty to dispense with the services of those Companies, in order to apply more usefully the limited funds at his disposal.

 No. 3.

Officers commanding Companies responsible for damage to Arms.

His Excellency the Commander in Chief desires to impress upon Officers commanding Companies, that the custom of permitting their men to keep their own arms and accoutrements is directly in opposition to Section 13 of the Militia Act.

Forty dollars are granted to each commanding Officer, in accordance with that Section, to defray the expense of keeping the arms, &c. under his own care or in a private armory; consequently, the commanding Officer of a Company will be responsible for any loss or damage arising from their remaining in the possession of his men.

A supply of muzzle-stoppers and snap-caps, required to replace those lost, can be obtained by each Captain, upon application to Thomas M'Kenzie, Col. Sergt. 64th Regt., Saint John.—The price charged will be three cents for each article.

 No. 17.

Regulations for Target Practice.

His Excellency the Commander in Chief is pleased to direct that a supply of Ball Cartridge shall be forwarded during the ensuing month, (May), to Officers commanding Companies of Militia, in order that they may commence the annual course of Rifle Practice.

Two Forms for the Annual Return will be sent immediately to each Officer commanding a Company, one of which may be retained by him, and the other is to be filled in and punctually delivered at the Office of the Adjutant General on or before the 31st October next.

In order to ensure uniformity in the practice, His Excellency desires that of the sixty rounds issued gratuitously for each Volunteer, fifteen may be fired four times over at the three ranges of 200, 300, and 400 yards, the targets and position being strictly according to the Hythe Regulations.

Never less than five rounds should be fired at one practice: otherwise the Return can not be properly kept.

Although each Volunteer may not fire more than sixty rounds of the ammunition issued gratuitously, His Excellency considers it by no means necessary or desirable that every man should be required to fire that quantity. Every commanding Officer should insist upon the members of his Company performing the amount of preliminary position and

aiming Drill prescribed in the Musketry Regulations, before they are permitted to fire. Should this course not be rigidly pursued, a mere waste of ammunition will, in the majority of cases, be the result.

His Excellency directs that in each year the annual course of Musketry shall not commence before the 1st of May; but, in this instance, should any of the ball cartridge remaining in possession of the different Companies at the end of 1862, have been already expended in *regular* practice, it must be entered in the Returns; should it have been used in *private* practice, it will be charged against commanding Officers, or is to be made good out of the ammunition obtained by them from the Government by purchase.

No. 21.

Regulations for the Enrolment of the Militia.

His Excellency the Commander in Chief desires to remind Officers commanding Battalions of the Militia, that the particular object of the Muster of Classes B and C of the Active Militia for one day, is to correct the Enrolment Returns already made, or in cases where no steps have hitherto been taken towards enrolment, to do so for the first time.

As the Volunteers or Class A of the Active Militia are called out annually for *Inspection*, it is not obligatory upon them to appear at the Muster.

In accordance with Section 27 of the Militia Act, the Sedentary Militia also are to "be carefully enrolled from time to time." This will be done according to the judgment of the Officers commanding Battalions; and His Excellency expects that their number will be returned to Head Quarters in its proper place in the Form for Enrolment.

As the Muster is for one day only, His Excellency is of opinion that in most cases any drill will prove impracticable and useless, but the commanding Officers are at liberty to take any steps with reference to this object that they may themselves deem expedient.

His Excellency suggests that under the existing circumstances of the undrilled Militia, a Company division might number as many as 200 active men; for should a Regiment be embodied, a large proportion would be unable to proceed on service, which would probably reduce a Company nominally consisting of 200 men to its proper number. Thus fewer Officers will be necessary than have hitherto been assigned to each Battalion. One good Officer in each Company division will probably be able to keep the Muster Roll of that division correct; although in many cases the Officers, including those who have received their Commissions as Volunteers but now have no Companies, are so numerous as to render the duty merely nominal if the Officer commanding a Battalion should avail himself fully of their services.

At the Annual Muster it is the duty of Officers commanding Companies to correct their rolls by inserting alterations of ages, classes, and residences, and to account for the absence of those who may be unable to attend.

It is the duty of the Adjutant, assisting his commanding Officer, to collect these returns, and to see to the best of his ability that they are correct, by afterwards visiting the districts, or otherwise. He will then insert the numbers in the printed forms, which will be forwarded in every instance from Head Quarters; and the Officer commanding the Battalion will forward one of these forms to the Office of the Adjutant General. When this has been sent in and approved, each Adjutant this year will receive the sum of \$30.

His Excellency the Commander in Chief is pleased to inform Officers commanding Battalions that all necessary promotions and appointments will be made as soon as possible.

1864.

No. 19.

Ammunition will be issued from the Magazine on the first Thursday in each month; Captains of Volunteer Companies requiring the same, are requested to make application to the Adjutant General's Office on or before the first Monday in each month.

No. 30.

His Excellency the Commander in Chief, having observed that the recommendations for promotions and new Commissions are irregularly made, and also that some doubt exists as to the precedence of Officers, has been pleased to publish the following Rules based on Her Majesty's Regulations, and desires that they may be strictly adhered to:—

1st. All recommendations for promotions or appointments are to be forwarded through the Commanding Officers of Battalions to the Adjutant General of Militia, with the regulated fee enclosed. The Adjutant General of Militia, on obtaining the approval of His Excellency, will forward the fee and the necessary information to the Provincial Secretary, who will make out the Commission.

Should the appointment not be approved of, the fee will, of course, be returned.

2nd. As in the Regular Service, all Commissions will, in ordinary cases, be dated the day they are Gazetted, but when two or more Officers are in the same Gazette, of the same rank, and belong to the same Corps, an interval of one day will take place between their Commissions.

3rd. When Corps serve together, the Senior Officer commands the whole. Where Commissions are of the same date, and the Officers belong to different Corps, reference will be made to former Commissions, and in case the former Commissions should also be of the same date, or in the case of Ensigns, where there are none, precedence will be taken according to the seniority of the Corps, as laid down in General Order 15th April 1863.

4th. Officers who are transferred from one Corps to another, go as the junior of their rank Regimentally, but retain their seniority in the Militia Force.

No. 32.

His Excellency the Commander in Chief has been pleased to direct that all requisitions made by Militia Officers to the Adjutant General's Office, be sent through the Adjutant of the Battalion to which they belong.

It is impossible for the Adjutant General of Militia to open an account with individuals, and after this date all articles supplied to the Battalion will be debited to the Adjutant.

This Order does not apply to Officers commanding Volunteer Corps.

No. 33.

His Excellency the Commander in Chief directs that no Drill Instructor be employed except those paid by the Province, without especial permission from the Adjutant General; and His Excellency wishes it to be understood that the act of drilling a body of men without authority is punishable by law.

No. 36.

Complaints have reached His Excellency the Commander in Chief, from various quarters, to the effect that different Volunteer Companies in the Province are armed with different weapons. His Excellency is desirous of distinctly stating that this is not the case. Every Volunteer Company in the Province is armed with the long Enfield Rifle. The short Enfield Rifle, used by many Volunteer Companies at home, is not issued, and never has been issued by Her Majesty's Government to this Province. It is obviously impossible that all Companies should be armed with Rifles of exactly the same date, unless at a much greater expense than the slender means at the disposal of His Excellency would warrant; and some Companies have newer Rifles than others, some also have Rifles with rather shorter stocks than others. Those with the longer stocks are supposed to be best adapted for tall men—those with short stocks to short men; but the barrel is one and the same in all.

No. 39.

His Excellency has been pleased to remind Officers Commanding Battalions of Militia, that the Adjutant General cannot issue the Adjutant's allowance, without a Certificate from them that the Adjutant has done his duty properly.

This Certificate ought to be attached to the Muster Roll, and thereby much delay and correspondence might be avoided.

Articles supplied to Officers of Militia will be charged to their respective Adjutants, who will recover the amount from individual Officers.

No. 46.

When the Captain of a Volunteer Company retires from the command of it, whether by promotion or resignation, he must give a certificate to his successor stating that no Debts are due to the Crown by the Company, and that the Arms, Accoutrements, &c. are complete and in good order; he will also furnish him with a list of the articles in charge, including Ammunition.

The new Captain will give a receipt for the articles received, and state that he accepts the whole of the responsibility of the Company.

Duplicates of these Receipts will be sent to the Adjutant General's Office.

1865.

No. 15.

His Excellency the Commander in Chief has been pleased to direct, where an Officer is permitted to retire, either with his rank or superior grade, the rank is to be considered honorary merely, and only authorizes the Officer to retain the title and wear the uniform of the rank specified. No Commission is issued for Honorary Rank, but all Officers who may have obtained it, may have their names retained in the Militia List, on sending their names, with date of rank and retirement, to the Adjutant General's Office on or before the fourth of March.

By Command.

THOMAS ANDERSON, *Lieut. Colonel,*
Adjutant General.

RULES TO BE ADOPTED BY VOLUNTEER CORPS.

The following Rules for the internal regulation of Volunteer Companies of Militia, are published as some general guide to those engaged in framing such Rules, uniformity of Regulations being manifestly required to ensure the efficiency of the Force. It is not, however, intended that they should be invariably adopted in all their details by every Volunteer Company, where circumstances may appear to render their modification or relaxation desirable.

1. The Company having been raised in connection with the ——— Battalion of Militia, the Members are consequently subject to the provisions of the Militia Act, and to all Regulations consistent therewith, which have been or shall be issued, under the authority of the Commander in Chief.
2. The Company shall consist of two classes, (1) Enrolled Members, consisting of Effectives and Non-Effectives, and of (2) Honorary Members, the latter contributing to the funds of the Company, but not being enrolled for service.
3. All subscriptions shall fall due on the ——— yearly, except as aftermentioned, and shall be paid to the Treasurer within ——— from that date.
4. The annual subscriptions of Members of the Company shall be for Effectives and Non-Effectives, \$— —, and for Honorary Members, \$— —.
5. In the event of the retirement or death of any of the Officers now appointed, it is the duty of the Officer in command to propose to the Officer commanding the Battalion, for transmission to the Commander in Chief, the names of Gentlemen for the vacant Commissions. In the discharge of this duty he will endeavour to recommend such persons as shall be agreeable to the Company, but the responsibility of the recommendation rests with himself, in the same manner that the responsibility of forwarding it does with the Officer commanding the Battalion, should he transmit it to the Commander in Chief.
6. The Non-Commissioned Officers shall be appointed by the Officer in command.
7. Each Member must be provided with the Uniform of the Provincial Militia.
8. Each Member shall be responsible for the due preservation of all articles issued to him which are the property of the Government of the Province, or of the Company, fair wear and tear only excepted.
9. The commanding Officer shall fix the time and place for Parades, Drills, and Rifle Practice, under such penalties for non-attendance, as may from time to time be fixed by the Company.
10. The Senior Officer in command shall have power, subject to the approval of the Commanding Officer, to inflict such fines for irregular conduct on Parade, and in the ranks when at attention, and for want of punctuality in attendance at the hour fixed for Parade, as shall seem proper, but the fine for each offence shall not exceed \$— —.
11. The following fines shall also be imposed by the Senior Officer in command:—

*For loading contrary to Orders: for having the Rifle at full cock except when ordered, or shooting out of turn, \$— —
For discharging the Rifle accidentally, \$— —
For pointing the same loaded or unloaded at any person without orders, \$— —
12. All fines imposed on Members of the Company shall be entered in a Book kept for that purpose.

*The fines for the last two shall be double that of the first.

13. All fines shall become due on the first day of every month succeeding that in which they have been incurred, and shall be collected by one of the Company Sergeants, and paid by him to the Treasurer.

14. The property of the Company is placed under the care of the commanding Officer ; but a Committee to transact the general business of the Company, and to aid the commanding Officer in the management and disposal of the funds of the Company, shall be appointed yearly, at an Annual General Meeting of the Members, to be held [*the time to be stated.*] This Committee shall consist of Commissioned Officers, the Secretary and Treasurer, and [*number to be stated*] Members of the Company.

15. A Secretary and Treasurer shall be appointed yearly at the Annual General Meeting of the Company above mentioned, who shall be ex-officio a member of the Committee.

16. An Abstract of the Treasurer's Accounts for the preceding year shall be annually prepared for the information of every Member of the Company, and after being audited by the Committee, shall be submitted to the Annual General Meeting to be held as above mentioned.

17. The Secretary shall call a General Meeting of the Members of the Company on the requisition of any five Members, but no question affecting the discipline of the Company is to be brought under the consideration of such General Meetings. Notice of all General Meetings, stating the object thereof, shall be given at least two days before the Meeting takes place.

18. Honorary Members shall not interfere in any way with the Military duties of the Company, neither shall it be obligatory on them to provide themselves with uniform.

19. Every Officer and Non-Commissioned Officer is recommended to provide himself with the latest Edition of the Field Exercise and Evolutions of Infantry.

20. The Committee shall have power from time to time to enact such Bye Laws as may seem necessary for the government and management of the Company's affairs, and may impose fines for the breach of such Bye Laws ; but no such Bye Laws shall be of any force or validity until sanctioned and approved by the Commander in Chief.

21. The commanding Officer has a veto on the admission of any Member of the Company.

21. All Members on joining to express their consent to the Rules.

ERRATA.

First Battalion Charlotte County Militia, page 39, the date of Captains Bradford and Chandler's Commissions should be "1865" instead of 1864.

Second Battalion, for Captain James *Boyme*, read Captain James *Bogue*.

Page 56, Dress Regulations, New Brunswick Artillery, for Lieut. Colonel, *star*, read Lieut. Colonel, *crown*.

52	April 10.	The Lieutenant Governor of Nova Scotia to the Lieutenant Governor.	Transmits copy of Resolution submitted to Nova Scotia Legislature on Union of Maritime Provinces.
53	April 18.	The Lieutenant Governor to the Lieutenant Governor of Nova Scotia.	Acknowledges preceding Despatch.

CORRESPONDENCE

CONCERNING

PROPOSALS FOR INTER-COLONIAL UNION, LEGISLATIVE AND FEDERAL.

No. 1.

The Administrator of the Government of Nova Scotia to the Lieutenant Governor.

Government House, Halifax, N. S., 8th February, 1864.

SIR,—I have the honor to bring under the notice of Your Excellency the following extract from the Speech addressed to the Legislature of this Province on the 4th instant, relative to the proposed Union of the three Maritime Provinces, in the hope that corresponding action may be taken by the Government of New Brunswick :—

“ The importance of consolidating the influences and advancing the common progress of the three Maritime Provinces, whose interests are closely identified, has for some time attracted a large share of public attention, and I propose to submit for your consideration a proposition in which the co-operation of the Governments of New Brunswick and Prince Edward Island will be invited, with a view to the Union of the three Provinces under one Government and Legislature.”

In accordance with the announcement thus made, the Government propose to submit to the Legislature a Resolution authorizing the appointment of Delegates, to confer with Delegates who may be appointed by the Governments of New Brunswick and Prince Edward Island, for the purpose of arranging such preliminaries as may be considered necessary for the Union of the three Provinces under one Government and Legislature, such action to take effect only when confirmed by the Legislatures of the three Provinces, and approved by Her Majesty the Queen.

I have the honor, &c. (Signed) HASTINGS DOYLE.

No. 2.

The Lieutenant Governor to the Administrator of the Government of Nova Scotia.

Fredericton, 17th February, 1864.

SIR,—I have the honor to acknowledge the receipt of your Despatch of the 8th instant, and beg to assure Your Excellency that the important subject to which it relates will receive the best attention of my responsible advisers.

I may venture to suggest to Your Excellency, that the words of the Resolution referred to in Your Excellency's Despatch, should be agreed upon in common by the Governments interested previously to their introduction, in order that they may be presented in precisely the same form to each of the three Legislatures.

I have, &c. (Signed) ARTHUR H. GORDON.

No. 3.

From the Administrator of the Government of Nova Scotia to the
Lieutenant Governor.

Government House, Halifax, 27th February, 1864.

SIR,—I have the honor to acknowledge the receipt of Your Excellency's Despatch of the 17th instant, and in reply have to state that the Government here propose to introduce the annexed Resolution upon the subject of the Union of the Maritime Provinces, but will defer doing so at present in order that they may receive any suggestion upon the terms of the Resolution which Your Excellency's Government may wish to offer—as it is certainly much to be desired that the wording of the Resolutions proposed to the different Legislatures should be as nearly identical as possible.

I have, &c. (Signed) HASTINGS DOYLE.

[Enclosure.]

Resolved, That His Excellency the Administrator of the Government be requested to appoint Delegates (not to exceed five) to confer with Delegates who may be appointed by the Governments of New Brunswick and Prince Edward's Island, for the purpose of arranging a preliminary plan for the Union of the three Provinces under one Government and Legislature, such Union to take effect when confirmed by the Legislative enactment of the various Provinces interested, and approved by Her Majesty the Queen."

No. 4.

The Lieutenant Governor to the Administrator of the Government of
Nova Scotia.

Fredericton, 11th March, 1864.

SIR,—I have communicated to my Council the draft Resolution enclosed in Your Excellency's Despatch of the 27th ultimo, and have now the honor to transmit to Your Excellency the draft of a corresponding Resolution which it is the intention of my advisers to introduce into the Legislature of this Province, and which, as Your Excellency will observe, is substantially identical with that to be introduced in the Nova Scotia Legislature.

I have, &c. (Signed) ARTHUR H. GORDON.

[Enclosure.]

Resolved, That an humble Address be presented to His Excellency the Lieutenant Governor, requesting him to appoint Delegates (not to exceed five) to confer with Delegates who may be appointed by the Governments of Nova Scotia and Prince Edward's Island for the purpose of considering the subject of the Union of the three Provinces under one Government and Legislature, such Union to take effect when confirmed by the Legislative enactment of the various Provinces interested, and approved by Her Majesty the Queen."

No. 5.

The Lieutenant Governor to the Secretary of State for the Colonies.

Fredericton, 14th March, 1864.

MY LORD DUKE,—I have the honor to transmit for Your Grace's information, the copy of a Despatch which I have addressed to the Administrator of the Government of Nova

Scotia, enclosing a draft of the Resolution which it is the intention of my Government to introduce into the Legislature of this Province, concerning the Union of New Brunswick, Nova Scotia, and Prince Edward Island.

I have, &c. (Signed) ARTHUR H. GORDON.

[Enclosure—See preceding Despatch.]

No. 6.

The Secretary of State for the Colonies to the Lieutenant Governor.

Downing Street, 1st April, 1864.

SIR,—I have the honor to acknowledge the receipt of your Despatch of the 14th March, containing a draft of a Resolution on the subject of the Union of New Brunswick, Nova Scotia, and Prince Edward Island, which it is the intention of your Government to introduce into the Provincial Legislature.

I have, &c. (Signed) NEWCASTLE.

No. 7.

The Lieutenant Governor to the Lieutenant Governor of Prince Edward Island.

Fredericton, 18th March, 1864.

SIR,—I have the honor to transmit to Your Excellency the enclosed draft of a Resolution which it is the intention of my advisers to introduce into the Legislature of this Province.

I have, &c. (Signed) ARTHUR H. GORDON.

[Enclosure—See Enclosure in No. 4.]

No. 8.

The Lieutenant Governor of Prince Edward Island to the Lieutenant Governor.

Government House, P. E. I., 28th March, 1864.

SIR,—I have the honor to acknowledge, with thanks, the receipt of Your Excellency's Despatch of the 18th instant, transmitting draft of a Resolution which it is the intention of your advisers to introduce into the Legislature of New Brunswick.

I have, &c. (Signed) GEORGE DUNDAS.

No. 9.

The Lieutenant Governor to the Administrator of the Government of Nova Scotia and the Lieutenant Governor of Prince Edward Island.

Fredericton, 11th April, 1864.

SIR,—I have the honor to enclose for Your Excellency's information, the copy of an Address which has been presented to me by both Houses of the Provincial Legislature, together with my Reply.

If such an arrangement should not appear objectionable to Your Excellency, I should venture to suggest the close of the month of July or the beginning of August as the date for the meeting of the Delegates.

I have, &c. (Signed) ARTHUR H. GORDON.

[Enclosure.]

Address.

MAY IT PLEASE YOUR EXCELLENCY,

" We, Her Majesty's faithful subjects, the { Legislative Council } of New Brunswick, Commons } request Your Excellency to appoint Delegates, not to exceed five, to confer with Delegates who may be appointed by the Governments of Nova Scotia and Prince Edward Island, for the purpose of considering the subject of the Union of the three Provinces under one Government and Legislature; such Union to take effect when confirmed by the Legislative Governments of the various Provinces interested, and approved by Her Majesty the Queen."

Reply.

" I receive this Address with the utmost satisfaction, and trust that the Delegates whom, in conformity with the wishes therein expressed, I shall immediately proceed to appoint, will be enabled to devise satisfactory means for accomplishing the object with reference to which it will be their duty to deliberate."

No. 10.

The Lieutenant Governor to the Secretary of State for the Colonies.

Saint John, 12th April, 1864.

MY LORD DUKE,—I have the honor to transmit for Your Grace's information, the copy of a Resolution which has been passed in the same terms by both branches of the Provincial Legislature, as also a copy of my Reply to the Address consequently presented to me.

I have great satisfaction in forwarding this Resolution to Your Grace, and trust that the most desirable object to which it relates may be accomplished at no very distant period.

I have, &c. (Signed) ARTHUR H. GORDON.

[Enclosures—See preceding Despatch.]

No. 11.

The Secretary of State for the Colonies to the Administrator of the Government, (Colonel Cole.)

Downing Street, 5th May, 1864.

SIR,—I have the honor to acknowledge the receipt of Mr. Gordon's Despatch of the 12th April, enclosing copy of a Resolution passed by both branches of the Legislature of New Brunswick, respecting the proposed appointment of Delegates to confer with Delegates who may be appointed by the Governments of Nova Scotia and Prince Edward Island, for considering the subject of the Union of the three Provinces.

I have, &c. (Signed) EDWARD CARDWELL.

No. 12.

The Lieutenant Governor of Prince Edward Island to the Administrator of the Government.

Government House, Prince Edward Island, 19th April, 1864.

SIR,—I have the honor to enclose a copy of a Resolution passed on the 18th instant in the House of Assembly of this Island, respecting a proposed Union of the Provinces of Nova Scotia, New Brunswick, and Prince Edward Island.

I have, &c. (Signed) GEORGE DUNDAS.

[Enclosure.]

“ Resolved, That His Excellency the Lieutenant Governor be authorized to appoint
 “ Delegates (not to exceed five) to confer with Delegates who may be appointed by the
 “ Governments of Nova Scotia and New Brunswick, for the purpose of discovering the
 “ expediency of a Union of the three Provinces of Nova Scotia, New Brunswick, and
 “ Prince Edward Island, under one Government and Legislature; the Report of said
 “ Delegates to be laid before the Legislature of this Colony before any further action
 “ shall be taken in regard to the proposed question.”

No. 13.

The Lieutenant Governor of Prince Edward Island to the Administrator
 of the Government.

Government House, Prince Edward Island, 4th May, 1864.

SIR,—I have the honor to acknowledge the receipt of your Despatch of the 11th
 April, enclosing copy of an Address of the Legislature of New Brunswick to the
 Lieutenant Governor, on the subject of an Administrative and Legislative Union of the
 Provinces of Nova Scotia, New Brunswick, and Prince Edward Island.

I have referred that communication to the Executive Council of this Island, and
 there does not appear to be any objection to the time you propose for the meeting of the
 Delegates.

This will, however, in a measure depend upon the place decided upon for the meeting
 of the Delegates.

I have, &c.

(Signed)

GEORGE DUNDAS.

No. 14.

The Governor General of Canada to the Administrator of the Government.

Quebec, 30th June, 1864.

SIR,—I have the honor to inform you, that it is the wish of the Canadian Government
 to send a Delegation to attend the Conference which it is proposed to hold this year, of
 gentlemen representing respectively, Nova Scotia, New Brunswick, and Prince Edward
 Island, with a view to the Union of those Provinces.

The object of the Canadian Government is to ascertain whether the proposed Union
 may not be made to embrace the whole of the British North American Provinces.

I shall feel much obliged if you will inform me of the time and place which have been
 fixed for the meeting; and I trust the presence of a Canadian Delegation will be
 agreeable to their brethren of the Maritime Provinces.

I have, &c.

(Signed)

MONCK.

No. 15.

The Administrator of the Government to the Governor General of Canada.

Fredericton, 12th July, 1864.

MY LORD,—I have the honor to acknowledge the receipt of your Excellency's
 Despatch of the 30th ultimo; and in reply I beg to assure you that, as far as the Govern-
 ment of this Province is concerned, they would cheerfully meet the Delegation from the
 Canadian Government at the Conference which it is proposed to hold for the purpose of
 discussing the question of a Union of the Maritime Provinces.

I will not fail to give Your Excellency the earliest information of the time and place that may be agreed upon for the meeting of the Conference.

I have, &c.

(Signed)

J. COLE.

No. 16.

The Lieutenant Governor of Nova Scotia to the Administrator of the Government.

Government House, Halifax, N. S., 11th July, 1864.

SIR,—I have the honor to inform you, that his Lordship the Governor General of Canada has applied to me for information as to the intended time and place of meeting of the Delegates, who, in accordance with Resolutions of the several Legislatures of Nova Scotia, New Brunswick, and Prince Edward Island, are to confer on the expediency of a Union of those Provinces.

2. I find that although the Resolution authorizing the appointment of those Delegates, has been regularly passed by the Legislatures of all three Provinces, no further step has yet been taken in the matter. Lest it might be supposed that it devolves on this Province, as originating the idea, to initiate also further action, and that any delay can be fairly charged on the Executive here, I wish to inform Your Excellency that, having consulted my Executive Council, I am prepared to nominate five Delegates on the part of this Province, three to represent the existing Government and two Her Majesty's Opposition.

3. In reference to the time and place for the meeting of the Delegates, I can only say that whilst I and my Ministry would very cordially welcome the Representatives of New Brunswick and Prince Edward Island in this capital, we prefer leaving to them the choice of such place of meeting, as may be in their opinion most appropriate and most agreeable to themselves.

4. I see some advantages in the selection of Charlottetown for that purpose; but the point is one on which any determination taken by the authorities of New Brunswick and Prince Edward Island will be at once acted on by myself and my Ministry.

5. I would therefore suggest the expediency of your conferring with His Excellency the Lieutenant Governor of Prince Edward Island, on the early appointment of Delegates, and the time and place for their meeting. Beyond a desire that no further delay, which can be avoided, should take place, neither I nor my Ministry have any thing to suggest. We are prepared to act promptly and willingly in any decision at which your Government and that of Prince Edward Island may jointly arrive.

I have, &c.

(Signed)

RICHARD GRAVES MACDONNELL.

No. 17.

The Administrator of the Government to the Lieutenant Governor of Nova Scotia.

Fredericton, 25th July, 1864.

SIR,—I have hitherto delayed replying to your Excellency's Despatch of the 11th inst., because, as the Lieutenant Governor was expected to return to this Province before this time, I considered that the arrangements for the proposed Conference would in that case be made with greater propriety by him. As, however, I do not wish that any further delay should be incurred, I have now the honor to inform you that my Government are

willing to accede to the proposal understood to have been made by that of Prince Edward Island, that the Conference should be held at Charlottetown, on September 1st. If this arrangement be agreeable to Your Excellency, (as from your Despatch of the 11th inst. I am led to believe that it will be,) I shall appoint Delegates to represent this Province on that occasion.

I have, &c. (Signed) J. COLE.

No. 18.

The Administrator of the Government to the Lieutenant Governor of
Prince Edward Island.

Fredericton, 25th July, 1864.

SIR,—I have the honor to inform Your Excellency, that my Government are prepared to nominate Delegates to attend the Conference on the subject of the Union of the Maritime Provinces; and that they are willing to accede to Your Excellency's suggestion that the Conference should meet at Charlottetown on the 1st September.

I have, &c. (Signed) J. COLE.

No. 19.

The Lieutenant Governor of Prince Edward Island to the Administrator
of the Government.

Government House, Prince Edward Island, 28th July, 1864.

SIR,—I have the honor to acknowledge the receipt of your Despatch, dated 25th July, informing me that the Government of New Brunswick is prepared to nominate Delegates to attend the Conference on the subject of the Union of the Maritime Provinces, and also that the Government is willing to accede to my suggestion that the Conference should be held at Charlottetown on September 1st.

I have to acknowledge the promptitude with which the Government of New Brunswick has acceded to this proposal.

My Ministers will heartily welcome to Charlottetown the gentlemen who may represent New Brunswick at the forthcoming Conference.

I enclose for your information, copy of a Correspondence with the Governor General of Canada on the subject of the proposal of the Canadian Government to send a Delegation to attend the Conference.

I have, &c. (Signed) GEORGE DUNDAS.

[Enclosure No. 1.]

The Governor General of Canada to the Lieutenant Governor of Prince
Edward Island.

(See No. 14.)

[Enclosure No. 2.]

The Lieutenant Governor of Prince Edward Island to the Governor General
of Canada.

Government House, Prince Edward Island, 25th July, 1864.

MY LORD,—I have the honor to acknowledge Your Lordship's Despatch of the 30th ultimo, informing me that it is the wish of the Canadian Government to send a Delegation to attend the Conference which it is proposed to hold, this year, of gentlemen repre-

senting respectively, Nova Scotia, New Brunswick, and this Island, and further stating that the object of the Canadian Government is to ascertain whether the proposed Union may not be made to embrace the whole of the British North American Provinces.

2. While the Government of Prince Edward Island is fully sensible of the many advantages that are likely to result from the meeting of Representatives of Canada with those of the Maritime Provinces, and would cordially welcome their presence, a difficulty in recognizing, in an official capacity, Delegates from Canada at this Conference, presents itself—since the local Legislature has, in the present instance, authorized the appointment of a Delegation for the specific purpose of discussing the expediency of a Legislative Union of the Provinces of Nova Scotia, New Brunswick, and Prince Edward Island.

3. I shall have the honor to inform Your Lordship of the time and place of meeting, so soon as they are decided upon, and I have only to add that it will afford my Ministers much pleasure to hear that some of the public men of Canada will visit, at that time, the place which may be appointed for the meeting of this Conference.

I have the honor to be, &c.

(Signed)

GEORGE DUNDAS.

No. 20.

The Administrator of the Government to the Governor General of Canada.

Fredericton, 23rd July, 1864.

MY LORD,—I am now able to inform Your Excellency that the Conference on the Union of the Maritime Provinces, to which Canada has requested to be allowed to send Delegates, will, by mutual consent of the Governments of New Brunswick, Nova Scotia, and Prince Edward Island, be held at Charlottetown on the 1st September.

I have, &c.

[Same as preceding Despatch.]

No. 24.

The Lieutenant Governor of Nova Scotia to the Lieutenant Governor.

Government House, Halifax, N. S., 27th August, 1864.

SIR,—I have been unable, owing to various fortuitous circumstances, to supply sooner a list of the Delegates appointed to represent this Province in the meeting of Delegates which is to assemble at Charlottetown on the 1st proximo for the purpose of considering the expediency of a Union between the Lower Provinces.

I am now enabled to give the following names, with the proviso, however, that some further change may be necessary at the last moment.

The list, as now settled, is the Honorable Charles Tupper, Provincial Secretary, the Honorable William A. Henry, Attorney General, the Honorable R. B. Dickey, M. L. C., Adams G. Archibald, Esq., M. P. P., and John Locke, Esq., M. P. P.

I have, &c.

No. 25.

The Governor General of Canada to the Lieutenant Governor.

Quebec, 1st September, 1864.

SIR,—I have the honor to enclose, for your information, a copy of a Report of my Executive Council, approved by myself, in reference to the Conference of Delegates from the Maritime Provinces at Charlottetown.

I have, &c.

(Signed)

MONCK.

Copy of a Report of a Committee of the Honorable the Executive Council, approved by His Excellency the Governor General in Council, on the 29th August, 1864.

The Committee in Council have given their best consideration to the Despatches which have passed between Your Excellency and the Lieutenant Governors of New Brunswick, Nova Scotia, and Prince Edward Island, on the subject of the Conference proposed to be held at Charlottetown, with reference to the future Union of these Provinces with Canada.

The Committee entirely concur in the opinion expressed by the Lieutenant Governors, that the proposed meeting must necessarily be of an informal character, but they consider that very great advantage will flow from the opportunity that will then be afforded of considering the practicability of uniting under one Government the respective Provinces; and should it be found that a reasonable prospect exists of such an Union being practicable, the Committee consider that it will then be possible to proceed to a more formal Conference, and to place before the Imperial Government such a general outline of the policy proposed as may enable Her Majesty's Ministers to determine whether the interests of the Empire will be promoted thereby, and of giving the sanction of the Queen to the future negotiations on the subject.

The Committee therefore respectfully recommend to Your Excellency, that such of Your Excellency's advisers as can conveniently be spared from their official duties at Quebec should be authorized to proceed to Charlottetown for the purpose of conferring informally with the Representatives from the Maritime Provinces. (Certified.)

(Signed)

U. A. HIMSWORTH, Acting C. E. C.

No. 26.

The Secretary of State for the Colonies to the Lieutenant Governor.

Downing Street, 8th September, 1864.

SIR,—I have the honor to acknowledge the receipt of Your Despatch of the 15th of August, reporting the names of the gentlemen whom you had appointed to attend the Conference at Charlottetown, respecting the proposed Union of the Lower Provinces of British North America.

I have, &c.

(Signed)

EDWARD CARDWELL.

No. 27.

The Lieutenant Governor to the Secretary of State for the Colonies.

Fredericton, 12th September, 1864.

SIR,—You are already aware that during the Spring of the present year Addresses were presented to me and to the Lieutenant Governors of Nova Scotia and Prince Edward Island, by the Legislative bodies of the different Provinces, respecting the appointment of Delegates who might confer together upon the expediency of effecting an immediate Legislative and Administrative Union of the Maritime Provinces of British North America. It was subsequently settled that the Delegates should meet at Charlottetown, in Prince Edward Island, on the 1st instant.

According to this arrangement, the Delegates of the three Provinces met at Charlottetown on the day appointed. Their meeting, however, took place under circumstances which had been by no means foreseen at the time when the Conference had been first resolved on.

You are aware that in the month of June a ministerial crisis took place in Canada, which led to the formation of a Cabinet the Members of which, among other things, pledged themselves to propose a plan for the Federal Union of the whole of the British North American Provinces. The Canadian Government accordingly suggested that an opportunity should be afforded them, during the meeting at Charlottetown, of stating the nature of their plans before the Delegates there assembled. The Government of Canada were informed that no objection could be entertained to an unofficial communication of their views, but that as the Delegates were appointed solely for the purpose of considering the proposed Legislative Union of the Lower Provinces it would not be competent for them officially to discuss the larger and more novel proposal now made by Canada.

Availing themselves of the opening thus afforded for unofficially communicating the scheme which they had prepared, and for discussing its merits, nearly all the Members of the Canadian Cabinet appeared at Charlottetown on the morning of the 1st September. The avowed and formal object of the Conference thus became in fact subsidiary to one of wider scope and greater importance.

I had been requested to visit Charlottetown at this time, and as I have long taken a warm interest in the Legislative and Administrative Union of the Lower Provinces, I willingly repaired there, and have now the honor to report to you the views entertained on this subject, and on that of a Federal Union, by the Members of the Conference who,

as you are aware, comprise the leading men of the existing Government and also of the opposition in each of the three Provinces.

The Delegates from Nova Scotia were unanimous in favor of an immediate Legislative and Administrative Union of the Lower Provinces; but were divided in opinion as to the advantages to be derived from the adoption of any wider scheme. Those from this Province were not all quite so warm in their advocacy of the Legislative Union as those from Nova Scotia; but, though some doubt or hesitation might exist on the part of individuals, no dissent was expressed from the opinion in its favor entertained by a majority of their colleagues. Those from Prince Edward Island were almost without exception hostile to the original proposal of a Legislative Union which the Conference were assembled to consider, but appeared not disinclined to the adoption of a Federal Union with Canada, provided their separate institutions were maintained as now existing.

I had also a good deal of conversation with the Canadian Ministers, and ascertained the nature of the scheme of Federation which had been discussed by the Canadian Cabinet. This scheme appeared to involve as a preliminary the entire union of the three Maritime Provinces. It was proposed, on this being effected, that Upper Canada, Lower Canada, and the Maritime Province, should each possess a Local Legislature, the powers of which should be carefully restricted to certain local matters, to be specified and defined by the Act establishing the Confederation; whilst all general legislation should be dealt with by, and all undefined powers and legislation reside in, a Central Legislature, which should in fact be not only a Federal Assembly charged with the consideration of a few topics specially committed to its care, but the real Legislature of the country, the local Assemblies being allowed to sink to the position of mere Municipalities. I need hardly remark on the importance of the distinction between a Federal system in which all powers except those specially conceded are retained by the Provincial Legislatures, and one where all powers are vested in the central body, except such as are explicitly conferred upon the local Assemblies.

I enquired whether the local Legislatures according to this plan were to be not only inferior to, but under the control of the central one, and liable to have their attributes and constitutions altered and modified by it from time to time, or whether, within their own limits, they were to be entirely independent, and unsusceptible of further change except through the agency of an Act of the Imperial Parliament? On this subject the response was not very clear. A wish appeared to exist to make the central authority supreme, but it seemed to be regarded as impossible to effect this at present.

Whilst, however, these views are held by at all events some Members of the Canadian Government, I am bound to state that they are not those generally entertained, nor do they harmonize with the interpretation usually affixed to the word "Federation" in these Provinces.

A "Federal Union" in the mouth of a Lower Canadian usually means the independence of his Province from English and Protestant influences. In the mouth of an inhabitant of the Maritime Provinces it means the retention of the machinery of the existing local Executive Government, the expenditure within each Province of the revenue raised from it, except a quota to be paid towards Federal expenses, and the preservation of the existing Legislatures in their integrity, with the somewhat cumbrous addition of a Central Parliament to which the consideration of some few topics of general interest is to be confided under restraints prompted by a jealous care for the maintenance of Provincial independence.

It is my duty, however, to inform you, Sir, that I am perfectly convinced that the more popular idea which I have just now sketched, will be gradually adopted, in order to

render the passage of some scheme of Federation more feasible. This has already, as I am informed, been to some extent the case.

Since my departure for Charlottetown I understand the project of the immediate Union of the Lower Provinces, which alone the Delegates were empowered to discuss, and which then appeared certain of adoption, has gradually drifted out of sight, and that they have since been occupied in the discussion of a Federal Union of the nature referred to in the preceding paragraph; by which each Province, as now existing, would retain its virtual independence. But on this point you will doubtless receive fuller information from Sir Richard MacDonnell, as the Conference has adjourned from Prince Edward Island to Halifax.

I have, &c. (Signed) ARTHUR H. GORDON.

No. 23.

The Lieutenant Governor to the Secretary of State for the Colonies.

Fredericton, 22nd September, 1864.

SIR,—In my Despatch of 12th instant, I stated that the Conference of Delegates appointed to consider the Union of the Lower Provinces had adjourned from Charlottetown, in Prince Edward Island, to Halifax. The Delegates have since removed to Saint John, and on the 15th instant reached Fredericton, still accompanied, as they have been throughout their journeyings, by the Canadian Cabinet. From hence they returned to Saint John, where they separated, with the intention of meeting again at Quebec on the 10th proximo.

It is not, however, to chronicle the rambles of this ambulatory Conference that I now address you, but to convey to you such further information as I have been able to collect with respect to the probable results of its deliberations.

As I anticipated, the Union of the Lower Provinces appears to be for the present totally lost sight of in the consideration of the larger scheme now proposed, and the apprehensions which I expressed in my Despatch of 12th instant have been realized; for the principle that the Lower Provinces should enter the Federation as three separate and independent bodies was, with little apparent reluctance, conceded by the Canadian Ministers, when it became evident that a persistence in the idea that the Legislative Union of the Lower Provinces should form a preliminary to the subsequent Federal Union was likely to endanger the success of the latter scheme.

The discussions of the Conference were for the most part conducted in a conversational and informal manner. Two subjects, however, were, I understand, debated at some length, in more elaborately prepared speeches. These subjects were—the composition and mode of election of the Legislative Council, and the authority from which appointments to the local judiciary should emanate.

With regard to the former subject less difference of opinion was found to exist than I should have anticipated. It was agreed that the Federal Legislative Council should consist of 60 members, 20 from Upper Canada, 20 from Lower Canada, and 20 from the Maritime Provinces. It was generally desired that the members of this body should be nominated for life by the Crown, and with hardly an exception, the elective principle, as applied to the Legislative Council, was decidedly condemned. The system of nomination is on the whole, perhaps, the best feasible method of appointment. The very best mode of selection would, in my opinion, be that of election for life by a very highly qualified constituency—but in this case a perpetual agitation would probably be kept alive for the reduction of the qualification. In my opinion, however, the mode of selection is far less important than the retention of the seat for life when once obtained. The possession of a

seat for life tends to encourage an honest freedom of thought, speech and action on the part of Members of the Upper House, and it is in this character of comparative independence that one of the main uses of the Legislative Council is to be found.

With respect to the appointment of the Judges, a very animated discussion took place; and I am informed that one of the Delegates made an extremely effective speech on the subject. He showed that were the Federation established, and the local Legislatures consequently deprived of much of their present importance, there would be less temptation than now exists for leading members of the Bar to enter into the field of local politics. Those who wished to enter public life at all, would naturally look to the Federal Legislature as the scene of their labours; and if the local Governments were allowed to appoint Judges to be selected from their own supporters in the local Assemblies, the Bench might be speedily filled with men who would fail to command the respect of those practising before them. He, therefore, strongly urged that the appointment of all the Judges should be vested in the Central Government, and urged the adoption of some measure which should entirely remove these appointments from the influence of party politics. On the other hand considerable reluctance to adopt this view was, I learn, exhibited by some Members of the Conference.

With regard to the important question of the attributes to be assigned to the respective Legislatures and Governments, there was a considerable divergence of opinion.

The result of the discussion roughly appears to be the following apportionment of subjects as those to be dealt with by the General and Local Legislatures respectively.

To the Federal Legislature is given the control of—

Trade,
 Currency,
 Banking,
 General Taxation,
 Interest and Usury Laws,
 Insolvency and Bankruptcy,
 Weights and Measures,
 Navigation of Rivers and Lakes,
 Lighthouses,
 Sea Fisheries,
 Patent and Copyright Laws,
 Telegraphs,
 Naturalization,
 Marriage and Divorce,
 Postal Service,
 Militia and Defence,
 Criminal Law,
 Inter-Colonial Works.

The Local Legislatures are to be entrusted with the care of—

Education, (with the exception of Universities,)
 Inland Fisheries,
 Control of Public Lands,
 Immigration,
 Mines and Minerals,
 Prisons,
 Hospitals and Charities,

Agriculture,
Roads and Bridges,
Registration of Titles,
Municipal Laws.

As I have already observed, it is proposed that the Conference should meet again at Quebec on the 10th proximo, and I suppose that some decision will then be adopted as to the Constitution of the local Legislatures and local Executive Governments, a subject which at present has only been touched on with great hesitation, and treated with the utmost vagueness.

I have, &c. (Signed) ARTHUR H. GORDON.

No. 29.

The Governor General of Canada to the Lieutenant Governor.

Quebec, 23rd September, 1864.

SIR,—I have the honor to transmit a copy of an approved Minute of the Executive Council of Canada respecting the proposal to hold a Conference of Delegates from the Colonies of Nova Scotia, New Brunswick, Prince Edward Island, and Newfoundland, with the Ministers of Canada, to consider the question of a Union of these Colonies and to digest a scheme for the practical realization of the idea, which may be submitted as embodying the joint opinions of the Governments of the several Provinces to the Secretary of State for the Colonies, with a view to obtaining Her Majesty's sanction for legislation on the subject.

In conformity with the request contained in this Minute, I have the honor to invite you to name a deputation to represent your Province in the approaching Conference, which will meet at Quebec on the 10th October.

I have, &c. (Signed) MONCK.

Copy of a Report of a Committee of the Executive Council approved by His Excellency the Governor General, on the 23rd September, 1864.

The Committee of Council has the honor to inform your Excellency that the Deputation from the Executive Council who met the Delegates from the Maritime Provinces at Charlottetown on the 1st instant, in accordance with the order in Council on the 29th ultimo, have reported that such Conference duly met, and that the question of a Confederation of the British North American Colonies was discussed at length, and such progress made that it was thought desirable by the Conference that the subject should be resumed in a formal and official manner, under the authority of the Governments of the several Provinces.

The Committee have therefore the honor to advise and submit for your Excellency's approval, that the several Governments of Nova Scotia, New Brunswick, Prince Edward Island, and Newfoundland, be invited to appoint Delegates under the authority of the Despatch of the Secretary for the Colonies to the Lieutenant Governor of Nova Scotia, dated 6th July, 1862, and communicated by the Colonial Office to your Excellency by a Despatch of the same date, to confer with the Canadian Government on the subject of a Union or Federation of the British North American Provinces.

The Committee beg leave further to recommend that Quebec be selected as the place, and the tenth of October next the time, for the meeting, as they have ascertained that such time and place will meet the views and convenience of the several Governments.

(Certified.)

(Signed) WM. H. LEE, C. E. C.

No. 30.

The Lieutenant Governor to the Governor General of Canada.

Fredericton, 7th October, 1864.

MY LORD,—I have the honor to inform you that, in accordance with the request contained in Your Lordship's Despatch of the 23rd September, I have appointed the Honorable S. L. Tilley, the Honorable W. H. Steeves, the Honorable P. Mitchell, the Honorable J. M. Johnson, the Honorable E. B. Chandler, the Honorable J. H. Gray, and Charles Fisher, Esquire, to be Delegates to attend the Conference on the subject of a Federal Union of the British North American Colonies to be held at Quebec on the 10th instant.

I have, &c. (Signed) ARTHUR H. GORDON.

No. 31.

The Governor General of Canada to the Lieutenant Governor.

Quebec, 14th October, 1864.

SIR,—I have the honor to acknowledge the receipt of your Despatch of the 7th instant, acquainting me with the names of the gentlemen appointed by you to represent New Brunswick at the Conference at Quebec, on the proposed Union of the British Provinces.

I have, &c. (Signed) MONCK.

No. 32.

The Lieutenant Governor to the Secretary of State for the Colonies.

Fredericton, 8th October, 1864.

SIR,—I have the honor to enclose the copy of a Despatch which I have received from the Governor General of Canada, relative to a meeting of Delegates from the various Provinces of British North America, to consider the practicability of a Federal Union between them; and I have the honor to inform you that I have, in compliance with that invitation, nominated the Honorable S. L. Tilley, the Honorable W. H. Steeves, the Honorable P. Mitchell, the Honorable J. M. Johnson, the Honorable E. B. Chandler, the Honorable J. H. Gray, and Charles Fisher, Esquire, as Delegates to represent New Brunswick at the proposed Conference.

I have, &c. (Signed) ARTHUR H. GORDON.

No. 33.

The Secretary of State for the Colonies to the Lieutenant Governor.

Downing Street, 1st October, 1864.

SIR,—I learn from the Lieutenant Governor of Nova Scotia that it is in contemplation to resume at Quebec the discussion of the question of an Inter-Colonial Union, which is now engaging the attention of British North America.

Lord Monck has intimated his intention of addressing me on this subject, and, as I learn that it is desired that the intended meeting should be held early in October, I think it expedient to inform you at once, that I entertain no objection to this proposed mission of some of the Members of your Government, if the Meeting at Quebec should be finally resolved on.

I have, &c. (Signed) EDWARD CARDWELL.

No. 34.

The Lieutenant-Governor to the Secretary of State for the Colonies.

Fredericton, 24th October, 1864.

SIR,—I have the honor to acknowledge the receipt of your Despatch of the 1st instant, authorizing me to appoint Delegates to attend the Conference at Quebec. You will perceive from my Despatch of the 8th instant, that, in anticipation of the receipt of such authority. I have already appointed Delegates to the Conference in question.

I have, &c. (Signed) ARTHUR E. GORDON.

No. 35.

The Secretary of State for the Colonies to the Lieutenant Governor.

Downing Street, 1st November, 1864.

SIR,—I have the honor to acknowledge the receipt of your Despatch of the 8th ultimo, reporting the selection of Delegates to represent New Brunswick at the Conference at Quebec, on the subject of a Union between the British North American Provinces.

I have, &c. (Signed) EDWARD CARDWELL.

No. 36.

The Governor General of Canada to the Lieutenant Governor.

Government House, Quebec, 12th November, 1864.

SIR,—Referring to my Despatch of the 23rd September, and to your answer of 3rd October, I have the honor to inform you that the gentlemen named by you to represent New Brunswick, began their consultations with the Delegates from the other Provinces, and the Ministers of Canada, on the 10th October.

The Members of the Conference chose Sir E. P. Tache, Prime Minister of Canada as their Chairman, and I have now the honor to transmit to you a copy of the Resolutions adopted by the Conference, authenticated by the signature of that gentleman.

I have also transmitted a similar copy to Her Majesty's Secretary of State for the Colonies, and to the Lieutenant Governors of Nova Scotia and Prince Edward Island, and the Governor of Newfoundland.

I have, &c. (Signed) MONCK.

Report of Resolutions adopted at a Conference of Delegates from the Provinces of Canada, Nova Scotia, and New Brunswick, and the Colonies of Newfoundland and Prince Edward Island, held at the City of Quebec, 10th October, 1864, as the Basis of a proposed Confederation of those Provinces and Colonies.

1. The best interests and present and future prosperity of British North America will be promoted by a Federal Union under the Crown of Great Britain, provided such Union can be effected on principles just to the several Provinces.

2. In the Federation of the British North American Provinces the System of Government best adapted under existing circumstances to protect the diversified interests of the several Provinces and secure efficiency, harmony and permanency in the working of the Union,—would be a General Government charged with matters of common interest to the whole country, and Local Governments for each of the Canadas, and for the Provinces of Nova Scotia, New Brunswick, and Prince Edward Island, charged with the control of local matters in their respective sections,—Provision being made for the admission into the Union on equitable terms of Newfoundland, the North-West Territory, British Columbia, and Vancouver.

3. In framing a Constitution for the General Government, the Conference, with a view to the perpetuation of our connection with the Mother Country, and to the promotion of the best interests of the people of these Provinces, desire to follow the model of the British Constitution, so far as our circumstances will permit.

4. The Executive Authority or Government shall be vested in the Sovereign of the United Kingdom of Great Britain and Ireland, and be administered according to the well understood principles of the British Constitution by the Sovereign personally or by the Representative of the Sovereign duly authorized.

5. The Sovereign or Representative of the Sovereign shall be Commander in Chief of the Land and Naval Militia Forces.

6. There shall be a General Legislature or Parliament for the Federated Provinces, composed of a Legislative Council and a House of Commons.

7. For the purpose of forming the Legislative Council, the Federated Provinces shall be considered as consisting of three divisions, 1st. Upper Canada, 2nd. Lower Canada, 3rd. Nova Scotia, New Brunswick, and Prince Edward Island, each division with an equal representation in the Legislative Council.

8. Upper Canada shall be represented in the Legislative Council by 24 Members, Lower Canada by 24 Members, and the three Maritime Provinces by 24 Members, of which Nova Scotia shall have Ten, New Brunswick, Ten, and Prince Edward Island, Four Members.

9. The Colony of Newfoundland shall be entitled to enter the proposed Union, with a representation in the Legislative Council of Four Members.

10. The North-West Territory, British Columbia, and Vancouver, shall be admitted into the Union, on such terms and conditions as the Parliament of the Federated Provinces shall deem equitable, and as shall receive the assent of Her Majesty; and in the case of the Province of British Columbia or Vancouver, as shall be agreed to by the Legislature of such Province.

11. The Members of the Legislative Council shall be appointed by the Crown under the Great Seal of the General Government, and shall hold Office during Life; if any Legislative Councillor shall, for two consecutive sessions of Parliament, fail to give his attendance in the said Council, his seat shall thereby become vacant.

12. The Members of the Legislative Council shall be British Subjects by Birth or Naturalization, of the full age of Thirty Years, shall possess a continuous real property qualification of four thousand dollars over and above all incumbrances, and shall be and continue worth that sum over and above their debts and liabilities, but in the case of Newfoundland and Prince Edward Island, the property may be either real or personal.

13. If any question shall arise as to the qualification of a Legislative Councillor, the same shall be determined by the Council.

14. The first selection of the Members of the Legislative Council, shall be made, except as regards Prince Edward Island, from the Legislative Councils of the various Provinces, so far as a sufficient number be found qualified and willing to serve; such Members shall be appointed by the Crown at the recommendation of the General Executive Government, upon the nomination of the respective Local Governments, and in such nomination, due regard shall be had to the claims of the Members of the Legislative Council of the opposition in each Province, so that all political parties may, as nearly as possible, be fairly represented.

15. The Speaker of the Legislative Council (unless otherwise provided by Parliament) shall be appointed by the Crown from among the Members of the Legislative Council, and shall hold office during pleasure, and shall only be entitled to a casting vote on an equality of votes.

16. Each of the twenty-four Legislative Councillors representing Lower Canada in the Legislative Council of the General Legislature, shall be appointed to represent one of the twenty-four Electoral Divisions mentioned in Schedule A of Chapter First of the Consolidated Statutes of Canada, and such Councillor shall reside or possess his qualification in the Division he is appointed to represent.

17. The basis of Representation in the House of Commons, shall be Population, as determined by the Official Census every ten years: and the number of Members at first shall be 194, distributed as follows:

Upper Canada,.....	82
Lower Canada,.....	65
Nova Scotia,.....	19
New Brunswick,.....	15
Newfoundland,	8
and Prince Edward Island,.....	5

18. Until the Official Census of 1871 has been made up, there shall be no change in the number of Representatives from the several sections.

19. Immediately after the completion of the Census of 1871, and immediately after every Decennial Census thereafter, the Representation from each section in the House of Commons shall be re-adjusted on the basis of Population.

20. For the purpose of such re-adjustments, Lower Canada shall always be assigned sixty-five Members, and each of the other sections shall at each re-adjustment receive, for the ten years then next succeeding, the number of Members to which it will be entitled on the same ratio of representation to population as Lower Canada will enjoy according to the Census last taken by having sixty-five Members.

21. No reduction shall be made in the number of Members returned by any section, unless its population shall have decreased relatively to the population of the whole Union, to the extent of five per centum.

22. In computing at each decennial period, the number of Members to which each section is entitled, no fractional parts shall be considered, unless when exceeding one half the number entitling to a Member, in which case a Member shall be given for each such fractional part.

23. The Legislature of each Province shall divide such Province into the proper number of constituencies, and define the boundaries of each of them.

24. The Local Legislature of each Province may, from time to time, alter the Electoral Districts for the purposes of Representation in the House of Commons, and distribute the Representatives to which the Province is entitled, in any manner such Legislature may think fit.

25. The number of Members may at any time be increased by the General Parliament, regard being had to the proportionate rights then existing.

26. Until provisions are made by the General Parliament, all the Laws which, at the date of the Proclamation constituting the Union, are in force in the Provinces respectively, relating to the qualification and disqualification of any person to be elected or to sit or vote as a Member of the Assembly in the said Provinces respectively—and relating to the qualification or disqualification of voters, and to the oaths to be taken by voters, and to Returning Officers and their powers and duties,—and relating to the proceedings at Elections,—and to the period during which such Elections may be continued, and relating to the trial of Controverted Elections, and the proceedings incident thereto and relating to the vacating of seats of Members, and to the issuing and execution of new Writs in case of any seat being vacated otherwise than by a dissolution,—shall respectively apply to

Elections of Members to serve in the House of Commons, for places situate in those Provinces respectively.

27. Every House of Commons shall continue for five years from the day of the return of the writs choosing the same, and no longer, subject, nevertheless, to be sooner prorogued or dissolved by the Governor.

28. There shall be a Session of the General Parliament once at least in every year, so that a period of twelve calendar months shall not intervene between the last sitting of the General Parliament in one Session and the first sitting thereof in the next Session.

29. The General Parliament shall have power to make Laws for the peace, welfare and good government of the Federated Provinces, (saving the Sovereignty of England,) and especially Laws respecting the following subjects:—

1. The Public Debt and Property.
2. The Regulation of Trade and Commerce.
3. The imposition or regulation of Duties of Customs on Imports and Exports, except on Exports of Timber, Logs, Masts, Spars, Deals, and Sawn Lumber, and of Coal and other Minerals.
4. The imposition or regulation of Excise Duties.
5. The raising of money by all or any other modes or systems of Taxation.
6. The Borrowing of Money on the Public Credit.
7. Postal Service.
8. Lines of Steam or other Ships, Railways, Canals, and other works, connecting any two or more of the Provinces together or extending beyond the limits of any Province.
9. Lines of Steamships between the Federated Provinces and other Countries.
10. Telegraphic Communication and the incorporation of Telegraph Companies.
11. All such works as shall, although lying wholly within any Province be specially declared by the Acts authorizing them to be for the general advantage.
12. The Census.
13. Militia—Military and Naval Service and Defence.
14. Beacons, Buoys and Light Houses.
15. Navigation and Shipping.
16. Quarantine.
17. Sea Coast and Inland Fisheries.
18. Ferries between any Province and a Foreign Country, or between any two Provinces.
19. Currency and Coinage.
20. Banking, Incorporation of Banks, and the issue of paper money.
21. Savings Banks.
22. Weights and Measures.
23. Bills of Exchange and Promissory Notes.
24. Interest.
25. Legal Tender.
26. Bankruptcy and Insolvency.
27. Patents of Invention and Discovery.
28. Copy Rights.
29. Indians and Lands reserved for the Indians.
30. Naturalization and Aliens.
31. Marriage and Divorce.
32. The Criminal Law, excepting the Constitution of Courts of Criminal Jurisdiction, but including the procedure in Criminal matters.

33. Rendering uniform all or any of the laws relative to property and civil rights in Upper Canada, Nova Scotia, New Brunswick, Newfoundland, and Prince Edward Island, and rendering uniform the procedure of all or any of the Courts in these Provinces ; but any Statute for this purpose shall have no force or authority in any Province until sanctioned by the Legislature thereof.
34. The Establishment of a General Court of Appeal for the Federated Provinces.
35. Immigration.
36. Agriculture.
37. And generally respecting all matters of a general character, not specially and exclusively reserved for the Local Governments and Legislatures.
30. The General Government and Parliament shall have all powers necessary or proper for performing the obligations of the Federated Provinces, as part of the British Empire, to Foreign Countries, arising under Treaties between Great Britain and such Countries.
31. The General Parliament may also, from time to time, establish additional Courts, and the General Government may appoint Judges and Officers thereof, when the same shall appear necessary or for the public advantage, in order to the due execution of the Laws of Parliament.
32. All Courts, Judges and Officers of the several Provinces shall aid, assist and obey the General Government in the exercise of its rights and powers, and for such purposes shall be held to be Courts, Judges and Officers of the General Government.
33. The General Government shall appoint and pay the Judges of the Superior Courts in each Province, and of the County Courts of Upper Canada, and Parliament shall fix their salaries.
34. Until the Consolidation of the Laws of Upper Canada, New Brunswick, Nova Scotia, Newfoundland, and Prince Edward Island, the Judges of these Provinces appointed by the General Government, shall be selected from their respective Bars.
35. The Judges of the Courts of Lower Canada shall be selected from the Bar of Lower Canada.
36. The Judges of the Court of Admiralty now receiving salaries shall be paid by the General Government.
37. The Judges of the Superior Courts shall hold their offices during good behaviour, and shall be removeable only on the Address of both Houses of Parliament.

LOCAL GOVERNMENT.

38. For each of the Provinces there shall be an Executive Officer, styled the Lieutenant Governor, who shall be appointed by the Governor General in Council, under the Great Seal of the Federated Provinces, during pleasure ; such pleasure not to be exercised before the expiration of the first five years, except for cause : such cause to be communicated in writing to the Lieutenant Governor immediately after the exercise of the pleasure as aforesaid, and also by message to both Houses of Parliament, within the first week of the first Session afterwards.
39. The Lieutenant Governor of each Province shall be paid by the General Government.
40. In undertaking to pay the salaries of the Lieutenant Governors, the Conference does not desire to prejudice the claim of Prince Edward Island upon the Imperial Government for the amount now paid for the salary of the Lieutenant Governor thereof.
41. The Local Government and Legislature of each Province shall be constructed in such manner as the existing Legislature of such Province shall provide.
42. The Local Legislatures shall have power to alter or amend their constitution from time to time.

43. The Local Legislatures shall have power to make Laws respecting the following subjects :—

1. Direct Taxation and the imposition of Duties on the Export of Timber, Logs, Masts, Spars, Deals, and Sawn Lumber, and of Coals and other Minerals.
 2. Borrowing Money on the credit of the Province.
 3. The establishment and tenure of local Offices, and the appointment and payment of local Officers.
 4. Agriculture.
 5. Immigration.
 6. Education ; saving the rights and privileges which the Protestant or Catholic minority in both Canadas may possess as to their Denominational Schools, at the time when the Union goes into operation.
 7. The sale and management of Public Lands, excepting Lands belonging to the General Government.
 8. Sea Coast and Inland Fisheries.
 9. The establishment, maintenance and management of Penitentiaries, and of Public and Reformatory Prisons.
 10. The establishment, maintenance and management of Hospitals, Asylums, Charities and Eleemosynary Institutions.
 11. Municipal Institutions.
 12. Shop, Saloon, Tavern, Auctioneer and other licenses.
 13. Local Works.
 14. The Incorporation of private or local Companies, except such as relate to matters assigned to the General Parliament.
 15. Property and civil rights, excepting those portions thereof assigned to the General Parliament.
 16. Inflicting punishment by fine, penalties, imprisonment or otherwise for the breach of laws passed in relation to any subject within their jurisdiction.
 17. The Administration of Justice, including the Constitution, maintenance and organization of the Courts—both of Civil and Criminal Jurisdiction, and including also the Procedure in Civil Matters.
 18. And generally all matters of a private or local nature, not assigned to the General Parliament.
44. The power of respiting, reprieving and pardoning Prisoners convicted of crimes, and of commuting and remitting of sentences in whole or in part, which belongs of right to the Crown, shall be administered by the Lieutenant Governor of each Province in Council, subject to any instructions he may from time to time receive from the General Government, and subject to any provisions that may be made in this behalf by the General Parliament.

MISCELLANEOUS.

45. In regard to all subjects over which jurisdiction belongs to both the General and Local Legislatures, the laws of the General Parliament shall control and supersede those made by the Local Legislature, and the latter shall be void so far as they are repugnant to or inconsistent with the former.

46. Both the English and French languages may be employed in the General Parliament and in its proceedings, and in the Local Legislature of Lower Canada, and also in the Federal Courts and in the Courts of Lower Canada.

47. No lands or property belonging to the General or Local Government shall be liable to taxation.

48. All Bills for appropriating any part of the Public Revenue, or for imposing any new Tax or Impost, shall originate in the House of Commons or the House of Assembly; as the case may be.

49. The House of Commons or House of Assembly shall not originate or pass any Vote, Resolution, Address or Bill for the appropriation of any part of the Public Revenue, or of any Tax or Impost to any purpose, not first recommended by Message of the Governor General, or the Lieutenant Governor, as the case may be, during the Session in which such Vote, Resolution, Address or Bill is passed.

50. Any Bill of the General Parliament may be reserved in the usual manner for Her Majesty's Assent, and any Bill of the Local Legislatures may in like manner be reserved for the consideration of the Governor General.

51. Any Bill passed by the General Parliament shall be subject to disallowance by Her Majesty within two years, as in the case of Bills passed by the Legislatures of the said Provinces hitherto, and in like manner any Bill passed by a Local Legislature shall be subject to disallowance by the Governor General within one year after the passing thereof.

52. The Seat of Government of the Federated Provinces shall be Ottawa, subject to the Royal Prerogative.

53. Subject to any future action of the respective Local Governments, the Seat of the Local Government in Upper Canada shall be Toronto; of Lower Canada, Quebec; and the Seats of the Local Governments in the other Provinces shall be as at present.

PROPERTY AND LIABILITIES.

54. All Stocks, Cash, Bankers' Balances and Securities for money belonging to each Province, at the time of the Union, except as hereinafter mentioned, shall belong to the General Government.

55. The following Public Works and Property of each Province, shall belong to the General Government, to wit:—

1. Canals;
2. Public Harbours;
3. Light Houses and Piers;
4. Steamboats, Dredges, and Public Vessels;
5. River and Lake Improvements;
6. Railway and Railway Stocks, Mortgages and other Debts due by Railway Companies;
7. Military Roads;
8. Custom Houses, Post Offices and other Public Buildings, except such as may be set aside by the General Government for the use of the Local Legislatures and Governments;
9. Property transferred by the Imperial Government and known as Ordnance Property;
10. Armories, Drill Sheds, Military Clothing and Munitions of War; and
11. Lands set apart for Public purposes.

56. All lands, mines, minerals and royalties vested in Her Majesty in the Provinces of Upper Canada, Lower Canada, Nova Scotia, New Brunswick, and Prince Edward Island, for the use of such Provinces, shall belong to the Local Government of the Territory in which the same are so situate; subject to any trusts that may exist in respect to any of such lands or to any interest of other persons in respect of the same.

57. All sums due from purchasers or lessees of such lands, mines or minerals at the time of the Union, shall also belong to the Local Governments.

58. All assets connected with such portions of the public debt of any Province as are assumed by the Local Governments, shall also belong to those Governments respectively.

59. The several Provinces shall retain all other Public Property therein, subject to the right of the General Government to assume any Lands or Public Property required for Fortifications or the Defence of the Country.

60. The General Government shall assume all the Debts and Liabilities of each Province.

61. The Debt of Canada not specially assumed by Upper and Lower Canada respectively, shall not exceed, at the time of the Union,.....\$62,500,000

Nova Scotia shall enter the Union with a debt not exceeding... 8,000,000

And New Brunswick with a debt not exceeding..... 7,000,000

62. In case Nova Scotia or New Brunswick do not incur liabilities beyond those for which their Governments are now bound, and which shall make their debts at the date of Union less than \$8,000,000 and \$7,000,000 respectively, they shall be entitled to interest at 5 per cent. on the amount not so incurred, in like manner as is hereinafter provided for Newfoundland and Prince Edward Island; the foregoing resolution being in no respect intended to limit the powers given to the respective Governments of those Provinces by Legislative authority, but only to limit the maximum amount of charge to be assumed by the General Government. Provided always, that the powers so conferred by the respective Legislatures shall be exercised within five years from this date or the same shall then lapse.

63. Newfoundland and Prince Edward Island, not having incurred Debts equal to those of the other Provinces, shall be entitled to receive by half-yearly payments in advance from the General Government the interest at 5 per cent. on the difference between the actual amount of their respective Debts at the time of the Union, and the average amount of indebtedness per head of the Population of Canada, Nova Scotia and New Brunswick.

64. In consideration of the transfer to the General Parliament of the powers of Taxation, an annual grant in aid of each Province shall be made, equal to 80 cents per head of the population, as established by the Census of 1861, the population of Newfoundland being estimated at 130,000. Such aid shall be in full settlement of all future demands upon the General Government for local purposes, and shall be paid half-yearly in advance to each Province.

65. The position of New Brunswick being such as to entail large immediate charges upon her local revenues, it is agreed that for the period of ten years from the time when the Union takes effect, an additional allowance of \$63,000 per annum shall be made to that Province. But that so long as the liability of that Province remains under \$7,000,000, a deduction equal to the interest on such deficiency shall be made from the \$63,000.

66. In consideration of the surrender to the General Government by Newfoundland of all its rights in Mines and Minerals, and of all the ungranted and unoccupied Lands of the Crown, it is agreed that the sum of \$150,000 shall each year be paid to that Province, by semi-annual payments. Provided that that Colony shall retain the right of opening, constructing and controlling Roads and Bridges through any of the said Lands, subject to any Laws which the General Parliament may pass in respect of the same.

67. All engagements that may, before the Union, be entered into with the Imperial Government for the defence of the country shall be assumed by the General Government.

68. The General Government shall secure, without delay, the completion of the Inter-Colonial Railway from Riviere du Loup through New Brunswick to Truro in Nova Scotia.

69. The communications with the North Western Territory, and the improvements required for the development of the Trade of the Great West with the Scaboard, are

regarded by this Conference as subjects of the highest importance to the Federated Provinces, and shall be prosecuted at the earliest possible period that the state of the Finances will permit.

70. The sanction of the Imperial and Local Parliaments shall be sought for the Union of the Provinces, on the principles adopted by the Conference.

71. That Her Majesty the Queen be solicited to determine the rank and name of the Federated Provinces.

72. The proceedings of the Conference shall be authenticated by the signatures of the Delegates, and submitted by each Delegation to its own Government, and the Chairman is authorized to submit a copy to the Governor General for transmission to the Secretary of State for the Colonies.

I certify that the above is a true copy of the original Report of Resolutions adopted in Conference.

E. P. TACHE, *Chairman.*

No. 37.

The Governor General of Canada to the Secretary of State for the Colonies.

Government House, Quebec, 7th November, 1864.

SIR,—Referring to my Despatch of the 23rd of September, in which I have informed you that I had invited the Lieutenant Governors of Nova Scotia, New Brunswick, and Prince Edward Island, and the Governor of Newfoundland, to send Representatives to confer with the Members of the Canadian Government on the feasibility of effecting a Union between the Colonies of British North America, and to my Despatches of the 14th October and the 2nd November, in which I enclosed to you the answer received to that invitation, I have the honor to report that the several gentlemen named in the communications above referred to as representatives of those Colonies respectively, arrived at Quebec on Monday the 10th October, the day named for the assembling of the Conference.

They immediately proceeded to the consideration of the important question, the discussion of which constituted the object of their meeting, having appointed Sir E. P. Tache, Prime Minister of Canada, as Chairman, to preside over their deliberations.

Their sittings began on the 10th October, and continued *de die in diem* until the 28th of the same month.

I have now the honor to transmit the Resolutions agreed to by the Conference, for which I would ask the favorable consideration of yourself and Her Majesty's Government.

I may state that an extended intercourse with the Members of the Conference enables me to assure you that they were one and all actuated by the strongest feelings of loyalty to the Queen, the most earnest desire to maintain the connection with England, and the wish to make the proposed Union work so as to strengthen that connection, by enabling the Provinces to take upon themselves more largely the responsibilities of a self-governing community.

I do not enter into an argument to prove that a consolidation of these Provinces is desirable, if it can be effected on principles which will give guarantees for strength and durability.

The advantages of a well-considered plan of Union, whether looked at from the point of administration, commerce, or defence, appear to me so obvious that it would be a waste of time to state them, and the fact that the most eminent public men of all the Provinces concur in desiring such a Union, appears to me to go a long way in superseding the necessity for any abstract arguments in its favor.

The plan which has been adopted by the Conference, you will observe, is the Union of all the Provinces on the monarchical principle under one Governor, to be appointed by the Crown, with Ministers responsible, as in England, to a Parliament consisting of two Houses, one to be nominated by the Crown and the other elected by the people.

To this Central Government and Legislature will be committed all the general business of the United Provinces, and its authority on all such subjects will be supreme, subject, of course, to the rights of the Crown and of the Imperial Parliament.

For the purpose of local administration, it is proposed to have in each Province an Executive Officer, to be appointed by the Governor, and removable by him for cause to be assigned, assisted by a Legislative body, the constitution of which it is proposed to leave to the decision of the present local Legislatures, subject to the approbation of the Imperial Government and Parliament.

To these local bodies are to be entrusted the execution of certain specified duties of a local character, and they are to have no rights or authority beyond what is expressly delegated to them by the Act of Union.

To the General Government it is proposed to reserve the right of disallowing Acts passed by the local Legislatures.

I think this will be found a fair general outline of the constitutional portion of the proposed scheme of Union, and I trust it will be found of such a nature as to merit the general approbation of Her Majesty's Government.

I do not allude to the proposed financial arrangements between the different members of the proposed Union, as these relate to questions exclusively affecting the Provinces, and upon which I presume they may safely be allowed to adopt any course which they may themselves think conducive to their interests.

In transmitting these Resolutions for your consideration, I venture to state my opinion, that a desire for a consolidation of British North America, has taken strong hold of the minds of the most earnest and thoughtful men in these Provinces, and I trust, whether on the plan suggested by these Resolutions, or on some modification of it, a Union may be effected which will satisfy the aspirations of so loyal and influential a portion of Her Majesty's subjects.

I have, &c. (Signed) MONCK.

No. 38.

The Secretary of State for the Colonies to the Lieutenant Governor.

Downing Street, 8th December, 1864.

SIR,—I transmit to you a copy of the reply of Her Majesty's Government to the Despatch in which Viscount Monck enclosed the Resolutions adopted by the Conference at Quebec. You will see that Her Majesty's Government have cordially accepted as a whole the proposed central organization, and have reserved for further consideration, when the provisions of the intended Bill shall be under review, the details of the arrangement by which the control of that central organization over the intended local Governments is to be secured. They highly appreciate the spirit in which this important and difficult subject has been dealt with by the Conference, and are anxious on their own part to give all the assistance in their power towards the successful completion of the work.

I have to instruct you, therefore, to render to the Governor General all the support you can in those future measures which he is about to take in the furtherance of the scheme.

I have, &c. (Signed) EDWARD CARDWELL.

[Enclosure.]

Downing Street, 3rd December, 1864.

MY LORD,—Her Majesty's Government have received with the most cordial satisfaction Your Lordship's Despatch of the 7th ultimo, transmitting for their consideration the Resolutions adopted by the Representatives of the several Provinces of British North America, which were assembled at Quebec.

With the sanction of the Crown, and upon the invitation of the Governor General, men of every Province, chosen by the respective Lieutenant Governors without distinction of party, assembled to consider questions of the utmost interest to every subject of the Queen, of whatever race or faith, resident in those Provinces, and have arrived at a conclusion destined to exercise a most important influence upon the future welfare of the whole community.

Animated by the warmest sentiments of loyalty and devotion to their Sovereign,—earnestly desirous to secure for their posterity throughout all future time the advantages which they enjoy as subjects of the British Crown,—steadfastly attached to the institutions under which they live, they have conducted their deliberations with patient sagacity, and have arrived at unanimous conclusions on questions involving many difficulties, and calculated, under less favorable auspices, to have given rise to many differences of opinion.

Such an event is in the highest degree honorable to those who have taken part in these deliberations. It must inspire confidence in the men by whose judgment and temper this result has been attained, and will ever remain on record as an evidence of the salutary influence exercised by the Institutions under which these qualities have been so signally developed.

Her Majesty's Government have given to your Despatch, and to the Resolutions of the Conference, their most deliberate consideration. They have regarded them as a whole, and as having been designed by those who have framed them, to establish as complete and perfect an union of the whole into one Government, as the circumstances of the case, and a due consideration of existing interests, would admit. They accept them, therefore, as being, in the deliberate judgment of those best qualified to decide upon the subject, the best framework of a measure to be passed by the Imperial Parliament for obtaining that most desirable result.

The point of principal importance to the practical well-working of the scheme, is the accurate determination of the limits between the authority of the Central and that of the Local Legislatures, in their relation to each other. It has not been possible to exclude from the Resolutions some provisions which appear to be less consistent than might, perhaps, have been desired with the simplicity and unity of the system. But, upon the whole, it appears to Her Majesty's Government that precautions have been taken, which are obviously intended to secure to the Central Government the means of effective action throughout the several Provinces, and to guard against those evils which must inevitably arise if any doubt were permitted to exist as to the respective limits of Central and Local authority.

They are glad to observe that although large powers of legislation are intended to be vested in local bodies, yet the principle of central control has been steadily kept in view. The importance of this principle cannot be overrated. Its maintenance is essential to the practical efficiency of the system, and to its harmonious operation both in the General Administration and in the Governments of the several Provinces. A very important part of this subject is the expense which may attend the working of the Central and the Local Governments. Her Majesty's Government cannot but express the earnest hope that the arrangements which may be adopted in this respect, may not be of such a nature as to

increase, at least in any considerable degree, the whole expenditure, or to make any material addition to the taxation, and thereby retard the internal industry, or tend to impose new burdens on the commerce of the country.

Her Majesty's Government are anxious to lose no time in conveying to you their general approval of the proceedings of the Conference. There are, however, two provisions of great importance which seem to require revision. The first of these is the provision contained in the 44th Resolution with respect to the exercise of the prerogative of pardon. It appears to Her Majesty's Government that this duty belongs to the Representative of the Sovereign, and could not with propriety be devolved upon the Lieutenant Governors, who will, under the present scheme, be appointed not directly by the Crown, but by the Central Government of the united Provinces.

The second point which Her Majesty's Government desire should be reconsidered, is the Constitution of the Legislative Council. They appreciate the considerations which have influenced the Conference in determining the mode in which this Body, so important to the Constitution of the Legislature, should be composed. But it appears to them to require further consideration whether, if the Members be appointed for life, and their number be fixed, there will be any sufficient means of restoring harmony between the Legislative Council and the popular Assembly, if it shall ever unfortunately happen that a decided difference of opinion shall arise between them.

These two points relating to the Prerogative of the Crown and to the Constitution of the Upper Chamber, have appeared to require distinct and separate notice. Questions of minor consequence, and matters of detailed arrangement, may properly be reserved for a future time, when the provisions of the Bill intended to be submitted to the Imperial Parliament, shall come under consideration. Her Majesty's Government anticipate no serious difficulty in this part of the case, since the Resolutions will generally be found sufficiently explicit to guide those who will be intrusted with the preparation of the Bill. It appears to them, therefore, that you should now take immediate measures, in concert with the Lieutenant Governors of the several Provinces, for submitting to the respective Legislatures this project of the Conference; and if, as I hope, you are able to report that these Legislatures sanction and adopt the scheme, Her Majesty's Government will render you all the assistance in their power for carrying it into effect.

It will probably be found to be the most convenient course that, in concert with the Lieutenant Governors, you should select a deputation of the persons best qualified to proceed to this country, that they may be present during the preparation of the Bill, and give to Her Majesty's Government the benefit of their counsel upon any questions which may arise during the passage of the measure through the the two Houses of Parliament.

I have, &c. (Signed) E. CARDWELL.

No. 39.

The Governor General of Canada to the Lieutenant Governor.

Government House, Quebec, 23rd. December, 1864.

SIR,—Referring to my Despatches to you noted in the margin, I have the honor to transmit for your information a copy of a Despatch from the Secretary of State for the Colonies in reference to the Resolutions adopted by the Conference which assembled at Quebec in October last, to consider the propriety of effecting a Union of the Provinces of British North America.

In this Despatch Mr. Cardwell desires me "to take immediate measures in concert with the Lieutenant Governors of the several Provinces for submitting to their respective Legislatures this project of the Conference."

In pursuance of these instructions I have the honor to inform you that I have summoned the Canadian Parliament to meet on Thursday the 19th January, 1865, when I propose to bring before both Houses of the Legislature the important subject referred to in Mr. Cardwell's Despatch, in order that, if the Legislature shall think fit, an Address may be adopted to the Queen, praying Her Majesty to direct that steps may be taken for passing an Act of the Imperial Parliament to unite the Provinces of British North America on the basis laid down in the resolutions adopted by the Quebec Conference.

I shall feel much obliged if, after consulting your advisers on the subject, you will inform me what course you intend to pursue for the purpose of giving effect to Mr. Cardwell's instructions.

I have, &c. (Signed) MONCK.

[Enclosure—See preceding Despatch.]

No. 40.

The Lieutenant Governor to the Governor General of Canada.

Fredericton, 9th January, 1865.

MY LORD,—I have the honor to acknowledge the receipt of Your Lordship's Despatch of the 23rd December.

I have communicated that Despatch, with its Enclosure, to my Executive Council, and when I receive the advice of its Members as to the steps which, in their opinion, may be best calculated to give effect to the Resolutions of the Quebec Conference, I will not fail to do myself the honor of again addressing Your Lordship.

I have, &c. (Signed) ARTHUR H. GORDON.

No. 41.

The Lieutenant Governor to the Governor General of Canada.

Fredericton, 23rd January, 1865.

MY LORD,—In my Despatch of the 9th instant I informed Your Lordship that when I had consulted the Members of my Council as to the steps most calculated to give effect to the Resolutions of the Quebec Conference, I would do myself the honor of again addressing Your Lordship.

I have now accordingly to inform Your Lordship, that it is my intention, with the advice of my Executive Council, immediately to dissolve the existing Legislature of this Province, and that the new Parliament will be summoned to meet towards the end of the month of March, when the question of the Confederation of the British North American Provinces will be immediately submitted for their consideration.

I have, &c. (Signed) ARTHUR H. GORDON.

No. 42.

The Governor General of Canada to the Lieutenant Governor.

Quebec, 30th January, 1865.

SIR,—I have the honor to transmit for your information a copy of the Resolution which it is proposed by my Government to move in both Houses of the Legislature of this Province, on the subject of the proposed Union of the British North American Provinces.

I also enclose, as printed by the Legislative Assembly, copies of Correspondence that has been laid before both Houses of the Canadian Legislature.

I have, &c. (Signed) MONCK.

[Enclosure.]

Resolved.—That an humble Address be presented to Her Majesty, praying that she may be graciously pleased to cause a measure to be submitted to the Imperial Parliament, for the purpose of uniting the Colonies of Canada, Nova Scotia, New Brunswick, Newfoundland, and Prince Edward Island, in one Government, with provisions based on the following Resolutions, which were adopted at a Conference of Delegates from the said Colonies, held at the City of Quebec on the tenth of October, 1864.

[Here follow the Resolutions verbatim.]

No. 43.

The Lieutenant Governor to the Secretary of State for the Colonies.

Fredericton, 30th January, 1865.

SIR,—I have the honor to forward to you a copy of the Report of the Conference appointed to consider the question of the Legislative Union of the three Maritime Provinces.

2. The greater scheme for the Federation of the whole of British North America, rendered the further consideration of this plan at present unnecessary.

3. There was a great unanimity of opinion among the Delegates as to the facility with which the Legislative Union in question might have been accomplished, and I cannot but regret that it does not form a part of the more extended scheme or was not adopted as a preliminary to it.

I have, &c. (Signed) ARTHUR H. GORDON.

[Enclosure.]

Report of proceedings of a Conference held to consider the question of a Legislative Union of Nova Scotia, New Brunswick, and Prince Edward Island.

The Conference was composed of the following Delegates:

Honorable Charles Tupper, Provincial Secretary;
 “ W. A. Henry, Attorney General;
 “ Jonathan McCully, M. L. C.;
 “ R. B. Dickey, M. L. C.;
 Adams G. Archibald, Esq., M. P. P.
 Honorable S. L. Tilley, Provincial Secretary;
 “ W. H. Steeves, M. L. C., M. E. C.;
 “ J. M. Johnson, Attorney General;
 “ E. B. Chandler, M. L. C.;
 “ J. H. Gray, M. P. P.
 Honorable Col. J. H. Gray, M. E. C.;
 “ W. H. Pope, Colonial Secretary;
 “ Edward Palmer, Attorney General;
 “ George Coles, M. P. P.;
 “ Andrew McDonald, M. L. C.

The Delegates met at the Colonial Building, Charlottetown, P. E. Island, on the 1st day of September, 1864, when on motion of the Hon. Charles Tupper, seconded by the Hon. S. L. Tilley, the Hon. Col. Gray was appointed Chairman of the Conference. The Hon. Charles Tupper and the Hon. S. L. Tilley were appointed Joint Secretaries.

After some time spent in general discussion it was decided to receive a deputation from the Government of Canada, who had arrived for the purpose of explaining to the Conference the views of that Government upon the Union of British North America.

In conformity with that decision, the following Members of the Canadian Government were received by the Conference on the 2nd day of September :—

- Honorable J. A. McDonald, Attorney General, C. W. ;
- “ G. E. Cartier, Attorney General, C. E. ;
- “ Geo. Brown, M. P. P., President of the Executive Council ;
- “ A. T. Galt, Minister of Finance ;
- “ T. D. McGee, Minister of Agriculture ;
- “ Wm. McDougall, Provincial Secretary ;
- “ Alex. Campbell, M. L. C., Commissr. Cr. Lands ;
- “ L. H. Langevin, M. P. P., Solicitor General, C. E.

The Conference met separately, and with these gentlemen daily, until Wednesday, the 7th of September, and full and free discussion took place between them and the Members of the Conference. Upon the 7th September, at the invitation of the Delegates from Nova Scotia, the Conference was adjourned to meet at Halifax, where, on the 10th September, it was reassembled at the Legislative Council Chamber, and the discussions continued with the Members of the Canadian Government. On the 12th of September, upon the invitation of the Delegates from New Brunswick, the Conference was adjourned to meet at St. John, N. B.

Previous to adjournment, the Honorable J. A. McDonald announced to the Conference that the Executive Council of Canada would advise His Excellency the Governor General to invite the Lieutenant Governors of Nova Scotia, New Brunswick, Newfoundland, and Prince Edward Island, to appoint Delegates to attend a Conference at Quebec, to take formally into consideration the subject of a Union of all the British North American Provinces.

Pursuant to adjournment, the Conference met at Stubbs' Hotel, St. John, N. B., on the 16th of September, when it was decided to adjourn until after the Conference to be called at Quebec had formally discussed the larger question in all its bearings.

An adjournment accordingly took place until again called by the Chairman to meet at such time and place as he should think fit, of which due notice should be given by the Secretaries to the Members.

Such adjourned meeting was duly called, and held at the Queen's Hotel, Toronto, C. W., on the 3rd of November, when it was Resolved—

“ That in view of the Resolutions passed at the Quebec Conference in favor of a
 “ Confederation of the British North American Provinces, this Conference decide to
 “ postpone the consideration of the question of a Legislative Union of the Maritime
 “ Provinces, and that the Joint Secretaries be requested to draw up a Report of the pro-
 “ ceedings of the Conference for the information of the Lieutenant Governors and of the
 “ Legislatures of the Maritime Provinces.”

A vote of thanks having been passed unanimously to the Chairman for the able manner in which he had discharged the duties of his office, the Conference was, on motion, adjourned *sine die*.

(Signed)

J. HAMILTON GRAY, *Chairman*.
 CHARLES TUPPER, } *Joint Secretaries*.

No. 47.

The Lieutenant Governor to the Secretary of State for the Colonies.

Fredericton, 27th February, 1865.

SIR,—A discussion has lately taken place in this Province with respect to one of the conditions of the Federal Union of British North America, which has excited much interest, and with respect to which it appears to me desirable that I should be placed in possession of the views of the Government.

The Resolutions agreed to at Quebec, and which are to form the basis of the proposed Federal Union of the British American Provinces, have reference to a great variety of subjects of very different degrees of importance. With some of these matters the Local Legislatures are already fully competent to deal, whilst others are of a character which removes them beyond their cognizance.

It was my belief that the aid of the Imperial Parliament would be sought only to give effect to those general provisions of a constitutional nature which could not be brought into operation by the existing Local Assemblies; that it would be called upon to enact the Federative Union, and to define the limits of the authority of the Central and Local Governments and Legislatures, but that the arrangement of matters of purely or mainly local interest would be left to the Federal Legislature, or to those of the separate Provinces, as it may fairly be presumed that these bodies would faithfully carry into execution the conditions upon which their Union had itself been based.

I find, however, that a very general impression prevails that the construction of the Inter-Colonial Railroad from Riviere du Loup to Truro, is to be provided for by a clause in the Imperial Act giving effect to the proposed Federal Union.

I do not myself consider it probable that Her Majesty's Government will make such a suggestion to the Imperial Parliament, for I cannot but conceive that such a proposal would

appear to Her Majesty's Government to be either unnecessary or unjust; unnecessary if, (as we must conclude will be the case should no unforeseen and insuperable obstacles arise,) the new Federal Legislature votes the construction of a work, the immediate commencement of which forms one of the conditions of the agreement to which they owe their existence; unjust, if it were to have the effect of forcing on the people of British America the execution of a work which their Representatives in Parliament may consider it inexpedient to undertake.

Nor does it appear to me very likely that the British Parliament would enact a law involving a very large expenditure of money not collected under its own authority, a law moreover which it would be impossible to enforce, as no penalty could be inflicted after the passage of the Act, in the event of the subsequent neglect of its provisions by the Federal Government and Legislature.

Neither do I imagine that, the question being one which primarily concerns the people of British North America, the British Parliament would consent to fetter the discretion of their representatives in dealing with it as they may consider most conducive to the advantage of the United Provinces, more especially when it is remembered that the subject is one which the local Legislatures are already, even under the existing state of things, fully competent to consider.

Still less do I think it probable, even were a clause of a general character, enacting the completion of this great work, to be incorporated in an Act of the Imperial Parliament, that Her Majesty's Government would consent to introduce into the Bill, or that Parliament would consent to sanction, all those details which would be required to render such a clause effective; for, unless the route, the mode of construction, the minimum sum to be annually devoted to the work, and the time at which it is to be completed, are all prescribed, the scheme may be subject to ultimate defeat by the rejection of one of these points by the Federal Parliament; whilst the assumption of those who believe that a clause concerning the Railway will form part of the Imperial Act is that the completion of the work is to be so secured as to remove all liability of its being affected by any subsequent action on the part of the Federal or Local Governments and Assemblies.

I confess, therefore, that I am unable altogether to share the confident belief of my Council, that this work—(of the importance of which I need not say I am very fully sensible)—will be undertaken under the direct authority of the Imperial Parliament.

At the same time it is possible that I may be mistaken as to the views and intentions of the Government, and I therefore respectfully request to be instructed as to the course which I am to pursue, in the event of my being urged to state in my Speech from the Throne on the opening of the Provincial Legislature, that such a provision will undoubtedly form part of the Act of Union, or be embodied by the Imperial Parliament in a separate Act.

Such a declaration, if it were afterwards proved by facts to be erroneous, would, I need not say, excite very general and not ill-founded irritation.

Mr. J. A. Macdonald, a leading member of the Canadian Government, is reported to have lately used, what appears to me very sensible language in connection with this subject, to the effect that the construction of the Railway was certainly not part of the Constitution,—(a proposition which is self-evident)—and that consequently, with many other details agreed to by the Conference, it would not be embodied in the Imperial Act, but that it was one of the conditions on which the Union was based, and must therefore be carried into effect at the earliest possible period by the Legislature of the Federated Provinces. I am, however, informed that Mr. Macdonald has subsequently stated that the provisions for the construction of the Railroad will form part of the Imperial Act.

As the Legislature of this Province will meet probably in the first week of April, it is highly important that I should be enabled by that time to reply distinctly to the queries which may be put to me by my advisers and by the Legislature, whether, in the event of the Federation of the British American Provinces being accomplished, Her Majesty's Government will be prepared to submit to the Imperial Parliament, either as a clause of the Constitutional Act, or as a separate Bill, provisions to secure the completion of the Inter-Colonial Railway from Riviere du Loup to Truro within a definite time, and framed in such a manner as to preclude the possibility of any subsequent action in a contrary sense on the part of the Federal Government and Legislature.

I have, &c. (Signed) ARTHUR H. GORDON.

No. 48.

The Secretary of State for the Colonies to the Lieutenant Governor.

Downing Street, 18th March, 1865.

SIR,—I have the honor to acknowledge the receipt of your Despatch of the 27th February, in which you request instructions whether provisions will be made for the completion of the Inter-Colonial Railway in the Act of Union, or be embodied by the Imperial Parliament in a separate Act. In reply, I have to acquaint you that Her Majesty's Government have expressed their cordial approval of the proceedings of the Conference at Quebec, and have engaged that if, as they hope, the Provincial Legislatures sanction the scheme of the Conference, they, on their part, will submit to the Imperial Parliament the measures which may be necessary for carrying that scheme into effect.

Of the Resolutions adopted by the Conference, the 68th provides that the General Government shall secure without delay the completion of the Inter-Colonial Railway. Her Majesty's Government have understood that Resolution, with reference to the Correspondence which had previously passed with the Governments of the several Provinces; while, therefore, they have entered into no new stipulations on the subject, they have by no means excepted the 68th Resolution from the general approval which they have expressed of the entire scheme, or from the engagement respecting it to which I have referred.

What steps it may be proper hereafter for Her Majesty's Government to take in pursuance of this engagement, cannot be stated positively, until it shall be known what course has been taken by the Provincial Legislatures, and until Her Majesty's Government shall have received the communications which they hope to receive from persons deputed by the Governor General to give to Her Majesty's Government the benefit of their counsel upon the various measures necessary for carrying the Resolutions of the Conference into effect.

I have, &c. (Signed) EDWARD CARDWELL.

No. 49.

The Lieutenant Governor to the Secretary of State for the Colonies.

Fredericton, 27th March, 1864.

SIR,—I have the honor to enclose a copy of the Report submitted to me by the Delegates appointed to attend the Conference held at Quebec in October last. Though dated November 15th, it was only delivered to me last Saturday.

I have, &c. (Signed) ARTHUR H. GORDON.

[Enclosure.]

To His Excellency the Honorable Arthur Hamilton Gordon, C. M. G., Lieutenant Governor and Commander in Chief of the Province of New Brunswick, &c. &c. &c.

MAY IT PLEASE YOUR EXCELLENCY,—

The undersigned having been appointed by Your Excellency, at the request of the Governor General, to confer with the Government of Canada, and with Delegates appointed by the Governments of Nova Scotia, Newfoundland, and Prince Edward Island, upon the subject of a Federal Union of the British North American Provinces, have the honor to submit their Report.

The Conference consisted of the following members:—

FOR CANADA.

The Hon. Sir E. P. Tache, M. L. C., Receiver General and Minister of Militia.
 John A. M'Donald, M. P. P., Attorney General, (Upper Canada.)
 G. E. Cartier, M. P. P., Attorney General, (Lower Canada.)
 George Brown, M. P. P., President of Executive Council.
 O. Mowatt, M. P. P., Postmaster General.
 A. F. Galt, M. P. P., Minister of Finance.
 T. D. M'Gee, M. P. P., Minister of Agriculture.
 William M'Dougall, M. P. P., Provincial Secretary.
 Alexander Campbell, M. L. C., Commissioner of Crown Lands.
 J. C. Chappias, M. P. P., Commissioner of Public Works.
 J. H. Langevin, Solicitor General, (Lower Canada.)
 James Cockburn, M. P. P., Solicitor General, (Upper Canada.)

FOR NOVA SCOTIA.

The Hon. Charles Tupper, M. P. P., Provincial Secretary.
 W. A. Henry, M. P. P., Attorney General.
 J. M'Cully, M. L. C.
 Robert B. Dickey, M. L. C.
 Adams G. Archibald, Esq., M. P. P.

FOR NEW BRUNSWICK.

The Hon. S. L. Tilley, M. P. P., Provincial Secretary.
 W. H. Steeves, M. L. C., M. E. C.
 J. M. Johnson, M. P. P., Attorney General.

No. 50.

The Lieutenant Governor of Prince Edward Island to the Lieutenant Governor.

Government House, P. E. I., 6th April, 1865.

SIR,—I have the honor to enclose a copy of an Address of the Legislative Council and House of Assembly, which I have been requested to transmit to Her Majesty the Queen, praying that Her Majesty will be pleased not to give Her Royal Assent or sanction to any Act or Measure founded upon the Resolutions or Report of the Conference at Quebec or otherwise, that would have the effect of uniting Prince Edward Island in a Federal Union with Canada or any other of Her Majesty's Provinces in America.

I have, &c.

(Signed)

GEORGE DUNDAS.

[Enclosure.]

TO THE QUEEN'S MOST EXCELLENT MAJESTY.

MOST GRACIOUS SOVEREIGN,

We, your Majesty's loyal and faithful Servants, the Legislative Council and House of Assembly of Prince Edward Island, having had under our consideration the Resolutions or Report of the Conference of Delegates from the Provinces of Canada, Nova Scotia, and New Brunswick, and the Colonies of Newfoundland and Prince Edward Island, held at the City of Quebec on the 10th October, 1864, upon the subject of a proposed Confederation of those Provinces and Colonies, and the Despatch of the Right Honorable Edward Cardwell, Your Majesty's Principal Secretary of State for the Colonial Department, to Lord Viscount Monck, Governor General of Canada, dated the 3rd December, 1864, relative thereto, humbly beg leave to approach Your Majesty's Throne, for the purpose of conveying to Your august Majesty the expression of our desire and determination, as the Constitutional Representatives of the people of Prince Edward Island, in regard to the great question involved in the said Report; and having, after most mature deliberation, arrived at the conclusion that the proposed Confederation, in so far as it is contemplated to embrace Prince Edward Island, would prove disastrous to the best interests and future prosperity of this Colony, we would humbly crave leave to state the grounds upon which that conclusion is based.

First, Prince Edward Island, being entirely dependent on its Agriculture and Fisheries, has no staple commodity to export for which Canada can furnish a market (Canada being also essentially an agricultural country, and possessing valuable and extensive fisheries in the Gulf of St. Lawrence). That while such is, and ever must be, the relative commercial position of this Island and Canada, the products of our soil and fisheries find in

the extensive markets of our Parent Country, the United States, and the West Indies, ready and profitable customers. That the proposed Union, while admitting the produce and manufactures of Canada into this Island free, would by assimilation of taxes, enormously increase the duty to which those of Great Britain and the United States are at present subject in this Island, thereby compelling this Colony to take a large portion of its imports from Canada, making payment therefor in money, instead of procuring them from countries which would receive our produce in exchange, an arrangement so inconsistent with the fundamental principles of commerce, that it would not only greatly curtail our commercial intercourse with Great Britain and the United States, but materially diminish our exports to those countries, and prove most injurious to the agricultural and commercial interests of this Island.

Second, That if the relative circumstances of Canada and this Island rendered a union practicable, the evident injustice of the terms agreed to by the Quebec Conference would prevent their being ratified by this Island. Without entering into full detail on this branch of the subject, or adverting to the fact, that by the proposed terms of the Confederation we are called upon to transfer to the Confederate Exchequer a steadily increasing revenue, and that, too, under our comparatively low tariff, for a fixed and settled annual subsidy of a greatly diminished amount, we would briefly notice some of the objectionable features of the said Report.

And first, in reference to the fundamental principle upon which the Confederation is proposed to rest, namely, representation according to population. Without admitting this principle under all circumstances to be sound or just, we consider it to be particularly objectionable as applied to this Island in connection with Canada, from the fact that the number of our inhabitants is and must continue comparatively small, in consequence of this Island possessing no Crown Lands, mines, or minerals, or other extraneous resources, and that we never can expect to become, to any great extent, a manufacturing people, by reason of our navigation being closed for nearly half the year, and all trade, and even communication with other countries (except by telegraph and the medium of a fragile ice-boat) stopped. And when we consider the provision of the said Report which is intended to regulate the mode of re-adjusting the relative representation of the various Provinces at each decennial census, and reflect upon the rapid rate of increase in the population of Upper and Lower Canada—particularly the former—heretofore, and the certainty of a still greater increase therein in the future over that of the population of this Island, it follows, as a certain and inevitable consequence, if a Federation of the Provinces were consummated upon the basis of the said Report, that the number of our representatives in the Federal Parliament would, in the course of a comparatively short number of years, be diminished to a still smaller number than that proposed to be allotted to us at the commencement of the Union.

Third, In further noticing the injustice of the terms of the said Report, as applicable to us, we would advert to the old Imperial policy, so pregnant with ill-consequences to us, by which all the lands in this Colony were granted in large tracts to absentees, and which deprives this Island of the revenue drawn by the sister Colonies from these sources,—to our insular position and numerous harbours, furnishing cheap and convenient water communication, which render expensive public works here unnecessary,—to the Revenue to be drawn by the proposed Federal Government from this Island and expended among the people of Canada and the other Provinces, in constructing railways, canals, and other great public works, thereby creating a trade which would build up cities, and enhance the value of property in various parts of those Provinces,—advantages in which this Island could enjoy a very small participation,—and to our complete isolation during five months of the

year, when ice interrupts our trade and communication with the mainland, and during which period this Island could derive no possible benefit from the railroads and other public works which they would, equally with the people of those Provinces, be taxed to construct. These, and many other circumstances, placing Prince Edward Island in an exceptional position in regard to the other Provinces, but which seem to have been entirely ignored, ought, in our opinion, to have produced an offer of a financial arrangement for this Island very different in its terms from that contained in the Report of the said Conference.

Fourth, That while we fully recognize it to be the duty of this Colony to use every means, to the extent of its limited resources, to aid in defending its inhabitants from foreign invasion, we cannot recognize the necessity of uniting in a Confederation with Canada for the purpose of defence, upon terms which, in other respects, are so unfair to the people of Prince Edward Island, and thereby sacrificing our commercial and financial interests for the sake of securing the co-operation of Canada in a military point of view, it being our abiding hope and conviction, that so long as we remain a loyal and attached Colony of Great Britain, under whose protecting sway and benign influence we have so long had the happiness to live, and endeavour to aid, by a reasonable contribution towards the defence of our Colony, by placing our Militia service upon a sounder and safer footing than it has hitherto attained, the powerful aid of our Mother Country will continue, as heretofore, to be extended to us in common with the other North American dependencies of the British Crown. For the foregoing reasons, and many others which we could urge, we beg most humbly and respectfully to state to Your Majesty, that we, the Representatives of your faithful subjects, the people of Prince Edward Island, in Colonial Parliament now assembled, do disagree to the recommendations contained in the said Report of the Quebec Conference, and on the part of Prince Edward Island do emphatically decline a Union which, after the most serious and careful consideration, we believe would prove politically, commercially, and financially disastrous to the rights and best interests of its people.

We do, therefore, most humbly pray that Your Majesty will be graciously pleased not to give your Royal assent or sanction to any Act or Measure founded upon the Resolutions or Report of the said Conference, or otherwise, that would have the effect of uniting Prince Edward Island in a Federal Union with Canada or any other of Your Majesty's Provinces in America.

No. 51.

The Lieutenant Governor to the Governor General of Canada.

Fredericton, 4th April, 1865.

MY LORD,—Upon the 12th November last Your Lordship did me the honor to address to me a Despatch enclosing a copy of the Resolutions agreed to by the Delegates appointed to consider the question of a Federation of the British North American Provinces. To the copy so transmitted the following certificate was attached:—

*“ I certify that the above is a true copy of the original Report of Resolutions adopted
“ in Conference.*

“ E. P. TACHE, Chairman.”

In this copy the 24th Resolution stands as follows:—

“ 24. The local Legislature of each Province may from time to time alter the Electoral Districts for the purpose of Representation in the House of Commons, and distribute the Representatives to which the Province is entitled in any manner such Legislature may think fit.”

In the copy of the Resolutions presented to me on their return by the Delegates from this Province, the same words are found.

In the Papers laid before both Houses of the Imperial Parliament, by command of Her Majesty, on the subject of the proposed Federal Union, a Despatch addressed by Your Lordship to the Secretary of State for the Colonies, on the 7th November, will be found, (at page 4) transmitting to Mr. Cardwell a copy of the Resolutions, in which also the 24th Resolution is couched in the same words, and the accuracy of which copy is also certified by Sir E. P. Taché.

My attention has, however, been called to the fact that, in the Papers laid before the Canadian Parliament, and transmitted to me by Your Lordship on the 30th January last, although the same Despatch from Your Lordship to the Secretary of State is printed at page 3, the Enclosure reads somewhat differently; the 24th Resolution standing as follows:—

“ 24. The local Legislature of each Province may from time to time alter the Electoral Districts for the purpose of Representation in such local Legislature, and distribute the Representatives to which the Province is entitled in such local Legislature in any manner such Legislature may see fit.”

This alteration is not altogether unimportant. In the one copy the Resolution refers to the House of Commons of the Federal Legislature, in the other to the local Legislature alone.

I am requested by my advisers to ask Your Lordship to have the goodness to explain the cause of this discrepancy, and to inform me, after directing a reference to the original document, (which is, I presume, preserved at Quebec,) which version was in fact that signed by the Delegates. From the circumstance that in the Papers laid before the English Parliament, the same words occur as in the copy forwarded to me by Your Lordship on the 12th November, it would appear that the copy certified by Sir E. P. Tache is correct, and that the inaccuracy has arisen in copying the documents to be laid before the Canadian Parliament.

I am further requested to state, that the Delegates from this Province have never authorized any alterations in the Resolutions as signed by them, and that, indeed, their assent to any such alteration has never yet been sought.

I have, &c. (Signed) ARTHUR H. GORDON.

No. 52:

The Lieutenant Governor of Nova Scotia to the Lieutenant Governor.

Government House, Halifax, N. S., 10th April, 1865.

SIR,—I have the honor to transmit herewith for Your Excellency's information, copy of a Resolution submitted by this Government to the Nova Scotian Legislature this day, and suggesting the resumption of negotiations for a Legislative Union of the Maritime Provinces, on the ground that there appears no immediate prospect of carrying out a general confederation of all the British North American Provinces.

The result of the elections in New Brunswick is regarded here as conclusively terminating, for the present, all discussion of that project in Nova Scotia; because no Federal Union of this Province with Canada is feasible, so long as New Brunswick declines to form part of such Federation.

In the meantime, there is no reason for regarding a Union of the Maritime Provinces, or even of Nova Scotia or New Brunswick alone, as being less conducive now to the general convenience and good government of those Provinces, than it would have been if carried out in accordance with the Resolution of last Session.

This Government, therefore, anticipates, under the special circumstances of the case, an increased desire on the part of New Brunswick to effect that more limited union which identity of interests and race, combined with close neighbourhood, had, from the first, pointed out as a step mutually advantageous.

I have, &c. (Signed) RICHARD GRAVES MACDONNELL.

[Enclosure.]

Whereas, under existing circumstances, an immediate Union of the British North American Provinces has become impracticable ;

And Whereas a Legislative Union of the Maritime Provinces is desirable, whether the larger Union be accomplished or not ;

Resolved, That in the opinion of this House, the negotiations for the Union of Nova Scotia, New Brunswick, and Prince Edward Island, should be renewed in accordance with the Resolution passed at the last Session of the Legislature.

No. 53.

The Lieutenant Governor to the Lieutenant Governor of Nova Scotia.

Fredericton, 18th April, 1865.

SIR,—I have had the honor to receive your Despatch of the 10th, and shall lose no time in communicating it to my advisers, by whom, as well as by myself, I need hardly assure you, the proposition which it contains will be considered with the attention demanded by the importance of the subject to which it relates.

I have, &c. (Signed) ARTHUR H. GORDON.

APPENDIX XI

REPORTS ON RAILWAY SURVEYS, &c.

Report of Survey by J. Edward Boyd, Esq., C. E., on Line between European and N. American Line and Nova Scotia Boundary.

Saint John, N. B., 19th December, 1864.

To the Honorable the Provincial Secretary.

SIR,—I have the honor to submit the following Report on the Railway Surveys between the European and North American Railway, and the Boundary Line between New Brunswick and Nova Scotia.

The instructions received from the Government did not confine me to any particular route, but were such as left it open to me to explore the whole district lying between the Bay of Fundy and the Straits of Northumberland, with a view to ascertaining the most favorable.

The lines previously surveyed by Major Robinson, R. E., and Mr. Wilkinson C. E., ran in the direction of Bay Verte, and as far as I am aware, no attempt had before been made to find a line through that more populous part of Westmorland which lies on the side of the Isthmus next the Bay of Fundy. The probable cause of this was the difficulty presented in the continuation of such a line over the Cobequid Mountains in Nova Scotia. Prior to the commencement of my survey in New Brunswick, that obstacle had been surmounted by Mr. Beattie, C. E., who had been engaged for some months in making a survey from Truro to the Boundary. This survey was made, I was informed, under the auspices of the Acadia Iron Mining and Spring Hill Coal Mining Companies, their object being to open a communication with the head of the Bay of Fundy and the Harbour of Saint John. The inconvenience of not being able to ship the Iron at all seasons of the year at Londonderry, N. S., and the difficulty of getting vessels just where they are registered, make it a matter of importance to the Iron Mining Company to get access to some better place of shipment such as Saint John. A connection between their respective works would be mutually beneficial to both Companies, and the Coal Mines cannot be worked to advantage without an outlet at some convenient shipping place.

Having had an interview with Mr. Beattie, at which I learnt from him that he had been successful in finding a line over the Cobequid Mountains, and having made such preliminary examinations of the country about Memramcook, Dorchester, and Sackville, as enabled me to judge of the probability of finding a practicable line through that district, I determined, accordingly, to make a survey to connect with Mr. Beattie's at the Missiguash.

I was the more decided in this course because the country in the direction of Bay Verte was already known from Mr. Wilkinson's survey and the exploration made by Mr. Munro of Bay Verte in 1852-3.

I began the survey on the 26th May. The first line tried began at Cook's Brook Station on the European and North American Railway, and ran in a direct line towards Charters', passing through the Painsee settlement. I expected at that time to get down to the level of the Dorchester Marshes, either by the valley of Ayer's Brook or the west bank of the Memramcook River. This however proved impracticable, owing to the height of the range of hills between the Petitcodiac and Memramcook Rivers. This survey is shown by blue lines on the general Plan.

It was then decided to try a line on the eastern side of the Memramcook. This line, which is the one adopted, begins on the ninety sixth mile of the European and North American Railway, about a mile and a half farther east than the first line, and runs in a southeasterly direction until it strikes Meadow Brook, a tributary of the Memramcook, and following the valley of this stream, crosses the Shediac and Dorchester Road at its junction with the Painsee Road.

From the junction with the European and North American Railway to this point, a distance of five miles, the country is thickly wooded; the land is generally poor and not well timbered, though here and there, especially near the Painsee Road, are belts of hardwood where the land is good. About three miles from the junction, indications of Coal Oil were discovered, which, it is thought, are worthy of a closer examination than it was in my power to make. The Alignment and Grades are both easy on this section, and no structures of any consequence will be required.

After crossing the Shediac and Dorchester Road, the line still follows the Meadow Brook to its junction with the Memramcook River, and crossing the River here with a bridge of forty feet span, keeps down its western bank to a point about half a mile above Calhoun's, formerly Kinnear's, Mill; again crossing the River with a bridge of one hundred feet span, it follows the hill sides on the eastern bank until it reaches the level of the Dorchester Marshes at Charters', eleven and a half miles from the junction.

For the first four miles from the Shediac and Dorchester Road crossing, the line runs through partially cleared and burnt land; from Teakles' Mill to Charters' the land is cleared and cultivated. The formation is sandstone, which would be suitable for culvert masonry, but appears to come out in layers too thin to be fit for the larger structures. The quarries, however, have not been sufficiently opened to make it possible to give a decided opinion as to the value of the stone for building purposes. Below the forks of the Memramcook, the banks of that River are high and steep, with occasionally a narrow belt of intervalle. This makes it necessary to follow the course of the River rather closely, and a good deal of curvature is in consequence required. The gradients, however, are easy. By two short diversions, one of Meadow Brook, and one of the River, near the first

bridge over the latter, one crossing of the Brook and two of the River will be avoided.

From Charters', the line runs on the Marsh, merely cutting through some points of upland, as far as Crowson's Aboideau. This Aboideau can be widened at the upper side, and a bridge over Breau's Creek thus rendered unnecessary. At Crowson's, two lines diverge, one keeping on the Marsh round Black's Point, and the other running straight over Taylor's Hill. The latter involves rather more earthwork than the former, and a slight grade, but it is 446 feet shorter, and dispenses with eighty six degrees of curvature. Upon the whole, the line over the hill is the more favorable, and is the one recommended. From the point where these lines converge, the route lies almost altogether on the Marsh as far as the mouth of Palmer's Brook at Dorchester.

The country between Charters' and Dorchester, a distance of about nine miles, is thickly settled and under partial cultivation. Near Crowson's there is a hill of gravel of very good quality, and capable of supplying enough ballast for the whole line. With the exception of a small quantity near Bulmer's Mill, Sackville, and perhaps some from Fowler's Hill, Au Lac, this is the only source from which good ballast can be obtained.

At Dorchester the principal difficulties of the survey began. As far as I could ascertain, the valley of Palmer's Brook is the only pass by which the range of hills between Dorchester and Sackville can be crossed. The line runs up this valley to the summit. A very careful exploration of the summit was made by running cross levels, &c., and it is believed that the line as laid down, crosses the ridge at the lowest point. The line might perhaps be improved between Dorchester and the summit by keeping more to the eastward, as shewn by the dotted line, but this would involve more frequent crossings of Palmer's Brook. The profile of a trial line run 6,000 feet in that direction is shewn. The country here is densely wooded, and in such cases there is always a hope of improving upon the most careful location by prolonged exploration.

After passing the summit two lines were run, one on the south and the other on the north side of Bulmer's Mill Pond. These lines do not differ materially in length and curvature, but the line to the north being altogether the more favorable as regards quantities is the one recommended.

Crossing the Post Road rear Bulmer's Mill, the northern line runs down Frosty Hollow and crosses the Post Road again near the Westcock Aboideau. Thence it runs across the flat land near Boultenhouse's shipyard and Dixon's Landing to the Tantram or Sackville River, which it crosses 150 feet below the Post Road Bridge. The Post Road Bridge has a clear water-way of 400 feet, but this seems to be rather confined, so that for the Railway a bridge with three spans of 150 feet each, giving a water-way of 450 feet, is recommended. There will be some difficulty in building the piers of this bridge, owing to the rapid ebb and flow of the tide, which will limit the working time to from four to six hours a day. I had not the means of

making a very thorough examination of the foundations, but I do not anticipate much difficulty as regards solidity. The rush of water will, however, undoubtedly be a cause of both trouble and expense.

From the Sackville River the line runs straight across the Tantramar Marsh to the River Au Lac. Here, as at Crowson's, a bridge may be avoided by widening the Aboideau. This is important, as the foundations of a bridge in this place could not fail to be extremely expensive.

After crossing the Au Lac, the line curves away directly towards Fort Cumberland, and passing round Westmorland Point close to the foot of the upland, stretches across the Fort Cumberland Marsh to the Missiguash River, which here forms the boundary between the Provinces.

It will be seen from the foregoing remarks, that the line generally is extremely easy of construction. The section from the Junction to Charters' is not by any means difficult. A large proportion of the excavation will, in all probability be rock, but it is all either sandstone or a soft conglomerate, and as in rock cuttings of this nature, the saving in quantity nearly balances the extra cost per cubic yard, I have estimated for the grading as if the material were all earth.

Over the Dorchester, Tantramar and Fort Cumberland Marshes, all that will be required will be an embankment, made from side-cuttings, of sufficient height to ensure the drifting off of the snow in winter. The flood on these marshes in September last, was caused chiefly by the unusually high tides and the long continuance of south-westerly winds, partly however by the dykes being out of repair. The elevation of the highest tide was marked at the time, and the height of formation originally designed, was found to be sufficient to secure the track from risk of overflow.

The term "Marsh," as applied to the dyked lands at the head of the Bay of Fundy, hardly conveys a correct idea of their nature. Being composed entirely of marine deposit, which, from its containing between three and four per cent of various mineral salts, generally produces a formation far more fixed and solid than the alluvium of fresh water, these "Marshes" are quite as well adapted for the site of a railway as the uplands. The soil even when first thrown up into dykes does not appear to be injuriously affected by frost, and soon becomes covered with a vegetation which effectually protects it from any disturbance by the weather.

The only section which presents any real difficulties of construction, is that between Dorchester and Sackville. On other parts of the line I had limited myself to a minimum radius of 1,910 feet, and a maximum grade of 1 in 100, or 52 8-10 feet per mile, but after passing Dorchester Island Road these limits became impracticable. In passing from the Dorchester Marshes into the valley of Palmer's Brook, two sharper curves, one of 1,719 feet, and the other of 955 feet radius, were found necessary. In this and in every other instance, (with one exception) where curves of less radius than half-a-mile were introduced, they were raised as much as possible by being compounded at the ends with curves of larger radius.

Curves of such small radius as those just mentioned, are, though objectionable, not unadmissible, especially, when, as in this case, they occur near a Station. On American Railways, curves of even smaller radius are common. The Baltimore and Ohio has innumerable curves of 600 feet radius; the Reading Railway of 700 feet radius. The Virginia and Tennessee Railway, (five feet gauge) has 13 7-10 miles of curves not greater than 955 feet in radius, and of this distance 3 miles are of 819 feet radius, and one quarter of a mile 717 feet radius. The engines on the New York and Erie (six feet gauge,) run daily through curves of 799 feet radius. Numerous other examples could be given. Even in Great Britain, where so much pains has been taken to avoid sharp curves, they occur on some of the short lines. The Chester and Crewe Railway leaves Crewe with a curve of 1,188 feet radius. The Grand Junction near its junction with the Liverpool and Manchester line, has two curves of 660 feet radius each. The Taff Vale Railway has curves of 990, 792, 726, 660, and I believe, even 462 feet radius, but it does not appear that any difficulty has been experienced in working the engines round these curves at a velocity of twenty miles an hour. On the Tudela and Bilbas Railway in Spain, a model of which was shown in the Great Exhibition of 1862, the minimum radius is 921 feet.

Next as regards the incline on each side of the summit. The gradients are as follow, beginning at the Dorchester end:—

6000 feet	39.6 feet per mile	or 1 in 133 $\frac{1}{2}$
3000 "	52.8 " " " " " "	100
7000 "	79.2 " " " " " "	66 $\frac{2}{3}$
300 "	Level on summit.	
9000 "	79.2 feet per mile	" " " 66 $\frac{2}{3}$
5200 "	52.8 " " " " " "	100

The average incline ascending being 60 feet per mile, (1 in 88) and descending 69 feet per mile. (1 in 76 $\frac{1}{2}$.)

The subject of Railway gradients is one which is attracting great attention at the present time, and forms one of the chief points of consideration as to the practicability of introducing railways into districts as yet unaccommodated. Considering the enormous expense of constructing easy gradients in a mountainous country, it becomes a question of deep interest to the public, whether lines cannot be built at a moderate first cost, involving only a proportionate increase of power. The working of steep inclines is only limited by the power of the locomotive, and modern improvements have materially reduced the difficulties formerly experienced. Locomotives are now heavier and more powerful, and the application of their power is better understood. It is mainly therefore a question of how far the increased expense in locomotive power and repairs of permanent way, entailed by a steep gradient, is counterbalanced by the saving in first cost, and also to what extent is "the great purpose of Railway travelling, economy of time," affected by it.

In the case under consideration, as nearly as I can estimate the cost per annum of an extra engine to assist trains up the incline, would be equal to

the interest at 6 per cent. on \$125,000, which is less than one-sixth of the probable expense of reducing the gradients to a maximum of 1 in 100.

The economy of the use of auxiliary power depends on the constancy with which it can be kept at work, and this of course depends on the nature of the traffic. It is therefore a matter for future deliberation, whether it will be more economical to employ an auxiliary engine for this incline, or to work the whole road with engines sufficiently powerful to need no assistance, especially, as there will be, I understand, inclines of 1 in 75 on the Nova Scotia portion of the line, one of which will be, if I am not mistaken, seven or eight miles long.

I have been induced to enter more fully into this subject of gradients than may seem justifiable in a Report on a survey of some 36 miles of railway; but when it is considered that this is a link in the great chains of the "Inter-Colonial" and "European and North American" Railways, it rises from its apparent insignificance. Again, from the fact that 45 feet per mile has hitherto been the maximum gradient on the Government Railways in this Province, a certain amount of prejudice exists against anything beyond that limit, which it may perhaps be as well to remove. In the twelve years that have elapsed since that maximum was adopted, great improvements have been made in the system of working heavy inclines. It may therefore be interesting to glance at what is being done in this way in other countries.

And first in America. The Baltimore and Ohio Railway has thirty miles of gradients, ranging from 106 feet to 116 feet per mile, (1 in 50 and 1 in 46½) one of the 116 feet gradients being eleven miles long. The ordinary load on this incline is 114 tons, though on several occasions the engines have hauled 200 tons. The "Pennsylvania Central" has an incline 12 miles long, averaging 85½ feet per mile, (1 in 61¼.) Up this, passenger trains weighing 120 tons are run with an auxiliary engine at the rate of 20 miles per hour. The "New York Central" has a gradient of 95 feet per mile, (1 in 55½) for three miles out of Albany, worked with auxiliary engines, the passenger trains weighing from 90 to 160 tons, and running about 20 miles an hour. The "Western Railway" of Massachusetts has 12 consecutive miles of heavy gradients, (2¼ miles 55 feet, 7¼ miles 78 feet, one mile 70 feet, and 1½ mile 83 feet per mile.) The passenger trains are not very heavy, and do not average more than 17 miles an hour on this incline.

In England, the "Leckey" incline on the Birmingham and Gloucester Railway is 142 7-10 feet per mile, (1 in 37,) for about 2 miles. Freight trains weighing 240 tons are taken up at the rate of 6½ miles per hour with auxiliary engines, and passenger trains are run up at the rate of 12, 15 or 20 miles an hour, according to their weight. The "Hunt's Bank" incline on the "Manchester and Leeds" is 115 feet, and 88 feet per mile, (1 in 46 and 1 in 60.) The "Accrington" incline on the "East Lancashire" averages 120 feet per mile, (1 in 41) and is two miles long only, two-thirds of a mile of this distance being straight and the remainder in curves of from 3,696 to 2,640 feet radius; up this passenger trains are run at the rate of 20

miles an hour, and freight trains weighing 179 tons, inclusive of engines, at the rate of $6\frac{1}{2}$ miles an hour, the freight engine used, was however light, weighing only 26 tons.

On the European Continent, the "Semmering" incline on the Vienna and Trieste Railway is 112 feet per mile, (1 in 47) for $13\frac{1}{4}$ miles. The load is generally 110 tons, exclusive of engine and tender, taken up at the speed of $11\frac{1}{2}$ miles per hour. The "Giovi" incline on the Turin and Genoa, is 147 feet per mile, (1 in 36) and some 8 or 10 miles long. The Tudela and Bilbas, before mentioned, has gradients of 75 feet per mile, (1 in 70).

The most remarkable features are met with on the South American Railways. In Chili, the Copiapo Extension Railway has 14 miles of gradients, averaging 176 feet per mile, (1 in 30) and on the next $9\frac{1}{2}$ miles 240 feet per mile, (1 in 22). The Coquimbo Railway has grades of 1 in 70, (75 feet per mile). On the Valparaiso and Santiago Railway, the "Tabon" incline is 12 miles long, 114 feet to the mile, (1 in $46\frac{1}{2}$) combined with curves of 604, 633 and 702 feet radius. The summit level of this line is 2,640 feet above the sea. On the Pabellon and Chanarcillo, is an incline of 1 in 25, (211 feet per mile) nine miles in length, with curves of 500 feet radius, up which engines ascend daily, to an altitude of 4,400 feet above the sea, the greatest altitude yet attained by the locomotive. The Don Pedro, Second, Railway in Brazil, has an incline $15\frac{3}{8}$ miles long, ranging from 1 in 100, ($52\frac{1}{2}$ feet per mile) to 1 in 55, (96 feet per mile,) nearly 11 miles out of the $15\frac{3}{8}$ being at the last mentioned rate. On this incline, curves of 739 feet radius occur. The engines designed by Mr. Zerah Colburn for this Railway, combine great tractive power and the merit of running easily through sharp curves, with cheapness in construction, and economy in working. They are probably the best examples in existence of the kind of engines required for working Railways in this country. The passenger engines are estimated to be capable of drawing on the inclines, above mentioned, a gross load of not less than 110 tons, (exclusive of engine and tender,) at the rate of 20 miles an hour, and the freight engines a gross load (exclusive of engine and tender,) of from 200 to 225 tons, (though the ordinary load was not estimated at more than 175 tons,) at a mean speed of 12 miles an hour.

Indeed such has been the progress in mechanical engineering, that there seems to be scarcely any limit to the power of working steep inclines. A proposition is now before the French and Italian Governments, for constructing a Railway over the Alps, the gradients on which will be one in twelve and one in thirteen. Actual experiments made in England on an incline of the same rate, with an engine of novel and peculiar construction, were quite successful, the engine working up and down, and even stopping and starting on the incline with the greatest ease.

In consequence of my appointment as General Superintendent of the European and North American Railway, I was unable, after completing the survey of the first line to make any further personal examination of the country. Mr. S. P. Tuck was therefore put in charge of the party, with in-

structions, to run a line, from the Aboideau of the Riviere Au Lac, to the Railway Station at Shediac. I had no doubt that a very easy line could be found in that direction, and the result has proved that I was not mistaken. The details of this survey are given in Mr. Tuck's Report, which is appended.

In order to make the Report on the District as complete as possible, I have reduced the profile of Mr. Wilkinson's Exploratory Line to Bay Verte, to the same scale as those of the other lines, and made an estimate of the probable cost of the line on his proposed location.

In the following Tables the lines are numbered according to the distance from Saint John of their respective junctions with the European and North American Railway. No. 1 being the Line through Dorchester and Sackville to the Missiguash; No. 2, Mr. Wilkinson's Line to Bay Verte, and No. 3 the Line from Shediac to the Missiguash. The Line from the Au Lac Aboideau to the Missiguash is common to Routes Nos. 1 and 3.

It is always difficult to make a reliable estimate of the future traffic of a Railway, but the following Tables of the probable annual local passenger and freight traffic may, if not *positively* correct, serve to give an idea of the *comparative* prospects of the three routes. It is hardly necessary to say that the through traffic must eventually become very large when the connections with the United States and Canada are completed. The Mail subsidy alone, will be an important source of revenue, and this will, in all probability become the main route for passenger travel between the Continents of Europe and America. The local traffic will of course increase as the greater facilities for getting to market induce the proprietors of the fertile lands at the head of the Bay of Fundy to adopt improved methods of cultivation.

ANNUAL LOCAL TRAFFIC, ROUTE NO. 1.

STATIONS.	No. of Passengers.	Tons of Freight.
Junction,	2,000	500
Painsee,	1,000	500
Memramcook,	3000	2,500
Dorchester,	12,000	2,500
Sackville,	12,000	5,000
Fort Cumberland,	4,000	2,000
	<hr/> 34,000	<hr/> 13,000

ROUTE No. 2.

STATIONS.	No. of Passengers.	Tons of Freight.
Junction,	1,500	500
Aboushagan Road,	500	500
Bay Verte,	4,000	2,000
	<u>6,000</u>	<u>3,000</u>

ROUTE No. 3.

STATIONS.	No. of Passengers.	Tons of Freight.
Shediac,	2,000	500
North Lakes Road,	1,000	500
Sackville,	12,000	5,000
Fort Cumberland,	4,000	2,000
	<u>19,000</u>	<u>8,000</u>

The comparative running distance and length of line to be built on each of the lines are as follows, taking Halifax and Saint John as the termini:—

ROUTE No. 1.

Halifax to Truro,	60	miles.
Truro to Boundary,	68	"
	<u>128</u>	miles in Nova Scotia.
Boundary to Junction with European and North American Railway, ...	36½	miles.
Junction to Saint John,	96	"
	<u>132½</u>	miles in New Brunswick.
Total running distance,	<u>260½</u>	"
To be built,	68	miles in Nova Scotia.
"	36½	" New Brunswick.
Total,	<u>104½</u>	miles.

ROUTE No. 2.

Halifax to Truro,	61	miles.
Truro to Bay Verte,	86½	"
	<u>147½</u>	" in Nova Scotia.

Bay Verte to Junction with European and North America Railway,	26	miles.
Junction to Saint John,	98	"
	<u>124</u>	" in New Brunswick.
Total running distance,	<u>271½</u>	"
To be built,	86½	miles in Nova Scotia.
"	26	" New Brunswick.
Total,	<u>112½</u>	miles.

ROUTE No. 3.

Halifax to Boundary as in Route No. 1.	128	miles in Nova Scotia.
Boundary to Shediac,	29½	"
Shediac to Saint John.	106	"
	<u>135½</u>	" in New Brunswick.
Total running distance,	<u>263½</u>	"
To be built,	68	miles in Nova Scotia.
"	29½	" New Brunswick.
Total,	<u>97½</u>	miles.

The comparative merits and defects of the three routes may now be summed up. No. 1 passes through the coal and iron districts of Nova Scotia, and the great centres of population in Cumberland County, N. S., and Westmorland, N. B. The inhabitants of part of Albert County, N. B., will also be accommodated by the Station at Dorchester. It has in consequence the best prospects of local traffic. The running distance between Halifax and Saint John, is three miles less than by No. 3, but the length of line to be built is seven miles greater. The heavy inclines between Sackville and Dorchester, are serious objections to this route. No. 2, as compared with the other lines, has little to recommend it; except that as regards New Brunswick there is less line to be built. The running distance is eleven miles greater than by No. 1, and eight miles greater than by No. 3, and the total length to be built, eight miles greater than on No. 1, and fifteen miles greater than on No. 3. The line between Truro and the Provincial Boundary is common to No. 1 and No. 3, they have therefore certain advantages in common; but after passing the Four Corners, Sackville, No. 3 is deficient in local traffic. The gradients and alignment are both good, and No. 3 has the advantage over both the others of taking in the whole of the present Railway from Saint John to Shediac. The cost per mile of the parts of each line lying in New Brunswick, are estimated as follows, viz: No. 1, \$36,081, No. 2, \$29,525, No. 3, \$26,926. Detailed estimates of each line are appended.

The permanent way is estimated for at the same weight of rails, (63lbs per lineal yard,) and the same pattern of cast iron chairs, which are found to answer well on the Saint John and Shediac line. It may perhaps be thought preferable to adopt a fresh joint, but this will not materially affect the cost per mile. The allowance for sidings is rather larger than that usually made.

The estimate of Rolling Stock is liberal, but not, it is thought, more so than the prospects of traffic will warrant.

Stations have been provided for at the points which now are the principal centres of trade along the line.

A statement shewing the expenses of the Surveys is also submitted.

I have, Sir, the honor to be

your obedient servant,

J. EDWD. BOYD, *C. E.*

J. EDWARD BOYD, Esquire, *C. E.*

SIR,—Having at the time of your assuming the active duties of the superintendency of the European and North American Railway, been appointed to the charge of the Eastern Railway Surveying Party, with orders to make an exploratory survey of that portion of country lying along an almost direct route between the Provincial Boundary and the Shediac terminus of the present Railway, I beg leave to make the following brief Report of the operations of the party.

The season was already far advanced before the survey of the route through Dorchester was completed, and the succession of heavy rains which prevailed during the greater portions of the month of October, filling the streams, and rendering the swamps and peat-bogs almost impassable, prevented the work on this part of the survey from being prosecuted with as much rapidity as might otherwise have been the case. There was, on the other hand, the advantage of inspecting the country passed over in the worst possible condition for the purposes intended.

The general features of the country are, of course, very much the same as characterized that part of Westmorland traversed by the party when under your more immediate control; and that portion of your located line, lying between the Missiguash River, and the Au Lac Aboideau, seeming to admit of no improving change, is therefore common to both lines.

Beginning then at the Au Lac Aboideau, I shall, for convenience of reference, speak of my exploration, as if divided into three sections; that part lying wholly on the Tantamarre Marsh, constituting the first section; the second being that portion between the Marsh and the summit in the immediate vicinity of Towse's; and the third consisting of the remaining portion, between the summit and the Railway near Shediac.

The land of the first or Marsh section is, for the most part, higher and more solid, than on the Marshes passed over in the earlier parts of the survey, on the borders of the Memramcook. As the higher lands at the head

of the Tantamarre are approached, one encounters the swamps and fenlands bordering on the Sackville lakes. Great pains are being taken, however, to drain these, and numerous tidal canals, cut in almost every direction, together with the extending and deepening of the natural water-ways, are rapidly giving to the soft earth of the bogs, all the firmness and compactness of the more cultivated Marshes. Should this line ever be permanently located, it is probable that all the heaviest structures would occur on this division. This is owing to the fact that the various tributaries unite to form the main Tantamarre River below, where it will be necessary to cross them, and that these have been widened and deepened for purposes of irrigation, while a tidal canal, cut entirely for this purpose, has been so enlarged by abrasion as to require quite an extensive Pile Bridge.

The structures involving the heaviest outlay on this part of the line, will probably be three Iron Girder Bridges, over successive tributaries of the Tantamarre, as will appear on reference to the estimate of cost of Line No. 3. There may be some difficulty in finding foundations for two of these bridges, as the bank on either side seems to be very soft; at the third, the rock will, I think, be found at no great depth below the surface. I may add, however, that the time at my disposal did not admit of the borings, necessary to enable me to speak positively, being made.

This section passes conveniently near to the upper village of Sackville, and might reasonably be supposed to offer every necessary facility to the valuable farming interests of this, and the adjacent Parish.

The second section, rising from the Marshes to the summit, presents no features needing especial comment. It passes for almost its entire distance through forests of spruce and hardwood, with only an occasional attempt at cultivation. The land itself, seems to be good, and easily made productive. By this line the Aboushagan Road, leading from Sackville to Shediac, is crossed three times; provision has, therefore, been made in the estimate of cost, for its diversion. No structures of any magnitude will be needed on this section, except at the crossing of the road leading from Towse's to the head of the Sackville lakes, where an over-bridge with embanked approaches will be required.

The land, after leaving the Marsh, rises very rapidly, so that I was compelled to abandon the first line I ran, because of the impracticability of the grades. By diverging to the right, immediately after quitting the Marsh, and taking a longer distance in which to rise, I was enabled to reduce the gradient within easy limits, but it still remains the heaviest on the entire line, being one foot in a hundred. This, however, might be still further reduced by increasing the amount of work to be performed, without materially affecting the average cost per mile of the whole route.

The third section, extending from the summit to the European and North American Railway line near Shediac, passes entirely through forests of spruce, hackmatack and hardwood. Swampy barrens of considerable extent, from which are said to flow the streams that form the Dorchester

River, were encountered here. These were generally of no great depth, and were, at the time of our passage, in the worst condition possible for them to be, being entirely filled with water. They might indeed be entirely avoided by a divergence either to the right or left. Wild meadows were also met with, but these presented no serious obstacle, being easily rendered compact and hard by proper drainage.

By reference to the accompanying general Plan, it will be observed that, in nearing the European and North American Railway, my exploratory line crosses the Scadouc River in two places. Both these crossings may be dispensed with, and the River entirely avoided, by diverging slightly to the right before reaching it. This will not materially increase the length of the line, and will have the desirable effect of bringing it out much more favorably in regard to the Railway terminus at Shediac, than it now comes. No provision has therefore been made in the estimate for a bridge at either of these crossings. No structures, other than the ordinary culverts, occur on this section. Provision has been made for the diversion of two or three streams, near whose beds the line ran. These might be dispensed with, and the location of the line possibly improved by keeping farther to the right or left.

It may not be amiss for me to mention here, that I conceived it to be my duty, owing to the lateness of the season, to hasten as directly as possible to the Railway, ascertaining as well as I was able the main features of the country on either side of the Route, rather than complicate, and perhaps delay the work, by locating any portion of the line.

From the accompanying profile, it will be observed that the work on this line is very light, averaging about fourteen thousand cubic yards per mile. Its entire length, when properly located to the station at Shediac, will be found to be about twenty-nine and one-half miles.

Appended will be found tables showing the estimated cost of the line, estimated cost of engineering per mile, of superstructure per mile, of rolling stock, and of stations, together with a table of alignment, and of the length of line, equated for curves and grades.

I have the honor to be, Sir,

Yours very sincerely,

S. PARKER TUCK.

Saint John, N. B., 15th January, 1865.

REPORT

OF THE

SURVEY OF EXTENSION

OF THE

European and North American Railway

TO THE

AMERICAN BOUNDARY,

AND

BRANCH LINE TO FREDERICTON.

By E. R. BURPEE, C. E.

FREDERICTON:

PRINTED BY JOHN GRAHAM, "HEAD QUARTERS" OFFICE.

1865.

PROVINCIAL SECRETARY'S OFFICE,

FREDERICTON, *April 27th*, 1864.

SIR,

I beg to inform you that his Honor the Administrator of the Government in Council has been pleased to appoint you as Engineer, to explore and Survey a line of Railway from the City of St. John to the Boundary of the State of Maine, *via* the Douglas Valley; and you are hereby authorised and empowered to employ the necessary Surveyors and Assistants to enable you to prosecute that Survey with all convenient speed.

I have the honor to be,

Sir,

Your obedient servant,

S. L. TILLEY.

E. R. Burpee, Civil Engineer, St. John.

REPORT

OF THE

SURVEY OF RAILWAY EXTENSION.

ST. JOHN, *April 24th*, 1864.

TO THE HON. A. H. GILLMOR, PROVINCIAL SECRETARY.

SIR,—Having been previously notified of the appointment confirmed in the foregoing letter, I had, in order that the work should be completed with as little delay as possible, already secured the services of Mr. Thos. Ramsey, long and favorably known as an explorer of experience, had organized a staff, and had made arrangements for a thorough survey, during the summer, of the different routes through Portland and Carleton, to connect with the present line from St. John to Shediac, so that immediately on the receipt of formal instructions, I was enabled to commence work in both directions, and from that time until the last of January of the present year, was fully occupied with the out door work on the main line and a branch to Fredericton. Since, the work on both has been plotted, quantities calculated and estimates of cost prepared, and I am now happy to be able to report that a line has been found, which, although, perhaps, susceptible of improvement, yet presents few engineering difficulties, can be constructed at a very moderate cost, and traverses a district of country which will produce a remunerative tariff, capable of being largely increased.

General Route of the Line.

The line, shown by the deep red line on the map accompanying the other drawings and this report, starts from the present depot of the European and North American Railway, passes either through Portland to the Suspension Bridge, where it crosses the St. John river, or from the present water terminus extended to harbour line, by means of a ferry, it may connect with some of the lines on Western side and through Carleton, with the main line a short distance West of the bridge. Thence skirting the West shore of South Bay and the St. John river for 16 miles, it reaches the mouth of the Nerepis, and follows its left bank for 8 miles; then leaving that river and crossing the road to Fredericton it enters the Douglas Valley, from which it passes by the North side of Gaspereaux Lake and the valley of the Back Creek, until it crosses the South Branch of the Oromocto river. Thence by a direct course, it crosses the North West Branch of the same river near Hartt's Mills, 43½ miles from St. John;—from which point the branch line to Fredericton diverges. Leaving this place it takes a Westerly course and follows the North West Branch of the Oromocto and its tributary, the Yoho, for some distance. Crossing the latter and two branches of the Lyons' stream, it intersects the main post road between Fredericton and St. Stephen, 26 miles distant from the former, and 53 from the latter place. Thence it reaches the shore of Cranberry Lake, crossing an arm, of which it makes, by a direct line, the outlet of the large Maguadavic lake; from thence, bending somewhat to the South, it passes the North side of Mink Lake and Mount Prospect, and crossing the "New Brunswick and Canada Railway" 42 miles from St. Andrews, it reaches the American boundary on the St. Croix river, not far from the outlet of the Cheputneticook lakes, the distance being 88½ miles from St. John.

By this route a line has been procured, which requires no grade exceeding 53 feet per mile, or curve of less radius than 1637 feet, and which will be found to compare favorably with most lines on this continent both as to total amount of grades, curvature and cost.

Characteristic Features of the Line and Works.

Leaving that part of the line East of the Suspension Bridge, and the different means of connecting with the terminus of the European and North American Railway to be afterward considered, I will proceed to remark on the characteristic features of the line from that point Westward, and as there is no very great difference in the length of the terminal lines, it is to be understood that in all cases, where distances from St. John are given, they are reckoned from the present depot of the European and North American Railway, and by the line through Portland, over the falls.

From the Suspension Bridge around the South Bay as far as Sutton's Mills the work will not be difficult, but on reaching that point it will be necessary to cut through a spur of limestone rock, 40 feet in depth by 200 feet long, the material can be used to form part of a heavy embankment required across an arm of the bay. It is also proposed here to erect an iron bridge of 50 feet span, this being the natural outlet of the water from Spruce Lake. Thus far, it is possible to shorten the line at least $1\frac{1}{4}$ miles, and reduce the curvature very considerably, by adopting a line across the South Bay near the line of piers of the Boom Company, but it was found, on examination, that to build a wharf or embankment sufficient to withstand the wash of the water in so exposed a situation, with the necessary bridges and dams, besides interfering with the operations of the Boom Company, would entail an outlay exceeding that on the longer line, by at least \$100,000.

From South Bay to Vernon's mill pond the work will be light, but thence to Law's stream, the eastern boundary of King's County, a distance of about 3 miles, serious obstacles are to be encountered because of the highlands, which, (skirting the South side of the St. John,) here jut out abruptly into the river, forming Stevens' Cove on the East and Clark's Cove on the West side of Clark's Mount. To avoid a tunnel either through this hill, or the point of high land immediately West of Clark's Cove, which was resorted to in former surveys to overcome the difficulties here met with, much time was spent in a thorough examination of the country for some distance from the river. A practical, and I may add not immoderately expensive line, was found by crossing to the South side of the Fredericton road, (at Stevens'), and recrossing a short distance before reaching Law's stream,—the summit being overcome by a grade of 49 feet per mile, for a distance less than one mile on the Eastern side and about half a mile on the Western side, while the line was generally straight.

A survey and estimate has also been made of an alternative line at this point (shown by a blue line on the plan,) which, passing round the edge of Clark's Point, avoids the summit to be surmounted by the inland route, but being half a mile longer, requiring curves of less radius than 1450 feet, and on the whole being not less expensive, is not recommended.

For the next 4 miles the country is rough and much broken, so that the work will be necessarily above the average per mile, although the grades are within the prescribed limits and the curvature is moderate. Law's and Scovil's mill streams are each in deep valleys, requiring heavy embankments and bridges of 25 feet span. The highland, extending out into the St. John river at Brandy Point, is passed by taking advantage of a natural valley, most favorably situated, immediately South of that point in a direct line with the general course.

After this, the ground is much more favorable, and little needing special remark is met with, until reaching the vicinity of Eagle Rock, some distance up the Nerepis and 20½ miles from St. John.

I may here remark, however, that to avoid the necessity of frequently crossing the post road on this section, in order to secure the safety of the travelling public, a large amount of road diversion will be required.

At Brundage's Point, 13 miles from St. John, a cutting of 400 feet long and 40 to 50 feet deep is shown on the section, apparently of material suitable for ballast. The existence of a good ballast pit at this point would be highly advantageous, but should the material prove to be not so good as anticipated, the excavation can be diminished by slightly altering the location, which, to a small extent, would increase the curvature.

As the nature of the country at Belyea's, two miles farther on, is such as to admit in location of little choice of ground, considerable expense may be expected in damage to property, but, should the present line, on final location be adhered to, the damage may be considerably reduced, by lessening the width of the cutting and bridging a sufficient portion of it, to allow the proprietor accommodation for his ordinary business. This bridge would also serve for the road leading from this place across the Nerepis river to Brittain's Point.

In the vicinity of Eagle Rock, it will be necessary to encroach slightly upon the Nerepis river, for about 200 feet, where the slope will require to be protected by rip-rap, and probably piling for a very short distance. There will, here also, be a cutting of about 50 feet depth, but as at Brundage's Point, the material can be advantageously used as ballast.

The line now enters the level country near the junction of the Douglas stream with the Nerepis, crossing the Fredericton road near the residence of Charles Bayard, Esq.; leaving which, with a short curve of 2700 feet radius, it crosses the two branches of the Douglas stream, (each requiring a bridge of 24 feet span,) and enters the Douglas valley. An alternative line is here suggested, (as shown on the plan by the blue line,) which, although adding slightly to the curvature, will cause considerable saving in construction, without injuring the character of the road.

After this, the line skirts the foot of Douglas mountain and the hills on the West side of the valley, avoiding as much as possible the soft ground in the vicinity of Harcourt Lake, and reaches the summit of land between the waters of the Nerepis and Oromocto rivers, 27 miles from St. John, and at an elevation of 171 feet above high tide. The whole of the works on this section are more than ordinarily light, the curvature small, and only once is the maximum grade of 52.80 feet per mile attained.

Leaving this summit, the line first crosses and then recrosses the back creek, the northern side of which it follows nearly to its mouth; thence in about two miles of straight line it crosses the South Branch of the Oromocto, at the head of tide water, and 40 miles from St. John. The work on a portion of this section is somewhat broken, but not heavy or expensive. Several alternative lines have been run in this distance, but although they reduce the amount of curvature and length of time a little, the necessity for heavier grades and increased expense in construction more than counterbalance these advantages. The crossing of the South Branch of the Oromocto, at a place everyway favorable, is proposed to be effected by an iron girder bridge of 100 feet span; thence to Hartt's mills, on the North West Branch of the Oromocto, the country is level, and consequently the works light, and grades easy.

From this point two lines were presented for consideration. One up the North West Branch of the Oromocto river, and by the South side of the Oro-

mocto lake, across the Maguaguadavic river to the "New Brunswick and Canada Railway;" the other in a nearly direct West course across the country to the North of that lake through Harvey Settlement, and crossing the Maguaguadavic much nearer its source, to the "New Brunswick and Canada Railway."

From explorations made by parties, under Mr. Wilkinson, in 1850, it seemed quite clear no line could be obtained on the former direction, from the Oromocto lake, across the valley of the Maguaguadavic to the high ground between it and the Digdeguash, without grades exceeding 53 feet per mile, and more than ordinarily heavy work, and it also was evident that the distance must be longer than by the Northern route, while to overcome the necessity for heavy grades and expensive work, by going farther to the South the line would have to be made of even still greater length. I determined, after having had the ridge of highland on the West side and North of the Oromocto lake, (which separate the waters of the Oromocto from those of the Maguaguadavic,) and the valley of the North East Branch of the Maguaguadavic, explored by a small party during the progress of the survey East of Hartt's mills, and having found that a shorter practical line could be had on the North side of the lake, to leave the Southern route to be further examined at some future time should circumstances warrant it, and proceeded with the Northern route.

Having adopted this course, it was necessary to cross the North West Branch of the Oromocto, so soon as a suitable place could be selected. This was found at a very short distance above Hartt's mills, and at a point every way favorable, the width of the valley being contracted and the bed of the stream rock. It is proposed to effect this crossing by means of an iron girder bridge of two spans of 75 feet each.

After crossing the stream, a table land is soon gained, when a straight and easy line is found up the West side of it for some distance, passing Tracey's mills 47 miles from St. John, and crossing Porcupine Brook near its confluence with the Oromocto, where a heavy embankment of 52,000 cubic yards, and bridge of 24 feet span will be required. Immediately, on leaving this stream, a deep and long cutting occurs, and the maximum grade of 53 feet per mile is required for one mile. It is probable, that by increasing the curvature, so as to cross Porcupine Brook a little farther from its mouth, the summit of land between it and the Yoho could be attained by means of a shorter grade and at less expense.

As the country from this point Westward was a complete wilderness, wholly unexplored and without roads, it was a tedious and somewhat difficult task to decide upon the best route, but after a thorough survey of the Yoho stream, and exploring a large tract of the adjacent country, the line now adopted reaching the Cork Settlement road 58½ miles from St. John, was found to be the most favorable, the work being under the average, with few and easy curves and grades generally less than the maximum.

There will be required over the two branches of the Yoho, bridges of 24 feet span.

Leaving this point the greatest difficulties were encountered, requiring a most thorough examination of the country, and it is highly probable that further explorations may furnish improvements in the lines ultimately adopted, or lead to results more satisfactory respecting those which have been abandoned.

From this point, two routes to the "New Brunswick and Canada Railway" again present claims for consideration. The first crossing the Lyons' Stream near its forks; thence by the head of Dead Brook, to what is known as the Long Swamp on the Fredericton and St. Stephen road, (through which it was intended to pass the Harvey Settlement ridge,) and crossing the North East

Branch and main Maguaguadavic Rivers, and following the head of Davis Brook to the South side of Mount Prospect, it would reach the New Brunswick and Canada Railway about 41 miles from St. Andrews. The second route, following the Lyons' Stream to Cranberry Lake; thence maintaining nearly the same elevation, by keeping as nearly as possible to the head of all the Maguaguadavic waters, and passing on the North side of Mount Prospect, joins the New " Brunswick and Canada Railway," not far from the point at which the former does.

The first mentioned route being the shorter by about 2 miles, was looked upon with much favor, and was not given up until much time had been spent in exploring it, and the lateness of the season rendered it imperative to adopt some one. Although no difficulty was found in getting a good line from the Cork Settlement road to Dead Brook, all our explorations as yet, lead to the conclusion, that to make the summit of the Long Swamp, a grade of 60 feet per mile would be required, which, notwithstanding the work would be light, it is not though fit to recommend. It was also ascertained, after having run a number of trial lines, that neither the valley of the North East nor Main Maguaguadavic Rivers could be crossed, so as to reach the " New Brunswick and Canada Railway" South of Mount Prospect, without steeper grades and much heavier work than would be desirable. Finding then, that both of these streams flow and fall rapidly, while the highland on their banks retains its full height, so that a good line in this direction was not likely to be found without much further exploration, if at all, and considering the season was so far advanced, it was decided to keep, as nearly as possible, the elevation attained at the Cork Settlement, and cross both those streams as near their sources as possible.

This led to the adoption of the Northern or second named route on which for 8 miles two lines have been surveyed as shown on the plans, both of which come within the required limits as to grade and curvature.

That by Cranberry Lake (upon which the estimates are based,) crossing the Harvey Road at an elevation of 55 feet lower than any other can, is shorter by a few feet, is much the straightest and presents the smallest amount of heavy gradients. It traverses a heath for two miles, (some three or four hundred feet of which may require to be covered with poles or bush before a bank is laid thereon,) and then after some distance in a swamp, rises with a grade of $52\frac{3}{4}$ feet per mile from the head of Lyons' Stream through a gorge, the contracted limits of which will admit of very little alteration on final location, to the Post Road from Fredericton to St. Stephen, at an elevation of 471 feet above tide level.

Leaving the Post Road it immediately traverses a cove of Cranberry Lake, with a curve of 1637 radius passes a point of rock, (which makes out from the Southern shore and requires to be excavated to a depth of 45 feet,) and then crossing an arm of the lake 800 feet wide, it rises with an easy grade of 20 feet per mile for 500 feet to an elevation of 488 feet above high tide, the summit between St. John and the "New Brunswick and Canada Railway." The depth of water in the Lake where the line crosses was found to be 16 feet, and with the material furnished from the rock cutting it would not be difficult to make through it a substantial wharf or embankment. The quantity of rock estimated to be excavated at this point is 40,000 cubic yards, (by far the heaviest cutting on the line,) but by increasing the curvature, the quantity of excavation and also the depth of water can be lessened considerably, while at the same time the requirements of a first class road will be adhered to.

The alternative line shown in blue on the plan runs almost entirely on firm ground, but, as it involves the necessity of an increased number of sharp curves,

a higher summit by 40 feet, and consequently a greater length of heavy grades, without reducing the length or to any considerable extent the cost of the line, it is not recommended.

Leaving Cranberry Lake, the line is straight to the Maguaguadavic river, which it is proposed to cross by an iron girder bridge of 50 feet span. On this length the grades are easy and the work light, while there is little doubt but it can be still further improved on final location. The North-East Branch is crossed near the mouth of Deadwater brook and will require a bridge of 30 feet span.

The Maguaguadavic river is crossed a short distance below the outlet of the big Maguaguadavic Lake, and although approached on either side by a grade of 52 $\frac{1}{4}$ feet per mile, still requires an embankment of 89,000 cubic yards. The valley through which this river flows is much lower than the lands on either side, which will account for this section being among the most difficult and expensive on the line. This valley widens and its depth increases in descending from the Lake, so that the only chance of finding a more favorable crossing must be confined to the short space between the present location and the Lake, where no doubt, from what examinations have been made, the embankment may be considerably diminished in quantity.

After leaving the valley of the Maguaguadavic the country is much more favorable, and following the location we cross Mink Brook nearly one mile from where it enters the Maguaguadavic Lake, and keeping on the right bank of a lake of the same name at its head, skirting the foot of Oak Mountain until the South fork of the Cranberry Brook is crossed near its source, and then traversing heaths and swamps for two or three miles we reach the vicinity of Mount Prospect. Passing this mountain on the narrow strip of level but stoney land between it and Foster Lake, with a short curve of 5270 feet radius toward the South, we cross the head of White Beaver Brook and without difficulty reach the "New Brunswick and Canada Railway" on the level. On the whole of this distance, 10 miles, the location is almost entirely straight, the grades easy and the work not expensive.

Leaving the railway the line keeps still to the South in order to avoid the hills on the Western shore of the second Digdequash Lake, and at the 84th mile from St. John passes a summit of 500 feet above tide level by 2 miles of the maximum grade, then turning to the right and descending with easy grades reaches the American Boundary at the St. Croix, (88 3-5 miles from St. John,) which river it crosses at an elevation of 381 feet above high tide.

Some portions of the work on this section of the line are heavier than an average of the whole, but there is little doubt it can be made lighter on final location. To effect the crossing of the St. Croix will require an iron bridge of two spans of 80 feet each, the expense of one-half which would necessarily devolve upon the company constructing that portion of the line on the American side of the boundary.

Description of Terminal Lines through Carleton and Portland.

Before entering upon the question of cost, it is deemed preferable to make a few remarks on the different lines connecting with the terminus of the European and North American Railway, and with the waters of St. John harbour.

A line tolerably favorable, has been surveyed to the terminus of the E. & N. A. Railway, crossing the St. John river about 150 feet above the bridge. From this, it curves to the left and follows the hillside to the vicinity of the iron works on the Straight Shore, thence crossing the timber ponds and the Straight Shore road near Hawes' Cottage, passing over Sheriff street, under Simonds' street, and following from Acadia street, along the rear of the houses on Main street, (Portland,) it reaches the long wharf and thence commences to

curve to the right. Then reversing it passes over Mill street, and through the wooden buildings attached to Harris' foundry, joining the present railway near Dorchester street crossing. From near the suspension bridge to within 700 feet of the present station, the grade descends at a uniform rate of 35 feet per mile. Bridges will be required over Mill street and the long wharf, under Simonds' street, over the Straight Shore road, and trestle work over a portion of the mill pond. The whole of the excavation required will be rock, and through Portland it is proposed to tunnel 250 feet in length.

This may be considered as favorable a line as can be found to connect with our present railway by the Eastern side of the river, but it is very evident that apart from the bridge over the St. John river the works alone are heavy and must prove expensive.

With a view, if possible, to obviate this objection as well as to furnish more accommodation for heavy freight and lumber traffic, several others have been surveyed on the Western Side of the river, which are shown on the plan of the harbour and its vicinity.

The first of these leaves the main line at a point "A" (on the plan) 140 West of the bridge by a sharp curve, and passing through the grounds of the Lunatic Asylum, and a little to the West of Peters' mill, follows the bank of the river to Front Row, in Carleton; thence passes between high and low water mark, crossing two or three wharves and the head of Buttermilk Channel to Navy Island. This is only about $1\frac{1}{2}$ miles in length and is the shortest line from the West to the harbour in deep water. It is, however, liable to some objections. The curves near the Suspension Bridge are only of a radius of 1437 feet, and the elevation of ground at the point where it leaves the main line is such that the maximum grade of one foot per hundred is required to within 700 feet of the terminus in order to make a descent to a level with the wharves, while at the same time the works are both heavy and of an expensive nature.

Another line diverges from this some distance before reaching Front Row, then crossing King and Union streets and the heads of the wharves East of Union street, it extends to deep water at Sand Point. This line is about 800 feet longer than the first, which will admit of some diminution in the inclination and will lessen the quantity of work near the Suspension Bridge, but it is liable to the same objection in respect to curvature and to the short distance between the foot of the grade and the terminus.

A trial line was run from station 26 on the main line, crossing the Manawagonish road to the back of Clark's house, then recrossing the road and along the slope of the hill below Tilton's to near the back of the Church on King Square, and thence into Lancaster street, as shown by the light red line on the plan.

This was found to be impracticable on account of the height of the land at the road crossing West of King Square.

It then became quite evident, the only chance of obtaining a more favorable line must be to pass on the West side of Carleton Heights. A line was therefore started from point "B" or station 35, on the main line running through the ridge of land on which is the road to St. Andrews, around the highlands to Negro Point, and thence through Carleton to Navy Island. As this line is about 2 miles longer than the others it may be a question if its length does not more than compensate for the advantages it possesses in grades, curvature and works. It is, however, certain this line can be carried from Negro Point to deep water at Sand Point with a saving both in distance and expense, while at the same time (should a terminus be made there,) it would assist in forming a

breakwater for the protection of the harbour. And should it be found practicable on examination to carry it through the ridge on the Manawagonish road further to the West, so to connect with the main line near Sutton's mills, it will compare to advantage with the other lines.

It is pretty certain that the lines through Carleton cannot be departed from to any great degree, but a more extended survey than the time and means at my disposal warranted might furnish information that would improve them and at the same time diminish their cost. Indeed in works of so heavy a nature and likely so seriously to affect the value of property through which they pass, the slightest improvement in location would, in construction, many times repay the expense of any survey that *could be made*.

It has been proposed to bridge the harbour from Navy Island to the Round Reefs near Hilyard's wharf, but in order not to prevent the navigation of the St. John river as at present conducted, it would be necessary to attain such an elevation (as shown by the profile plans,) as would prevent a junction with our present railway, except by grades steeper than could be recommended, beside which the cost of the structure and its approaches would probably exceed one million dollars. If, therefore, it should not be deemed expedient at first to erect so expensive a work as a bridge at the Falls to connect through Portland, with the present line, the much more expensive one from Navy Island is out of the question, and there only remains to choose the best line on either side to deep water and connect by ferry.

Terminal Lines on Eastern side St. John Harbour.

Having disposed of the different feasible lines on the West side, it only remains now to discover at what point it is best to obtain access to deep water on the Eastern side of the harbour from the present railway.

Four distinct plans for doing this have been proposed at different times. One line leaving the railway near the Marsh Bridge passes round the back of the City to the breakwater nearly opposite Sand Point; a second from the present station by a tunnel under the property of the late Judge Chipman to the Market Square; thence by Water street to Reid's Point; a third from the crossing of Mill street, by the head of Union street slip to North Market wharf; and a fourth from the present water terminus across Long and St. Helena wharves to Rankin's wharf nearly opposite Navy Island.

The line by the Back Shore to the Breakwater was surveyed under the late Chief Engineer of the European and North American Railway, and subsequently, by the City Engineer, and in both cases with a view of its being made applicable as a route to a terminus at the Breakwater. Now, whatever may be its fitness for that purpose, or its claims with a view to extending the business limits of the City and increasing the value of its property, it seems unnecessary to spend time in surveying a line that must be very expensive, when the only object sought was the easiest and safest means of extending our present line of railway Westward.

That the second line through Chipman's Hill, whatever its advantages in location, would be too expensive, is obvious, so that only the third and fourth remain for consideration.

Of these, the third is the shortest and probably would be the cheapest in construction, but it is a matter of some doubt if sufficient room can be found without interfering too much with the business proper of the place.

The fourth is the most direct and (Navy Island being the terminus on the Western side,) would reduce the width of the ferry to about 1500 feet, over a portion of the harbour as sheltered from storms and as free from currents as could be found on any other practicable route.

Should either of these lines be adopted, there are so many questions involved which do not come within the province of an engineer to decide, that it is impossible for me to more than indicate that either is feasible and can be constructed (damage to property excepted,) at a very moderate expense.

Estimate of Cost.

The cost of the whole line is influenced so much by the location of this terminus, that I have thought it more satisfactory to make an estimate on the cost of the main line from the American Boundary to the Suspension Bridge, and append estimates which at best can only be approximate of the several terminal lines.

The calculations for the quantities in the following estimate are based upon the requirements of a first class road; the width of roadbed on embankments being 18 feet, with a slope of 1½ to 1, and in cuttings from 24 to 30 feet, according to the material, with the same slope; ballast 1 foot for depth under the sleepers, and a rail weighing 63 lbs. to a lineal yard. A fair allowance has been added to the quantities of earthwork for shrinkage, ditches, &c., while the facilities for approaching the line with plant, and the abundance of good building material for the works (in most cases within a few yards,) are such that the prices affixed are supposed to be ample for their performance. The station accommodation is not intended to be of so expensive a character as on the present railway, but is calculated on a liberal scale, for the country traversed, and the equipment estimated would, properly managed, be sufficient to meet the requirements of a larger traffic than I have ever yet calculated upon.

Estimate of the Cost of the Main Line of Railway from the Suspension Bridge at St. John to the American Boundary.

65 miles of clearing at 200 dollars per mile,	\$13,000	
50 miles of fencing at 700 dollars per mile,	35,000—	\$48,000
2,020,000 cubic yards earth in embankment, at 25 cents,	505,000	
196,400 cubic yards solid rock excavation, at 1 dollar,	196,400—	701,400

Masonry.

696 cubic yards Ashlar in bridge abutments, at 8 dols.,	5,568	
5,205 cubic yards dry rubble bridge abutments, at 7 dols.,	36,435	
15,710 cubic yards culvert masonry, at 4 dollars,	62,840	
6,000 cubic yards rip rap protection walls, at 1 dollar,	6,000—	110,840
1,010 lineal rods of road diversion, at 2 dollars,	2,020	
18 public road crossings,	5,750	
100 farm and other crossings,	1,250—	9,020
155 tons Iron girder bridging in place, at 150 dols. per ton,		23,250
86.74 miles single track, including ballast, sleepers, and laying, at 8,000 dollars per mile,	693,920	
5 per cent. additional for sidings,	34,697—	728,617
Land damages on 100 farms, at 100 dollars each,	10,000—	10,000

Stations.

1 Engine house at terminus,	15,000	
2 Engine houses, intermediate, at 8,000 dollars each,	16,000	
3 principal stations, at 2,500 dollars,	7,500	
5 second class stations, at 1,000 dollars,	5,000	
10 flag stations, at 300 dollars,	3,000	
8 woodsheds and water tanks, at 400 dollars,	3,200—	49,700
Engineering and superintendence, at \$1,000 per mile,		86,750

Forward,

*Forward,**Rolling Stock.*

10 locomotives, at 10,000 dollars each,	100,000	
3 snow-ploughs, at 1,000 dollars each,	3,000	
16 first class passenger cars, at 2,650 dollars each,	42,400	
8 second class passenger cars, at 1,750 dollars each,	14,000	
4 baggage and express cars, at 1,500 dollars each,	6,000	
70 box freight cars, at 700 dollars each,	49,000	
170 platform cars, at 600 dollars each,	102,000—	316,400
		<u>\$2,083,980</u>
Add for contingencies and unforeseen expenses, 15 per cent.,		312,600
		<u>\$2,396,580</u>

Estimate of Terminal Lines, and Bridge over St. John River.

The following are approximate estimates of the cost of different terminal lines connecting the main line with deep water and the present line of railway, damages to property apart.

In the estimate for the line through Portland, the most important item of expense is the bridge over the St. John river, which it is proposed to make on the suspension principle, similar to that at Niagara.

The site, about 150 feet above the toll bridge, is very favorable, the rock on which the towers would rest being at considerable elevation above high tide, and presenting every appearance of being well fitted to receive them and the anchorages. The Eastern bank will require excavation, and the Western some embanking, in order to bring the roadway 75 feet above high tide, as required by law, to permit the free navigation of the St. John river. The span will be 620 feet, being longer than any tubular bridge, and about 200 feet shorter than the suspension bridge at Niagara, which answers the double purpose of railway and carriage road. Comparing the natural advantages in the site, the diminution in span, the work it would have to perform, and the facilities for construction with those at Niagara, the conclusion arrived at is that the cost of the proposed structure would not exceed \$200,000.

By erecting abutments from extreme low water on either side, the span can be reduced to 500 feet, at which a tubular or girder bridge would become practicable, and in stiffness and consequent adaptability for rapid transit, might possibly present advantages sufficient to warrant the extra expense required in its construction. From surveys made, an approximate estimate of the cost of both a suspension bridge of 620 feet, and a tubular one of 500 feet span, has been made, and will be found appended to this report.

Estimate of a Line from West side of St. John River, through Portland to the present Line of Railway.

70,000 cubic yards rock excavation, at 1 dollar,	\$70,000
400 lineal feet trestle bridging, at 20 dollars,	8,000
2,600 cubic yards rock excavation in tunnel, at 5 dollars,	\$13,000
650 cubic yards masonry, lining tunnel, at 8 dollars,	5,200—
Bridges over Mill street, Long Wharf, and two over Straight Shore road,	33,000
Over bridge Simonds street,	1,000
<i>Forward,</i>	

<i>Forward,</i>	
Level crossings, Sheriff street, road to Bentley's house, Ruddock's, and post road,	1,000
1 7-8 miles superstructure and sidings,	20,000

4 3-4 miles superstructure,		38,000
		<u>\$162,100</u>

Deduct saved in construction on Main Line.

30,000 cubic yards earth excavation, at 25 cents,	\$7,500	
2,000 cubic yards rock excavation, at 1 dollar,	2,000	
134 cubic yards culvert masonry,	656	
7 1-10 miles of superstructure,	5,600—	15,756
		<u>\$146,344</u>
Add approaches on Eastern side, and ferry-boats, as before,		91,000
		<u>\$237,344</u>

A considerable saving may be made in a line to deep water, by stopping the Carleton Shore line at or near Front Row, and making the level of the terminus or wharves about 20 feet above tide level, in which case the cost, with the necessary hoists for heavy freight, would probably not exceed \$100,000.

It may be remarked here that damage to property, unless borne by the districts respectively traversed, would form on some of the lines a considerable additional charge. The line through Portland will be the most expensive in that respect, while that by Negro Point to Sand Point will be very trifling.

In comparing the merits of a continuous line by bridge over the Falls and through Portland, with that through Carleton and by ferry, it must be remembered that a large additional expense will be continually incurred in running the ferry-boats. It admits of very little doubt but that this expense, and the loss of traffic from detention in transit of passengers and light freight, would much

more than meet the interest on the extra expense required for the construction of a bridge, so as to make the connection with the present railway complete.

Estimating, therefore, on a through line from the present railway to the American boundary, we have the following results:—

86½ miles from boundary of the State of Maine to Suspension Bridge, costing, as per estimate,	\$2,366,580
1 86-100 miles through Portland and over bridge at Falls, as per estimate,	351,200
88 6-10 miles,	<u>\$2,747,780</u>

By this estimate it appears the European and North American Railway can be extended to the American boundary, and fully equipped, for \$2,750,000, or a little over \$30,000 per mile. The cost of the New England roads average about \$44,000 per mile, and the present European and North American Railway nearly the same. The Grand Trunk cost about \$40,000, and the Nova Scotia railways about \$50,000, while both of these are inferior in character to the proposed line. After allowing an ample margin for additions usually made in rolling stock on all roads after completion, and which tend to swell the cost of those now in operation, the average of lines on this continent cannot be set down at much less than \$40,000 per mile.

To show that the difference in the cost of these, and the estimate for Western Extension, is not without reason, it is only necessary to mention a few particulars which tend largely to swell the cost of other roads, but, in this case, are either very small or unknown. Save that, on the first ten miles from the Suspension Bridge, the grading is very light, the country traversed after leaving the St. John river being mostly on the heads of those streams emptying into the Bay of Fundy, causes the amount of bridging to be uncommonly small, lakes and bogs, ordinarily requiring large sums in draining, filling, &c., are almost entirely avoided, and in case of connecting with the European and North American Railway, the outlay for terminal buildings (usually amounting to a large sum per mile,) will not be required.

By a reference to the tables, it will also be seen that the line presents many features highly favorable to its being operated at a moderate cost. The length of curved line is only 25 miles, or little over one-fourth of the whole distance, while but a very small portion of this curved line is on a less radius than 2,900 feet. Of heavy grades, only 14 miles are varying from 45 to 52 3-4 feet per mile, and, of this distance, 10½ miles descend Eastward, or toward St. John, a result of great importance with reference to the carrying capacity of the road, and in view of the heavy lumber traffic expected in this direction.

Deviations from Route Adopted.

Some deviations from the course adopted, and still within the requirements of a line *via* the Douglas Valley, being urged at different times, as possessing peculiar advantages, have occupied a portion of my attention, and require some notice here.

Route by South Side of Oromocto Lake.

First among these, I would refer to that, already noticed, up the North-West Branch of the Oromocto river, and by the South side of the Big Oromocto Lake, across the valley of the Maguaguadavic, and by Trout Brook to the St. Andrew's Railway.

It was ascertained during the course of the summer's work, that the level of

the water in the Maguaguadavic and Cheputneticook Lakes differed but little from that of those of the Oromocto and Kedron, and also, that the bed of the Maguaguadavic River fell at the rate of 15 feet per mile after leaving the lake. The distance on the course of the river to the point where it must be crossed by a line South of the Oromocto Lake, was known to be not less than ten miles, while from the shore of the lake it could not be more than three. The conclusions arrived at from this information was, that the obstacles in the way of getting a line in this direction were of a serious nature, but, in order to leave the matter as little doubtful as possible, Mr. Stewart was dispatched with a small party in January last, to traverse and level what was pointed out as being the most favorable ground accessible on both sides the Maguaguadavic.

This line, as also one run by J. Wilkinson, Esq., C. E., and another by Wm. Mahood, Esq., in 1860, are shown on the General Map, and profiles of each accompany the other drawings.

The result of this exploration is as follows:—The Maguaguadavic at this point of crossing is in a deep valley, 220 feet above tide level, while the lake is 371, and the table land on the West side of the valley 465. As the high ground on the South of the Oromocto Lake extends a considerable distance toward the river, it appears impossible to make the descent without two miles of maximum grade, and work of a very heavy nature. On the West side of the river the ascent may be accomplished by three and half miles of the same grade, and with less expensive works than was at first supposed, but still the distance will be longer and the cost greater than on the adopted line. It has been proposed to carry the line farther toward the South, below the Kedron Lakes, and although by thus increasing the distance the valley of the Maguaguadavic is reached with easier work, yet it is heavier and the grades are steeper in leaving it and gaining the elevation of the high ground to the Westward than would be desirable. In fact, all the information I have been able to gather respecting this country, leads unavoidably to the conclusion that no line can be found here without sacrificing something, either in distance, works, or grades, and this without furnishing any corresponding benefit in traffic.

Spruce Lake Route.

Another deviation from the adopted line has been proposed near St. John. Leaving the Suspension Bridge, and following nearly the course of the St. Andrew's road four miles, it then turns to the right of Spruce Lake, and following the right shore of Menzie's Lake, passing between Belvidere and Nelson Lakes, and to the right of Loch Alva, it joins the adopted line a little below Eagle Rock on the Nerepis, and near the entrance to the Douglas Valley. This line was explored by parties for A. C. Morton, Esq., C. E., in 1853, with a view to avoid the expensive rock cutting and tunnelling on the line following the shore of Grand Bay. By a profile of their survey, which is in my hands, it appears this line would be nearly two miles longer, and though some of the work is not expensive, yet to ascend the high grounds to the North of Spruce Lake, and again make the descent to the valley of the Nerepis, would require steeper grades and more expensive works than any on the adopted line. As this exploration was hasty, and, no doubt, susceptible of improvement, it was at first my intention to have examined this district, with a view to finding a less expensive line than by the river, but having succeeded in avoiding the necessity for tunnelling, and having obtained a line which presents no excessively heavy work, and has more favorable grades than could be hoped for on the Spruce Lake route, I did not consider myself justified in expending the time and money required for its thorough exploration, while the necessity of devoting all the remaining portion of the season fit for such work, to the survey of the Fredricton branch, would have prevented my doing so, had it been deemed advisable.

FREDERICTON BRANCH.

The survey of this line, made in the months of November and December, 1864, and January, 1865, leaving the main line at the crossing of the North-West Branch of the Oromocto, skirts along between the high ground and freshet level until after passing the Rushagonis River, 10½ miles from Hartt's Mills, thence rises to a summit 105 feet above tide level at Baker's Brook; crossing which it descends with a grade of 53 feet per mile for 5,000 feet, and through a very easy and level country reaches Mill Stream, near its head, and following its left bank on a nearly straight line, with light works, and (with the exception of 3,000 feet of the maximum,) easy grades, approaches the St. John River near Morrison's Mills, and thence, with very easy work and nearly a straight line, enters the town at the rear of the principal streets, and doing little damage to property.

By making the terminus at Odell's Grove, the whole distance is 21½ miles from Hartt's Mills, which is considerably shorter than the travelled road, and the nearest approach to an air line that I think will be found practicable.

The line was extended to the grounds of the Agricultural Society, which, though adding very little to the cost of the line, is nearly one-half mile longer.

The ground in Fredericton, and its immediate vicinity, is so favorable for railway construction that there will be no difficulty in taking the line to any point in it that the necessities of trade, or the interests of the community, may desire.

Of the characteristic features of the work there is very little to be said. As will be seen by reference to the tables appended, the curvature and gradients are both favorable, while the works are more than ordinarily light. An iron bridge of 100 feet span is proposed over the Rushagonis, which, with three small bridges at other points, will cover all demands for that class of work.

This line traversing nearly its entire length through barrens and unimproved land, damages to property, except in the vicinity of Fredericton, will be light.

The following estimate, based upon the requirements of the same class of road as the main line, shows that it can be constructed for \$495,357, or about \$22,000 per mile.

Estimate of Cost of Fredericton Branch Line.

20 miles of clearing, at 200 dollars,	\$4,000	
21½ miles of fencing, at 700 dollars,	15,050—	\$19,050
397,840 cubic yards earth excavation, at 25 cents,	99,460	
5,000 cubic yards rock excavation, at 1 dollar,	5,000—	104,460

Masonry.

472 cubic yards masonry in crumb rubble, at 8 dollars,	3,776	
635 cubic yards masonry in dry rubble, at 6 dollars,	3,810	
2,300 cubic yards masonry, culverts, at 4 dollars,	9,200—	16,785
45 tons iron girder, Rushagonis, at 150 dollars,		6,750
21½ miles superstructure, at 8,000 dollars,	174,000	
5 per cent. for sidings,	8,700—	182,700
Rolling stock, at 8,000 dollars,		88,000
Stations,		8,000
Land damages,		5,000

\$430,746

Superintendence and contingencies, 15 per cent.,

64,611

\$495,357

E. R. BURPEE.

APPENDIX.

Estimate for Railway Suspension Bridge, 620 Feet Span, over St. John River at Falls.

1100 cubic yards masonry in towers, at 20 dollars,	\$22,000	
1,500 cubic yards masonry in abutments and anchorages, at 12 dollars,	18,000—	\$40,000

Cables and Suspenders.

12,000 strands No. 10 wire, 1,000 feet long, 600,000 lbs., at 15 cents,	90,000	
20,000 lbs. wrapping wire, at 20 cents,	4,000	
24,000 lbs. wrought iron in suspenders, at 12 cents,	2,880—	96,880

Saddleplates and Anchorage.

25 tons cast iron, at 80 dollars,	2,000	
30,200 lbs. anchorage chains, at 12 cents,	3,624—	5,624
600 lineal feet truss, at 20 dollars,	12,000	
4,800 cubic feet timber in floor girders, at 60 cents,	2,880	
Flooring,	4,000	
Stays and painting,	2,000—	20,880
Excavation for towers, anchorage, &c.,		2,000

\$165,384
16,538

Add contingencies,

\$181,922

Estimate for Tubular Girder Bridge across St. John River, 500 Feet Span.

2,700 cubic yards masonry, at 20 dollars,	\$54,000	
1,500 tons iron work in girder, at 150 dollars,	225,000	
Suspension staging, say,	182,000	

\$461,000

The PROVINCIAL SECRETARY.

SIR—

I beg to submit, for the information of His Excellency the Lieutenant Governor in Council, the Accounts and Reports of the operations on the European and North American Railway for the year ending 31st October, 1864.

Quarterly Accounts of all expenditures, liabilities, and receipts, have been furnished in accordance with the law.

The Traffic Accounts and Vouchers have been audited in St. John by Mr. Johnson, from the Auditor General's Office.

The following are the Capital Account, Revenue Account, General Balance, and Abstracts, to the end of the financial year.

CAPITAL ACCOUNT.

\$18,729 68		\$21,634 45

I append a Report from Mr. Boyd, Engineer and Superintendent.

The amount expended by authority of Government on Capital Account for the year 1864, is as follows:—

Norton Station Platform,.....	400 00
Norton Station Siding.....	162 50
Safety Chains for Cars,.....	454 94
New Store Room, St. John Station,.....	38 75
Cattle Guards, Rothesay,.....	15 40
Cattle Guards, Moncton,.....	10 20
Fencing,.....	61 90
Enlarging Freight Office, Peticodiac Station,.....	21 23
Slope to Platform, Peticodiac Station,.....	61 12
Gate and Railing, Freight House, Point du Chene Station,.....	16 59
Engiaccring,.....	621 83
Brackets for Lamps, First Class Cars,.....	19 22
Registering Lands, Torryburn,.....	2 40
Mooring Post, Moncton Wharf,.....	4 00
Blowers to Engines, "Sussex" and "Scadouc,".....	20 00
Making Road to Guerney's Siding,.....	19 60
Portion of Commissioners' Salary and Office Expenses, ...	170 42
	<u>\$2,110 10</u>

The net surplus Revenue for the year, excluding damages arising from the accident at Rothesay in February 1863, has been \$41,427 74.

The damages and law expenses connected with the Rothesay accident amount to \$9,455 21.

Early in the year, a suspicion was entertained that J. H. Beek, the Station Master at St. John, was not keeping his accounts properly.

While an investigation was being held, Beek went off clandestinely to the United States, and it was found that he was a defaulter to the extent of \$1,282 22. He had managed to conceal this deficiency, which had extended over a considerable period, by borrowing from his friends to make up his monthly settlements.

A Deep Water Terminus at St. John, was arranged for early in the year, and is nearly finished at a cost of about \$21,000, not including land damages which have to be appraised.

Respectfully submitted,

R. JARDINE,

CHAIRMAN.

ENGINEER AND SUPERINTENDENT'S REPORT.

SAINT JOHN, N. B., Dec. 1st. 1864.

R. JARDINE, Esq.,
Chairman of Railway Commissioners.

SIR,—

I beg leave to submit the following Report of the Railway operations during the year ending 31st October last.

The following Table shows the Receipts and Expenses and net Revenue of 1864 as compared with those of 1863.

REVENUE.	1863.		1864.	
Passengers,	57,832	70	64,292	52
Freight,	61,388	78	71,999	74
Mails and Sundries,	10,051	04	8,765	60
	129,272 52		145,057 86	
EXPENSES.				
Locomotive Power, G.	28,319	75	33,691	99
M'dse. and Passenger Cars, H	17,013	03	22,008	64
Maint. of Way and Buildings, J.	24,471	83	26,295	04
General Charges, K.	18,729	68	21,634	45
	88,534 29		103,630 12	
NET REVENUE.	\$40,738 23		\$41,427 74	

The per centage of Revenue from different sources, and that of Expenses of different departments, are given in Table No. 16. The Law Expenses connected with the Rothesay Accident, not being legitimate charges against the actual cost of working the Road, are not taken into account in this place.

The increase in total receipts from Passenger Traffic is \$6,459 82.

The number of Passengers has increased 8,866. Of these 8,177, or 92.2 per cent., were Way Passengers, with an average mileage of 20.42 miles, and 689 or 7.8 per cent. through Passengers, whose average mileage was 107.41 miles. Of 139,554, the total number of Passengers carried, 95 per cent. were Way Passengers.

As regards Classes, the First Class Way Passengers have *decreased* 1,095, the Second Class have *increased* 9,272. The First Class Through Passengers have *decreased* 1,721, the Second Class have *increased* 2,401. On the whole the *decrease* in First Class Passengers has been 2,816, or 3·04 per cent., and the *increase* in Second Class 11,682, or 30·46 per cent.

The effect of this decrease in the higher paying Passengers has been counterbalanced in the case of the Way Traffic, by the increase in numbers and greater average mileage, which latter is 1·06 mile greater than in 1863, the average receipts per Passenger shewing a corresponding increase of 2·1 cents. With the Through Traffic, however, this is not the case; the *increase* in the average mileage is ·732 of a mile, but the average receipts per Passenger have *decreased* 10·03 cents. The average receipts per Passenger have been also reduced by the greater number of Family Tickets used, 22,443 Passengers having passed on them last year, against 18,090 in 1863. On the whole the average receipts per Passenger have increased 1·8 cent. See Tables No. 10, 11 and 12.

The total receipts from Freight Traffic have increased \$10,610 96.

The Way Freight has increased 7,904 tons, and the Through Freight 2,117 tons, in all 10,021.

The average mileage of Way Freight has decreased 1·23 mile, and of Through Freight ·64 of a mile. The average receipts per ton have decreased ·066 of a cent on Way Freight, and ·093 of a cent on Through Freight, and ·05 of a cent on both.

The average receipts per ton per mile have decreased ·083 of a cent on Way Freight, and increased ·032 of a cent on Through Freight, a decrease of ·094 of a cent on both. This is owing to the greater per centage of Fourth Class Freight carried.

The Way Freight was 83·6 per cent of the whole quantity carried.

The per centage of Dead Weight hauled is less than in any former year, and the statement shows that the cars have, on the average, been fully loaded in one direction, so that no dead weight has been hauled which could have been avoided. Any measure that will have a tendency to draw up freight to the road will operate beneficially in reducing still further the percentage of dead weight. Of the 55,355 tons of Freight which passed over the road, 38,309 tons, or 70 per cent., came West, leaving of course a great many cars to be hauled back empty. The Passenger Traffic is slightly the other way, the number going East exceeding those going West by 5,158, or 3·7 per cent. See Tables 13, 14 and 15.

It is satisfactory to note the somewhat slow but steady increase in the Local Traffic, both in Passengers and Freight. Experience in other countries has shewn that the

Local Traffic is most valuable, and that it is important that it should be fostered in every way. It is said that on the English Railways 70 per cent. of the passenger fare is paid by passengers whose average mileage is not more than seven miles, and in the freight Traffic similar results have been observed. Some of the Railway Companies in the United States have proved by experience that the local traffic is not to be neglected with impunity.

The receipts from Mails and Sundries are less than those from same sources in 1863 by \$1,285 44. This source of Revenue fluctuates from so many causes that no very close estimate can be made of it.

The Locomotives ran 9,850 miles more during the past year than in 1863. The Car mileage shows an increase of 45,462 miles, and the gross tons moved one mile were 851,813 more than in 1863.

The expenses of Locomotive Power have increased \$5,372 24. Of this \$3,145 is in fuel, and the remainder in repairs. This excess in fuel is due in part to additional mileage and weight moved, in part to advanced price of Wood, and in part to a deficiency in the Stock on hand. There had not been an opportunity to take an accurate measurement of the stock for two years, and the deficiency is now all charged against the consumption of 1864.

The Locomotive averages, given in Tables 6, 7, 8 and 9, compare favorably with those of former years, and with those of other lines.

The expenses of Merchandise and Passenger Cars have increased \$4,995 61, chiefly in cost of repairs. As the wooden trucks wear out they are being replaced with iron ones; fourteen of these were put under the cars during the year. If the Platform Freight Cars were constructed entirely of iron, I have no doubt a large saving would be the ultimate effect.

The increase in the cost of Maintenance of Way was caused altogether by the great quantity of slurry removed from the ditches.

An accident occurred at Pine Hill in January last, which increased the General Expenses \$1,661 27. Two engines were running from Moncton to Shediac with the Snow Plough. Owing to the blocking on one side of the truck having fallen out, the the Snow Plough settled down low enough to strike the end of the rail of the siding. The Snow Plough and leading Engine were thrown across the track. The second Engine struck the other full on the side, doing serious damage. Providentially no one was hurt. An alteration has since been made in the Snow Plough which will prevent the occurrence of a similar accident in future.

The Track is in good order: 6,490 sleepers, 686 chairs, and 204 rails have been

renewed during the year; 21,000 sleepers have been contracted for at an exceedingly moderate rate, to be laid next summer between Moncton and Shediac. The sleepers on that district have now been laid between eight and nine years.

The Freight Siding at Norton has been lengthened and a Freight Platform built.

More of the Cars have been fitted with safety chains. The benefit of these has already been experienced in cases where derailment has taken place.

Cattle guards have been put in at Rothesay and Moncton.

The freight room at St. John is very limited, and much inconvenience arises from having to receive and discharge freight in a building which is barely large enough for either purpose singly.

Three First Class, three Second Class, and two Express Cars have been varnished; three First Class and one Second Class have been painted and varnished; and twenty-six Box Freight Cars have been painted; and fifty wheels have been renewed.

The water terminus at St. John, now nearly completed, is already found to be a great convenience. There will be sufficient track to hold thirty freight cars, and 1120 feet of wharf for the accommodation of vessels and scows, besides 28,000 square feet of piling ground. It will be seen from this that the most has been made of the area appropriated for the terminus.

I did not take charge of the line as Superintendent until September last, and I must take this opportunity of acknowledging the courtesy with which Mr. Carvell, the late Superintendent, who was then retiring, afforded me all the assistance in his power to obtain an insight into the duties of the office. The excellence of the system introduced by him becomes more apparent the more I become acquainted with its details.

I cannot help expressing at the same time my satisfaction at the hearty assistance I have received from every member of the Staff. Taking charge as I did without much previous acquaintance with the routine of duties, I was more than ordinarily dependent on their co-operation and I must say that but one spirit seems to actuate them individually and collectively, and that is to advance the interests of the Railway by every means in their power.

I am, Sir,

Your obedient servant,

J. EDWARD BOYD,

ENGINEER & SUPERINTENDENT.

ANNUAL RETURNS

OF

TRADE AND NAVIGATION

FOR THE

Province of New Brunswick,

FOR THE YEAR 1864.

FREDERICTON.

G. E. FENETY, PRINTER TO THE QUEEN'S MOST EXCELLENT MAJESTY.

1865.

# TRADE AND NAVIGATION.

---

## Annual Returns of Trade and Navigation for the Year 1864.

---

CUSTOM HOUSE, ST. JOHN, N. B., 18th July, 1865.

To His Excellency The Hon. ARTHUR HAMILTON GORDON, C. M. G., Lieutenant Governor, Commander in Chief, Imperial Commissioner of Customs, &c. &c. &c., of the Province of New Brunswick.

MAY IT PLEASE YOUR EXCELLENCY,

I herewith have the honor to submit to Your Excellency the Annual Returns of Trade and Navigation for the Province of New Brunswick for the year ending 31st December, 1864, which have been compiled for the Imperial Blue Book, and for the information of the Local Legislature.

These Returns will shew Your Excellency that as regards the Trade, Navigation and Revenue of New Brunswick during the period mentioned, New Brunswick has no great reason to complain. The Imports and Import Revenue have greatly increased over the previous year, and there has also been a slight increase in our Exports. Our ship building operations have also been increased, although with less remunerative results to the builders than during the previous year. The mechanical and labouring population of the Province have had ample employment and liberal wages during the first part of the year, while all descriptions of provisions have been abundant and very reasonable in price. Towards the end of the year, as the value of new Ships in the Liverpool market decreased, and the prospects for ship-builders became more discouraging, wages receded in proportion, and the demand for skilled labour diminished; not, however, to such an extent as to throw a large number of persons altogether out of employment, as the quantity of new shipping on the stocks was still large, and builders, although employing fewer hands, had to proceed with the work so as to bring their property to a market. The crops during the past year were good, and with the exception of hay, which was very light on the uplands, were quite equal to an average.

The amount of Duties received in the Province in 1864 having been much in excess over the previous year, and the importations having been much larger than the demands of the country required, with a declining consumption on the part of a large portion of the working population, left much heavier stocks of goods in the hands of the importers at the close of the year than is usually held by them, and must have a very serious effect on the importations of the present year. The large amount of outfits and fastenings for new ships which were imported last year would account for a small portion of the increase of our Import Revenue. Our wood trade still continued depressed during 1864; and although the shipments did not very materially fall off during the Imperial year, the prices in England were low, while they were well maintained in this country, which would have the effect of leaving any profit on such transactions in the hands of the

lumberers who bring the logs to a market, and but little, if any, in the hands of the shippers. The high rate of interest prevailing in England during the past year has had a very depressing effect on our trade, and more particularly on our shipbuilding interests, the demand for ships in England generally decreasing as money becomes scarce and interest advances. Last year the rate of interest in England ranged as high as nine per cent. and never fell below six per cent. The Banks in this country being limited to six per cent. interest, has also a tendency during a period like last year, when the rates in England exceeded our legal rate, to curtail the circulation of the country, as it could not be expected that the Banks here would lend much money at six per cent. if they had to pay nine per cent. for the balance against them in England. These sudden contractions on the part of the Banks, necessitated by their being limited to six per cent., are dangerous to persons doing a large business on a small capital, and who depend in a great measure on the accommodation furnished from time to time by the Banks. The most advantageous branch of our trade in 1864 has probably been that of shipowning, which, although not exceedingly prosperous for some time past, has been the means of introducing into the Colony a large amount of gold or its equivalent in exchange, to pay for our heavy imports during the year, as a considerable amount of our new shipping which was sent forward for sale remained unsold at the close of the year, and some of those vessels which were sold did not realize any thing like the cost of their production. Nearly all the smaller class of vessels belonging to this Port, and employed in the Coasting, West India, and Gulf of Mexico trades, have been doing tolerably well during 1864, although there are some of them which barely paid their running expenses and insurance. Many persons in this community, representing nearly all the different professions and trades in the country, have been investing their means in small shares of vessels, and some of them with very favourable results. If the success attending this kind of business in some of the shipowning Ports in the United States and Nova Scotia, can be taken as a criterion, the prospects here would be very encouraging, as this is essentially a shipbuilding country, where ships can be produced, with reference to their quality, fully as cheap as in any part of the world.

It is now a gratifying feature of the business of this country that there is scarcely a foreign mail arrives here which does not bring a remittance to some of the people of New Brunswick on account of the earnings of their vessels abroad.

The quantity of new shipping registered in the Province during last year, including those which proceeded to England under Governor's passes for the purpose of being registered there, was 163 vessels, measuring 92,605 tons register. The largest amount of new tonnage registered, &c. in the Province during any one year, was in 1854, when it reached 135 vessels, 99,426 tons, which apparently is somewhat larger in tonnage than in 1864. If the tonnage registered in 1864 had been measured under the Act which was in operation in 1854, the amount would have been about ten per cent.

more than it now is, or about 101,865 tons in 1864. This would shew a greater amount of tonnage registered, &c. in 1864, than was ever recorded in the history of the Province. We may reasonably look, however, for a great falling off in the quantity produced during the current year, as at present selling prices in Liverpool, New Brunswick built ships would scarcely pay their bills. Of the tonnage registered, &c. last year, 53 were ships measuring 59,724 tons register, 52 barques, 23,410 tons, 28 brigs and brigantines, 6,024 tons, 23 schooners, 2,409 tons, 6 woodboats, 352 tons, and one steamer, 686 tons. These vessels were built at the following mentioned places:—At Saint John and its immediate neighbourhood, 36 vessels, 35,711 tons; at places on the Kennebecasis River, 8 vessels, 3,709 tons; at places on the Saint John River, including Oromocto and the Grand Lake, 15 vessels, 2,443 tons; at Saint Martins and Tynemouth, 10 vessels, 5,820 tons; at Musquash, 5 vessels, 1,205 tons; at Saint Andrews, 9 vessels, 3,557 tons; at Saint George, Lepreaux, and Pennfield, 5 vessels, 836 tons; at Moncton, 6 vessels, 3,768 tons; at Hillsborough, Harvey, and Hopewell, 8 vessels, 1,973 tons; at Dorchester, 6 vessels, 1,536 tons; at Sackville, Tidenish, and Port Elgin, 6 vessels, 1,655 tons; at Shediac, 1 vessel, 384 tons; at Buctouche, 1 vessel, 499 tons; at Richibucto, 4 vessels, 2,839 tons; at Miramichi, 21 vessels, 17,113 tons; at Dalhousie, 2 vessels, 850 tons; at Caraquet, 1 vessel, 35 tons; at Ports in Nova Scotia, 8 vessels, 3,017 tons. These last mentioned vessels were fitted out in Saint John, and were built principally for Saint John owners. Of the total quantity of new shipping registered last year, 61 vessels, measuring 51,730 tons were surveyed by Lloyd's officers to class 7 A. This is the highest classification our Colonial ships receive, and means that such vessels stand on Lloyd's Register for 7 years as regards the hull, and when they proceed to England and complete the requirements of Lloyd's as regards their outfits and ground tackle, they obtain the full classification of 7 A 1. This grade of vessels must be constructed principally of pitch pine or haematack, but as the supply of the former description of wood has been entirely cut off for the last three or four years, our builders have had to depend on the haematack of the country for building such vessels. Our Railway, therefore, has been the means of bringing to the Saint John market a large quantity of haematack and other ship timber, cut from the new grounds in the vicinity of which the line passes, which otherwise would not have been available for such a purpose. 43 vessels, 28,614 tons, were surveyed by Lloyd's officers to class 4 A, such vessels being constructed principally of spruce; 5 vessels 1,942 tons, were classed 5 years at the office of French Veritas, which Society is generally termed "French Lloyd's." This Society, for the classification of vessels, has been in operation for many years, the chief office being in Paris, with branches in Liverpool, London, and other principal Seaport Towns. Last summer their Surveyor General visited this Province, and appointed Capt. Marsters, of Saint Martins, N. B., Surveyor for the Society in New Brunswick and Nova Scotia; and their recently appointed Surveyor informs me that during the latter part of the year, since he has been acting

in this capacity, he has classed 23 new vessels in his district. This description of classification appears to satisfy the different interests concerned, so far as regards spruce ships built for the purpose of being owned by the people of the Province, although for selling in the English market a classification at British Lloyd's appears to be essential. This French Society allows a classification of 5 years for spruce vessels with extras, whereas British Lloyd's only allow 4 years for a similar description of vessels. The Register Maritime of Bordeaux, (which Society is sometimes termed new French Lloyd's,) has also a Surveyor for the Provinces of New Brunswick and Nova Scotia, residing at Digby, N. S., who classed last year, of the shipping registered in this Province, 9 vessels measuring 2,715 tons, for grades ranging from 5 to 7 years. Some of the vessels surveyed, while building, by the officers of British Lloyd's, were afterwards classed at the offices of either French Veritas or Register Maritime, for the purpose of securing a classification of 5 years instead of 4. Of the vessels which were built without reference to survey or classification, 32, measuring 6,929 tons, were over 100 tons; and 13, measuring 675 tons, under 100 tons. It will be seen from these figures that of the total quantity registered last year, viz. 92,605 tons, 80,344 tons were built under the rigid inspection of British Lloyd's Surveyors, (of whom there are two in this Province) and 4,657 tons under the inspection of the Surveyors for these two French offices, making altogether 85,001 tons built under inspection, or about 92 per cent. of the total quantity. This system of inspecting the vessels while building has no doubt tended greatly to raise the quality and character of our ships, and make them more valuable either for owning in the Colony or selling in England. The value of our ships in the Liverpool market fluctuated considerably, and gradually receded towards the close of the year, a number of them at that time remaining unsold. At the commencement of the year vessels of the 7 year's grade realized from £8 to £9 sterling, and such of them as had been previously contracted for brought even higher prices than these, ranging from £9 to £9 17 6; but later in the year they gradually receded to about £8, and in some cases even lower than that, more particularly in cases where sales had to be forced to realize the advances made to the builders in this country. In one case a seven year's North Shore built vessel was sold in Liverpool for £6 5s. sterling per ton, which is much less than the cost of production. The average value therefore of the vessels of that grade registered last year throughout the Province might fairly be stated at £8 sterling, which is certainly as low a figure as they could be produced for. This would make their total value (viz. 51,730 tons, equal to about 55,000 tons Carpenter's measurement, by which vessels are usually bought and sold,) £440,000 sterling. The vessels of the 4 year's grade, and those classed at the offices of French Veritas and French Register Maritime, ranged in value from £6 to £7 10s. per ton, and would average about £6 10s. sterling per ton. Of these three grades there were 33,271 tons registered, equal to about 37,000 tons Carpenter's measurement. This amount of tonnage at £6 10s. per ton would represent £240,500 sterling. Of the unclassed vessels, 6,929 tons, equal to

about 8,000 tons old measurement, were upwards of 100 tons register, ranging in value from £5 10s. to £6 10s., and would average about £6 per ton, equal to £48,000 sterling. The unclassed vessels under 100 tons register, viz., 675 tons register, would represent about 1000 tons Carpenter's measurement, and were worth about £5,000 sterling. The total value of our new shipping registered last year would therefore amount to £733,500 sterling or \$3,520,800.

The new vessels built in this country for sale in the United Kingdom generally reduce their value to the extent of 15s. sterling per ton, after paying disbursements, by carrying home a cargo of wood, and this amount the builder calculates as a part of the price of his vessel. The new tonnage proceeding to England for sale last year might be estimated at 85,000 tons, which at 15s. per ton would make £63,750 sterling, or \$306,000. The total value of the new shipping therefore, and the first freight home, would amount to \$3,826,800 against \$3,901,200 in 1863. It will be seen that although the quantity registered, &c. in 1864 was considerably in excess of 1863, the value was a little less. This is owing to the depreciation in the value of our Colonial ships which has taken place in 1864 as compared with 1863. The quantity of new shipping which will be put afloat during the current year will probably be much less than in either of the two preceding years, as the demand has so seriously abated and the value has so materially been reduced. Two of our shipbuilders, who for several years past have probably launched more tonnage than any other two persons here, have abandoned their business under pecuniary difficulties. The total quantity of new ships built in New Brunswick during the last forty years was 4,169, measuring 1,584,386 tons, and the quantity built in 1864 was much above an average of these years. The total number of existing vessels, old and new, on the Registry Books of New Brunswick on the 31st December last, was 958, measuring 233,225 tons, which is much in excess of any previous year in the history of the Province. This is partly owing to the actual increase of shipping owned by the people of the Colony, partly to the fact that some of the purchasers of our New Brunswick ships find it more convenient for certain reasons to keep their vessels registered here, for a shipowner can now have his vessels registered in any British registering port, without reference to his place of residence, and partly to the fact that a number of American vessels which came here for British Registers during the troubles in the States, still remain on the Registry Books of New Brunswick. The number of United States built vessels registered at this Port during last year was 11, measuring 9,035 tons register, of which 3 were steamers. Two of these steamers, viz., the "Foong Suey" and the "Fire Queen," were very large vessels, intended to run on Chinese rivers, and after being registered here they immediately started for China. They were probably sent here for British registers merely for the purpose of being protected from Confederate Cruisers on their voyage out to China. At Saint Andrews there were 10 vessels of United States build, measuring 2,481 tons, registered during 1864. The number of United States vessels sold

and transferred to British subjects throughout the British Dominions during the year 1863 was 608, measuring 328,665 tons register. The total number of steamers registered in New Brunswick on the 31st December last was 27, measuring 4,685 tons register, which is the net tonnage after deducting the space occupied by machinery, boilers, crew, &c. Three of these, viz., the "Foong Suey," "Maria," and "Flora," have never been here since they were registered, and are not owned by any persons in this Colony. The other steamers registered in New Brunswick were employed in the trade of the Colony, and were owned by residents of this country. The total value of all the shipping registered in New Brunswick on the 31st December last, viz., 233,225 tons, at £5 sterling per ton, would be £1,166,125 sterling, and deducting £206,125 sterling as the value of those vessels registered in the Province, but not actually owned here, it would leave £960,000 sterling as the value of shipping owned in New Brunswick. Freights during 1864 were not quite so good for New Brunswick vessels as they were in 1863, although nearly all the vessels owned here did a fair remunerative business both in the Coasting Trade to the States, and in the East and West India, and other Foreign Trades. Freights to and from the West Indies varied considerably during the year, but an average of such freights may be fairly stated as follows, viz:—From Saint John to the West Indies, boards \$8.50 per thousand superficial feet; box shooks 24 cents each. From the West Indies to the United Kingdom and the Continent of Europe, sugar and molasses £2.15 sterling per ton net weight delivered. Vessels usually deliver on an average one ton of sugar in hogsheads for every register ton; of box sugars 10 per cent. more than register tonnage; and of molasses 20 per cent. in excess of such tonnage. Outward coal freights from England to the East Indies on the average of the year declined from 10 to 20 per cent. below the rates of the preceding year. Coal freights to Callao advanced a trifle on the average, while the same freights to Rio Janeiro receded a little on the average; outward freights from England to the Australian Colonies were also much depressed during 1864, and lower rates prevailed during that period than for many years previous. Homeward freights from the East and Pacific were lower in 1864 than in 1863, Bombay rates having fallen as low as 7s. 6d., the maximum rate being 70s. Guano charters to the United Kingdom ranged from 65s. to 80s. The recent disturbance between the Peruvian Government and Spain affected the earnings of some of our large ships which were employed in the guano trade, as the demand for tonnage in that direction was very limited during last year. Freights between the United States and Europe were also very dull during 1864. Saint John ships, however, obtained a very good share of this trade, and many of our small vessels were well employed between Ports in the United States and West Indies and South America throughout the year. This class of vessels has also done a very good business carrying coal between Cape Breton and the other coal districts in Nova Scotia, and New York and Boston. Freights for deals from Saint John to the United Kingdom were low during the year 1864, and in some cases would scarcely leave anything to the ship after pay-

ing disbursements and insurance; some vessels lost money in this trade last year. Low freights appear to be necessary now to our shippers of deals, as prices of our wood in England, since the equalization of the Foreign and Colonial Timber Duties have been very depressed, and would not admit of high freights without loss to the shippers. The rates from Saint John to Liverpool opened at £2 17 6 sterling per standard at the commencement of 1864, and closed at the end of the year at £3 with little fluctuation throughout the season. The lowest point reached was £2 16 3, and the highest, viz. in June, was £3 6 3. In July they were £3 2 6 to £3 5s. Anything below £3 is considered by shipowners a losing business for a good ship. Freights from Saint John to London and Out-Ports are generally a little higher than the rates mentioned, say from 5s. to 10s. per standard. North Shore freights may be quoted about the same. The following rates from Saint John to Liverpool during the last seventeen years, will shew the various fluctuations:—

|                                       |               |                    |                                      |                    |   |
|---------------------------------------|---------------|--------------------|--------------------------------------|--------------------|---|
| Latter end of June 1848, £4 sterling; |               |                    | latter end of May 1849, £4 sterling. |                    |   |
| July 1850, £2 18s. stg.               | July 1851, £3 | stg.               | July 1852, £3 3 9,                   | stg.               |   |
| July 1853, £4                         | “             | July 1854, £4 2 6, | “                                    | July 1855, £3 13s. | “ |
| July 1856, £4 3s.                     | “             | July 1857, £3 5s.  | “                                    | July 1858, £3 11 3 | “ |
| July 1859, £2 16s.                    | “             | July 1860, £4 5s.  | “                                    | July 1861, £4 2 6  | “ |
| July 1862, £4 2 6,                    | “             | July 1863, £4 2 6, | “                                    | July 1864, £3 3 9  | “ |

The total tonnage of all nations cleared outwards from this Province in 1864, was 742,690 tons, against 727,722 tons in 1863, and 586,973 tons in 1862. Of the total tonnage cleared in 1864, 346,128 tons cleared from Saint John. The entry of the steamers in the Tonnage Returns, each time they enter and clear from and to places outside the Province, swells up the total amount of tonnage in these returns. The total tonnage entered inwards at all the Ports in the Province in 1864, amounted to 669,796 tons. The excess of the tonnage cleared over the tonnage entered is accounted for by the large amount of new vessels produced in the Colony. Of the total tonnage cleared from the Province last year, 347,271 tons carried cargoes of wood to the United Kingdom, against 359,457 tons in 1863. Of the foreign vessels which carried cargoes to the United Kingdom last year, the Americans secured the principal share, and the Norwegians came next. The vessels belonging to Norway appear to be preferred at the Ports on the North Shore, while the United States vessels generally come to Saint John. The amount of British and British Colonial tonnage which carried cargoes from New Brunswick to the United Kingdom last year was 263,236 tons, while the foreign tonnage was 84,035 tons, being about 75 4-5ths per cent. of British, and 24 1-5th of Foreign. In 1863 the proportion was 79 British and 21 Foreign; in 1861, 50½ British and 49½ Foreign; and in 1860, 68 British and 32 Foreign. There is still a number of United States vessels registered at this Port, and sailing under the British flag, in which American subjects are supposed to be interested either by mortgage or otherwise.

The Revenue of the Province for the financial year ending 31st October 1864, as made up by the Provincial Treasurer, was \$1,060,815.85 against

\$844,894.55 for the previous year, shewing an increase of \$215,921.30 on 1864 as compared with 1863. The Revenue of last year was the largest ever received in the history of the Province, 1863 was the second, 1860 was the third, and 1854 was the fourth; each of these four years having been over \$800,000. The sources of Revenue from which the Treasurer makes up his statement, are as follows:—Railway Impost, \$181,994.07 in 1864, against \$138,300.28 in 1863; Import Duty, \$743,315.01 in 1864, against \$585,069.75 in 1863; Export Duty, \$67,640.66 in 1864, against \$61,834.25 in 1863; Casual and Territorial Revenue, \$30,738.31 in 1864, against \$23,293.56 in 1863; Supreme Court Fees, \$3,402 in 1864, against \$4,050 in 1863; Auction Duty, \$227.72 in 1864, against \$323.44 in 1863; Provincial share of Seizures, \$1,059.56 in 1864, against \$680.81 in 1863; Light House Duties, \$21,363.85 in 1864, against \$20,998.56 in 1863; Sick and Disabled Seamen Duties, \$7,405.68 in 1864, against \$7,090.48 in 1863; Buoy and Beacon Duties, \$3,668.99 in 1864, against \$3,213.42 in 1863; Distillery Licences, \$40 in 1863, in 1864 *nil*. The Post Office Receipts, the Fishery Fund, Sinking Fund, Indian Reserve Fund, and Copyright Duties, are not included in the above named receipts as made up by the Treasurer. The importations of last year amounted in value to £1,863,615 sterling, against £1,595,513 sterling in 1863, shewing an increase on last year over the previous one of £268,102 sterling. It has now been ascertained that the importations of last year were much too heavy for the wants of the country, and reduced importations and declining revenue this year are the results of the heavy Imports in 1864. The principal increase was on goods from the United Kingdom, the value of which rose from \$2,584,266 in 1863, to \$3,598,125 in 1864. There was also a large increase on Imports from Nova Scotia, the value of which rose from \$1,094,281 in 1863 to \$1,360,342 in 1864. This is accounted for by the fact that British goods sent out from England by the Cunard Steamers for this place and landed at Halifax, and transported here by Rail and Steamer, via Windsor, appear in our Returns as Imports from Nova Scotia. The Imports from the United States have declined to some extent in 1864, as compared with the previous year, while the Imports from Cuba and Porto Rico nearly doubled last year over the previous one. Our importations of wheat flour in 1864 amounted to 256,996 barrels, against 243,391 barrels in 1863, 232,237 barrels in 1862, 210,676 barrels in 1861, 198,323 barrels in 1860, 205,356 barrels in 1859, 226,649 barrels in 1858, and 153,515 barrels in 1857; making 1,727,143 barrels of flour imported during the last eight years, or an average of 215,893 barrels per annum.

Our importations into the Province of all kinds of agricultural produce in 1864 amounted in value to \$1,811,662, composed of the following named articles, viz:—Flour and meal of all kinds, bread, beans, peas, and pot barley, \$1,216,229; grain of all kinds, bran, horse and pig feed, \$82,506; vegetables, including potatoes, \$65,720; meats, viz., salted, cured and fresh, including poultry, \$158,310; butter, cheese, lard and eggs, \$134,538; animals, including horses, oxen, cows, calves, sheep and pigs, \$46,054; apples, pears, plums, &c. \$44,307; tallow and soap grease, \$24,334; hops, \$4,372; hay and

straw, \$6,582; shrubs, trees and seeds, \$17,877; wool, \$7,833, amounting altogether in currency to £452,915 10s. against £515,175 currency in 1863. A small portion of the produce mentioned above as having been imported into the Province was probably exported again to the States, as produce from Prince Edward Island is sometimes brought down to Saint John by rail, via Shediac, and shipped here for the American markets. Last year the amount of through freight carried over our Railway from Shediac to Saint John was 38,809 tons, being an increase of 2,117 tons over the previous year. A line of steamers having recently been established between Prince Edward Island and the States may probably prevent much increase in freight from the Island over our Railway.

Of butter and cheese we imported last year 500,160 lbs. against 382,229 lbs. in 1863. A large portion of this butter was imported from Portland, Maine, and was, no doubt, the produce of Canada.

The value of haberdashery imported last year, which includes all kinds of silks, woolens and cottons, was \$2,281,097, on which duty was paid to the extent of \$325,515, or nearly 36 per cent. of all the import duty received during the year. In 1863 it amounted to \$1,617,714, duty \$240,715. The cotton manufactory in Saint John is now in operation, although from the scarcity and expense of the raw material it has not affected to a great extent our importations yet. In future, however, it will probably do so, as the last year the proprietors imported cotton wool to the extent of \$50,713 in value.

Our importations of hardware last year amounted to \$239,897, duty received \$31,975.09, against \$194,266, duty \$26,806 in 1863.

The boots and shoes, including India rubbers, imported last year, amounted in value to \$80,475, duty received \$8,880.83, against \$59,851, duty \$7,521. Large quantities of leather boots and shoes are manufactured in Saint John, but no India rubber manufactories have been established in the Colony yet.

The quantity of molasses entered for home consumption last year was 961,947 gallons against 905,057 gallons in 1863, and 897,372 gallons in 1862. The duty paid last year on this article was \$28,371.47. In addition to this the Sugar Refining Company imported 219 hogsheads melado, which is something between sugar and molasses, and as it is a non-enumerated article in our tariff, it was charged duty at the rate of 15½ per cent. The Sugar Refining Company, which started operations in this City on the 24th June, 1864, continued working until the 24th December of the same year, when it stopped working, as from a variety of reasons they were unable to manufacture refined sugar at a profit; some of the retail dealers complained that it was too damp, and did not suit the requirements of the market here. The machinery of the manufactory has since been taken down and sent to Halifax, where it is proposed to erect another Sugar Refinery. During the period they operated in Saint John they manufactured about 6,200 cwt. of refined sugar, which they made from brown sugar and melado, and 13,000 gallons syrup. The selling price of their sugar was 10 cents at first, but it subsequently fell much below this when it had to be forced on the market. The selling price of syrup averaged about 40 cents

per gallon. The Company exported 18,452 lbs. of their refined sugar, on which the Government allowed them a drawback of 1 4-5ths cents per lb., amounting to \$332.10. The principal part of the sugar made by this Company was termed C. C. sugar, (crushed coffee sugar). The financial result to the stockholders of the Company was the total loss of all their capital, amounting to nearly \$40,000. As a general rule, Joint Stock Companies have not been very successful in this Province.

The quantity of sugar entered for home consumption in this Province in 1864 was 3,459,882 lbs., duty \$53,295.37, against 3,460,106 lbs., duty \$53,162 in 1863, shewing that the consumption had varied very little.

The quantity of tea entered for home consumption in 1864 was 1,058,752 lbs., duty \$51,090.29, against 974,835 lbs., duty \$46,987 in 1863. The consumption of tea appears to be increasing.

The value of the tobacco, snuff and cigars imported into New Brunswick in 1864 was \$169,817, duty \$26,919.54, against \$208,914, duty \$29,534 in 1863.

The quantity of spirits entered for home consumption in 1864 was 311,688 gallons, (exclusive of wines and cordials), against 279,673 gallons in 1863. In 1862 it was 258,951 gallons. The consumption of spirits appears to be on the increase. The quantity of wine entered for home consumption in 1864 was 27,400 gallons, against 27,491 gallons in 1863. Seventy two per cent. of the quantity entered was valued as costing less than \$1 per gallon at the Port of shipment. The duty realized from wines in 1864 was \$16,683, against \$17,730 in 1863.

The total value of our importations of spirits, wines and cordials in 1864 was \$361,558, duty received \$177,889, against \$209,443, duty received \$148,964, in 1863. The heavy increase that took place last year over the previous one was on gin, whiskey, and rum. The smuggling of spirits into the Province has nearly ceased, owing to the stringent regulations in force in the States. Last year there were only 319 gallons alcohol and 81 gallons wine seized at Saint John. Our specific and ad-valorem duty on wine of the lowest grade, costing less than a dollar per gallon, amounted last year to nearly 41 cents per gallon; on wine costing between one and two dollars, it amounted to \$1.03 per gallon; and on wine costing upwards of two dollars, it amounted to \$1.36 per gallon. In England the duty on wine under 26 degrees is 1s. per gallon, and 2s. 6d. on wine between 26 and 42 degrees. Four-fifths of the wine consumed in England is of the latter description.

The duty received on coal oils in 1864 was \$4,676.56 against \$4,679.73, shewing a stationary consumption of foreign coal oils.

The value of the following principal articles imported in 1864, in fitting out our new vessels, viz., canvas, cordage, chains, anchors, copper, yellow metal, oakum, sails, and rigging, amounted to \$821,792, on which \$30,500 duty was paid, against \$740,453, duty \$27,795, in 1863. There are considerable quantities of other articles which enter into the construction of new ships in addition to those above mentioned, and which are liable to duty,

such as hardware, iron, nails, spikes, pitch, &c. which would increase the amount contributed to our Revenue by our new ships.

The amount of duty which would be paid to the Government of New Brunswick on the imported articles requisite for the construction of a thousand ton copper fastened ship, would be about \$520, or 52 cents per ton.

In England there is a duty of 1s. sterling per ton on Foreign and Colonial built ships on their first registry in that country; and in France the prohibitory duty of 25 francs, or about \$5 per ton, has been reduced to 2 francs or 40 cents per ton on foreign shipping on their first registry in that country. This concession on the part of France may open a market for some of our small sized vessels. Last year four Canadian built vessels were sold in France, and this year two new vessels have been built in Canada on French account.

The two principal articles which contribute to our Revenue are Haberdashery and Liquors, which include wines and spirits. Last year the amount of import duty paid on these articles amounted to upwards of 55 per cent. of all the import revenue received. In the United Kingdom sugar and tobacco are the two principal articles on which Customs' duty is collected.

The value of our importations from Canada was \$245,020 in 1864, against \$177,328 in 1863. These figures represent the values of goods, such as flour and provisions, which are imported into the North Shore Ports direct from that Colony. Any importations from Canada of flour or other produce into Saint John, would come via Portland, and consequently would appear in the returns as Imports from the States. No correct idea can be formed therefore from these returns of our trade with Canada.

From Prince Edward Island our importations amounted to \$112,728 in 1864, against \$108,686 in 1863, shewing but a very slight increase. The trade between New Brunswick and the Island does not appear to progress much, considering the facilities for transit between these two Colonies. From France our importations amounted to \$63,226 in 1864, against \$17,180 in 1863.

A considerable quantity of the brandy and wine produced in France and consumed here, comes through England and the States, and would therefore appear in the returns as importations from these places.

From the United States we imported goods in 1864 amounting in value to \$3,316,824, against \$3,550,383 in 1863. The fluctuations in the price of gold may probably have had something to do with the decrease of importations from that country in 1864, during which year it fluctuated from 151 to 285, the average for the year being 204. In 1863 it was 146, and in 1862, 118.

The large quantity of British and Foreign goods which reach New Brunswick from the States, accounts for our heavy importations from that country.

The Reciprocity Treaty was ten years in operation in New Brunswick on the 12th November last. During the ten years ending 31st December 1864,

our importations from the States amounted in value to £6,728,896 sterling, against £3,730,752 sterling, during the ten years immediately preceding that period.

Some allowance must be made, however, for the British goods which have been coming to this Province, via Boston and Portland, in larger quantities during the last ten years than formerly. Importers of fine goods at Saint John now prefer their being landed at Halifax and sent via Windsor.

From Cuba and Porto Rico our importations are gradually increasing from year to year. In 1864 they amounted to \$178,302; in 1863, \$95,231; 1862, \$73,370; and in 1861, \$33,671.

Our total Imports from all countries in 1864 amounted to £1,863,615 sterling, against £1,595,513 sterling in 1863. In 1854 they were £2,068,773; for that year, however, the revenue was much less than in 1864, as the tariff was lower than it now is.

Our total Exports to all countries in 1864 amounted to £1,052,891 sterling, against £1,029,329 sterling in 1863, shewing a slight increase of £23,562 sterling on last year as compared with the previous year. The Exports of 1853, 1854, 1856, and 1859, were greater in value than those of 1864. The great excess of the value of Imports over Exports, is owing to the fact that new ships, our principal staple article of export, are not included in our accounts of Exports, although the outfits and fastenings are included in our Import account. The value of our new ships built last year with their first freight home, amounted to £797,250 sterling, which, with the value of the exports before mentioned, would make £1,850,141 sterling as the value of Exports, against £1,863,615 sterling as the value of our Imports; according to these figures there would remain a balance against the Province, as excess of Imports, of £13,474 sterling. But the earnings of our vessels abroad must have amounted to a very large sum last year, consequently the material interests of the Province must have progressed during that period.

Our Exports to Canada, Nova Scotia, Bermuda, Barbadoes, Nassau, Jamaica, Cuba, Porto Rico, and South America, increased last year over the previous year, while to the United Kingdom and Prince Edward Island they decreased to some extent. To the United States they remained about stationary. The increase of Exports to Cuba is principally owing to the fact that some of our Mill-owners have been turning their attention recently to the manufacture of sugar box shooks, and a much larger quantity than usual was manufactured here last year and shipped to Cuba.

The prices of deals in the Liverpool market last year receded from the prices of 1863, while there was also a gradual declension in their price each year since 1860. The highest selling price reached in 1864 in Liverpool was £7 14s. sterling per standard, which was about the end of May, while the lowest price was £7 about the end of October. At the commencement of the year they realized in that market £7 9 3 sterling, and closed at the end of the year at £7 6 6 sterling, giving an average throughout the year of £7 7 5 sterling against £7 15 3 as the average of 1863. The price of deals throughout the United Kingdom is generally regulated by the Liver-

pool market, which is the principal one in that country. The following were the average prices of deals in Liverpool during the last eight years:—1857, £7 11 7 sterling; 1858, £7 5 7; 1859, £8 2 10; 1860, £9 4 2; 1861, £8 6 6; 1862, £7 17s.; 1863, £7 15 3; and 1864, £7 7 5, sterling.

Shippers of deals in this country feel much discouraged with the present appearance of the wood markets in the United Kingdom.

The duty on sawed lumber and timber exported from the Ports in this Province during the year ending 31st December last, amounted to \$60,648, or about £12,635 sterling. This export duty of 20 cents per thousand superficial feet, equal to ten pence sterling, is collected on all sawn lumber exported from the Province, with the exception of such as is exported from the Saint Croix River, and such as is the produce of the State of Maine when exported to the United States. The total quantity of sawn lumber of all kinds exported in 1864, including deals, boards, deal ends and scantling, was 325,886,924 superficial feet; in 1863 it was 338,565,750 feet; in 1862 it was 252,846,750 feet; in 1861 it was 316,657,750 feet; and in 1860 273,943,000 feet.

The quantity of pine timber exported last year was only 19,810 tons, shewing that as an article of export from the country it is gradually being exhausted. The following named quantities of this article exported from New Brunswick during the last nine years, shew this conclusively:—1856, 100,000 tons; 1857, 86,926 tons; 1858, 71,453 tons; 1859, 76,002 tons; 1860, 39,291 tons; 1861, 41,947 tons; 1862, 29,237 tons; 1863, 26,920 tons; and in 1864, 19,810 tons. Our exportations of birch timber increased a little last year as compared with the previous year, the quantity exported in 1864 being 17,267 tons, against 12,795 tons in 1863.

The stock of logs and deals on hand in the Province on the 1st January last was estimated by one of the principal shipping firms here to be 88 millions feet, 35 millions of which was estimated for Saint John, and 53 millions for all the Out-Ports. This was considered to have been the smallest stock on hand at that period for several years. The stock of pine timber was also estimated at a very reduced figure, viz., 4,500 tons on the 1st January, 1865, against 7,000 tons on the 1st January 1864.

Our principal exports in 1864 may be classed as follows:—Produce of the forest, including furs, value \$3,405,863, against \$3,657,096 in 1863. Produce of the mines and minerals, including coal, limestone and lime, \$324,359, against \$270,566 in 1863. Produce of the fisheries, including fish oil, \$305,682, against \$265,724 in 1863.

Of all the various Companies which have been formed from time to time for the purpose of developing the mineral resources of this Province, and making fortunes for themselves, very few, if any, have been successful in realizing their wishes and expectations, as far as making money is concerned, with the exception of the Albert Mining Company, which has been eminently successful, although unfortunately it is principally owned by Americans. During 1864 that Company raised 19,465 tons of their valuable coal, which they sold at \$9 per ton, with the exception of a small quantity which the

Company sold to the Saint John Gas Company, the Saint John Oil Works, and the Halifax Gas Company. This coal went to the United States where it is used for making oil and gas. This year they are obtaining \$11 for it, although the quantity raised will probably be smaller than last year on account of the mine having been on fire for some weeks. There is a prospect at present of some wealthy men in New York organizing themselves into a Company for the purpose of operating in Albert County in oils, mines and minerals. The demand for building stone having nearly ceased in the United States during the operation of the war, some of the stone quarries at the head of the Bay of Fundy either stopped working or conducted their operations on a very limited scale. The demand for stone having again commenced, they are now being more vigorously worked.

The total value of the imports and exports of last year at Saint John was \$9,892,186, or 70 per cent. of the aggregate value of the imports and exports of the whole Province. The amount of the import and export duties collected at Saint John in 1864 was \$723,866, or nearly 75 per cent. of the total amount of import and export duties collected in the Province.

The Port next in importance to Saint John, so far as imports and exports are concerned, is Newcastle, then Saint Andrews stands next on the list, (the shipping Port of the Woodstock Railway), then Chatham, then Saint Stephen, then Shediac, then Richibucto and Bathurst. In point of import and export duties the principal Out-Ports stand as follows:—1st, Newcastle; 2nd, Chatham; 3rd, Saint Stephen; 4th, Fredericton; 5th, Bathurst; 6th, Richibucto; 7th, Saint Andrews. The total amount of bullion and specie imported into New Brunswick in 1864 by the Banks was \$170,840, and the amount exported by them was \$188,855. In addition to this, considerable quantities of coin are constantly being carried backwards and forwards by travellers and private individuals between this Province, the United States, and England.

The immigration returns still continue to shew very unsatisfactory results. The number of emigrants which arrived in the Province direct from Europe during 1864 was 602, being rather less than during either of the two preceding years. Of this number there were probably not more than 500 remained in the Province, the balance no doubt found their way to the States, some of them probably taking this route for the sake of economy or convenience.

There were 26 emigrants, in addition to the number above mentioned, arrived at Saint John from Boston and Portland by the International line of Steamers, with the intention of settling in New Brunswick. It is supposed that a much larger number than is here mentioned arrived in Saint John by the same line of Steamers, but as they come as regular cabin passengers, no record could be kept of them. The number of passengers which arrived by these steamers during 1864 was in excess of the number carried away from the Province by 210; so that it is probable there was some slight addition to the population of the Colony from that quarter, although it is not by any means a sure criterion by which to estimate any permanent addition to our numbers, as Saint John is a central point in these

Maritime Provinces, through which a considerable portion of the travellers pass on their way to and from Nova Scotia, Prince Edward Island, Newfoundland, and England. In consequence of the internal difficulties unhappily prevailing in the United States during the last four years, and the anxiety on the part of many of the subjects of that country to avoid the several drafts which have taken place, as well as the increased taxation, considerable numbers of persons have moved across the lines from time to time, and settled in this Province. Some persons formerly doing business in Calais have also found it more convenient to move across the bridge to Saint Stephen, as the taxes and duties are much smaller on the British than on the American side. The number of emigrants admitted into the Alms House during 1864 was 14, viz. 9 males and 5 females. The Government defrayed their expenses while there, viz., for subsistence, \$176; clothing, \$14.07; coffins, &c. \$2; making altogether \$192.07. The rate paid for each emigrant was 80 cents per week.

There were only two pauper passengers sent back to Boston during last year under the Provincial Law, which was enacted with the view of preventing an influx of paupers or helpless persons into the Colony, who would become public burdens. George Freeman, an insane person, was brought from Boston on the 26th August last in the steamer "New England," and on his arrival here was placed in the Lunatic Asylum until the 5th September, when he was reshipped back to Boston. He had formerly been in the Lunatic Asylum at Charleston, Massachusetts. Timothy Cotter, aged 30, an Irishman, arrived here from Boston on the 11th November, and was immediately sent back. He had been in the United States Army.

No Emigrant Duty is now collected in New Brunswick.

The arrivals of emigrants and passengers in Canada in 1864 numbered 19,147, viz. 17,937 steerage and 1,210 cabin. Of the steerage passengers, 10,540 were from the United Kingdom, 2,113 from Germany, 5,162 from Norway and Sweden, and 122 from other countries. The amount of Emigrant tax collected in Canada during 1864 was \$18,235, and the total expenditure for emigration purposes, \$42,664.48, of which \$13,722.34 was for direct relief to emigrants. In addition to the direct emigration from Europe, as stated above, there were 1,169 persons came into Canada by steamers from the United Kingdom, via Portland, besides 15,673 emigrants from the United States, who arrived in Canada by inland routes. With the demand for labour in the farming districts in Canada West and the Western portion of the United States, we cannot expect to have much immigration into New Brunswick.

The following statistics relative to the British North American Colonies for 1864, will shew the amount of our revenue, trade, shipping, &c. as compared with our neighbours:—

*Newfoundland.*—Population at last census taken in 1857, 122,638; estimated population at the commencement of 1864, 137,000; amount of Customs' Revenue in 1864, £103,925 sterling, against £97,727 in 1863; Excise, 1864,

£305, against £1,651 in 1863; total, £104,230 sterling, in 1864. The gross Revenue in 1864, including £696 sterling for Crown rents, and £963 from Post Office, was £106,965, against £102,403 sterling in 1863. Amount of expenditure in 1864, £110,176 sterling; Public debt, £177,262; value of Imports in 1864, £1,067,062; Exports, £1,111,330; cost of collecting Customs and Excise, £7,892 sterling; amount expended for educational and literary purposes, £13,343. Shipping registered in the Colony, 1,417 vessels, 85,738 tons; new vessels built in the Colony in 1864, 49, 1,865 tons; 6 steamers, 540 tons, are employed in the Colony, two of them in the seal fishery, two as tug boats, and two carrying passengers and mails. Estimating the population in 1864 as above, the amount of Customs and Excise Duty would be equal to about \$3.65 per head.

*Prince Edward Island.*—Population at last census, 80,857; estimated population at the commencement of 1864, 85,992; Import duty, 1864, £33,553 sterling; Excise duty, £1,944; gross Revenue, £44,216 sterling. Total Import duty and Excise revenue, £35,497 sterling, or about \$1.98 per head on estimated population as above. Imports, £337,927 sterling; Exports, £202,668 sterling. New shipping built in 1864, 24,688 tons register, value, £172,816 sterling. Total shipping registered at the Island on 31st December last, 371 vessels, 46,838 tons.

*Nova Scotia.*—Population at last census, 330,857; estimated population at the commencement of 1864, 349,300. In this Colony the Government has recently altered the time of making up their financial statements, from 31st December to 30th September, so that their Revenue returns for last year are only for nine months instead of a year. The revenue from Customs and Excise for the nine months ending 30th September last, was \$692,819, less drawbacks, \$12,804, or about \$1.95 per head for that period. This would be equal to about \$2.69 for the year, assuming the collections for October, November and December to be equal to the average of the previous nine months. Value of Imports for the year ending 30th September last, \$12,604,642; Exports, \$7,172,816. New shipping built in the year ending 30th September last, 304 vessels, measuring 73,038 tons register, value \$2,943,204. Total shipping registered in Nova Scotia on the 30th September last, 3,748 vessels, measuring 364,864 tons, valued at \$11,388,873. Total Revenue of Nova Scotia for the nine months ending 30th September last, including Post Office and Railway receipts, \$1,074,173. Total expenditure, including Railway interest and expenses, and drawbacks, \$949,767.

*Canada.*—The Government of this Colony has also altered the termination of the year, with reference to their Trade Returns and Financial Statements. Instead of the year ending on the 31st December it now closes on the 30th June, so as to allow enough time for the examination and compilation of their returns, which under this arrangement can now be laid before the Legislature at its opening. The returns recently published by the Canadian Government are made up therefore for the half year ending 30th June last. Population at last census, 2,506,755; estimated population at the commencement of 1864, 2,783,079; Customs' Revenue for six months ending 30th

June last, \$3,074,800; Excise, \$519,351; total, \$3,594,151, less drawbacks on shipbuilding materials, \$19,606; other Custom drawbacks, \$16,113, and Excise drawbacks, \$1,017; or about \$1.28 per head of the population for Customs and Excise duties for six months. Assuming that the last six months of the year produced as much revenue as the first six months, it would make the amount of Customs and Excise taxation for Canada for 1864, equal to \$2.56 per head. The reason why the taxation from Customs and Excise is less in Canada than either in New Brunswick, Nova Scotia, or Newfoundland, although the Canadian tariff is higher than any of the tariffs of the British North American Colonies, is probably owing to the successful operation of manufactories in that Colony, and the limited consumption of dutiable articles, such as tea, tobacco, sugar, liquors, and expensive haberdashery, by the people of Lower Canada. The value of the dutiable goods imported into Canada during the half year alluded to, was \$14,309,886, or 66.85 per cent. of the whole; free goods, \$7,096,826, or 33.15 per cent. of the whole Imports, making altogether \$21,406,712. Coin and bullion imported, \$2,475,504. The duties collected for the half year alluded to, averaged 21.44 per cent. on the value of the dutiable goods, and 14.33 per cent. on the value of all the goods imported, including free goods. Exports, \$13,883,508. New vessels built in Canada during the half year alluded to, 79, 30,068 tons, valued about \$1,227,520. The most of the tonnage was built at Quebec; 28 of the new vessels built at Quebec were sold abroad. This would give as the new tonnage built in Canada for the year ending 31st December last, about 60,136 tons. The gross receipts of Canada from all sources for the half year ending 30th June 1864, was \$8,126,939, against \$6,855,962 for the previous corresponding half year; and the payments for the half year ending 30th June 1864, including the collection of all the public revenues, interest on public debt, &c. was \$7,789,575, against \$7,611,477 for the corresponding previous half year. From this it would appear that the receipts exceeded the payments of the half year ending 30th June 1864, to the extent of \$337,364.

*New Brunswick.*—Population at last census, 252,047; estimated population at the commencement of 1864, 272,780. Customs' Import Duty for the year ending 31st December 1864, \$907,997, less drawbacks about \$52,000, or about \$3.10 per head. The large quantity of new shipping built last year, as compared with the small population of the Colony, along with the increased demand for haberdashery by persons visiting Saint John from the United States, Nova Scotia, and Prince Edward Island, will partially account for this large rate of Customs' taxation per head, as compared with the other Colonies. Our gross Revenue, including Post Office Receipts, for the financial year ending 31st October last, was \$1,112,279.80, and our Expenditure, including interest on Railway Debentures, Drawbacks, &c., was \$915,011.68, shewing a balance in favour of the year's operations of \$197,286.12. Our importations of dutiable articles in 1864 amounted in value to \$6,692,488, or 74.82 per cent. of the whole; and of free goods to \$2,252,864, or 25.18 per cent. of the goods imported. The duties collected in New Brunswick

in 1864 on the dutiable goods averaged 13.57 per cent. on their value, and on all the goods, including free goods, they amounted to 10.15 per cent. on their value.

I herewith submit, along with the Returns, a Table shewing the different rates of Customs' Duty chargeable on the importation of goods into the respective Colonies of New Brunswick, Canada, Nova Scotia, Newfoundland, and Prince Edward Island, classified according to the official list of articles in the New Brunswick tariff. From this it will be seen that of these Colonies named, Prince Edward Island and Nova Scotia have the lowest tariffs, the bulk of articles imported into these Colonies paying 10 per cent. *ad-valorem*; Newfoundland is the next highest, 11 per cent. being the rate chargeable on the bulk of their importations; New Brunswick is the next highest, 15½ per cent. being the rate on the principal part of our importations; and Canada is the highest of all, 20 per cent. being the rate chargeable on the bulk of their importations.

In the Canadian tariff there are a few articles on which the duty is less than in ours, such as brandy, gin, whiskey, wines, printed books, music, dried fruit, &c., while there are several articles on which we levy duty which are altogether free under the Canadian tariff, such as particular kinds of canvas, large anchors and chain cables over a specified size, and other enumerated articles suitable for outfits for new ships, printing ink and printing presses, mahogany, lignumvitæ, corkwood, wool, lime, coal, salt, seeds, slates, dye stuffs, dye woods, oranges, lemons, guano, hides, hemp, hair, moss, indigo, marble, naval stores, oakum, rice, and several other minor articles, but the revenue derived from these articles imported into New Brunswick is only nominal, and is of very little practical importance when estimating the results of each of the tariffs. The total amount of duty levied on such articles in New Brunswick last year did not amount to \$20,000, which, under the Canadian tariff, would be admitted free. Last year we collected on brandy, gin, whiskey and wines, \$118,695, while under the Canadian rates we would have only collected \$81,834, shewing a difference in favour of the Canadian rates on these articles of \$36,861. But while we can shew a reduction on a number of articles at the Canadian rates, as compared with the rates under our own tariff, to the extent probably of \$50,000 or \$60,000, it is very evident that on the main articles of consumption, from which we draw the great bulk of our revenue, the Canadian rates of duty are very much heavier than those of New Brunswick. In 1864 we collected on haberdashery and hardware (at 15½ per cent.) \$357,489, or nearly 4-10ths of our whole import duties. At 20 per cent., the Canadian rate, we would have collected \$461,161, a difference of \$103,672 in favour of the New Brunswick tariff. On molasses and treacle we collected \$28,371; under the Canadian tariff we would have collected \$71,280, or \$42,909 more than was received under the New Brunswick tariff. On alcohol and rum we collected \$57,157; under the Canadian tariff we would have collected \$200,087. Large quantities of alcohol and whiskey are manufactured in Canada, but

there is an excise duty on all distilled spirits manufactured in that Colony, amounting to 30 cents per gallon proof. The alcohol imported into this Port is generally 90 or 95 per cent. over-proof, and the duty here is only 35 cents per gallon, without reference to strength, and 3 per cent. *ad valorem*. On sugar we collected \$53,295; under the Canadian tariff we would have collected \$97,226. On tea we collected \$51,090; under the Canadian rates we would have collected \$81,633. On tobacco, snuff, and cigars, we collected \$26,919; under the Canadian tariff we would have collected upwards of \$83,815. Owing to the different wording and rating of several articles in the Canadian and New Brunswick tariffs, it would be impossible to arrive at the exact amount of excess of duty which would have been levied on our importations of last year, had the Canadian tariff been levied on such importations; but with reference to all the main articles of consumption, from which we draw the great bulk of our revenue, there is not much difficulty in estimating the amount of duty which would be produced under the different tariffs.

In the year ending 31st December, 1864, we collected in New Brunswick import duties to the extent of \$907,997. Had the Canadian tariff been applied to each of the articles in our list of imports, after making due allowance for the Canadian free list of goods, and such of them as are chargeable with lower rates under the Canadian tariff than under ours, there would have been collected in New Brunswick, at the lowest calculation, \$1,388,205, or \$480,208 more than we actually collected under our present tariff. It is very probable, however, that if there was no duty chargeable in this Province on Canadian manufactures, many of such manufactures, such as distilled spirits, malt liquors, tobacco, snuff, cigars, refined sugar, India rubber, and leather boots and shoes, &c., would find their way into this Province, and thereby reduce the amount of duties which would be collected here. There is an excise duty in Canada, however, on certain of these manufactured articles which would have to be paid by the consumer either here or at the place of manufacture, viz: on malt liquor, 3 cents per gallon; distilled spirits, 30 cents per gallon proof; snuff, dry, 10 cents per lb.; tobacco, Cavendish, 10 cents per lb.; common cut, 5 cents per lb.; fine cut, 15 cents per lb.; Canada twist, 2 cents per lb.; cigars, value not over \$4 per M., \$1 per M.; value over \$4 per M. and not over \$10, \$2 per M.; value over \$10 and not over \$20, \$3 per M.; value over \$20 and not over \$40, \$4 per M.; value over \$40, \$5 per M. There is also a stamp duty of 3 cents in Canada, on promissory notes of \$100, and the same for each \$100 additional in the same note. Bills of exchange are considered the same as promissory notes. There is no duty on receipts.

Respectfully submitted.

WM. SMITH,

Controller of Customs and Navigation Laws,  
Registrar and Surveyor of Shipping,  
and Receiver General of Admiralty Droits.

Number, Tonnage and Crews of Vessels Entered at all the Ports

| COUNTRIES.                                                                                                                                                                                                                                                                                                                                                                                                                                                        | BRITISH.     |         |        |            |         |       |         |         |        | FOREIGN.     |         |       |
