The whole of this system was swept suddenly away before the tide of the Revolution, but amid the troubled times that succeeded, it was long ere rulers could find peace and leisure for the erection of a substitute. In 1800, Napoleon appointed a commission to draw up a project of a civil code. The project when prepared was circulated for comment and suggestion, and was afterwards, along with the observations made on it by the different courts of law, discussed in the council of state and the tribunate. Thus was formed the *Code Civil*, or civil code of France, more generally known by the term *Code Napoleon*, which was applied to it under the empire. Nearly at the same time, and in the same manner, was framed the *Code de Procedure Civile*, or code for regulating the form of process in civil actions, and specifying the jurisdictions of the various courts. Being a subject more connected with technical detail, and involving less of general principle than the civil code, its provisions were left almost entirely to the arrangement of the lawyers. Besides the technical directions in which lawyers are almost wholly interested, there are in this manual many which concern the ordinary proceedings of citizens at large, such as directions for the order to be taken regarding the effects of a deceased person, &c. This code is generally accompanied by a table of fees in law proceedings. In 1807, another code was promulgated called the *Code de Commerce*, consisting of 648 sections. This is the commercial code of France, regulating partnership, bills and notes, banking, shipping, bankruptcy, &c. By this code provision is made for merchants choosing boards or courts from among their own number, called *Tribunaux de Commerce*. The jurisdiction of these courts, which are very numerous, extends to questions between merchants, and disputes arising out of commercial transactions. In criminal legislation, a different order was pursued from that adopted in the civil; the procedure code was prepared and adopted before the crimes to which it was to apply, and the punishments it was to enforce, were defined. The *Code d'Instruction Criminelle* was promulgated in 1808, and the *Code Pénal* in 1810.

Such were the laws issued under the government of Napoleon, commonly called *Les Cinq Codes*, or the Five Codes. There are other collections of regulations, which should be added to make up a complete body of French laws—a military code, issued by Napoleon; regulations concerning woods and forests, issued under Charles X.; various laws as to the press and theatrical exhibitions, and alterations of the penal code, issued under the government of Louis Philippe, &c. It is simply in the Five Codes, however, passed under Napoleon and confirmed at the restoration, that the modern laws of France are known to Europe at large. They are generally published in a small, thick, closely-printed volume; and for the conciseness, clearness, and elegance of their language, and their intrinsic merits, they are a favourite subject of study with many British lawyers, while there are few places in civilized Europe in which they are not generally known. Independently of the division into books and sections, the paragraphs in each code are numbered straight on from the commencement, an arrangement which gives peculiar facilities for reference. Thus there are in the civil code 2281 consecutively numbered paragraphs. In a country where the material of the law is so gigantic as it is in England, it is of the highest interest to mark the practical working of this grand effort at simplification. To an unlearned person in this country, it is a much easier thing to know the law of France on any particular point, than the law he is living under. If an English lawyer is asked a question, his answer involves reference to commentaries, decisions, and statutes innumerable; but in the general case, the answer of a French lawyer bears simple reference to such a paragraph of such a code.

The French codes adopt the phraseology of the Roman law and many of its principles. The most striking deviation from the previous law of France, and the present systems of other countries, is perhaps in the rules respecting succession. The children succeed to equal shares of the parents' property, whether it consist of land or movables; and if there be no legitimate children, illegitimate children may succeed. The parent is limited in the disposal of his property by will. He can only bequeath the half if he have one legitimate child, and the third if he have two. Restrictions somewhat similar are to be found in other countries with respect to movable property, but not as to land. The effect which the extensive partition, naturally occasioned by this law, has effected, and may effect in France, is a subject of great interest to political economists. In the mercantile law there are several provisions unknown to this country, such as registers for hypothecs or securities held over moovable goods or merchandize, and societies "en commandite," or partnerships in which certain managing members are responsible for the obligations of the company to the extent of their whole property, while the sleeping partners who advance money are not responsible beyond the amount of their shares. The chief improvement in the criminal law effected during the Revolution, and sanctioned by the code of instruction, was jury trial, to which Napoleon was much opposed; the system, as finally settled, bore more resemblance to the Scottish than to the English form, prosecutions being

conducted by public prosecutors, there being no grand jury, and the jury of final trial deciding by a majority. In other respects, the criminal law is more remarkable for its austerity than for its subserviency to the general good of the public. With Napoleon, though that object was not neglected, it was made secondary to the consolidation of his own power; and offences are measured less by their pernicious effects on society at large, than by the trouble or danger they might occasion to rulers. Hence was adopted in many cases the stern and simple method of putting arbitrary power over criminals into the hands of the administrators of the law, while punishments of the highest kind were reserved for offences against the authorities.

POPULATION—POOR LAWS—LIFE-ASSURANCE.

POPULATION.

The rate at which human beings naturally increase, the proportion which this increase bears to the means which exist for their subsistence, and the laws which operate to bring the increase and the means of subsistence into conformity, were subjects scarcely reflected on by our ancestors, but have been matter of keen controversy during the first thirty years of the present century.

As far as population was at all thought of in former times, the prevalent doctrine was, that the greater the numbers of a nation, the stronger was the state, and the more likely was that country to be a scene of both agricultural and commercial industry. So useful were numbers considered for increasing the means of subsistence, and also of national defence, that in many countries it was thought proper to make laws for encouraging matrimony, and to put bounties on all families exceeding a certain number. So lately as the time of Louis XIV., pensions were given in France to individuals who had ten or more children.

Dr. Adam Smith, in his *Wealth of Nations*, was perhaps the first to suggest any thing like a law as regulating the increase of population. He remarked, that "the demand for *men*, like that for any other commodity, necessarily regulates the production of men; quickens it when it goes on too slowly, and stops it when it advances too fast. It is this demand," says he, "which regulates and determines the state of population in all the different countries of the world—in North America, in Europe, and in China; which renders it rapidly progressive in the first, slow and gradual in the second, and altogether stationary in the last."

VIEWS OF MR. MALTHUS.

This hint, for it is little else, is said to have been what suggested the celebrated essay of Mr. Malthus, which first appeared in 1798, but was almost reconstructed in a second edition of 1803. There was something so startling in the views of this writer, and at the same time so much plausibility in his arguments, distressing as they were to natural feelings, that his work attracted great attention, and many of the ablest thinkers and writers of the day became converts to its main doctrines.

An abridgment of Mr. Malthus's views, given in the *Edinburgh Review* for August 1810, sets out by showing that "the rate of population is by no means the same in all parts of the world." The variations in the rate are universally preceded and accompanied by variations in the means of maintaining labourers. "Where these funds are rapidly increasing, as in North America, the demand for an increasing number of labourers makes it easy to provide an ample subsistence for each; and the population of the country is observed to make rapid advances. When these funds increase only at a moderate rate, as in most of the countries of Europe, then the demand for labourers is moderate: the command of the labourer over the means of subsistence is consequently much diminished; and the population is observed to proceed at a moderate pace, varying in each country, as nearly as may be, according to the variations in the funds for its support. Where these funds are stationary, as we are taught to believe is the case in China, and as has certainly been the case in Spain, Italy, and probably most of the countries of Europe during certain periods of their history, there the demand for labour being stationary, the command of the labourer over the means of subsistence is comparatively very scanty, and population is observed to make no perceptible progress, and sometimes to be even diminished.

"In the second place, it is a fact equally notorious, that the actual increase of the funds for the maintenance of labour does not depend simply upon the physical capacity of any particular country to produce food and other necessaries, but upon the degree of industry, intelligence, and activity, with which these powers are at any particular time called forth. We observe countries possessing every requisite for producing the necessaries and conveniences of life in abundance, sunk in a state of ignorance and indolence, from the vices of their governments, or the unfortunate constitution of their society, and slumbering on for ages with scarcely any increase in the means of subsistence, till some fortunate event introduces a better order of things; and then the industry of the nation being roused and allowed to exert itself with more freedom, more ample funds for the maintenance of labour are immediately provided, and population is observed to make a sudden start forwards, at a rate quite different from that at which it had before proceeded.

"This seems to have been the case with many of the countries of Europe during some periods of their history; but is more particularly remarkable in Russia, the population of which, though very early inhabited, was so extremely low before the beginning of the last century, and has proceeded with such rapid steps since, particularly since the reign of Catharine II.

"It is also a fact, that has often attracted observation in a review of the history of different nations, that the waste of people occasioned by the great plagues, famines, and other devastations to which the human race has been occasionally subject, has been repaired in a much shorter time than it would have been, if the population after these devastations had only proceeded at the same rate as before. From which it is apparent, that after the void thus occasioned, it must have increased much faster than usual; and the greater abundance of the funds for the maintenance of labour, which would be left to the survivors under such circumstances, indicates again the usual conjunction of a rapid increase of population with a rapid increase of the funds for its maintenance. Just

after the great pestilence in the time of Edward III., a day's labour would purchase a bushel of wheat; while, immediately before, it would hardly have purchased a peck.

"With regard to the minor variations in the different countries of Europe, it is an old and familiar observation, that, wherever any new channels of industry and new sources of wealth are opened, so as to provide the means of supporting an additional number of labourers there, almost immediately, a stimulus is given to the population; and it proceeds for a time with a vigour and celerity proportionate to the greatness and duration of the funds on which alone it can subsist."

From these and other premises, Mr. Malthus laid it down as a proved fact, that population tends to increase at the rate of a doubling every twenty-five years. He, at the same time, endeavoured to show that, as man begins to use the best lands first, and then has to go to worse and worse, it becomes always more and more difficult to obtain the means of subsistence for increasing numbers. He concluded that, at the utmost, the means of subsistence would be found, at the end of each successive quarter of a century, to have increased only at the rate of double for the first, triple for the second, quadruple for the third, and so on. Thus, (said he,) while population would go on increasing in a geometrical ratio, that is, as 1, 2, 4, 8, 16, 32, 64, 128, &c., food would increase only in an arithmetical ratio, that is, as 1, 2, 3, 4, 5, 6, 7, 8, &c.; and the consequence of an unchecked increase of the one, with the utmost possible increase of the other, would be that, when the population of the globe had advanced to 500,000 millions, there would only be food for 10,000 millions, or a fiftieth part of the number!

Considering, then, that there is a power and a tendency in human beings to increase so rapidly, and that, in point of fact, it is only in a few favoured spots that they do increase at such a rate, Mr. Malthus concluded that there must be some counteracting agencies, or *checks*, in constant operation, in almost all communities, to restrain population at a lower rate of increase, or to keep it stationary. In looking about to discover these checks, he satisfied himself that they were of two orders: first, there was the mortality produced by the effects of deficient food and of wicked passions; these he called *positive checks*: then there was the check produced by a prudent forethought in human beings, leading them to avoid marriage, on account of the little prospect they have of being able to rear a family in comfort; this he called the *preventive check*.

Arriving at this point, Mr. Malthus and his followers proceeded to show how their doctrines were applicable for the benefit of communities. It was held that there could be no choice between the two kinds of checks; it was clearly preferable that population should be restrained by the preventive check.

"It is observed," says the *Edinburgh Review*, "in most countries, that in years of scarcity and dearness, the marriages are fewer than usual; and if, under all the great variations to which the increase of the means of subsistence is necessarily exposed from a variety of causes—from a plenty or scarcity of land, from a good or bad government, from the general prevalence of intelligence and industry or of ignorance and indolence, from the opening of new channels of commerce or the closing of old ones, &c. &c.—the population were proportioned to the actual means of subsistence, more by the prudence of the labouring classes in delaying marriage than by the misery which produces premature mortality among their children, it can hardly be doubted that the happiness of the mass of mankind would be decidedly improved.

"It is further certain, that, under a given increase of the funds for the maintenance of labour, it is physically impossible to give to each labourer a larger share of these funds, or materially to improve his condition, without some increase of the preventive check; and, consequently that all efforts to improve the condition of the poor, that have no tendency to produce a more favourable proportion between the means of subsistence and the population which is to consume them, can only be partial or temporary, and must ultimately defeat their own object.

"It follows, therefore, as a natural and necessary conclusion, that in order to improve the condition of the lower classes of society, to make them suffer less under any diminution of the funds for the maintenance of labour, and enjoy more under any actual state of these funds, it should be the great business to discourage helpless and improvident habits, and to raise them as much as possible to the condition of beings who 'look before and after.' The causes which principally tend to foster helpless, indolent, and improvident habits among the lower classes of society, seem to be despotism and ignorance, and every plan of conduct towards them which increases their dependence and weakens the motives to personal exertion. The causes, again, which principally tend to promote habits of industry and prudence, seem to be good government and good education, and every circumstance which tends to increase their independence and respectability. Wherever the registers of a county, under no particular disadvantages of situation, indicate a great mortality, and the general prevalence of the check arising from disease and death over the check arising from prudential habits, there we almost invariably find the people debased by oppression and sunk in ignorance and indolence. Wherever, on the contrary, in a country without peculiar advantages of situation, or peculiar capability of increase, the registers indicate a small mortality, and the prevalence of the check from prudential habits above that from premature mortality, there we as constantly find security of property established, and some degree of intelligence and knowledge, with a taste for cleanliness and comforts, pretty generally diffused.

"Nor does experience seem to justify the fears of those who think, that one vice at least will increase in proportion to the increase of the preventive check to population. Norway, Switzerland, England, and Scotland, which are most distinguished for the smallness of their mortality, and the operation of the prudential restraint on marriage, may be compared to advantage with other countries, not only with regard to the general moral worth and respectability of their inhabitants, but with regard to the virtues which relate to the intercourse of the sexes. We cannot, as Mr. Malthus observes, estimate with tolerable accuracy the degree in which chastity in the single state prevails. Our general conclusions must be founded on general results; and these are clearly in our favour.

"We appear, therefore, to be all along borne out by experience and observation, both in our premises and conclusions. From what we see and know, indeed, we cannot rationally expect that the passions of man will ever be so completely subjected to his reason as to enable him to avoid all the moral and physical evils which depend upon his own conduct. But this is merely saying, that perfect virtue is not to be expected on earth; an assertion by no means new, or peculiarly applicable to the present discussion. The differences observable in different nations, in the pressure of the evils resulting from the tendency of the human race to increase faster than the means of subsistence, entitle us fairly to conclude, that those which are in the best state are still susceptible of considerable improvement, and that the worst may at least be made equal to the best. This is surely sufficient both to animate and to direct our exertions in the cause of human happiness; and the direction which our efforts will receive, from thus turning our attention to the laws that relate to the increase and decrease of mankind, and seeing their effects exemplified in the state of the different nations around us, will not be into any new and use

pious path, but into the plain beaten track of morality. It will be our duty to exert ourselves to procure the establishment of just and equal laws, which protect and give respectability to the lowest subject, and secure to each member of the community the fruits of his industry; to extend the benefits of education as widely as possible, that, to the long list of errors from passion, may not be added the still longer list of errors from ignorance; and, in general, to discourage indolence, improvidence, and a blind indulgence of appetite without regard to consequences; and to encourage industry, prudence, and the subjection of the passions to the dictates of reason. The only change, if change it can be called, which the study of the laws of population can make in our duties, is, that it will lead us to apply, more steadily than we have hitherto done, the great rules of morality to the case of marriage, and the direction of our charity; but the rules themselves, and the foundations on which they rest, of course remain exactly where they were before."

This must be considered as the mildest possible exposition of the application of Mr. Malthus's doctrines: his theory almost necessarily led to some other practical inferences, of a kind to which it is not so easy for a humane mind to assent. It came to be held, for instance, that, where the preventive check had not operated, it was quite legitimate to allow the positive to come into operation. A human being, who had come into existence undemanded by the state of the funds for subsistence, was to be told that the places at Nature's table were all occupied, and there was no cover for him. To the man who married when there was a redundancy of population, "all parish assistance," said Mr. Malthus, "should be most rigidly denied; and if the hand of private charity be stretched forth in his relief, the interests of humanity imperiously require that it should be administered very sparingly." These notions were adopted very generally by a class of political economists, and for twenty years they were in vogue in England, where the notorious abuses of the old poor-law had prepared the minds of many for taking extreme views with regard to public charity. But it was impossible for the great bulk of the community to give a cordial reception to doctrines so violently in opposition to the dictates of the natural feelings.

OBJECTIONS TO MR. MALTHUS'S VIEWS.

A reaction at length took place against the Malthusian theory, and opposite views were presented by various writers, the most distinguished of whom was Mr. M. T. Sadler, whose work, entitled *The Law of Population*, appeared in 1830.

By these writers it was represented, that, in America and the Australian colonies, there was an evident tendency in subsistence to increase in a more rapid ratio than population, insomuch that flocks and herds became a drug, and it was not uncommon in Brazil to use fat carcasses of mutton as fuel in lime-kilns. The only difficulty experienced in those regions was in obtaining a market for the vast amount of produce not needed by the native population. Here, it was said, is a clear case in disproof of the proposition that population always tends to increase more rapidly than food.

As for the geometric ratio of the human increase, by which so great an alarm had been excited, what was it, after all, but a different form of the obvious truth, that the more people there were, there would be the more parents, and consequently the more children? Suppose ten families, existing in 1800, having become twenty in 1825, it might certainly be expected that the addition between the last date and 1850 would be other twenty, not ten merely, seeing that the start was not from ten, as it had been before, but from twenty. Such is but an unavoidable consequence of population swelling by multiplication and not by addition. But if the human family follows this ratio of increase, so do all the orders of organic beings, animal and vegetable; sheep, oxen, and hogs, increase at the geometric ratio as well as mankind, and what is more, they begin to multiply at a much earlier period of life. Poultry, for instance, could probably multiply themselves a million of times, before a couple of the human race could do so once. The vegetable food of man is capable of a still more rapid increase. Wheat generally returns from ten to twenty fold in one year. The produce of a single acre of this grain, increased year after year in the ordinary way, would require only fourteen years to reach an amount which would occupy the whole cultivable surface of the globe. And as it is with wheat, so is it with most of the other plants on which we depend for food, either for ourselves or for the animals which become food to us. So that, instead of there being any such disagreement between the natural possibilities of increase in human beings and subsistence, as Mr. Malthus insisted on, there would appear to be a discrepancy in exactly the contrary way; that is to say, subsistence appears to be capable of a much more rapid increase than human beings.

But—the Malthusians object—when the best soils are all under cultivation, it is necessary to resort to the inferior. These require more labour and afford less return. There is therefore a *decreasing fertility* in the country, while its population is always increasing. To this it is replied by the opposite party, that, while worse and worse soils are in the course of being resorted to, better and better modes of culture are coming into operation, so as to make, perhaps, a third-rate soil capable of producing as much, by a certain amount of labour, as a second-rate soil was a few years before, and so on with the other qualities, each being raised a degree in the scale by every fresh effort of human ingenuity. In point of fact, the best British soils do now bear four times the quantity of grain which they did a few centuries ago, and millions of acres then deemed unfit for tillage now produce as much by the same degree of labour as the best soils did at that time. Perhaps the answer is less satisfactory on this point than on any of the rest.

The Malthusians, however, were said by their opponents to derive the strength of their case from limiting their views to a certain region. Their propositions, it was admitted, might be true with regard to a population shut up in a certain small space, without any connection with what was beyond. But such a population never existed, and therefore the apprehended evils never could take place. From the earliest notices we have of the human family, it appears to have been their custom to spread abroad over the soil, when they found that food could be more easily obtained at a distance from the natal spot than at the natal spot itself. The original command given to man, *to increase, and multiply, and replenish the earth*, is only in accordance with what has always appeared as a tendency of the race. It is probable that, at the present time, not above one-hundredth part of the earth's surface is cultivated, and not one-hundredth part of that cultivated in a scientific or advantageous manner; while, from what has taken place, we may reasonably calculate upon the productiveness of the best cultivated parts being yet greatly increased. With such an almost indefinite field still before us, it seems absurd to be under any anxiety as to the supposed tendency of the human family to a too rapid increase. The superabundance of one district has only to go to some yet unpeopled spot, or to exert ingenuity and industry to raise more food from that which they do occupy, in order to maintain themselves in comfort. There is another means whereby it may chance that a superabundant population can support itself in the native locality, though the productiveness of that locality falls short of the demand for food. If it possess advantages for manufactures, it can exert

its industry in that way, and exchange the products for food raised in other countries, where subsistence exceeds population, and advantages for manufactures do not exist.

The opponents of Mr. Malthus combated his notion of checks on moral and religious grounds; and here, certainly, the natural feelings of mankind greatly favoured their views. It was held as an impeachment of that system of wisdom and benevolence seen throughout all nature, that one of the most powerful tendencies of human beings should be supposed to require being put under an absolute arrestment, upon the penalty of its otherwise leading to misery in the individual and embarrassments in the community. It was held that the preventive check, supposing it to be capable of operating without an increase of immorality, was necessarily attended by an abridgment of human happiness, in as far as it involved a denial and repression of the domestic affections. Its cruelty was also partial, for it bore solely on the poorer classes, to whom celibacy is a greater hardship than to the rich. And even supposing that it could be morally carried into effect, so as to keep down population at a certain level, it was, after all, an uncalled-for interference with divine arrangements, which, from all analogy, as well as from their practical effect, might be supposed as having been designed for good ends. For do we not see that the charge of a family acts in all well-constituted minds as an incentive to industry? and can we doubt that equally will a growing population tend, in ordinary circumstances, to increase the industry of a nation? Contemplated thus, the tendency to increase would appear as a means, in Providence, to stimulate men and nations to the utmost possible exertions for the improvement of the materials placed at their command, so that no faculty of their being might lie waste, and no power of physical nature remain useless. Supposing this to be one of the final causes of the population principle, the preventive check of the Malthusians must, of course, appear as an impious attempt to control one of the Creator's most important designs.

OBSERVATIONS.

Such is an outline of the arguments which have been used on this famous question. It must, we think, be generally evident to new and dispassionate inquirers, that there is some truth in the views of both parties, but that the full and exact truth has not been stated by either. For arriving at this, the means do not perhaps exist in the present imperfect state of statistical science; but in the mean time we may present a few considerations which have occurred to ourselves on this subject.

It appears to us to be only an assumption that there is everywhere a tendency to double the population every twenty-five years. We certainly see that such is the case in North America; but possibly this is considerably owing to temptations which are presented by the state of the country, labour being so expensive in all such regions that a bounty may be said to be put upon the possession of a family. Perhaps the natural tendency is there drawn into something approaching to an unnatural state of activity.

Allowing that the increase is no more than what the natural inclinations of that people dictate, it is by no means clear that all nations possess natural inclinations in the same degree. We know that many features of human character are manifested in very different degrees in different nations; and it is therefore not unreasonable to suppose that there are also national differences in those feelings which lead to the increase of the human family. Individuals, it is well known, are characterized very differently in this respect. There are also obvious differences in families, the peculiarity being apparently hereditary. Why, then, may there not be differences also in nations? Perhaps the light to be derived from the history of families and of individuals, has not yet been taken sufficient advantage of for the illustration of this question. A careful inquiry would probably show a far greater amount of natural causes for the obstruction of population, and these altogether independent of Mr. Malthus's checks, than philosophers are at all prepared for.

The history of many families of historical note incontestably shows, that often, with all external advantages, there is surprisingly little tendency to increase. The extinct peerage and baronetage of England forms, it will be recollected, a pretty large book. In that high rank, there is greater longevity, and consequently, it may be presumed, better health, than in lower grades; yet the line often fails for lack of heirs. To take a few cases which happen to be familiar to us—When George fifth Duke of Gordon died a few years ago, it was necessary, in order to get an heir for one of his titles destined to heirs-male, to go back to the ancestor who had flourished in the time of the civil war, all the intermediate persons having failed to send down male heirs, though many had had several sons born to them. When the main line of the Keith Mareschal family became extinct in 1778, it was necessary to go back for a male representative to a collateral line which sprung off from the main one at the end of the fifteenth century, although many goodly representatives and male cadets had flourished in the interval. It is well known that no representative of the royal family of Stuart since Robert III., who died in 1406, has at this time legitimate male descendants. In short, it would appear that families may exist in flourishing circumstances for hundreds of years, and after all, the male progeny may become extinct, and the name of the race be in time looked for in vain. The contrary is, no doubt, often true: for example, the male progeny of the above-mentioned Scottish king exist in great numbers, in all conditions of life. But, while it is the lot of some to be thus multiplied exceedingly, it is not less true that many leave not one copy of themselves, and that even whole clans, numerous at one time, will ultimately shrink, like an exhaled river, and disappear from the land, and all this notwithstanding an apparent sufficiency of what is necessary to comfortable existence. An illustration occurs to us, to which, we believe, many of our readers will readily find parallels within their own knowledge. A citizen of Edinburgh, who died about thirty years ago, had seventeen sons and daughters, most of whom reached maturity. All the members of this second generation have ever since been in comfortable circumstances: some are now dead; the rest have passed on to such periods of life that it is not to be expected that children will hereafter be born to any of them. And what is the number of the third generation of this family? Only *eight*, the offspring of two marriages. Thus showing that the progeny of a single pair may look large at the first remove, but shrink at the second. We may add, that this family appears decidedly marked by much less than the average of a tendency to matrimonial life. As facts are what is here wanted, the writer may be excused for mentioning a circumstance in his own family history. He can trace its course with tolerable clearness for two hundred years, and is pretty well assured that, during the whole of that time, till the generation immediately preceding himself, no representative of the family had more than one son to transmit its name and property. Local antiquaries are familiar with instances of families once numerous in a certain province, but now extinct. The present writer has reason to believe, that his own family existed for more than twice the space of time above mentioned, in one particular place; yet the county in which that place is situated, does not now contain one person of the name.

Were it even admitted that communities are naturally equal in respect of the inclination and power, it still

remains to be shown, that these tend to be equally manifested in all social circumstances. The readiness with which the Malthusians have assumed that this is the case, seems to us highly unphilosophical.

In dense communities, where all social circumstances are in the best condition, there are many enjoyments not known in ruder states of society. It may not merely be that these enjoyments compensate for the want of others, but they may absolutely take away or supplant the inclination for those other enjoyments, so as to make the "checks," as far as they are concerned, a mere empty name. Following out this line of argument, supposing it to be sound, we arrive at the conclusion, that, when a country becomes filled up with people, it is also in general attended with circumstances which moderate the tendency to increase, without that being felt as any hardship.

The noted case of Ireland tends to support this hypothesis. Singularly deficient in the compensatory or rather preclusive conditions, this country has long been remarkable for the rapid increase of its population. The common people, reduced to a degree of poverty which admits of no hope, and exposed to a constant privation of all the ordinary solaces of life, are driven to matrimony as the only comfort in their power, just as others in their condition are driven to the use of intoxicating liquors. The consequences lead to greater poverty, and greater poverty tends to increase the evil; and thus will such a system of things go on until counteracting agencies are brought into operation. Such agencies are now at work in Ireland; wealth and its enjoyments are increasing; and we may therefore hope speedily to see the advance of population in that country less of a wonder than it has been.

Granting the above arguments to be sound, it follows that the stationary condition of the population of old countries is not necessarily to be supposed to be attended with either the hardship of restraint or an extraordinary mortality. If the wealth and ordinary solacements of a people in such circumstances are not in the way of being lessened, they may fairly be presumed to be as well off in all respects as the rapidly increasing multitudes of America.

Where we see the inhabitants of an old country rapidly increasing, we must come to one of two conclusions, either that that country is in a flourishing state, so that there is a kind of bounty put upon children, or that it is in a state of such wretchedness that the intercourse of the sexes is the only attainable enjoyment. With regard to Ireland, we presume there can be no doubt of its liability to pass into the latter category. But the rapid increase of the English people in the last forty years will probably be the subject of a doubt. To determine this question, it might be inquired if the increase of the agricultural products and of the manufacturing industry of the country has been in an equal ratio, and if labouring men, skilled and unskilled, can now obtain for their wages as large a share of the comforts of life as formerly. Notwithstanding popular declamations to the contrary, we suspect this to be the case, and consequently believe the increase of population in England to be, upon the whole, of a healthy description.

POOR-LAWS.

In all stages of society there has existed a class, emphatically termed *the Poor*, composed of persons who, but for the charity of their neighbours, would be nearly or totally destitute, being themselves unable, or all but unable, to supply their own wants. It is easy to see how this has been and must be; for, from accidents in the operation of the natural laws presiding over the birth of individuals, some come into the world without the usual gifts of body and mind required for obtaining a sufficient subsistence; the accidents of life deprive others of the use of their full powers; many reach an infirm old age, without having laid up a store to help them over it; the consequences of vice and error—of all those countless temptations which beset human nature, and from which no one is altogether safe—leave many in a helpless state; finally, in the imperfection of all political institutions, there are circumstances which press severely upon classes and persons, tending to make their own efforts for their subsistence insufficient. The operation of accidents upon one class of parents, and the vices and neglect of others, likewise leave many young and helpless children in a state in which they would be destitute but for the aid of neighbours. All of these causes being inherent in human nature and in society, we may be assured that "the poor we shall have with us always," however it may be possible, by judicious and humane efforts, to keep their numbers within comparatively moderate bounds.

In an early state of society, the relief of the poor is left to the operation of benevolence amongst individuals; and the destitute are either succoured by those locally near them, or go forth to beg relief in a wider circle. Generally, the efficacy of benevolence for this end is made the greater, in consequence of the succour of the poor being set forth as a duty in almost all religions. In addition to occasional and particular acts of charity, donations are made and legacies left, for the purpose of affording a more or less regular and systematic relief within certain bounds. As society, however, advances, it is found that the charity of individuals is either an insufficient means of succouring the poor, or is attended with certain inconveniences. The classes of society becoming more detached from each other, cases of destitution make appeal, almost exclusively, to the parties nearest in poverty; while the rich, and the comparatively rich, are saved from all concern in the matter, merely because local and social circumstances spare them a personal connection with it. A relief by benevolence is found to be oppressive to those who have kind feelings, while the niggardly and ungenerous escape. A dense and highly artificial state of society rendering it impossible to keep watch over particular cases of destitution, the relief afforded is unavoidably partial and unequal—no one knowing the real needs of a petitioner, or how far he is relieved by others; so that a door is opened for the practice of gross imposture, while the more modest poor are probably the least liberally treated. It is also generally found, that this state of society is attended with an increase of the numbers of the poor, rendering individual efforts insufficient, and tending to such disorders that a public provision becomes necessary as a matter of police. A new principle is then evolved from the natural fact of the existence of a poor class, namely, that the community cannot be safe from imposture, spoliation, the propagation of disease, and other evils, unless it combine to assure itself that no person in the country shall want the necessaries of life.

It is then that states begin to make arrangements for the regular relief of the poor; and, generally, these arrangements are of a more or less advanced and efficient nature, in proportion to the advanced social condition of the respective countries. In the most of the Catholic states of Europe, the system adopted consists simply in the ministers of religion taking charge of the voluntary contributions of the people, and administering them to the best of their ability. In Portugal, Sardinia, Venice, France, Belgium, Holland, and some other countries, the same system exists, excepting only that the ministers of religion are superseded in their charge by officers appointed by the state. We need scarcely remark, that the single fact of the funds being voluntary renders it impossible, as to any of these countries, to be certain that

the provision for the poor is sufficient in amount. In England, Ireland, Prussia, Bavaria, Wurtemberg, Mecklenberg, Berne, Russia, Denmark, Sweden, and Norway, the principle is recognised that a compulsory provision ought to be made to ensure that all the members of the community shall have the means of subsistence. In England, this has been in operation for nearly three centuries; but, in the most of the other countries enumerated, it is of comparatively recent adoption. In America, all the states of the Union which are of English origin have, from their commencement as colonies, adopted this principle. In Scotland, laws for a compulsory provision have existed nearly as long as in England, but have never been carried out into full operation. In that country, a voluntary system is followed in more than one-half of the parishes, and a compulsory system in the rest, the clergy being, in almost all instances, the administrators; but nowhere is the principle of a legal right in the poor to relief, or, what is identical therewith, of its being the interest of the community that relief be granted, practically recognised.

ARRANGEMENTS FOR THE POOR IN ENGLAND.

Acts respecting the poor in England only made arrangements as to the places in which they should beg, until, in 1536, immediately after the dissolution of the religious houses, by which the poor had previously been in a great measure supported, it was found necessary to make an effort to repress the enormous prevalence of vagrancy, by enacting that head officers in parishes, towns, and counties, should take charge of the impotent poor and collect alms for their support, and at the same time use force to compel able-bodied mendicants to work for their own livelihood. This and subsequent acts of a similar character appear in a great measure to have failed in their object, chiefly perhaps from the severity of the penalties imposed for disobedience. In 1572, we find the first trace of compulsory assessment for the poor—a measure then resorted to, apparently, because all other means of collecting money had proved insufficient.

It was, however, by the famous act 43 Elizabeth, c. 2, (1601), that the basis of the present system of poor-relief in England was laid. The professed objects of this law were, "to set the poor to work, to relieve the lame, impotent, old, and blind, and to put out their children as apprentices." To attain these objects, the inhabitants of every parish in the county were required to raise a fund sufficient to maintain their own poor; and the administration of this fund was placed in the hands of parish overseers, under the control of justices of the peace. The leading merit of this act was, its requiring that the claims of the able-bodied for relief should be subjected to a *test*, to prove that the alleged want was not the result of an indolent disposition: *such persons were to receive relief only on condition that they should work for it.* To make this rule certain of operation, an act passed eight years after (7 Jac. I. c. 4) ordered the building of *houses of correction*, to be provided with cards, mills, and other implements, and where the vagrant able-bodied poor should be set to work. This may be considered as the origin of the workhouse system in England.

It is clear from the statutes of this period, that the chief evil which the legislature found itself called upon to consider and provide for, was the indolent and vagrant disposition of a large section of the people. It was not, as now, that many men occasionally find a difficulty in getting work, but that many were unwilling to work, preferring to wander about the country in idleness. It appears that these vagrants were accustomed to stay only for a short period in one place, and to flit about to wherever they thought they would be best supported; nor can it be doubted that, in lonely places, they would not be backward to use means for terrifying the lieges into contributions for their benefit. That, in such circumstances, these people would want all moral culture, and be a source of danger to the community, is of course evident. It required many years' operation of the law to reduce this evil; but at length, about the end of the seventeenth century, it seems to have been considerably lessened. The same class of persons then began to prefer the benefits to be obtained through the claim which the law gave them upon their native parishes, and the evil of vagrancy was gradually exchanged for one of another but less grievous kind—an inclination to a timid and slothful dependence on the relief to be obtained at one fixed place. The houses of correction were mainly penal establishments; and it was not till 1723 that workhouses, as now understood, were established. An act passed in that year enabled parishes, either singly or in union, to provide themselves with houses wherein to employ the poor; and enacted that, in case any person refused to be relieved in those houses, he should not be entitled to any other relief. This might be severe upon the real pauper, but it effectually unmasked the voluntary one and the impostor, and proved a protection to parishes against the orders of justices, over-liberal of money not their own. The operation of this law was so favourable to the public, that some began to imagine that paupers might even become profitable; and this was partly the cause of an act (22 Geo. III. c. 83) in 1782, usually called *Gilbert's Act*, which threw upon guardians the duty of finding work for the poor near their own residences, and making up what was required for their subsistence out of the poor-rates. The use of the workhouse as a test of real indigence and inability was thus in a great measure undone, and all its benefits in repressing a pauper population lost. Gilbert's act may be said to have been the foundation of all the evils for which the English poor-laws were latterly so remarkable.

In 1795, the price of wheat, which, at an average of the three preceding years, was 54s., rose to 74s., and the condition of the labouring classes consequently became one of considerable privation and hardship. Instead of temporary measures for getting over a temporary difficulty, one of a permanent nature was adopted. The magistrates of Berkshire in that year issued tables, stating what the wages of a labourer per week ought to be, according to the magnitude of his family and the price of the gallon loaf; directing at the same time the overseers, and others concerned in the management of the poor, to regulate their allowances accordingly. The minimum weekly wages of an unmarried labourer, supposing the gallon loaf to sell at one shilling, were set down at 3s.; when married, and having one child, wages were to be at least 6s.; if he had five children, they were to be at least 12s.; if he had seven children, they were to be 15s. In the event of the price of the gallon loaf rising to 1s. 6d., the wages of an unmarried man were not to be less than 4s. 3d. per week; while the wages of a married man, with a single child, were not to be less than 8s. 3d.; and those of a married man with seven children, not less than 20s. 3d. These regulations, which remind one of the ignorant legislation of the fourteenth century, were made binding, universal, and permanent, by an act passed in the ensuing year (36 Geo. III. c. 23). It cannot fail to be remarked what a mean opinion of the character of the labouring classes of England must have been entertained amongst the more enlightened men of that day, when it was thus thought necessary to undertake for them some of the simplest duties which they owed to themselves, and to make them everywhere pensioners upon the public for a considerable part of their subsistence. As an attempt to secure to a portion of the community the same supply of food in scarce as in plentiful years, and consequently to relieve them from the necessity of those retrenchments by which a deficient supply is distributed over the whole year, and absolute famine averted, the act was further liable to be considered as a

gross absurdity. The evils of the regulations themselves were increased by peculiarities in the administration, by which the labouring classes became a means of enabling one class of rate-payers to carry on a constant warfare against the pockets of another. The general evils of the poor-laws were much aggravated by the arrangements with respect to *settlement*; virtually, the labouring classes were *imprisoned* in the parishes of their nativity, or where some subsequent circumstance, as apprenticeship, marriage, and inheritance, had given them a claim. Thus, the population was distributed not as required by the demand for labour, but as certain accidental circumstances might direct; and, accordingly, there were often hordes of useless labourers at one place, and a great amount of labour without hands to undertake it in another. "Practically, in a pauperized district, where the labourers' wages were composed partly of wages and partly of allowance, the married man had no more free-will as to the parish in which he should reside, the master whom he should serve, or the subsistence which he and his family should receive, than the horse which he drove. In parochial language, he *belonged* to the parish in which he had his legal settlement."* There can be no doubt that the condition of the working classes in England, during the prevalence of this system, was a species of slavery. The system lasted with little alteration for nearly forty years; but long before that time, its moral evils, and the enormous increase of expenditure which it demanded, had excited great alarm, and made England, with regard to this particular part of its domestic polity, a wonder to neighbouring nations. The sum raised for poor-rates in 1776, while the workhouse system of 1723 was still in operation, was only £1,720,316; in the three years after the passing of Gilbert's Act (1783-4-5) it averaged £2,167,749. But the average of 1801-2-3 was £5,348,205; in 1818, a year of scarcity, it reached the enormous sum of £9,320,440; and even in the fair seasons of 1830, 31, 32, and 33, it was above eight millions. This was an increase far exceeding that of the population, and the more alarming as it took place during a period of progressive national prosperity. Almost everywhere it pressed very severely upon the property of the country, and in some places had even caused property to be abandoned, the rates exceeding all that could be derived from the land.

The evil being generally felt and acknowledged, a royal commission was issued in 1832 for inquiring into it, in order that parliament might apply a remedy. The following is a condensed summary of the report which this body drew up, after a careful investigation conducted throughout every part of England and Wales:—"That wherever the expenditure has most increased, there, also, the industry of the labourer had proportionally degenerated, because in such places subsistence from the poor-rates was more easily obtained than by labour. That under such influences the prudence and thrift were discarded, because they could, with the utmost success, only secure for him, by present sacrifice of enjoyment, the same future advantages of which the parish held out a prospect without the necessity of any sacrifice save that of independence. That his sobriety and temperance were thus left without encouragement, and, on the other hand, exposed to the temptations of comparative idleness, and the facilities for the indulgence in idleness and intemperance which always accompany the growth of pauperism: his respectability of demeanour was now useless, as respectability of character ceased to be relied on as a means of securing employment, itself no longer an object of desire. That in the same proportion as he became independent of regular industry, did he also become independent or regardless of the comforts of his home, which are indispensable to the labourer after a day of toil, but are rarely sought or valued as a change after a day spent in idleness or dissipation. It was also observed that, as the habit of pauperism increased, the standard of subsistence of the labourers in the district was lowered, the relief never being sufficient of itself to maintain the pauper independent of all work; and yet, by rendering him partially so, constantly tempting him to forego that further portion of comfort which was attainable only on the comparatively hard terms of earning it by the sweat of his brow. The standard of the paupers' subsistence being once lowered, that of the industrious labourers amongst whom they lived, and who occasionally felt the effects of their competition, fell also. Where the system prevailed of allowing relief in aid of wages, there the operation was immediate, as all the labourers were at once pauperized, being equally exposed to the effects of a system which left all industry, beyond a certain point, without its reward, and therefore without a visible object. While these influences were destroying the industry and morality of the able-bodied labourers, the bastardy-law was holding out encouragement to female unchastity, in the way of a money allowance for each bastard, which, by its amount, of itself elevated her condition in proportion to the number of her spurious offspring, rendering a mother of several bastards better off than she would have been as a mother of as many lawful children, and securing her a dower which usually tempted some man to marry her; while the same law, by subjecting the supposed father to punishment, often subjected him, at the woman's discretion, to the alternative of marriage or a jail—the former of which was generally chosen as the least present evil. Under these influences female chastity had, in many districts, so far ceased to be valued as a virtue, that not only the woman herself, but her parents and her husband, seemed, where the law had had its full effect, to have become indifferent to it.

"The evils of the system were not confined to the paupers, but extended to all who had to administer the law. So large a fund as between seven and eight millions, administered without any practical responsibility, naturally tempted the cupidity of the officers through whose hands it passed. The office of overseer was, therefore, generally sought by a class of small farmers and tradesmen, to whom the office must have been most burdensome had it been discharged gratuitously as the law provided. It was found that the overseers were usually appointed, in places where the evil had reached a great height, not from the class of the *substantial householders* of the parish, as the statute of Elizabeth requires, but were usually needy persons to whom the indirect advantages of the office were important, and who were helped into the office by the efforts of persons similarly interested, either as tradesmen of the parish, or as owners of the dwellings which the paupers inhabited, or in other ways, more as receivers, directly or indirectly, of the rates, than as rate-payers. The spirit of the enactment in the 45 Geo. III. c. 54, § 1, which provides that no contract for the lodging, keeping, or maintaining of the poor, or for taking the benefit of their work for their better maintenance, shall be valid, unless the person with whom it is made shall be resident within the parish, was fully carried out in practice in nearly the whole of the 15,000 parishes and places separately maintaining their own poor, every tradesman of the parish, and every employer of labourers, being bribed to maintain whatever system the vestry adopted, by a share in the profitable supply of the parish poor, or by the payment of a part of the wages of his labourers in the shape of relief to them out of the rates. The refractory parishioners were constrained to acquiesce, on pain of losing these and similar advantages, which, being withdrawn or denied, left to them only the obligation of paying those rates. To secure the full operation of this system, the parish was not permitted to

* *Edinburgh Review.*

deal elsewhere for any commodity with which any parishioner could supply it, and was thus usually confined to the very worst market for the goods it purchased, in the same manner as, by the settlement laws, it had been cut off from the supply of other labourers while any belonging to the parish remained unemployed.

"The evidence seems also to prove that the functions of the magistracy had almost invariably ceased to be applied to the objects for which they had been created. The magistrates of counties were usually too dispersed, and too little immersed in the actual business of the several parishes, to avail themselves of the advantages which the overseers and the other more immediate administrators of the system derived from it. The magistrates of corporate boroughs, towns, and cities, were, however, in many instances, found to be not less rapacious or ready to apply the administration of the law to their pecuniary profit or direct advantage than the parochial officers. But although the magistracy must generally be acquitted of having sought to derive an immediate pecuniary advantage from the administration of the poor-laws, they were none the less ready to pervert the law to purposes utterly at variance with its original purposes and with the prosperity of the community. Very many of the magistrates, influenced by benevolent intentions, were ready on all occasions to admit the claim of the pauper, and to compel overseers to administer relief when they inclined to refuse it: such magistrates were constantly resorted to by paupers in preference to others who more vigilantly examined the grounds of their claims; and a reputation for being the *poor man's friend* was easily earned by the lavish and immoderate expenditure of the fund of the general rate-payers. This reputation was found to be useful in many ways, and was thus sought for political purposes, or for the attainment of local power, or for the mere gratification of vanity, by many magistrates whose sympathy for the pauper would never have been excited if it had been incapable of being gratified at the expense of the rate-payers. When it is considered that the county magistrates lived in the midst of a population of willing paupers, and the means of annoyance which the latter possessed, if they found occasion to use it, against an obnoxious person, are also borne in mind, it is not to be wondered at that the magistracy generally purchased the good-will of their neighbours by sacrificing the interests of the rate-payers, whom they never had personally before them, and who were very inadequately represented by the overseer, whose interests were too frequently found to coincide more with the demand of the pauper and the inclination of the magistrate than with the strict line of his duty."*

In consequence of the report of the commissioners, an act was passed (4 and 5 Will. IV.), usually called the *Poor-Law Amendment Act*, by which these monstrous evils were for the most part extinguished, and a return made to the just principles and practices dictated by the acts of 1601 and 1723. Both parties in the state supported this measure in almost all of its provisions,† and it was only opposed by a few individuals. With regard to the impotent poor, this act rather increased than diminished the liberality of the arrangements, while it made several other considerable improvements. The great class of adult persons who, from old age or infirmity of body, are wholly unable to work, were to remain, as before, entitled to a support by means of out-door allowances. Of destitute children, those unlikely from natural defects to be able to win their own bread, were provided for by out-door relief; those, on the other hand, who were likely to prove useful members of society, were taken in charge and reared in separate establishments, where their education and training for industrious callings were particularly cared for. Judicious provisions were also made for their being ultimately set afloat in the world, as apprentices. With regard to illegitimate children, several former provisions of evil tendency were annulled, and it was provided that no regard should be paid to them till they became actually chargeable upon the parish, when relief should be extended through the mother, she being in this respect treated as a widow. Persons unable to support themselves through accident or from sudden and dangerous illness, were to receive temporary relief, and to have all necessary medical attendance. Insane paupers were to be placed in proper asylums at the expense of the public.

The provisions for *able-bodied* claimants formed the most important part of this act, as indeed it was in this department that the abuses of the old system were the most glaring. The main feature of the new arrangements was the erection of workhouses by unions of parishes, where relief should be offered to able-bodied claimants, on the condition of their giving their labour in return, and submitting to the rules of the establishment. This was only a revival of the *test* applied by the act of 1723, the object being to check applications for relief from the slothful, and to throw upon the able-bodied in general the duty, which is everywhere else the lot of free-labourers, of finding work for themselves. The new law contemplated that the food and accommodations of the workhouse should be good and sufficient, but yet not quite so good as those which the free labourers of the district could obtain by their own exertions; so that it might, upon the whole, be more agreeable to the able-bodied man to work for himself than become chargeable. At the same time, it being acknowledged that a change from one system to another could not be expected to be suddenly effected, provision was made for enabling the administrators of the law to exercise a humane discretion in applying the new regulations.

Some material changes were made in the machinery for the administration of the poor-laws. The rate-payers elect for each union of parishes a board of guardians, each rate-payer having votes in proportion to his property, and the proceedings of these boards are under the control of a central board, composed of three commissioners appointed by the crown. Under the chief commissioners there are twelve assistant ones, each of whom inspects a particular district, and reports upon whatever he sees amiss, with a view to its being amended.

Gradually, under the operation of the Poor-Law Amendment Act, the greater part of England has been formed into unions, each under a board of guardians and each provided with a workhouse. Down to 1841, there were 588 unions formed, including all the parishes excepting about eight hundred, and a population, by the census of 1831, of 12,182,031 persons. In the first year of the new system, the commissioners issued a general order, prohibiting relief in money to the able-

* M'Culloch's Statistical Account of the British Empire, vol. i. pp. 615-16.

† To prove what is here stated, all who know any thing of parties, and their connections in this country, will be ready to own that no better means could be fallen upon, than to make such extracts as the following from the two leadings *Reviews*:—

The *Edinburgh Review* of March, 1831, after remarking that the intended benevolence of the allowance system had proved a "bitter curse;" that it robbed the rate-payer to pay farm labour, and enslaved the labourer; adds that "*its abolition is the imperative duty of the legislature.* We say abolition, for nothing short of this can be of any material service."

The *Quarterly Review* of January, 1834, after making an extract from the part of the Commissioners' Report drawn up by Mr. Chadwick, says, "It is gratifying to us to find the immediate abolition of the allowance system here insisted upon so strongly. We might have wished this suggestion to have taken precedence of every other, as being *by far the most important and indispensable of any.* * * An improvement in the management of work-houses is highly necessary. *They should be made places of strict confinement and hard labour to the able-bodied,* with a moderate diet, and a *total denial of all indulgence*, in order to render a residence within their walls *as irksome and distasteful as possible*, and the last resource of those only who cannot, by their utmost exertions, obtain a maintenance elsewhere.

bodied in the employment of individuals, thus throwing their entire support upon their masters. In the second year, they began, in a cautious manner, in obedience to the spirit of the act, to put a stop to out-door relief to the able-bodied—meaning labourers who, with their families, are in health, but excepting widows with young children. This order was issued at first to sixty-four unions, and afterwards it was applied to others, until the total number to which it was extended was, in May, 1841, 437, comprising a population, according to the census of 1831, of 7,372,021 persons. By these means the expenditure upon the poor was reduced from £7,511,219 in 1834 to £4,044,741 in 1837, or almost to one-half. Since 1837, the expenditure has again been on the rise, and in 1840 it was £5,110,683.

The first effects of the stop put to the allowance system was most surprising. The so-called surplus population—the hordes of unemployed men who had required to be partially or entirely sustained by the parish funds, who had been condemned to stand in the parish pound for days, and spend half their lives in a kind of idleness in the parish gravel-pits—disappeared as if by magic. It was found that, left free to seek employment where it could be had, and furnished with the usual motives to exert their industry, they all obtained employment. On this subject the earlier reports of the commissioners gave some valuable information, showing how delusive must have been those views which held forth the population as redundant, and as needful of artificial support. The whole evil seemed to be one of derangement. Once disengaged from the trammels which confined men to certain spots of ground and put a bounty upon their remaining idle, the people quickly fell once more into natural arrangements, and there was an independent maintenance for all. To quote an able writer on this subject—"When the bonds which confined them to their parishes were broken, they distributed themselves where their services were most wanted. When they were allowed the free disposal of their services, they endeavoured to make those services valuable. When the application of more efficient labour increased the employer's returns, and at the same time reduction of rates diminished his outgoings, he had a larger fund for the purchase of those services. The redundancy vanished with its causes. The able-bodied pauper is the result of art. He is not the natural offspring of the Saxon race. Unless his pauperism is carefully fostered by those who think it their interest to preserve it, he rapidly reverts to the *normal type*—the independent labourer."*

The union workhouses are in general remarkably well-arranged establishments. The food, both in quality and quantity—the accommodations of all kinds—the moral discipline and order, are in general all that the humane and the enlightened could wish. The arrangements for the education of the young are particularly worthy of commendation. Workhouses are for the most part occupied only by some portion of the aged poor, and by young children. Though held open for the reception of the able-bodied under any exigency to which they may be presumedly liable, they are rarely resorted to by such persons, partly because, the labour-market being freed, there is in general no lack of means for an independent subsistence, and partly from the natural dislike to a life of restraint. One regulation of these houses may be supposed to have operated powerfully in keeping idle married men at a distance from them. In most instances, they are not allowed to live in the same part of the house with their wives. Partly this was needful for the sake of order, and to avoid sundry gross evils which flourished under the old system. Partly it is owing to a principle laid down by the commissioners, that a pauper is not entitled to be in this respect on a level with the man who works for himself and his family. The regulation has attracted much censure, and perhaps it would have been much better, at least in a point of expediency, not to have had it introduced.

The new law was enacted for only five years. It has been oftener than once renewed for a brief period; and there is at this time (Autumn 1841) a general expectation that, before being renewed permanently, it will be considerably altered. Excellent as the measure has been in its main features, and though it has redeemed the English labouring classes from a kind of slavery, it has been the subject of an outcry of the most violent character. This is partly traceable to those who profited by the abuses of the old system, partly to an ignorant sentimentalism, and partly to the arts of politicians. There is too much probability that this outcry will prevail to a considerable extent, and that England is about to see some of the worst abuses of her old poor-laws restored.

ARRANGEMENTS RESPECTING THE POOR IN SCOTLAND.

The poor are provided for in a much more sparing manner in Scotland than in England; and the able-bodied, so far from having even the offer of maintenance in a workhouse, are totally overlooked.

The early acts of the Scottish parliament respecting the poor, contain, like those of the English parliament, only provisions for the repression of begging. At length, in 1579, an act, apparently suggested by one of the English parliament seven years earlier, introduced the principle of a compulsory assessment for the impotent poor, providing at the same time that able-bodied beggars should be punished as vagrants. The administration of this law was committed to justices of peace, which class of functionaries did not then exist, but were contemplated, though no such appointments in reality took place at that period. Acts of 1592 and 1663 ultimately committed the management of the poor, in country parishes, to the heritors (proprietors) jointly with the kirk-sessions—the latter being parochial ecclesiastical courts, composed of the minister and a small body of lay elders—and to the magistrates in royal burghs. From these administrators there is no appeal except to the supreme civil court of the country (Court of Session), an arrangement of course equivalent to there being no appeal at all. Three years' residence confers a *settlement*.

In 236 parishes, containing 1,137,646 persons (nearly the half of the population of the country), a legal assessment has been resorted to. In 126 parishes, with a population of 305,654, there is what is called a "voluntary assessment," which may be considered as only a regulated and equitable mode of voluntary contribution. In the remaining 517 parishes, containing a population of 872,628, there is no assessment whatever, and the funds for the poor arise from voluntary contribution, chiefly in the form of offerings at the church doors. The average annual sums collected under this system during the years 1835, 6, and 7, were—by collections at the church doors, £38,300, 10s. 2d.; by other voluntary contributions, £18,976, 10s. 2d.; from sessional fees, &c., £20,604, 12s. 10d.; from assessment, £77,239, 19s. The aggregate is £155,121, 12s. 2d. It is remarkable that the whole sum here described as raised by assessment, being for 236 parishes, including Edinburgh, Glasgow, and all the other considerable towns in Scotland was just about a seventh more than the sum raised for the poor in *one London parish* in 1833 (St. George's, Hanover Square).* In Scotland, the expenditure for the poor is equal, on the average of the above three years, to 1s. 3¾d. a head on the population; in England,

* *Edinburgh Review*, lxxiv. 33.

* The sum raised for the poor in that parish in 1833 was £67,336. The new law reduced it in 1835 to £27,391.

during the same period, the expenditure was equal to 6s. 10½d. a head on the population.

As might be expected, the provision for individual paupers, is, in Scotland, extremely slender, and almost everywhere a vast number of claimants are altogether rejected. In the two workhouses of Edinburgh, for example, the average annual expense for each inmate is from £6 to £8. Excepting in these instances, the provision for the poor in Scotland may be said to consist in a small weekly dole of money, considered as a loan or aid, for which the relations of the parties, or the parties themselves, might afterwards be held chargeable, supposing that their circumstances allowed of its being refunded. In the case of persons who, from infirmity, fatuity, or infancy, can do nothing for themselves, and who at the same time have no relations able to aid them, the dole is considered as a full provision for maintenance: from 2s. to 4s. are given in such cases. Where any remains of health and strength exist, the allowance is usually less in proportion, and may be said to range from 6d. to 2s. a week. It is in these cases considered strictly as an aid, in addition to what the individual can gain by personal exertions. In the unassessed parishes, the average allowance was, a few years ago, £1, 0s. 4½d. per annum. The administrators of the funds (usually the kirk-session) subject every application for relief to a rigid scrutiny, and never continue any relief when they think it ceases to be strictly necessary. Generally, it may be said, the provision is more liberal in towns than in the country, and in the Lowlands than in the Highlands. In the last districts the funds for the poor are extremely small. "There is something," says a late writer, "approaching to the ludicrous in finding the minister of Alness, in Ross-shire, saying, in his statistical account, that people come to his parish for the benefit of its poor allowance: the fund is £58, 18s. 4d., divided among 110 paupers, the highest annual allowance being £1, and the lowest 6s. If we make allowance for a resident and humane landlord, and take a glance at the provisions in the neighbouring parishes, we shall find, however, that this choice is not made without reason. In the very useful report of the General Assembly in 1839, we find that Dingwall, the immediate neighbouring parish, gives an annual uniform allowance of 5s.; Foderty gives a maximum of 12s. and a minimum of 2s. 6d.; Cairnach a maximum of 12s. and a minimum of 4s.; Edderton a maximum of 8s. 6d. and a minimum of 5s. 6d.; Knockbain a maximum of 10s. and a minimum of 5s.; and Kirkmichael a maximum of 10s. and a minimum of 3s. 6d. These are all annual allowances; nay, there is one parish called Criech, which gravely reports itself as giving its poor a maximum of 3s. a year, and a minimum of 1s. Intense, indeed, must be the misery that makes human beings barter independence for sums like these. It is only by knowing such facts that an Englishman can comprehend how the 7s. a month of Edinburgh and Glasgow, given only to those who suffer under permanent bodily disability, should exercise a power of attraction at 200 miles' distance, and stand forth as the crowning and rich reward of a toilsome journey, and three years of patient suffering. And yet, it seems, that it is not alone among those who obtain the wretched pittances of the Highland parishes that we are to look for the misery of the land; we must take into view those who are denied the boon. The report of the Assembly, speaking of the numbers who in the Highlands and Isles are denied a place on the poor's roll, gives the following characteristic illustration:—

"'The parish of Kilmuir, in the Island of Skye (cutting off the district attached to the parliamentary church of Steinscholl), contains a population of 2275; the average amount of funds, distributable among the poor, is about £3 annually, and a distribution is made only once in two years. The last distribution, prior to the date of the return (21st August, 1838), took place on the 3d March, 1836, when the sum of £6, 3s. 6d. was divided among 68 paupers.' The minister states, 'As the amount of church collections has varied little for several years back, it has been found necessary to restrict the number of paupers to about 60 or 70 at each distribution; but, were the funds of greater amount, it would be necessary to admit no fewer than 200 paupers on the roll.'"—*Westminster Review*, xxxvi. 394.

The smallness of the provision for the poor in Scotland, is not to be rashly attributed to want of feeling on the part of the nation. There is in Scotland a strong prejudice against all but self-dependent modes of existence. It is a general opinion that all systematic succour held out to the poor is productive of evil instead of good, even to the poor themselves. This succour is thought to be particularly detrimental, when it is the result of a fixed assessment or rate, for then it is supposed that the poor are led more particularly to depend on the public charity instead of their own exertions or the kindness of relatives. The smallness of the sums given to the helpless, can only be attributed to this general prejudice against pauper relief; for it may be presumed, that, if there were another feeling in the case, the ordinary slender funds would be augmented by a sufficient assessment. What proves very strikingly that opinion, and not want of benevolent feeling, is the main cause of the small provision, is, that the humbler classes in Scotland have, in general, as great a disinclination to ask public charity, as the wealthier classes to give it. They are generally anxious to avoid resorting to the kirk-session as long as possible, and only do so when all other resources fail. This, we say, is generally the case, for of late years there have been strong symptoms of a change of feeling on this subject among the Scottish people.

Practically, the Scottish poor are only in part supported by public provision. Everywhere, private benevolence steps in to give a share of the maintenance required. There is thus a constant contention between two principles; the session being anxious to throw as much of the burden as possible upon private parties, while private parties, on the other hand, only give what the session pertinaciously withholds. There is also a constant contention between one court of relief and another. A penurious parish, striving, as the phrase is, to *keep down the roll* as much as possible, drives off the poor to other places, where, possibly, an assessment allows of a somewhat handsomer provision, and where a new settlement can be acquired in three years. From the Highlands to the Lowlands, from country parishes to towns, there is a constant flowing of paupers, under the attraction of better allowances. There have even been instances of niggardly parishes extending aid for the purpose of enabling their paupers to acquire a settlement in towns. It has been found that, among the dependants of public charity in Edinburgh, only 871 are natives, while 1931 are from other places—234 of them being from the five northern Highland counties, two hundred miles distant. On the Dundee poor's roll, there are 344 natives, and 655 from a distance. On that of Aberdeen the disproportion is still greater, 420 to 1097.

Till a recent period, scanty provisions for the poor, and the repression of pauperism, were subjects of pride in Scotland. In the evidence taken by the English commissioners a few years ago, the practice of this northern kingdom was held up in favourable contrast with the ultra-liberality of the English system. It used to be a boast with a kirk-session, that it had few or no poor, or that they were kept down at little more than nominal allowances; and the opposite case of an assessed parish would be pointed to, as a proof of the fatal nature of such a mode of poor-relief, the parties altogether overlooking

the fact, that they themselves, by denying or stinting relief in their own district, were the great causes of the undue burden that befell their neighbours. It was at that time that Dr. Chalmers propounded his schemes for an improved management of the poor, the main features of which were, that voluntary contributions at the church-doors should be the sole fund looked to for public relief, (a compulsory tax being considered as tending to throw benevolence out of action)—that the kirk-session should take all charge of the poor—that they should, in the first place, when a claim was made, endeavour to make the parties help themselves by their labour; if totally unfit for work, then throw the burden upon relatives; if there were none such with any means, then upon neighbours, no matter how poor; and only when all such means failed, was any public relief to be given;—a plan so obviously inequitable, as tending to save the rich at the expense of the poor, that it has never, to our knowledge, met with a single advocate besides its author.

A considerable change in public opinion upon this subject has been wrought by the publication of a pamphlet by Dr. Alison, of Edinburgh.* The object of this essay is to prove that the system of excessive restriction pursued in Scotland is attended by evils which ought to make it a subject of shame rather than pride to the community. He contends that, in large towns more especially, it is productive of wide scenes of misery, shocking to all benevolent feeling, and positively dangerous in some respects to the rest of the inhabitants. He shows, that in Edinburgh, Glasgow, Dublin, and other large cities, where there is no adequate system of relief for the poor, fever has been of late years prevalent to a degree quite unknown in any English town—a fact which must in the main be ascribed to the wretched condition of great hordes of people gathered in the meaner parts of those cities. Will it be believed that, in two late years, one-*sixteenth* of the population of Edinburgh, and one-*sixth* of the population of Glasgow, were affected by dangerous fevers? The average number of cases treated in the hospitals of Glasgow during the last seven years, has been 1842, while in Leeds, where the inhabitants are a little more than a half, the average for the same period has been 274; and in Newcastle and Gateshead, where the inhabitants are about a fourth, only 39; there being in Bath, during the same period, "only a few cases." It is true, that want of cleanliness, bad ventilation, and so forth, are proximate causes of fever; but Dr. Alison contends, and apparently with success, that destitution is the main and primary cause. He also shows that, as fever is more apt to carry off the adult than the young, it burdens the public with immense numbers of orphans, many of them the children of persons who, if spared, would have kept them above public charity. Thus, so far, the restrictive system seems to spread, instead of limiting, the evil of pauperism. When a fatal epidemic breaks out in one of the towns in question, subscriptions are generally raised by the wealthy classes to succour the suffering poor; and the evil is thereby perhaps alleviated in some, but only in a slight degree. The victims of the pestilence have been prepared for it by years of unrelieved suffering, and that generosity which once might have prevented disease, is now unable to arrest its calamitous progress.

The popular doctrine in Scotland is that advanced by some political economists, that systematic relief for the poor leads to habits of improvidence, and encourages marriages among persons unable to support their offspring, thus tending to increase, instead of diminishing, pauperism. Dr. Alison, on the contrary, maintains that "poor-laws, such as exist in England, do not interfere with moral restraint, but support and strengthen it; and that moral restraint is nowhere so feeble, and population (in a long-inhabited country) nowhere makes such rapid progress, as where there is no legal provision for the destitute, and where therefore the prospect of destitution is always clear, obvious, and immediate." A pauper population is increased by the continuance of a state of abject poverty and a want of the necessaries of life. He says—"Below a certain grade of poverty, the preventive check of moral restraint has no power. Twenty-five years of observation of the habits of the poor have shown me, that there are none among whom population makes so rapid progress as those who see continually around them examples of utter destitution and misery. In such circumstances, men hardly look forward to the future more than animals. It is easy for us to say, that by cutting off from a poor family any prospect of relief, in case of destitution, we can make them careful and prudent. The practical result is widely different. Another alternative is uniformly embraced. *They lower their habits;* and those who have not been accustomed to observe them, are not aware how much reduction of comfort the family of a labouring man, disabled or deprived of employment, may undergo, and not only life be preserved, but the capacity for occasional irregular and precarious employment continue. On the other hand, when men are preserved from this state of hopeless and abject destitution, they all (or with few and trifling exceptions) gradually fall, more or less, under the dominion of *artificial wants*, and form to themselves a *standard of comfort*, from which they will never willingly descend, and to maintain which they will keep themselves under a degree of restraint unknown to those of the poor who are continually struggling to obtain the first necessaries of life."

The object of Dr. Alison's pamphlet has been opposed by various writers; but the views upon which he proceeds have not been satisfactorily replied to, and they have unquestionably made a considerable impression on the public mind in Scotland. The conviction is spreading that the present system is inequitable with respect to districts, and nowhere so liberal as a true policy, not to speak of humanity, requires.

ARRANGEMENTS RESPECTING THE POOR IN IRELAND.

In Ireland, there was till a recent period no systematic provision for the poor, but the country was by no means destitute of institutions designed for their benefit.

Legislative enactments had progressively, during the last century, established county infirmaries, dispensaries, lunatic asylums, houses of industry, and receptacles for destitute infants and old people; and similar institutions, together with schools, lying-in hospitals, houses of refuge, and mendicity houses, had been set on foot in various places by private benevolence. But, while much was thus done for the alleviation of temporary and casual distress, there was a mass of mendicancy, and an amount of general suffering from occasional famine and consequent epidemics, which made Ireland singular among the countries of Europe. It was calculated that, out of a population of between seven and eight millions, upwards of two millions were in a state not much short of permanent mendicancy. The great bulk of the people being an agricultural peasantry, living on small patches of land, and depending mainly on the potato crop, a failure of that product was attended with wide-spread misery, invariably followed up by destructive fevers. The epidemic of 1817, which was the effect of the failure of the crop of 1816, affected a million and a half of persons, and carried off 65,000. The people, moreover, having no resources when they lost possession of their little pieces of ground, and lords found that they were rapidly

* Observations on the Management of the Poor in Scotland, and of its Effects on the Health of the Great Towns. By William Pulteney Alison, M.D., F.R.S.E., Professor of the Institutes of Medicine in the University of Edinburgh. Blackwood and Sons: 1840.

losing all power over their property. Desperation made the tenants cling to their ground with a pertinacity which nothing could overcome. A common danger having united them in one common cause, the forcible extrusion of a tenant was resisted by one and all, or, if effected, it was sure to be savagely avenged. Practically, the tenant was able to remain on the ground as long as he chose, without much regard to the payment of rent, unless his *good-will* was purchased either by the new tenant or by the landlord. The inconveniences experienced in consequence of the bulk of the people being thus always on the verge of destitution, and without any resource when they reached that point, had become, in addition to those of actual mendicancy, so grievous, that a poor-law began to be contemplated as necessary for Ireland; and in 1833 a royal commission was issued for an inquiry into the subject.

In consequence of the report of this body, an act was passed (1 and 2 Victoria, c. 56), for the introduction of a modified poor-law into Ireland. In the principal arrangements, those adopted in England under the Poor-Law Amendment Act were followed; and the general superintendence was confided to the same commissioners. The system is still in its infancy; but it has so far worked well. In March 1841, 127 unions had been formed and declared, and 60 workhouses were in progress, or in operation. It is anticipated that three more unions will be all that are necessary.

GENERAL OBSERVATIONS.

Poor-laws are, after all, only an expedient for meeting an evil partly inherent in human nature, and partly the consequence of its erroneous moral and political condition. Were all born equally sound, and were all so instructed and so placed socially that each man realized a reasonable sum for his labour, and was disposed to make a proper use of his gains, there would be no need for poor-laws. Such conditions not existing, this expedient is unavoidably called into use, and we must not be surprised that, as one designed to meet great evils, its own operation is attended by less ones. By far the worst effect of poor-laws is the moral degradation which they produce in those for whose benefit they are established. The man who has to ask for public relief to his necessities, loses from that moment the self-respect on which much of his virtue depends. A fatal lesson is taught him—that his wants may be supplied without his own exertions—and the motive to an independent and industrious course of life is greatly shaken, perhaps destroyed. This is itself an evil of such serious magnitude, that it forms with many an insuperable objection to all regular provisions for paupers. Such may be said to have been, till a recent period, the public feeling of Scotland on this question, and it still is the predominating sentiment of a large portion of society in that country. It is an objection which we, for our own part, would have difficulty in overcoming, if we did not see around us the awful effects which an inadequate provision for the poor works, in the present condition of society. Unquestionably, nothing but a consideration of the horrible inhumanity, and the extreme dangers to the common weal, which are inseparable from the neglect or repulse of pauper claims, could excuse the deterioration which we unavoidably effect in a man's nature, by giving him that for which he has not laboured.

Another great evil of poor-laws is, that they take away part of the fruits of industry from those who have legitimately acquired them, and bestow them upon the idle. Industry is by this means discouraged, and sloth and improvidence are in a proportionate degree fostered. In England, this had reached to an enormous height, and even now the abstraction of five millions from the gains of the industrious, must operate very seriously in retarding the progress of the country. It is, however, as already said, a tax unavoidable in present circumstances, if we would escape more serious evils.

While a reasonable doubt can scarcely be entertained as to the propriety of both succouring the helpless and offering a modified provision to the able-bodied in a needful state, it must be equally clear that the more that habits of foresight and self-dependence are propagated in the country—the more that all-sustaining moral influences are diffused through it—we may expect to see the less need for poor-laws. Although there are upwards of twenty millions in savings' banks, and benefit societies are widely spread, still the great bulk of the labouring classes of this country live from hand to mouth, without any store whatever on which to fall back in the event of sickness or an occasional lack of employment. This is a preposterous state of things. What is to be expected of a people, the great bulk of whom are contented to live with only a little accident between them and a state of dependence on private or public bounty? Sickness is what all are liable to at all times; failures of employment take place at frequent intervals everywhere. There surely might be some better provision against such contingencies than a public provision, which makes the recipient a degraded man for ever. Individuals might be induced, by an improvement of the moral agencies of the country, to do much for the securing of their own independence, and the remainder of the required provision might perhaps be obtained by systematic contributions from the labouring classes towards a common fund, from which succour could never be a degradation, seeing that they had themselves created it. Proposals of this kind are apt to strike the mind unfavourably, from their being new; but the position at which this country has arrived is in some degree new, and accordingly calls for measures of a different kind from what we are accustomed to contemplate. Certainly, while only the expedient of poor-laws is adopted, the community can never be inspired, in all its departments, with that manly and independent feeling which is the inseparable associate of all the other virtues, and the great distinction between the freeman and the slave.

LIFE-ASSURANCE.

Life-Assurance, in its ordinary character, is a means of securing, by a present payment in full, or of an annual payment, a sum to be realized after the decease of the party.

It is obvious that, to many persons, the having this in their power is of great importance. To none is it so important as to individuals in the middle walks of life, who, for the present, are perhaps able to maintain their families in comfort, but being unable to accumulate a large surplus capital, cannot be sure that, in the event of their death, those dependent on them will not be thrown into poverty. To such persons, life-assurance presents itself as a ready and convenient means of providing for those in whom they are interested. With a certain annual sum laid aside from a professional income, or from the profits of trade, such a person can make sure that, though death cut him off abruptly, his widow and children will have something to look to, either for an entire maintenance, or to aid in enabling them to gain one for themselves. By the same means, an individual, possessing an entailed estate, can make provision out of its current rents for those younger and female children, who, at his death, would cease to be benefited by it. An individual, also, incurring a risk in behalf of another, or having a large claim upon him in the form of a debt, can insure upon the life of that person such a sum as would be sure to cover all loss, in the event of that person's sudden death. There are many other circumstances in which life-assurance may become highly bene

ficial; but its chief utility lies in securing a certain sum to helpless persons, in the event of the decease of those on whom they depend

The principle on which life-assurance mainly rests, is one which it has been reserved for modern times to discover, namely, that, while the duration of the life of a single person is of all things the most uncertain, it is possible to ascertain, with tolerable clearness, how many of a *multitude* of persons of a particular age will die within next year, how many in the second year, how many in the third, and so on. The medium or average gives what is called the *expectation of life* for each person of the set. A certainty, in short, is attained on this proverbially uncertain subject, when we take a great number of persons, and consider them with regard to the circumstances in which they live. It is found, for instance, that, of 100,000 persons, aged 52, residing in this country, the number who will die before another year has elapsed, will be about 1521, or rather more than one and a half per cent. Supposing that these 100,000 persons were to associate for the purpose of making sure that the widows or other heirs of all those who died within a year should have £1000. It would only be necessary, in that case, for each person to contribute as much to a common fund as would make up £1,521,000, or a thousand times 1521; that is to say, each would have to pay in £15, 4s. 2d. It is clear that those who died, or their heirs, would profit to the extent of £984, 15s. 10d.; but without injury to those who survived, for these also had their chance of gaining, for which it was but fair that they should pay. This would be a simple transaction in life-assurance, and may serve to convey an elementary idea of what life-assurance is, though, in practice, the transactions are usually of a somewhat more complicated kind.

An assurance is rarely transacted for a single year. The object of most is to pay a certain sum each year, as long as they live, in order that a sum may be realized at their death. Assurers are also of various ages; the young have the expectation of longer life than the old. It therefore becomes proper that they should pay less than those more advanced in life. Indeed, there ought to be a payment appropriate to each particular age; and this, accordingly, is the case. Another point calls for particular consideration. The payments being made, not to clear off one year's claims, but to make good a sum many years hence, large funds become accumulated, and upon the improvement of these much depends. If a high rate of interest is obtained, the funds experience a rapid increase, and the less payments are required to effect insurances. If, on the contrary, the interest realized be small, the insurers require to make their original payments so much the higher.

Life-assurance is effected in this country either in offices established by joint-stock companies, who look to making a profit by their business, or by mutually assuring societies. The former are shortly called *proprietary*, and the latter *mutual* offices. Offices of the first kind are usually held by a joint-stock copartnery, with a large subscribed capital; and the chief advantage which they hold forth, is the ample security for all claims presented by the capital, and the respectability of the shareholders. In the case of a mutual office, there is only, it may be said, an association of customers, each of whom is concerned in insuring his neighbour. In this case, however, all surplusages, instead of going into the hands of a trading company, remain the property of the insurers, and are liable to be divided among them. For a long time, the business was conducted almost exclusively by companies; but it was at length seen that all desirable security was to be obtained on the association principle; and for some years this system has been advancing much more rapidly than the other. In various instances, companies have scales of charges allowing of a participation in surplusages; and these are usually called *mixed* proprietary and mutual offices.

The existing British offices are about eighty in number, most of them of recent origin. The oldest is the Amicable, of London, established on the mutual principle in 1706. At the time when it was set up, no calculations as to life existed; and the conductors were accordingly obliged for many years to proceed in a great measure at random, charging the same premiums or annual payments for all ages under forty-five! The other offices, dating from the last century, are the following:—The Sun, 1710, proprietary; the Union, 1714, mixed; the London, 1721, mixed; the Royal Exchange, 1722, proprietary; the Equitable, 1762, mutual; the Westminster, 1792, proprietary; the Pelican, 1797, proprietary; and the Palladium, 1797, mixed. Ten were established during the first ten years of the present century:—The Globe, 1803, proprietary; the Albion, 1805, proprietary; the London Life-Association, 1806, mutual; the Provident, 1806, mixed; the Rock, 1806, mixed; the West of England, 1807, mixed; the Hope, 1807, mixed; the Eagle, 1807, mixed; the Atlas, 1808, mixed; and the Norwich Union, 1808, mutual. The rates charged by these offices are very various, but in all cases they have been found sufficient for the risks. In most instances, the companies divide large profits, while the mutual offices have realized equally large surplusages, which they have divided amongst the insurers, in proportions according to the sum assured and the duration of the insurance, or upon some other principle which may be thought preferable.

Life-assurance grew up in the last and present centuries amidst such an imperfect knowledge of the data on which it depends, that there is little to be wondered at in the great variety of rates charged by the different offices. These data are now much better understood, and it has become possible to arrive at a comparatively close estimate of what charges are really required from an individual, in order to make good a sum at his death for the benefit of his survivors. There might be greater closeness still, if the laws of mortality, now so well ascertained, were alone concerned; but the rate of interest upon money also enters into the calculation, and this, as is well known, is liable to fluctuation. Loose as the matter thus remains in some measure, enough is ascertained to admit of an approximation being made to something like a standard for the conducting of this important branch of business.

The rate of mortality and the rate of interest upon money are the two principal data on which life-assurance practically depends. We shall first consider

THE RATE OF MORTALITY.

Tables of mortality are founded on the assumption that human life is of a certain average endurance; and by means of them we estimate the number of deaths that may be expected among a given number of individuals, from the proportion that has been observed to occur among another class similarly circumstanced.

The tables of mortality adopted in this country as the basis of calculation for insurance companies, are *three* in number. That known by the name of the *Northampton table*, is the oldest now in use. It is founded upon observations made by the celebrated Dr. Price, of the deaths registered for the population of one of the parishes of the town of Northampton, during the years between 1735 and 1780. This table, it is now acknowledged, shows far too high (or rapid) a rate of mortality, owing partly to no effect having been given to the fluctuations in the population of that parish, from immigration and other such causes, and partly to the great improvement which has taken place in the value of life since the middle of last century, consequent upon the introduction of vaccination and other improvements in medical

science, as well as in the habits and modes of living of the people. In 1827, a select committee of the House of Commons, appointed to investigate this subject, reported—"The evidence appears to your committee to be strong and decisive in favour of the use of tables which give an expectation of life higher than the Northampton. In truth, there is not even a *prima facie* case in their favour."

The *Carlisle table* was formed, not from the register of burials among a floating population, but from observations of the deaths which occurred, at each year of life, among a certain stated number of persons in the town of Carlisle. The observations were conducted by Dr. Heysham, and the calculations made, in the most scientific manner, by Mr. Joshua Milne, author of a valuable work on annuities.

Finally, the *Government tables* were compiled from observations on the progressive mortality occurring among the government annuitants and other selected classes, distinguishing the sexes. They were prepared, under the directions of government, by Mr. Finlaison, actuary to the National Debt; and in 1829 were adopted by parliament as the basis upon which their future calculations should proceed. Mr. Finlaison's researches established the fact of the longer duration of female life. He also observed "a very extraordinary prolongation of human life" in the course of the time over which his inquiries extended—so great "that the duration of existence now, as compared with what it was a century ago, is as 4 to 3 in round numbers."

Besides these three, a table was framed by Mr. Griffith Davies from the deaths reported from time to time among the members insured in the great Equitable Society of London, from its commencement in 1762 down to 1829, which has since been recalculated and continued down to a later period by Mr. Morgan, the actuary to that society. This table is very valuable, as confirming the substantial accuracy of other observations, with which it very nearly corresponds. The relation which these tables bear to each other may be seen at a glance from the following table, showing the *mean expectation of life* at various ages according to each.

At Age.	By Northampton.	By Carlisle.	By Government.			By the experience of the London Equitable.
			Males.	Females.	Mean.	
20	33·43	41·46	38·39	43·99	41·19	41·67
25	30·85	37·86	35·00	40·81	38·36	38·12
30	28·27	34·34	33·17	37·57	35·37	34·33
35	25·69	31·00	30·17	34·31	32·24	30·93
40	23·08	27·61	27·02	31·12	29·07	27·40
45	20·52	24·46	23·75	27·81	25·78	23·87
50	17·99	21·11	20·30	24·35	22·33	20·36
55	15·59	17·59	17·15	20·79	18·97	16·99
60	13·21	14·34	14·39	17·32	15·86	13·91

Independently of the acknowledged deficiency of the data on which the first-mentioned table is founded, the mere fact of its differing so much from any other authentic observation, is of itself conclusive against it; and, by parity of reasoning, the close agreement of the others affords strong presumptive evidence in their favour, and imparts a high degree of certainty to calculations based upon them. The Carlisle table occupies a mean place between the male and female observations of government, showing a somewhat shorter duration than the mean of these. It also coincides very nearly with the experience of the Equitable Society. Considering that it is thus supported by two other sets of observations, and that the whole three extend over a period during which life was not so good as it has since become, the general opinion in favour of the safety of the Carlisle tables for life-assurance may be held as well founded. This opinion receives corroboration from the experience of the Scottish Widows' Fund, which extends over the last twenty-five years. In 1834, the auditor of that society reported, as the result of a careful investigation, "that the expected number of deaths by the Northampton table, which is the table of the society, is to the actual number during the whole progress of the society, as 100 to 57; and the proportion of the expected number by the Equitable experience is to the actual number as 100 to 87." We have understood that the experience of the Scottish Widows' Fund since 1834 is even more favourable to life. If, then, we were to take the whole twenty-five years' experience of this society as a criterion we should come to the conclusion that the Equitable experience, the Carlisle tables, and the Government mean, are considerably within the verge of safety, while the Northampton tables are so far from the standard of modern life as to be, particularly with regard to the younger class of lives, quite unfit for use.

We have now to advert to

THE RATE OF INTEREST,

meaning the rate at which the yearly premiums may be expected to be improved.

This subject is one which does not admit of the same certainty as the other, and on which, accordingly, there may be great differences of opinion. In 1829, Mr. Finlaison writes—"I take it for granted that it will be considered safe enough to assume that money, in a long course of years, will so accumulate, through all fluctuations, as to equal a constant rate of 4 per cent.; because, in point of fact, money has hitherto accumulated at 4½ per cent., whether we reckon from 1803 or from 1783." Other writers, again, and among them Mr. De Morgan, looking chiefly to the high price of the 3 per cents. of late years, say that not more than 3½ per cent. should be counted on. Practically the investments of assurance offices are made on terms much more favourable. It appears, from the published report of the Edinburgh Life-Assurance Company, dated December, 1838, that for the three preceding years (1836, 1837, and 1838, when interest was unusually low), the average rate realized on their funds was £4, 16s. 6d. per cent.—about 1½ per cent. higher than the return from the 3 per cents. during the same time. And this, it is stated, was obtained without any part being laid out in the purchase of reversions—on which, it is known, a much higher rate can be got. The example of this office is quoted merely from the circumstance of their report happening to state the precise return at that period. Other Scottish offices are said to have obtained a higher rate. Most of them state that their funds are invested "about," "at," or "above," 5 per cent. Indeed, it is not conceivable that the offices could make such large returns to proprietors and members, in the shape of dividends and bonuses, if they did not generally improve money at about the rate last mentioned. From all of these circumstances, it does not appear likely that calculations for life-assurance, in which the interest of money is assumed at *four per cent.*, will, while Britain remains in nearly its present condition, prove unsound.

EXAMPLE OF LIFE-ASSURANCE CALCULATION.

According to the Northampton tables, out of every 11,650 persons born alive, there will be 46 living at the age of 90. From these tables being ascertained to be unfavourable to life, this must be understood as not strictly the case, but it may be adopted for the sake of illustration. The same tables make it appear that, of the 46, 12 will die in the course of the first year, 10 during the second, 8 during the third, 7 during the fourth, 5 during the fifth, 3 during the sixth, and the last remaining life will fall in the course of the seventh year. It is a favourite mode of exemplifying life-assurance calculation, to suppose these 46 persons, aged 90, associating for the purpose of assuring £100 to each at death

They are supposed to proceed upon the principle of paying all that is required in one sum at first, thus forming a fund which is to answer all the demands which are to be made upon it. In this calculation the improvement of money has been assumed at 3 per cent. The object is to ascertain what sum, by way of present payment, each is to contribute to the fund, so that it may discharge £1200 the first year, £1000 the second, £800 the third, and so on. In order to discharge

£	£	£	s.	d.
1200, at the end of the first year, the society must be provided with	1200, discounted at 3 per cent., for one year, - -	1165	1	0
1000, at the end of the 2d year,	1000, ditto, for 2 years,	942	12	0
800, at the end of the 3d year,	800, ditto, for 3 years,	732	2	0
700, at the end of the 4th year,	700, ditto, for 4 years,	621	18	7
500, at the end of the 5th year,	500, ditto, for 5 years,	431	6	0
300, at the end of the 6th year,	300, ditto, for 6 years,	251	5	0
And in order to discharge the remaining £100 at the end of the seventh year, with £100, discounted at 3 per cent., for seven years, - - - - - -		81	6	2
In all, - - - - - -		£4225	10	9

This, divided by 46, gives £91, 17s. 2d. as the sum (technically called *premium*) which each person would need to pay in at the foundation of the society. And this sum of £91, 17s. 2d. is the present value of a *reversion* of £100, at the age of 90, according to the Northampton tables, and taking interest at 3 per cent.

Supposing such a society to be constituted, and £4225, 10s. 9d. to be paid in by the 46 members, we shall see how its business would proceed until, at the close of seven years, death put a period to the account:—

The original contribution of £4225, 10s. 9d. being put out to interest, at the end of the first year amounts to - - - - - - - - - -	£4352	5	2
From which deduct for the twelve lives which fail in the course of the year - - - - -	1200	0	0
Fund remaining at the commencement of the second year - - - - - - - - -	3152	5	2
Which, bearing one year's interest, will amount to	£3246	16	8
From which deduct for the ten lives which fail in the course of the year - - - - -	1000	0	0
Fund remaining at the commencement of the third year - - - - - - - - - -	2246	16	8
Which, bearing one year's interest, will amount to	£2314	8	2
From which deduct for claims - - - - -	800	0	0
Fund remaining at the commencement of the fourth year - - - - - - - - - -	1514	8	2
Which, bearing one year's interest, will amount to	£1559	16	8
From which deduct for claims - - - - -	700	0	0
Fund remaining at the commencement of the fifth year - - - - - - - - - -	859	16	8
Which, bearing one year's interest, will amount to	£885	10	5
From which deduct for claims - - - - -	500	0	0
Fund remaining at the commencement of the sixth year - - - - - - - - - -	385	10	5
Which, bearing one year's interest, will amount to	£397	1	8
From which deduct for claims - - - - -	300	0	0
Fund remaining at the commencement of the seventh year - - - - - - - - -	07	1	8
Which, bearing interest, will amount to - -	£100	0	0
Which will exactly discharge the last remaining claim - - - - - - - - - -	100	0	0

Practically, life-assurance is not effected upon lives so advanced as ninety years. It is common to confine business to ages under 60; and the great bulk of insurers are between 27 and 40, the time about which men in this country begin to feel the responsibilities of a family. But the calculations followed for the various ages are formed exactly in the above mode. All the persons of a particular age in a life-assurance society are considered as a distinct group insuring each other. Of those, for instance, at 30 years of age, it is calculated what proportion will die the first year, what the second, and so on; and from each the society looks for such a contribution, present or prospective, as may make up an aggregate sufficient, with the accumulation from compound interest, to pay the sum assured upon each life in that group. It is quite the same thing to the society, or, we shall say, to the general interest, whether the individual insurers pay the whole required contribution at once, or in a series of annual payments, which, as the plan convenient for most, is that generally adopted.

FORMATION OF RATES.

According to the principles of which we have given a slight outline, offices form scales of rates at which they profess to do business. In these rates a great discrepancy exists, for many continue to calculate mortality according to the Northampton tables, which, as shown, give the decrement of life too high; while others proceed upon those more recently formed, which are certainly much nearer the truth; and some, again, assume interest at only three or three and a half per cent., while others deem four not too high. There is also an allowance for the expenses of business to be added to the naked sums required by a regard to mortality and interest, and here also the minds of parties may differ, some allowing more and some less on this account.

In most cases, the charges for life-assurance are considerably within the verge of safety. Hence companies generally divide good profits, and societies realize large surplusages, which fall to be divided among the insurers, in the form of additions to the sums stated in their policies. The scales of the various offices may be classed in three grades or sets, of each of which we shall give a few examples, endeavouring, at the same time, to show how each particular grade of charges operates in the realization of profits and surplusages.

Scales of the first or lowest grade are followed as yet by comparatively few offices; but the number is increasing. We presume that they proceed upon modern tables of mortality, and the expectation of four per cent at an average, as, with regard to one of the following (the Scottish Provident), we have been informed that it follows the government table of males, and calculates upon money being improvable at the above-mentioned rate, adding from 10 to 15 per cent., according to age, for expenses of management, and as a guarantee against any unfavourable fluctuations of mortality and interest. We here, as elsewhere, limit ourselves to offices of undoubted probity.

	20	25	30	35	40	45	50	55	Total Premiums between 20 and 60.
Aberdeen Assurance Company, - -	£1 14 7	£1 18 1	£2 2 0	£2 7 3	£2 14 5	£3 4 6	£3 19 8	£4 10 0	£129 7 9
Standard L. Assurance Company, Edin., -	1 12 10	1 17 6	2 2 11	2 9 1	2 17 2	3 6 5	3 10 9	5 0 0	
Scottish Provident Institution, (mutual)	1 15 8	1 18 0	2 1 6	2 6 10	2 14 2	3 5 9	4 1 7	5 1 11	131 6 8

The high premiums borne by the stocks of the two above companies, form a tolerably fair evidence (notwithstanding their having also higher scales) that business can be profitably transacted at these rates. It may likewise be mentioned, that the Edinburgh Life-Assurance Company, which presents a scale nearly the same in aggregate amount as the above (£133. 4s.), divides 6 per cent. upon its stock, the £10 shares of which stand

at £14, 10s. in the market. The Scottish Provident is of five years' standing only; but it has done a large amount of business, and its experience as yet tends to show that the rates are considerably within the verge of safety. The following is a selection of respectable offices in which somewhat higher rates are charged:—

	20	25	30	35	40	45	50	55	Total Premiums between 20 and 60.
Economic Company, London.	£1 14 7	£1 19 0	£2 4 3	£2 10 11	£2 19 9	£3 11 9	£4 8 9	£5 10 3	£141 12 6
Norwich Union Society,	1 19 6	2 3 8	2 8 10	2 14 10	3 2 0	3 11 0	4 6 0	5 5 3	142 10 4
Guardian (mixed),	2 1 0	2 5 4	2 10 7	2 17 0	3 5 0	3 14 11	4 8 0	5 4 8	146 3 3
Scot. Widow's Fund Scot. Equit. Societies,	2 1 6	2 5 10	2 11 1	2 17 6	3 5 6	3 15 6	4 8 4	5 4 2	146 12 6

The Economic is a proprietary office, giving three-fourths of the surplusages or profits to the assured. It was established in 1823. In 1834, a bonus, amounting to 16 per cent. on the premiums paid, was declared; and in 1839 there was a second bonus, amounting to 31 per cent. on the premiums paid during the preceding five years. The Norwich Union, in 1816, gave a bonus of 20 per cent. on the amount of premiums deposited by the members insured previous to June 1815; a second bonus of 24 per cent. in 1823; and a third of 25 per cent in 1830. The Guardian is a proprietary office, in which a proportion of profits not stated is given to the assured. Established in 1821, its first division of profits was made in 1828, and a second in 1835. At each period, the bonuses averaged rather more than 28 per cent. on the amount of the premiums paid thereon during the preceding seven years. The Scottish Widows' Fund and Scottish Equitable have both declared large surplusages. At the division of the first of these highly prosperous societies, in 1825, the policies opened between 1815 (the commencement of the society) and 1820, were declared entitled to 2 per cent. for each year of their currency. In 1832, the same policies received a further addition of 3½ per cent.; and at the same time those opened between 1820 and that time, were declared entitled to additions amounting to 1½ per cent. per annum. In 1839, a retrospective bonus of 2 per cent. per annum was declared on all policies. The effect of these additions is, that policies for £1000, opened before 1820, at whatever age, will amount in 1845 to £1809, 8s. 7d. In 1841, the Scottish Equitable made its first division of surplusages, amounting to 2 per cent. per annum on all policies of above five years' standing; so that the heirs of a person who insured £500 in 1831, (the first year of the society,) would now, in the event of his decease, realize £600, and so on in proportion.

A third class of offices, adopting, like the preceding, the Northampton tables, and generally of old standing, and acting upon old calculations, present higher scales of rates, of which we shall give a few examples:—

	20	25	30	35	40	45	50	55	Total Premiums between 20 and 60.
Globe Company,	£2 3 7	£2 8 1	£2 13 5	£2 10 10	£3 7 11	£3 17 11	£4 10 8	£5 0 4	£151 5 2
Sun Company (mixed),	1 16 11	2 2 5	2 9 2	2 16 8	3 6 [illegible]	3 17 8	4 14 2	5 19 11	154 16 6
Amicable Society (London),	2 0 6	2 5 6	2 10 6	2 17 0	3 5 0	3 18 6	4 16 6	5 18 0	155 3 6

There are a few offices which charge still higher rates. The aggregate premiums of the London Assurance and National (mixed offices), are respectively £157, 0s. 8d., and £158, 3s. The London Life (mutual) is the highest, the aggregate of the scale being £171, 18s.

It is clear that, if business can be transacted by a company at a profit, on a scale of rates amounting in the aggregate to £129, 7s. 9d. (as in the case of the Aberdeen Company), the last set of rates ought to give companies very large profits, and societies equally considerable additions to policies. The scale of the Globe is also that of the Rock and Atlas, proprietary offices granting a share of profits to the assured. In the Rock, where three-fourths of the profits are divided, policies opened in 1806 for £1000, at whatever age, are now £2001, 11s. In the Atlas, which has not announced to the public the share of profits extended to the assured, policies for £1000, opened in 1816, ranged in 1837 from £1338 to £1789, according to age.

The high rates are defended on various grounds. A company making high charges, and consequently good profits, may be supposed to have more stability than one making moderate charges; while, of a society pursuing business on the same plan, it may be said that the overplus becomes a kind of bank deposit, to be ultimately realized by the depositor. With regard to companies, the defence may or may not be sound, according as business is managed discreetly or otherwise—and there certainly are offices of that nature, entitled to the most implicit confidence, although they present moderate scales. The defence is of greater force with regard to societies; but even there it is not free from objections. The high-rate societies, proceeding upon the Northampton tables, commit a constant injustice to young and middle-aged members, in favour of the old. The needless amplitude of their funds tend to occasion a less careful use of them in conducting the concern: there is, for instance, a greater temptation to give large commission to persons, who, as it is said, bring business; a practice in no respect different in morality from that of butchers and grocers who bribe cooks and butlers to favour them with their masters' custom. But the greatest objection to a needlessly high scale, is that it must act as an obstruction to the first step in what is generally one of the most important moral acts of a lifetime—the effecting of a life-assurance. We would here be understood to draw a broad distinction between an unsound low rate and one which is sufficient to satisfy a reasonable anxiety for security. Rates much below the first of the above three scales would be decidedly unsafe, taking all likely contingencies into account. On the other hand, it ought certainly to be possible to transact perfectly safe business upon a medium of that scale. Those who, for further caution, prefer the next scale, must be said to pay highly for it, if they resort to a company which gives no share of profits to the assured: if they become members of a society, large periodic additions to policies will be no more than their due.

In order to convey still more distinct notions respecting

rates of Life-assurance, we subjoin a scale of those which are required, exclusive of expense for management, upon the Carlisle tables, taking money variously at 4 and 3½ per cent.:—

	25	30	35	40	45	50	55
4 per cent.,	£1 10 4	£1 15 1	£2 0 5	£2 7 6	£2 15 6	£3 7 3	£4 5 8
3½ per cent.,	1 12 1	1 16 11	2 2 5	2 9 7	2 17 10	3 9 9	4 8 2

The rates actually charged by the offices which we have cited, may easily be compared with these. It will be found that the additions made for management and the security of the concern, even to the 3½ per cent. rate, are very considerable. The aggregate of the above ages at 3½ per cent., is £18, 16s. 9d.; and that of the same ages by the actual rate of the Aberdeen Company, is £21, 4s. 11d., or nearly 12¼ per cent. higher; that of the same ages by the Scottish Widows' Fund, is £24, 7s. 11d., or 29½ per cent. higher; while that of the London Amicable, is £25, 11s., or above 35½ per cent. higher.

MORAL DUTY OF LIFE-ASSURANCE.

On this subject we add some remarks from a paper in *Chambers's Edinburgh Journal*, No. 373. They are conveyed in language which is apt to appear unmeasured to one who has not given the subject much consideration—but, we believe, *only to him*.

"Such being the equitable and beneficial principles on which mutual-assurance societies are established, it is clear that they present, to men in the enjoyment of income, but possessing little property, a most suitable and favourable means of providing, in a greater or less measure, for the endeared and helpless relatives who may survive them. That only about 80,000 persons in the United Kingdom should have taken advantage of life-assurance, being but one in sixty-two of the supposed number of heads of families, surely affords a striking view of—shall we call it the improvidence of mankind, or shall we not rather designate it as their culpable selfishness? For what is the predicament of that man who, for the gratification of his affections, surrounds himself with a wife and children, and peaceably lives in the enjoyment of these valued blessings, with the knowledge that, ere three moments at any time shall have passed, the cessation of his existence may throw wife and children together into a state of destitution? When the case is fully reflected upon, it must certainly appear as one of gross selfishness, notwithstanding that the world has not been accustomed to regard it in that light. It is unquestionably the duty of every man to provide, while he yet lives, for his own: we would say that it is not more his duty to provide for their daily bread during his life, than it is to provide, as far as he can, against their being left penniless in the event of his death. Indeed between these two duties there is no essential distinction for life-assurance makes the one as much a matter of current expenditure as the other. One part of his income can be devoted by a head of a family to the necessities of the present; another may be stored up, by means of life-assurance, to provide against the future. And thus he may be said to do the whole of his duty towards his family, instead of, as is generally the case, only doing the half of it.

"It may be felt by many, that admitting this duty in full, their income is nevertheless insufficient to enable them to spare even the small sum necessary as an annual premium for life-assurance. The necessities of the present are in their case so great, that they do not see how they can afford it. We believe there can be no obstacle which is apt to appear more real than this, where an income is at all limited; and yet it is easy to show that no obstacle could be more ideal. It will readily be acknowledged by everybody who has an income at all, that there must be some who have smaller incomes. Say, for instance, that any man has £400 per annum: he cannot doubt that there are some who have only £350. Now, if these persons live on £350 why may not he do so too, sparing the odd £50 as a deposit for life-assurance? In like manner, he who has £200 may live as men do who have only £175, and devote the remaining £25 to have a sum assured upon his life. And so on. It may require an effort to accomplish this; but is not the object worthy of an effort? And can any man be held as honest, or any way good, who will not make such an effort, rather than be always liable to the risk of leaving in beggary the beings whom he most cherishes on earth, and for whose support he alone is responsible?"

For a further account of modes of life-assurance, we refer to article SOCIAL ECONOMICS OF THE INDUSTRIOUS ORDERS.

PAGAN AND MOHAMMEDAN RELIGION.

PAGANISM is a disbelief or ignorance of the only true God, the Creator and Preserver of all; and in this debased and unhappy state all mankind appear to have been, until illuminated by the light of revelation and cultivated reason. In this state of mental darkness in which many savage and but partially improved races are found, Paganism may be said to prevail. Of this Paganism, however, there are evidently various degrees—some forms of religious belief ascending much higher than others, from the blinded reverence of *gods* made from blocks and stones, up to the worship of a plurality of creators, preservers, and destroyers.

It is generally allowed that the lowest forms of religious belief are those which prevail among the Negro tribes in the central and western parts of Africa, and which consist in the reverencing and worshipping of objects usually classed under the name of fetishes. The word *fetish* or *fetich*, which is believed to be from the Portuguese language, signifies any object in nature or art to which, by a process of consecration, a supernatural or divine power is supposed to have been communicated, and which is therefore deemed worthy of religious veneration and worship. A fetish is thus a kind of idol, or visible representation of deity, and may be ranked with the household gods and presiding genii of the Egyptians, Greeks, and other nations of antiquity. The rude natives of Africa seem to possess no rule to determine the kind or number of their fetishes; it is a matter of free choice, so that whim and accident, much more than any definite feeling, settle which shall be the revered objects of their hopes and fears. There are national, local, and private fetishes; and besides one which is the tutelary genius of every single individual, the Negroes provide themselves with many others for particular purposes. Like the ancient inhabitants of Ethiopia, Nigritia, and Egypt, they often take along with them upon their journeys a living animal as a fetish, which is preserved with extraordinary care. Inasmuch, also, as the ancient Egyptians and their neighbours went to war on account of injury or insult to their gods—on one occasion there was a furious religious war between the cat and rat worshippers—so vindictive wars and dissensions spring up between Negro tribes, if either maliciously or accidentally kill or injure a fetish of the other.

The Moors of Northern Africa, who, as Mohammedans, are opposed to the worship of idols, are attached to fetishism. They honour the fetishes as divine beings of an inferior rank, and carry them about their persons as amulets or charms. In Whiddah, and other parts of Africa, towards the south, a small insect, called the creeping-leaf, is highly honoured; he who gets a sight of one considers it a happy omen, and he who kills one despairs of success; the serpent, also, is worshipped as a fetish in temples by priests set apart for the purpose. In Benin, fetishes are more numerous, and, in part, of an entirely different description. The whole material universe is believed to be animated and furnished with spiritual powers; water, land, animals, stones, trees, and vegetables of every description, are all full of divine spirits and secret influences. He who makes any eatable article his fetish, touches nothing of that sort whatever, whilst he consumes, without the slightest hesitation, what others consider holy. There is a depth and mystery in this superstition which cannot be very clearly understood. As far as can be reasonably conjectured, this species of fetishism implies a connection betwen the visible and invisible, and that every thing may by certain means be made to have a relation to man and his destiny. The quality of the thing arbitrarily set apart and invested with an attribute of divinity, is of no consequence; it may be a piece of bone, egg-shell, or clay, indeed no matter what; there must merely be a belief of a relation subsisting between it and man, which relation often commences only for the first time when the thing is consecrated; in a word, every thing properly consecrated and revered as the residence or tangible investiture of deity, is supposed to have a divine power, which, when evoked, is able to incline the Deity to comply with the wishes of men. Under different names, this superstitious reverence for visible objects has prevailed in all ages and countries. At Cape Coast there is a rock projecting into the sea, invested with the character of a fetish, and worshipped by the priests, who annually offer sacrifices to it, with ridiculous gestures and strange invocations. In the great temple of Mohammedanism at Mecca, there is a stone which is the object of unbounded respect and adoration. The Lacedæmonians had a sacred stone, which, at the sound of a trumpet, is said to have raised itself to the surface of the water, from the bottom of the Eurotas. The ancient Germans and Gauls had also their holy rocks, caves, seas, springs, and trees, which afforded miraculous aid, and delivered oracles. In Iceland there was a stone in which a divine spirit was supposed to reside, and was therefore an object of religious worship. The Laplanders had a sacred mountain and a consulting drum. All these superstitions are not a whit more respectable than the belief of the Negroes in fetishism; they are, indeed, almost the same thing.

According to the visionary ideas of some ancient sages, a divinity was supposed to reside in matter, and to be liable to be roused from his latent state into activity, by means of consecration and the performance of solemn mysteries. In some of the islands of the Pacific, if any person wishes to protect his property, such as a house, field, or place of sepulture, from robbery or intrusion, he declares that it is *tabooed*, or placed under the guardianship of his gods; and the belief that such is the case being universal, the property is safe from aggression. Mr. Ellis, in his "Missionary Tour through Hawai," mentions some interesting particulars regarding the superstitious delusions of the natives, which incline us to think that these remotely situated people must have had some early connection with the ancient natives of Asia and Africa, from whom the Greeks and Romans imported their learning and mythological observances. These Hawains, as we are told, previous to their embracing Christianity, believed in a number of ideal gods, who were ministered to by priests, and were propitiated by sacrifices of animals: in making these sacrifices, the diviners observed "the manner in which the victims expired, the appearance of the entrails, and other signs. Sometimes, when the animal was slain, they embowelled it, took out the spleen, and holding it in their hands, offered their prayers. If they did not receive any answer, war was deferred. They also slept in the temple where the gods were kept, and after the war-god had revealed his will by a vision or dream, or some other supernatural means, they communicated it to the king and warriors, and war was either determined or relinquished accordingly." The images of the gods who constituted the guardians of the tabooed places of sepulture, are described as figures oddly carved in pieces of wood; these were stuck on the fences and trees of the enclosure, and with their horrid aspect and ragged garments, seemed no improper emblems of the system they were designed to support. Adjoining the sacred enclosure,

the author was shown a *Pohu Tabu*, or city of refuge, which was open for the reception and security of all classes of delinquents, and resembling in its regulations the sanctuaries of antiquity. These, and some other circumstances mentioned by Mr. Ellis, open an interesting field for speculation on the probable connection of ancient and modern superstitions, or at least on the similarity of the delusions by which the untutored human being has in all ages been affected.

Fetishism has long been practised among the Negroes of the West Indies, under the name of *Obeah* or *Obi*—a term most likely originating in Egypt and the adjacent parts of Africa, where anciently there was a deity of a demoniacal character, with the name Ob, or Oub, and from which Moses commanded the Israelites to abstain from making inquiries. Obi is therefore one of the exploded oracles of the ancient world, which has been carried by captured Negroes to the West Indies, and there set up as an oracle and the patron of incantations, charms, and all other superstitious delusions. The adepts who practice this kind of fetishism are called Obeah-men, or Obeah-women, for both sexes engage in the mysteries of this species of jugglery and imposture. We believe, that since the abolition of slavery in the West Indies, and the spread of education and Christianity, the practice of Obi has gone out of repute and notice.

At one period the religion of the Parsees or Fire-worshippers existed throughout Persia and other parts of Asia, but is now confined chiefly to the deserts of Caramania, towards the Persian Gulf, where it is followed by the Guebres or Giaours (infidels), as they are called by the Mohammedans. The great prophet or improver of the Parsee religion was Zoroaster, who flourished about two thousand years ago, and taught the doctrines of there being an eternal spirit of Good or Light (Ormuzd), and an eternal spirit of Evil or Darkness, (Ahriman), with a vast number of inferior good and bad genii. In this there was a glimmering of a pure theism; but besides a variety of absurd imaginations respecting the organization of nature, the belief in one God was obscured by a typical worship of the sun, and of fire, both being supposed emanations, or at least emblems, of the spirit of Good and Light. Fire-worship, as practised by the Persian magi, disappeared before the spread of Christianity and Mohammedism, and, as we have said, exists chiefly among the Guebres, a detached remnant of the old Persian nation.

HINDOOISM.

Hindooism or Brahminism is the religion professed by a majority of the inhabitants of Hindostan; and while possessing the force of great antiquity, it is supported by a skilful priesthood and the division into castes, rendering it the most ineradicable of any system of false belief and worship which exists.

The Hindoos recognise the existence of a supreme and invisible Ruler of the universe, entitled Brahma, but at the same time believe in the existence of other two deities, one of whom is Vishnu the Preserver, and the other Siva the Destroyer. Previous to the creation, Brahma is said to have reposed in silence and self absorption—a mode of existence considered by the Hindoos as the most perfect and god-like. Having a desire to draw out of his own divine essence a glorious creation, to supplant the deep primeval gloom, he by a thought created the water, and deposited therein a golden egg, blazing like ten thousand suns, which remained inactive for millions of years, till Brahma, who lay enclosed in this shining receptacle, by the energy of his own thought, split it asunder, and sprang forth the Divine Self-Existing, famed in all worlds as the creator of rational beings and the forefather of all spirits. Brahma is represented as a golden-coloured figure, with four heads and four arms; but although he gives names to the great caste of the Brahmins or priests, no sects derive their appellation from him; he attracts little attention or worship, and he has neither temples erected, nor sacrifices offered to him, nor festivals celebrated in his honour.

Vishnu makes a very conspicuous figure in the sacred annals of India, and the fundamental idea of the Hindoo religion, that of metamorphoses or transformation, is exemplified in the *avatars* or appearances upon earth of this deity. In his character of preserver, or rather deliverer, he has, says the Vedas, interposed whenever any great calamity threatened the world: and thus the great ends of his providence are brought about by the various incarnations of the Hindoo deity. Of these transformations there are ten, and they fill up the Indian *yugs*, which compose a certain series of periods intended to effect a junction with God, and comprising 4,320,000 years. The yugs have been considered as an allegorical description of the year, divided by the solstices and equinoxes, and of the procession of the equinoxes. Nine avatars have already taken place, and the tenth is yet to come.

It is unnecessary to dwell at any length on the wonderful and ridiculous avatars of Vishnu. He first appeared in the character of a fish, for the purpose of recovering the sacred writings given by Brahma, which had been swallowed by a giant (typical of the rebellious human soul,) and buried along with himself in the depths of the ocean. He successively appeared as a tortoise, a boar, a man-lion, what is called the Brahmen or linguin dwarf, and so on. The transformations are of the most ridiculous nature; and were we to recite them, they should only excite pity for the ignorance of the wretched believers in such absurdities.

In his subsequent avatars under different forms, Vishnu delivered the world from successive monsters and giants which threatened its tranquillity. In the ninth avatar, which is supposed to have taken place in the year 1014 before the Christian era, Vishnu assumed the form of Boodh, the author of a rival creed distinct from that of Brahma. It appears pretty evident that Boodhism at one time very extensively prevailed throughout India; and several great dynasties, particularly that of Magadha, were Boodhist. But a war having taken place between the devotees of Brahma and those of Boodh, the latter were worsted, and dispersed throughout the countries to the east and north of Hindostan, and Boodhism is no longer professed in India. The rival systems will be noticed after we have described the other deities, male and female. In the tenth avatar, Vishnu will descend to the earth mounted on a white horse, and armed with a scimitar blazing like a comet, to root out evil from the earth, and eternally to punish the wicked. Vishnu is represented of a black or blue colour, with four arms, and a club to exercise chastisement on the wicked. The emblems under which he is represented refer to his vindictive character. He has three eyes, to denote the three great divisions of time past, present, and future. A crescent in his forehead refers to the measuring of time by the lunar revolutions, as a serpent denotes it by years; and the necklace of skulls which he wears, the extinction of mankind in successive generations.

The third member of the Hindoo triad is Siva the Destroyer. It may be here remarked, that the distinguishing appellations applied to these deities are not altogether characteristic of their functions—Vishnu the Preserver frequently employing himself in acts of destruction, and Siva on the other hand in acts of beneficence. But much vagueness, inaccuracy, and confusion, prevail throughout the whole of the Hindoo creed; and this no doubt arises from the love of the marvellous and indescribable, by which they are led to grasp at phantoms of thought as undefinable as they are impalpable. Siva, it appears, has had an equal share of personal adventure with Vishnu, although the characters

which he assumed were not so various, nor his exploits so important or striking. His female partner is called Doorga, and to her the appellation of destroyer is more applicable than to him. She is the chief among the female deities; in short, the most formidable and warlike personage of the Hindoo pantheon. She has rivalled Vishnu in the number of forms which she has assumed, and the conflicts in which she has borne the most conspicuous part; and the giants and others who have fallen victims to the prowess of her arm, occupy a prominent place in the wild records of Hindoo mythology. As an object of adoration, the appearance which she is made to assume shows a remarkable obliquity of moral vision in those who framed at first, and those who worship still, this horrible personage. Under the name of Kalee, she is black, with four arms, wearing two dead bodies as earrings, a necklace of skulls, and the hands of several slaughtered giants circling her waist like a zone. Her eyebrows stream with blood; and not content, as the male divinities generally are, with the simple productions of nature, her altars are made to flow with the blood of animal oblations. Old records even give directions how human sacrifices are to be offered to this cruel goddess. India has no deity more popular, not only among banditti, who hold her in especial veneration, but with the more reputable classes of the community, who offer lavish gifts on her shrine. The disgrace of her religion consists in the worship of impure imagery, which it is impossible to mention.

It is unnecessary to enumerate even the more important of the minor deities; as for the whole, they are altogether innumerable. Some have taken the trouble to reckon up three hundred and thirty millions of them. There are gods of the elements, of war, of the sun, of the winds, of fire, of water, and so on. Every river, fountain, and stream, is either a deity itself, or has one presiding over it. The worship or deification of the Ganges forms a distinguishing element in the belief of the Hindoos. Into this large river, all who dwell within a certain distance of its banks crowd morning and evening to bathe; and the water of this sacred stream is carried to all parts of India, and is sworn by in courts of justice. At Allahabad, where the streams of the Ganges and Jumna unite, the country for many miles round is considered sacred ground; and so great is the number of pilgrims who resort thither for bathing, that the vizier has received in one year half a lac of rupees for permission to enjoy the benefit of immersion in the sacred flood. Oftentimes may be witnessed children hurrying their parents to the river side, fearful lest they should die before being able to reach its banks. Nothing can be more distressing to the feelings than to behold these poor expiring creatures, some calling upon Rham, some upon one of their false gods, others upon another, with their bodies half in the water and half out, the rising tide soon to overwhelm them. Many are laid where the tide cannot reach them, and their case is more pitiable still. Beneath a burning sun, they are left without food, and many of them, who would no doubt recover from their disease, if proper attention were paid to them, are literally starved to death, or devoured by jackals at night.

Among the degrading doctrines of the Hindoo faith, a veneration for and even a worship of members of the brute creation, is not the least remarkable. The cow, in particular, commands the most exalted reverence; and this venerable quadruped may be seen in cities sauntering up and down in the most public places, perfectly at her ease, and calling forth expressions of profound respect. The monkey, like those ranks among the higher grade of animals, and is allowed to roam at large wherever he lists—a chartered thief, now levying the confectioner's sweetmeats under tribute, and anon taxing the fruiterer for a portion of his juicy store. But this superstition reaches its climax in the hospitals which are erected for affording shelter and succour to sick and infirm brutes, including lice, fleas, and other insects. It must be an exceedingly nice investigation for those who preside as medical attendants over such institutions, to determine the state of health of such patients. Other animals besides these are held sacred, but some quadrupeds are treated with great cruelty. The draught horses, in particular, Bishop Heber informs us, are barbarously abused; nor is there much sympathy shown to human beings, who are allowed to perish from disease or hunger under the canopy of heaven, without awakening a sigh in the bosom of the onlookers. Lepers are regarded as objects of divine wrath, and are treated accordingly, sometimes being burned or buried alive.

The peculiar character of the Hindoo creed is derived from their tenet respecting the transmigration of souls. The spirits of the dead are said to enter a receptacle corresponding to the previous character of the individual. The immortal part of the just and good, however insignificant the person may have been, migrates into a hermit, a Brahmin, a demigod, and so forth, rising in dignity according to the degree of merit. The wicked, on the other hand, not only are degraded as human beings, but are compelled to lodge in the bodies of animals. The Hindoo oracles endeavour to establish a degree of conformity between the punishment awarded and offences committed. The pilferer of grain is metamorphosed into a rat, and he who stole fruits or roots becomes an ape. Others are degraded into worms, insects, and so on. The person thus lowered in the scale of creation, must pass through a long succession of degraded births before he can re-assume the human form. This system of rewards and punishments, although confined to the earth, does not exclude the belief of a heaven and a hell hereafter. The celestial mansions, like those of the Mohammedan, are replete with objects of voluptuous enjoyment, but only Brahmins and persons of high attainments or great sanctity are permitted to enter these blissful abodes. Some ardent devotees aspire to a higher destiny, and hope to be absorbed into the essence of the Supreme Being, where they shall repose for ever on an unruffled sea of bliss. The place of final punishment, in like manner, consists of different compartments, the penalties inflicted in which correspond to the iniquities of those who are doomed to enter their dismal precincts.

The devotion of the Hindoos consists in a system of ceremonious observances, not only troublesome in themselves, but encroaching on the moral duties, nay, the whole business of life. Such a stock of atoning merit is by this means conferred, that the weightier matters of the law seem to be superseded; at all events, this external devotion is not inconsistent with the most scandalous crimes. The observances commence in the morning with ablutions and prayers, the worship of the rising sun, in the inaudible recitation of their holy writings, in meditation, and the like. The five sacraments are then performed, which are, teaching and studying the sacred books, offering cakes and water, an oblation of fire, in giving rice and other food to living creatures, and in receiving guests with honour. The whole of these ceremonies are necessarily abridged, for the entire day would scarce suffice for their perfect [illegible] The early Hindoos seem to have borrowed, and to have greatly extended, the typical impurities of the Mosaic law; and the rules on this subject, pointing out the causes of defilement and the modes of purification, are numerous and absurd. The death or birth of a child, touching a dead body, a new-born child, an outcast, and so on, render people unclean; and the modes of purification are either bathing, stroking a cow, looking at the sun, or having the mouth sprinkled with water.

Penance and self-torture are regarded as essential to the attainment of a character for holiness; but in their attempts to suit the amount of penance to the magnitude

of the offence, there is almost a total subversion of all moral distinctions. Acts naturally indifferent are classed with heinous immoralities; for instance, eating things forbidden is put on the same footing with killing a friend, and drinking forbidden liquor with killing a Brahmin. A particular class of devotees, called *yogues* or *fakirs*, signalize their piety by enduring the severest tortures with a firmness and perseverance worthy of the holiest cause. These consist in burying themselves in the depths of forests, either in a state of perfect nakedness, or having their bodies coated with ashes and cow-dung; in allowing the nails of their hands and feet to grow till they assume the dimensions and appearance of bird's claws; roasting themselves before huge fires; immuring themselves in the ground, and leaving only a small breathing-hole; going about with small spears or rings pierced through the most tender parts of the body, and hot irons applied to the side; holding their hands above their head till they have lost the power of bringing them down again, and become withered like that of the individual mentioned in the Evangelists; clenching the fists till the nails penetrate the palms; turning their faces to the sun till they cannot regain their natural position, or gazing on his intense blaze till their eyesight is extinguished; lying on [illegible] tearing the flesh with whips; chaining themselves for life to the foot of a tree; and performing other such-like acts of slow suicide. Some of their austerities are exceedingly fantastical; for instance, Bishop Heber saw a devotee hopping about on one foot, having made a vow never to put the other to the ground, which was now shrivelled up, contracted, and useless. Begging holds a conspicuous place among the religious duties of the Hindoos. Mr. Ward affirms that an eighth part of the inhabitants of Bengal and Behar subsist in this manner; thus constituting a mendicant population of upwards of two millions. Religious pilgrimages are held in high esteem, and the holy places have generally been established near the sea, the sources and junctions of rivers, the tops of remarkable hills, hot springs, caves, waterfalls, and places of difficult or dangerous access. All the principal roads are crowded with people hastening to these holy places. Some are held in higher veneration than others, and it is no uncommon occurrence, in the crush and tumult of the multitude to reach these Bethesdas, for numbers to be trodden to death under foot, or precipitated into the water and drowned.

The sacred writings of the Hindoos are of two kinds —the Vedas and Shastres. The former may be termed their scriptures, the latter expositions of them. The Vedas are divided into four books, all written in the Sanscrit language. The first book is called *Rug Veda*, which signifies the Science of Divination, concerning which it principally treats. The second is distinguished by the title of *Shecham*, which signifies Piety or Devotion, and this book treats of religious and moral duties. The third is the *Judga Veda*, which, as the word implies, includes the whole science of religious rites and ceremonies. The fourth is denominated *Obater Bah*, or the knowledge of the Good Being, and accordingly this book comprehends the whole essence of theology and metaphysical philosophy. These various books are acknowledged to be of great antiquity, but abound in such absurdities as to be of little or no value as historical documents.

The temples for the celebration of Hindoo worship appear to have been in ancient times of the most magnificent description, as is proved by the remains of those of Elephanta and Salsette. The temples of the present day do not exhibit such elaborate grandeur, many containing only one apartment, and few having more than three or four. The crowds which besiege them on solemn occasions celebrate their observances in an open area fronting the gates, so that nothing is required within but accommodation for the images and one or two attendants. The idols are composed of every possible kind of material, from gold down to wood or clay, smeared over with a little red paint. Any figure, either of brute or man, or centaur-like combinations of both, serves for a god, and is reverenced as such by the ignorant Hindoos, after a Brahmin has consecrated them by a process of solemn buffoonery. When placed in the temple, every image has a daily round of homage performed before it, and is furnished with a regular allowance of food, which, after remaining for a limited time, is served out among the attendants. These offerings are profusely lavished on great annual festivals, while the multitudes without sing indecent songs, and throw themselves into the most fantastical attitudes and motions. The various articles of maintenance bestowed upon the goddess Kalee, in her temple at Kaleeghata, are considered by Mr. Ward as worth £9000 annually.

There is no doubt that, at no very distant period, the bloody deities of the Hindoos were propitiated with human sacrifices, and, in confirmation of this, some of the rites still remain. Children were sacrificed by being thrown into the river Ganges, until the practice was put a stop to by the British government. Old women are still occasionally burned, in order that their spirits may haunt the spot where they are offered up, and entail a curse upon it. The *suttee*, or custom of a widow burning herself on the funeral pile of her husband, is a well-known rite of the Hindoo religion; and the festival of Juggernaut is celebrated by the sacrifice of numerous victims. This idol-car is a lofty ornamented structure, in which are representations of the god, and of Bala Rama and Soobhadra, said to be his brother and sister. This infernal machine, for it deserves no better name, is dragged along amid shouts of triumph by the infatuated multitude, and its path being marked by the bodies of mangled victims, who voluntarily throw themselves before the wheels, and are crushed to death. The most indecent figures are pourtrayed on the chariots used at the temples. With such an impure religion, it is not a matter of surprise that the state of morals is very low in India.

From time to time during the lapse of ages, various sectaries have arisen among the Hindoos, each with peculiar objects of adoration and modes of worship. Brahma, as already observed, is at the head of no sect; and Vishnu and Siva, the two powers next to him, divide in a great measure the worship of Indian devotees. Among forty-three leading denominations, Mr. Ward reckons twenty to attach themselves to Vishnu, nine to Siva, four to his wife Doorga, under the name of Saktas, while ten select inferior objects of adoration. The zealous adherents of the rival sects of Vishnu and Siva are avowed enemies, and hold each other up to odium and ridicule. But the most important schism is that between the disciples of Brahma and the adherents of Boodh, to which allusion has already been made. The latter have objects of worship, a creed, ceremonies, and institutions entirely peculiar. Their temples are much more splendid than those of the followers of Brahma, and their priests live in spacious convents. Boodhism is no longer professed in India-proper, but there is a sect called the Joinas, very numerous in Western Hindostan. They combine in some measure the practice and doctrine of the two rival systems above named. The Seika are a sect who have attempted to form an alliance between the Mohammedan and Hindoo creed, and with some degree of success.

Decidedly the most vicious part of the Hindoo religion is the division of the people into castes, or distinct classes, for such an arrangement strikes at the very root of social progress, and prevents all rational improvement. The whole Hindoo population is divided into four branches or tribes, denominated Brahmins, Kyetra, Bhysya, and Soodra. The rank, occupation, and duties of these

several castes, are fully explained in their Vedas, or holy books. The Brahmins are the priests; they are required to be virtuous, learned, just, peaceable, and self-denying. If these were ever the distinguishing traits of their order, the very reverse are the features of their character now. The Kyctra is the military caste: the Vedas require of them a thirst for glory; to die rather than retreat; generosity and princely conduct to captives. Bhysya form the agricultural part of the community; their duties are briefly defined as cultivators and traffickers. The fourth or Soodra caste, consists of labourers, who are enjoined to serve with patience and fidelity; the former, perhaps, they generally do, but as for the latter, it is only when constrained by fear of punishment or loss of pay. The two middle castes have almost become extinct, or rather amalgamated with the former and latter. Thus, it may almost be said that the whole Hindoo nation is now composed of Brahmins or Soodras, both of which are divided into a great many degrees or sub-castes, so that there are many orders of Brahmins as well as Soodras. Of the latter, the Koit is the highest, and the Hurry the lowest, which caste embraces shoemakers, mat-makers, bird-catchers, tanners, skinners, snake-catchers, and many others. By this division of caste, no possible means exist for any person to rise in the scale of society; all motives to exertion or mental improvement are cut off; no actions, however noble, no discoveries, however important to society, would ensure honour to a person of low caste; and those of high caste lose no honour or reputation by their ignorance and vice. Whatever be the mental abilities of a Hindoo, if born a Soodra, a Soodra he must remain; if the father be a snake-catcher, all his sons must be snake-catchers too; and the influence of caste follows him through all the ramifications of life. Persons of different castes or occupations cannot eat, drink, or smoke together; neither can they intermarry, nor meddle with each other's employment. If a Hindoo loses caste, which is the case if he breaks through any of the foregoing rules, the most distressing consequences ensue; no one will eat with him, or suffer him to come near his dwelling, or marry his children; his own wife and family disown him; looked upon as an outcast of society, he is deprived of all privileges, or means of comfort as long as he lives; and however respectable he may have been before, the meanest caste consider him a vagabond, and will not associate with him. It is caste that renders so many servants necessary to do the work which one or two might easily accomplish. They are born to one particular department of service, and no other can they perform without losing caste. Thus the man who fetches water cannot wait at table, nor the man who cooks the dinner serve it up; neither will the person who attends the table sweep the room afterwards—and so on through all the different pursuits of life. A native embracing Christianity loses caste by partaking of the Lord's Supper; it requires, therefore, great fortitude of mind to make a profession of faith in the gospel. There are many who have no caste, having been excommunicated because of some breach of the ceremonial laws of their religion, either by themselves or their forefathers; these are all termed Pariahs, and dare not touch the person, garments, food, utensils, or dwelling of a Hindoo of caste, as contamination follows. The Brahmins are a very lordly domineering race, and exact the most severe homage of the Soodras. They themselves are under great restrictions, as well as the Soodras, particularly in the article of food, being prohibited from eating any thing that has had life, except fish. This probably arises from their belief in the doctrine of transmigration; and as they believe that although the spirits of their ancestors may have entered the bodies of all beasts, birds, reptiles, and insects, yet they do not enter into another element, so that they may eat fish with impunity Rice, with spices, milk, and ghee, is their principal diet, although they may partake of the flesh of such animals as are offered in sacrifice to the gods, the laws of the religion permitting this.

The Brahmins, though all eligible to the priesthood, yet do not all follow it. Some enter the military service of the East India Company, and others become clerks and copyists; but none are permitted to engage in menial employments, and in whatever state they are found, the same **honour** is paid by their associates, though perhaps not to that degree as if in priestly office. So great is the pride of the Brahmins, that they claim precedence of kings, and the noblest rajah will partake of food cooked or presented by a Brahmin, while the meanest Brahmin will not taste that which has been prepared by a Soodra, although the Soodra should occupy a much higher station, civilly, than himself. The religion which inculcates these arrangements, is found to be almost unconquerable by Christian missionaries, for the adoption of Christianity involves a total change of opinion on the constitution of society; and it is a melancholy fact that few except the worst of the Hindoo populace will become proselytes. It is now generally acknowledged that in order to make any impression on the religion of the Hindoos, it will be absolutely necessary to commence with the instruction of the young in various branches of useful knowledge, to which happily the Brahmins offer no objection, while such instruction is universally desired by the people.

BOODHISM.

Boodhism, or the religion of Boodh or Bhud, is considerably elevated above either pure paganism or Hindooism, and is deeply interesting from being the most prevalent form of religion upon earth. The number of the whole human race being estimated at 965,000,000, nearly the one half, or 400,000,000, are Boodhists. According to the account of Mr. Howard Malcolm, in his "Travels in the Burman Empire," to whom we are indebted for the following particulars, Boodhism is professed by half of the population of China, Lao, Cochin-China, and Ceylon; all of Camboja, Siam, Burmah, Thibet, Tartary, and Loo-Choo; and a great part of Japan, and most of the other islands of the southern seas, are of this faith. In some parts of India it is the great rival of Hindooism; but its principal stronghold is in the adjoining empire of Burmah.

Gaudama.

"*Boodh* is a general term for divinity, and not the name of any particular god. There have been innumerable Boodhs, in different ages, among different worlds, but in no world more than five, and in some not any. In this world there have been four Boodhs, namely, Kan-ka-than, Gau-na-gông, Ka-tha-pa, and Gaudama. One is yet to come, namely, Aree-ma-day-eh.

"It has often been supposed that Boodhism resembles Brahminism or Hindooism, which is a great mistake. No two systems can be more opposite or bear less evidence of being derived from each other. Brahminism has incarnations, but Boodhism admits of none, for it has no permanent god. That has a host of idols; this only one. That enjoins bloody sacrifices; this forbids all killing. That requires atrocious self-tortures; this

inculcates fewer austerities than Catholicism. That makes lying, theft, and other vices, sometimes commendable, and describes the gods as excelling in these enormities; this never confounds right and wrong, and never excuses any sin. That makes absorption into deity the supreme good; this annihilation. In fine, I know of no important resemblance.

"Boodhism inculcates no principle of caste, which is a striking difference from what prevails among the Hindoos; and from this and other causes it is believed to be much more ancient as a religion than Brahminism. The probability seems to be, that Brahminism grew out of Boodhism, and gained power and numbers in Hindostan till the close of the first century of the Christian era, when the Brahmins were able to commence that persecution of which their own records speak, and which drove out the teachers of Boodhism into Farther India, whence it extended into China.

"The most extraordinary peculiarity of Boodhism is the want of any existing God. Adoration or respect is merely paid to the image of Gaudama, who was a god at a former period, but is now annihilated, or entered into annihilation. Gaudama was the son of a king, and born about 626 years before the commencement of our era. He had previously lived in four hundred millions of worlds, and passed through innumerable conditions in each. In *this* world he had been almost every sort of worm, fly, fowl, fish, or animal, and in almost every grade and condition of human life. Having in the course of these transitions attained immense merit, he at length was born son of the above-named king. The moment he was born, he jumped upon his feet, and, spreading out his arms, exclaimed, 'Now am I the noblest of men! This is the last time I shall ever be born!' His height, when grown up, was nine cubits. His ears were so beautifully long, as to hang upon his shoulders; his hands reached to his knees; his fingers were of equal length; and with his tongue he could touch the end of his nose! All which are considered irrefragable proofs of his divinity.

"When in this state his mind was enlarged so that he remembered his former conditions and existences. Of these he rehearsed many to his followers. Five hundred and fifty of these narratives have been preserved—one relating his life and adventures as a deer, another as a monkey, elephant, fowl, &c. &c. The collection is called *Dzat*, and forms a very considerable part of the sacred books. These legends are a fruitful source of design for Burman paintings. Of these I purchased several, which do but bring out into visible absurdity the system which they would illustrate.

"He became Boodh in the thirty-fifth year of his age, and remained so forty-five years, at the end of which time, having performed all sorts of meritorious deeds, and promulgated excellent laws far and wide, he obtained 'nic-ban,' that is, entered into annihilation, together with five hundred priests, by whom he had been long attended. This occurred in Hindostan about 2330 years ago, or B. C. 546. At his death he advised that, besides obeying his laws, his relics and image should be worshipped, and pagodas built to his memory, till the development of the next Boodh. He is invariably represented in the same manner, except that sometimes he is made to wear a crown, necklace, ornaments on his arms, &c. I have seen them of all sizes, from half an inch long to seventy-five feet—of wood, stone, brass, brick, clay, and ivory.

"The next Boodh is to appear in about seven or eight thousand years from the present time. His height will be eighty cubits; his mouth will be five cubits wide, and the length of the hairs of his eyebrows five cubits. The precise time of his arrival is not predicted. No laws or sayings of the first three Boodhs are extant. Those of Gaudama were transmitted by tradition, till four hundred and fifty years after his decease, when they were reduced to writing in Ceylon, that is, A. D. 94. These are the only sacred books of the Burmans, and are all in the Pali language. They are comprised in three divisions, each of which is divided into distinct books, or sections. The whole is called *the Bedagat*.

"According to the Bedagat, the universe consists of an infinite number of systems; each system consists of a great central mountain surrounded by seas, and four great islands, each surrounded by five hundred smaller ones. This earth is the southern cluster of islands, and we are living on the larger one. It is a convex plane, not a sphere; and is divided by mountains and navigable seas. Below its upper crust, on which we live, is water twice as deep as the earth is thick. The whole is supported on a stratum of air twice as deep as the water. Beneath is a vacuum. The celestial regions consist of twenty-six principal heavens, one above another; and the infernal regions of eight principal places of punishment, each surrounded by sixteen smaller ones. In one of the heavens, there are pleasant habitations for mortals after death; and at the king's principal residence there is an elephant of stupendous size. This animal is of immense height, and has seven heads; each head has sunken tusks, and each tusk seven tanks. In each of these tanks grow seven lilies; each lily has seven blosoms; each blossom has seven petals; each petal bears up seven palaces, and in each palace are seven nymphs, or wives of the king, each surrounded by 500 attendants. Another elephant has one great head, thirty uzenas long, on which the king occasionally rides; and thirty-two smaller heads, for the thirty-two royal princes. Of the principal bells, four inflict punishment by heat, and the other four by cold.

"Not only has the universe and all its systems existed from eternity, but also the souls of all the inhabitants, whether animals, men, or celestials. These souls have from eternity been transmigrated from one body to another, rising or falling in the scale of existence and enjoyment, according to the degree of merit, at each birth. This rise or fall is not ordered by any intelligent judge, but is decided by immutable fate. In passing through these various forms of existence, the amount of sorrow endured by each soul is incalculable. The Bedagat declares that the tears shed by any one soul, in its various changes from eternity, are so numerous, that the ocean is but a drop in comparison! Existence and sorrow are declared to be necessary concomitants; and therefore the 'chief end of man' is to finish this eternal round of changes, and be annihilated.

"The great doctrines of the faith are five—namely, 1. The eternal existence of the universe, and all beings. 2. Metempsychosis. 3. Nic-ban, or annihilation. 4. The appearance, at distant periods, of beings, who obtain deification and subsequent annihilation. 5. The obtaining of merit. Of the first four of these enough has been already said. The last is more deserving of notice, embracing as it does the whole system of morals.

"Merit consists in avoiding sins and performing virtues, and the degree of it is the sole hope of the Boodhist. The sins which are to be avoided are described in a moral code, consisting of five principal and positive laws:—1. Thou shalt not kill. 2. Thou shalt not steal. 3. Thou shalt not commit adultery. 4. Thou shalt not lie. 5. Thou shalt not drink any intoxicating liquor. These are explained and branched out, so as to include all sins of the same kind, under each head. The first of these laws is extended to all killing, even that of animals for food. The very religious will not kill vermin. War and capital punishments are considered forbidden by the first law.

"Sins are divided into three classes:—1. Those of the body—such as killing, theft, &c. 2. Those of the tongue—as falsehood, discord, harsh language, idle talk, &c. 3. Those of the mind—as pride, covetousness, envy heretical thoughts, adoring false gods, &c. The more

books pourtray strongly the evils of pride, anger, covetousness, and inordinate appetites. Men are urged to avoid excessive perfumes, ornaments, laughter, vain joy, strong drink, smoking opium, wandering about the streets in the night, excessive fondness for amusements, frequenting bad company, and idleness. Those who aspire to nic-ban are cautioned to abhor sorcery, not to credit dreams, nor be angry when abused nor elated when approved, not to flatter benefactors, nor to indulge in scorn or biting jests, and most carefully to avoid enkindling strife.

"The states of the mind are resolved into three classes:—1. When we are pleased in the possession of agreeable things. 2. When we are grieved and distressed by evil things. 3. When neither do good things gratify us, nor evil things distress. The last is the best state, and in it a man is rapidly preparing for nic-ban. In this there is no small resemblance to the doctrine of the Stoics, and some approach to the Christian doctrine of weanedness from the world. Some of their books abound in good comparisons, such as, that he who runs into sinful enjoyments is like a butterfly who flutters round a candle till it falls in; or one who, by licking honey from a knife, cuts his tongue with the edge. There is scarcely a prohibition of the Bedagat which is not sanctioned by our Holy Scriptures, and the arguments appended to them are often just and forcible.

"Merit is of three kinds:—1. *Theela*, or the observance of all the prohibitions and precepts, and all the duties fairly deducible from them; such as beneficence, gentleness, integrity, lenity, forbearance, condescension, veneration for parents, love to mankind, &c. &c. 2. *Dana*, or giving alms and offerings. This includes feeding priests; building kyoungs, pagodas, and zayats; placing bells at pagodas; making public roads, tanks, and wells; planting trees for shade or fruit; keeping pots of cool water by the way-side for the use of travellers; feeding criminals, birds, animals, &c. 3. *Bawana*, or repeating prayers, and reading religious books.

"Alms-deeds are meritorious according to the objects on which they are bestowed, and proportioned to the following scale:—1. Animals. 2. Common labourers, fishermen, &c. 3. Merchants and the upper classes, when in necessity. 4. Priests. For alms of the first class, the rewards are long life, beauty, strength, knowledge and prosperity, during a hundred transmigrations; for those of the second class, the same during a thousand transmigrations; for the third, the same during ten thousand; for the fourth, a vastly greater number, but indefinite, being graduated according to the degree of sanctity the particular priests may possess.

"Many discourses said to have been delivered by Gaudama are given in the Bedagat. In these, the duties of parents, children, husbands, wives, teachers, scholars, masters, slaves, &c., are drawn out and urged in a manner which would do honour to any casuist.

"The following is part of one of these, addressed to a distinguished personage, who sought his instruction how to avoid evil:—

"'Know thou, that to keep from the company of the ignorant, and choose that of learned men; to give honour to whom it is due; to choose a residence proper to our station, and adapted for procuring the common wants of life; and to maintain a prudent carriage, are means to preserve a man from evil doings. The comprehension of all things that are not evil, the exact knowledge of the duties of our station, and the observance of modesty and piety in our speech, are four excellent modes of renouncing wickedness.

"'By ministering a proper support to parents, wife, and family by purity and honesty in every action, by alms-deeds, by observing the divine precepts, and by succouring relations, we may be preserved from evil. By such a freedom from faults, that not even the inferior parts of our nature manifests any affection for them, by abstinence from all intoxicating drink, by the continual practice of works of piety, by showing respectfulness, humility, and sobriety before all, and gratitude to our benefactors; and, finally, by listening often to the preaching of the word of God, we overcome evil inclinations, and keep ourselves far from sin. Docility in receiving the admonitions of good men, frequent visits to priests, spiritual conference on the divine laws, patience, frugality, modesty, the literal observance of the law, keeping before our eyes the four states into which living creatures pass after death, and meditation on the happy repose of nic-ban—these are distinguished rules for preserving man from wickedness.'

"Pagodas are innumerable. In the inhabited parts there is scarcely a mountain peak, bluff bank, or swelling hill, without one of these structures upon it. Those of Pegu and Siam are all formed upon one model, though the cornices and decorations are according to the builder's taste. In general they are entirely solid, having neither door nor window, and contain a deposit of money, or some supposed relic of Gaudama. From the base they narrow rapidly to about mid-way, and then rise with a long spire surmounted with the sacred tee. Some of those around Ava, and especially those of Paghan, are less tapering, and more resembling temples.

"Zayats are not exclusively religious buildings. Some are intended to contain idols, and some are for the accommodation of worshippers and travellers, and for town-halls. The majority contain no idols, and are intended only to afford shelter for worshippers and travellers. Some of these are mere sheds, open on all sides; but in almost all cases they are built in a far more durable and costly manner than dwelling-houses.

"Every village has a zayat, where the stranger may repose or stay for many days, if he please; and many a time I found them a comfortable lodging-place. Like the chultries of Hindostan, they are of unspeakable utility in a country destitute of inns, and where every house has its full complement of inmates. Many zayats, especially near great cities, are truly beautiful, and very costly. The ceilings and pillars are not only elaborately carved, but completely gilded, and the stucco floors rival marble in hardness and polish.

"Worship is not performed collectively, though crowds assemble at the same time on set days. Each one makes his offerings and recites his prayers alone. No priests officiate; no union of voice is attempted. On arriving at the pagoda, or image, the worshipper walks reverently to within a convenient distance, and laying his offering on the ground, sits down behind it, on his knees and heels, and placing the palms of his hands together, raises them to his forehead, and perhaps leans forward till his head touches the ground. This is called the *sheeko*. He then utters his prayers in a low tone, occasionally bowing as before; and having finished, rises and carries forward his gift, laying it somewhere near the idol or pagoda. Some proceed first to one of the great bells which hang near, and strike several times with one of the deer's horns which always lie beneath. When one goes alone, this is seldom omitted. There are four set days in every lunar month on which the people assemble in greater numbers at the pagoda to offer their individual prayers. These days are at the new and full moon, and seven days after each; so that sometimes their Sabbath occurs after seven days and sometimes after eight.

"Boodhist priests are not a caste or hereditary race. Any one may become a priest, and any priest may return to a secular life at pleasure. Thousands, in fact, return every year, without the least reproach. On becoming a priest, a yellow robe is assumed, and celibacy, with numerous mortifications, is enjoined. Their office may be called a sinecure, as they seldom preach or perform any service, except teaching and giving special religious ad

vice. They are of different degrees of rank, and subsist entirely on the contributions of the people. Their number is very great. Ava, with a population of 200,000, has 20,000 priests.

Boodhist Priest.

"In point of moral obligation, and the inculcation of purity of life, Boodhism is infinitely superior to Hindooism. It has no mythology of obscene and ferocious deities, no sanguinary or impure observances, no self-inflicted tortures, no tyrannizing priesthood, no confounding of right and wrong, by making certain iniquities laudable in worship. In its moral code, its descriptions of the purity and peace of the first ages, of the shortening of man's life because of his sins, &c., it seems to have followed genuine traditions.

"At the same time, we must regard Boodhism with unmeasured reprobation, if we compare it, not with other false religions, but with truth. Its entire base is false. It is built, not on love to God, nor even love to man, but on personal merit. It allows evil to be balanced with good, by a scale which reduces sin to the shadow of a trifle. To sheeko to a pagoda, or offer a flower to the idol, or feed the priests, or set a pot of cool water by the wayside, is supposed to cancel a multitude of sins. The building of a kyoung or pagoda will outweigh enormous crimes, and secure prosperity for ages to come. Vice is thus robbed of its terrors, for it can be overbalanced by easy virtues."

LAMAISM.

In Thibet, Tartary, and other parts of central Asia, inhabited by the Mongolian race, Boodhism assumes a different form and name, being more a religion of pure priestcraft and external observance, and including a belief in the continual personal presence of a supreme God. This branch of Boodhism, as it is believed to be, is usually called Lamaism, the word *Lama* literally signifying priest. Like Boodhism, this religion acknowledges no eternal, self-existing being. The idols, to the number of a hundred and eight, are representatives of created beings, who ascended into the rank of gods before the present world was created, on account of their holiness. The chief god is Shigemooni, who appeared in the world for the last time a thousand years before the Christian era, and then instituted Lamaism, with a visible living representative or appearance of himself, called Dalai-Lama, or the Great Lama. The worship of this Grand Lama, therefore, is a principal feature in the system of belief.

It is understood and inculcated, that when the Grand Lama expires in the course of nature, his spirit immediately takes possession of some other body in a supernatural manner, which it is impious to inquire into, and is only comprehended by the attendant priests. In point of fact, the religion which inculcates this absurdity is idol worship under a different name, the idol being a living creature instead of an inanimate object, as in ordinary paganism; and the whole system seems to have been devised in order to support a numerous host of priests and religious establishments.

Dalai-Lama, or the Grand Lama, is at the head of both ecclesiastical and secular affairs in Thibet, which may be considered a theocratical state. The usual residence of the Dalai-Lama is in two monasteries situated in the vicinity of the capital, Lassa, in each of which he dwells alternately. He is surrounded in every direction by a vast number of priests; but no woman is permitted to pass the night in the building where he lodges. This arises, undoubtedly, from the purity which is attributed to him, for he is called the *immaculate*. The natives, as well as a great crowd of foreigners (for all the Mongol tribes in Russia acknowledge him), undertake fatiguing pilgrimages in order to pay their homage to him, and obtain his blessing. He receives them sitting upon a kind of altar upon a large and splendid seat, with his legs crossed. The Tartars, next to the inhabitants of Thibet, pay him the greatest reverence. They come to him from the most distant regions, and the princes, to whom he shows no more respect than to others, submit to the same ceremonies as their people. He salutes no one, never uncovers his head, rises up before no one, and is satisfied with laying his hand upon the head of his worshipper, who believes that he has thereby obtained the pardon of his sins. His worshippers believe that the supreme divinity lives in him, that he knows and sees every thing in the deepest recesses of the heart, and never needs to make inquiry in regard to any thing. If he does this, it is only that unbelievers and the evil-minded may not have cause for complaint. He sometimes distributes, it is said, little balls of consecrated dough, which the Tartars use in many superstitious practices; but it is not true that balls made from his excrement are distributed, preserved in golden boxes, and even mixed with articles of food. His power was once greater than it is now, and he appointed and deposed the khans; but at present he is dependent on the Emperor of China, although the latter, in a religious respect, is subjected to him. Two Chinese mandarins, with a garrison of 1000 Chinese, are maintained in his capital, and, in the palace at Pekin, the Chinese emperor supports a subordinate Lama, who is sent as a nuncio from Thibet.

When the Dalai-Lama dies, it is then necessary to discover where his spirit has chosen to be born anew. In this case all must submit to the opinion of some of the Lamas, who alone are acquainted with the signs by which he may be known, or, rather, who know what child the deceased has appointed for his successor. The worshippers of the Lama are divided, in general, into two sects, known by the titles of the *yellow* and *red caps*. Each sect is under three Lamas; the former is under the Dalai, Teeshoo or Bogao, and Taranaut Lamas; the latter, under the three shammars. The Dalai-Lama is the most distinguished of all, and next to him is the Teeshoo-Lama, who dwells at Teeshoo-Loomboo, ten days' journey from Lassa. The three shammars dwell in separate monasteries, the most distinguished of which is at Tassasudon, the capital of Bootan. Subordinate to them are numerous priests of different ranks, who are held in great respect, who superintend instruction, and some of whom live in a state of celibacy, according to certain rules, similar to those of the Christian monks. At Lassa alone there are 3000 monasteries.

MOHAMMEDISM.

The religion of Mahomet, or Mohammed, and called Mohammedism, partakes of a much more exalted character than any of the mythological superstitions already adverted to, inasmuch as it approaches a pure theism, or a belief in the one true God. This famed religion, which now prevails in Arabia, Egypt, the Moorish states, Turkey, Persia, and is extended in a scattered manner over south-eastern Asia, and numbers 100,000,000 of followers, originated in Arabia at the beginning of the seventh century of the Christian era.

At this period, eastern countries were in a condition to receive a new and vigorously conducted form of religious belief. The scattered branches of the Christian church in Asia and Africa were at variance with each other, and had adopted the wildest heresies and superstitions. They were engaged in perpetual controversies, and torn to pieces by the disputes of the Arians, Sabellians, Nestorians, and Eutychians; whilst the simony the incontinence, and general barbarism and ignorance which were to be found amongst the clergy, caused great scandal to the Christian religion, and introduced uni-

versal profligacy amongst the people. While Christianity, in the manner it was abused by unenlightened followers, was of little avail in civilizing the Asiatics, while the religion of the Jews was sunk into comparative insignificance, and while paganism still flourished in the east, Mohammedism was introduced upon the scene, and in a wonderfully short period of time, gave an entirely new cast to manners and form of belief. Arabia being the country in which this new religion was first promulgated, it is considered desirable to mention the nature of the religion which the people previously professed and now abandoned.

"The ancient Arabs are supposed to have been what are termed pure theists; that is, they are supposed to have believed in and worshipped one sole, omnipotent, and everlasting God. Historians, however, have seldom correctly appreciated the meaning of these magnificent expressions in the mouth of a savage. In his mind such language is connected with ideas and feelings far other than those which a civilized man would express by it. These splendid epithets are the mere expressions of flattery and fear. The Deity, now addressed, and whose favour is the object of present desire, is for the time the sole object of adoration. The very same savage, who believes in a host of gods, will address each of them by the term of THE ONE. If among many deities one is thought more powerful than the rest, he will be the oftenest addressed, the oftenest soothed by flattery. No epithet is so flattering as that which asserts his single existence. It exalts him above all beings, and leaves him without a rival. No epithet, therefore, will be so frequently employed. Being the most constantly adored, this more powerful divinity will have this epithet expressive of his sole existence so frequently connected with his name, that it will at length be regularly attached to, and form part of, that name. This was precisely the case with the Arabian objects of worship. It is strange that, when complete evidence of this fact exists, really intelligent and circumspect historians should have believed in the pure theism of the Arabians. Sale, like many others, was deceived by pompous expressions:—'That they acknowledge one supreme God, appears (to omit other proof) from their usual form of addressing themselves to him, which was this:—"I dedicate myself to thy service, O God!—I dedicate myself to thy service, O God! Thou hast no companion, except thy companion of whom thou art absolute master, and of whatever is his."' In the very next passage, however, Sale adds, 'They offered sacrifices and other offerings to idols, as well as to God, who was also often put off with the least portion, as Mohammed upbraids them.' Their scheme of divine government was simple, and like most others formed in the same state of civilization. One god was supposed to be the supreme ruler; and subject to his sway was a vast multitude of inferior deities. 'The Arabs acknowledged one supreme God, the creator and lord of the universe, whom they called Allah Taala, the most high god; and their other deities, who were subordinate to him, they called simply Al Ilahat, that is, goddesses.'* Idols were set up and worshipped; every field, every rivulet, had its divinities. The fixed stars and planets were also exalted into gods, and as such received adoration. Heaven, moreover, was peopled with angels, who, with the wooden, stone, and clay idols on earth, were regularly worshipped. How the Arabians can be supposed believers in a single godhead, under such circumstances, appears extraordinary.

"The manner in which these various divinities were rendered propitious, at once marks that no very exalted conception of a divinity existed in the minds of these barbarians. Fasts, pilgrimages, sacrifices, long and unmeaning prayers, were the means employed to obtain the divine favour.

"'They are obliged to pray three times a-day (some say seven times a-day): the first, half an hour or less before sunrise, ordering it so, that they may, just as the sun rises, finish eight adorations, each containing three prostrations; the second prayer they end at noon, when the sun begins to decline, in saying which they perform five such adorations as the former; and the same they do the third time, ending just as the sun sets. They fast three times a year: the first thirty days, the next nine days, and the last seven. They offer many sacrifices, but eat no part thereof, but burn them all. They abstain from beans, garlic, and some other pulse and vegetables.'*

"'The same rites which are now accomplished by the faithful Mussulman, were invented and practised by the superstition of the idolaters. At an awful distance they cast away their garments; seven times, with hasty steps, they encircled the Caaba, and kissed the black stone; seven times they visited and adored the adjacent mountains; seven times they threw stones into the valley of Mina, and the pilgrimage was achieved as at the present hour, by a sacrifice of sheep and camels, and the burial of their hair and nails in the consecrated ground.'"† The Arabians had many other superstitious practices; they held their women in a degraded condition; and, though refined in some points of manners, they had no written law, were governed despotically by chiefs, and were really barbarians and idolaters. It was the debased religion of this people which Mohammed designed to improve, and we have now to see who this singularly bold and ingenious man was, and how he carried his plans into execution.

Mohammed was born at Mecca, the capital city of Arabia Felix, A.D. 569, during the reign of Noosheervan, surnamed the Just, King of Persia. He was of the family of Haschem, and of the tribe of the Koreish, the noblest in Arabia. His father Abdallah was a younger son of Abdalmotalleb, and dying very young, and in his father's lifetime, left his widow and infant son in very mean circumstances, his whole substance consisting but of five camels and one Ethiopian female slave. Abdalmotalleb was therefore obliged to take charge of his grandchild Mohammed, which he not only did during his life, but at his death enjoined his eldest son, Abu Taleb, who was brother to Abdallah by the same mother, to provide for him for the future. This was very affectionately performed by Abu Taleb, who instructed him in the business of a merchant, which he followed; and to that end he took young Mohammed into Syria when he was but thirteen years old, and afterwards recommended him to Khadijah, a noble and rich widow, for her factor, in whose service he behaved so well, that, by making him her husband, she soon raised him to an equality with the richest in Mecca.

It was after he began, by this advantageous match, to live at his ease, that he formed the scheme of establishing a new religion, or, as he expressed it, of replanting the only true and ancient one professed by Adam, Noah, Abraham, Moses, Jesus, and all the prophets, by destroying the gross idolatry into which the generality of his countrymen had fallen, and weeding out the corruptions and superstitions which the latter Jews and Christians had, as he thought, introduced into their religion, and reducing it to its original purity, which consisted chiefly in the worship of one only God. He thereupon began to affect solitude, usually retiring for a month in the year to a cave in Mount Hara, near Mecca. He had indisputably a very piercing and sagacious intellect, and was thoroughly versed in all the arts of insinuation. The eastern historians describe him to have been a man of an excellent judgment and a happy memory; and these

natural parts were improved by a great experience and knowledge of mankind, and the observations he had made in his travels. He is represented as a man of few words, of an equal, cheerful temper, pleasant and familiar in conversation, of inoffensive behaviour towards his friends and acquaintances, and of great condescension towards his inferiors; to all which were joined a comely agreeable person, and a polite address—qualities of no small service in prepossessing those in his favour whom he attempted to persuade.

"When the prophet was about four years old," says Mahmut the Arabian,* "accompanying the sons of his nurse into the field, the blessed child retired into a cave, at the foot of the mountain Uriel, to pray, when the Archangel Gabriel appeared to him, and said, *Bismillar rahmanir rahimi;* that is, 'In the name of God, compassionate and merciful, O child greatly beloved, I am sent to displant from thy heart the root of evil; for thy ejaculations made the gates of Paradise to fly open!' The young resigned one said, 'The will of thy Lord and mine be done.' Then the angel opened his breast with a razor of adamant, and, taking out his heart, squeezed from it the black contagion which was derived from Adam; and having put the child's heart in its place again, he blessed him, and retired to the invisibles. From that time the young favourite of Heaven grew up and prospered in all things, having the smiles of God and man. He was under the tuition of his uncle Abu Taleb, who, discerning the mark of an immense soul in his young nephew, was more solicitous for his welfare than if he had been his son. His fortune being low in the world, he had no other way to provide for his illustrious charge than by placing him as a factor to Khadijah, a widow of the same tribe with Mohammed, which was the noblest among the Arabians."

Mohammed's marriage with Khadijah took place when they were respectively twenty-five years of age; and it was not till twelve years after this marriage that he began to fabricate his imposture, in the cave of Mount Hara, about three miles from Mecca, to which he usually retired during the month of Ramazan, being the time of Lent. At length, A. D. 609, when he was fully forty years old, he disclosed his prophetic mission at first only to his own wife Khadijah. He told her that the Angel Gabriel had appeared to him in glory, and declared that God had commissioned him as an apostle to reform the world; *that he then delivered to him the Koran for a divine law*, which should complete all antecedent revelations. Khadijah gained for her husband an important proselyte in her uncle Waraka, a Christian, who was well read in the Old and New Testaments. He pronounced Mohammed *"to be the great prophet foretold by Moses the son of Amram."* It is much more probable that Waraka was the assistant of Mohammed in composing the Koran than Sergius the monk, or any other person.

The next proselyte was Abubeker, a rich and respectable inhabitant of Mecca; and his example being followed by many others, Mohammed ventured on a bolder demonstration of his mission. At a numerous assemblage of the Koreishites, at a public entertainment to which he had invited them, he demanded who would become his vizier, or prime minister, assuring them that both happiness in this world and in that to come would accrue to his followers. The guests remained silent in surprise, when Ali, the son of Abu Taleb, a boy about fourteen years of age, started up enthusiastically, and said, "I will be thy vizier, oh Prophet of God! I will break the teeth, pluck out the eyes, rip up the belly, cut off the legs of thine enemies." The joy and approval testified by Mohammed to the zeal of his youthful disciple, was an apt and early specimen what manner of spirit he and his deputy were of. The hostile proceedings and denunciations of the prophet against their idolatry, at length aroused the enmity of the Koreishites; but their threats were despised by him, and, in reply to the prudent remonstrances of his uncle Abu Taleb, he exclaimed, "Though the Koreishites should arm against me the sun and the moon (alluding to the divinities whom they ignorantly worshipped), the one on my right hand, and the other on my left, I would not be shaken from my resolution." He, however, retired for a while to a castle in Mount Safa, and his followers were banished from the city of Mecca. After this persecution, which lasted five years, in the tenth year of his mission (A. D. 618), he sustained a serious loss in the death of his uncle Abu Taleb: and this was followed a short time after by the death of his affectionate wife Khadijah, who had so generously made his fortune. On account of these misfortunes, this year was called the Year of Mourning. Instead of sinking under these adversities, however, upon being violently urged by the Koreishites, who still derided his pretensions, to exhibit some miracle, Mohammed ventured, in the twelfth year of his mission, to publish the revelation of his night visit or journey to the seven heavens.

This event formed a striking epoch in his mission, and displayed in the strongest manner the dexterity as well as boldness of his measures. The question so forcibly put to him, of establishing his mission by miracles, is therein artfully parried, and replied to by an appeal to the wonders wrought by Moses, which did not cause the reformation of Pharaoh, and to those of Jesus, which failed with the Jews; he also incidentally remarked, that miracles were designed rather to strike terror and to punish than to convince.

This famous journey is thus described by Mohammed: While he was in the Caaba, or sacred square building at Mecca, reclining on the sacred stone, the Angel Gabriel came to him; he opened his breast, took out his heart, and washed it in a golden basin full of the water of *faith*, and then restored it to its place. The angel had seventy pairs of wings, and had the beast Alborak with him, on which the prophets used to ride: it was white and partly horse, ass, and mule, or a middle between the two last, and went as fast as the lightning, which the name Alborak, in Arabic, signifies. When he was brought to Jerusalem by the angel, all the prophets met him, and owned his superiority. He ascended to heaven with the angel, on a ladder of divine light, and left the beast Alborak at Jerusalem till he descended again. He went through seven heavens before he came to the throne of God, which was in the last one, and Gabriel left him at the entrance of it, and waited till he returned from conversing with God, who gave him the offer to be next himself; but he rather chose to descend again to the earth to propagate his religion. His heavens were all 500 years' journey distant from one another. One was of silver, another of gold, another of emeralds, &c., and the last of light. He met some one of the patriarchs or prophets in each of them. In the first he met and discoursed with Adam; in the second, with John the Baptist and Jesus; in the third, with the patriarch Joseph; in the fourth, with Edris or Enoch; in the fifth, with Aaron; in the sixth, with Moses; in the seventh, with Abraham. Thence he was carried up to *Sedrat*, the lotus tree, whence were the sources of the four rivers of Paradise. He saw angels in the likenesses of all creatures in these heavens. He saw a great bull bearing the earth on his horns, and when he shook his head there was an earthquake. There was also a cock, which stood on one heaven, and his head reached another; his voice was heard through heaven and earth, and set all the cocks on earth a-crowing. He saw an angel of such stature that there was 70,000 days' journey between his eyes. The proportion of a man's height to the distance between his eyes is as seventy-two to one so that his

* Turkish Spy, vol. v. p. 190.

stature must then have been 14,000 years' journey, four times the height of all his heavens together, in which he was quite out of his mathematics. In the seventh heaven, where God and Christ were, was an angel with 70,000 heads; and in each head 70,000 tongues, with which he praised God. Gabriel accompanied him down from heaven to Jerusalem, and from thence conveyed him, with the beast Alborak, to Mecca; and all this was done in the tenth part of a night. In the conclusion of this extraordinary fabrication, he skilfully adds, that when he was enjoined to repeat fifty prayers each day, he entreated for his nation, and they were finally reduced at his intercession to five. To finish the wonder, he was returned back to the Caaba ere the crier called him to prayers; and "thus," concluded Mohammed, "did I bring with me the prescribed number of prayers, and lessened the burden for my nation."

This story seemed so absurd and incredible, that several of his followers left him on account of it; and it had probably ruined the whole design, had not Abubeker vouched for his veracity, and declared that, if Mohammed affirmed it to be true, he verily believed the whole; which happy incident not only retrieved the prophet's credit, but increased it to such a degree, that he was secure of being able to make his disciples swallow whatever he pleased to impose on them for the future. "And I am apt to think," says Sale, "this fiction, notwithstanding its extravagance, was one of the most artful contrivances Mohammed ever put in practice, and what chiefly contributed to the raising of his reputation to that great height to which it afterwards attained."

In this memorable year twelve citizens of Medina swore allegiance and obedience to the Prophet, whence they were styled, by way of dignity, *Al Ansar*, that is, "The Defenders;" and the year A. D. 620 was denominated the "accepted year." On Mount Aksba, near Mecca, seventy-three proselytes were soon after added to their number, and swore to defend the prophet from all insult, as they defended their own wives and children. "If," said they to the apostle of God, "we be slain in thy cause, what shall be our reward?" He answered, "Paradise." Then, said they, "Stretch forth thy right hand," and he did so; then they took the oath of obedience, promising rather to die than be perjured. He now established twelve apostles of Islamism, which was the name he gave to his religion, himself being the prime instructor and chief of all the true believers; and he then sent away the Ansars, his followers, and his family, to Medina, for security, and remained behind at Mecca, attended only by Abubeker and his son-in-law Ali.

By the protection which his uncle Abu Taleb had extended to Mohammed, he had been preserved thus far from his enemies; but the charge and dignity of the priest and guardian of the Caaba, having now, by the death of Abu Taleb, become the post of a member of the family of Ommiyah, a declared enemy to the family of Haschem, to which Mohammed belonged, the Koreishites, irritated and alarmed at the progress making by the new doctrine at Medina, resolved to destroy its author and chief support. This conspiracy was scarce formed, when, by some means or other, it came to Mohammed's knowledge, and he gave out that it was revealed to him by the Angel Gabriel, who had now ordered him to retire to Medina. Whereupon, to amuse his enemies, he directed Ali to lie down in his place, and wrap himself in his green cloak, which he did; and Mohammed escaped miraculously, as they pretend, to Abubeker's house, unperceived by the conspirators, who had already assembled at the prophet's door. They, in the mean time, looking through the crevice, and seeing Ali, whom they took to be Mohammed himself, asleep, continued watching there till morning, when Ali rose, and they found themselves deceived.

In the recesses of a cave near Mecca, Mohammed and Abubeker eluded for three days the pursuit of their enemies. "There are only two of us," said the apprehensive disciple, when he expected the pursuers to penetrate their retreat. "There is a third, even God himself," said the intrepid chief; "he will defend us." According to tradition, Mohammed, afterwards asserted that a miracle was here wrought in his behalf; for that his enemies, approaching the cave, found that its entrance was covered by spiders' webs hanging from the trees, which convinced them that no person had entered it for a long time. After a perilous journey, Mohammed entered Medina in triumph, being enthusiastically received by the Ansars, who disputed for the honour of entertaining the prophet, and took hold of the bridle of his camel. Mohammed then desired them to let her take her own way, for she was a stubborn beast; which she took, accordingly, and stopped at the stable of two rich orphans, Sahali and Sohaili, where the prophet dismounted. This spot he purchased from the orphans, after refusing their offer to bestow it upon him, and Abubeker paid the money. He erected thereon a mosque, and a habitation for himself, on which he laboured with his own hands. Medina henceforth received the august title of *Medinat al Nabi*, or the "City of the Prophet."

The Mohammedan era, called the Hejira, takes its commencement from the date of Mohammed's flight from Mecca to Medina. The generality of writers place this epoch on Friday, the 16th of July, A. D. 622. It is this event which has rendered Friday the solemn day of the week for his followers; this choice also agreeing with the customs of the Arabians, who held their assemblies usually on the Fridays. The word *Hejira* is derived from the Arabic verb *Hajara, to abandon one's native country, to emigrate on account of persecution*; which comes from the Hebrew *Hagar, the stranger* or *emigrant*, the name of Ishmael's mother.

It was from this period that Mohammed, having fully ascertained the hate of his enemies and the extent of his own power, proceeded to lay aside the arts of persuasion and patient endurance, whereby he had hitherto sought to propagate his tenets; and, elated by the devotion of his disciples and his reception at Medina, he framed henceforth the revelations of the Koran in a tone which proclaimed him a persecutor, and empowered his followers to make war against all opposers. The successful battle of Beder followed soon after; and he then made known those doctrines which have rendered the arms of the Mussulmans so formidable, namely, "that no one can escape his destiny; inasmuch as the man whose days are not complete will escape unhurt from a shower of arrows, when he whose fatal term has arrived cannot escape death by any precaution whatsoever." The second incitative is that which the present occasion furnished him with:—"The sword," exclaimed the prophet, "is the key of heaven and of hell; *a drop of blood shed in the cause of God, a night spent under arms*, is of more avail than two months of fasting and prayer. Whosoever falls in battle, his sins are forgiven: at the day of judgment, his wounds shall be resplendent as vermilion and odoriferous as musk; the loss of his limbs shall be replaced by the wings of angels and of cherubim."

This victory, the first of Mohammed's battles, was gained, in the second year of the Hejira, over the idolatrous Meccans, headed by Abu Sofian, in the valley of Beder, which is situated near the sea, between Mecca and Medina. Mohammed's forces consisted of no more than 319 men, and the enemy's army of near 1000; notwithstanding which odds, he put them to flight, having killed seventy of the principal Koreish, and taken as many prisoners, with the loss of only fourteen of his own men. This first victory, although it may seem no very considerable action, was yet of great advantage to him, and

the foundation of all his future power and success; for which reason it is very famous in Mohammedan history, and is frequently vaunted of in the Koran as an effect of the divine assistance, through the miraculous interposition of the Angel Gabriel. The gaining of the battle was, however, wholly attributable to the extraordinary stratagem of Mohammed, by his expedient, at the critical moment, of scattering a handful of dust against his enemies, at the same time exclaiming, "Let their faces be confounded!"—which action so invigorated his fainting followers, that they charged and overthrew their foes. Mohammed captured the whole caravan, which consisted of 1000 camels, richly laden, from Syria; and this afforded him the means of rewarding his followers, and inciting them to further exertion by the allurements of wealth and the hope of plunder.

Some reckon as many as twenty-seven expeditions wherein Mohammed was personally present, in nine of which he gave battle; besides several other expeditions, undertaken by his orders, in which he was not present. His forces he maintained partly by the contributions of his followers for this purpose, which he called by the name of *zacat* or alms, and the paying of which he very artfully made one main article of his religion; and partly by ordering a fifth part of the plunder to be brought into the public treasury for that purpose, in which matter he likewise pretended to act by the divine direction.

In a few years, by the success of his arms, he considerably raised his prophetic character and power. In the sixth year of the Hejira, he set out with 1400 men to visit the temple of Mecca, not with any intention of committing hostilities, but in a peaceable manner. However, when he came to Al Hodeibiya, which is situated partly within and partly without the sacred territory, the Koreish sent to let him know that they would not permit him to enter Mecca unless he forced his way; whereupon he called his troops about him, and they all took a solemn oath of fealty or homage to him, and he resolved to attack the city; but those of Mecca, sending Arwa Ebn Masud, prince of the tribe of Thakif, as their ambassador, to desire peace, a truce was concluded between them for ten years, by which any person was allowed to enter into league either with Mohammed or with the Koreish, as he thought fit.

Having subdued the chief part of the pagan tribes, and by his relentless severity exterminated the Jewish classes who dwelt peaceably in Arabia, in the seventh year of the Hejira (A. D. 628), he assumed the state of a sovereign, and sent embassies to the neighbouring monarchs, exhorting them to embrace Islamism.

In the eighth year of the Hejira, a quarrel, real or feigned, gave him the opportunity of possessing himself of Mecca, and of the sacred square edifice called the Caaba. Mohammed appearing suddenly at their gates with 10,000 men, before the troops of Mecca had even been apprized of his departure from Medina, they had no choice left but an immediate surrender or destruction. Thus pressed, and menaced with instant death, the Koreish submitted to the superior power of Mohammed. Their final submission to him, and their acceptance of his faith, were ratified subsequently on the hill El Safa. Having visited the holy building of the Caaba, and broken in pieces the idols wherewith it was encircled, Mohammed went in procession seven times round the building, and touched respectfully the black stone which was held sacred by the Arabs; then entering the edifice, he repeated the formulary, "*God is great.*" Afterwards he went to the well Zemzem—which is believed by them to be the same that the angel showed to Hagar—drank of the water, and performed the required ablution. Artfully blending attention to exterior observances with zeal, and pursuing a mixed system of mercy and rigour, he subdued the hearts of his high-minded countrymen, and soon superadded to his claims of power he more imposing and indissoluble bonds of superstitious reverence and awe. The capture of Mecca, and the submission of the powerful race of the Koreish, was soon followed by the conversion to Islamism of most of the remoter pagan tribes, until all Arabia bowed the neck beneath his yoke.

Mohammed, having thus become master of all Arabia, made great preparations for the conquest of Syria; but this vast enterprise was reserved for his successors. He gradually, however, paved the way for their successes, and brought the celebrated region of Arabia into one complete and powerful union. He established the law which still obtains in all the Mussulman states, of imposing a personal tax on such as do not embrace Islamism. By this custom, still subsisting among all the sovereigns who acknowledge the Koran, every reputed infidel pays a *kharaj*, or capitation-tax, over and above the imposts which he supports equally with the rest of the subjects. He absolutely prohibited all idolaters from making the pilgrimage to Mecca, or any foreigner from entering the Caaba, under pain of death. These were strokes of profound policy. He retained the pilgrimage to Mecca, which had been of ancient standing among the descendants of Abraham and Ishmael. Though he destroyed the images used at Mecca as objects of idolatrous worship, he carefully retained the holy relics of the black stone and the supposed impression of Abraham's foot. The black stone had been immemorially venerated there; the angels, it was said, had brought it *white* to the Caaba, and the sins of mankind had transformed it to *black*. Hence, in allusion to this stone, the Orientals use the compliments, "May God whiten thy face;" "May the shah make thy face white," &c.

These practices no less forwarded the progress of Islamism than did the sword of Mohammed. Everywhere the petty Arabian tribes overthrew their idols and submitted themselves to the new faith. Thus was Mohammedism established, and idolatry rooted out, even in Mohammed's lifetime, throughout all Arabia; and the Arabs, being then united in one faith and under one prince, found themselves in a condition for making those conquests which extended the Mohammedan faith over so great a part of the world.

In the tenth year of the Hejira (A. D. 631), Mohammed set forth on a solemn and pompous embassy to Mecca, accompanied by all his wives, and by at least 90,000 pilgrims. He sacrificed with his own hands sixty-three victims, and liberated sixty-three slaves, in thanksgiving for each year of his life; he shaved his head, and scattered the hair among the multitude, who eagerly seized portions of it as sacred relics. He closed the solemnity with the following apostrophe, which, as if pronounced from heaven, concludes the Koran:—"Henceforth, wretched and miserable shall they be who deny your religion. Fear not them, but fear me; this day I have perfected your religion, and completed my grace toward you. I have willed that Islamism be your religion." He established the lunar movable year, still in use with the Mohammedans; and, finally, as supreme Pontiff, or Imam, dismissed the people with a farewell, the last, as he declared, that he should give them; whence this pilgrimage derived its name of the Farewell.

Mohammed, having returned to Medina, now drew near the close of his extraordinary and fortunate career. His health had been for three years on the decline; but he had neither relaxed his duties nor his labours. Being at length affected with a mortal malady, he was conveyed to the house of his favourite wife, Ayesha, where he expired, in the eleventh year of the Hejira (A. D. 632), in the sixty-first year of his age. Of all his wives, the first alone bore him any children, of whom only his daughter Fatima, wife of Ali, survived him.

Having thus presented a sketch of the life of this re-

markable man, we proceed to a notice of the religion which he founded. As already mentioned, Mohammed must be viewed chiefly in the light of an improver on the old modes of belief and practice of the Arabians; and his merit (if we may so call it) in this respect appears to have been the combining of a variety of religious opinions into one form of faith, superadding an implicit belief in his own prophetical character, and enunciating the whole of his code in the writings of the Koran. At the period of his death, he bore the character both of a divinely appointed vicegerent and of a secular prince, the latter being gained by his conquests; and his successors claimed the same double qualification. After the prophet's decease, the election of a successor occasioned considerable excitement, his father-in-law Abubeker, and his son-in-law and cousin Ali, each claiming the office of caliph. Abubeker was finally successful in the competition, and he, as is known to the readers of history, was succeeded by the ferocious Omar. Ali became the fourth caliph, but he was summarily cut off by poison; and from the long contests which afterwards occurred, it is difficult to say in what line the caliphate was ultimately settled.

The Koran, or prescribed record of the Mohammedan faith, consists of 114 chapters, each with a distinct title, but varying in length from a few sentences to several pages. No continuous subject can be said to run through the work, each chapter being in the form either of a separate revelation, or treating of a peculiar matter in faith, morals, or law. Among the titles to the various chapters, we find the following:—The Cow; the Family of Imran; Women; the Spoils; Jonas; Joseph; Abraham; The Night Journey; The Cave; The Assembly; The News; Divorce; The Fig; The Resurrection, &c. The whole is a singular jumble of highly poetical passages, narratives characterized by great simplicity and beauty of style, garbled extracts from the Old Testament, and pious exclamations. The praise of the Almighty is a prevailing theme in all parts of the work, along with a deep inculcation of the principle that Mohammed is the greatest of all prophets who ever appeared on earth. The work certainly contains much that is excellent as respects moral admonition, but also a great deal that is incomprehensible and ludicrous. Mohammed did not live to complete his Koran in the shape we now see it. With the assistance, unquestionably, of a person versant in the Jewish Scriptures, he from time to time, as was suggested by passing circumstances, composed his fragments, which he declared to have been revealed to him from God by the Angel Gabriel; and these having been collected by his followers, were, by succeeding caliphs, formed into a volume entitled *Al Koran* (pronounced *Kooran*), or The Book.

Whatever we may advance against the authority of the Koran, it is certain that it has been received by Mohammedans with a degree of reverence rarely witnessed among Christians towards the Holy Scriptures. In it they view the whole code of religious belief, civil law, and moral obligation. The belief which they generally profess, as drawn from the Koran, consists in the following leading points:—Religion is divided into two branches—faith and practice. Faith includes belief in God, in his angels, his revelations in the Koran, his prophets, the resurrection and day of judgment, and God's absolute decrees. Practice includes prayer, comprehending under this head the purifications necessary before prayer, almsgiving, fastings, and the pilgrimage to Mecca. The religion, as a whole, is called the religion of *Islam*, or *Islamism*. "The word *islam* signifies an entire submission to the will of God, and thence the attaining of security, peace, and salvation. This act is performed, and these blessings are obtained, according to the doctrine of the Koran, by acknowledging the unity of God and the apostleship of Mohammed. Every man who makes this profession (*aslama*) is a *Moslem*, that is, one who has entirely given himself up to the will of God, and is, on that account, in a state of salvation (*salam*). As it happens that *Muslimani*, the dual of *Muslim*, is commonly substituted for the singular by the Persians and Turks, the words *Mussulman* or *Mussulmans*, has in those, as well as in European languages, now nearly superseded the shorter and more correct term."—(*Encyclopedia Americana.*)

The notions of God and his attributes appear from the Koran to be just, and favourable to devotion. The belief in angels is, however, mingled with many singular fancies. They are believed to have been created of fire, to have pure and subtle bodies requiring no support, and that there is no distinction of sexes among them. The angels are supposed to have various forms and offices assigned to them; some adoring God, singing praises to him, or interceding for mankind, while others are engaged in writing down the actions of men, carrying the throne of God, and performing other services. The Mohammedans also believe that there are two guardian angels appointed to attend upon every human being, who observe and write down his actions, and who are changed every day.

There are four angels whom the Mohammedans believe to be more in the favour of God than any of the others. These are Gabriel, who is sometimes called the Holy Spirit and the Angel of Revelations, from his being employed in writing down the decrees of God; Michael, the friend and protector of the Jews; Azrael, the angel of death; and Israsil, who is to sound the trumpet at the resurrection. The devil, called in the Koran Eblis, is supposed to have been one of those favoured angels, but he fell because he refused to worship Adam, with the other angels at his creation. In the eighteenth chapter of the Koran, however, he is said to have been one of the genii, a species of beings whom the Mohammedans believe to be intermediate between angels and devils. The genii are said to have been created, like the angels, of fire, free from smoke; but, unlike the angels, they eat and drink, propagate their species, and are subject to death. Some are supposed to be good, and others bad. In the seventy-second chapter of the Koran, a company of the genii are described as believing in the doctrine of Mohammed on hearing him read it.

With respect to the belief in prophets, the Koran inculcates the doctrine that God has at various times given revelations of his will to several prophets, whose books originally amounted to one hundred and four. Of these, ten were given to Adam, fifty to Seth, thirty to Enoch, ten to Abraham, and the other four to Moses, David, Jesus, and Mohammed. All these, except the four last, they believe to be lost; and that, after Mohammed, no other revelation may be expected. It appears that they have some prayers of Moses, Jonas, and others, a book called the Psalms, which consists of extracts from our version mixed up with other matter, and a history of Christ said to be written by St. Barnabas. In this book, Christ is made to predict the coming of Mohammed under the title of "Famous," that being the signification of his name in Arabic. According to tradition, there have been from time to time no fewer than 224,000 prophets sent into the world; and of these, 313 were apostles, charged with commissions to reclaim mankind from the infidelity into which they had fallen. Six of them, namely, Adam, Noah, Abraham, Moses, Jesus, and Mohammed, were sent especially to promulgate new laws or dispensations. The Mohammedans believe some of these apostles to have been superior to the others; to the last six, for instance, they give the first place. They believe them to have been free from great sins, although not perfectly pure, and that they all professed the same religion. In this list of prophets they introduce many whose names are mentioned in scripture as patriarchs, such as Adam, Seth, Lot, &c., and also many others who

are not mentioned in the sacred writings. But of all the prophets of God, the Koran enforces the leading doctrine that Mohammed is the greatest, and that his mission is to be believed in under the most severe penalties. "God will render of none effect the works of those who believe not, and who turn away men from the way of God; but as to those who believe and work righteousness, and believe in the revelation which hath been sent down unto Mohammed (for it is the truth from their Lord), he will expiate their evil deeds from them, and will dispose their heart aright. When ye encounter the unbelievers, strike off their heads, until ye have made a great slaughter among them; and bind them in bonds; and either give them a free dismission afterwards, or exact a ransom, until the warriors shall have laid down their arms. This shall ye do."—Chap. xlvii. From numerous passages of this kind, the Mohammedans have framed the brief enunciation of their belief—"There is no God but God, and Mohammed is his prophet," a saying which is ever in their mouths, and may be called their popular creed.

Regarding the resurrection, the Mohammedans believe that, when a dead person is laid in the grave, he is received by an angel, who gives him notice of the coming of the two *Examiners*. These are two black angels of a terrible appearance, named Mouker and Nakir. They order the dead person to sit upright, and examine him concerning his faith in the unity of God and the mission of Mohammed. If he answer correctly, his body is allowed to lie at rest, and is refreshed with the air of paradise; but if he appeared skeptical they beat him on the temples with iron rods, till he cries with anguish so loud as to be heard by all except men and genii. As to where the soul dwells after death, the Mohammedans seem to have a variety of opinions, which need not to be particularized. Mohammedans are also divided as to the nature of the resurrection, some believing that it will be merely spiritual, others that the body only will be raised; but it is believed that all who have ever lived will appear for judgment. It is likewise believed that the irrational animals will be judged at the resurrection, and the weak animals will take vengeance on the strong until satisfaction is given to the injured. The Koran enjoins kindness to all animals whatsoever, although it pronounces some to be unclean; and it is allowed that the conduct of Mohammedans in this respect far excels that of the generality of Christians.

It is supposed by the more orthodox Mohammedans, that the books wherein the bad actions of a man are registered will be put into one scale, and the good into another, and according as these preponderate sentence will be given. After this will follow the satisfaction which every one takes of his fellow, or the retaliation made by them for the injuries they have received. The manner of giving this satisfaction will be to take away from one man a portion of his good works and give it to one whom he has injured. "Which being done," says Mr. Sale, "if the angels say, Lord, we have given to every one his due, and there remaineth of this person's good works so much as equalleth the weight of an ant, God will of his mercy cause it to be doubled to him, that he may be admitted into paradise. If, on the contrary, his good works be exhausted, and there still be some to receive satisfaction from him, God will order an equal amount of their sins to be heaped upon him, that he may be punished in their stead. The trials being over and the assembly dissolved, the Mohammedans hold that those who are to be admitted into paradise will take the right-hand way, and those who are destined for hell-fire the left; but both of them must first pass the bridge called in Arabic *al Sirat*, which they say is laid over the midst of hell, and describe to be finer than a hair and sharper than the edge of a sword."

The Mohammedans believe hell to be divided into seven apartments designed for the reception of different degrees of sinners. The first is designed to receive the wicked Mohammedans, the second for the Jews, the third for the Christians, and the rest for other sects and unbelievers. Over these will be placed nineteen angels, to whom the condemned will confess the justness of God's sentence, and beg them to intercede with him in their behalf. The punishment of infidels will be continued for ever, but wicked Mohammedans will be released after a certain period of suffering.

Before entering paradise, the righteous will drink of the pond of Mohammed, which is supplied with water from the four rivers of paradise. It is described as a month's journey in compass, and whoever drinks of the water will thirst no more. It is a matter of keen dispute whether paradise is already created, many supposing that it will be different from the paradise in which Adam was placed. The more orthodox opinion, however, is, that it is the same, and that it was created before the world. It is supposed to be situated above the seven heavens, immediately under the throne of God, and is described as a place of great beauty. The trunks of the trees are of gold, one of which, the tree of happiness, will yield all sorts of fruit for the consumption of true believers.

God's absolute decree and predestination of both good and evil, is a doctrine which Mohammed always took occasion to impress upon his followers. He said that God had not only predetermined the adverse or prosperous fortune of every person in the world, but also his faith or infidelity, which fate it is impossible by any foresight to avoid. By this doctrine Mohammed taught his followers to have the greatest contempt for danger, which was of material service to him in the propagation of his creed.

Of the four points of religious practice required by the Koran, prayer is the first. Mohammed included under this act purifications of the body, by total immersion at certain periods, and by washing the face, hands, and feet, at others. To make his followers punctual in the observance of these purifications, Mohammed declared that the practice of religion is founded on cleanliness, without which prayer would not be heard by God. A Mohammedan is obliged to pray five times in the twenty-four hours, at stated periods—before sunrise in the morning, when noon is past, in the afternoon before sunset, in the evening after sunset, and before the first watch of the night. Public notice is given of these periods by the *muezzins*, or criers, and every Mohammedan prepares himself for prayer. This he performs either in the mosque, or any other place, provided it be clean, after a prescribed form, and with a certain number of ejaculations, which he is on no occasion to abridge, unless when on a journey or preparing for battle. It is also necessary that he should kneel in an humble posture, and turn his face towards Mecca, as expressed in the second chapter of the Koran: "Turn, therefore, thy face towards the holy temple of Mecca, and wherever ye be, turn your faces towards that place." The direction of Mecca is pointed out within the mosque by a niche on the outside, by the situation of the doors and the steeple; and tables have been calculated for finding this out when they have no other guide. A Mohammedan is also obliged to lay off all costly parts of his dress before prayers, that he may not appear proud. Females are not allowed to enter the mosques along with the men, but they may visit them at other periods.

The prayers of the Mohammedans consist chiefly of pious exclamations, praising the greatness and goodness of God; and one of the more common of these prayers consists in a repetition of the first chapter of the Koran, called the *Fathat*, or Belief. It is in these words "Praise be to God, the Lord of all creatures; the most merciful, the King of the Day of Judgment. Thee do we worship, and of Thee do we beg assistance. Direct us in the right way, in the way of those to whom Thou

hast been gracious; not of those against whom Thou art incensed, nor of those who go astray."

Alms-giving is a necessary part of the religious practice of Mohammedans. These consist of cattle, money, corn, fruits, and wares which can be sold. At the end of the fast of the Ramadan, every Mohammedan is obliged to give in alms, for himself and for every one of his family, a measure of wheat, barley, dates, rasins, rice, or other provisions. "The legal alms," says Mr. Sale, "were at first collected by Mohammed himself, who employed them as he thought fit in the relief of his poor relations and followers, but chiefly applied them to the maintenance of those who served in his wars, and fought, as he termed it, in the way of God. His successors continued to do the same, till, in process of time, other taxes and tributes being inposed for the support of the government, they seem to have been weary of acting as almoners to their subjects, and to have left the paying of them to their consciences."

Fasting is the third point of religious practice among the Mohammedans. It consists in abstaining from satisfying the appetites; in restraining the ears, eyes, tongue, hands, feet, and other members, from sin, and the fasting of the heart from worldly cares, and thinking of nothing but God. During the month of the Ramadan, Mohammedans are obliged to fast from the time the new moon first appears till the appearance of the next new moon. In this month they abstain from eating and drinking from daybreak till sunset; and this injunction they observe so strictly, that while they fast, they suffer nothing to enter their mouths or the other parts of the body, esteeming the fast broken if they smell perfumes, bathe, or even purposely swallow their spittle. The old and the sick are exempted from this fast; but in the case of the latter, when they recover, they must fast the same number of days. After sunset the people are allowed to refresh themselves—to eat, drink, and enjoy the company of their wives till daybreak. The more rigid, however, commence the fast again at midnight.

According to the injunctions of the Koran, every man is to perform a pilgrimage to Mecca once in his life, except prevented by poverty or ill health. It is clear that such an observance is altogether inapplicable to the condition and situation of the great hulk of the human race: and what is impossible in human practice, can never have been enjoined by the Creator. Mohammed, it is evident, only thought of Arabia and its neighbourhood, when he planned this idle ceremonial observance. Aware that, even within that limited district, his followers would have a difficulty in performing such a pilgrimage, he allows any one who is wealthy enough, to hire and send a deputy; many, we are informed, neglect this duty who cannot plead a lawful excuse. The temple of Mecca stands in the midst of the city, and is called the sacred or inviolable temple. Within it are said to be the tomb of Ishmael, and a remarkable black stone, which bears the mark of Abraham's foot. This temple was held in great veneration by the Arabians long before the time of Mohammed; some even say that it was built by Adam immediately after his expulsion from paradise. To this place pilgrimages are made from all parts where the Mohammedan religion is professed. A number having collected from any particular district, form themselves into a caravan for the purpose of mutual protection, which is very necessary from the number of robbers who infest the route. The pilgrims meet at different places around Mecca, according to the direction in which they have come, and are obliged to be there by the beginning of the first month, called Dhulhajja.

"It is not," says Mr. Lane, "by the visit to Mecca, and the performance of the ceremonies of circuiting the temple seven times, and kissing the black stone in each round, and other rites in the holy city, that the Moslem acquires the title of the *hadji* (pilgrim). The final object of the pilgrimage is Mount Arafat, six hours journey from Mecca. During his performance of the required ceremonies at Mecca, and also during his sojourn at Arafat, and until his completion of the pilgrimage, the Moslem wears a peculiar dress called *ehhram* generally consisting of two simple pieces of cotton, or linen, or woollen cloth, without seam or ornament, one of which is wrapped round the loins, and the other over the shoulders; the instep and heel of each foot, and the head, must be bare; but umbrellas are now used by many of the pilgrims. It is necessary that the pilgrim should be present on the occasion of a Khootbeh, which is recited on Mount Arafat in the afternoon of the 9th of the month Dhulhajji. In the ensuing evening, after sunset, the pilgrims commence their return to Mecca. Halting the following day in the valley of Mina, or Moona, they complete the ceremonies of the pilgrimage by a sacrifice (of one or more male sheep, he-goats, cows, or she-camels, part of the flesh of which they eat, and part give to the poor), and by shaving the head and clipping the nails. Every one after this resumes his dress, or puts on a new one, if provided with such. The sacrifice is called *el fida* (or the ransom), as it is performed in commemoration of the ransom of Ishmael by the sacrifice of the ram, when he was himself about to have been offered up by his father; for it is the general opinion of Mohammedans, that it was this son and not Isaac who was to have been sacrificed by his father."

The laws by which Mohammedans are governed are in a great measure derived from the Koran. Where this sacred book is silent, reference is made to the traditions of the prophet to direct the decisions of the judge. Regarding the Koran as a book of jurisprudence, we quote the following from the Library of Useful Knowledge:—"Nothing but the prejudices of education could make a reasonable man look upon the Koran as a book of jurisprudence capable of conveying instruction to any but a nation of savages. Deficient in form, deficient in clearness, incomplete, it possesses not one single quality requisite to a body of law. In the midst of a vast farrago of nonsense, hidden amidst unmeaning explanations and dark mysterious prophecies, there sometimes appears a command respecting the distribution of property or the punishment of offenders. But no explanations are given—no regular description of the means by which property may be acquired; no enumeration of those by which the rights to it may be lost, is even attempted. The rights of individuals, in their several capacities, to the services of others, are nowhere distinctly mentioned; nor is there any the most distant approximation to a systematic view of the several obligations to which it was intended to subject the members of the community. As occasion prompted, or when a dispute happened, Mohammed was accustomed to issue a revelation, which answered for the immediate purpose. But the original unwritten customs of the Arabs remained in full force, receiving little modification from the decrees of the prophet. One advantage, and one alone, he may be supposed to have originated—his were *written* decrees; it was a commencement for a body of laws, though a rude and imperfect one. This benefit, however, is more than counterbalanced by the evil of their being irrevocable. What the ignorant barbarian instituted, succeeding generations have been obliged to retain. No matter how absurd, how injurious the decree, religion commands the faithful Moslem to abide by it. The Almighty was its author, and he is all-wise; and, moreover, is as wise at one time as another. How, then, shall we pretend to amend the divine ordination, or fancy that he himself need amend it? The conclusion is irresistible, provided the premises be allowed. The nations who have assumed the Moslem faith have consequently remained, and, while professing it, will remain, barbarians."

One of the worst features of the Mohammedan faith

the degraded position which it assigns to women. This, indeed, forms a radical error in the constitution of society in Mohammedan countries, and must be removed before there can be a steady advance in rational improvement. Women are considered in every respect inferior to men. Few of them, even among the highest classes, receive any instruction; they are carefully secluded from public observation; assigned in marriage without their own consent, on payment of a trifling sum in form of dowry; and are divorced at pleasure—all which tends to debase their minds, and to produce the worst kind of social vices. Polygamy and legal concubinage add to the evils caused by such practices. The Koran allows a man to marry four wives, and to maintain as many concubine slaves as he may choose. He may divorce any of his wives at any instant which caprice or passion may suggest, merely by uttering the emphatic words, "Thou art divorced!" and she must return to her parents or friends accordingly. He may take her again as a wife, and again divorce her; and even divorce her a third time, provided she has in the interval been married to and divorced from another man. Mr. Lane, in his work on Egypt, says, that he has known cases in which men have, in the course of a few years, married as many as twenty or thirty wives; and also cases of women who had been married to a dozen or more men successively. In most instances, we are told, a man marries no more than one wife; but as these practices are common, we can easily judge of the depravity of manners which prevails in those countries professing the Mohammedan creed.

From the manner in which females are treated, it has been generally supposed by Christians that the Mohammedans believe that women have no souls. But this is a mistake. Women are believed to have souls, and are not to be excluded from paradise, though they are there to perform offices of a subservient nature. The meanest person in paradise, it is believed, "is to have eighty thousand servants, and seventy-two wives of the girls of paradise, besides the wives he had in this world; that he is to inhabit a tent composed of pearls, jacinths, and emeralds; at meals he will be served in dishes of gold; and he is to be at liberty to drink freely of the wine of paradise, which will not intoxicate." In such promises of felicity, we have a striking proof of the mean ideas of eternal happiness formed by the prophet, as well as of his knowledge of mankind.

The Koran forbids the use of wine or any intoxicating liquors; and this is among the best injunctions which it contains. Opium and other inebriating drugs are understood to fall within the line of prohibition, though not mentioned. The use, therefore, of either intoxicating drinks or drugs, is considered immoral in all Mohammedan countries. Musselmans of all ranks are remarkable for their sobriety and temperance in food. The eating of swine's flesh is strictly prohibited; and, indeed, most animals forbidden to be eaten by the Mosaic law are alike forbidden by that of Mohammed. All animals used for food must be killed by cutting their throat; and, in performing the operation, the butcher must say, "In the name of God! God is most great!" Gambling is also prohibited; also usury, and the making of any images or pictorial resemblances of any thing that has life. Perhaps the desire to extinguish idolatry influenced the prophet in laying down the last-mentioned law. Apostacy from Islamism is deemed a most heinous sin, and must be punished with death.

The Mohammedan creed enjoins no Sabbath, like that of either the Jews or Christians, but selects Friday as a day in the week to be distinguished by more than usual solemnity of devotion. Friday has been pitched upon, because it is said Adam was created on that day, and because the resurrection is prophesied to be on that day of the week. Perhaps a desire to avoid Saturday or Sunday, the days reverenced respectively by Jews and Christians, may also have influenced its adoption. This day is called *El-Goumah*, or The Assembly, and on the forenoon of that day large congregations assemble in the mosques, when, in addition to the usual prayers, a sermon or address is delivered, and lessons read from the Koran, by the officiating imams. After prayers all kinds of work go on as usual.

All religions, above the meanest paganism, have possessed a body of priests, or functionaries to whom the knowledge of the faith was confided, and by whom its precepts were enforced. Considering that Mohammed must have been conversant with the constitution and import of the Jewish priesthood, as laid down in the Levitical law, and also acquainted with the arrangements of the Christian church, it is remarkable that he instituted no order of clergy, but, on the contrary, left his religion to be professed by the people at large, without any distinction as to rank or qualification. On this account, Mohammedism has no priesthood, and cannot be said to constitute in any country what we understand by the term church. Wherever it is established as the religion of the community, *mosques* or chapels have been erected, generally by endowments from wealthy individuals; and these are individually under the charge of a warden, who is custodier of the revenues, and appoints the ministers of religion and inferior servants. "Two imams are employed to officiate in each of the larger mosques: one of them, called the *khateeb*, preaches and prays before the congregation on the Friday; the other is an *imam ratib*, or ordinary imam, who recites the five prayers of every day in the mosque, at the head of those persons who may be there at the exact times of those prayers: but in most of the smaller mosques both these offices are performed by one imam. There are also to each mosque one or more *muezzins* (to chant the call to prayer) and *bowwabs* (or doorkeepers); and several other servants are employed to sweep the mosque, spread the mats, light the lamps, and attend the water-wheel by which the tank or fountain, and other receptacles for water, necessary to the performance of ablutions, are supplied. The imams, and those persons who perform the lower offices, are all paid from the funds of the mosque, and not by any contributions exacted from the people. The condition of the imams is very different, in most respects, from that of Christian priests. They have no authority above other persons, and do not enjoy any respect but what their reputed piety and learning may obtain them: nor are they a distinct order of men set apart for religious offices, like our clergy, and composing an indissoluble fraternity; for a man who has acted as imam to a mosque may be displaced by the warden of that mosque, and with his employment and salary, loses the title of imam, and has no better chance of being again chosen for a religious minister than any other person competent to perform the office. The imams obtain their livelihood chiefly by other means than the service of the mosque, as their salaries are very small, that of a khateeb being generally about a piastre (nearly 2½d. of our money) per month."—(*Lane's Egypt.*)

"The Mohammedans," continues the same authority, "observe the utmost decorum in their public worship. Their looks and behaviour in the mosque are not those of enthusiastic devotion, but of calm and modest piety. Never are they guilty of a designedly irregular word or action during their prayers. The pride and fanaticism which they exhibit in common life, in intercourse with persons of their own or of a different faith, seem to be dropped on their entering the mosque, and they appear wholly absorbed in the adoration of their Creator."

Mohammedans have an extreme reverence for a green colour, which is used exclusively as the hue of turbans or other garments by those who claim hereditary descent from the family of the prophet. Europeans generally imagine the crescent to be a common symbol of Mo-

hammedism, as the cross is of Christianity; but we believe this is founded on mistake. The crescent, from a very early period of history, was a heraldic ensign of Byzantium or Constantinople, and has been appropriated by the Turks since their capture of that city.

The Mohammedans are generally affected with the most superstitious reverence for imaginary saints and "favourites of God." They imagine that idiots and lunatics are under the immediate inspiration of Heaven; and, unless these be dangerously mischievous, they are permitted all sorts of license. "Most of the reputed saints of Egypt," says Mr. Lane, "are either lunatics, idiots, or impostors." Any one who is deranged by religious excitement becomes a *welee*, or an especial favourite of the Almighty, and is supposed to be gifted with supernatural powers. Almost every celebrated saint, deceased, is honoured by an anniversary birthday festival; and on occasion of these festivals, many persons visit the tomb of the saint, both as a duty and as a supposed means of obtaining a special blessing. Besides the various classes of saints, there are different orders of *durweeshes*, or dervises, some of whom subsist by begging, and others by performing at religious festivals; a few devote themselves to religious seclusion, and gain a character for exalted piety.

Mohammedism, from shortly after the death of its founder, has been divided into two great parties or sects, who split upon the disputes concerning the Caliphate, or spiritual and civil supremacy, and received the name of *Sunnites* and *Shiites*. The Sunnites take their appellation from the *Sunna*, or collections of traditions relating to Islamism, which they believe to be of equal importance with the Koran. The term *Shiites* signifies heretics, which they are called by the opposite party from their misbelief. The adherents of the doctrine that Ali, son-in-law of Mohammed, was properly his successor, reject the Sunna. The Turks are Sunnites, and the Persians are Shiites, and each hates the other with implacable animosity. The Sunnites, we believe, are reckoned the orthodox sect, and acknowledge the reigning sultan as the true successor of Mohammed.

Besides differing as to the credibility of the Sunna and the successorship of the prophet, the Mohammedan world is divided into four minor sects, the *Hhanafees*, *Shafees*, *Malikees*, and *Hhambeleen*, being so called from the respective doctors whose tenets they have adopted. "The Turks," says Mr. Lane, "are of the first sect, which is the most reasonable." About the middle of last century a great schism, or attempt at reformation, broke out in Arabia, headed by Mohamed, son of Abdel Wahab, a pious and learned sheikh. Young Mohamed claimed divine inspiration, and taught, like the Koran (the doctrines of which he but partially received), the existence of an only God, the Creator of the world, the rewarder of the good and the punisher of the bad; but he rejected all the stories contained in the Koran, especially those concerning Mohammed, whom he considered merely a man beloved of God, but branded the worship of him as a crime directly opposed to the true adoration of the Deity. He also condemned the ornaments and splendour which are found in the mosques and the sepulchres of pretended saints. In short, he stripped Mohammedism of all its trappings, and reduced it to little else than a pure Theism. All who should oppose this new doctrine were to be destroyed by fire and sword. His doctrines, being adopted by some influential chiefs, spread with wonderful celerity, and the *Wahabees*, as his followers were called, shook the stability of the empire of the Turks in Asia. After a hot war of many years, the Wahabees were suppressed by Mehemet Ali, the present Pasha of Egypt: but their doctrines are still far from being exterminated.

SUPERSTITIONS.

MANKIND have in all ages been prone to the most lamentable superstitions. The enlightened nations of antiquity were no more exempted from them than the most ignorant. The Jews, as we are repeatedly informed in Scripture, could with difficulty be restrained from idolatrous and superstitious practices, and confined to the worship and service of the only true God. This remarkable tendency of the Hebrew nation was in all likelihood caused by their sojourn for the space of four hundred years among the Egyptians, whose whole system of religion was a mass of idolatrous observances. They had a number of ideal gods to whom they erected temples of prodigious size and architectural splendour; the principal of these deities were Osiris and Isis, which are thought to have been typical of the sun and moon. But they also offered worship to various animals, as the ox or bull (hence the golden calf of the Hebrews), to which they gave the name of Apis; the dog, the wolf, the hawk, the ibis or stork, the cat, and other creatures; they likewise paid adoration to the Nile, personifying it in the crocodile, to which temples were erected, and priests set apart for its service. The Egyptians, notwithstanding their learning, also believed in dreams, lucky and unlucky days, omens, charms, and magic. In a word, they were grossly superstitious, and seem to have had but a feeble conception, if any, of the laws which regulate the ordinary phenomena of nature.

The absurdities of Egyptian superstition formed a basis for what followed among the Greeks and Romans, who had no idea of an omnipresent and omnipotent God, the Creator and Ruler of the universe. Their notions of divinity, like those of other pagans, were grovelling and contemptible. The gods whom they adored were imagined to have been at one period rulers or heroes on earth, and still had their habitation somewhere within the Grecian territory, or at no great distance from it. Besides their belief in this vain mythology, both Greeks and Romans put faith in divination, oracles, the magical power of amulets, and dreams. Bees, ants, and various reptiles and beasts, were imagined to have the power of giving omens of good or bad fortune. The phenomena of the atmosphere and planetary bodies were likewise a fertile source of superstitious delusions. The appearance of comets, and also eclipses, were ominous of great public disasters, it being the general belief that they were special signs made by the gods to warn mankind of approaching troubles; in all which we see a lamentable proof of the follies to which even a refined people may be exposed, if ignorant of the laws of nature.

The superstitious delusions of the Greeks and Romans may be said to have died out at the final dismemberment of the Roman empire, and the overrunning of western Europe by the Gothic nations. The introduction of Christianity also tended powerfully to root out the old

superstitious usages, though a few survived to a later date. For these reasons the superstitions and matters of credulous belief which afterwards affected the people of northern and western Europe, including the British islands, were in a great measure of Scandinavian and Gothic origin. The only superstitions of eastern growth worth mentioning, which were perpetuated in Europe generally, was that of astrology, or a belief that the stars exercised an influence over the destiny of mortals; and alchemy, or the pretended art of transmuting the baser metals into gold; both of which delusions finally vanished before the light of knowledge that spread abroad in the seventeenth and eighteenth centuries.

SCANDINAVIAN SUPERSTITIONS.

The superstitions of the European Northmen, or Scandinavians—under which term are included the early inhabitants of Denmark, Norway, Sweden, and Iceland—were of a kind remarkably accordant with the cold and stern character of the regions which they occupied. Like the ancient Greeks, the Scandinavians had seats of the gods and of the blest, which they called Asgard and Walhalla (or Valhalla), and these bore the same relation in their character to the Olympus and Elysium of the Greeks, that the countries of the north, with their stormy climes, their icy mountains, and perilous waters, bore to the perfumed and verdant plains of Hellas, and the fair blue skies overhanging the smooth Ionian Sea. Nothing could afford better proof of the utterly fanciful nature of all these mythologies, than the fact that they were thus modelled and modified in every case by the earthly habits, likings, territorial position, and ignorance of geography and astronomy, of the individual tribes among whom they respectively originated.

The deification of one or more great princes or rulers seems to have constituted the basis of the Scandinavian as well as of every other pagan mythology. Odin, the supreme deity of the Scandinavians, and the ruler of heaven and earth, appears, like the Hellenic Jupiter, to have been a distinguished chief and warrior of early times. Although it is asserted by some that a divinity of the name of Odin was worshipped from the most remote ages, there is reason to believe that the worship of this personage, in the north at least, had its real origin a few centuries before the commencement of the Christian era, when a powerful chieftain of the name was driven by the Romans from his dominions between the Euxine and Caspian, and took refuge in Scandinavia, the whole of which he subjected to his sway. Like Mohammed, this chief appears to have established a new religion, of which he himself assumed to be the earthly head, as the servant or minister of a divine being of the same name. In the course of time, however, this distinction was entirely lost, and the persons and acts of the divine and earthly Odin became inextricably blended in the mythology and traditions of the north. The great records of the religious and legendary knowledge of the Scandinavians, are the Eddas and Sagas of Iceland, partly written in poetry and partly in prose. The oldest of the Eddas, a series of poetical fragments, was collected from oral tradition in the eleventh century, and the others are of later date. The acts of the deities and heroes of the north, the creation of the world, and prophetic revelations, form the general subject of these pieces.

The Scandinavians, like the Greeks, believed that the universe was originally a chaos, or mass of confused vapours, peopled by a race of Rimthursar, or evil spirits of gigantic bulk. A being of nobler nature sprung up among these, named Bure, from whom were descended Odin and his two brothers Vile and Ve. These younger divinities followed exactly the same course with the northern giants, that was pursued by Jupiter and his brothers with regard to the Titans, or older and gigantic deities of Greece. Odin began to war with the Rimthursar, and having at last overcome their great chief Ymer, he created the world out of that giant's body. His flesh became the mould, his bones the rocks, his hair the vegetable tribes, his blood the ocean, and his skull the heavens, at the four corners of which were placed certain dwarfs, called North, South, East, and West, whose duty it was to sustain the celestial dome. After this, the luminaries of the sky were set in their places, and the order of the seasons appointed. Natt (night) wedded one of the Aser, or celestial family of Odin, and gave birth to Dag (day). These deities travel alternately round the world in cars, drawn by single horses. Every great body, as in the Grecian mythology, was represented by a divinity. Frigga, or the earth, was the daughter of Odin, and also became his wife. The inhabitants of the earth, or mankind, were created by Odin and his brothers. Two pieces of wood, the one of ash and the other of elm, formed the materials of the first pair of mortals, who were distinguished for personal beauty and intellectual ability.

The race of deities inhabited Asgard, a place supposed by some to have been the city in Asia whence the real or mortal Odin was expatriated. The fabulous Asgard was pictured as containing numerous palaces and halls, the largest of which was the Mansion of Joy, where Allfader (Odin) sat on his throne amid his divine family. This throne was named Lidskialfa, or the Terror of Nations, and from it he could overlook the whole earth. Two ravens, Hugin (Spirit) and Muninn (Memory), sat always at his ear, and communicated to him intelligence of all things that were going on in the universe. Among the deities who dwelt in Asgard, one of the most important was Thor, or Asathor, son of Odin by Frigga, and the Mars, or warrior-god, of the Scandinavians.

Thor is described as the god of thunder, and the strongest of beings, earthly or heavenly. He is the son of Odin and Frigga, or, in other words, of the Sun and the Earth. When he moves, the earth trembles. He holds in his hand a powerful hammer, called the Crusher (*miölner*), with which he annihilates all who oppose him, and who offend the gods. In battle Thor is always girt with a magic girdle, which has the power of inspiring him with a divine fury, and redoubling his strength. On his right hand he wears an iron gauntlet, with which he grasps and wields the formidable crusher. This latter instrument was forged by a dwarf, named Sindri, the prototype of the deformed blacksmith-deities of the Greeks, Vulcan and his Cyclops. The hammer possesses the wonderful power of never missing its aim, and when launched at any object, returns to the hand of Thor, after having destroyed his foe. Thor is sometimes called Aukistor, or Thor of the Car, from his riding on a chariot, drawn by two powerful he-goats, named Sangniostr and Tangrisner. This deity has a spouse named Sipia, famous for her beautiful hair.

After Odin, Thor was the most cherished deity of Scandinavia, and had statues and temples erected to him everywhere. The statues of him were usually formed of clay, and represented a tall figure, with a red-painted beard, indicative of the lightning which he was supposed to wield. Bread and meat were supplied daily to the god by his worshippers, and at stated times libations were poured out in his honour.

Balder, the second son of Odin, was the most beautiful and amiable of the Aser or gods. Unlike the rest of his brethren, he was fond of peace, and had the power of allaying tempests, and acting as a mediator, to avert divine wrath. His decrees were irrevocable. In some points he resembled the Apollo of the Greeks, but the general qualities of that personage found a closer representative in Braga or Bragi, the god of eloquence and poetry. Niord, the god of the sea, and his son Freya, the god of rain were also important deities of the north. Every element or important natural phenomenon, was

under the guidance, in like manner, of some celestial personage. Frigga, the Scandinavian Juno, was the bestower of fertility and plenty. Freia, or Freya, the daughter of Niord, was the Venus of Asgard and the patroness of matrimony. Freia was assisted in her duties by Siona and Sofna, the first of whom made lovers faithful, while the other reconciled them when they quarrelled. Eyra was the physician of the gods. There were various other minor divinities in the Scandinavian mythology, though not nearly so many as in the Grecian roll. The deficiency was made up among the northerns by the assignment of more multitudinous duties to the greater deities. Thus Odin, from the extent of his government, received as many as one hundred and twenty distinct names, each indicating some individual quality ascribed to him.

The great hall appointed for the reception of the spirits of the brave, when they left earth for the seat of the gods, was called Valhalla. Twelve beautiful yet terrible nymphs, named Valkyries (*choosers of the slain*), were the guides of the good spirits to the hall of Valhalla, and supplied them with mead. The occupation of drinking this northern nectar, and of eating the fat of the wild boar Serimner, which, after serving as the daily food of thousands, became whole again every night, filled up all those intervals of time in Valhalla that were not passed in fighting. None but those who had shown surpassing bravery on earth were admitted into this Scandinavian paradise, and when there, their daily amusement was to fight with one another till all or nearly all were cut in pieces. But little harm was done in this way, for the spiritual bodies soon reunited, and enabled the warriors to appear, entire in lithe and limb, at the feasts that followed these extraordinary engagements. The skulls of enemies were the drinking-cups used at the entertainments of Valhalla, and the guests are described as being almost perpetually in a state of inebriation. It was only when the cock announced the arrival of morning that these terrible heroes arose from table, to issue to the field of battle through the five hundred and forty gates of Valhalla, and hack each other to pieces anew. Such was the never-ending round of employment destined for the departed heroes of Scandinavia.

The mythology of the Scandinavians survived till a much later date than any other system of heathen worship in Europe. It was not abolished till the eleventh century St. Olaf, King of Norway, and a zealous supporter of Christianity, usually receives the credit of having overturned this most barbarous form of religion. In the course of his efforts to Christianize his subjects, he ordered a statue of Thor, and the pedestal on which it stood, to be broken in pieces, and showed the people that the meat which had been laid down for the use of the god was not eaten by him, but by a host of rats and other vermin that had formed a lodgment about the foundation of the colossal image. Whatever might have been the influence of the mythology of the Scandinavians in Britain, it disappeared shortly after its overthrow on the continent of Europe, or only lingered in a kind of traditional existence amidst the remote islands of Orkney and Shetland, till finally banished by the progress of a more general intelligence. The dread names of Odin, Thor, and other deities of the north, who for centuries weighed down the human faculties, and kept up the reign of superstition, are now only perpetuated in the appellations affixed to some of the days of the week. Thus our term *Wednesday* is derived from Odin's or Wodin's day, that being the day of the week in which the northern Jupiter or supreme ruler of the gods was most honoured and worshipped. *Thursday* is from Thor, the second in dignity among these fabulous deities: as this day was called Dies Jovis by the Romans, we have here a confirmation that Thor the thunderer was equivalent either to Mars, or the thundering Jove of the Grecian mythology. *Friday* takes its appellation from Freya the daughter of Niord, and corresponds with the Dies Veneris, or Venus day of the Greeks and Romans. *Saturday* is derived in the same manner from the god Saeter of the Scandinavians, and Saturn of the Greeks. *Tuesday*, or anciently Tiesday (a pronunciation still preserved in Scotland), is supposed to be from Tisa, the wife of Thor, and the reputed goddess of Justice. *Sunday* and *Monday* were respectively named from the Sun and Moon, both by the northern and southern nations of Europe, from a remote period of time. The circumstance of there being such a marked resemblance between the characters of the deities whose names were employed to distinguish the same days of the week both by Greeks and Scandinavians, is not a little remarkable, and has never, as far as we know, been the subject of explanation by philologists or antiquaries. The fact is only certain, that the names of the days of the week now used by every civilized people, are based upon the mythological observances of either the Grecian or Scandinavian races.

ANGLO-SAXON SUPERSTITIONS.

At a comparatively early era, the mythology and minor superstitions of the Scandinavians, as well as the follies of Druidism, disappeared in Britain as the familiar superstitions of the Anglo-Saxon race became predominant. Like the Scandinavians of the north, the Anglo-Saxons deduced their descent from Odin, whom they worshipped along with Thor, Freya, and other imaginary deities of the Gothic people. They also worshipped idols emblematic of the sun, moon, earth, and various seasons and circumstances. In particular, they sacrificed to one goddess called Eostre, in the month of April, and her name still expresses the festival of Easter in the Christian church. In token of devotional feelings towards the sun, they solemnized a festival to that luminary on the day of December in which the days began to lengthen, a log of wood being burnt on the occasion as an emblem of returning light and heat. From this ancient practice, therefore, may be traced the custom of bringing the Yule log at Christmas, which is still continued in many parts of England. Among the Anglo-Saxon superstitions was included a belief in giants, dwarfs, and elves, all of a spiritual order, but partaking in some degree of human attributes and feelings. In the term *elfi* or *elves*, we have one of the earliest traces on record of those ideal fairy tribes who afterwards figured in the familiar superstitions of the British islands. The Gothic nations, of whom the Anglo-Saxons were a branch, had various orders of elves, who were understood to haunt the fields, the woods, mountains, and waters, and received denominations accordingly, as field-elfin, dun-elfin, &c. Whether this varied race of spirits originated in the east, whence so many superstitions spread into ancient Europe, is not satisfactorily known, although it is probable that they did, and were of the same genus as the *peri* of the Persians, a being not dissimilar in character to our fay, or fairy. Both in the Scandinavian and Anglo-Saxon superstitions, elves formed an important order of beings, not unlike in character to the demigods, nayads, driads, and other imaginary spirits of the Greek and Roman mythologies, and like them exerted a certain influence over human affairs.

Besides a belief in these mysterious elfin tribes, the Anglo-Saxons brought with them to England the still darker and more dangerous doctrines of witchcraft and divination, before which the reasoning powers of the people quailed, and all intellectual advancement was impeded. The general introduction of Christianity about the year 600, abolished, as a matter of course, the more gross pagan observances, but failed to extirpate the familiar and less obvious superstitions of the people.

Witchcraft, wizardry, magic, divination, preparations of charms, and other mystic follies having no foundation in truth, continued to flourish, although opposed both by the more intelligent clergy and the kings. It is from the statutes, indeed, which Alfred, Canute, and other monarchs, passed for the prevention of magical practices, that we chiefly know their nature and extent. *Wiglaer*, a wizard, and *wicca*, a witch, are persons severely denounced. Penalties are enjoined if any one should destroy another by *wiccecraeft*. They appear to have used philtres, for it is declared a crime in any one to use witchcraft, or potions to produce another's love. Canute enjoins his people not to worship fire or floods, wells or stones, or any sort of trees; not to frame death-spells, either by lot or otherwise; and not to effect any thing by phantoms. Wizards, we also learn, pretended to the power of letting loose tempests, and controlling the visible operations of nature.

The introduction of Christianity, as has been mentioned, failed to dissipate the familiar superstitions of the English; a circumstance which can excite no surprise, as no pains were taken to enlighten the understandings of the people, or make them acquainted with the true causes of natural phenomena. We accordingly find that from the seventh to the sixteenth century, the belief in demons, spirits, lubber fiends, and elves, of every shade and character, prevailed without intermission, and with no further challenge from the clergy than as being individually manifestations of the devil, on whom now the whole load of superstition was based. One goblin, in particular, formed the theme of innumerable legends. What was his name originally in continental Europe, whence he emigrated with the Anglo-Saxons, is of little consequence; in England he became known by the title of Father Rush, from a belief that he had on one occasion personated a monk or friar, and, to serve his own malignant purposes, had in that capacity long imposed on a religious brotherhood; afterwards this appellation went out of repute, and he was popularly known and feared by the familiar name of Robin Goodfellow, and performed many useful services in the rural districts of England. It is not a little strange that both monks and clergy sanctioned these fancies, and increased their number by the propagation of legends, which we venture to say could not now receive the approbation of a single individual, lay or clerical, in England. Of these it is only necessary to mention the absurd stories which were fabricated and circulated respecting Dunstan, Abbot of Glastonbury, and afterwards Archbishop of Canterbury, who died in the year 988. When a boy, he is said to have studied theology so sedulously as to reduce him to the point of death, when he was suddenly restored by some divine medicine sent to him by an angel in a storm. So extraordinary a circumstance could not but demand grateful thanksgivings, and Dunstan started from his bed and ran with full speed towards the church. Satan met him in the way, surrounded him with numerous black dogs, and endeavoured to defeat his pious intention. But Dunstan was not to be overcome; he instantly prayed for ability, and he was enabled to cudgel the devil and his black dogs so effectually, that they left him and the angel together; the latter of whom, finding the church door fastened, took up the pious youth in his arms, and conveyed him to his devotions through the roof. Another time the devil attempted to intrude himself upon St. Dunstan's studies in the laboratory, but the saint speedily punished his impertinence, by taking from the fire his tongs, which were red hot, and with them seized the nose of the fiend, who was thereupon glad to make his escape. It is lamentable to think how such vain imaginations should have so long weighed upon the understandings of the people, and engrafted an habitual dread of the supernatural, which till this day exerts an influence over the untutored mind.

FAIRIES

Among the various supernatural beings to whom the ignorance and credulity of mankind have given an imaginary existence, the Fairies occupy a prominent place, and are especially worthy of notice. The characters of different classes of spirits have become so mingled and confounded together in the lapse of time, that it is difficult to define individual species with correctness and precision; but there is one characteristic which appears to distinguish the fairy from every other being of a similar order. Most spirits could contract and diminish their bulk at will, but the fairy alone seems to have been regarded as essentially small in size. The majority of other spirits also, such as dwarfs, brownies, and the like, are represented as deformed creatures, whereas the fairy has almost uniformly been described a beautiful miniature of the human being, perfect in face and form. These points of distinction, with a dress of pure green, are the principal ones which mark the personal individuality of the fairies as a supernatural race.

The origin of the fairy superstition is ascribed by most writers to the Celtic people, but the blending of the Gothic tribes with the Celts led to the admixture of many attributes of the northern spirits with those proper to the fairies. Thus, the latter race, which appears to have been intrinsically good and benevolent, has been gifted with attributes of the very opposite kind, borrowed from the trolls and elves of the north. In Scotland, and other countries where the Celtic traditions predominated, the fairies retained, in part, the original and better features of their character, and were usually called the Good Neighbours, or the Men of Peace; but even there, their character was deteriorated by a considerable leaven of elfin or dwarfish malignancy. This evil part of their nature caused much annoyance to mankind, and, more especially, their propensity to the kidnapping of human beings. Unchristened infants were chiefly liable to this calamity, but sometimes adult men and women were also carried off. The reason for these abductions is to be found, according to the authorities on this subject, in the necessities which the fairies lay under of paying "kane," as it was called, to the master-fiend, or, in other words, of yielding up one of their number septennially into his hands by way of tribute. They greatly prefer, on such occasions, to make a scape-goat of some member of the human family. They also carried off young married women to be nurses to their infants; and in Ireland, at this day, when a young woman falls victim to puerperal disease, the country people firmly assert that she has been removed for this purpose.

The necessity for the latter kind of kidnapping shows the fairies to have been *family* people. They are always represented as living, like mankind, in large societies, and under a monarchical form of government. The Salique law seems to have had no countenance among them, for we more often hear of fairy queens than of fairy kings, though both are frequently spoken of. The Land of Faërie was situated somewhere under ground, and there the royal fairies held their court. In their palaces all was beauty and splendour. Their pageants and processions were far more magnificent than any that eastern sovereigns could get up, or poets devise. They rode upon milk-white steeds. Their dresses, of brilliant green, were rich beyond conception; and when they mingled in the dance, or moved in procession among the shady groves, or over the verdant lawns of earth, they were entertained with delicious music, such as mortal lips or hands never could emit or produce. At the same time, most of the legendary tales on the subject represent these splendours as shadowy and unsubstantial. When the eye of a seer, or any one gifted with supernatural powers, was turned upon the fairy pageantries or banquets, the illusion vanished. Their seeming treasures of gold and silver became slate-stones, their stately halls became damp caverns,

and they themselves, from being miniature models of human beauty, became personifications of fantastic ugliness. In short, the Fairy Eden was a dream—a thing of show without substance.

This is the general account given of the fairy state, but few of the legends on the subject agree on all points. From a very early period, however, every fairy annalist concurred in giving to the king and queen of the fairies the names of Oberon and Titania. Oberon is the Elberich or Rich Elf of the Germans, and was endowed with his modern name, as well as with new attributes, by the old French romancers, who represented him as a tiny creature of surprising loveliness, with a crown of jewels on his head, and a horn in his hand that set all who heard it to the dancing.

It was the belief that unchristened children were peculiarly liable to be carried off by the fairies, who sometimes left little changelings, of their own blood, in place of the infants of mortal kind. Ben Jonson, in his Sad Shepherd, makes the tending and nurture of human changelings to be one of the favourite elfin employments.

> "There, in the stocks of trees, white fays do dwell,
> And span-long elves, that dance about a pool,
> With each a little changeling in their arms."

Various charms were used in Scotland for the restoration of stolen children. The most efficacious was believed to be the *roasting* of the supposititious child, upon live embers, when it was understood that the false infant would disappear, and the true one be left in its place. It is to be hoped that this cruel and monstrous practice was seldom followed. The possession of what are called *toadstones* was also held to be an efficient preservative against the abduction of children by the fairies. In Waldron's Account of the Isle of Man, we find various stories of children kidnapped by the fairies. In one case, where a woman had given birth to a child, her attendants were enticed from the house by the cry of "Fire!" and while they were out, the child was taken from the helpless mother by an invisible hand; but the sudden re-entry of some of the gossips compelled the fairies to drop the child, and it was found sprawling on the threshold. The fairies, who seemed to have taken a particular liking to this woman's offspring, tried to carry off her second child in the same way, but failed again. On the third trial, they succeeded, and left behind them a changeling, a withered and deformed creature, which neither spoke nor walked during an existence of nine years, and ate nothing but a few herbs. It is to be feared that this changeling superatition must have been the cause of much deplorable cruelty That very member of a family, who from natural misfortunes and defects required the kindliest tending, would but too often be neglected and wretchedly misused, on the plea of its being an alien. We may smile at many of the credulous fancies respecting the fairies, but there are in this order of superstitions, as in almost all others, some points which strongly exhibit to us the baleful effects inevitably attendant upon ignorance of every kind.

Numberless stories of a ridiculous kind have been told relative to the intercourse of the fairies with mankind. Some of the poor creatures arraigned in Scotland in past times for witchcraft, admitted having had correspondence with the fairies. There can be little doubt that these wretched beings, whom the *torture* forced into the confession of *some* kind or other of supernatural traffic, were induced to admit an association with fairies, in the hope that this would be looked upon as less sinful than a league with the enemy of mankind. The trials of Bessie Dunlop and Alison Pearson, in the year 1576 and 1588, illustrate this statement. Bessie Dunlop avowed that her familiar was one Thome Reid, the ghost of a soldier slain at Pinkie, in 1547, and who after his death seems to have become an inmate of Elf-land. She related that this Thome Reid, who appeared frequently to her in the likeness of an elderly man, gray coated and gray-bearded, wished her to go with him to the fairy country, and gave her herbs to cure various diseases. He even once brought her to the queen of the fairies, who, to the confusion of poetry, was a fat woman, fond of ale, and, in short, most unlike the Titania of romance. Alison Pearson also admitted her familiarity with the fairies, from whom she frequently received herbs for the cure of disease. It is remarkable that Patrick Adamson, an able scholar and divine, who was created Archbishop of St. Andrews by James VI., actually took the medicines prescribed by this poor woman, in the hope that they would transfer an illness with which he was seized to the body of one of his horses. This feat, it was believed, was accomplished by the prescription. The unfortunate women who confessed these things, were deceived in the expectation which led to the act. They could not so save themselves. They were both convicted, and perished at the stake.

It may not be improper in this place to allude to the fancies of the poets on the subject of the fairies. Shakspeare stands pre-eminent in this department. His Midsummer Night's Dream is a poem of exquisite beauty, and one corresponding in every respect with the delicately fanciful nature of the subject. In Romeo and Juliet, he has also described an important fairy, Queen Mab, who has almost dethroned Titania of late years. Mr. Tennant's Anster Fair has been of great avail to the fame of Mab. Whoever chooses to consult Drayton and the poets mentioned, will have the pleasure of observing and enjoying the exercise of poetical fancy of the highest order on the subject of fairies.

The superstitions now described are not yet extinct in the British Islands. In Ireland, the Scottish Highlands, and Wales, in particular, the fairies are yet objects of general belief. Education has not yet shed its enlightening influence there, and by education alone can the darkness of superstition be dispelled. This is almost a truism, for superstition and ignorance are nothing else than equivalent terms. The spirit is abroad, however, which will extinguish this remnant of barbarism, and it is consoling to think so, for the ills which have flowed from this source are numberless.

WITCHCRAFT.

A belief that certain individuals possessed magical powers, and could exercise a supernatural influence over their fellow-creatures, existed in ancient Rome, and those who practised, or rather *pretended* to exercise, such arts, were punishable by the civil magistrate. It is to be observed, that neither among the Roman nor the Pagan nations of northern Europe, was witchcraft deemed an offence against *religion*; in some instances, indeed, the witch was supposed to derive her powers from spirits friendly to mankind, and her profession, though feared, was held in honour by her infatuated dupes. Upon the introduction of Christianity, witchcraft assumed a new form, though retaining all its old attributes. Instead of ascribing the supernatural powers of the practitioner to the gods, to Odin, to spirits of good or evil qualities, or to supposed mysteries in nature, the people imputed them to the great fallen spirit mentioned in Scripture. This potent being, from a wicked desire to destroy all that was good and hopeful in man's destiny, was believed to enter into a compact with the aspirant witch, in which, for an irrevocable assignment of her soul at death, he was to grant all her wishes, and assist in all her malevolent projects. These new features in witchcraft, as we shall speedily perceive, thoroughly changed and prodigiously extended the superstition throughout Europe. From being rather sportive jugglery, or trick in practical magic, and at most only a civil offence, it was recognised as a crime of the deepest dye, meriting the most severe chastisement which the ecclesiastical and civil power could inflict.

We must here notice, however, that the demon or master-fiend of the witchcraft legends was a very different being from that great fallen spirit, held, in a graver view of things, so deeply to influence the best interests of humanity. As this superstition gained force in the Christian world, which it did by slow and successive steps through the whole of the middle ages, or from the fifth century till about the fifteenth, the devil—for it is impossible to avoid the mention of this emphatic name, disagreeable as it is commonly said to be to ears polite—gradually lost many of the former features of his character; or, rather, a different being was substituted for him, combining the characteristics of the Scandinavian Lokke with those of a Satyr of the heathen mythology—a personage equally wicked and malicious as the sterner spirit of evil, but rendered ludicrous by a propensity for petty trickery, and by such personal endowments as a pair of horns, a cow's tail, and cloven feet. There can be no doubt that the demon of the middle ages borrowed these attributes from his human representatives in the old mysteries and plays, where a laudable endeavour was made to make the evil one as ugly as possible. We are told, it is true, that he could at will assume any specious disguise that suited him, but the eye of the initiated observer could readily detect the "cloven foot"—or, in other words, penetrate his true character. Such as he was, he played an important part in the annals of modern witchcraft, which was supposed to rest entirely on the direct and personal agency of himself and the imps commissioned by him. Nor was this supposition confined to the illiterate, or to persons of peculiarly credulous temperament. Authors, distinguished for sense and talent, record with great seriousness, that the devil once delivered a course of lectures on magic at Salamanca, habited in a professor's gown and wig; and that at another time he took up house at Milan, lived there in great style, and assumed, rather imprudently one would say, the suspicious yet appropriate title of the "Duke of Mammon." Even Luther entertained similar notions about the fiend, and, in fact, thought so meanly of him as to believe that he could come by night and steal nuts, and that he cracked them against the bedposts, for the solacement of his monkey-like appetite.

The powers ascribed to this debased demon were exceedingly great. The general belief was, that through his agency storms at sea and land could at all seasons be raised; that crops could be blighted and cattle injured; that bodily illness could be inflicted on any person who was the object of secret malice; that the dead could be raised to life; that witches could ride through the air on broomsticks, and transform themselves into the shapes of cats, hares, or other animals, at pleasure. An old writer, speaking of the powers of witches, says—"1. Some work their bewitchings only by way of invocation or imprecation. They wish it, or will it; and so it falls out. 2. Some by way of emissary, sending out their imps, or familiars, to crosse the way, justle, affront, flash in the face, barke, howle, bite, scratch, or otherwise infest. 3. Some by inspecting, or looking on, or to glare, or peep at with an envious and evil eye. 4. Some by a hollow muttering or mumbling. 5. Some by breathing and blowing on. 6. Some by cursing and banning. 7. Some by blessing and praising. 8. Some revengefully, by occasion of ill turnes. 9. Some ingratefully, and by occasion of good turnes. 10. Some by leaving something of theirs in your house. 11. Some by getting something of yours into their house. 12. Some have a more speciall way of working by severall elements—earth, water, ayre, or fire. But who can tell all the manner of wayes of a witch's working; that works not only darkly and closely, but variously and versatilly, as God will permit, the devil can suggest, or the malicious hag devise to put in practice!"

In the present age of comparative intelligence, it is difficult to understand how human beings could be so deplorably ignorant as to entertain such a gross superstition. We must, however, recollect that the belief was greatly fostered by religious impressions, and that it was long considered a mark of impiety to doubt the existence of witches. Various other circumstances helped to cherish and magnify the error. The true causes of th majority of natural phenomena were unknown. The nature of the atmosphere, and of certain meteoric appearances—of the laws which regulate storms at sea, and tides—of human maladies and their remedies—were enveloped in obscurity. Natural causes being unknown, and the very doctrine of them unacknowledged, the weak and easily terrified mind flew to the conclusion that all evil proceeded from a power malignant to man, and that by certain impious dealings it was possible for man himself to direct that power against his neighbour.

The superstition seems to have approached its height about the end of the fifteenth century. In his bull of 1484, Pope Innocent charged inquisitors and others to discover and destroy all such as were guilty of witchcraft. This commission was put into the hands of a wretch called Sprenger, with directions that it should be put in force to its fullest extent. Immediately there followed a regular form of process and trial for suspected witches, entitled *Malleus Maleficarum*, or a Hammer for Witches, upon which all judges were called scrupulously to act. The edict of 1484 was subsequently enforced by a bull of Alexander VI. in 1494, of Leo X. in 1521, and of Adrian VI. in 1522, each adding strength to its predecessor, and the whole serving to increase the agitation of the public mind upon the subject. The results were dreadful. A panic fear of witchcraft took possession of society. Every one was at the mercy of his neighbour. If any one felt an unaccountable illness, or a peculiar pain in any part of his body, or suffered any misfortune in his family or affairs, or if a storm arose and committed any damage by sea or land, or if any cattle died suddenly, or, in short, if any event, circumstance, or thing occurred out of the ordinary routine of daily experience, the cause of it was witchcraft. To be accused was to be doomed, for it rarely happened that proof was wanting, or that condemnation was not followed by execution. Armed with the Malleus Maleficarum, the judge had no difficulty in finding reasons for sending the most innocent to the stake. If the accused did not at once confess, they were ordered to be shaved and closely examined for the discovery of the devil's marks; it being a tenet in the delusion that the devil, on inaugurating any witch, impressed certain marks on her person; and if any strange mark was discovered, there remained no longer any doubt of the party's guilt. Failing this kind of evidence, torture was applied, and this seldom failed to extort the desired confession from the unhappy victim. A large proportion of the accused witches, in order to avoid these preliminary horrors, confessed the crime in any terms which were dictated to them, and were forthwith led to execution. Other witches, as has been said, seemed to confess voluntarily, being probably either insane persons, or feeble-minded beings, whose reason had been distorted by brooding over the popular witchcraft code. A few extracts from the work of Dr. Hutchinson will show the extent of these proceedings:—

"A. D. 1485.—Cumanas, an inquisitor, burnt forty-one poor women for witches, in the county of Burlin, in one year. He caused them to be shaven first, that they may be searched for marks. He continued the prosecutions in the year following, and many fled out of the country.

"About this time, Alciat, a famous lawyer, in his *Parergu*, says, 'One inquisitor burnt a hundred in Piedmont, and proceeded daily to burn more, till the people rose against the inquisitor, and chased him out of the country.'

"A. D. 1488.—A violent tempest of thunder and light-

ning in Constance destroyed the corn for four leagues round. The people accused one Anne Mindelin, and one Agnes, for being the cause of it. They confessed, and were burnt.

"About this time, H. Institor says, one of the inquisitors came to a certain town, that was almost desolate with plague and famine. The report went, that a certain woman, buried not long before, was eating up her winding-sheet, and that the plague would not cease till she had made an end of it. This matter being taken into consideration, Scultetus, with the chief magistrate of the city, opened the grave, and found that she had indeed swallowed and devoured one-half of her winding-sheet. Scultetus, moved with horror at the thing, drew out his sword, and cut off her head, and threw it into a ditch, and immediately the plague ceased! and, the inquisition sitting upon the case, it was found that she had long been a reputed witch.

"A. D. 1524.—About this time a thousand were burned in one year, in the diocese of Como, and a hundred per annum for several years together."

From other authorities it is learned that the devastation was as great in Spain, France, and northern Germany, as it was in the Italian states. About the year 1515, five hundred witches were burned in Geneva in three months, and in France many thousands. An able writer in the Foreign Quarterly Review,* sums up the following particulars respecting the executions for witchcraft in some of the German states:—

"In Germany, to which indeed the bull of Innocent bore particular reference, this plague raged to a degree almost inconceivable. Bainberg, Paderborn, Wurtzburg, and Treves were its chief seats, though for a century and a half after the introduction of the trials under the commission, no quarter of that great empire was free from its baneful influence. A catalogue of the executions at Wurtzburg for the period from 1627 to February 1629, about two years and two months, is printed by Hauber in the conclusion of his third volume of the Acta et Scripta Magica. It is regularly divided into twenty-nine burnings, and contains the names of 157 persons, Hauber stating at the same time that the catalogue is not complete. It is impossible to peruse this list without shuddering with horror. The greater part of this catalogue consists of old women or foreign travellers, seized, as it would appear, as foreigners were at Paris during the days of Marat and Robespierre: it contains children of twelve, eleven, ten, and nine years of age; fourteen vicars of the cathedral; two boys of noble families, the two little sons of the senator Stolzenburg; a stranger boy; a blind girl; Gobel Babelin, the handsomest girl in Wurtzburg, &c. And yet, frightful as this list of 157 persons executed in two years appears, the number is not (taking the population of Wurtzburg into view) so great as the Lindheim process from 1660 to 1664; for in that small district, consisting at the very utmost of 600 inhabitants, thirty persons were condemned and put to death, making a twentieth part of the whole population consumed in four years.

"How dreadful are the results to which these data lead! If we take 157 as a fair average of the executions at Wurtzburg (and the catalogue itself states that the list was by no means complete), the amount of executions there in the course of the century preceding 1628, would be 15,700. We know that from 1610 to 1660 was the great epoch of the witch trials, and that so late as 1749, Maria Renata was executed at Wurtzburg for witchcraft; and though in the interval between 1660 and that date, it is to be hoped that the number of these horrors had diminished, there can be little doubt that several thousands fall to be added to the amount already stated. If Bainberg, Paderborn, Treves, and the other Catholic bishoprics, whose zeal was not less ardent, furnished an equal contingent, and if the Protestants, as we know, actually vied with them in the extent to which these cruelties were carried, the number of victims from the date of Innocent's bull to the final extinction of these prosecutions, must considerably exceed 100,000 in Germany."

* No. XI. 1830.

WITCHCRAFT IN SCOTLAND.

The mania respecting witchcraft, which sprang up into vigour throughout southern Europe in consequence of the edicts of Innocent and Leo, spread in time to Scotland, and acquired strong possession of the public mind during the reign of Queen Mary. At that period, an act was passed by the Scottish Parliament for the suppression and punishment of witchcraft; but this only served, as the papal bulls had done, to confirm the people in their maniacal credulity, and to countenance and propagate the general delusion. In terms of these ill-judged statutes, great numbers of persons, male as well as female, were charged with having intercourse with the devil, convicted and burned on the Castlehill of Edinburgh and elsewhere. This continued during the early part of the reign of James VI., whose mind, unfortunately for the more aged of the female part of his subjects, was deeply impressed with the flagrant nature of the crime of witchcraft. In 1590, James, it is well known, made a voyage to Denmark, to see, marry, and conduct home in person, his appointed bride, the Princess Anne. Soon after his arrival a tremendous witch conspiracy against the happy conclusion of his homeward voyage was discovered, in which the principal agents appeared to be persons considerably above the vulgar. One was Mrs. Agnes Sampson, commonly called the *Wise Wife of Keith* (Keith being a village in East-Lothian), who is described as "grave, matron-like, and settled in her answers." On this occasion, the king was induced by his peculiar tastes to engage personally in the business of judicial investigation. He had all the accused persons brought before himself for examination, and even superintended the tortures applied to them to induce confession. The statements made by these poor wretches form a singular tissue of the ludicrous and horrible in intimate union.

"The said Agnis Sampson was after brought again before the king's majestie and his council, and being examined of the meetings and detestable dealings of those witches, she confessed, that upon the night of All-Hallow Even she was accompanied, as well with the persons aforesaid, as also with a great many other witches, to the number of two hundred, and that all they together went to sea, each one in a riddle, or sieve, and went in the same very substantially, with flaggons of wine, making merrie and drinking by the way in the same riddles, or sieves, to the Kirk of North-Berwick, in Lothian, and that after they had landed, took hands on the land, and danced this reil, or short daunce, singing all with one voice,

'Cummer, goe ye before, cummer, goe ye;
Gif ye will not goe before, cummer, let me.'

At which she confessed that Geillis Duncan did goe before them, playing this reil or daunce upon a small trump, called a Jew's harp, until they entered into the Kirk of North-Berwick. These made the king in a wonderful admiration, and he sent for the said Geillis Duncan, who upon the like trump did play the said daunce before the king's majestie, who, in respect of the strangeness of these matters, took great delight to be present at their examinations."

In the sequel of Agnes Sampson's confession we find some special reasons for the king's passionate liking for these exhibitions, in addition to the more love of the marvellous. The witches pandered to his vanity on all occasions, probably in the vain hope of mitigating their own doom. Agnes Sampson declared that one great object

with Satan and his agents was to destroy the king; that they had held the great North-Berwick convention for no other end; and that they had endeavoured to effect their aim on many occasions, and particularly by raising a storm at sea when James came across from Denmark. "The witches demanded of the divell why he did beare such hatred to the king? who answered, by reason the king is the greatest enemie hee hath in the world." Such a eulogy, from such a quarter, could not but pamper the conceit of "the Scottish Solomon."

The following further points in the deposition of Agnes Sampson are worthy of notice. "*Item*, She went with the witch of Carrieburn, and other witches, to the Kirk of Newton, and taking up dead folks and jointing them [cutting off fingers, &c.], made enchanted powders for witchcraft. *Item*, She went with other witches in a boat, the devil going before them like a rock of hay. *Item*, The devil, in the shape of a dog, gave her responses concerning her laird's recovery, and endeavoured to put awa ane of the ladies' daughters. *Item*, She raised a universal great storm in the sea when the queen was coming to Scotland, and *wrote a letter* to that effect to a witch at Leith. *Item*, She used this prayer in the healing of sickness:—

All kinds of ill that ever may be," &c.

The repetition of these and such like verses by the confessing witches, has been matter of frequent surprise. But it must be remembered that a code of witchcraft, extensively known and accredited, existed at that day, regular forms and rules for its exercise having been laid down in the course of time. It must be recollected, also, that these poor creatures, though guiltless of all supernatural intercourse, had really pretended to the gift of healing by charms and incantations in many cases, and had to invent or learn formulas for the purpose. Besides, we find these doggrel scraps chiefly in the revelations of Agnes Sampson. She, it is stated, could write, and of course could read also; and hence she is to be regarded as a person who had superior opportunities for acquiring a knowledge of the witchcraft code, as well as superior capabilities for filling up deficiencies on the spur of the moment. In her confession she implicated one Doctor Fian, otherwise called John Cunningham, master of the school at Saltpans, in Lothian, a man whose story may be noticed at some length, as one of the most curious and instructive in the whole annals of Scottish witchcraft.

Mrs. Sampson deposed that Dr. Fian was always a prominent person at the witch-meetings, and Geillis Duncan, the marvellous trump-player, confirmed this assertion. Whether made through heedlessness or malice, these averments decided Fian's fate. He was seized, and after being "used with the *accustomed paine* provided for those offences inflicted upon the rest, first, by *drawing of his head with a rope*, whereat he would confess nothing;" and, secondly, being urged "by fair meanes to confesse his follies," which had as little effect; "lastly, hee was put to the most severe and cruell paine in the world, called the bootes, when, after he had received three strokes, being inquired if he would confesse his actes and wicked life, his tongue would not serve him to speake; in respect whereof, the rest of the witches willed to search his tongue, under which was founde two pinnes thrust up into the heade, whereupon the witches did say, now is the charme stinted, and showed that those charmed pinnes were the cause he could not confesse any thing; then was he immediately released of the bootes, brought before the king, and his confession was taken." Appalled by the cruel tortures he had undergone, Fian seems now only to have thought how he could best get up a story that should bring him to a speedy death. He admitted himself to be the devil's "register," or clerk, who took the oaths from all witches at their initiation, and avowed his having bewitched various persons. In proof of the latter statement he instanced the case of a gentleman near Saltpans, whom he had so practised upon, he said, that the victim fell into fits at intervals. This person, who seems to have been either a lunatic or afflicted with St. Vitus's dance, was sent for, and "being in his majestie's chamber, suddenly hee gave a great scritch, and fell into madnesse, sometimes bending himself, and sometimes capring so directly up, that his heade did touch the seeling of the chamber, to the great admiration of his majestie." On these and other accounts Dr. Fian was sent to prison, but he contrived soon after to escape from it. "By meanes of a hot and harde pursuite," he was retaken, and brought before the king to be examined anew. But the unfortunate man had had time to think, and like Cranmer under somewhat similar circumstances, resolved to retract the admissions which the weakness of the body had drawn from him, and to suffer any thing rather than renew them. He boldly told this to the king; and James, whom these records make us regard with equal contempt and indignation, ordered the unfortunate man to be subjected to the following most horrible tortures. "His nailes upon all his fingers were riven and pulled off with an instrument called in Scottish a *turkas*, which in England are called a payre of pincers, and under everie nayle there was thrust in two needles over, even up to the heades; at all which tormentes, notwithstanding, the doctor never shrunk a whit, neither would he then confesse it the sooner for all the tortures inflicted on him. Then was hee, with all convenient speed, by commandement, convaied again to the torment of the bootes, wherein he continued a long time, and did abide so many blowes in them, that his legges were crusht and beaten together as small as might bee, whereby they were made unserviceable for ever." Notwithstanding all this, such was the strength of mind of the victim, or, as King James termed it, "so deeply had the devil entered into his heart," that he still denied all, and resolutely declared that "all he had done and said before was only done and said for fear of the paynes which he had endured." As, according to this fashion of justice, to confess or not to confess was quite the same thing, the poor schoolmaster of Saltpans was soon afterwards strangled, and then burned on the Castlehill of Edinburgh (January, 1591).

Much about the same time that Agnes Sampson made her confessions, some cases occurred, showing that witchcraft was an art not confined to the vulgar. A woman of high rank and family, Catherine Ross, Lady Fowlis, was indicted at the instance of the king's advocate for the practice of witchcraft. On inquiry it was clearly proved that this lady had endeavoured, by the aid of witchcraft and poisons, to take away the lives of three or more persons who stood between her and an object she had at heart. She was desirous to make young Lady Fowlis possessor of the property of Fowlis, and to marry her to the Laird of Balnagown. Before this could be effected, Lady Fowlis had to cut off her sons-in-law, Robert and Hector Munro, and the young wife of Balnagown, besides several others. Having consulted with witches, Lady Fowlis began her work by getting pictures of the intended victims made in clay, which she hung up, and shot at with arrows shod with flints of a particular kind, called elf-arrow heads. No effect being thus produced, this really abandoned woman took to poisoning ale and dishes, none of which cut off the proper persons, though others who accidentally tasted them lost their lives. By the confession of some of the assistant hags, the purposes of Lady Fowlis were discovered, and she was brought to a trial; but a local or provincial jury of dependants acquitted her. One of her purposed victims, Hector Munro, was then tried in turn for conspiring with witches against the life of his brother George. It was proved that a curious ceremony had been practised

to effect this end. Hector, being sick, was carried abroad in blankets, and laid in an open grave, on which his foster-mother ran the breadth of nine riggs, and, returning, was asked by the chief attendant witch, "which she chose should live, Hector or George?" She answered, "Hector." George Munro did die soon afterwards, and Hector recovered. The latter was also acquitted, by a provincial jury, on his trial.

These disgraceful proceedings were not without their parallel in other families of note of the day. Euphemia Macalzean, daughter of an eminent judge, Lord Cliftonhall, was burned at the stake in 1591, having been convicted, if not of witchcraft, at least of a long career of intercourse with pretenders to witchcraft, whom she employed to remove obnoxious persons out of her way —tasks which they accomplished by the very simple means of poisoning, where they did accomplish them at all. The jury found this violent and abandoned woman, for such she certainly was, guilty of participation in the murder of her own god-father, of her husband's nephew, and another individual. They also found her guilty of having been at the Wise Woman of Keith's great witch-convention of North-Berwick: but every witch of the day was compelled to admit having been there, out of compliment to the king, to whom it was a source of agreeable terror to think himself of so much importance as to call for a solemn convocation of the powers of evil to overthrow him. Euphemia Macalzean was "burnt in assis, *quick*, to the death." This was a doom not assigned to the less guilty. Alluding to cases of this latter class, a writer (already quoted) in the Foreign Quarterly Review remarks, "In the trials of Bessie Roy, of James Reid, of Patrick Currie, of Isobel Grierson, and of Grizel Gardiner, the charges are principally of taking off and laying on diseases either on men or cattle; meetings with the devil in various shapes and places; raising and dismembering dead bodies for the purpose of enchantments; destroying crops; scaring honest persons in the shape of cats; taking away women's milk; committing housebreaking and theft by means of enchantments, and so on. South-running water, salt, rowan-tree, enchanted flints (probably elf-arrow heads), and doggrel verses, generally a translation of the Creed or Lord's Prayer, were the means employed for effecting a cure." Diseases, again, were laid on by forming pictures of clay or wax; by placing a dead hand or some mutilated member, in the house of the intended victim; or by throwing enchanted articles at his door. A good purpose did not save the witch; intercourse with spirits, in any shape, being the crime.

Of course, in the revelations of the various witches, inconsistencies were abundant, and even plain and evident impossibilities were frequently among the things averred. The sapient James, however, in place of being led by these things to doubt the whole, was only strengthened in his opinions, it being a maxim of his, that the witches were "all extreme lyars." Other persons came to different conclusions from the same premises, and before the close of James's reign, many men of sense began to weary of the torturings and incrimations that took place almost *every day*, in town or country, and had done so for a period of thirty years (between 1590 and 1620). Advocates now came forward to defend the accused, and in their pleadings ventured even to arraign some of the received axioms of "Daemonologie" laid down by the king himself, in a book bearing that name. The removal of James to England moderated, but it did not altogether stop, the witch prosecutions. After his death they slackened more considerably. Only eight witchcraft cases are on the Record as having occurred between 1625 and 1640 in Scotland, and in one of these cases, remarkable to tell, the accused escaped. The mania, as it appears, was beginning to wear itself out.

As the spirit of puritanism gained strength, however, which it gradually did during the latter part of the reign of Charles I., the partially cleared horizon became again overcast, and again was this owing to ill-judged edicts, which, by indicating the belief of the great and the educated in witchcraft, had the natural effect of reviving the frenzy among the flexible populace. The General Assembly was the body in fault on this occasion, and from this time forward the clergy were the great witch-hunters in Scotland. The Assembly passed condemnatory acts in 1640, 43, 44, 45, and 49, and with every successive act the cases and convictions increased, with even a deeper degree of attendant horrors than at any previous time. "The old impossible and abominable fancies," says the review formerly quoted, "of the *Malleus* were revived. About thirty trials appear on the Record between 1649 and the Restoration, only one of which appears to have terminated in an acquittal; while at a single circuit, held at Glasgow, Stirling, and Ayr, in 1659, seventeen persons were convicted and burnt for this crime." But it must be remembered that the phrase "on the Record" alludes only to justiciary trials, which formed but a small proportion of the cases really tried. The justiciary lists take no note of the commissions perpetually given by the privy-council to resident gentlemen and clergymen to try and burn witches in their respective districts. These commissions executed people over the whole country in multitudes. Wodrow, Lamont, Mercer, and Whitelocke, prove this but too satisfactorily.

The clergy continued, after the Restoration, to pursue these imaginary criminals with a zeal altogether deplorable. The Justiciary Court condemned twenty persons in the first year of Charles II.'s reign (1661), and in one day of the same year the council issued fourteen new provincial commissions, the aggregate doings of which one shudders to guess at. To compute their condemnations would be impossible, for victim after victim perished at the stake, unnamed and unheard of. Morayshire became at this particular period the scene of a violent fit of the great moral frenzy, and some of the most remarkable examinations signalizing the whole course of Scottish witchcraft took place in that county. The details, though occasionally ludicrous for their absurdity, are too horrible for narration in the present pages.

The popular frenzy seems to have exhausted itself by its own virulence in 1661–62, for an interval of six years subsequently elapsed without a single justiciary trial for the crime of witchcraft, and one fellow was actually whipped for charging some person with it. After this period, the dying embers of the delusion only burst out on occasions, here and there, into a momentary flame. In 1678, several women were condemned, "on their own confession," says the Register; but we suspect this only means, in reality, that one malicious being made voluntary admissions involving others, as must often have been the case, we fear, in these proceedings. Scattered cases took place near the beginning of the eighteenth century, such as those at Paisley in 1697, at Pittenweem in 1704, and at Spott about the same time. It is curious, that, as something like direct evidence became necessary for condemnation, that evidence presented itself, and in the shape of possessed or enchanted young persons, who were brought into court to play off their tricks. The most striking case of this nature was that of Christian Shaw, a girl about eleven years old, and the daughter of Mr. Shaw, of Bargarran, in Renfrewshire. This wretched girl, who seems to have been an accomplished hypocrite, young as she was, quarrelled with a maid-servant, and, to be revenged, fell into convulsions, saw spirits, and, in short, feigned herself bewitched. To sustain her story, she accused one person after another, till not less than twenty were implicated, some of them children of the ages of twelve and fourteen! They were tried on the evidence of the girl, and five human beings perished through her malicious impostures. It is remarkable that

this very girl afterwards founded the thread manufacture in Renfrewshire. From a friend who had been in Holland, she learned some secrets in spinning, and, putting them skilfully in practice, she led the way to the extensive operations carried on in that department of late years. She became the wife of the minister of Kilmaurs, and, it is to be hoped, had leisure and grace to repent of the wicked misapplication, in her youth, of those talents which she undoubtedly possessed.

The last justiciary trial for witchcraft in Scotland was in the case of Elspeth Rule, who was convicted in 1708, and—banished. The last regular execution for the crime is said to have taken place at Dornoch, in 1722, when an old woman was condemned by David Ross, sheriff of Caithness. But we fear the provincial records of the north, if inquired into, would show later deaths on this score. However, here may be held to end the tragical part of the annals of Scottish witchcraft. The number of its victims, for reasons previously stated, it would be difficult accurately to compute, but the black scroll would include, according to those who have most attentively inquired into the subject, upwards of FOUR THOUSAND persons! And by what a fate they perished! Cruelly tortured while living, and dismissed from life by a living death amid the flames! And for what? For an impossible crime! And who were the victims, and who the executioners? The victims, in by far the majority of cases, were the aged, the weak, the deformed, the lame, and the blind; those to whom nature had been ungentle in her outward gifts, or whom years and infirmities had doomed to poverty and wretchedness; exactly that class of miserable beings, in short, for whom more enlightened times provide houses of refuge, and endow charitable institutions, aiming, in the spirit of true benevolence, to supply to them that attention and support which nature or circumstances have denied them the power of procuring for themselves. Often, too, was the victim a person distinguished by particular gifts and endowments: gifts bestowed by the Creator in kindness, but rendered fatal to the possessor by man. These were the victims of witchcraft. The executioners were the wisest and greatest of their time. Men distinguished above their fellows for knowledge and intelligence, ministers of religion and of the laws, kings, princes, and nobles—these, and such as these, judged of the crime, pronounced the doom, and sent the poor victim of delusion to the torture, the stake, and the scaffold.

WITCHCRAFT IN ENGLAND.

Witchcraft was first denounced in England by formal and explicit statutes, in the year 1541, in the reign of Henry VIII. Previously to that time, many witch trials had taken place, and severe punishments had even been inflicted on the parties concerned; but this was occasioned by the direction of the arts of sorcery, in these particular instances, against the lives and well-being of others, and not from the legal criminality of such arts themselves. Shakspeare has made some early cases of this nature familiar to us, and in particular that of the Duchess of Gloucester, who, for conspiring with witches against the life of the reigning sovereign, Henry VI., was compelled to do public penance, and imprisoned for life. But, as has been said, the mode of prosecuting the guilty purpose was here altogether a subsidiary matter. If a person waved his hat three times in the air and three times cried "Buzz!" under the impression that by that formula the life of another might be taken away, the old law and lawmakers (as, for example, Selden, who states this very case) considered the formulist worthy of death as a murderer in intent; and upon this principle the trafficking with witches was punished in early times.

Witchcraft, however, by and by assumed greater statutory importance, in England as elsewhere. Henry VIII.'s two acts were levelled against conjuration, witchcraft, false prophecies, and pulling down of crosses. Here the charge was still something beyond mere sorcery, and it was left for Elizabeth, in 1562, to direct a statute exclusively against that imaginary crime. At the same time, that princess extenuated her conduct in part, by limiting the penalty of the crime, when stripped of its customary accessories, to the pillory. The first transgression, at least, received no heavier punishment. The cases of Elizabeth's reign were chiefly cases of pretended possession, sometimes, however, involving capital charges against those said to have caused the possession. In one famous case, of which the main features were as ludicrous as the issue was deplorable, three poor persons, an old man named Samuel, with his wife and daughter, were tried at Huntingdon, for having bewitched the children of a Mr. Throgmorton. Joan Throgmorton, a girl of fifteen, and the eldest of the children, was the main witness for the prosecution. She related many scenes, in which the actors were herself and a number of spirits sent by Dame Samuel to torment her, and to throw her into fits. These spirits, she said, were on familiar terms with her, and were named Pluck, Hardname, Catch, Blue, and three Smacks, who were *cousins*. Among other things she said that one of the Smacks professed himself an admirer of her's, and beat the rest for her sake, as in the following instance related by her. One day Smack appeared before her. "Whence come you, Mr. Smack?" she said to him. "From fighting Pluck and the rest, with cowl-staves, in Dame Samuel's back-yard," replied Smack; and soon thereafter, accordingly, Pluck and Blue walked in, the one with his head broken, and the other limping. "How do you manage to beat them?" said the young lady to the victorious Smack; "you are little and they are big." "Oh," says Smack, "I can take up any two of them, and my cousins beat the rest." Of such stuff were these charges made. It would appear that they were either the offspring of insanity on the part of the youthful Throgmortons, or that, having begun the farce in sport or spite, the accusers found at length that they could not retreat without a disgraceful confession of imposture. In part, the conduct of the poor Samuels was affecting, and even high-minded. After lengthened worrying, the accusers got Dame Samuel indirectly to confess her guilt, by making her repeat a prescribed charm, which had the effect of at once bringing the children out of their fits. But the old man and the daughter steadily maintained their innocence. The unfortunate family were condemned on the 4th April, 1593, and soon after executed.

When James I. ascended the English throne, he unfortunately conceived it to be his duty immediately to illuminate the southerns on the subject of witchcraft. An act of the first year of his reign defines the crime with a degree of minuteness worthy of the adept from whose pen it undoubtedly proceeded. "Any one that shall use, practise, or exercise any invocation of any evil or wicked spirit, or consult or covenant with, entertain or employ, feed or reward, any evil or wicked spirit, *to or for* ANY *purpose*; or take up any dead man, &c. &c. &c.; such offenders, duly and lawfully convicted and attainted, shall suffer death." We have here witchcraft first distinctly made, of itself, a *capital* crime. Many years had not passed away after the passing of this statute, ere the delusion, which had heretofore committed but occasional and local mischief, became an epidemical frenzy, devastating every corner of England. Leaving out of sight single executions, we find such wholesale murders as the following in abundance on the record. In 1612, twelve persons were condemned at once at Lancaster, and many more in 1613, when the whole kingdom rang with the fame of the "Lancashire witches;" in 1622, six at York, in 1634, seventeen in Lancashire; in 1644, sixteen at Yarmouth; in 1645, fifteen at Chelmsford; and in 1645 and 1646, sixty persons perished in Suffolk, and nearly

an equal number, at the same time, in Huntingdon. These are but a few selected cases. The poor creatures, who usually composed these ill-fated bands, are thus described by an able observer:—"An old woman with a wrinkled face, a furred brow, a hairy lip, a gobber tooth, a squint eye, a squeaking voice, or a scolding tongue, having a ragged coat on her back, a spindle in her hand, and a dog by her side—a wretched, infirm, and impotent creature, pelted and persecuted by all the neighbourhood, because the farmer's cart had stuck in the gateway, or some idle boy had pretended to split needles and pins for the sake of a holiday from school or work"—such were the poor unfortunates selected to undergo the last tests and tortures sanctioned by the laws, and which tests were of a nature so severe that no one would have dreamed of inflicting them on the vilest of murderers. They were administered by a class of wretches, who, with one Matthew Hopkins at their head, sprung up in England in the middle of the seventeenth century, and took the professional name of *witch-finders*. The practices of the monster Hopkins, who with his assistants moved from place to place in the regular and authorized pursuit of his trade, will give a full idea of the tests referred to, as well as of the horrible fruits of the witchcraft frenzy in general. From each town which he visited, Hopkins exacted the stated fee of twenty shillings, and, in consideration thereof, he cleared the locality of all suspected persons, bringing them to confession and the stake in the following manner:—He stripped them naked, shaved them, and thrust pins into their bodies to discover the witch's mark; he wrapped them in sheets with the great toes and thumbs tied together, and dragged them through ponds or rivers, when, if they sunk, it was held as a sign that the baptismal element did not reject them, and they were cleared—but if they floated (as they usually would do for a time), they were then set down as guilty, and doomed; he kept them fasting and awake, and sometimes incessantly walking, for twenty-four or forty-eight hours, as an inducement to confession; and, in short, practised on the accused such abominable cruelties that they were glad to escape from life by confession. If a witch could not shed tears at command (said the further items of this wretch's creed), or if she hesitated at a single word in repeating the Lord's Prayer, she was in league with the evil one. The results of these and such like tests were actually and universally admitted as evidence by the administrators of the law, who, acting upon them, condemned all such as had the amazing constancy to hold out against the tortures inflicted. Few gave the courts that trouble. Butler has described Hopkins in his Hudibras, as one

> "Fully empower'd to treat about
> Finding revolted witches out.
> And has he not within this year
> Hang'd *three score* of them in *one* shire?
> Some only for *not* being drown'd;
> And some for sitting above ground."

After he had murdered hundreds, and pursued his trade for many years (from 1644 downwards), the tide of popular opinion finally turned against Hopkins, and he was subjected, by a party of indignant experimenters, to his own favourite test of swimming. It is said that he escaped with life, but, from that time forth, he was never heard of again.

The era of the Long Parliament was that, perhaps, which witnessed the greatest number of executions for witchcraft. *Three thousand persons* are said to have perished during the continuance of the sittings of that body, by legal executions, independently of summary deaths at the hands of the mob. Witch-executions, however, were continued with nearly equal frequency long afterwards. One noted case occurred in 1664, when the enlightened and just Sir Matthew Hale tried and condemned two women, Amy Dunny and Rose Callender, at Saint Edmondsbury, for bewitching children and other similar offences. Some of the items of the charge may be mentioned. Being capriciously refused some herrings, which they desired to purchase, the two old women expressed themselves in impatient language, and a child of the herring-dealer soon after fell ill—in consequence. A carter drove his wagon against the cottage of Amy Dunny, and drew from her some not unnatural objurgations; immediately after which, the vehicle of the man stuck fast in a gate, without its wheels being impeded by either of the *posts*, and the unfortunate Amy was credited with the accidents. Such accusations formed the burden of the ditty, in addition to the bewitching of the children. These young accusers were produced in court, and, on being touched by the old women, fell into fits. But, on their eyes being covered, they were thrown into the same convulsions by *other* parties, precisely in the same way. In the face of this palpable proof of imposture, and despite the general absurdity of the charges, Sir Matthew Hale committed Amy Dunny and Rose Callender to the tender mercies of the hangman. It is stated that the opinion of the learned Sir Thomas Browne, who was accidentally present, had great weight against the prisoners. He declared his belief that the children were truly bewitched, and supported the possibility of such possessions by long and learned arguments, theological and metaphysical. Yet Sir Matthew Hale was one of the wisest and best men of his time, and Sir Thomas Browne had written an able work in exposition of Popular Fallacies!

This case occurred in 1664. For some subsequent years trials and executions were yet far from unusual. Chief-Justice North and Holt, to their lasting credit, were the first individuals occupying the high places of the law, who had at once the good sense and the courage to set their faces against the continuance of this destructive delusion. In one case, by detecting a piece of gross imposture, Chief-Justice North threw into disrepute, once and for all, the trick of *pin-vomiting*, one of the most striking and convincing practices of the possessed. A male sorcerer stood at the bar, and his supposed victim was in court, vomiting pins in profusion. These pins were straight, a circumstance which made the greater impression, as those commonly ejected in such cases were bent, engendering frequently the suspicion of their having been previously and purposely placed in the mouth. The chief-justice was led to suspect something in this case by certain movements of the bewitched woman, and, by closely cross-questioning one of her own witnesses, he brought it fully out that the woman placed pins in her stomacher, and, by a dexterous dropping of her head in her simulated fits, picked up the articles for each successive ejection. The man was found guiltless. The acquittal called forth such pointed benedictions on the judge from a very old woman present, that he was induced to ask the cause. "Oh, my lord," said she, "twenty years ago they would have hanged me for a witch if they could, and now, but for your lordship, they would have murdered my innocent son."

The detected imposture in this case saved the accused. It was under Holt's justiceship, however, that the first acquittal is supposed to have taken place, in *despite* of all evidence, and upon the fair ground of the general absurdity of such a charge. In the case of Mother Munrings, tried in 1694, the unfortunate pannel would assuredly have perished, had not Chief Justice Holt summed up in a tone so decidedly adverse to the prosecution, that the verdict of Not Guilty was called forth from the jury. In about ten other trials before Holt, between the years 1694 and 1701, the result was the same, through the same influences. It must be remembered, however, that these were merely noted cases, in which the parties withstood all preliminary inducements to confession, and came to the bar with the plea of not guilty. About the same period, that is, during the latter

years of the seventeenth century, summary executions were still common, in consequence of confessions extracted after the Hopkins fashion, yet too much in favour with the lower classes. The acquittals mentioned only prove that the regular ministers of the law were growing too enlightened to countenance such barbarities. Cases of possession, too, were latterly overlooked by the law, which would have brought the parties concerned to a speedy end in earlier days, even though they had done no injury to other people, and were simply unfortunate enough to have made compacts with the demon for the attainment of some purely personal advantages. For example, in 1689, there occurred the famous case of a youth, named Richard Dugdale, who sacrificed himself to the devil, on condition of being made the *best dancer* in Lancashire. The dissenting clergy took this youth under their charge, and a committee of them fasted and prayed, publicly and almost incessantly, for a whole year, in order to expel the dancing demon. The idea of this impostor leaping for a twelvemonth, and playing fantastic tricks before these grave divines, is extremely ludicrous. But the divines played tricks not less fantastic. They became so contemptuously intimate with the demon, as to mock him on account of saltatory deficiencies. A portion of their addresses to him on this score has been preserved, but of too ridiculous a nature for quotation in these pages. If any thing else than a mere impostor, it is probable that Dugdale was affected with St. Vitus's Dance: and this is the more likely, as a regular physician brought his dancing to a close after all. But the divines took care to claim the merit of the cure.

After the time of Holt, the ministers of the law went a step further in their course of improvement, and spared the accused in spite of condemnatory *verdicts*. In 1711, Chief-Justice Powell presided at a trial where an old woman was pronounced guilty. The judge, who had sneered openly at the whole proceedings, asked the jury if they found the woman "guilty upon the indictment of conversing with the devil in the shape of a cat?" The reply was, "We do find her guilty of that;" but the question of the judge produced its intended effect in casting ridicule on the whole charge, and the woman was pardoned. An able writer in the Foreign Quarterly Review remarks, after noticing this case, "yet frightful to think, after all this, in 1716, Mrs. Hicks, and her daughter, aged *nine*, were hanged at Huntingdon for selling their souls to the devil, and raising a storm by pulling off their stockings, and making a lather of soap! With this crowning atrocity, the catalogue of murders in England closes." And a long catalogue, and a black catalogue it was. "Barrington, in his observations on the statute of Henry VI., does not hesitate to estimate the numbers of those put to death in England, on this charge, at THIRTY THOUSAND!"

We have now glanced at the chief features in the history of witchcraft in England, from the enactment of the penal statutes against it. These statutes were not finally abolished till the middle of the eighteenth century, and unhappy consequences followed, in various instances, from their being left unrepealed. Though among the enlightened classes the belief in witchcraft no longer existed, the populace, in town and country, still held by the superstitions of their forefathers, and, having the countenance of the statute-book, persecuted the unfortunate beings whose position and circumstances laid them open to the suspicion of sorcery. The ban of public opinion told severely enough upon the comforts of such poor creatures, but the rabble occasionally carried their cruel and ignorant oppressions to a greater length. On the 30th of July, 1751, an aged pauper named Osborne, and his wife, were seized by a mob in Staffordshire, dragged through pools, and otherwise so vilely misused, that the woman died under the hands of her assailants. The attention of the law, and the indignation of the humane, were aroused. One man, who had taken a prominent share in the brutal outrage, was condemned on trial and executed. Immediately afterwards, the penal statutes against witchcraft were abrogated by the legislature, and the remembrance of them only remains, as a wonder and a warning to the posterity of those who practised and suffered from them, as well as to mankind at large.

It must not be imagined, we may observe in conclusion, that the present generation has no need of such a warning, or is relieved by its increased enlightenment from all chance of falling into similar errors. The nineteenth century has witnessed such impostors as Johanna Southcote, Matthews, and Thom, and has seen a degree of enthusiastic and unhesitating credence given to their pretensions by many persons moving in a most respectable rank in society, which shows that the credulous spirit that created and supported witchcraft is not by any means extinguished. It is indeed a spirit only to be fully eradicated by such a universality of education and intelligence as can scarcely be expected to exist, excepting after the lapse of long-coming centuries of improvement. The subject which has been treated of here has therefore a moral. In brief words, the world may learn from it the peril of encouraging the idea of the possibility of direct spiritual influences and communications in these latter days—a thing discountenanced alike by the lights of reason and scripture.

SPECTRAL ILLUSIONS.

The subject of spectral illusions, or, to use the common phraseology, apparitions or spectres, is now, in the estimation of scientific and properly informed men, one of the simplest and most intelligible to which the mind can be directed; while, to the ignorant, it still appears full of doubt and mystery. An apparition, spectre, ghost, or whatever it may be called, is vulgarly supposed to be a supernatural appearance—a thing occurring out of the common order of nature. No particular time or place is assigned for the appearance; but we may observe that the time is usually evening or night, and the place solitary or apart from the busy haunts of man. According to old theories on the subject, the person who declared that he had seen such an appearance was either set down as the fabricator of an untruth, or his story was fondly believed, and in the latter case the supernatural incident was added to the mass of credible history. We shall now endeavour to set this conflict of testimony and opinion to rights. In all cases, it is quite possible for the declarant to speak the truth as respects what he saw, or thought he saw, and yet that no real apparition may have occurred. The whole affair, as we shall explain, is simply a mental delusion, caused by some species of disease in the organs which affected the vision.

Mental and bodily disorder, organic or functional, is now allowed by physicians to be the basis of all kinds of spectral illusion. Organic disorder of the body is that condition in which one or more organs are altered in structure by disease. Disease of the brain, which involves organic mental disorder, is properly disease of the body, but enduring lunacy or fatuity, existing (if they can do so) without disease in the structure of the brain, may also be called organic disorder of the mind. These explanations will show what is meant by that epithet, as applied either to affections of the mind or body. Functional disorder, again, of the mind or body, is that condition of things where the healthy action of the organ or organs, in part or whole, is impeded, without the existence of any disease of structure. It may be said that violent excitement of the imagination or passions constitutes functional mental disorder; "anger is a temporary madness," said the Romans wisely. As for functional bodily disorder, temporary affections of the digestive organs may be pointed to as common cases of

such a species of physical derangement. All these disorders, and kinds of disorders, may appear in a complicated form, and, what is of most importance to our present argument, the *nervous system*, on which depends the action of the *senses*, the power of *volition*, and the operation of all the involuntary functions (such as the circulative and digestive functions), is, and must necessarily be, involved more or less deeply in all cases of constitutional disorder, organic or functional. These powers of the nerves, which form the sole medium by which mind and body act and react on each other, give us a clue to the comprehension of those strange phenomena called spectral illusions, which depend on a combination of mental and physical impressions.

Organic mental disorder generates spectral illusions. Almost every lunatic tells you that he sees them and with truth; they are seemingly present to his diseased perceptions. The same cause, simple insanity, partial or otherwise, and existing either with or without structural brain disease, has been, we truly believe, at the foundation of many more apparition-cases than any other cause. By far the greatest number of such cases ever put on record, have been connected with fanaticism in religious matters; and can there be a doubt that the majority of the poor creatures, men and women, who habitually subjected themselves, in the early centuries of the church, to macerations and lacerations, and saw signs and visions, were simply persons of partially deranged intellect? St. Theresa, who lay entranced for whole days, and who, in the fervour of devotion, imagined that she was frequently addressed by the voice of God, and that our Saviour, St. Peter, and St. Paul, would often in person visit her solitude, is an example of this order of monomaniacs. That this individual, and others like her, should have been perfectly sensible on all other points, is a phenomena in the pathology of mind too common to cause any wonder. We could ascribe, we repeat, a large class of apparition-cases, including these devotional ones, to simple mental derangement. The eye in such instances may take in a correct *impression* of external objects, but this is not all that is wanting. A correct *perception by the mind* is essential to healthy and natural vision, and this perception the deranged intellect cannot effect. A three-footed stool may then become a kneeling angel. We would therefore have such persons regarded, not in the uncharitable light of impostors, but of poor creatures who mistook natural hallucinations for supernatural.

Undoubtedly, however, many of those cases of spectral illusions, which have made the deepest impression on mankind, have not arisen from organic mental disease on the part of the sight-seers. The lunatic is apt to betray his condition, and, that once recognised, his visions become of no weight. We have then to turn to other causes of spectre-seeing; and, first, let us notice the mode of operation, and effects of certain *functional* disorders of the system, operating on the visual perceptions through the nerves. A bodily disorder, which ought in itself to afford a solution of all apparitions, is that called *delirium tremens*. This is most commonly induced, in otherwise healthy subjects, by continued dissipation. So long (say medical authorities) as the drinker can take food, he is comparatively secure against the disease, but when his stomach rejects common nourishment, and he persists in taking stimulants, the effects are for the most part speedily visible, at least in peculiarly nervous constitutions. The first symptom is commonly a slight impairment of the healthy powers of the senses of hearing and seeing. A ringing in the ears probably takes place; then any common noise, such as the rattle of a cart on the street, assumes to the hearing a particular sound, and arranges itself into a certain tune perhaps, or certain words, which haunt the sufferer, and are by and by rung into his ears on the recurrence of *every* noise. The proverb, "as the fool thinks, so the bell tinks," becomes very applicable in his case. His sense of seeing, in the meanwhile, begins to show equal disorder; figures float before him perpetually when his eyes are closed at night. By day, also, objects seem to move before him that are really stationary. The senses of touch, taste, and smell, are also involved in confusion. In this way the disturbance of the senses goes on, increasing always with the disorder of the alimentary functions, until the unhappy drinker is at last visited, most probably in the twilight, by visionary figures, distinct in outline as living beings, and which seem to speak to him with the voice of life. At first he mistakes them for realities, but, soon discovering his error, is thrown into the deepest alarm. If he has the courage to approach and examine any one of the illusory figures, he probably finds that some fold of drapery, or some shadow, has been the object converted by his diseased sense into the apparition, and he may also find that the voice was but some simple household sound converted by his disordered ear into strange speech; for the senses, at least in the milder cases of this sort, rather *convert* than *create*, though the metamorphosed may differ widely from the real substance. The visitations and sufferings of the party may go on increasing, till he takes courage to speak to the physician, who by great care restores his alimentary organs to a state of health, and, in consequence, the visions slowly leave him. If, however, remedies are not applied in time, the party will probably sink under the influence of this disorder. The spectral figures and voices, being solely and entirely the creation of his own fancy, will seem to do or say any thing that may be uppermost in that fancy at the moment, and will encourage him to self-murder by every possible argument—all emanating, of course, from his own brain. The whole consists merely of his *own fancies bodied forth to him visibly and audibly*. His own poor head is the seat of all; there is nothing apart from him—nothing but vacancy.

Dr. Alderson, a respectable physician, mentions his being called to a keeper of a public-house, who was in a state of great terror, and who described himself as having been haunted for some time with spectres. He had first noticed something to be wrong with him on being laughed at by a little girl for desiring her to lift some oyster shells from the floor. He himself stooped, but found none. Soon after, in the twilight, he saw a soldier enter the house, and, not liking his manner, desired him to go away; but receiving no answer, he sprang forward to seize the intruder, and to his horror found the shape to be but a phantom! The visitations increased by night and by day, till he could not distinguish real customers from imaginary ones, so definite and distinct were the latter in outline. Sometimes they took the forms of living friends, and sometimes of people long dead. Dr. Alderson resorted to a course of treatment which restored the strength of the digestive organs, and gradually banished the spectres. At the close of the account, it is said that the man emphatically expressed himself to have now received "a perfect knowledge of the nature of ghosts."

Many additional cases from Hibbert, Abercromby, and other writers might be quoted, in which the visual impressions and perceptions were in a similar way affected by the influence of digestive derangement. But as no doubt can rationally exist on the point, from the comparative commonness of the disease, no more proof need be brought forward. However, the inference naturally deducible from these facts is too important to be overlooked. Here we find, by unquestionable medical evidence, that a man walking about in apparent bodily health, and mentally sane, may nevertheless be subject to most distinct visitations of spectral figures, some of them in the semblance of *dead* persons. We find this, we repeat, to be within the range of natural phenomena. Now, is it not more likely, in those cases where wonderful apparitions are reported to have been seen, that the

whole was referable to such natural causes, than that the grave gave up its dead, or that the laws of the universe were specially broken in upon in any other way? Even with only one such admitted source of spectral illusions as the malady alluded to, we should certainly err in passing it by to seek for explanations in supernatural quarters. But in reality we have *many* causes or sources of them, and to these we shall now look, in continuation of our argument.

Among the other varieties of bodily ailments affecting either structure or function, which have been found to produce spectral illusions, fevers, inflammatory affections, epileptic attacks, hysteria, and disorders of the nerves generally, are the most prominent. As regards fevers and inflammatory affections, particularly those of the brain, it is well known to almost every mother or member of a large family, that scarcely any severe case can occur without illusions of the sight to a greater or less extent. In hysteric and epileptic cases, also, where fits or partial trances occur, the same phenomena are frequently observed. But we shall not enlarge on the effects produced by the influence of severe and obviously existing maladies, as it is in those cases only where the spectre-seer has exhibited *apparent* sanity of mind and body, that special wonder has been excited. It is so far of great importance, however, to notice that these diseases do produce the illusions, as in most cases it will be found on inquiry that the party subject to them, however sound to appearance at the time, *afterwards* displayed some of these complaints in full force; and we may then rationally explain the whole matter by supposing the seeds of the ailments to have early existed in a latent state. A German lady, of excellent talents and high character, published an account some years back of successive visions with which she had been honoured, as she believed, by Divine favour. Dr. Crichton, however, author of an able work on Insanity, found that the lady was always affected with the *aura epileptica* during the prevalence of the illusions; or, in other words, that she was labouring under slight attacks of epilepsy. Thus simply was explained a series of phenomena which, from the high character for veracity of the subject of them, astonished a great part of Germany. Another case, where functional bodily disorder of a different and very simple kind was present in an unrecognisable state, and produced extraordinary illusions, was the famous one of Nicolai, the Berlin bookseller. This individual, when in perfectly fit state to attend to his ordinary business, was suddenly visited one day, when casually excited by some annoying circumstance, by the figure of a person long dead. He asked his wife, who was present, if she saw it; she did not. The bookseller was at first much alarmed, but, being a man of sense and intelligence, he soon became convinced of the illusory yet natural character of the spectra, which subsequently, for a period of two whole years, appeared to him in great numbers and with daily frequency. "I generally saw (says he) human forms of both sexes, but they took not the smallest notice of each other, moving as in a market-place, where all are eager to press through the crowd; at times, however, they seemed to be transacting business with one another. I also saw several times people on horseback, dogs, and birds. All these phantasms appeared to me in their natural size, and as distinct as if alive; none of the figures appeared particularly terrible, comical, or disgusting, most of them being of an indifferent shape, and some presenting a pleasing aspect. The longer these phantoms continued to visit me, the more frequently did they return." They also spoke to him repeatedly.

These phantasms lasted, as we have said, two years. The issue is peculiarly worthy of note. Nicolai had in former years fallen into the habit of periodical bloodletting by leeches, but had ventured to stop the practice previous to the accession of phantoms, and during their prevalence he had only been advised to attend to the state of his digestive organs. After they had endured for the time mentioned, it was thought fit to renew the blood-letting. At eleven in the morning, while the room was crowded with the spectral figures, the leeches were applied. As the bleeding slowly proceeded, the figures grew dimmer and dimmer, and finally, by eight o'clock in the evening, they had all melted into thin air, never to re-appear! This most remarkable case, the first in which any individual dared calmly to come forward and avow such an affection, at the risk of incurring the charge of insanity, was founded, we thus see, simply on a plethoric or surcharged state of the blood-vessels. Nicolai deserves great credit for the philosophic composure with which he recorded the phenomena presented to him; but his statement, which has often been republished in this country, seems defective in some points, and, from the interest of the subject, we may be pardoned for presuming to notice these. Generally speaking he represents his spectral visitants as things which came and went, and assumed various shapes, and appeared in certain numbers, *uninfluenced* directly *by himself*. The total dependence which they had upon his own fancy of the *moment*, is not put clearly before us, though, by the truthful accuracy of the narrative, he unconsciously makes that fact apparent every instant. The surcharged state of the vessels was the fundamental cause of the phantasms, but his own passing fancies moulded them for the passing moment into shape, regulated their numbers and gave them words. How could it be otherwise? The whole panorama was exhibited on his own retina, and the working brain behind was the manager and scene-shifter of the show.

Second-Sight.—Second-Sight, taking the word in its common acceptation of supernatural sight-seeing, is one of the varieties of spectral illusion. Certain mental functions becoming diseased, the sense of sight is imposed upon by the appearance of things which are purely imaginary, but nevertheless supposed to be prophetic of future events. Idleness, solitude, insufficient diet, and an imagination led astray by ruminating too intensely on the causes of human weal and wo, may be assigned as the prevailing causes of the disease. The Lowland Scotch used occasionally to see *wraiths*, or spectral appearances of persons who were soon to quit this mortal scene; the Irish were also accustomed to the spectacle of *fetches*; and the Highlanders had their *second-sight*—the whole, be it observed, being but a variety of the same mental disease and delusion.

Second-sight, however, has formed the subject of a more regular profession than any other species of spectral frenzy. There were persons, who, possessing from infancy a defective mental constitution, or having a taste for imposture, gave themselves out as habitual sight-seers, and were reverenced accordingly by their unsophisticated neighbours. According to the credulous account of second-sight, the power of the seer is a natural endowment, and cannot be acquired by communication, or in any other way. It is usually talked of by its possessors as a painful and troublesome gift, and one which they would gladly be rid of, if they could. Its vaticinations relate only to things to come, and not to past events. Young and old may alike possess the second-sight, and it is common, also, to men and women. The visions are sometimes predictive of good, and sometimes of evil. Occasionally, the vision simply gives in different tidings.

These are a few of the most common peculiarities attendant on this faculty. There are likewise numberless rules affecting its exercise, and the interpretation of its visions. If a vision occur by day, for example, the accomplishment of what it is supposed to predict will be speedy; if by night, less so. An exact proportion, indeed, is maintained in this respect—the morning vi

being sooner fulfilled than that of noon; the latter more quickly than that of the afternoon; and so on. If the seer beholds a figure in a shroud, it is considered a sure sign of death to the party represented by the figure; and, according to the extent to which the shroud covers the body, the end will be quicker or slower. If a woman be seen at a man's left hand, it is a presage that she will be his wife, and this will be the case (say the true believers), though even both should then be married. If more than one woman be seen standing at a man's left hand, they will be married to him in rotation, as they stand nearer or farther from his arm. A seer often announces that such and such a guest will arrive at a certain hour, and, though a hundred miles away, the guest, it is said, will appear at the stated time. If a seer observe a vision of trees and crops in some spot or another, though perfectly barren and bare at the moment, wood and grain will, it is believed, there be seen in due time. A visionary house is beheld by the gifted eye, in a place where stone and lime were never laid, or expected to be laid. Yet there will the real house forthwith be seen. To see a seat, as if vacant when one is setting it, is a presage of the party's death. The seer may behold crowds of people, or single individuals, and very frequently he meets imaginary funeral parties, and determines the coming decease by the apparent mourners.

These rules of vaticination are *said to be* unvarying. No ordinary person sees the vision while it is present to the seer, but the same vision often appears to two or more of the gifted, either while they are together or apart. The Highlanders believe that children and the lower animals, such as cows and horses, behold the appearances while they are before the seer. This is made plain, they say, in the case of the animals, by the trembling which seizes them at the moment; and frequently the children will cry, and, if asked the reason, will tell what unusual thing they behold or have beheld. It is almost needless to say, that the stories told to prove the truth of these notions, rest on no sure foundation, and that, at the best, the prophecies of the sight-seer only come to pass by chance.

Atmospheric Illusions.—Spectral or illusory appearances also take place from the power of refraction in the atmosphere. In certain conditions of the atmosphere, things at a distance, and really out of sight, as on the opposite side of a hill from the spectator, are represented in mid-air; but there is nothing supernatural in this—the whole is the effect of a simple cause. The following is an example of atmospheric illusion:—A gentleman and his servant in the year 1744, beheld a troop of cavalry riding and performing various military evolutions on the side of Souter (or Soutra) Hill, in a spot so precipitous as to render it absolutely impossible for man or beast to maintain a footing. The servant had in the previous year observed a single horseman hunting in nearly the same place, and had then come to the conclusion that the sight was illusory, it being impossible for a rider to cross a perpendicular precipice at speed. The troop of cavalry, therefore, was at once set down as an atmospheric deception, and numbers of persons of the district came to look on the extraordinary scene, which continued visible till nightfall. An explanation of the circumstance was afforded by the rebellion of the following year. Some party of rebels were most probably exercising in secret, in a spot where the evening sun so caught their figures as to reflect them on the acclivity of Souter Hill. The legend of the spectre of the Brocken, in Germany, in like manner arises from the fact of the ground being favourable to the reflection of a visiter's figure against the evening sky. Our ancestors were occasionally alarmed with visions of armies fighting in the air, and similar illusions; had they been acquainted with the laws of atmospheric refraction, all would have appeared simple natural phenomena, having no relation to any future event, good or evil.

Dreams.—It has now been seen that there are various modes in which the system may be so disturbed as to produce spectral illusions, and that, in the majority of these cases, the parties subject to them might seem to be not only of sound mind, but in perfect bodily health. Another mode of explaining cases of this description may now be pointed out. Many of the apparitions which have been vouched for by those subjected to them, have certainly been neither more nor less than *vivid dreams*. A dream is a slight and ill-arranged action of the thinking faculties during a state of partial sleep; in other words, when we dream we are only thinking in a partially wakened state. The dream or the thought is in all cases but a momentary impression, perfectly natural in its operation; the state of mind which causes it being produced by temporary functional derangement; the stomach is usually less or more out of order. No dreams take place during sound sleep. In the greater number of instances, the half-awakened mind embarrasses itself with shreds of recollections of things formerly seen or thought of, and dressing these up in a new and fantastic form, a kind of drama is performed, having the semblance of reality. A servant girl living in a family where there were some phrenological busts, and, among others, a conspicuous one of Curran, awoke her bed companion one morning with the alarming information that the ghost of Curran stood at the foot of the bed dressed in a sailor's jacket, and having on his pale face the unwonted and unbustlike ornament of an immense pair of black whiskers. The other servant could see nothing, though the apparition seemed to her companion to remain visible for some minutes. On the tale being told, a pretty strong light was thrown on the matter. The master of the house had a yacht, and its sailors at that period were frequently about the premises. Going to bed much fatigued, and having her dreaming thoughts divided between her household duties and some gay whiskered beau of the yacht, the girl's fancy had dressed up Curran's bust, an object most familiar to her retina, in the way mentioned, giving him the sailor's person and whiskers as a fitting appendage. Had the object called up to the eye in this case, instead of being a bust of Curran, chanced to be a portrait of some wicked ancestor or ancestress of the family, as might easily have occurred from the greater comparative impression made on the mind by portraits of that cast, then should we have had a splendid instance of the preternatural appearance of a spirit stung by remorse, and haunting restlessly the scene of its mortal guilt. The girl, without imposture, might have conscientiously reiterated her conviction of the reality of the vision, and the possession of a haunted chamber would have most certainly been assigned to the mansion, inspiring such terror that renewals of the illusion might really have taken place in consequence. Where the whole affair is not a fiction in such haunted-chamber cases, some solution of this kind may be with certainty applied. The practice of believing that dreams are indicative or symbolic of coming events, is one of the silliest superstitions, and is now very properly ridiculed by every rational mind.

MISCELLANEOUS SUPERSTITIONS.

During the seventeenth century, the belief in witchcraft, fairies, apparitions, charms, and every other species of supernatural agency, was universal in Britain, both among high and low, clergy as well as laity. So ill instructed were the people in the art of tracing events to simple natural causes, that there appears to have been a continual liability to ascribe occurrences to the direct influence of good or evil spirits, but particularly to the devil. "Give me leave," says a respectable writer of that age, "here to relate a passage which I received from a person of quality: namely—it was believed, and that not without good cause, that Cromwell, the same morn-

ng that he defeated the king's army at Worcester fight, had conference personally with the devill, with whom he made a contract, that to have his will then, and in all things else for seven years after that time (being the 3d of September, 1651), he should, at the expiration of the said years, have him at his command, to do at his pleasure both with his soul and body. Now, if any one will please to reckon from the 3d of September, 1651, till the 3d of September, 1658, he shall find it to a day just seven years, and no more, at the end whereof he died; but with such extremity of tempestuous weather, that was by all men judged to be prodigious."* Such is a specimen of the egregious fallacies which passed for sound argument among our ancestors.

In Scotland, where religion assumed the garb of gloom and fanaticism, a belief in the personal appearance of devils was universal in the seventeenth century, and continued among the vulgar till within the last fifty years. The narrations of Satan's mean pranks, in assaulting ministers, waylaying travellers, and disturbing families while at worship, would fill a large volume. In the Rev. Mr. Robert Law's "Memorials of Memorable Things, from 1638 to 1684,"† we find the following entry:—

"October, 1670.—There was a devill that troubled a house in Keppoch, within a mile of Glasgow, for the matter of eight days tyme (but disappeared again), in casting pots, and droping stones from the roof, yet not hurting any, like that which appeared in the west, in a weaver's house, a good man, about fourteen yeirs agoe, which did the lyke, and spoke to them audibly." The tricks of the devil here referred to, as having taken place in a weaver's house in the west, about the year 1656, and which were implicitly believed by the most learned clergy of the time, are related at great length by Mr. George Sinclair, professor of philosophy in the College of Glasgow, in his work, "Satan's Invisible World Discovered." The alleged events occurred at Glenluce, in Wigtonshire, and would be too contemptible for quotation, if it were not desirable to show what paltry tricks were played off, and believed to be supernatural in those days. The family of the weaver, being vexed with noises and appearances, send for the neighbouring clergyman to allay the devil, between whom and the worthy man a dialogue takes place, from which we extract a few passages:—"The minister returned back a little, and standing upon the floor, the devil said, 'I knew not these scriptures till my father taught me them.' Then the minister conjured him to tell whence he was. The foul fiend replied, 'That he was an evil spirit come from the bottomless pit of hell to vex this house, and that Satan was his father.' And presently there appeared a naked hand, and an arm from the elbow down, beating upon the floor till the house did shake again, and also he uttered a most fearful and loud cry, saying, 'Come up, my father—come up. I will send my father among you; see, there he is behind your backs!' Then the minister said, 'I saw, indeed, a hand and an arm, when the stroke was given, and heard.' The devil said to him, 'Saw you that! It was not my hand, it was my father's; my hand is more black in the loof (palm). Would you see me,' says the foul thief, 'put out the candle, and I shall come but the house (into the outer room) among you like fireballs,'" &c. The visit of the minister was unavailing. "About this time the devil began with new assaults; and taking the ready meat which was in the house, did sometimes hide it in holes by the door-posts, and at other times hid it under the beds, and sometimes among the bed-clothes and under the linens, and at last did carry it quite away, till nothing was left there save bread and water. The goodwife, one morning making porridge for the children's breakfast, had the wooden plate, wherein the meal lay, snatched from her quickly. 'Well,' says she, 'let me have my plate again.' Whereupon it came flying at her, without any skaith done." Any further extract from this ridiculous, though at one time universally believed, narrative, would be unnecessary. A modern police-officer would have effectually relieved "the afflicted family," by instantly discovering the performer of the tricks, and taking him into custody.

Besides the belief in aërial and terrestrial spirits, our credulous ancestors put faith in all kinds of romancing stories of river and sea demons. The more prevalent of these superstitious notions was a belief in mermaids and mermen, a class of creatures who lived in the sea, and had bodies half-human, half-fish. Mermaids appear to have been much more common than mermen. The mermaid, we are told, possessed the body, from the middle upwards, of a beautiful female, with a head flowing with long yellow hair, which she incessantly combed with one hand, while she held a small mirror with the other. This female monster of the deep is described as having been a constant schemer of destruction to confiding navigators, or those who haunted unfrequented parts of the sea-shores.

Another of the vulgar superstitions of our ancestors was a belief common to nations of Germanic origin, that the corpse of a murdered person would bleed on being touched by the person who was guilty of the murder. Strange to say, this species of evidence of guilt was at one time admitted in the Scottish criminal courts. The following incredible instance was communicated to Sir Walter Scott, and is given in his Minstrelsy of the Scottish Border (vol. ii. p. 54). "Two young men, going a-fishing in the River Yarrow, fell out, and so high ran the quarrel, that the one, in a passion, stabbed the other to the heart. Astonished at the rash act, he hesitated whether to fly, give himself up to justice, or conceal the crime; and in the end, fixed on the latter expedient, burying the body of his friend very deep in the sands. As the meeting had been accidental, he was never suspected, although a visible change was observed in his behaviour, from gayety to a settled melancholy. Time passed on for the space of fifty years, when a smith, fishing near the same place, discovered an uncommon and curious bone, which he put in his pocket, and afterwards showed to some people in his smithy. The murderer being present now an old white-headed man, leaning on his staff, desired a sight of the little bone; but how horrible was the issue!—no sooner had he touched it, than it streamed with purple blood. Being told where it was found, he confessed the crime, was condemned, but was prevented by death from suffering the punishment due to his crime." We need only add, that no evidence is given of the truth of this improbable tale, and it is utterly unworthy of belief.

Ignorance has often been justly termed the mother of superstition; wherever mankind are most ignorant, or least accustomed to trace events to their natural and proximate causes, there do all kinds of superstitious notions luxuriantly flourish. When the mind once allows that matters of ordinary occurrence may take place by the interference of invisible agents, such as spirits, apparitions, devils, and so forth, there is obviously no limit to the actions they are supposed to perform. Hence the number of events believed to be ominous of evil in unenlightened society. The appearance of two or three magpies, the spilling of salt at table, the cracking of furniture, the howling of dogs, putting on the left shoe first, the ticking noise of an insect in rotten wood (death-watch), and a hundred other trifling occurrences, are imagined to be harbingers of evil. It is distressing to find, that notwithstanding the great advances of intelligence, a large portion of the people are still affected by the most absurd minor superstitions; for example, believing in the influence of charms, with as true a devotion to error as signalized

* Walker's History of Independency.

† Edited by C. Kirkpatrick Sharpe, from the MS. Edinburgh 1818.

our ancestors of the seventeenth century. The following instance of this species of credulity, given in a Norwich newspaper, April, 1840, was mentioned as having lately occurred in that city:—"Children who are sickly are taken to a woman for the purpose of being cut for a supposed disease called the *spinnage*. The infants are on a Monday morning taken to this woman, who, for threepence, cuts through the lobe of the ear with a pair of scissors, then makes a cross with the blood upon the forehead and breast of the child. On the following Monday, the same barbarous ceremony is performed upon the left ear; and on the succeeding Monday the right ear is again doomed to undergo the same ceremony. In some cases it is deemed necessary to perform the operation nine times."

The occurrence in 1840 of a fatal disease in cattle, called the *murrain*, and which was susceptible of remedy by proper surgical means, led to the exposure of various superstitious observances among a respectable class of the rural population of England. In Northumberland, a fire kindled by rubbing together two pieces of hard wood, was carried about in an old shoe from one house to another, and thus passed through the country; with this a bonfire was lighted, and the cattle were made to pass through its smoke, which was supposed to render them invulnerable to the attacks of the disease.

In Scotland, cattle are the subject of scarcely less superstitious maxims. In many districts, if a cow has been seized with *phthisis pulmonalis*, or any inflammatory disorder, or if she has become *hide-bound*, or rumination has been accidentally stopped, the wise people called in to minister know but one explication of the mystery: the beast has got the *tail-ill*. This is an imaginary disorder supposed to reside in the tail, and to show itself by eating away the bone of that organ. To prove its presence, the cow-doctor will ask the owner of the animal to feel the tail near its extremity, and satisfy himself that the bone is "clean awa," the fact being that in that region there is only a soft cartilage. Under this miserable delusion, the people make incisions in the tails of cattle, into which they rub salt, soot, or horse turpentine, thus adding to the pains of the animal, without doing the least for the relief of the real malady. Often a considerable portion of the tail is cut off, by way of making the cure more certain. An educated veterinary surgeon of our acquaintance informs us that, in some cow-houses in his neighbourhood, there is not a cow with a tail above sixteen inches long.

One of the most remarkable charms now or very lately in use in Lanarkshire for the cure of illnesses in cattle, is a talisman of great antiquity, still preserved at Lee, a gentleman's house in that county, and popularly known as the *Lee Penny*. The following account of this ancient talisman is given in the Picture of Scotland, by R. Chambers:—

"Simon Locard of Lee accompanied the good Sir James Douglas to Palestine [in the fourteenth century], bearing the heart of King Robert Bruce enclosed in a locked case, on which account his name was changed to Lockhart, and he obtained for his armorial bearings a heart attached to a lock. Engaging in the wars of the Holy Sepulchre, this hero, who, at the death of Douglas in Spain, became the leader of the mission, had the good fortune to make a Saracen of rank his prisoner. The lady of the warrior came to pay his ransom, and was counting out the money, when she happened to drop from her purse a small jewel, which she immediately hastened to pick up with an air of careful solicitude. Lockhart eagerly inquired the nature of the jewel, and learning that it was a medicatory talisman, refused to deliver up his captive, unless it were added to the sum previously stipulated. The lady was obliged to comply, and Simon brought it home to Scotland, where it has ever since continued in the possession of his descendants, perhaps the only existing memorial of the Crusades in this country. It is called the Lee Penny, on account of its being set in the centre of an old English silver coin. Triangular in shape, it measures about the third of an inch each way, and is of a dark red colour, but perfectly transparent. The nature of the stone cannot be determined by lapidaries, being apparently different in all respects from any known in this quarter of the world. To the edge of the coin a small silver chain has been attached, and the whole is deposited in a gold box which the Empress Maria Theresa presented to the father of the late Count Lockhart.

"The Lee Penny did not lose its talismanic property on being transferred to a country of Christians. On the contrary, it has been all along, even till the present day, remarkable for medical virtue. It is especially sovereign in the diseases of horned cattle. The mode of administering it is this:—Holding it by the chain, it is three times plumped down into a quantity of water, and once drawn round—*three dips and a swell*, as the country people express it—and, the cattle or others affected drinking this water, the cure is speedy and effectual. Even at this day, rife as the gospel is now said or supposed to be, people sometimes come from great distances with vessels, which they fill with water charmed in the manner described, and which they take home in order to administer it to their bestial. In the reign of Charles I, the people of Newcastle being affected with the plague, sent for and obtained a loan of the Lee Penny, leaving the sum of £6000 sterling in its place as a pledge. They found it so effectual, or were impressed with so high an opinion of its virtues, that they proposed to keep it, and forfeit the money; but the Laird of Lee would not consent to part with so venerable and so gifted an heir-loom. The laird of that time was a high Cavalier, and one of the charges brought against him by the party whom he had to oppose, was, that he effected cures by means of necromancy. One other remarkable instance of its efficacy is recorded. About the beginning of the last century, Lady Baird of Saughtonhall having been bit by a mad dog, and exhibiting all the symptoms of hydrophobia, her husband obtained a loan of the talisman; and she, having drunk and bathed in water which it had sanctified, got completely better. That this transaction really took place, seems indubitable, for an ancient female member of the Lee family, who died lately, remembered hearing the laird who lent the Penny to Lady Baird, describe how he and his dame had been invited to Saughtonhall, and splendidly entertained, in gratitude for the use of the talisman. Being now visited by an incredible number of persons, whose curiosity has been excited respecting it, Sir Charles M'Donald Lockhart, the present proprietor, has adopted the idea of keeping an album in which their names are recorded. We have all seen the use made of it by the author of Waverley, in his fine chivalric tale, 'the Talisman.'"

We need only add, what is here omitted to be mentioned, that the supposed influence of the Penny, like every similar charm, has been an entire delusion; and that if the cures were performed, as stated, something else than the charm of the talisman must have been the cause. In this, as in all similar traditions, the testimony is defective, every circumstance unfavourable to the superstition being suppressed.

DOMESTIC ECONOMY—COOKERY.

Cookery is an art upon which so much of our daily comfort and health depends, that it is of the highest importance that it be well performed. Every housewife may not be able to procure the finest kinds of food, but every one has it in her power to make the most of that which she does procure. By a certain degree of skill and attention, very humble fare may be dressed in such a manner that it will almost rival the most expensive dishes, both in savouriness and nutritiousness. A good housewife suffers nothing to be lost or spoiled. Mere scraps, which a careless individual would perhaps throw away, are put to a proper use, and, by means of certain auxiliary seasoning, brought to table in a new and attractive guise. Even if little or nothing be absolutely saved by these economical arrangements, the dressing of food in a tasteful manner is a point of some importance. When a dish has a slovenly appearance, is smoked, underdone, or prepared with rancid or unclean seasoning, both the eye and the appetite are offended, which is a serious evil in itself, independently of the injury which may possibly be done to the stomach of the eater. In every respect, therefore, it is consistent with good judgment to prepare food for the table in the most tasteful and agreeable manner.

One of the chief points to be attended to in cookery is *cleanliness*—scrupulous cleanliness in every department of the business of the kitchen. The hands of the cook, in particular, should be always clean; that is, washed every time after doing any kind of work which has soiled them, or before proceeding to handle meat for dressing. She should also be careful in having her hair always neatly trimmed up, so that no loose hairs may drop into the dishes. The next point of regulation is to keep all the saucepans and other utensils perfectly clean in their inner parts, and also in the insides of the lids; carefully washing with hot water, and scouring when necessary. If the cooking utensils are not kept thoroughly clean, they will be very apt to taint the food prepared in them, and will certainly detract from the agreeable taste of the dishes. It is the duty of every housewife, either in her own person or by her deputy, the housekeeper, to see that these and all other rules affecting the cleanliness of the kitchen are attended to by servants, for she is understood to be responsible both for the wholesomeness and the tidy appearance of the dishes presented at table.

Another essential point in cookery is *attention*. Many persons think they have done all that is necessary, when they have fairly commenced or set a going any particular process in cooking. They seem to imagine that they may safely leave a joint to roast by itself, or leave a pot with soup or broth to boil by itself, and that they have only to go back to the fire at a certain time, and they will find the things ready for dishing. Now, this kind of inattention is certain to spoil the best meat ever put to a fire. Some processes require much less attention than others, but none can be properly performed if left long to itself. A good cook is pretty frequent in her visits to the fire, to see how the operation of dressing is going on, and seizes the proper moment in giving her assistance.

Perfection in the art of cookery is only attainable by lengthened experience, and a careful study of the qualities of meats, and the application of sauces and seasonings. It is chiefly in knowing how to make and apply sauces that a cook shows her skill. We therefore recommend this branch of the art to very careful attention.

KITCHEN ARRANGEMENT.

A young and thriftily disposed housewife will, if possible, proceed to market herself, in order to lay in butcher-meat and other fresh provisions for her family. By this plan she will possess two advantages—that of selecting the best pieces, and of getting them at the lowest price. The frequency of her visits to the market will, of course, depend on the number of her family, and their taste as to the staleness or freshness of the meat to be purchased. If circumstances permit, it is advisable to purchase a whole week's provisions at a time, at least the chief things which will be required for the ensuing eight days. We would recommend a housewife to act upon a system in varying the kinds of meat which she buys, not only as they may be suitable to the seasons, but as calculated to promote the health of a family. It is of considerable consequence that food should be varied; indeed, sameness of diet will produce the most injurious effects, whatever be the quality of the food which is taken. Let the housewife, therefore, exercise a little ingenuity and judgment in her marketing expeditions, contriving to present at table a succession of different descriptions of animal and vegetable food; as, for example, sometimes meat roasted, and sometimes boiled or stewed; sometimes fresh meat, and sometimes salted; sometimes butcher-meat, and sometimes fish; and so on, according to taste and other circumstances. It does not necessarily follow, that, in thus varying the bill of fare, greater expense is incurred than if the same kind of articles were continually purchased.

The best meat is that which is moderately fat. If it be lean, or almost free of fat, it is an indication that the animal has been ill fed, and that the meat will prove tough and tasteless. Avoid lean beef—it forms wretched fare, and will be dear at any price. The fat of good beef is slightly yellowish; the fat of good mutton is pure white. The flesh of both beef and mutton should be of a clear red colour. The mutton of black-faced sheep, or Southdowns, is the most tender or sweet, and may be known by the shortness of the shank. Mutton is in perfection at between four and five years, but is seldom to be had older than three years. Cow and bull beef are considerably inferior to ox beef.

In choosing lamb, select that which has a delicate appearance and is perfectly fresh. Young veal has a dark and flabby look, and is tasteless when dressed. Veal is best when the animal is between four and six months old. The flesh is then white and delicate, and is firm in the fibre. Pork should be white and delicate like veal, and thin in the skin. Lamb, veal, pork, and all other young or white meat, should be fresh, and not bought long before being used.

Fowls, ducks, and other feathered animals, should be purchased young, and should be all firm and fleshy to the touch. If the thin bone which projects over the belly feel hard on being handled, the animal is old; if it feel softish, like gristle, the animal is young. This is the safest rule for choosing young feathered animals. The age of game is of little consequence, as it is hung for a considerable length of time before dressing.

All kinds of fish, except salmon, should be purchased as fresh as possible. Freshness in cod, haddock, and generally all fish, is indicated by stiffness in all parts of

the body, and a clear glittering appearance in the scales. Freshness is likewise known by the smell. If there be the least staleness, the fish has an offensive odour. As tricks are sometimes performed with the eyes and gills, freshness of appearance in these is not to be trusted.

It is very difficult to ascertain when eggs are perfectly fresh. There are different rules on the subject, but they are all liable to failure. One mode of judging, is to hold the egg between the eye and the light of a candle, shadowing the eye with the hand; if the appearance is universally luminous without any cloudiness, the egg is fresh; if cloudy or not uniformly luminous, it is probable that the egg is unfit for use.

Butter may be easily selected by the taste and the smell; but in buying both eggs and butter, it is best to deal with a person on whom you can rely, as it is troublesome to be continually seeking out and examining these articles to determine their freshness.

Good ham and bacon have a fresh savoury smell; the fat is white, and free from any yellowness. If it be yellow, reject it, as it will soon become rank and rusty.

Flour for culinary purposes should be new and fresh. Old flour is liable to spoil and become full of animal life, in which condition it is unfit for pastry and other dishes. The best kind of salt for the kitchen is that which is purchased in lumps and cut down.

Keeping Meat.—A larder is a place where fresh meat is kept till it is in a fit state for being cooked, and where cold meat or any other kind of food may be set aside. The larder should be cool and dry, with the outer air playing freely through it. It should also be impervious to vermin or insects, particularly flies. Two or three shelves, and a few strong iron hooks for hanging the meat, are the only furniture.

Beef and mutton are always improved by hanging some time after being killed before they are cooked. The length of time which they may be kept depends on the state of the weather. The best weather for the purpose is when the atmosphere is cool, clear, and dry; in such circumstances, beef and mutton may hang from four to ten days; mutton, if well managed, may hang a fortnight or even three weeks. A moist thick atmosphere is the worst for keeping meat; and when it occurs, great care must be taken with the contents of the larder. The meat should be wiped daily with a cloth, to free it as much as possible from the moisture that gathers upon all meat when kept for many days. In all cases, fresh meat should hang from a hook, and not be laid on a plate.

In most instances, fresh meat is cooked too soon after being killed, a circumstance perhaps arising from the general deficiency of proper larders, and the dread of the meat being spoiled. The consequence is, that, instead of being tender and palatable, the meat is tough and disagreeable, and not so nutritious or so easily digested as it ought to be.

While beef and mutton may with great propriety be kept some days to become tender, veal, lamb, and pork (being young or white meat), will not endure keeping more than a day, or two days at the utmost. Game may be kept for two or three weeks, that which is feathered being kept with the feathers on, and hares being embowelled or paunched. A fowl will keep a week, and a turkey a fortnight. A goose will not keep above nine or ten days. Great care should be taken in picking feathered animals which have been kept, for their skin will in such a case be easily torn.

Keeping Cold Meat.—When newly cooked meat is brought from table, and has to be set aside for after use, put it on a clean dry dish; if any liquor or gravy be left about it, the meat is apt to become sour. The drier and more cool that cold meat is kept, the better. Cold meat is always best when it has not been cut while warm, as in that case the juices have not run out, but remain to enrich the meat.

Keeping Vegetables.—Vegetables of all kinds should be used as soon after gathering as possible. They begin to ferment, and to lose both their flavour and their wholesomeness, very shortly after being taken from the ground. When they have necessarily to be kept for a day or two, place them in a perfectly dry and cool situation, but not exposed to currents of wind. Keep also each kind of vegetable separate from another, to prevent contamination of flavour. They should never be washed or placed in water till immediately before being used.

Kitchen Range.—The most important part of the cooking apparatus is the range or grate. In general, too little care is bestowed by young persons when setting up housekeeping, in making a proper choice of this article. A common error consists in buying ranges which are too large, and which consume a great deal more fuel than is necessary, either for cooking or giving forth heat. One of the chief points in housekeeping, is to cook victuals with the smallest possible quantity of coal. To effect this desirable object, let the range be of a small size, consisting of a fireplace in the centre, large enough for only one vessel, with an oven upon the one side and a boiler on the other; the boiler also going round the back of the fireplace; the top of the whole to be flat. The fire in the grate will thus heat the water in the boiler without any trouble, and will in a great measure render the use of a kitchen kettle unnecessary. The fire will also assist greatly in heating the oven, which at least will at all times heat dinner plates; and if required for baking, a very small quantity of live coal put into the furnace beneath will be sufficient. A range of this description will cost about £4, 10s., will at once roast meat in front, boil water, bake a dish in the oven, though not so well as by a separate or large oven, and keep boiling or simmering at least three vessels on the fire and top of the boiler and oven. Care should be taken to have the range set in such a manner that the smoke from the oven may pass upwards behind to the chimney. By being altogether of iron, this kind of range requires very little building.

The main advantage of such a range is the constant and large supply of hot water which it affords. Every one experienced in family arrangements knows that a *house should never be without hot water*, as it may be wanted at a single moment's notice for various purposes; among others, for hot fomentations, bathing of infants, and so forth. A life may be saved by the ready supply of this article alone.

Boiling and Stewing Vessels.—The choice of these vessels will depend on the taste and judgment of the purchaser. The best kind (called goblets in Scotland, and saucepans in England) are those made of iron, well tinned inside, and these may be had of all sizes. It is convenient to have one or two of the very smallest dimensions, made of block tin, and also to have several to be kept for delicate stews or preparations. It is likewise advantageous to have a few shallow saucepans to be used for stews, or where little liquor is required. Also, one large fish-kettle with a flat drainer to place below the fish in boiling, and for lifting to the dish when done. All the vessels should have tightly-fitting tin or iron covers.

Roasting and other Utensils.—Roasting is always best performed with a twirling hook and bottle-jack. A spit spoils a small piece of meat, and is an instrument which, with the jack that moves it, should never gain an entrance into the kitchen of a family in the lower or middle ranks of life. The bottle-jack, which is in every respect preferable, should be attached to the top of a tin screen of the usual semicircular form. This screen reflects the heat upon the meat, and aids the roasting. Sometimes the screen has the effect of drawing out the

...se from the chimney; when this is the case, have the upper part of the screen taken away, and suspend the jack from a projecting arm or rack on the chimney-piece. This arm, which may be folded back when not used, is made of brass, and may be had for about eighteenpence from any London or other ironmonger. A tin box with an open side, called a Despatch, and resembling a bachelor's oven, is a most useful utensil in a kitchen for baking small puddings or potatoes. Two other main utensils for cooking are a gridiron and frying-pan.

ROASTING MEAT.

Meat is roasted by being exposed to the direct influence of fire. This is done by placing the meat before a fire, and keeping it constantly in motion, to prevent scorching on any particular part. Roasting is generally considered to be the least thrifty mode of dressing meat; but much of the loss may be avoided by care and cleanliness in saving the dripping for other processes of cookery.

Dripping.—Roast beef yields a dripping, which is a valuable article in the economy of the kitchen. It should be removed from the pan beneath the meat before it becomes overheated, or scorched, by the fire, leaving sufficient for basting. Dripping is prepared for future use in the following manner:—As taken hot from the dripping-pan, pour it into boiling water, when all particles of cinder or other improper matter will fall to the bottom, and leave the pure fat on the surface. Collect these cakes of fat, and by heating them in a jar, placed in a saucepan of boiling water, the whole will become a solid mass, and may be thus put aside for use. This process not only purifies dripping, but gives it a clear white colour. A little salt must be infused, to assist in preserving it.

The dripping from mutton, being tallowy, is little used in cookery, and the dripping from most other kinds of meat and poultry is deemed equally valueless. The dripping from lamb may be [illegible] for use in frying fish, or making pie-crust.

To roast Beef.—The best p[illegible]eef for roasting is the sirloin. If the suet be not required, it may be ordered to be cut off before purchasing the joint; a small piece of suet is all that is requisite for the purpose of basting. Do not wash the meat, unless when it is musty, as already directed. Wipe it quite dry, and hang it on the hook of the jack, in the way most advantageous for being operated upon uniformly by the fire. Handle it as little as possible. At first, place it at such a distance from the fire that it may be warmed thoroughly before being scorched on the outside. The fire must be quite clear and brisk. It is customary to allow a quarter of an hour for every pound of the meat. While roasting, baste it very frequently with its own dripping. In dishing, pour a little boiling water and salt over it for a gravy. A well-roasted joint ought to have a nice rich brown tinge all over, and this is to be obtained only by careful basting, attention to the fire, and removing at the proper time, when experience tells that the joint is "done." Garnish with scraped horse-radish.

To roast Mutton.—The best parts of mutton for roasting are the leg (called in Scotland the gigot), the shoulder, and the loin. The piece may be kept longer than would be desirable for mutton for boiling. It should have a clear and brisk fire. A leg will take two hours to roast; but this, as well as the time for roasting the other parts, must be regulated by the fire and the weight of the meat, and can be learned only by attention. The joint of mutton should be basted the same as beef, with its own dripping. A gravy for roast mutton, as in the case of beef, may be made by pouring a little hot water and salt over it; if wanted of a richer quality, a gravy sauce may be made from beef, as directed under the head Sauces. Most persons prefer mutton "well done." In roasting the loin, take away the fat surrounding the kidney, otherwise the dish, on being brought to table, will, when cut up, be floated with oil. The back-ribs and loin of mutton ought to be well jointed or cut before being put to the fire.

To roast Venison.—Venison is roasted in the same manner as mutton, but requires longer time at the fire. It is such a dry meat, and the fat is so easily melted, that it should be covered with buttered paper, and well basted. Serve with a good gravy and currant jelly.

To roast Veal.—The best parts of veal for roasting are the fillet, the breast, the loin, and the shoulder. The fillet and the breast should be stuffed, particularly the fillet; the stuffing to be composed of crumbs of bread, chopped suet and parsley, a little lemon peel, and pepper and salt, wet with an egg and a little milk. The piece should have a slow fire at first, and will require longer time to dress than beef or mutton. Let it be well basted with butter when there is not sufficient dripping from the joint. The gravy for roast veal is either the usual hot water and salt, or thin melted butter, poured over the meat.

To roast Fillet of Veal.—The fillet of veal, which is the thick fleshy part of the hind leg, requires care in the preparation for roasting. The knuckle or bone must be cut out neatly, without disfiguring the joint; then stuff the flap, as above; roll it up firmly, and bind it with tape or string. Allow the stuffing in this, as in all other cases, room to expand in dressing. Cover the ends with buttered paper, and baste the piece frequently with butter. Take off the paper a short time before the meat is done. Gravy as above. This dish may be garnished with sliced lemon.

To roast Lamb.—Lamb also requires to be well roasted. It is usually dressed in quarters; all parts, particularly the spinal bone, should be well jointed or cut by the butcher or cook; and the ribs of the fore quarter broken across the centre, in order to accommodate the carver. In roasting, baste, as for already described, with its own dripping. The gravy for lamb may be the same as for beef and mutton, namely, hot water and salt poured over it; it is also customary to serve it up with mint sauce in a small tureen.

To roast Pork.—Pork requires a longer time in roasting than any of the preceding meats. When stuffing is to be used, it must be composed of chopped sage and onion, pepper and salt. The pieces should be neatly and well scored in regular stripes on the outer skin, to enable the carver to cut slices easily. Before putting to the fire, rub the skin with salad oil, to prevent its blistering, and baste very frequently. The basting may be done by rubbing it with a piece of butter in a muslin bag, where there is not enough of dripping. The gravy for pork may be the same as for other joints, hot water and salt poured over it on the dish. It is considered an improvement to have apple-sauce served in a small tureen, as it assists in overcoming the richness or lusciousness of the meat, and imparts a slight acidulous flavour.

To roast Sucking-Pig.—The animal being properly prepared and cleaned by the butcher, the cook will proceed to cut off the feet, and fill the inside with a stuffing composed of chopped sage, crumbs of bread, butter, pepper, and salt. The quantities of these respective ingredients must be regulated by the judgment and taste of the individual. The principal ingredient is bread. The stuffing being mixed and filled in, sew up the slit. No skewering is required. In roasting, baste with butter, as directed for pork. The time for roasting will be from two or three hours, according to the size. The skin should be crisp, and nicely browned. Before bringing to table, split down the back from head to tail, and lay it

flat in the dish with the skin side uppermost. The head is cut off, and, being split in two, a half is laid at each end. The brains are taken out, and, with the liver, which has been previously boiled and finely chopped, is mixed either with beef or veal gravy in a small tureen. Apple-sauce is also used. This is the most approved mode of serving up sucking-pig.

To roast Bullocks' Heart.—Wash the heart well, freeing it completely from blood. Then fill all the openings at the top or broad end with a stuffing composed of crumbs of bread, chopped suet, parsley, pepper and salt, moistened with an egg and a little milk. Suspend with the pointed end downwards. An hour and a half or two hours, according to the degree of heat, will cook the dish. It should, however, be well done. Send to table with beef gravy.

To roast Pigeons.—Pick and draw them well, and truss, keeping on the feet. Make a stuffing of the liver chopped, crumbs of bread, minced parsley, pepper, salt, and a little butter; put this inside. Make a slit in one of the legs, and slip the other leg through it. Skewer and roast them for half an hour, basting them well with butter. Serve with brown gravy in a small tureen. Some serve roast pigeons, or game, with toast bread beneath them, and bread sauce.

To roast Fowls.—Pick, draw, and singe them. A fowl should be so cleanly or well drawn as to require no washing. Take care not to break the gall-bag in drawing; if the gall be spilled, it will communicate a bitter taste to every part it touches. Press down the breast-bone. Break the legs in the middle of the first joint, drawing out the sinews, and cutting off the parts at the break. It being proper that roast fowls should have a neat appearance at table, it is customary to truss them, that is, to fix their legs and wings in a particular position. This is done by fixing down the knees of the animal close to the tail by a skewer or piece of string, leaving the stumps of the legs projecting. The pinion ends of the wings are then turned round on the back, the liver being placed as an ornament in one wing and the gizzard in the other. Cut the head off close to the body, leaving a sufficiency of the skin to be tied or skewered on the back. Baste well with butter for some time after putting to the fire. Suspend neck downwards. The time of roasting will vary from half an hour to an hour, according to the size of the chicken or fowl. When fowls are large, they are frequently stuffed like turkey.

Serve roast fowls with melted butter or gravy sauce. Before sending to table, remove all skewers and strings which may have been used in trussing. This, which should be done in all cases of serving dishes to table, is too frequently neglected, and shows slovenliness in cookery. Fowls and all other feathered animals are served with the breast upwards.

To roast Turkey.—Pick, draw, and singe the turkey well. Press down the breast-bone, and follow all the directions given for trussing fowls. The breast should be stuffed with crumbs of bread, minced beef suet or marrow, minced parsley, a little nutmeg, pepper and salt; wet it with milk and egg; a little sausage meat may also be added. On finishing, sew up the orifice or neck. Before putting to the fire, cover the breast with a sheet of writing-paper well buttered, to preserve it from scorching, and which may be removed a short time before taking from the fire, to allow the breast to be browned. Baste well with butter. A turkey will take from an hour and a half to two hours. Serve with gravy sauce and bread sauce.

To roast Partridges.—Pick, draw, singe, and clean these birds the same as fowls. Leave the head on. Make a slit in the neck, and draw out the craw. Twist the neck round the wing, and bring the head round to the side of the breast. The legs and wings may be

trussed in much the same manner as fowls. The feet are left on, and crossed over one into the other, as seen in the annexed figure. Baste well with butter before a clear fire. When about half done, dust a little flour over them to be browned. A partridge will take from twenty minutes to half an hour, and a pheasant three quarters of an hour. Serve on toasted bread, with gravy and bread sauce; the toasted bread may be dipped in the gravy.

Grouse and blackcock should be dressed and served in the same manner; the head being trussed under the wing. Snipes and woodcocks are not drawn.

To roast Goose.—Pick, draw, and singe the goose well. Cut off its head and neck. Take off the legs and wings at the first joint. The portions of the legs and wings that are left are skewered to the sides. Stuff with chopped sage and onion, and crumbs of bread, with pepper and salt. The skin of the neck must be tied securely, to prevent the gravy from running out. Paper the breast for a short time. A goose does not require so much basting as fowl or turkey, for it is naturally greasy. It will require from two hours to two hours and a half in roasting. It ought to be thoroughly done. Serve with gravy sauce and apple sauce. The liver, gizzard, head, neck, feet, and the pinions of the goose; form what is termed the *giblets*, and compose a good stew or pie.

To roast Ducks.—Pick, draw, and singe them well. Take off the head. Dip the feet in boiling water to take off the outer yellow skin. Truss them neatly, turning the feet flat upon the back. Stuff as in the case of goose, and serve with the same sauces. A duck requires about an hour in roasting.

To roast Pheasants.—Pick, singe, and draw them, the same as fowls. Truss them by twisting the head round one of the wings, and turning both wings on the back. The legs are fixed on each side, much in the same manner as in a roast fowl, the feet being left on, as here represented. Serve with beef gravy and bread sauce.

To roast Hare.—A hare will keep with the skin on it, and paunched, for about three weeks in cold weather. It is then fit for roasting. First cut off the feet, and commence drawing off the skin at the hind legs, proceeding along the body to the head. Be careful not to tear the ears in skinning them. Soak and wash well in several waters, and then wipe quite dry. Stuff with crumbs of bread, chopped parsley, a bit of beef or veal suet chopped finely, a little grated lemon-peel and nutmeg, a piece of liver boiled and finely chopped or grated, and pepper and salt; the whole moistened with an egg, a little milk, and a spoonful of ketchup. The skin of the belly afterwards to be sewed. Commence trussing, by placing the hind and fore legs flat against the sides. To make the hind legs lie flat, the under sinews must be cut. Fix the head between the two shoulders, on the back, by running a skewer through it into the body. In roasting, suspend head downwards. It may be basted first with milk, afterwards with butter, flouring it lightly

it will require from an hour and a half to two hours. The hare is dished back upwards, as represented above, and served with a dish of rich beef gravy, and a dish of currant jelly.

BAKING MEAT.

Meat is prepared for baking in the same manner as for roasting. It should be placed in a deep dish for receiving the fat which flows from it; not laid, however, on the sole of the dish, but raised on a stand, to prevent the grease soaking into it. Small iron stands are made and sold for this purpose. Few dishes are so good when baked as when roasted, the meat being so liable to be shrivelled for lack of basting. Perhaps the only dishes which are better baked than roasted, are bullock's heart and leg of pork, because in roasting they are liable to be scorched on the outside before they are thoroughly cooked in the inner parts. In baking a heart, place it in a stand in a dish with the point downwards; a piece of writing-paper, buttered, may be placed over it, to keep the stuffing from drying. The sauce used is beef gravy.

BROILING.

Broiling is the rapid cooking of any kind of animal food, by the influence of fire. The apparatus required in broiling is very simple, and consists only of a gridiron, which should have small bars, and be kept thoroughly clean, not only on the tops, but on the sides of the bars. Let it be heated on the fire for a few minutes before placing the meat on it. If the bars, when warm, be rubbed with a piece of brown paper, the meat will be prevented from sticking to them. The operation of broiling requires a clear, strong fire, with no smoke. In almost all cases, the meat ought to be frequently turned, which may be best done by a pair of small tongs; a fork should on no account be used in turning, for it breaks the skin of the meat, and allows the gravy to run out. Broiling possesses the peculiarity of being applicable only to meat which is to be eaten immediately on being dressed. This is an advantage when expeditious cooking is required, but a disadvantage when there is any uncertainty as to the time at which the meat is to be eaten.

To broil Beef-steak.—A beef-steak is the most suitable of all kinds of meat for broiling, and is a dish universally relished. There are several parts of beef used for steaks, but in every case it should not be too newly killed. The best steak is that cut from the rump (called in Scotland the *heuk-bone*), because it is the most juicy and well flavoured. Steaks should be cut in slices of from three quarters of an inch to an inch in thickness, and into pieces of a convenient size for turning. Some persons dust the steaks with pepper before putting them to the fire, by which means the flavour of the pepper is infused through the mass. When placed on the gridiron, turn them very frequently; it is said, indeed, that the steaks should never be at rest, but this is carrying matters to an extremity. It is impossible to state any exact length of time to be employed in cooking a steak, for much depends on the tenderness and thickness of the meat, and the strength of the fire. The taste of the individual who is to eat the steak must also regulate the length of time; because, while some prefer steaks in a half-raw state, others wish them to be well done. When cooked to the extent which is required, place the steak on a hot dish, and, after rubbing the steak with a little good fresh butter, sprinkle it with a little fine salt.

Beef-steaks should be carried to table immediately on being dressed, and eaten forthwith, in order to be in perfection. Every moment they stand, they lose a portion of their flavour and juice. When sauce is required, either mushroom or oyster sauce may be used.

To broil Mutton-chops.—Mutton-chops should be cut from the middle of the hind loin, and about the same thickness as steaks. They are broiled in the same manner as steaks, and require equal attention. No butter is to be used on dishing, as the chop is sufficiently fat of itself. Sprinkle a little salt on it, and carry to the table immediately. Mushroom sauce may be used.

To broil Fowls and Pigeons.—Clean and prepare them as for roasting; then split them down the back, laying them quite flat. Dust with pepper. They should be broiled more slowly than steaks or chops, being thicker, and requiring to be more thoroughly dressed. Rub occasionally with a little butter, to prevent the skin from cracking. In no case should the skin be taken off before broiling. On dishing, sprinkle with salt.

Various sauces are used—parsley and butter, melted butter, beef gravy, or mushroom sauce.

FRYING.

Frying is as expeditious a mode of cooking as broiling, requires less activity and care, and is more thrifty. The thriftiness of frying is a point of material consequence, and may be thus explained. It affords a ready means of dressing in a savoury manner many odd pieces of uncooked or cold meat, thereby saving that which might otherwise have been thrown away as useless. A skilful housewife, with the aid of a frying-pan and some unexpensive vegetables, such as onions and potatoes, along with a slight seasoning, will make a small portion of meat dine a large family.

A trying-pan should be of malleable, not of cast, iron. It should also be thick in the bottom, and of an oval form. It should always be kept clean, by being washed with boiling water, but not scoured. In all cases of using, a small piece of dripping, butter, or lard, must be put into it and melted, to prevent the meat from adhering. In frying all meats, excepting those which are sufficiently fat of themselves, it is necessary to use some kind of grease or fat. The best fat for this purpose is lard, which is more economical, and less likely to burn than butter. When lard is not employed, the best substitute for it is dripping.

To fry Beef-steaks.—Cut the steaks as for broiling, and, on being put into the pan, shift and turn them frequently. Let them be done brown all over, and placed in a hot dish when finished. Gravy may be made by pouring a little hot water into the pan after the steaks are out, and the fat poured away, with a little pepper, salt, ketchup, and flour. The gravy so formed is to be poured into the dish with the steaks. Serve to table immediately.

If onions be required along with the dish, cut them in thin slices, and fry them till they are soft. They should be fried after the steaks, and merely with part of the fat in which the beef has been fried.

To fry Mutton-chops.—They require to be cut in the same manner as for broiling, and may be dressed according to the preceding directions for steaks. None of the grease which flows from the chops is to be used along with them, and the whole must be poured away before preparing the gravy.

To fry Veal cutlets.—Veal cutlets form a delicate dish, and should be fried with butter. The best cutlets are from the fillet, because they are free from bone; the fore or hind loin—that is, the back-ribs or loin—may be used, but the bone must be cut away, which causes a waste. Cut them half an inch in thickness. They require to be dressed slowly and thoroughly, and should be of a light brown tinge when finished.

Another and more tasteful way of dressing cutlets, is first to dip them in a beat egg and then strew them with crumbs of bread, and parsley chopped very fine, along with pepper and salt, after which put them in the pan. They will require more lard or dripping this way than when fried plain.

Gravy may be made for cutlets the same as for fried steaks, but add a little juice of lemon, and skim the gravy before pouring it over the cutlets.

To fry Lamb-chops.—Lamb-chops may be either simply fried in the same manner as mutton-chops, or dressed with egg and crumbs of bread (but with no parsley), as in the case of cutlets. Gravy made in the pan, as for fried steaks.

To fry Pork-chops.—Pork-chops should be cut rather thin, and be thoroughly dressed. They may be either simply fried in the same manner as chops, or fried after being dipped in egg, and sprinkled with crumbs of bread, and sage and onion finely chopped. No gravy is expected with pork-chops. If any sauce be used, it must be apple-sauce.

To fry Beef or Pork Sausages.—All sausages are fried alike, and require to be dressed very slowly. Before being put into the pan, they should be pricked in several places with a fine fork, to prevent their bursting by the expansion of the air within.

It is common in England to bring fried sausages to table, neatly laid out on a flat dish of mashed potatoes. The sausages and potatoes are helped together. They may also be laid in links on toasted bread, and garnished with poached eggs round the dish.

Fried sausages are sometimes used for garnishing roast turkey.

To fry Tripe.—The tripe must be washed well, and boiled till tender. Take the thickest parts, and dry them well with a cloth. Make a thick batter of egg, flour, and milk, seasoned with salt, and for those who wish it, a little minced onion. Dip the tripe into the batter so formed, after which fry in lard or good fresh dripping, of which there must be a sufficiency in the pan almost to cover the tripe. Let it be done to a light brown. Garnish with fried parsley.

To fry Parsley.—Parsley is fried only for garnishing. It must be thoroughly dried, and fried in hot butter or dripping. After frying, lay it on a sieve before the fire for the fat to drain from it; after which, place it round the edge of the dish.

To fry Bacon, or Ham and Eggs.—The bacon should be cut very thinly in slices not more than a quarter of an inch in thickness. The best bacon is that which is alternately streaked with fat and lean. No butter or dripping is required in the pan in frying bacon, which does not need much dressing, and is soon prepared. When done, take the slices from the pan, and place them in a hot dish before the fire. Have the number of eggs required previously broken, each in a separate cup, and place them gently in the pan, so as to preserve them in a round flat shape. Let them remain in the pan till the white is set, and take them out carefully with a slice, and place them on the bacon. The tasteful appearance of this dish is spoiled if the eggs be either broken or ragged, which is very apt to be the case if they are not previously put into cups.

To fry Collops.—The difference between this dish and fried steaks, is, that the collops or pieces of meat are partially stewed, as well as fried. Cut the meat thinner than for broiling, and put the slices in a pan along with a large piece of butter and sliced onions. Cover it close, and when the meat is sufficiently dressed, add a little hot water and ketchup to the liquor already in the pan.

BOILING.

Boiling is the preparation of meat in water, and it is necessary that the vessel employed be large enough to allow the meat perfect freedom; if it be cramped, and have only a little water, it will be stewed, not boiled. In all cases of boiling, there must be a sufficiency of water to cover the meat. In boiling meat there is less waste than in roasting; and, in some cases, soup may be made of the liquor. It is a general direction for boiling, that all meat, poultry excepted, should be put into cold water, and not boiled too fast. In every case, let care be taken to remove the scum from the top of the water, just before it boils; this keeps both the meat and the water clean, and agreeable in appearance. As the water decreases from evaporation, replenish with *hot* or *boiling* water, so as to keep the meat always covered. It is usual to allow a quarter of an hour for every pound of the meat in boiling, reckoning from the time the water begins to boil; but this is a rule which will, of course, be departed from, according as the meat is required to be over or under done. In some cases, slow simmering is the most advantageous mode of dressing, and it is always better to boil slowly than quickly. Rapid boiling hardens the meat. Perfectly fresh meat requires longer boiling than that which is tender or ripe. Good meat swells in boiling, whatever may be the loss of weight.

When meat of any kind is done and has to be lifted from the pot, take care not to put a fork into any part where there are juices; if this be not attended to, a portion of the juices will escape, and the marks of the fork will produce an unsightly appearance in the meat. All parts of mutton and lamb may be roasted, but it is only the leg, neck, and head, that are boiled.

To boil a salted Round of Beef.—If large, cut out the bone, roll it up firmly, and bind it with a tape; then put it into the pot, and keep the lid close. Boil it slowly and equally, allowing, as above mentioned, a quarter of an hour for each pound of the beef.

The appropriate garnishing for this and other pieces of boiled salt beef, is carrot and small greens; some add turnips. Put a little of the liquor in which it has been boiled in the dish.

To boil a Leg of Mutton.—A leg of mutton should be kept four or five days before boiling. Before putting it into the pot, bend round the shank, cutting the tendon at the joint if necessary, so as to shorten the leg. Two hours of slow equal boiling will be sufficient for a good-sized leg of mutton. Some persons, to make the leg look white and tasteful, wrap it tightly in a cloth in boiling; but this spoils the liquor for broth. It is not safe to boil vegetables with a leg of mutton, as they are apt to flavour the meat. Dish the leg with a little of the liquor, placing the lower side uppermost, conveniently for carving. A good leg of mutton will soon yield sufficient gravy.

The sauce used is finely chopped capers in melted butter. Turnips mashed or whole form the appropriate vegetable to be eaten with this dish.

To boil a Leg of Lamb.—A leg of lamb, when well boiled, is a delicate and excellent dish. It requires about an hour and a half. When whiteness is desirable, it is wrapped in cloth, the same as mutton. When dished, garnish with the loin cut into chops, and fried, to lay round it. The sauce used is plain melted butter, or parsley and butter.

To boil Veal.—Veal is seldom boiled, being too insipid by that mode of dressing. The only part boiled is the knuckle, which requires much boiling, in order to soften the sinews. It is eaten with boiled ham or bacon. The sauce used is parsley and butter. The liquor from boiled veal is the best of any for making soup.

To boil a Turkey.—Boiled turkey is one of the most delicate and excellent dishes which can be brought to table, and should be dressed with as much care as possible. Clean the turkey from all feathers, and singe the hair with burning paper, being careful not to blacken the skin. Clean it well inside by drawing and wiping. Cut off the legs at the first joints, and draw out the sinews; then pull down the skin and push the legs inside. Cut off the head close to the body, leaving the skin long, and draw out the craw. Make a stuffing of chopped suet, crumbs of bread, chopped parsley, pepper, salt, and a

little nutmeg, which wet with an egg and milk. Put this stuffing into the breast, leaving room for the stuffing to swell; after which draw the skin of the breast over the opening and sew it neatly across the back; by which means, when the turkey is brought to table with its breast uppermost, no sewing will be seen. Place the liver in one wing, and the gizzard in the other, turning the wing on the back, and fixing the wings to the sides with a skewer. The turkey being now ready for the pot, put it into a cloth and boil it for a length of time according to the size and age. A small young turkey will not require more than an hour and a half; an old and larger one perhaps two and a half or three hours. Let the water be warm in putting in, and of sufficient quantity to keep the turkey always covered.

When done, and placed in a hot dish, pour a little sauce over the breast, and put the remainder in a sauce tureen. The sauce used is various, as parsley and butter, celery, or oyster sauce. One of the most delicate and agreeable sauces, is that which is made of melted butter, boiled maccaroni, and milk.

To boil a Fowl.—A fowl is to be prepared for boiling in the same manner as a turkey, except that no stuffing is used. It may be boiled with or without a cloth. Small fowls will require from half an hour to three quarters of an hour; large fowls will require from an hour to an hour and a half. Sauce, parsley, and butter.

To boil Rabbits whole.—Wash them well in warm water. They may be either stuffed or not stuffed, according to taste. When stuffing is required, make it of crumbs of bread, suet, parsley, and onions—all chopped—and pepper and salt; moisten with milk and egg. Sew this neatly into the belly. Truss in the same manner as roast hare, and boil slowly for an hour. The sauce to be made of boiled onions, milk, melted butter, and flour, with pepper and salt, which pour over the rabbits when dished. This is called *rabbits smothered in onions.*

When two rabbits are dished together, lay the head of one in a contrary direction to that of the other.

To boil a Ham.—If the ham has been cured long, it may require soaking in cold water to soften it, from twelve to twenty-four hours before dressing. Put it in a large boiling vessel, with plenty of cold water, and let it simmer slowly from two to four hours, according to the size. Skim it frequently, to remove the grease which is constantly rising to the top. When done, skin it, and strew bread raspings over the upper side; then place it before the fire to dry and brown. Garnish with greens or cabbage.

To boil Leg of Pork.—Pork requires to be particularly well boiled. Place it in the pot with the skin side uppermost, with a plate below it, for pork is very apt to stick to the bottom of the pot. Peas pudding is generally served separately with this dish.

To boil a Tongue.—If hard, soak the tongue in water all night before using. Boil it from two hours and a half to three hours. Skin it before dishing. Garnish with greens or cabbage.

To boil Tripe.—When tripe is purchased from the butcher in a raw state it requires to be boiled a very long time to be thoroughly soft and tender. The length of time will depend on the age of the animal from which it has been taken. Sometimes, for young tripe six or seven hours will be sufficient, while old tripe will perhaps take ten or twelve. In all cases, boil, or rather simmer it very slowly, for quick boiling hardens it. It should be cut into moderately sized pieces for helping at table. When to be served plain, carry to table in a hash dish, in some of the water with which it has been boiled, with boiled onions in it. A tasteful way of serving, is to take it from its liquor after boiling, and stew it for about ten minutes in a saucepan with milk, which thicken with a little arrowroot, or flour and butter, and season with pepper and salt. This makes a delicious and cheap dish.

To boil Cow-heel.—Cow-heel should be boiled for five or six hours, or till the bones will slip out. Serve with a sauce of chopped parsley and butter.

STEWS, HASHES, AND MADE DISHES.

Stewing is the preparing of meat by slow simmering or boiling, and by which all the liquor is to be used along with the meat at table. This is a much more savoury mode of cookery than boiling, because the substance of the meat is partly in the liquor, and is seasoned to have a high relish or flavour. Generally, much more can be made of meat by stewing, than by roasting, broiling, or frying, because nothing is lost in the process of dressing. It also possesses the decided advantage of being a way by which meat may be dressed for a person whose time of dining is uncertain. A stewed steak, for instance, will keep warm and in good condition for an hour, but a broiled or fried steak cannot keep a minute after dressing.

To stew a piece of Beef, or make Beef Bouilli.—Take a piece of beef—the brisket or rump, or any other piece that will become tender. Put a little butter in the bottom of the stew-pan, and then putting in the meat, partially fry or brown it all over. Then take it out, and lay two or three skewers in the bottom of the pan; after which replace the meat, which will be prevented from sticking to the pan by means of the skewers. Next, put in as much water as will half cover the meat. Stew it slowly, with the pan closely covered, till done, with a few onions, if required. Two hours are considered enough for a piece of six or eight pounds. When ready, take out the meat, and thicken the gravy with a little butter and flour. Cut down into handsome shapes a boiled carrot and turnip, and add them to the liquor; season with pepper, salt, and a little ketchup. Boil all together for a few minutes, and serve in a hash dish.

To stew a Shoulder of Mutton.—Take a shoulder of mutton, and cut out the blade bone without injuring the form of the meat. Make a stuffing of crumbs of bread, chopped suet and parsley, a little green or dried sweet herbs, chopped onion, and pepper and salt, moistened with egg and milk. Lay this stuffing in the place from which the bone was cut out; then roll it up, and skewer or bind it firmly with tape. Rub the bottom of a stew-pan with suet or butter, and brown the mutton. When sufficiently brown, lay two skewers in the bottom of the pan; add a little stock or boiling water, and let it stew for an hour and a half; the gravy drawn from itself will be sufficiently rich for sauce, seasoned with pepper and salt. Skim it before serving, to remove the fat.

To stew Steaks and Chops.—Cut the beef in slices rather thinner than for broiling or frying. Put them in a stew-pan, with water sufficient to make gravy. Add grated carrot, turnip cut in small squares, and pepper and salt. Stew for an hour, or till tender. Skim if necessary. When done, thicken the gravy with a little arrowroot or flower, and flavour with ketchup. Some persons add a little maccaroni or vermicelli, which requires from ten to twenty minutes' boiling along with the stew.

Mutton-chops are stewed in the same manner, but require to be trimmed of the superfluous fat, and more carefully skimmed. This is called *harricot of mutton* when the chops have been previously browned. The same directions will serve for stewing slices or pieces of any other kind of meat.

To stew Veal.—The best parts of veal for stewing are the fillet, the breast, and the shoulder. The shoulder must be stuffed when the knuckle is cut out, which must be done neatly, without disfiguring the meat; the stuffing

should consist of bread-crumbs, minced suet, chopped parsley, grated lemon-peel, white pepper and salt, moistened with egg and milk; fill the shoulder, and sew it up. Rub the bottom of a large stew-pan with butter, lay in the veal, and brown it on both sides. When sufficiently brown, put in a pint of cold water, and stew it slowly for two hours, or, if large, two hours and a half. Before it is to be dished, draw off the gravy, and if not thick enough, brown a little butter, and dust in a little flour; put it among the gravy, and season with Cayenne, salt, and the squeeze of a lemon (a glass of sherry will be an improvement); skim the sauce, and pour it over the meat before dishing.

To stew Kidneys.—Cut the kidneys into slices; wash them, and dry them with a clean cloth; dust them with flour, and fry them with butter until they are brown. Pour some hot water or beef gravy into the pan, a few minced onions, pepper and salt, according to taste; let them stew slowly for an hour, and add a spoonful or two of mushroom ketchup before dishing.

To stew Pigeons.—Pick and wash the pigeons well, trussing them as fowls for boiling. Put a piece of butter and some pepper inside; dust them with flour, and brown them in a covered stew-pan with a good piece of butter; put in a little flour; add some gravy or hot water. Season them highly, and let them stew slowly for twenty minutes or half an hour. Before dishing, add half a glass of port wine, if the flavour be approved.

To stew Rabbits.—Wash the rabbits well; cut them in pieces, and put them into scald for a few minutes. Melt a piece of butter, in which fry or brown the rabbits for a short time. When slightly browned, dust in some flour; then add as much gravy or hot water as will make sufficient sauce. Put in onions, ketchup, pepper and salt, according to taste. Stew for an hour slowly. When required, flavour the gravy with a small quantity of curry powder.

To make Irish Stew.—Take a piece of loin or back-ribs of mutton, and cut it into chops. Put it in a stew-pan with pared raw potatoes, sliced onions, pepper, salt, and a little water. Put this on to stew slowly for an hour, covered very close; and shake it occasionally, to prevent it from sticking to the bottom.

To make English Stew.—English stew is the name given to the following excellent preparation of cold meat. Cut the meat in slices; pepper, salt, and flour them, and lay them in a dish. Take a few pickles of any kind, or a small quantity of pickled cabbage, and sprinkle them over the meat. Then take a tea-cup half full of water; add to it a small quantity of the vinegar belonging to the pickles, a small quantity of ketchup, if approved of, and any gravy that may be set by for use. Stir all together, and pour it over the meat. Set the meat before the fire with a tin behind it, or put it in a despatch, or in the oven of the kitchen range, as may be most convenient, for about half an hour before dinner-time. This is a cheap and simple way of dressing cold meat, which is well deserving of attention.

To hash Beef or Mutton.—Cold roast beef, or cold roast or boiled mutton, may be dressed as a hash in the following manner. Cut the meat from the bones into small pieces, and lay them aside. Then put the bones in a stew-pan, with a little water and sliced onion. After stewing for a short time, take out the bones and put in the meat. When the meat is perfectly hot, thicken with a little flour and butter, and season with pepper and salt, and a little ketchup. Dish the hash, and stick small triangular pieces of dry toasted bread round the inner edge of the dish.

To dress Cold Boiled Beef, or make Bubble and Squeak.—Cut the beef in slices of about the third of an inch in thickness. Fry the slices till lightly browned, and heated through. Then take them from the pan, and place them on a warm plate before the fire, to keep hot. Fry some cabbage which has been previously boiled and chopped; stir this about a short time in the pan, and season with pepper and salt. Spread the cabbage in a dish, and place the slices of meat upon it; or heap the cabbage in the dish, and place the meat around it.

To mince Cold Veal.—Cut the veal from the bones, and mince it in small square bits, and lay them aside. Then put the bones in a stew-pan with a little warm water, to make a gravy. After stewing for a short time, take out the bones and put in the bits of veal, with a small piece of lemon-peel, chopped very fine. When perfectly heated, thicken with a little flour and butter, and season with pepper and salt, and a little lemon-juice. Dish with small pieces of toasted bread, as in hashed mutton.

To dress a Lamb's Head and Pluck.—Lambs' heads are procured skinned. Take the head with the neck attached; split up the forehead, and take out the brains, which lay aside. Wash the head carefully, cleaning out the slime from the nose, by rubbing it with salt, and take out the eyes. The head being thus cleaned, put it on to boil, along with the heart, and the lungs or lights. Let the whole boil for an hour and a quarter; then take them out, and dry the head and neck with a cloth. Rub it over with an egg well beaten; strew crumbs of bread, pepper and salt, over it; also stick small pieces of butter over it, and lay it in a dish before a clear fire, to be browned lightly. Mince the lungs and heart, and part of the liver, with some onion, parsley, pepper, salt, a little flour, grated nutmeg, and a table-spoonful of ketchup; mix all together, and add some of the liquor in which the head was boiled to form a gravy; let it simmer by the side of the fire for half an hour. Take the brains and beat them well with two eggs, two table-spoonfuls of flour, and a sprig of fine chopped parsley, also a little pepper and salt, and two or three table-spoonfuls of milk—the whole forming a batter. Have a frying-pan with a little lard or dripping, and fry the batter in small round cakes, which turn and brown lightly on both sides. Cut the remainder of the liver in slices, and dust it with flour, and fry it. Now, lay the head upon a dish; place the hash round it, and lay a slice of liver and a brain cake alternately on the hash all round.

This forms a handsome and a savoury dish, but requires great attention on the part of the cook, to have all the various parts hot and equally ready at the time of dishing.

To make Potted-Head.—This is a dish to be eaten cold as a jelly. Take the half of a bullock's head and clean it; soak it in warm water, with a cow-heel, for two or three hours. Then boil it with the heel till tender. When done, cut them in small pieces, and lay them aside; after which, strain the liquor in which they have been boiled, and let it stand till it is cold, so that the fat may be easily skimmed. Put the whole into a sauce-pan, and boil for half an hour, and season with pepper and salt according to taste. Pour it into basins, or tin or earthenware shapes, which stand in a cool place. When quite cold, it forms a jelly, and is ready for being turned out on a dish for use. If it do not come out easily, dip the basin or shape in hot water, and the heat will immediately loosen it. Garnish with sprigs of fresh parsley.

SOUPS AND BROTHS.

Soups are the substance of meat infused in water by boiling, and are of many different kinds, but may be divided into two classes, namely *brown* and *white*. The basis of brown soups is always beef, while the basis of white soups is generally veal. Broths are preparations of soup, but more simple in their nature, and usually containing some kind of vegetables or matter for thickening, as rice, barley, &c. Soups of every description

should be made of sound fresh meat and soft water. It is a general rule to allow a quart of water for every pound of meat; also to boil quickly at first, to make the scum rise, which is assisted by adding a little salt; and after skimming, to simmer gently.

To make Brow or Gravy Soup.—Take a shin or piece of the rump of beef, and break it in several places. Cut the beef from the bones; take out part of the marrow, and lay it on the bottom of the pot. If there be no marrow, use butter. Then lay in the meat and bones to brown. Turn the whole, when browned, on one side, and take care that it does not burn. When it is thoroughly browned, add a pint of cold water to draw the juice from the meat, also a little salt; and in a quarter of an hour after, fill in the quantity of cold water which may be requisite. Now add the vegetables, as for instance, two carrots, a turnip, and three or four onions, all sliced; also a stalk of celery, some sweet herbs, with some whole black and Jamaica pepper. Let the soup boil slowly for from four to five hours, after which take it off, and let it stand a little to settle. Then skim off the fat, and put it through a hair sieve to clear it. The soup, if cleared, may now be either served or set aside for after use. It should have a clear bright look, with a brownish tinge. Frequently, it is made the day before using, in order that it may be effectually skimmed of fat. In such a case, it is heated again before serving. On some occasions, it is served with a separate dish of toasted bread cut in small squares.

The meat which has made the soup is supposed to be divested of nearly all its nourishing qualities; but where thrittiness is consulted, it may form an agreeable stew, with vegetables, a little ketchup, and pepper and salt.

Brown soup made as above directed, forms what is called *stock*, that is, a foundation for every other soup of the brown kind, also a gravy for stews where richness is required. It likewise forms any kind of vegetable soup, by merely adding to it, when just finished boiling and clearing, the particular vegetable which may be required. Thus are formed *carrot soup*, the carrots being cut into small stripes or straws; *leek soup*, by adding leeks cut into short pieces, and boiling an hour; *vermicelli soup*, by adding boiled vermicelli; and so on with other vegetables.

Kidney Soup.—Make a stock, or gravy soup, as above directed. Cut two beef kidneys in slices; wash them well, and stew them in water or soup for an hour. Take out the kidneys and strain the soup. Then return the kidneys to the soup so strained, and add as much stock or gravy soup as is required. Let the whole boil for a few minutes, and serve in a tureen.

Pigeon Soup.—Make a stock, or gravy soup, as above directed. Add to this the livers and gizzards of your pigeons, and boil for half an hour. Then truss the birds as for boiling, and season them inside with pepper and salt; dust them over with flour, and brown them with a little butter in a frying-pan. Mix a little butter and flour, and stir it into the soup to thicken it. Strain the soup, and put the pigeons into it. Let the soup with the pigeons boil very gently for half an hour, skimming when required, and serve in a tureen.

Ox-tail Soup.—Make a quantity of brown soup, as previously directed. Take two or three tails, and separate them, at the joints, into pieces. Put the whole in the soup, and boil till the meat is tender, but not till it comes from the bones. Add a little ketchup, and serve with the pieces of tail in the soup.

Hare Soup.—Take a fresh hare, and, when skinned, wipe it well with a cloth. Cut it open, and take out the entrails, taking great care not to lose any of the blood. Then cut the body into separate pieces, and put them in a pot with two or three quarts of water, along with any blood that may have run out. Put into the pot, also, two or three pounds of beef cut into pieces, likewise a sliced carrot, turnip, and onion, a few sprigs of thyme, a few Jamaica pepper-corns and four table-spoonfuls of flour mixed with cold water. Keep stirring till it boil, and let it boil for an hour and a half. When this is done, take the best pieces of the hare, which are the back and upper joints of the hind legs. Lay these aside. Let the soup boil for other two hours. Then take out the remainder of the meat, and cut it off the bones and pound it in a mortar, or otherwise mash it well. Put the meat thus pounded back into the soup, and strain the whole through a hair sieve. Put the soup so purified into the pot, along with the best pieces of the hare which were laid aside, also two table-spoonfuls of ketchup. Boil this for half an hour: then add pepper and salt, and serve with the pieces of hare in the tureen.

Jugged Hare.—After having skinned, drawn and washed the hare, cut it into pieces, and put the pieces into a jar with an onion, a bunch of sweet herbs, and a little water. Cover the top of the jar so close that very little of the steam can escape from it; the cover may be tied down to the jar. Place it in a saucepan of water, the water not to cover the top of the jar. Keep the water constantly boiling. Boil between three and four hours. When done, skim off any fat, thicken the sauce with flour and butter, season with salt and pepper, and serve all together in a hash dish.

Mock-Turtle Soup.—This is made with a calf's head. It is best to get the head ready scraped and cleaned from the butcher, but with the skin on. If it be got in an uncleaned state, wash it, and put it into a pot with cold water, and boil it for a short time till the hair is loosened. Then scrape off the hair, split the head, clean it thoroughly, and take out the brains. The head is now supposed to be clean, and ready for making the soup. Put it into a pot with considerably more water than will cover it. Skim it frequently as it warms, and let it boil gently for an hour. Take out the head, and when it has cooled, cut the meat off into handsome pieces, of about an inch square. Scrape and cut the tongue in the same manner. Lay all these pieces aside. Then put into the water in which the head was boiled, about three or four pounds of hock of beef and a knuckle of veal, with the bones broken. Add to this four or five onions, a carrot and turnip sliced, a small bunch of sweet herbs, and some black and Jamaica pepper, whole. Add also the brains, after you have boiled them separately in a cloth, and pounded them. With all these additions let the soup boil slowly for four or five hours, after which strain it, and when cool, take off the fat. Take a quarter of a pound of fresh butter, and melt it in a stew-pan; when melted, put in two handfuls of flour and let it brown, stirring it all the time; add a little of the soup, a sprig or two of sweet basil, and a few heads of parsley. Boil this for a quarter of an hour; strain it through a sieve; then put this, the pieces of meat, and the soup, all together, and boil it for an hour. Add two table-spoonfuls of ketchup, the juice of a lemon, Cayenne pepper, and salt to taste. It is usual to put in at the same time four glasses of sherry wine. When dished in a tureen, put in two dozen of egg-balls.

Egg-balls for mock-turtle soup are made as follows. Boil four or five eggs till they are quite hard. Take out the yolks, and beat them in a mortar, with salt and Cayenne pepper. Make this into a paste with the white of one or two raw eggs. Roll the paste into balls the size of small marbles. Roll them in a little flour, and either fry them in butter or brown them before the fire, being careful to keep them whole and separate. They are now ready for being put into the soup.

Peas Soup.—This is an excellent soup, if well made, and is one of the cheapest dishes that can be put on the

table, for it may be formed of cold meat or marrow-bone, or, what is cheaper still, merely water, or the liquor in which any piece of mutton, lamb, or veal, has been boiled. We give the following two recipes for making it:—

Peas Soup, with meat or bones.—Take a good marrow-bone, or the bones of cold roast beef; a slice or shank of ham may be added, if the flavour be liked. Break the bones, and put them in the pot with four quarts of cold water. According to the thickness and quantity required, take two or three pounds of the best split peas, and put them among the cold water and bones; add to this two carrots, two turnips, half a dozen small onions, a stalk of celery cut in pieces, a bunch of thyme, and some whole black and Jamaica pepper. Let all this boil for two hours, stirring frequently, as the soup is very apt to burn. When the peas are quite soft and broken down, take the soup off, and put it through a sieve, into another pot; rub it well through until the pulp be mixed with the soup. Add salt melted among a little water, and boil the soup again for a few minutes. When to be served, cut a slice of toasted bread into small square pieces, and put in the tureen with the soup.

Peas Soup, without meat or bones.—Put two pounds or pints of peas in five quarts of water. Boil for four hours; then add three or four large onions, two heads of celery, a carrot and a turnip, all cut up; and season with salt, to taste. Boil for two hours longer. If the soup become too thick, add a little water. The peas may be boiled the evening before being used, and the longer they boil, the smoother and more mellow the soup will be; but do not put in the vegetables until the day the soup is to be used. By this plan the soup does not require straining.

Mutton Broth.—This is a broth of a mild nature, being intended chiefly for invalids. Take a scrag or thick end of a loin of mutton, and put it into a pot with cold water; the proportion being a quart of water to a pound of meat, which will allow for loss in boiling. Turnip and onion may be added when not considered injurious. Let this boil slowly for three hours, and skim off all the fat before serving. The meat is supposed to be useless.

Beef Tea.—Take a pound of lean beef, which cut in pieces, and put into a saucepan with a quart of cold water. Place it on a slow fire, and skim it carefully as it heats. Let it simmer gently for about an hour, and before serving, strain it through a hair sieve. Season with a little salt.

Another method.—Take a pound of good lean juicy beef, and cut it into very thin slices, which place in a basin. Then pour a pint and a half of boiling water on the meat, moving it frequently with a fork or spoon, to cause the water to act upon all sides of the meat, and so extract its juices. Let it remain in the water about a quarter of an hour, after which pour the water into a saucepan, and boil it for about ten minutes. Skim and season with salt. This is the most delicate way of making beef tea.

SCOTCH DISHES.

Sheep's Haggis.—There are different ways of making a haggis, as far as the exact composition of the materials is concerned. Some put minced tripe in it, others put no tripe. The following is the more common, and, we believe, the best manner of making it: Procure the large stomach bag of a sheep, also one of the smaller bags called the king's hood, together with the pluck, which is the lights, the liver, and the heart. The bags must be well washed, first in cold water, then plunged in boiling water, and scraped. Great care must be taken of the large bag; let it lie and soak in cold water, with a little salt, all night. Wash also the pluck. You will now boil the small bag along with the pluck; in boiling, leave the windpipe attached, and let the end of it hang over the edge of the pot, so that impurities may pass freely out. Boil for an hour and a half, and take the whole from the pot. When cold, cut away the windpipe, and any bits of skin or gristle that seem improper. Grate the quarter of the liver (not using the remainder for the haggis), and mince the heart, lights, and small bag very small, along with half a pound of beef suet. Mix all this mince with two small tea-cupfuls of oatmeal, previously dried before the fire, black and Jamaica pepper, and salt; also add half a pint of the liquor in which the pluck was boiled, or beef gravy. Stir all together into a consistency. Then take the large bag, which has been thoroughly cleansed, and put the mince into it. Fill it only a little more than half full, in order to leave room for the meal and meat to expand. If crammed too full, it will burst in boiling. Sew up the bag with a needle and thread. The haggis is now complete. Put it in a pot with boiling water, and prick it occasionally with a large needle, as it swells, to allow the air to escape. If the bag appears thin, tie a cloth outside the skin. There should be a plate placed beneath it, to prevent it sticking to the bottom of the pot. Boil it for three hours. It is served on a dish without garnish, and requires no gravy, as it is sufficiently rich in itself. This is a genuine Scotch haggis.

Lamb's Haggis.—This is a much more delicate dish, and less frequently made than a sheep's haggis. Procure the large bag, pluck, and fry of a lamb. The fry is composed of the small bowels, sweetbreads, and kernels. Prepare the bag, as in a sheep's haggis. Clean thoroughly the small bowels and other parts; parboil them, and chop them finely along with a quarter of a pound of suet. Mix with dried oatmeal, salt, and pepper, and sew the mixture in the bag. Boil it, and attend to it in the same manner as a sheep's haggis.

Broth or "Kail."—Broth is made of beef or mutton, but mutton is preferable, and is generally employed. The best broth is made as follows:—Put into a pot three quarts of cold water, along with a cupful of pearl barley, and let it boil. As soon as it boils, put in two pounds of the best part of the neck or back ribs of mutton. Allow it to boil gently for an hour, skimming occasionally, and watching to prevent boiling over. Then add one carrot grated, two small turnips cut in squares, a few small onions shred; also two or three pieces of carrot and turnip uncut. Instead of part of these vegetables, according to taste put in the half of a small cabbage chopped in moderately-sized pieces, or if cabbage cannot be procured, a similar quantity of greens. Leeks are also used instead of onions. Boil the whole for an hour longer, adding, if necessary, a small quantity of hot water to compensate the loss in boiling. The broth is now supposed to be done. Season with salt only, and serve in a tureen. The meat, which is not expected to be over-boiled, is served in a separate dish, garnished with the uncut pieces of turnip and carrot. By this preparation, both the broth and meat are used, so that a small quantity of meat produces food for a large number.

Hotch-potch.—This is a dish only to be obtained in perfection in summer, when green peas are in season. Put on two quarts of water, and when it boils, put in three pounds of the back ribs of mutton or lamb, paring off the fat if there be too much. Put in with the meat two or three carrots cut into squares, and two grated, also three or four sweet young turnips in squares, a cauliflower and a lettuce cut down, a few young onions shred, a little parsley, and about a pint of sweet young peas. Boil this for an hour and a half, then take out the meat and cut it in chops, laying it aside. Add another pint of young peas, seasoning with pepper and salt and when these peas are done, put in the chops. In a few minutes afterwards, serve up the whole in a tureen

Sheep's Head.—Procure as good a sheep's head as possible. The first thing done is to singe it with a hot iron, so as to free it completely from every particle of wool. This process is always performed in Scotland by a blacksmith, or some other person who makes a business of singeing heads. The horns should have been previously sawed off by the butcher. When singed and ready for the cook, soak the head for some time in warm water, and then scrape it till it is perfectly clean, and as nearly white as possible. The head must now be split, and the brains removed. Take out the eyes, and scrape and clean out the nose; after which wash the head again, and let it lie in warm water for a short time. It is usual to procure the trotters along with the head, and to subject them to a similar treatment, as regards singeing, cleaning, and washing. The head and trotters being now ready for the pot, put them in with a sufficiency of water, and let them boil till the skin is soft and tender, which may be in three hours. When ready, serve with the trotters round the dish, and garnish with boiled carrot and turnip. Some persons serve with parsley and butter.

Minced Collops.—Take a pound of good juicy beef, and a proportionate quantity of suet. Mince the whole very fine, as if for sausages, taking away any bits of gristle or skin. Melt a piece of butter in a frying-pan, and then put in the collops. Stir them well, adding a little flour, a little hot water or gravy, and season with pepper and salt, and a little ketchup. Onion may be chopped and put in along with the meat, if required. Ten minutes will dress a pound, which will form a dish for four or five persons. Serve in a hash dish.

Potato Soup.—Take any bones of cold roast meat, or a marrow-bone, or, failing these, a piece of dripping, which put into a pot with cold water, according to the quantity required. Let it boil a short time; then put in a quantity of potatoes well peeled or scraped, which have been previously soaked in boiling water to extract any disagreeable flavour from them. Add also one or two onions cut in pieces, a little pepper and salt, and let all boil for half an hour.

SAUCES AND FLAVOURS.

Sauces are liquid preparations to be used in giving a flavour or relish to dishes, and are of various kinds. A number are formed of melted butter, with an infusion of some other ingredients; others are in the form of gravies drawn from fresh juicy meat; and a third kind are composed partly of water and some preserves, condiments, or spices. There is little merit in making a good sauce when a person has good and proper materials to make it with. The chief method consists in furnishing a fine flavour from inadequate materials; as, for instance, giving a rich flavour of meat to a mass of potatoes, or some other plain dish, when no meat has been employed. This can only be done by knowing the qualities of various vegetable products, and how these, by means of cookery, may be made to resemble the juices of animal food. The vegetable products of which by far the most can be made by a skilful cook, are onions, mushrooms, and carrots. Onions and mushrooms, alone, furnish the most effectual substitutes for animal juices, and may be dressed so exquisitely as hardly to be distinguished from the gravy of beef.

Onion Flavour.—Onion flavour is made by stewing. Take several large onions, and remove the thin outer film from them. Put them in a saucepan with a little salt and flour, and a small piece of butter or dripping, to prevent their burning. Cover them quite close, and set by the fire to brown and stew gently. Two hours will dress them, and at the end of this time they will be quite soft, and, with the addition of a little water, they will yield a rich gravy. This may be used to fry potatoes with, or to flavour any other dish.

Mushroom Sauce.—Pick out the stems, and skin the mushrooms and the stems. Cut them in small pieces and wash them. Then put them in a saucepan, with rather more water than will cover them. Let them stew gently for about half an hour, or till they are soft. They will now have yielded a fine rich sauce. Stir in a little flour and butter kneeded together, and season with pepper and salt. This preparation may be eaten with potatoes, the same as meat; it also forms an excellent sauce to many dishes.

Melted Butter.—This must be made of fresh butter. Cut down the butter into small pieces, and put them into a small saucepan with cold water, in the proportion of an ounce of butter to a tablespoonful of water. Throw in flour from a dredger with the one hand, while with the other you turn the saucepan rapidly round, so as to cause the flour to mix without lumping. A small quantity of flour is sufficient. You now for the first time take the saucepan to the fire, and continue turning or shaking it till the butter is thoroughly melted. When it boils, it is ready; it should then have the consistency of rich cream. If it should oil in making, it may be partially recovered by putting a little cold water into it, and pouring it several times into and out of a basin.

This sauce is the foundation of a number of other sauces, various additions being made to it for the sake of variety.

Onion Sauce.—Skin the onions, and boil them in plenty of water. When they are soft, take them from the water, and chop them very fine. Melt butter as above, and stir them in, seasoning with a little pepper and salt.

Egg Sauce.—Boil three or four eggs till they are quite hard. Peel and chop them down, and then stir them into melted butter. Season with a little pepper and salt.

Caudle Sauce for plum-pudding.—Melt butter, as above directed, and stir into it a glass of sherry, half a glass of brandy or rum, a little sugar, grated lemon-peel, and nutmeg. Do not let it boil after the spirits are added.

Lobster and Crab Sauce.—Melt the butter, as above directed. Pick out the meat of a boiled lobster or crab; chop it down very fine, and put it amongst the butter. Season with Cayenne pepper, and salt. If the lobster be procured raw, with berries or spawn on the outside, these should be taken off previous to boiling, and being mashed in a little cold water, may be added to the sauce after the lobster is put in. By boiling a little, the whole will become a bright red. This forms an improvement on common lobster sauce.

Bread Sauce.—Grate down crumbs of bread. Put it in a saucepan on the fire, with as much sweet milk as will allow it to be thick. Add a piece of sliced onion, and stir it till the bread is soaked and the sauce is quite smooth. Season with pepper and salt.

Mint Sauce.—Take the leaves of fresh green mint. Wash them, and after drying them, chop them very fine. Mix them with vinegar, and add a little sugar.

Beef Gravy.—A pound and a half of beef will make a pint of good gravy. Cut the beef in slices, or score it very deeply. Place it in a saucepan, with a bit of butter to prevent it from sticking, and a sliced onion. Brown the meat gently, being careful not to let it burn. Cover it closely, and let it stand beside the fire for about half an hour, to allow the gravy to run from the meat. Then put in about a pint of hot water, and let it boil slowly for an hour and a half, with some whole pepper. Some persons put in to boil along with it, a piece of bread toasted hard and brown, which thickens the gravy a little and adds to its richness. Season with salt, and strain it through a hair sieve.

FISH.

Fish are dressed in a variety of ways, according to the taste of individuals. They are boiled, broiled, baked,

stewed, and fried; but the most common modes of preparation are boiling and frying—boiling when required to be done in a plain way, and frying when a high relish or flavour is to be given to them. In all modes of preparing fish, much care is required to prevent them from being broken or disfigured.

To boil Salmon.—Clean out, scale, and rinse the fish in water. Then put it in a good roomy fish-kettle, with plenty of cold water, and a handful of salt. The usual time allowed for boiling salmon is twelve minutes to each pound, but this must in a great measure depend on the thickness of the fish. The way to ascertain when it is ready, is to raise one end from the water, and try if a knife will pass easily betwixt the fish and the bone. If it pass easily, it is dressed sufficiently. When done, lift it immediately from the water, and place the fish drainer across the kettle, to allow the water to drip from the fish. Serve on a dish with a fish plate and white napkin under it, the napkin being next it. Garnish with green parsley. Sauce—plain melted butter, parsley sauce, or lobster sauce in a tureen.

To broil Salmon, or Salmon Steaks.—Cut slices from the thick part of the fish, and having cleaned and scaled them, dry them, and dust them with flour. Broil them on a gridiron over a clear fire. When ready, rub them over with butter, and serve hot, with any of the sauces used for boiled salmon. Slices of hung or *kippered* salmon are broiled in the same manner.

To fry Trouts, or similar Fish.—Trouts of a moderate size are dressed whole, and frying is the best mode of preparation. Take the trouts, and clean out and scale them. Dust them with flour, and put them in a frying-pan with hot dripping or lard. Turn them, so as to brown them on both sides. Lift them out and serve them on a dish; they will be improved by laying a napkin under them to absorb the grease.

In the country parts of Scotland, trouts are rubbed with oatmeal instead of flour, and some reckon that this improves the flavour.

To boil Turbot.—Select a thick fish of a white creamy colour. After cleaning, but not cutting any part except in gutting it, lay it in salt and water, with the addition of a little vinegar, and let it soak a short time before boiling. Put it with the white side or belly upwards in a fish-kettle on the fire, with plenty of cold water, a handful of salt, and a cupful of vinegar. Let it heat slowly, and boil for half an hour after it has come to the boil. When done, serve with belly upwards, and garnish with any small fish fried, or with parsley and scraped horse-radish. Sauce—lobster, oyster, or plain butter.

To bake Turbot.—Cut a small turbot into slices, which clean and free from bones. Dip the slices in beat egg, and roll them in a mixture of crumbs of bread, minced parsley, pepper and salt. Place them in a dish well buttered all round, and bake them in an oven not very hot, or in a bachelor's or Dutch oven before the fire. They must be basted frequently with butter. When done, lay the pieces in a dish, and pour round them lobster or oyster sauce, highly seasoned with Cayenne pepper, salt, and ketchup. Instead of being baked, slices of turbot may be fried after being prepared as above, and served with plain butter sauce.

To boil Cod.—Wash and clean it, and boil as directed for turbot. Serve it on a napkin, garnished with parsley and scraped horse-radish. Sauce—oyster sauce.

To dress a Cod's Head and Shoulders.—Take a cod's head and shoulders in one piece, which clean, and let lie among salt all night. When you are going to dress it, skin it, and bind it with tape to keep it firm. Put it in a fish-kettle, back upwards, with plenty of cold water, a handful of salt, and a little vinegar. Let it heat slowly, and boil for about half an hour. Then let it lie on the drainer across the top of the kettle, for the water to drip from it. After this, place it, back upwards, on the dish in which it is to be carried to table, cutting and drawing away the tapes very carefully. Brush it over with beat egg, strew crumbs of bread, pepper, and salt, over it, and stick pieces of butter thickly over the top. Set it before a clear fire to brown. A rich oyster sauce, made with beef gravy instead of water, and highly seasoned with Cayenne pepper, salt, and ketchup, is poured in the dish around the fish. Do not pour any on the top of the fish.

To dress a Middle Cut of Cod.—Clean the piece of cod, and make a stuffing of bread crumbs, parsley and onions chopped small, pepper and salt, a bit of butter, moistened with egg. Put this stuffing into the open part of the fish, and fix it in with skewers. Then rub the fish over with beat egg, and strew crumbs of bread, pepper, and salt, over it. Stick also some bits of butter on it. Set it in a bachelor's or Dutch oven before the fire to bake. Serve with melted butter or oyster sauce.

To boil Haddocks.—This is the simplest of all operations. Select haddocks of a middle size. Clean them well, and wash them, and boil with a little salt in the water. Twenty minutes or half an hour's boiling will be sufficient. Serve with oyster sauce.

To dress Haddocks.—This is a most delicious dish when well prepared. Take pretty large haddocks, which clean and wash well. They will be firmer and better if they lie for a night in salt. When to be dressed, wash them and dry them. Cut off the head, tail, and fins; then skin them, being careful not to tear the flesh. Cut the flesh neatly from the bone, and divide each side into two pieces. Dust them with flour, dip them into beat egg, and strew bread crumbs over them. Fry them in a frying-pan, with a sufficiency of hot dripping or lard to cover them. Be careful that the dripping is not hot enough to scorch the fish. The way to ascertain the proper degree of heat of the fat, is to dip a thin slice of bread into it, and when it makes the bread of a light brown tinge, put in the fish. If the fat be too hot, it will make the bread of a deep brown. Turn the pieces carefully, so as to brown both sides, and when done, lay them before the fire on a drainer for a few minutes. Serve in a dish, garnished with parsley. Sauce—oyster sauce, or plain melted butter.

The fat in which haddocks are fried will answer the same purpose again, if put through a hair sieve, and poured in a jar, and kept in a cool place.

To fry Skate, Soles, Flounders, Whitings, and Eels, and any other white fish.—Skate and soles are skinned and dressed in the same manner as haddocks, but soles are fried whole, not cut in pieces. Flounders are likewise fried in the same manner, whole, but do not require to be skinned. Eels must be skinned and cut in pieces.

To bake Haddocks.—Take two or three haddocks, gut and clean them, and lay them all night among salt. When to be used, skin them, and cut off the heads, tails, and fins. Make a stuffing of bread crumbs, chopped onions and parsley, and a little bit of butter. Sew this into the bellies of the fish. Rub them over with butter, strew bread crumbs over them, and bake them in an oven or before the fire.

Fish and Sauce.—Take two or three haddocks, gut and clean them, and lay them all night among salt. When to be used, skin them, cut off the heads, tails, and fins. Boil these trimmings for three quarters of an hour in a little water. Brown a little flour and butter in a stew-pan, and then strain the liquor and put it to the butter; add sliced onion, chopped parsley, salt, a little Cayenne pepper, and a spoonful of ketchup. When all this has been boiled for a few minutes, cut the fish in several pieces, and let it boil gently till dressed.

To scallop Oysters.—Scald the oysters in their own liquor. Pick them out of the liquor, and lay them in a dish, or scallop shells, or tins, strewing crumbs of bread

mixed with pepper and salt over each layer, and finishing with crumbs. Moisten the whole with a small quantity of the liquor in which the oysters were scalded, and stick pieces of butter thickly over the top. Place the dish before the fire to bake. From ten to twenty minutes will be required, according to the quantity.

DRESSING VEGETABLES.

All vegetables ought to be cooked fresh from being gathered, or as nearly so as possible. Excepting peas and spinach, each kind of vegetable should be boiled in a large quantity of water, to carry off any rankness of flavour. They should also be served as soon as dressed, and not permitted to lie a moment in the water after they are ready for dishing. All kinds of cabbage and greens are the better for being boiled with a little carbonate of soda in the water, which will preserve their green appearance. The carbonate of soda is a material resembling flour in appearance, and may be obtained from any druggist. Cauliflower and broccoli require great care in boiling, for the flower easily breaks, and their appearance is spoiled. The time for boiling vegetables depends so much on their age, freshness, and size, that no directions can be given on that point. The best way to ascertain when they are ready, is to pass a fork through the stem.

To boil Green Peas.—Peas should not be shelled till just before they are to be used. After shelling, put them into boiling water, just enough to cover them, with a little salt; and when they are not very young, put a little sugar in the water. They will require about twenty minutes to boil. When done, strain them through a cullinder, and put them into a vegetable dish with a few bits of butter; stir them gently till the butter is mixed with them.

To boil Carrots and Parsnips.—Carrots require to be scraped, and to boil till they are soft. The length of time for them boiling depends on their age and size. Small carrots are served whole, but large ones should be cut in four pieces lengthwise. Parsnips require to be scraped and prepared in the same manner.

To boil Turnips.—Old turnips require to be pared much deeper than young ones. When they are very small, peel off the skins but do not pare them; and after boiling, serve them whole, with a little melted butter in the dish. Large turnips are cut in pieces before being put in the pot, and they are either served in these pieces, or mashed with a little butter, pepper, and salt.

To boil French Beans and Scarlet Runners.—Cut off the tops and tails, and strip the strings from the backs of the pods. Then cut the pods in pieces slantingly across, or split them from one end to the other, and then cut them across. Lay them in cold water for a few minutes; and after straining them, put them into boiling water with a little salt and carbonate of soda. Boil till they are soft; strain them with a cullinder, and serve them with melted butter in a separate dish. Scarlet runners are prepared in the same manner, but usually require to be split into three or four pieces.

Potatoes.—These useful vegetables, as every one knows, may be dressed in a variety of ways. When to be presented plain at table, they may be either boiled in water or steamed. Some potatoes are best when boiled, while steaming is more suitable for other kinds. There is therefore no exact rule upon the subject. In general, they are better when they are boiled, and when put into just enough of cold water to cover them. A little salt should be put into the water to impart a flavour, and they should boil very slowly. Fast boiling will break their skins before they are soft in the inside. In most instances, they are spoiled by over-quick boiling. When sufficiently done, pour the water from them, and set them by the side of the fire with the lid off, to allow the steam to escape, or fold a napkin and place over them to absorb the moisture. Before serving, peel them, and place them in a dish with a napkin over them. Plain potatoes should never be sent to table without a napkin, for it keeps them warm, and, at the same time allows the moisture to escape. When potatoes are to be mashed, they are pared either before or immediately after boiling, and mashed so as to be completely free from lumps. Some milk and butter, and a little salt, are stirred in before serving.

Salads.—Salad is a general name for certain vegetables prepared so as to be served and eaten raw. Salads are composed chiefly of lettuce, endive, radishes, green mustard, land and water cresses, celery, and young onions. All or any of them should be washed, and placed ornamentally in a salad bowl; the lettuce is generally cut in pieces lengthwise, and stuck round the dish; the celery, also divided, is placed in the centre, and the small salads, such as cresses and radishes, are placed between. This is the mode of serving a salad plain.

A dressed Salad.—When a dressed salad is to be served, the whole is cut in small pieces, and mixed in the bowl with a dressing. The dressing is made in the following manner:—For a moderate quantity of salad, boil one egg quite hard; when cold take out the yolk and bruise it with the back of a spoon on a plate; then pour on it about a teaspoonful of cold water, and about a teaspoonful of salt. Rub all this together till the egg has become quite smooth like a thick paste. Add a teaspoonful of made mustard, and continue rubbing. Next, add and mix a table-spoonful of salad oil or cold melted butter. After this, add and mix a table-spoonful or more of vinegar. The dressing is now made, and may be either mixed with the salad, or put into a glass vessel called an *incorporator*, which is sent to table along with the salad. The top of the salad may be ornamented with small bits of the white of the egg, and pieces of pickled beet-root.

PIES AND TARTS.

Pies are of two distinct kinds—meat pies and fruit pies or tarts. Both are composed partly of paste, and therefore a knowledge of making pastry is indispensable in the economical housewife and cook. For this operation, the hands should be washed very clean, and care taken to have the board for working upon smooth, clean, and dry. A marble slab is better than a board, but few can command this convenience, and a board is usually kept for the purpose. Should the board or table be any way rough, lay a sheet of stout white paper upon it. Before commencing to roll or knead the paste, dredge a little flour upon it. In all cases of making paste, the butter, whether fresh or salt, should be perfectly free of taint, or any rankness of flavour. It is very necessary to give this direction, for many persons seem to imagine that butter of any kind, however bad, is good enough for paste. Dripping, when well prepared and kept, or lard, will answer as a substitute for butter and make the paste equally agreeable to the taste. At one time, raised pies—that is, pies covered all over with paste—were common, but these are now rarely seen of a large size for families. Pies are now made in earthenware dishes, and merely covered with paste. The way to make paste for raised and covered pies is as follows.

Paste for covering Meat Pies.—A good common paste for covering dishes or meat pies, and which paste is intended to be eaten, is made as follows: Three ounces of butter, and one pound of flour, will be sufficient for one dish. Rub the butter well among the flour, so as to incorporate them thoroughly. If the butter be fresh, add a little salt. Mix up the flour and butter with as much cold water as will make a thick paste. Knead it quickly on a board, and roll it out flat with a rolling-pin. Turn the dish upside down upon the flattened paste, and cut or shape out the piece required for the cover. Roll out

the parings, and cut them into strips. Wet the edges of the dish, and place these strips neatly round on the edges, as a foundation for the cover. Then, after putting in the meat, lay the cover on the dish, pressing down the edges closely to keep all tight. If any paste remain, cut or stamp it in ornaments, such as leaves, and place these as a decoration on the cover.

On taking pies from the oven, and while quite hot, the crust may be glazed with white of egg and water beat together, or sugar and water, laid on with a brush.

Beef-Steak Pie.—Take some slices of tender beef mixed with fat; those from the rump are the best. Season them with pepper and salt, and roll each slice up in a small bundle, or lay them flat in the dish. Put in a little gravy or cold water, and a little flour for thickening. Cover as above directed, and bake in an oven for about an hour.

Veal Pie.—Take chops from the back ribs or loin, and take out the bones. Lay the chops flat in the dish, and strew over each layer a mixture of minced parsley, flour, pepper, and salt. Add a little gravy, which may be made from the bones. Cover as above directed, and bake for rather more than an hour, for veal requires to be well dressed.

Pigeon Pie.—Pick and clean the birds well. Cut off the heads, and truss them by turning the wings on the back, cutting off the feet, and drawing the skin of the belly over the legs. Put a bit of butter, and a little pepper and salt, inside each bird. Place a single layer of beef or veal in the bottom of the dish. Lay the birds on the meat, with breasts upwards, and with the gizzards and livers round them. Some add a few whole hard-boiled eggs. Add a little gravy or water. Cover as above directed, and bake for an hour.

Icing for Tarts.—After tarts are baked, they are sometimes iced on the top, to improve their appearance. The icing is done in the following manner:—Take the white of an egg, and beat it till it is a froth. Spread some of this with a brush or feather on the top or cover of the tart, and then dredge white sifted sugar upon it. Return the tart to the oven for about ten minutes.

Apple Pie.—Pare and take out the cores of the apples, cutting each apple into four or eight pieces, according to their size. Lay them neatly in a baking dish, seasoning with brown sugar, and any spice, such as pounded cloves and cinnamon, or grated lemon-peel. A little quince marmalade gives a fine flavour to the pie. Add a little water, and cover with puff paste, as above directed. Bake for an hour.

Gooseberry Pie.—Pick the heads and stems from unripe or hard gooseberries, and rub them with a towel to clean them. Fill the dish with them, and add a considerable quantity of brown sugar, with a very little water. Cover as above directed, and bake for upwards of an hour. Some persons stew the gooseberries in sugar before putting them in the dish, in which case they require less baking.

Rhubarb Pie.—Take stalks of fresh-pulled rhubarb. Cut off all the leaf, and strip off the skins. Cut the stalks into pieces of an inch long. Fill the dish, adding plenty of sugar. Cover as above directed, and bake for half an hour. Some persons stew the rhubarb before baking; the advantage of this is, that more can be put into the dish, for it shrinks considerably in dressing.

Cranberry, Raspberry, and other Tarts.—Cranberries, raspberries, and other small fruits, may be made into pies in the same manner as gooseberries. All require to be picked and wiped, and to have sufficient sugar to sweeten them. The dish should also be well filled, and raised higher in the middle than the edges, for the fruits diminish considerably in bulk in baking.

Mince Pie.—Mince pie is a composition of meat, fruit, various spices and seasonings, and also spirits. The following is a properly proportioned mixture:—Take and mince a pound of beef suet, and a pound of roast beef, or dressed fresh bullock's tongue; also a pound of apples pared and cored, minced separately from the suet and meat; a pound of currants washed and picked, a pound of stoned and chopped raisins, an ounce of ground cinnamon, half an ounce of ground ginger, an ounce of orange and an ounce of lemon-peel, and a little salt; half a pound of raw sugar, one nutmeg grated, two glasses of brandy and two of sherry. Mix all these ingredients together, and lay the bottom of your dish or small tin pans with paste; fill these with the mince, and then cover them with puff paste. Put in the oven, and bake for half an hour. If the whole of the mixture be not used, what remains over will keep for a long time, if placed in a close jar. Some persons do not put any meat in their mince pies.

Open Tarts.—These are tarts without covers, made in flat dishes. Cover the bottom of the dish with a common paste; then cut a strip of puff paste and lay round the edge of the dish. Fill in the centre with any jam or preserved fruit. Decorate the top of the jam with narrow bars of paste crossed all over, or stamped leaves. Bake for half an hour.

PUDDINGS AND DUMPLINGS.

Care should be taken in making puddings to have the suet and the eggs which are put into them perfectly fresh. If there be any doubt of the freshness of the eggs, break each individually in a teacup, for one bad egg will spoil all the eggs in the dish. The cloths used for puddings should be of tolerably fine linen. Let them be carefully washed after using, and laid aside in a dry state, ready for the next occasion. Before putting the pudding into the cloth, dip the cloth in boiling water, and after the water has run from it, spread it over a basin, and dredge it with flour. Every pudding should be boiled in plenty of water, so as to allow it room to move freely; and it must be kept constantly boiling. It is a general saying among cooks, that a pudding *cannot be too well boiled*, and it is certain that there is much more danger of boiling it too short than too long a time. When you take the pudding from the pot, plunge it for a few seconds into a jar of cold water. This will chill the outside, and allow the cloth to be taken away without injuring the surface. The best way to dish a pudding, is to place it with the cloth in a basin, then open the cloth, and lay the face of the dish upon the pudding turn the whole upside down, lift off the basin, and remove the cloth.

Plum Pudding.—A plum pudding may be made either rich or plain, according to the quantity of fruit and spices put into it. The following is the direction for making what would be considered in England a *good Christmas pudding*:—Take a pound of good raisins and stone them; a pound of currants, which wash, pick, and dry; a pound of rich beef suet minced, and a pound of stale bread crumbs, and half a pound of flour. Mix the bread, flour, and suet in a pan. Beat six eggs in a basin, and add to them about half a pint of sweet milk. Pour this egg and milk into the pan with the suet and flour, and beat it well with a flat wooden spoon for some time. Then stir in the currants and raisins, mixing well as you proceed; mix in also a quarter of a pound of candied orange and lemon-peel, cut in thin small pieces, an ounce of powdered cinnamon, half an ounce of powdered ginger, a nutmeg grated, and a little salt. Next add a glass of rum or brandy. The pudding is now made, and ready to be either baked or boiled, according to taste. If to be baked, butter your tin or basin, and put the pudding into it, and bake in an oven for an hour and a half, or nearly two hours. If to be boiled, pour it into a cloth; tie the cloth, allowing a little room to swell if made of bread, and boil for six hours. Serve with caudle sauce.

Currant Pudding.—An excellent family pudding may be made of the following ingredients:—A pound of minced suet, a pound of bread crumbs or flour, three quarters of a pound of currants, washed and picked, a little powdered cinnamon and grated nutmeg, and a very little salt. Beat two eggs, and add as much milk to them as will wet the whole. Mix all together, tie in a cloth as previously directed, and boil for three hours. Serve with candle, or any simple sweet sauce.

Hard Dumpling.—This is the plainest of all puddings, and is sometimes served with boiled salt beef. It is also, sometimes cut in slices and placed in the dripping-pan below roasting meat, for about half an hour before the meat is dished. Take a quarter of a pound of suet minced very fine; mix it with a pound of flour; add a little salt, and wet it with water to the consistency of dough. Divide it into small dumplings, and put them into boiling water, and boil for an hour and a half, taking care that they do not stick to the bottom of the pot. No cloth is used.

Bread Pudding.—Boil as much milk as will be sufficient for the pudding you want. When it begins to boil or rise in the pan, pour it upon crumbled down stale bread in a basin. The quantity of bread should be as much as will thicken the milk to a stiff consistency. Cover it up for ten or fifteen minutes, to allow the bread to swell. Then beat or mash it up to make a fine pulp, stirring in a small piece of butter. Beat three or four eggs, a teaspoonful of ground cinnamon, a little grated lemon-peel, and sugar according to taste. Stir this among the pudding. A little brandy or rum may be added; also a few currants, if required. The pudding may be either boiled or baked. If to be boiled, put it in a well-buttered pudding shape or basin, with a buttered paper over it, and also a cloth over all: boil for an hour. If to be baked, put it into a buttered baking dish, and bake in an oven for half an hour.

Rice Pudding.—Take a pretty large cupfull of rice, pick it, and wash it well in cold water. Boil it in water for about five minutes. Drain the water off, and put it on again with as much milk as you require. Let it boil till the rice is quite soft, stirring it frequently to prevent it from burning. When done, put it into a basin, and stir in a piece of butter, or some suet minced very fine. When cold, add to it four eggs beaten, with a little ground cinnamon, grated nutmeg and lemon, and sweeten with sugar. All is to be mixed well together. It may be either boiled or baked, as directed for bread pudding. The above composition may be enriched by using more eggs and less rice, also by adding currants, spirits, and candied orange and lemon-peel.

Custard Pudding.—Take four eggs, and beat them well with two table-spoonfuls of flour and a little cold milk. Season this with sugar, ground cinnamon, grated lemon-peel, and pour on a pint of boiling milk, stirring all the time. It may be either baked or boiled. By using more eggs, the flour may be omitted.

Bread and Butter Pudding.—Cut several slices of bread rather thin; butter them on one side; put a layer of them in a pudding pan or dish, and a layer of currants above; then another layer of bread, and so on till the dish is full. Beat four eggs, with a little ground cinnamon and nutmeg, also some sugar. Add milk to this till there is sufficient to fill up the dish. Then pour it over the bread, and allow it to stand for a time to soak. It will now be ready for either baking or boiling, as directed for bread puddings.

Tapioca Pudding—Sago Pudding.—Take a quart of milk, and put in it six table-spoonfuls of tapioca. Place it on the fire till it boil; then sweeten to taste, and let it simmer for a quarter of an hour. Stir it frequently, and be careful that it does not burn. Then pour it into a basin, and stir into it a little fresh butter and three eggs well beaten; you may now pour it into a buttered pudding dish, and bake for about an hour; or, after adding another egg, boil it in a basin or mould for an hour and a half. Sago pudding may be made in the same manner.

Batter or Yorkshire Pudding.—Take a quart of sweet milk, and mix in it a large cupfull of flour, making the mixture very smooth. Beat four eggs, and strain them into the batter. Add a little salt, and mix all well together. Butter your dish or tin, and pour the batter into it. Place the dish either before the fire under roasting meat, or under meat sent to the oven. The pudding, when done, easily shakes out of the dish into another dish to be carried to table. It should have a nicely browned appearance. When dressed before the fire, either turn the pudding, or place the dish a short time on the fire to brown the under side.

Peas Pudding.—Pick a quart of split peas, that is, remove all impurities, or discoloured peas, or shells. Tie them loosely in a cloth, leaving plenty of room for the peas to swell. Boil till they are soft, which may be in from two to three hours. Take the pudding from the water and put it into a basin. Open the cloth, and bruise or mash the peas well. Mix in a piece of butter, with pepper and salt. Then tie it up tightly, and put it into the pot again, and boil for about half an hour. When ready, turn it out of the cloth into a vegetable dish. If properly managed, it will turn out whole.

Fruit Puddings.—Fruit puddings consist of fruit enclosed in a paste, and boiled. They may be made of apples pared and cut in pieces green unripe gooseberries, currants, raspberries, cherries, and other fruits. They are all made in the same manner. The best paste for them is made of beef suet chopped very fine, and flour, in the proportion of four ounces of suet to a pound of flour. Mix it into a dough with water and a little salt; then knead it and roll it out; place the fruit in it, gather up the edges, and tie it in a cloth, or place it in a basin, as directed for other puddings.

A Roll Pudding.—Make a paste of flour and dripping, or suet, as previously directed for plain paste. Roll it out flat, to about half an inch thick. Then spread gooseberry jam, or any other preserved fruit, over the paste, but not quite to the edges. After this, roll it up, and cause the outer edge to adhere. Next, roll it in a cloth, and tie the ends tightly. Boil it for an hour or an hour and a half, according to the size. When done, take the cloth off, cut the pudding in slices, and serve with any sweet sauce over it.

Meat Puddings.—Meat puddings are made in the same manner as fruit puddings, the only difference being, that pieces of beef, mutton, lamb, or veal, are placed inside of the paste instead of fruit. The meat should be seasoned with salt and pepper. One of the commonest of this kind of puddings is a beef-steak pudding. If it contain two pounds of meat, it will require about two hours and a half to boil, and if larger it will take a longer time.

LIGHT DISHES AND CONFECTIONS.

Under this head is included those various light and elegant dishes which are generally put upon the table in the last course, along with puddings and pies; also those preserves which are occasionally served at tea and supper parties. In making all articles of this description, very considerable care and cleanliness are required. The tin shapes or moulds for jellies should be kept particularly clean; if they are used with any particles of dirt inside, the jellies will in all likelihood not turn out neatly. It has been already mentioned, that the turning out may be facilitated by dipping the mould for an instant or two in hot water. It is a common belief that fruits, such as gooseberries and currants, cannot, without spoiling, be dressed for preserving, except in a brass, copper, or silver pan. This is an error. They may be

dressed equally well in a tinned iron saucepan. Every kind of berries for preserving should be gathered in sunny weather, when the fruit is as free of moisture as possible.

In the following directions, no exact definition can be given of the quantity of small seasonings and spices to be used; that is left to the taste of the cook.

Custards.—Boil a quart of sweet milk, with stick cinnamon, the rind of a lemon, and a few laurel leaves or bitter almonds, and sugar. Beat the yolks of eight eggs along with the whites of four of them; add a little milk, and strain the egg into another dish. When the quart of milk boils, take it off the fire, and strain it; then stir the egg into it. Return the whole to the saucepan, and set it on the fire again, stirring constantly. Let it come to the boiling point; then take it off the fire, pour it into a large jug, and continue stirring it till it is nearly cold. It should now have the consistency of thick cream, and is ready for being poured into custard glasses. When the glasses are filled, grate a little nutmeg over them.

Calf's-foot Jelly.—Take two calf's feet well cleaned; break them in several pieces, and put them in a saucepan with three quarts of cold water. Boil it slowly till it is reduced to about a quart and a half. Strain it, and let it stand till cold. Take off the fat carefully when cold. Put the jelly into a saucepan, keeping back the sediment; put in along with it the juice and the yellow rind of three lemons, two stalks of cinnamon, half a bottle of sherry wine, the whites of eight eggs well beaten, with the shells broken, and white sugar according to taste. Mix this all together, and put it on to boil for twenty minutes. Take it off, and let it settle with a cloth over it for a few minutes. Then pour it through a clean jelly-bag made of thick flannel. It will take some time to run; therefore hang the bag near the fire, cover it, and let the liquid run slowly from it into a jar. If not perfectly clear, run it through the bag again; but if as clear as is required, it is now ready, and may be poured into the shapes.

Plain calf's-foot jelly may be made with ale instead of wine, and vinegar instead of lemons.

Blamange.—Blamange, or Blanc-Mange—so called from its white appearance—is a jelly made of isinglass and milk. Take a quart of sweet milk, or cream, and put in it two ounces of the best isinglass. Put it in a saucepan, with the rind of a lemon, a blade of mace, and white sugar to taste. Let it boil a quarter of an hour. Take the skins off six bitter almonds and twenty-four sweet ones, and pound them to a paste with a little water. Mix this with the boiling milk, and strain it through a muslin sieve. Let it settle for a short time, and then pour it into the shape, keeping back the sediment. Turn out when cold, as already directed.

Arrowroot Blamange.—This is a jelly closely resembling the above, and is made with much less trouble. Take a quart of sweet milk, and put it all in a saucepan, excepting about half a pint. Sweeten it with white sugar. Mix about three tablespoonfuls of arrowroot with the half pint of milk, taking care to bray it all well down. When the milk on the fire boils, pour in the arrowroot, stirring quickly to prevent lumping or burning. It will become thick immediately. Let it boil for two or three minutes. Wet the shape with cold milk, and pour the arrowroot into it. Let it stand till cold, and turn out as already directed. Some persons flavour the milk in the pan with essence of lemon.

Moss Blamange.—There is a moss of a peculiar kind, found on the sea-shores of Iceland, Ireland, and other places, which is of a glutinous quality, like isinglass, and which, when boiled in milk, forms a fine smooth white jelly. The discovery of the properties of this plant is recent, and is yet not very generally known. We shall, therefore, be particular in our directions. The moss is called Iceland or Irish moss; it is sold by druggists, and when bought resembles dried sea-weed of a yellowish colour. Take one ounce (which will probably cost twopence), and pick from it all gritty or sandy particles. Soak it in cold water for about twelve hours. Take it from the water, place it in a cullinder, and drain it. Being drained, place it in a saucepan on the fire with a pint and a half of sweet milk. Let it boil for half an hour, and keep stirring it all the time, to prevent it from burning. During the boiling, sweeten it with sugar, and flavour it with cinnamon, or any other spice you please. At the end of the half-hour's boiling, the moss will be almost entirely dissolved, leaving nothing but a few thready fibres. You now strain it through a sieve, into a shape or mould. When cold, it will turn out easily, and have all the appearance of a firm blamange. This forms one of the cheapest blamanges that can be served to table; it is also agreeable to the palate, and very nutritious. In cases of a hurry in cooking, six hours' soaking of the moss will do, but this causes a waste.

Gooseberry Fool.—This is the simplest way of preparing gooseberries, and very wholesome for children. Take a quart of full-grown unripe gooseberries. Pick them, and put them into a saucepan with a cupful of water. Cover them, and let them heat very slowly. When the gooseberries are soft and dressed, but not so much heated as to burst, strain the water from them, and put the gooseberries in a dish. Bruise them to a fine pulp, with sufficient sugar to sweeten them. Let them stand till cool, and then mix milk or cream with them. Serve in a hash dish, or large bowl.

MISCELLANEOUS PREPARATIONS.

To Boil Eggs.—The boiling of eggs is a very simple operation, but is frequently ill performed. The following is the best mode:—Put the egg into a pan of hot water, just off the boil. When you put in the egg, lift the pan from the fire and hold it in your hand for an instant or two. This will allow the air to escape from the shell, and so the egg will not be cracked in boiling. Set the pan on the fire again, and boil for three minutes or more, if the egg be quite fresh, or two minutes and a half, if the egg has been kept any time.

To Poach Eggs.—Take a shallow saucepan or frying-pan, and fill it about half full of water. Let the water be perfectly clean, not a particle of dust or dirt upon it. Put some salt into the water. Break each egg into a separate tea-cup, and slip it gently from the cup into the water. There is a knack in doing this, without causing the egg to spread or become ragged. A good way consists in allowing a little water to enter the cup and get below the egg, which sets the egg to a certain extent before it is allowed to lie freely in the water. If the water be about boiling point, one minute is sufficient to dress the egg; but the eye is the best guide: the yolk must retain its liquid state, lying in the centre of the white. Have buttered toasted bread prepared on a dish, and cut in pieces rather larger than the egg; then take up the eggs carefully with a small slice, pare off any ragged parts from the edges, and lay them on the bread. They may be laid on slices of fried bacon, when preferred.

Buttered Eggs.—Put a piece of butter in a saucepan and melt it, adding a little milk. Break the eggs into a basin, and pour them into the saucepan. Season with salt and pepper, and continue stirring the eggs till they are sufficiently dressed. Serve on pieces of toasted bread.

Omelettes.—Omelettes are composed of eggs and anything that the fancy may direct to flavour and enrich them. For a common omelette, take six eggs, and beat them well with a fork in a basin; add a little salt. Next take a little finely chopped parsley, finely chopped eschalot or onion, and two ounces of butter cut into small pieces, and mix all this with the egg. Set a frying-pan

on the fire with a piece of butter in it; as soon as the butter is melted, pour in the omelette, and continue to stir it till it assume the appearance of a firm cake. When dressed on one side, turn it carefully, and dress it on the other. It will be dressed sufficiently when it is lightly browned. Serve it on a dish. The flavour may be varied, by leaving out the parsley and onion, and putting in finely chopped tongue or ham, oysters, shrimps, grated cheese, or other ingredients.

Pancakes.—Pancakes are made of eggs, flour, and milk, in the proportion of a tablespoonful of flour to each egg. To make two small pancakes, take two eggs, and beat them well, and add to them a little milk. Then take two tablespoonfuls of flour, and work it into a batter with the egg and milk; add a little salt. Set a clean frying-pan on the fire, and put a piece of butter or lard into it. When the butter is quite hot, pour in the batter. Shake it frequently, to prevent it from sticking. When the under side is of a light brown, turn it. Serve the pancakes folded, with sugar strewed between the folds. This is the way of dressing the common pancake; when required to be lighter, use more egg and less flour; and grated nutmeg may be added.

Fritters.—Make a batter of eggs, flour, and milk, as for pancakes, but with a little more flour. Apple fritters are made by cutting large pared apples in slices, dipping the slices in the batter, and frying them separately. They are done when lightly browned on both sides. Another, and perhaps more common way, is to cut the apples in small pieces, and mix them with the batter, frying them, a spoonful in each fritter. Fritters may be made with currants in the same manner. Serve all fritters with sugar sprinkled over them.

Barley Water.—This is a drink used by invalids, and is made from pearl barley. To make a quart, wash a tea-cupful of pearl barley in cold water, after which throw away the water. Put the washed barley into a saucepan with a little boiling water; after boiling a few minutes, throw this water away also. Then fill up the saucepan with two quarts of boiling water, and continue boiling until there is only one quart left. It may be flavoured with lemon or jelly.

Gruel.—Gruel for invalids is made either from grits or from oatmeal. A pint may be made as follows:—If from grits (called in London Embden grits) or groats, put on about two tablespoonfuls in rather more than a pint of water; let it boil for at least two hours. When boiled, strain it through a hair sieve. If from fine oatmeal, such as is sold in England, take about a tablespoonful and a half, and mix with it gradually about a pint of cold water, braying it as you mix, and boil it for half an hour. It is now done, and requires no straining. If the oatmeal be coarse, such as is used in Scotland, take a tea-cupful and put it into a basin. Mix it well with a small quantity of water. Pour this water off, then take another water from it: in this manner about a quart should be taken, the coarser particles of the meal being rejected. Put all the waters into a saucepan, and boil for twenty minutes, stirring the whole time. It is now ready, and, like other kinds of gruel, may be seasoned according to taste.

Lemonade.—Take a quart of boiling water, and add to it five ounces of lump sugar, the yellow rind of a lemon rubbed off with a bit of sugar, and the juice of three lemons. Stir all together, and let it stand till cool. Two ounces of cream of tartar may be used instead of the lemons, boiling water being poured upon it.

To boil Rice for Curry.—It is customary to serve boiled rice along with dishes which have been seasoned or stewed with curry. When rice is required for this purpose, it should not be soft or pulpy as in boiling for puddings; each grain should retain its perfect individual form, though swelled to nearly its fullest size. After picking and washing the rice, put it into boiling water, and let it boil smartly for about twelve minutes. Just before taking it out, put in a tablespoonful of salt. Drain the rice in a cullinder; then shake it gently out upon a doubled cloth, and lay it before the fire for a few minutes, with a fold of cloth over it. By this process the water will be absorbed from it, and it will be ready for dishing. Pour it lightly into the dish.

To make a Stuffing.—Roast veal, fowls, turkey, and some other things, require a stuffing. These stuffings have been alluded to in various recipes in the preceding pages, and may here be expressly defined. Take a quarter of a pound of the crumbs of stale white bread, a quarter of a pound of chopped beef suet or marrow, as much chopped parsley as will lie on a tablespoon, about half a spoonful of chopped sweet marjoram, and a little grated lemon peel, pepper, and salt. Mix all these, thoroughly together, with one beat egg and a little sweet milk. This forms a species of dough in sufficient quantity for a small turkey or large fowl.

Force-meat Balls.—These are balls formed of stuffing, used as a garnish for roast veal or veal cutlets. Make a stuffing like the above, but instead of being wet with one egg and milk, wet the mixture with two eggs. Roll the dough into small balls, about the size of nutmegs. Roll them in flour, and fry them with a little lard, butter, or dripping. When required to be more savoury, the composition may be enriched with a little chopped ham, tongue, or sausage meat.

POLITICAL ECONOMY.

"Political economy," says Wayland, "is the science which teaches the manner in which nations and individuals acquire wealth."

Wealth is a general term applied by mankind to any object or thing, no matter of what character, that possesses an inherent value, as diamonds, gold, silver, grain, goods and merchandise of every description.

The acquirement of wealth is one of the first objects of the human mind: how wealth may be produced is consequently one of its first questions.

Wealth can only exist where its subject possesses an inherent value, and it exists only in proportion to the quantity of that value—great, where it is great; and small, where it is small. The value of an article depends not upon the estimation in which it is held by its owner, but upon what other persons may offer in exchange for it: when, and then only, its value becomes determinate, and the article rises or falls as the case may be, to an equal value with that of the article offered in exchange. This brings us to the consideration of *price*. Price is whatever amount of money an article will command in the market; and it only becomes what is entitled *current price*, when the owner of the article is sure to obtain it whenever he offers his goods for sale.

The re-creation of objects under another and more useful form may be defined to be production, for the value mankind attaches to any object arises only from the fact that they can make some use of it; otherwise it would be valueless. Whatever, therefore, is useful is valuable, but the amount of its value can only be estimated by the extent of its utility, for there can be no real production of what is called wealth without an augmentation of utility.

OF THE VARIETIES AND NATURE OF INDUSTRY.

The usefulness of an object is increased in proportion to the amount of labour bestowed upon it. The application of this labour to the object is called industry Whatever objects are destitute of exchangeable value—objects not procurable by production, nor capable of being destroyed by consumption, as air and light—do not belong to the science of which we treat. There are others, however, equally as indispensable as these, such as the articles which constitute the food, raiment, and lodgings of man, which he could never enjoy except through the means of his own industry. This industry is of three kinds—*agricultural*, where it is applied to the production of natural products; *manufacturing*, where it re-creates the products of nature and fits them for the uses of man; or *commercial*, where it places in our reach objects of utility which we could not otherwise obtain.

Whatever industry furnishes for the use of man are entitled *products* and these products are rarely the fruits of any one particular branch of industry: on the contrary they may employ two, or all the branches. For instance, agricultural industry produces wheat, but manufacturing industry changes it into flour, while commercial carries it where it may be rendered more useful than it otherwise would have been.

OF CAPITAL.

Human industry, however great, when unassisted is insufficient to invest things with value. Man requires, first, tools and implements; secondly, those products which are necessary to sustain life, and lastly the raw material, to be fashioned into products by that industry. Raw materials are sometimes furnished gratuitously by nature, but they are oftener the products of previous labour in some of the branches of industry, as iron from the mine, wheat from the farmer, or articles brought by commerce from some other section of the earth. This brings us to the consideration of *capital*, which may be defined to be the value of the various articles employed in the production of a product. Capital is either *productive* or *unproductive*, *fixed* or *circulating*.

Whatever produces is productive capital; whatever is idle and useless is unproductive. Money, for instance, may be either. When employed in commercial industry, in the transportation of products from one country or place to another, it is the one; when locked up in the chests of a miser, the other. Money, however, is of small importance in political economy, for neither the merchant's, manufacturer's, nor farmer's capital consists wholly of gold or silver: on the contrary it is the least portion of it. The capital of the first consists in his goods and his ships; of the second, in his machines and manufactories; of the third, in his farms, manures, implements of husbandry, and other articles of agricultural utility Indeed, all hesitate at possessing more of it than is sufficient for their actual use.

The capital of government is that of individuals, for it is made up of what is possessed by individuals under its care. The circulating medium of a nation, however, is small when compared with its actual wealth, for while the gold and silver coin of a country may amount but to twenty millions of dollars, its fixed capital may be one hundred times that amount.

OF NATURAL AGENTS.

Natural agents are those which are not created by man, but which he avails himself of in the production of products, as, for example, land; it is in the nature of land, with the assistance of the sun, air, and rain, to produce crops; but land would produce nothing unless prepared for the purpose by the plough, the harrow, &c., pre-existing products by which the labourer is enabled to employ the natural agents to advantage, and which, as has been seen, form a considerable portion of his capital. Fire, air, water, and other natural agents, and the union of these with others, enable the labourer to produce more than he otherwise could do, were he unassisted by them. Wood, for instance, when joined to fire, naturally produces heat; heat when applied to water generates steam, and steam is daily used not only for manufacturing but commercial purposes to greater advantages than any other agent. The same may be said of water alone, which is employed in the irrigation of lands, or in forcing machinery, where steam would be too costly an agent, or of air, or rather of wind, which, by means of sails employed for the purpose, will propel the machinery of a mill for manufacturing purposes, or a ship from one place to another, with the assistance of water, for commercial. As may have been gathered, natural agents form a prominent part in the production of wealth.

HOW INDUSTRY, CAPITAL, AND NATURAL AGENTS CONCUR IN PRODUCTION.

It is not necessary that these three requisites should be united in one person, on the contrary, they may be divided.

One possessing land may lend it to one possessing capital, while an industrious person may lend his indus-

try to the latter or to the former, should he possess both capital and land.

Whenever any one of the three is lent, for they must all unite in the production of what is valuable, its use, being likewise so, demands an equivalent, which, in the case of land, is rent; capital, interest; and industry, wages.

Industry and capital, however, can sometimes act without land, but this is generally when articles of foreign cultivation only are employed, as is the case with American cotton in the factories of Europe. The use of land, therefore, is not absolutely necessary.

OF LABOUR, NATURE, AND MACHINERY.

Labour is human action exerted to increase the value of whatever is susceptible of industry; and wherever it is employed, is always productive, for labour which produces nothing is but folly, and not likely to be attempted by any one a degree removed from a fool. It may be divided into two kinds, the *labour of nature* and *of capital*, both of which are closely related and too often confounded; for tools or machines, which are actual capital, are mere expedients, the better to effect an object by means of natural resources. The object of tools and machines is to enlarge the power of production, that is, to enable one to do more than he otherwise could do unassisted by them. They consequently supplant human labour, for where an engine managed by one will perform as much labour as a hundred, ninety-nine must be thrown out of employ. This is often the cause of an outcry against machinery, the use of which has frequently been prevented by violence, and almost as often by the intervention of laws. Machinery, however, is productive of great good, for, as a necessary consequence, that which can be made cheaper can be sold cheaper, and is therefore capable of a wider circulation. Besides, it is useless to clamour against, or to prevent the introduction of machinery, for if destroyed here, they will be employed elsewhere, where a more liberal policy is adopted, and their products imported into the country will be bought, because they will be more uniform and better in character as well as cheaper, in preference to those made by hand, when the labourer will be as much out of employment as if they were in use in his vicinity. Besides, had they been in use, the greater amount of the products manufactured, in consequence of their wider circulation, would have employed as many hands as before.

Division of Labour.—Labour is capable of infinite division, for it is rarely that we find all the requisites necessary for the performance of a task united in the same person; the manufacture, therefore, of almost every article, is divided among those who are best capable of performing their several parts. For instance a book: the type-founder casts the type, the compositor sets it, the pressman prints it, when it passes into the hands of the book-binder, in whose establishment the labour is again subdivided. Now could one man perform all these parts, the time occupied in the preparation of a volume would be so great that its value would be materially increased, indeed, so much so, as to place it beyond the reach of the mass. By dividing the labour, however, and suffering each man to perform that part which he best understands, the product is produced in less time, in greater quantities, is far cheaper, and as a necessary consequence, is capable of greater circulation. Agricultural labour, however, is incapable of much division, for it is almost impossible to collect a sufficient number of agriculturists in one spot, and equally so to unite them in the cultivation of one particular product. Besides, agriculture does not permit a permanent occupation in any one thing: a man cannot always be ploughing, digging, sowing seed, or reaping, for each of these things have their separate seasons. Neither will land allow itself to be permanently used in the production of a particular kind of crop, for such a course would produce exhaustion, and the land itself finally become worthless.

Commercial Industry.—Commodities which are the subjects of commercial industry, depending as they do upon the varieties of soil and climate, are as diversified in their character as in their locality, and they are only abundant in those situations which nature has best adapted to their production. The transfer of commodities from one place where they are less, to another where they are more useful, is commercial industry.

Commerce is of three kinds, external, wholesale and retail; external, where the home market is supplied with foreign products or *vice versa*; wholesale, where larger quantities of merchandise are purchased for the purpose of vending them to inferior dealers, and retail where those inferior dealers resell to consumers. And here is a subtle division: all products bought for the purposes of sale are entitled merchandise; those for consumption, commodities.

Commerce is conducted by various persons, as the commerce of money in specie, whether in silver and gold or paper, as well as dealings in credit, is by the bankers; while the broker brings buyers and sellers in conjunction.

No matter how small or how large may be the agency of persons employed in commerce, each one possesses an equal degree of importance, for, though the merchant may import a cargo of tea from China, the retailer who sells his customer a single pound, is quite as indispensable to him. The only reason why this office both of wholsaleing and retailing is not performed by one is because it can be better and more efficaciously done by two.

Transportation increases the value of an article, but only so far as the cost of that transportation extends; as, for instance, where an article is sold in Philadelphia at ten cents per pound, and it costs one cent to transport it to New York, the transportation increases its value to eleven cents. But the transportation of products cannot be effected without the employment of a variety of means and persons, all of which have a value depending upon their extent and their services. For instance, there are two establishments, the one to forward, the other to receive goods, without any mention of the cost of package and warehousing; besides agents, insurers, brokers, carters, &c., to be recompensed. All of these occupations are, of course, productive, for without their agency, the consumer could never reach the products. Whatever, of course, lessens the power and increases the facilities of transportation lessens the price of a product, as when steam is used instead of horse-power by means of a railroad, or a canal in place of a wagon. These principles apply equally to external or internal commerce.

The internal commerce of a country is always more considerable than the external; this proposition may be doubted, it is nevertheless true. Take, for instance, any large entertainment, examine the articles consumed, and those of foreign growth will be found few and unimportant in comparison with those produced at home. It is, however, not more advantageous than the external, for were it so, the capital employed in one would be drawn to the other, and we should soon have no foreign commerce at all.

A still greater branch of commerce remains to be considered, that entitled the trade of speculation, which is purchasing goods at one time and re-selling them at another when a sale will be more advantageous. Even this trade produces, for it employs capital, ware houses, and care in preserving the goods or articles, and human ingenuity in taking a superabundance from a market where their value is depressed, to use it again when that value shall have increased. This branch of commerce, when it is employed in the purchase of the whole of an article, is entitled, *forestalling*. The carrying trade is another branch of commerce, and is the purchase of commodities in one country for re-sale in another, but it is only suited to

nations of large capital and redundant population; for where a nation is small and its capital limited, the whole of that capital should be employed in cultivating not its external but its internal resources.

OF THE CHANGES OF CAPITAL.

Our next consideration is the various transformations undergone by capital during the progress of production. The amount or extent of these transformations is of very little importance: they may be carried on *ad infinitum*, provided, however, that each transformation effects a proportionate increase in the value of the article operated upon: in other words, the change must pay for the labour given to effect it. An immense addition of value may be given to an object by a proper application of industry. Take, for example, check-springs, used in arresting the balance-wheels of watches. They are made of steel. This steel, however, was originally iron. Let us make a calculation. A pound of iron costs five cents. The manufacturer works it up into steel, of which the springs are composed. "Each of these springs," says Alagrotti, "weigh the tenth part of a grain, and are sometimes sold as high as three dollars." A pound of iron, allowing for loss of metal occurring in the progress of manufacture, will make 80,000. Multiply that amount by 3 and you have a capital originally but five cents, increased to one of $240,000. The same principle applies equally to agriculture, manufactures, and commerce. Let us look at an every-day change undergone in the latter branch of industry. A shipping merchant of London, possessing a surplus of specie is desirous of rendering it productive. He invests it in [illegible], and ships that flour to Rio Janeiro. During the voyage, however, a portion of his capital passes into the form of wages for his crew. On his arrival there he sells his cargo, and immediately invests the proceeds in hides and coffee, which are again converted into money at Charleston, and immediately re-invested in cotton, which forms the return cargo. Cotton is extensively used in manufacturing, and commands a ready sale; so at last the merchant, after all these transformations, receives his capital again, most probably with a very large increase, in its original form of specie.

OF THE MULTIPLICATION OF CAPITAL.

Productive capital, no matter how employed, notwithstanding its frequent changes, is always the same. It may, however, be equal; or inferior as well as superior in amount; equal, when the capital has merely resumed its former position; inferior, where the capital has been encroached upon, and superior, where it has steadily increased in the progress of its transmutations. This increase, of course, enables the holder to multiply his operations, for it is, in fact, so much additional capital; that is to say, his capital has increased as much as the surplus may be. This surplus may again and again be multiplied in the same way and to any extent, and it is the only proper process of augmentation, for were this surplus spent in riotous living, it would be destroyed in a single week, or perhaps month, as the case might be. But this destruction must be not understood as affecting the capital itself; it does not; it only affects value—which has gone out of existence without re-production. The re-employment of capital in the production of additional products is the proper and only way of increasing individual wealth, as well as of increasing the wealth of a community. But more products must always be created than have been consumed in their creation, otherwise there can be no saving, and as this saving or increase forms the ground-work of a perpetual annual profit, not only to the person saving it to all whose industry is set in motion, it ought always to be practised and encouraged, and, indeed, hailed as progression toward national prosperity

OF UNPRODUCTIVE CAPITAL.

Unproductive capital has already been described; it is, of course, the converse of productive. The non-employment of capital, by keeping it in an unproductive position, is a great evil, since it can do no good either to the possessor or those around him. Whether the amount be buried or concealed, or employed in the decoration of buildings, or in the mere ornament of the person, its unproductiveness is alike injurious, for it deprives not only the individual, but the nation of an increase of revenue, in itself an additional capital, which might of course produce again and again.

OF IMMATERIAL PRODUCTS.

An immaterial product is one where the value is consumed at the precise moment of production, as in the case of a physician in attendance on the sick. He examines the character of the disease, prescribes a remedy, and takes his leave without depositing any thing which is capable of transfer to any other person. His industry, however, has not been unproductive; he has possibly succeeded in preserving his patient's life. A product like this is certainly an object of exchange; the physician's advice was given for his fee, while the act of rendering that advice was its production, and the hearing it, its consumption; both consumption and production were simultaneous.

OF THE RIGHT OF PROPERTY.

Property, in the first place, was undoubtedly acquired by labour; indeed it could not have been acquired any other way. Originally held in common by all mankind, whoever first occupied it undoubtedly possessed the right to do with it what he chose. On his leaving it, his right ceased, and it again became common and susceptible of occupation, while the next comer, no matter whom he might be, could as readily enter on and possess himself of the land as any other person in the world. This state of affairs, however, was incapable of long continuance. As the world became more populous—men are always gregarious in their natures—each one, who had entered upon land, felled the trees and otherwise improved it, insisted on his right to continue that ownership which was undoubtedly, first, the product of his occupation, and afterward of his labour.

Wherever property exists, whether it consists of land or goods, the laws should protect the individual in his possession of it, for where they do not, what security has any one that his rights may not be invaded and he dispossessed of what it has cost him so much labour to acquire. Wherever a man is not protected in his property, as is the case in despotic governments, he has no incentive to labour. Why should he have? For any one, nay, even the government itself, might have watched him during his task, and the moment it had arrived at a state of completion, stepped in and possessed himself, or itself, of the fruits of his toil. Such governments and such countries are universally poor; while, on the other hand, those which cover the meanest individual with the same measure of protection that they extend to the noblest—countries like England, and our own beloved America—are ever the most wealthy; for protection of production always increases its growth. The right of property, however, may be as much invaded by obstructing the possessor in his enjoyment of it, as by actually dispossessing him of the property itself. Landed property, for instance, may be interfered with, by government prescribing certain modes of tillage; property in money, by prohibiting certain ways of employing it; and property in their own industry, where [illegible] exercise of a people's particular faculties and talents [illegible] restrained or prevented from having their full [illegible] effect. Taxation, when it transcends proper [illegible] produces the same result, for value can only be [illegible] upon such things as are productive and are valuable in themselves. The right of property, therefore, should always remain inviolate.

ON THE DEMAND FOR PRODUCTS.

It may be laid down, and that, too, as a general principle, that the greater the number of producers and the more various the productions of a country, the more prompt is the demand, and the more numerous and extensive are the markets for its productions, while, at the same time, they are more profitable to all concerned, for price increases in proportion with demand.

Each individual in a community is interested in the prosperity of the rest of its members, for the success of one branch of labour tends to promote that of all the others, for, no matter what line of business a man may be in, he finds employment more easily and is better paid for his labour when every one else is thriving around him. The same principle applies as well to external as to internal traffic, for where a country occupies a position contiguous to rich and industrious neighbours, it is of injury to its internal industry to purchase productions from them; for nothing can be bought from them except by exchanging what it itself produces for what its neighbours produce. Even where foreign produce is purchased with specie, that specie is almost always first obtained in exchange for our native productions somewhere else, for silver and gold are not always national products. But the mere consumption is not always beneficial to commerce, for the difficulty lies not in exciting the desire for consumption, but in supplying the means, which can only be furnished by production. A good government invariably stimulates labour, for labour increases production as the demand for products is proportioned to the activity with which they are produced.

OF BENEFITS ARISING FROM THE RAPID CIRCULATION OF MONEY AND COMMODITIES.

"Values engaged in actual production," says Saye, "cannot be realized and employed in production again, until they have arrived at the last stage of completion and been sold to the consumer." This is true. The sooner, therefore, an article is completed and sold, the sooner can the capital invested in that product be applied to the formation of a similar production. The rapidity with which this is done is productive of substantial benefit. Capital is always employed in production. It is here engaged but a short period, thereby causing a saving of interest to the capitalist as well as a saving in the charges of production.

There is no difference between the circulation of money and goods: the same principles apply to both. Money lying idle in a miser's chest is as inactive as the goods slumbering on a dry-good merchant's shelves: both should be circulated as soon as possible, and the latter, when of a perishable character, should be got rid of even at a partial loss, for it has always been considered wiser rather to lose a part than the whole.

OF THE EFFECT OF GOVERNMENT RELATIONS WHEN INTENDED TO INFLUENCE PRODUCTION.

Government, in the abstract, can do no act but what in some way or other affects production: nevertheless, it sometimes aims at a direct influence. The object in such an aim is twofold; either to prescribe the creation of certain particular kinds of produce, or to direct particular modes of production.

Those kinds of products more in demand by society pay better than others that are less cared for; the profits are consequently larger. When government at such a time intervenes and directs the attention of the producers to another production which is less desired and pays a less profit, it undoubtedly calls the producers of the country from a source of great to one of less profit. Such a course, when adopted, is always the result of ignorance, for that which produces most is the most beneficial to a government and its people. The same rules apply as well to agriculture as to commerce, for the agriculturist and the manufacturer, possessing a daily acquaintance with the details of their business, must know better what is to their advantage than the government, which can only arrive at a knowledge second hand, and, besides, is liable to misinformation. But, what, it will be asked, is the cause of the interference of government? By the way, governments throughout the world have interfered oftener with the external commerce than the agricultural interests of their several countries. The cause of the interference of government is a system entitled the *exclusive* or *mercantile system*, which always, but erroneously, attributes the profits of a country to what is generally called its

BALANCE OF TRADE.

The balance of trade, says the English translator of Saye, is the comparison a nation makes between the value of its exports to, and that of its imports from, foreign countries. When it has exported more merchandise than it has taken in, the country receives the difference between the amounts in money; then the balance of trade is in its favour, but with the converse, it is against it.

OF THE EFFECT OF REGULATIONS, FIXING THE MANNER OF PRODUCTION.

Whenever public authority interferes in the details of agricultural productions, that interference is generally beneficial. But it is only so where government confines itself to the granting premiums and offering encouragements, or to the diffusion of useful knowledge on the subject. On the other hand, no branch of industry has suffered so materially from interference, as has that of manufactures, governments generally limiting the number of labourers in each branch, either by directing them to remain in one trade, or by exacting certain particular terms on which they can alone carry on their business. Such a course of conduct gives rise to chartered companies and incorporated traders. The effect of this is easily seen. A monopoly is at once created, which tends to the benefit of the privileged few while the consumer pays for it. The whole system is a bad one. Labour, to be productive, should always remain untrammelled, for, after all, self-interest is the profoundest of instructors, while every restraint imposed by legislation upon the freedom of human action inevitably extinguishes a portion of the energies of a community, while it never fails to abridge its yearly product.

PRIVILEGED TRADING COMPANIES.

Companies of this kind do not exist in America, neither is it right that they should, for possessing, as they generally do, exclusive privileges, either in buying or selling certain particular articles, or in holding the monopoly of trade with some particular country, they would wield the power they hold of elevating the prices of their goods far beyond what they possibly could arrive at under the present state of affairs, where trade is free to all of our countrymen who choose to embark in it. The operation of such companies is to compel the consumer to pay more for an article than it is actually worth. It is supposed by some that a company, having the exclusive privilege of manufacturing a certain article, or of importing a certain kind of produce, may purchase either its materials or its merchandise at a less price. But, even this is to be taken with some considerable allowance, for the rule can only apply against the people of the companies' own government, and not those of others, who have the right to, and do compete with such associations, whenever it is their interest to do so. It will be seen therefore, that the above supposition is fallacious, and that while a privileged company does not possess the power of affixing a specific price on any article of foreign growth or ma

nufacture, in buying, it does possess both power and right to say what that article shall sell for at home, for no one is allowed to interfere with its peculiar branch of trade. Companies, therefore, always fix exorbitant prices upon every thing they have to sell. This, too, another evil feature, is no gain to the nation, for the price of every article is taken, not from strangers, but from the nation itself. Such companies, therefore, should always be discouraged.

OF THE EFFECTS ON NATIONAL WEALTH, ARISING FROM EFFORTS MADE AT PRODUCTION BY PUBLIC AUTHORITY.

It may be taken as a general principle, that there never can be any production of new value, therefore no increase of wealth, where the product of a productive concern does not exceed the cost of production. Whether government or individuals be the adventurers in a losing concern, at the same time that it ruins the nation, it leaves proportionably a less amount of value in the country. When the concern does not support itself, the receipt of course is less than the outlay, while the difference between the two, falls always on those who supply the expenditure of the government—the tax payers. Whether the state does business with its own private funds, or with the produce of the national lands, the result remains the same, for whatever is thus wasted, might have lessened the amount of the public burdens.

The manufacture of the Gobelin tapestry in France, owned and carried on as it is by the government, is an instance of a losing concern. Independent of the loss that almost always occurs to a government that embarks directly in trade or manufacture, and of course to the nation, such a course is always productive of greater evils. We instance one: the productive efforts of a government always counteract, if they do not destroy individual industry. A government is always a dangerous rival, for while it has unlimited means at command, it possesses but little care for its own interests. Whatever a government consumes, had always better be obtained from individuals, who can ever undersell, and of course supply cheaper, than the government itself can manufacture. There are some exceptions, however, to this proposition, the building of national vessels or arms, for example, with other things of like character, which a state of necessity keeps in its own hands. Arms, however, are generally purchased from individuals, and always with benefit to the state, which is compelled to act by deputy, or by the agency of a set of men whose interests directly oppose its own. In consequence it is invariably cheated.

OF EMIGRATION.

Emigration to a nation, whether temporary or permanent, ought always to be encouraged, for it invariably assists to increase the aggregate of its wealth. Not, however, to the total amount brought by the traveller into a country, for of course he receives value which he consumes in exchange for what he brings with him, but only as far as the per centage of profit on the principal may extend. A stranger, whether he be rich or poor, is a valuable acquisition to a nation. If rich, he brings with him both industry and capital, valuable auxiliaries, and if poor, industry alone, which, properly employed, will be advantageous not only to himself, and those around him, but to the nation itself, for as we have shown again and again, industry must necessarily produce, and production is almost always the production of value.

Emigration from a country, on the other hand, is as much a total loss to the one left as it is a gain to the one chosen. It is so much industry and capital gone for ever. The best mode of attracting and retaining citizens, is to treat them with kindness, justice, and benevolence; to protect every one in the enjoyment of those rights which he most reverentially regards; to allow him the free disposition of person and property, and of speaking, reading, and writing his sentiments in the most perfect security.

MONEY.

In society no one produces all those things which are necessary to supply the total of his wants. Indeed, it is rare that we find one able to create a single product. He must necessarily, therefore, procure whatever else he requires through the medium of exchange. He must first, however, create a sufficiency for his own use. This he always does, for individuals keep but a small portion of what they grow or create themselves; the rest they exchange.

Exchange and transfer have been erroneously thought the basis of wealth; they are, however, at best but secondary and accessory circumstances, for were each person to raise for himself all the objects of his consumption, as is the case in some of the remote western settlements, society might exist for ever, without a single instance of either. Both, however, are indispensable where civilization is at all advanced.

Insisting, then, on the necessity of exchange, what difficulties must arise if every one was compelled to exchange his products specifically, for instance, the bootmaker his boots for bread, the cutler his knives for cloth, the manufacturer his cloths for wheat, and so on *ad infinitum*. One might not want the articles the other was willing to exchange, but something else, and so on as before. There must then, of course, arise some commodity—for which all will exchange under any circumstances—which is always the representative of a fixed value, and one, too, not liable to any great degree of fluctuation. *Money* is exactly that commodity.

It is in constant demand on account of its inherent utility. It is always readily received in exchange, and it is capable of infinite subdivisions. Besides, it has two particular qualities which give it a general preference in value to the same amount of value in any other shape: First, its aptitude as an intermediate object of exchange to assist all who have any exchange or purchase to make toward the particular object of request; and secondly, its capability of subdivision and precise apportionment to the exact amount of the intended purchase or exchange, which capability is the strongest recommendation to every member of the community. Money becomes the more requisite the more a nation advances in civilization and the further it carries its division of labour, for, as has been seen, individuals rarely produce more than a part of one article; as, for instance, where a man makes not the whole of a watch, but a part of it only, its springs. These he is compelled to exchange or barter to supply himself with the necessaries of life, as bread, meat, clothes, &c.

The choice of the particular article that is to act as money, depends upon custom; it may be any thing, as shells, &c.; but in civilized communities it is generally gold and silver. It passes current like any other article, and people are at liberty to barter their goods for it, or in kind, as may please themselves. The single reason why it is preferred, is because it is more readily disposed of in the same way than any other. Dollars derive their circulation as money from no other authority than this preference, and if there were the slightest ground for any one's imagining any thing else would pass more currently, that other article, whatever it might be, would usurp its place the moment the fact was discovered. Custom, therefore, and not authority, prescribes what shall pass exclusively as money, let the latter be of what commodity it may. The frequent interchange of money for commodities has attached special terms to the transaction, as where one receives it in exchange for the act is

called SELLING; where he gives it in exchange, BUYING. And in this way commenced the use of money.

THE MATERIAL OF MONEY.

The material of money is of no great importance, as it is neither used as an article of household utility, food, nor attire. It is not capable of consumption, for it passes from hand to hand without any perceptible diminution. It is, therefore, of little importance whether it be gold or silver, parchment or paper. All that is requisite in it is the possession of some inherent and positive value, for no one would be fool enough to exchange that which was valuable for that which was not. Gold and silver possess both these requisites in an eminent degree, which has caused them to be universally adopted. The reasons of their fitness are simple. They are capable of minute subdivision without any sensible loss, so that the quantity may be easily adapted to the value of the article bought. They have the same quality everywhere, a grain of gold being the same either in Asia or America. Neither age, weather, nor wet can deteriorate them, and the relative weight of one determines the weight and value of another specific portion, four grains of gold being worth just twice as much as two. Their scarcity and dearness, besides, are not so great that the amount of gold or silver is too small for common use, and they are not sufficiently abundant and cheap as to make a great value amount to a great bulk or weight; while they are sufficiently malleable to allow them to receive a stamp or impression which certifies the weight and value of the price, and its proper degree of purity.

All money, however, is not pure; on the contrary, some meaner metal is always used with it, which lessens its value and which is called *alloy*. This alloy, however, is worthless, for the value of the coin depends not upon it, but on the quantity of the more precious metal used in its formation.

OF THE ACCESSION OF VALUE GIVEN TO A COMMODITY BY GIVING IT THE CHARACTER OF MONEY.

It has been seen that money is indebted for its currency not to government or authority, but to the fact that it possesses a particular intrinsic value. Its preference, however, as an object of barter to all other commodities of an equivalent value, is owing to its character as money. Every one must possess it, for none can exist without its use. But to proceed: The adopting any specific commodity and making it serve as money augments its value as an article of commerce. A new use being found for it, it becomes more in request, while the employment of the greater makes the lesser portion dearer than before. The use of the precious metals in manufacture therefore increases the value of the proportion that remains, while the non-use would render them cheaper, that is to say, it would take a larger amount to purchase the same quantity of merchandise when they were not employed in manufacture than it would do when they were being made up into plate, jewelry, and other articles of use or ornament.

The choosing any commodity to act as money in one section of the world, makes it dearer everywhere else, for another use immediately arises, that of exporting it where it is found more valuable. But specie, as money is often called, is subject to the same fluctuation in value as other commodities: it rises and falls according to the demand or supply. The demand for specie sometimes becomes so great as to induce the formation of what is called *paper money*, which is used as the representative of an equivalent amount of gold and silver. The *paper money* of this country, as well as of the nations of Europe, furnishes an excellent example.

OF COINAGE.

The precious metals receive an additional value from impression and coinage. Acting as money, they must necessarily pass from hand to hand. This passage is of hourly occurrence. What difficulties and delays in business would constantly arise if the seller of goods were compelled not only to provide himself with scales to weigh the amount of metal he would daily receive, and what blunders would occur from ignorance, awkwardness, or defective implements?

Metals, and here governments interfere, are reduced to an established standard, and divided into pieces of an established weight by the process of coinage. This, we have said, gives the bullion an additional value. The reason is plain, the new dress in which the metal appears saves the owner not only the cost of weighing and assaying, but the loss of labour and time such a course of procedure must create.

OF THE ALTERATION OF STANDARD MONEY.

Public authority, taking it upon itself to fix arbitrarily the commodity that shall serve as money, should never alter it, except in cases of absolute necessity, for it can neither raise nor depress the value of money without oversetting every thing like order and regularity; the value of goods always adjusting itself, not to that imaginary one authority may please to affix to them, but to the real value naturally and always attached to the article, money, by the conflicting and constant influence of demand and supply. Besides, such a course of procedure inflicts the most injurious effect on credit, commercial integrity, and industry. Carried to any considerable extent, it would destroy all commerce whatsoever.

WHY MONEY IS NEITHER A SIGN NOR MEASURE.

Money would be a mere sign or representative had it no intrinsic value of its own. On the contrary, in sale or purchase, the latter is the only thing considered. When an article is purchased for a dollar, neither the impression nor the name is offered or taken in barter, but the quantity of silver known to be contained in it. For instance, were government to coin pieces of brass, calling them dollars, they would be considered only as brass and not as silver. Their value as brass would be the only thing regarded, and it would take a much larger number to purchase the same amount of goods than it would of the coin of the former capacity of value.

OF A FIXED RATIO OF VALUE BETWEEN METALS.

The government of France when it sought to fix the relative value of metals and commodities, committed another error,—that of attempting to determine by act of law the relative value of metals acting as money, one to the other. It was an arbitrary measure, but it legally established the ratio of the nominal value of gold over that of silver. What has been the consequence? The relative value of the two metals to other commodities has been constantly fluctuating, as has also the relative value of the metals themselves, exchanged one with the other. It may be taken, however, as a fixed principle, that it is impossible in practice to assign any fixed ratio of exchangeable value to commodities whose ratio is always fluctuating; gold and silver must consequently be left to find their natural level.

OF COPPER COINAGE.

Copper coin, in the strictest sense, is not money, although it generally passes as such. In most of the countries in which it is issued, it is not a legal tender, except in such minute sums that their amount cannot be offered in gold or silver. Indeed, it is little more than the representative of a certain amount of silver too trifling to pay for the coinage. The government that

issues it should always be prepared to redeem it with silver, and should always do so on demand; otherwise, if it proceeds in coining, an excess is sure to follow beyond the wants of circulation. This would certainly place it at a discount, and every one holding copper coin would be anxious to get rid of it on any terms in exchange for gold and silver.

OF THE FORM OF COINED MONEY.

Coin suffers a diminution in value, corresponding to its extent of surface. Of two pieces of equal weight and value, that which offers the smallest portion of surface to friction will suffer least from being used as money. A flat cylindrical form has been adopted by most governments for this purpose, because it is best adapted to prevent loss. The less the cylinder is flattened, however, the better, and the piece should be thicker than broad.

As to the impression on the surface, it should be low, and if possible, an alto-relievo. This form of impression, however, can only be used where the coin is proportionably thick; it being liable to break. A basso-relievo form has been generally adopted.

OF REPRESENTATIVES OF MONEY.

1. *Bills of Exchange and Letters of Credit.*—Both of these, with promissory notes and checks, are obligations in writing, promising to, directing to, or causing to be paid, a specific sum of money at a certain time, either in the town or country in which they are issued, or at some other place. Such affairs, having an actual and present value, are in daily use as money in most transactions of purchase. The present value of which we speak, however, depends entirely upon their prospect of a future one. They are always representatives of sums due, and generally acknowledge upon their face that an actual value has already been received for them.

2. *Of Banks.*—Banks of deposits are institutions in which any one can lodge any amount of what passes for money, at its actual and present value at the time. This amount is of course placed to the credit of the owner, and is subject to his order or check, which, as has been seen, is a direction to the bank to pay a sum mentioned therein, to some particular person, or to the owner's self, as the case may be.

There is another kind of bank, which is founded on other and wider principles—one which consists of an association of capitalists, who each subscribe a certain amount of capital in shares that are capable of transfer, which capital is employed in various ways, but generally in the discount of notes and bills of exchange. Discount is the advance of the value of the paper offered to them, after the deduction of the legal interest for the time the paper has yet to run. They likewise perform another office, with the view of enabling them to enlarge their capital, and increase their amount of business: they issue notes, bearing on their faces a promise to pay to the bearer, on demand, the amount of gold or silver specified therein. The security they offer to individuals is the amount of commercial paper they hold, subscribed by individuals in good circumstances. These notes are entitled *bank notes*, and the institutions that issue them, banks of discount and circulation. The banking associations of this country, generally unite all the above-named qualifications, that is, while they receive deposits, they issue notes, and when able, give discounts, a complication of business which is extremely useful to the community, when such institutions are properly managed.

DISTRIBUTION.

OF THE BASIS OF VALUE.

We now come to a second branch of the science of Political Economy, that of Distribution. The various phenomena of Production have already been discussed. Human industry, it has been seen, assisted by capital and certain natural agents and properties, creates utility, which is the basis of value. Value is the object of distribution. We have shown again and again, that products are always the result of aggregate labour, and not of the toil of a single individual: one person rarely completes any thing; on the contrary, production is divided among many, all of whom assist in the formation of a product. One, for instance, is possessed of a farm, a second tills the ground and sows the seed, a third reaps the crop, and so on until the article grown is in the hands of the consumer. Each of them, of course, must be compensated for his labour. But how? With the price paid for the product created by their united efforts which must be justly and proportionably divided between them. The principles which regulate the whole of this transaction fall under the name of *distribution*. It may be asked, what is the valuation of an object. "It is nothing more nor less," says Say, "than the affirmation, that it is in a certain degree of comparative estimation with some other specified object; and any other object possessed of value may serve as the point of comparison. A house, for instance, may be valued in corn or money."

Whenever a thing is valued, the object so used is the fixed *datum*. In the instance just quoted, the house is the *datum*; for it is a definite amount of material put together in a particular way, and on a particular site.

Valuation is vague and arbitrary, when there is no certainty that it will be accepted by others. The nearest way to arrive at the truth of the value of any commodity, is to estimate it at what it is certain to bring in the market, the want or desire for it being always certain to fix its current price. This brings us to the consideration of

SUPPLY AND DEMAND.

Demand is of course the desire for some particular object or article, and is greater or less in proportion to the extent of that desire; while *supply* is the quantity of that article, which can readily be attained at any given time. The principal bound to demand is the inability to give some other product, whether it be money or otherwise, in exchange for it. Demand of course depends upon the number of consumers, and their ability to pay for the article desired.

OF THE SOURCES OF REVENUE.

It has already been shown that products are the offspring of productive means in the command of mankind, such, for instance, as industry, capital, and natural powers and agents. These products when raised by man form his revenue, and enable him to obtain such other things in exchange as are not given gratuitously either by nature or his fellow-man.

The right to the disposition of revenue is a natural consequence of possessing the means of production. Only such things as are the subject of human use are the sources of revenue: whatever are not, form no portion of human wealth, there being no such thing as wealth, except where property is known and certain, and possession acknowledged and beyond dispute.

Perhaps it would be well to suggest that property in human industry, and in what is generally known as capital, which has been before defined, is more holy and less capable of dispute than mere natural powers and agents.

Revenue, with the several sources of production, is a constituent proportion of wealth, yet it would be foolish to assert that the consumption of revenue could render any one poorer, for his productive means (his capital) remains untouched, and that still goes on producing revenue. Should his capital, however, be touched, his revenue would decrease, proportionably with its diminu

tion. Revenue, too, when unconsumed and added to capital, ceases to be revenue; it becomes capital, and its employment as a productive means causes it to become a source of additional revenue. The value of revenue is also large in proportion not to the value, but to the amount of the product arrived at—to the entire total of utility created. The ratio, therefore, of national revenue is determined not by the value of a product, but by its amount; with individual revenue the case is different.

Whenever any thing can be saved in the original cost of production, that saving is an increase of revenue to an equal extent, a less amount of capital being employed to furnish the same product. The saving, too, of course, becomes an additional means of production.

OF THE REAL AND RELATIVE VARIATION OF PRICE.

Price is exactly the amount of money any thing may be worth, and current price what it is certain to obtain at any particular place; the desire of obtaining any object varying in relation to the quantity obtainable, according to its locality.

Price obtained on the sale of any thing represents all other commodities procurable with the same amount. The price of a bushel of wheat, for instance, is 75 cents; it is therefore exchangeable for that amount of silver, or for such other products as that sum may procure. Price is of two kinds, buying and selling price; the former, where a certain sum is given to obtain possession of a product; the latter, where the same amount is obtained for the relinquishment of such possession.

The cost of producing an object is always its price; and its production, as well as its subsequent exchange for others, resolve themselves into a barter of one product for another, which barter is conducted upon a comparison of their respective current prices. One important particular, however, must not be passed by.

Supposing an ell of broadcloth has cost eight dollars in productive agency, it certainly will have cost the same amount in manufacture; if three-fourths, however, of that productive agency can be made to produce it, the same amount of broadcloth will cost the producer only six dollars, so that, while the current price of the productive agency remains the same, the actual cost of production will have varied in the ratio of the difference between six and eight dollars.

It is otherwise with regard to the variation of price of products already in existence, one to the other, without reference to their respective cost of production. For instance, when the wine of the last vintage, which but a short time previous sold at 10*l.* the tun, brings on sale only 8*l.*, money as well as other productions are dearer to the wine-seller. The reason is plain: the productive power which raised the wine receives less return than it otherwise would have done had the price remained as at first. It may be taken, therefore, as a general principle, that in the course of a *real* variation, such as the first example quoted, the wealth of the people at large is increased, while in the latter example, that of the wine-seller, it remains fixed and stationary.

Wherever a saving occurs in the cost of production, it implies the obtaining either of a larger product by the exertion of the same agency, or of an equal product by means of less agency, which are one and the same, while, at the same time, it is always followed by an increase of the product itself. It has been thought by some, but erroneously, that an increase of production is not always succeeded by an equal increase of demand, and that the price current of the product must consequently fall below the cost of producing it. This is a mistake: the fall of price always increases the quantity of consumers, and the increase of demand invariably outruns the increasing powers of an improved production operating on the same productive agency. Every enlargement therefore of productive means creates a demand for more of those means. The invention of the art of printing, and the increased demand for books now over that in the days of Faust, furnishes a striking example of the operation of this principle.

On the other hand, as a real advance of price always arises from a deficiency in the product raised by equal productive means, so it is invariably attended by a lessening of the aggregate of national wealth. The reason is this: the increase of price on each portion does not counterbalance the reduction that is sure to occur in the total quantity of the product raised, while the object of consumption becomes dearer to the consumer, who suffers a corresponding impoverishment.

Suppose a murrain or bad management causes a scarcity of sheep, the price of these animals will necessarily rise, but not in the same proportion with the reduction of the supply, for the demand decreases in proportion as the sheep grow dearer.

It may therefore be insisted on that every real reduction of price, instead of reducing it, augments the nominal value of produce raised, and that a real increase of price invariably reduces the amount of national wealth, while at the same time it lessens the quantity of human enjoyment.

The difference between a real and relative variation of price is a considerable one. A real variation is an increase or decrease of price, consequent upon some alteration in the cost of production; a relative, a change in price consequent on an alteration of the ratio of value of one article of produce to other articles. The first is beneficial to the consumer while it does no injury to the seller, and the converse; but in the other what is gained by the seller is lost by the consumer, and the converse.

Wherever sales of products occur between one country and another, the nation which vends the product that has advanced relatively, gains exactly the amount of the advance, while the purchaser loses in the same ratio. The rise of price adds nothing to the general wealth of the world, which only increases with the appearance of something new and useful, that may become the object of demand.

OF NOMINAL VARIATIONS OF PRICE, AND THE VALUE OF BULLION AND COIN.

In treating of the rise and fall of the price of commodities, although value has been expressed in money, no notice has been taken of the value of money itself; which, speaking truly, plays no part either in the real or the relative variation of the price of commodities. One product is ultimately bought with another, although paid for at first in money. When the price of any product is doubled, it can only be obtained by giving twice the quantity of every other commodity in exchange. It is no matter whether the exchange be made directly, or through the intermediate means of money. Money is capable of undergoing a real variation in the cost of its production, as well as a relative one in comparison with other products.

The discovery of the South American mines caused a considerable fall in the value of silver, at least three-fourths, while on the other hand price remained stationary.

The peculiar and inherent value of bullion or money has its rise in the various uses to which they are applicable. The degree of value is greater or less as they are more or less employed, or more or less abundant.

The major portion of the coin of the world may be said to be in constant circulation. In this respect it is wholly different from other commodities which only continue in circulation during the time they remain in the hands of the dealers, retiring from it as soon as they reach those of the consumer. Money, ever during the

time it is employed as capital, is not an object of consumption, but barter, every act of purchase being an offer of money in exchange, and an increase of its circulation.

Gold and silver, when employed in the purposes of manufactures, is only in circulation while it remains in the hands of the dealer, waiting for a customer. It retures from it when it reaches the hands of the consumer.

Nothing but a large influx of silver from some new source can eventually affect its value. Were it, however, like food or raiment, an object of necessity, the case would be different; for the constant impulse of humanity to the increase of their species to a level with their means of life, would make the demand coexist with the supply. The peculiar use of silver in the character of money depends upon the number of movable and stationary objects that may be intended to be circulated. Coin, therefore, would be more abundantly required in rich than in poor nations, but that the superior quickness of its circulation in wealthy communities makes a smaller quantity requisite in proportion to the whole amount of commercial transactions; while in a state of national wealth, credit is frequently used as a substitute for coin. By the latter expedient in its various shapes, as well as the use of convertible paper, the use of metal money becomes proportionably less. It may be asserted as a safe principle, that the more wealthy a nation is, the less amount of coin she uses when compared with other nations.

If the nations of the earth increase in wealth in the next, as they have in the last five centuries, their want of the precious metals will increase in proportion; but if the supply of gold and silver transcends the increase of the aggregate wealth of the world, it will fall in value in respect to all other commodities. Metal money may thus one day become as cumbrous as the tin coin of Lycurgus, but the use of gold and silver will become amplified in a proportionate degree.

OF THE DISTRIBUTION OF REVENUE AMONG SOCIETY.

The various causes which determine what is entitled the value of things, apply to all matters that exist, whether perishable or no; and among the rest is the productive service of industry, capital, and land, when in a state of productiveness. Those who have at their disposal any or all of these sources of production, are *vendors* of productive agency; those who consume the product, are *purchasers*. The relative value of the product rises with the demand, and in the inverse ratio with the supply.

Those who employ industry wholesale, are brokers between the vendors and the purchasers, who engage a proportionable quantity of productive agency to the demand for the product, which demand is greater or less in proportion to the product's utility. Farmers, manufacturers, and merchants are constantly comparing the prices which the consumers can and will give for a particular product, with the necessary cost of producing it. If the comparison is such as determines either one to produce it, he is the means by which a demand is made for all the productive agency applicable to the matter, and so becomes one of the bases of the value of that agency.

On the opposite hand all the agents of production, whether animate or otherwise, land, capital, and labour, are supplied in larger or smaller proportions, in accordance with various motives to be noticed hereafter, thus forming the other several bases of the value at which their agency is rated.

Every product, as has been seen, repays, when completed, by its superior value, the total amount of the agency employed in its production. A great part of this agency may have been paid for long before the entire completion of the work, advanced, of course, by some one, while other parts, however, may have been paid for at its completion; nevertheless the whole is ultimately paid for out of the value of the product. The total value of almost every product is shared or *distributed* among the various hands employed in its production long before it is finished. Each successive producer makes the advance to his predecessor of the value of the product at the time, with the value of the labour expended in advancing it to that stage. The consumer finally pays for all.

All the revenues of a community are distributed in a like manner.

That portion of the value produced, which accrues in this way to the land proprietor, is entitled the profit of lands. This is sometimes transferred to another, the farmer, in the consideration of a fixed rent. Whatever portion is assigned to the capitalist, however minute may be his advance, or for how short a space of time, is called the profit of capital. This capital is sometimes loaned, and the profit given up in consideration of a prescribed interest. That portion which is given to the mechanic or labourer, is entitled the profit of labour; which is again sometimes abandoned in consideration of certain wages. Each class consequently receives its share of whatever value is produced, and this share is its *revenue*. It is in this way that the entire amount of the value of products is shared among the various members composing a community. That only is profit to the producer which is made after all the necessary charges, expended in producing his particular products, are paid; and is termed his net produce. His gross produce is the total amount of his production without deducting his net profit.

The total amount of profit obtained by an individual from his land, capital, and industry, in the year, is his *annual revenue*. The total amount of all the profits of the individuals of a nation in the same space of time, is its *national revenue*. Its sum is the gross value of the amount of the national product, less what it exports; for the relation of nation to nation is the same as that of individual to individual.

The money into which revenue is converted must never be confounded with the revenue itself; the latter is the actual product of the producer's creation, which, by barter, may be converted into any shape the producer pleases, whether it be products of a similar or dissimilar character, or otherwise.

The same rules that apply to material, obtain with immaterial products. The advice of the lawyer and physician, for example, are the products of their respective talents, which are their productive agency. Whoever has occasion to use either, gives in exchange for it a commercial product converted into money. Each of these in turn consumes his revenue in the way best adapted to his peculiar desires.

OF THOSE KINDS OF PRODUCTION THAT YIELD THE BEST RECOMPENSE TO PRODUCTIVE AGENCY.

The profits of productive agency differ with the variety of the branches in which it is engaged; in some they are excessively large, while in others they are miserably small. Productive agents, to be sure, always strive to direct their agency to those employments which produce the largest amount of profit, and thus, by competition, decrease price in the same ratio as it is increased by demand. The efforts of competition do not always insure a proportionate remuneration, for it is impossible that they should ever properly proportion the supply to the demand.

As a general rule, the largest profits are made on such products as are most common and least able to be dispensed with, and not on those costlier ones which may be considered rather as objects of luxury than any thing else. The reason is plain; the demand for indispensable articles is created by actual necessity, and increases with every addition to production. Nothing tends so much to create a large population, as to supply it with plentiful means of subsistence. On the other hand, the demand

for luxuries depends almost entirely on contingencies. In the first place, they are not indispensable, but objects of secondary want, and the desire to obtain them is limited to the few who can indulge in them. The productive agency employed in the manufacture of superfluities is always worse paid than that employed in any other form. In large cities, the case is somewhat different; for where fashion commands, fools are always found to obey. There, objects of ornament, whether in dress, furniture, or otherwise, command a readier sale, and of course recompense the agency employed in their production, by more considerable profits. Nevertheless, the most fashionable tradesmen are most frequently found insolvent.

Commodities of common utility, on the other hand, lie within every one's reach; they are equally attainable by both rich and poor. The articles composing human food, for instance, as bread and meat, are indispensable, and, despite the briskness of the competition, yield the most certain and the largest profits. Bakers and butchers, sooner or later, retire from business with a competency; indeed, they are among the wealthiest of our citizens. The demand for such things, besides, is always steady. The farmer is never very long in disposing of his wheat or potatoes, while the hot-house cultivator finds it difficult to get rid of his forced pine-apples. There is a greater demand for the cotton goods of Lowell than for the laces of France, or the superb shawls of Cashmere.

OF THE REVENUE OF INDUSTRY.

1. *Of the general profits of industry.*—The motives which increase the demand for products have been examined before. There is little necessity therefore of enlarging on them.

When the demand for any product is lively, the productive agency which creates that urgency is also in demand, a consequence which increases its ratio of value. Industry, capital, and landed property, invariably yield the largest proportion of profit when the demand for products is brisk, affluence expanded, profits most widely circulated, and production most prolific and vigorous.

When the demand for some products increases over that for others, what is most sought for affords the greatest remuneration to the productive agency employed in its completion.

Examining the subject rather more in detail, we shall ask in what cases the profits of industry bear a greater or less proportion to those of capital and land, and the converse; and why certain methods of employing all these are more profitable than others.

Commencing with the first, and comparing the relative profits of industry with those of land, we find that they bear the greatest ratio where profusion of capital creates a demand for a large amount of industrious agency. Such is the case in a great proportion of the United States, because population, and, of course, the human agents who produce, bear but a small proportion to the extent of land and the constantly increasing amount of capital.

The profits of the different branches of industrial agency, taken one with the other, increase or diminish in proportion, first, to the extent of danger, trouble, or fatigue, which attend them, or to the extent of pleasure which they may afford; next, to the continuance or irregularity of the particular occupation; and, lastly, to the extent of skill or talent that they may require.

Each of these circumstances varies the natural ratio of profit, while it tends to diminish the *quantum* of labour in circulation in each branch.

Some professions receive a large proportion of their revenue in honour, as authorship of all kinds. Dancers and opera-singers, on the other hand, are better paid, because they are held in less estimation. The one balances the other. Every temporary occupation ought to receive a high recompense, for the labourer should be paid as well for the time occupied in his task as for that in which he is idle.

Employments of time and talent, requiring, as they do, a liberal education, receive more reward than those which demand a less one, education being capital which should yield interest exclusive of the ordinary profits of industry.

2. *Of the profits of the man of science.*—The man of science, labouring as he does for the welfare of mankind, receives but a minimum proportion of the profits of his industry, no matter how beneficial it may be. The reason is plain. He throws into circulation in a moment an immense stock of his product, which is one that suffers no deterioration by use; consequently it is unnecessary to resort to him for a fresh supply. No matter how much time or how much labour has been expended and exerted in the cause, the result must be the same. The information that may have taken years to accumulate, occupies but a few pages, and is instantly circulated in the greatest abundance. It is for this reason that enlightened governments, by special favours and flattering distinctions, indemnify the man of science for his labours in the cause of mankind.

These remarks, however, apply only to the revenue a man of science obtains directly from his calling. There is nothing to prevent him from being a land-holder, capitalist, or merchant, from either of which situations he may derive revenue.

3. *Of the profits of the master-agent in industry.*—Before we proceed in this section, we must repeat that the occupation of master-agent, or adventurer, as he has been distinctively styled, is one which is comprised in the second class of operations specified as necessary for the setting in motion all classes of industry, whether agricultural, manufacturing, or commercial. The farmer, or cultivator on his own account, the master-manufacturer, and the merchant, are all adventurers in their respective departments of industry. We are now to consider the nature of their profits.

The price of their labour is regulated by the ratio of the supply, or quantity of that labour in the market, to the demand for it. Two principal causes operate to limit the supply, both of which consequently assist this superior kind of labour to maintain a high price.

In the first place, the agent must possess the necessary funds. He need not be rich, for he may work on borrowed capital, but he must be solvent, possess the reputation of intelligence, prudence, probity, and regularity, and be able to procure that which he himself does not possess.

In the second place, this particular class of labour requires an association of moral qualities that do not often run together—judgment, perseverance, a knowledge of the world, and of business.

All branches of industry, however, do not require the same amount of capacity and knowledge. The farmer is not expected to possess the same business qualifications as the merchant; on the contrary, he may do well enough with the knowledge of two or three sorts of cultivation. The merchant, however, must be well versed in the nature and quality of his merchandise. He must have some knowledge of the extent of the demand, and of the markets whither his goods are sent for sale. He must also be constantly informed of the price current of the different parts of the world, be able to form a proper estimate of these prices, to do which he must be acquainted with the several national currencies and their relative value, or, to speak more technically, their rate of exchange; he must know the means of transportation, its risk and expense, and the laws and customs of the people he does business with, beside other matters of knowledge too numerous to mention here. It is not surprising therefore, but rather a necessary consequence, that the merchant who possesses all these requi-

sites, should be better paid than the farmer who possesses only two or three.

4. *Of the profits of the operative labourer.*—Simple labour may be exercised by any one who is possessed of life and health: bare existence, therefore, is all that is requisite to maintain a supply of this kind of industry; consequently its wages in any country rarely rise above what is necessary to the operative's subsistence. In the United States, however, it is better paid. The supply of operative labour nearly always maintains an equality with the demand: it sometimes, however, transcends it, for the difficulty lies not in the labourer acquiring existence but subsistence. Necessary subsistence may be taken as the standard of the wages of common raw labour, but the standard itself is extremely fluctuating, comfort having immense influence in the scale of human wants. What is necessary subsistence, then, depends partly upon the habits of the nation to which the workman may belong. His ordinary wages are generally low, and the product of his labour cheap, in proportion as the value he consumes is small or large. If his condition be improved and his wages raised, either his product becomes more expensive to the consumer, or the share of his fellow producers becomes less.

The wages of the labourer are always a matter of adjustment between the constantly conflicting interests of employer and employed, the former endeavouring to give as little, and the latter to get as much as possible. The advantage, however, lies in the hands of the employer, whose wants are fewer, although both are actually necessary to each other.

OF THE REVENUE OF CAPITAL.

Capital, when employed in production, renders a service which creates a further demand for other capital, to be employed in a similar manner, and enables the holders of it to charge more or less for its use.

It is no matter whether the capitalist employs his means himself, or loans it to another for that purpose; it still yields a profit, which is entitled the profit of capital, distinct as distinct can be from that of the industry using it. Where the capitalist employs his capital himself, the profit so gained is the *revenue* of his capital, which is added to that of his personal talent, industry, &c., and frequently confounded with it. Where he loans it to another, the revenue of his capital is exactly the sum paid for its use.

1. *Of loans at interest.*—The interest of capital lent, erroneously called the interest of money, is nothing more than rent for its use and enjoyment.

In ordinary cases the loan of capital is no longer what it once was, a resource in the hour of distress, but an agent and instrument which is beneficial both to society and individuals.

In common cases of exchange the transaction is finished when the exchange is completed, but in the matter of a loan, the lender always calculates the risk of recovering the whole, or, perhaps, only a portion of his capital. This risk is usually practically estimated and indemnified by the addition of interest.

The ratio of the premium of insurance, or, in other words, of the addition of interest, depends entirely on the degree of security presented by the borrower. This security consists in three circumstances—the safety of the mode of employment, the personal ability and character of the borrower, and the good character of the government he happens to reside in. Hazardous purposes, to which loans are sometimes applied, always enhance the premium of insurance.

Among other circumstances incident to the nature of the employment of money, that influence in a great degree the rate of interest, is the duration of the loan, the lender always being willing to loan for a less return when he can withdraw his funds either at pleasure, or what is nearly the same thing, in a very short period of time.

It may be taken as a general principle that the more abundant is disposable capital, the lower will the interest of borrowed fall; and that capital in search of employment, and industry in search of capital, to be fully satisfied, must have an entire liberty of dealing allowed in all matters relating to loans at interest. Any interference of government on the subject, in the shape of laws regulating the rate of interest, are always of little or no avail, for emergency compels their evasion. Interest nevertheless, in cases where there is no previous agreement about it, should be regulated by law as in the case of a legal recovery of a sum with interest, but no further. The word usury should become an exploded term.

2. *Of the profits of capital.*—In the first place, in investigating the causes of the profit derivable from the employment of capital, whether by a borrower or the proprietor personally, it is necessary to divide it from the profit of industry that turns it to account. This is always a matter of difficulty, and the best writers have become confused upon the subject.

Perhaps an approximation may be made towards the exact appreciation of the portion of the aggregate profit which pertains to capital and that which pertains to industry employing it, respectively, by comparing the mean ratio of total profit with the mean ratio of the difference of profit in the same line of business, a course which will afford a sure index of the difference of the skill and labour engaged. Suppose two firms, printers for example, to work each on a capital of $50,000, and to make, on the average, a yearly profit, the one of $12,000, the other of only $3000, a difference of $9000, fairly referable to the different extent of skill and labour, the mean of which is $1500; this may be considered as the gain of industry, which, deducted from $7500, the mean profit of the business, will leave $3000, the profit of the capital embarked in it.

Without any index to the precise line between the profits of capital, and those of industry employing it, we may take it as a rule that the first will always proportion themselves to the risk of total or partial loss, and to the duration of the employment. The profit of capital is always high in proportion to the hazard of the adventure, and the length of time it occupies. The profits also of a new employment are greater than those of an old; for in the one, competition is deterred by the uncertainty of success; in the other, allowed by its security of employment. In a word, in this, as in every thing else, the ratio is determined by the relative demand and supply for each manner of employment respectively.

3. *Of the employment of capital in ways most beneficial to society.*—The best employment of capital by the capitalist, says Saye, "is that which, with an equal division of risk, produces the largest proportion of profit." With the community at large, however, the case may be different, for what may be beneficial to the one may be the converse to the other. Capital has a particular faculty, that, besides producing a revenue distinctly its own, it is a means by which land and labour may create an additional revenue.

Capital, when embarked in domestic agriculture, is productive of most good to the interests of a nation, for it enhances the productive power of the land as well as of the labour of a country. It increases the profits of labour as well as the profit of real property.

For like reasons capital cannot be better employed than in aiding and strengthening the productive capabilities of nature, as in the creation of well-contrived and useful machinery for that purpose.

After this comes the employment of capital in manufacture and internal commerce, for the profits of the industry they set in motion are earned at home.

All these distinctions, however, are very subtle, and

may be questioned whether they really have any existence—whether, indeed, there can be any dividing line between the different channels into which capital may be directed. We think not.

OF THE REVENUE OF LAND.

1. *Of the profits of landed property.*—Land has the power of transforming and adapting to human use an immense variety of substances, which, without the assistance of mankind, would be of little or no service to them. Its agency in the production of various commodities may be called the productive service of land. Thence it is that the profit of the owner originates.

He may also derive a benefit from substances taken from its entrails, as in mining stone, coal, the precious metals, &c.

Land, as has been seen before, is not the only natural agent possessing the property of production, for the wind may turn our mill, or drive our vessels across the ocean, while water may propel our machinery, but it is the only one which man can claim an exclusive proprietorship of. If it were otherwise, capital and industry would never be employed on it, for no one would be foolish enough to make an outlay where he could reap no benefit.

Let us now look into the profit of land in the abstract, and the origination of that profit, without asking who may be the cultivator, whether the proprietor himself or a tenant under him.

The productive power of soil is possessed of no value unless its products are objects of desire, as in lands lying in an uninhabited district. As soon, however, as a settlement is made in the neighbourhood, those products, finding a market, become valuable, and cultivation immediately ensues. If any circumstance, however, should occur to increase the demand beyond this point, then the value of the products will exceed the ordinary rate of interest on the capital invested, when the actual cultivator, not himself the owner, is enabled to pay a rent to the proprietor after having first received the interest on his own advances and the profits of his own industry. From these products of the soil thus raised in value by the demand, and these only, can accrue to the owner thereof that profit which has been called the profit of land.

The rent of land nearly always depends on the situation of the land itself. Where it is distant from a market, the rent is low; where near, proportionably high. It may be asked, what is the difference between the profit and the rent of land? It consists in this: profit is great or small, according to the quality of the product: rent, according to the quantity of the purchase-money or price. An acre of land, producing a profit of $5 only, will bring as high a rent as another yielding a profit of $250, if fifty times more has been paid for the one than the other.

Landed property of all kinds nearly always yields a less rate of interest than money invested in other ways. The reason why so much capital is annually invested in it, is because of the superior stability of the investment, besides the accession of dignity which always appertains to one who is known as a landed proprietor.

The only thing which actually varies the amount of the productive agency of land in circulation, is the amelioration of the soil.

2. *Of rent.*—A farmer, leasing land, pays to the proprietor whatever profit accrues from its productive means, reserving to himself the wages of his own industry and the profit on the capital he embarks in the business. This profit, thus paid, is called rent.

Rent is generally placed at the highest rate of the profit of land, and for this reason:

Agriculture requires a smaller capital than almost any other class of industry; of course a greater number of persons are ready to embark in it. This creates a greater competition of bidders for the land on lease. Besides, the supply of land fit for cultivation is limited in all countries. Land owners are thus enabled to enforce a kind of monopoly against the cultivator. The number of acres to be rented in each section of country cannot be increased, but the number of persons desirous of renting them may be infinite. In such a case the bargain between the proprietor and tenant must be greatly in favour of the former. In case any portion of the soil should yield the latter more than the interest of his capital, and the wages of his industry, a higher bidder would soon offer himself.

Whenever a proprietor of land expends capital in the improvement of land, in draining, irrigation, sowing, building, &c., the rent then includes, in addition to the profit of the land, the interest of the capital thus expended. The farmer, however, may make these improvements himself, but he can only receive an interest on his outlay during the continuance of his lease, after which they belong to the landlord. The farmer, therefore, should only engage in such improvements as would be sure to repay him for them in that space of time. It is in this way that long leases operate to increase the products of the land. The effect, however, will always be found greater when the proprietor farms his land himself, for he is rarely liable to lose the benefit of his advances; on the contrary, every proper improvement yields him a permanent profit, and the original outlay is amply repaid when the land is ultimately disposed of.

OF THE EFFECT OF REVENUE DERIVED BY ONE NATION FROM ANOTHER.

One nation can never deprive another of the revenues of its industry. A French tailor establishing himself in the United States, makes a profit there in which his mother country has no participation. Should he, however, after the lapse of years, and the accumulation of a fortune, return to France, he injures America in the same proportion that an American would, who might emigrate with a similar amount of capital.

A nation, receiving a stray citizen back into its bosom, acquires what may be considered a real treasure; for it obtains with him a considerable accession to the profits of its national toil, and an increase of capital as well as an accession to its population.

Where capital is loaned by one country to another, the effect on their national wealth is exactly the same with that arising from the loan of money from one person to another. If America borrows from England, and devotes the money so obtained to a productive purpose, she gains the profits, whatever they may be, arising from the use of the capital so derived, in the same way that a manufacturer or merchant borrows for his own use and gains a profit after paying the interest of his loan.

When one state, however, borrows from another for the mere purpose of expenditure, and not for the purpose of production, the capital so obtained yields no return, and the national revenue is compelled to disburse a yearly interest to the foreign creditor. In such a case it is always better to borrow from a stranger than from a nation's own citizen, because the amount of the loan is not withdrawn from the national productive capital. In the one case they would only be compelled to disburse the yearly interest: but in the other, having lent the capital, they would be compelled to pay the interest too, at the same time being *minus* the benefit which their industry and land might have derived from its employment and agency.

Whenever any portion of the landed property of a country belongs to a foreigner, the revenue arising from it is an item of foreign and not of national revenue. The foreigner, however, could not have obtained it without having given its equivalent in money, which capital

is an acquisition in any case, but more so if the country is possessed of an abundance of land without a sufficiency of capital to employ it in production. There is nothing to be apprehended from the purchase of land by foreigners.

The mere form in which one nation receives revenue from another is a matter of no consequence. It may be sent in specie, bullion, or commodities. It is, however, necessary that it should have the choice of the mode of receipt, for whatever suits it will be the best for both countries. The exportation of specie for this purpose is sometimes but always erroneously checked. Nothing can be more absurd than to see a government prohibiting the export of national specie as a means of checking the emigration of wealth.

OF THE MODE IN WHICH QUANTITY OF PRODUCTS AFFECTS POPULATION.

1. *Of population as connected with political economy.*—Nature in her treatment of all organic objects seems to neglect the individual and afford protection to the species. The most powerful means which she employs for their perpetuation is the increase of germs in such immence profusion, that, notwithstanding the myriad things which occur to prevent their proper development, or to destroy them before they reach maturity, there is still sufficient left for subsistence. The same faculty of infinite increase obtains with man as with other organic bodies.

Animal existence depends only on the gratification of one want—food and sustenance—but man is enabled by the faculty of communication with his kind, to exchange one commodity for another. The owner or producer of an article of $10 value, may deem himself possessed of as much human food as he may be able to procure for that sum; for it is an established principle that when any exchange occurs, what is given on one side is of equal value to that given on the other, and the one is procurable for the other.

Trade, it has been seen, adapts products to the nature of the demand. Those for which the most desire is felt, are most in request, and the wants of every one are more or less satisfied in proportion to his ability to obtain them, which ability depends, in plain terms, on his revenue. Thus, in the end, families and nations, which are only organizations of families, subsist wholly on their own products, while the amount of the product in each instance necessarily limits the numbers of those who subsist on it.

Notwithstanding the forethought of man and the various restraints imposed on him, population always increases with the means of subsistence, indeed generally goes beyond that point. The consequence is, that even in the most thriving countries, a portion of the population perishes from not having at command all the necessaries of life, which, to be sure, are not denied; yet, nevertheless, are not afforded. It may be laid down as an established fact, that the population of a state is always proportionate to the sum of its productions, and that nothing tends so much to permanently increase population as the encouragement and advancement of production.

It will no doubt be asked by some, if the population of a country keeps pace with its means of subsistence, what will become of that population in times of scarcity and famine?

The result is unhappily too plain: despite every precaution, in times of great scarcity, some portion of the lower class must perish.

In fine, national population is uniformly proportionate to the quantity of national production, varying locally, however, within the limits of each state, according to the favourable or unfavourable operation of local circumstances.

2. *Of the influence of the quality of a national production or the local distribution of the population.*—For the cultivation of the earth, population should extend over its surface; for the growth of industry and commerce, it is also desirable to associate together in those places where there can be the greatest subdivision of labour. The dyer by this means is brought near the cloth manufacturer, the druggist near him, while the owner of a vessel employed in carrying drugs will naturally get as near the latter as possible. This association, when extended, in time naturally forms a city.

A city is always the focus of every kind of luxury, pleasure and amusement, and those who live without labour, on the interest of capital or the rent of land, naturally flock where they can find all these requisites.

There are, however, many country residents employed in manufacturing industry, besides others who make it their abode in preference. Local conveniences, running water, the neighbourhood of an extensive forest, or mines, will draw machinery and labourers from the precincts of a city. There are many kinds of work, too, which can only be performed in the vicinity of consumers, as shoemaking and tailoring. The number of these, however, is trifling, compared to the amount of industry exercised in the same branches in populous cities.

A prosperous country is capable of supporting in its cities a population equal to, if not greater than that of the country; but its industry must be conducted with skill, and its agriculture with intelligence, and without waste. But towns, when they create a product for foreign consumption, are enabled to draw provisions from abroad in return, and thus may sustain a much larger proportion of inhabitants than the country.

Where pasture land is extensively cultivated, as in Flanders and Holland, a greater portion of the inhabitants can devote themselves to other kinds of industry than they possibly can in corn countries, for pasture-land requires much less labour.

After all, nothing tends so much to advance the agricultural interests of a country as the growth of cities. Stud a country with cities, towns, and villages, and you will soon find it reaching its highest point of agricultural production. The towns then find subsistence on the agricultural products of the district, while the farmers are enriched by the productive industry of the town.

CONSUMPTION.

OF THE VARIOUS KINDS OF CONSUMPTION OF WEALTH

We have already touched, somewhat slightly to be sure, on the subject of consumption, but in the present, the last portion of our tract, we shall consider it separately. We have shown over and over again that the production of utility cannot take place without the consumption of the same, and that as production means the creation of utility, so consumption signifies its destruction. When the utility of any thing is once destroyed, the article itself becomes valueless, and, ceasing to remain an object of desire, is no longer an item of wealth. "Consumption, then," says Saye, "being the destruction of value, is commensurate, not with the bulk, the weight, or the number of the products consumed, but with their value."

Products of all kinds are not only capable of consumption, but liable to it, for the value which can be added may be afterwards subtracted from the object. When it has been added by industry, it may be subtracted by use, or in a hundred other ways. But it can only be destroyed once; when an article is once consumed, it cannot be consumed again. Consumption is either *rapid* or *gradual*, rapid, where a product is destroyed at once, or gradual, where the time of its destruction is of longer duration. A mansion or a vessel is as consumable as a piece of meat or a coat. Consumption, too, may only be *partial*. As, for instance, when an article is sold by its possessor, when a residue of value is left, for which

an equivalent is received at the time of the sale. It may also be *voluntary*, or *accidental*, as when goods are thrown overboard to lighten a ship in a storm in the first case, or when the ship itself with its cargo is wrecked, in the second. The latter case, however, is also one of involuntary consumption.

Value may be consumed either in the act of its production, or at some subsequent time. Time and labour are also capable of consumption, for both, when applicable to the creation of utility, are objects of value which, once consumed, can never be consumed again.

Whatever is incapable of being divested of value can never be consumed,—as landed property, for example. Its annual product, however, may, as may improvements expended on the estate itself. So, likewise, with any faculty of industry.

Products are created for the purpose of consumption, and are sooner or later consumed. Whenever, however, this is delayed after they have reached absolute maturity, their value becomes inert and neutralized for the time. The reason is plain. Value of every kind is reproductive and capable of continuing to yield a profit to its possessor; its non-use, therefore, is the loss of whatever might have been made by it, had it been properly employed.

All products being destined for consumption in the most speedy manner, it may be asked if an accumulation of capital, or rather of values produced, can ever take place? It can. Value may be accumulated, without its being always vested in the same particular product, but it must be perpetuated in some product or other, values, when employed as capital, being always continued by reproduction. All the products of which capital consists, as has been seen, are as much capable of consumption as other products, but just as soon as their value is destroyed by consumption, it reappears in another and generally an improved form. Manufactories, too, cannot be kept up without a considerable consumption of articles of food, as well as of the raw material employed in the manufacture itself. Nevertheless, however, while one value is undergoing consumption in these forms, another makes its appearance in the object manufactured. The various items that formed the capital are gone, but the capital, itself, still exists in another shape, like the former, liable either to consumption or reproduction.

The yearly consumption of any human being is the aggregate amount of all the values consumed by him in that space of time, understood, of course, as the gross and not as the net amount.

All the commodities which a nation imports must be considered as a part of its yearly product; all its exports as a part of its annual consumption. The French trade consumes all the value of the silk it sends to America, and produces, by way of balance, what cotton it receives in return.

There is a wide distinction between the retail annual consumption of a nation, or a person, and the aggregate consumption of capital. Capital may be consumed either wholly or partially again and again in that time. When a tailor buys cloth and manufactures it into garments, so much capital is consumed and reproduced. Suppose he expends $100 in the purchase of material and repeats the operation twenty times in a year, there will have been a yearly consumption of $2000 on a capital of only $100. On the other side, the implements with which he works may be only partially consumed, and their consumption may not amount to more than one-twentieth, or the one-fortieth of his capital.

Everywhere the desire of the consumer determines the character and quality of the article produced. Whatever is most desired is most in demand, and yields the largest proportion of profit to the producer, and the converse.

Total annual consumption may be either public or private; the former when it is effected by the public, or in its service; the latter when it is effected by individuals or families. Either class may be productive, or the contrary.

The members of every community are consumers—indeed, they could not be otherwise, for no one can exist without some want which must be gratified. On the other hand, all who do not subsist on mere charity contribute in some way to production either by their capital, their industry, or their estates, who thus may be said to be both consumers and producers. The great bulk of consumption takes place among the poorer portion of society, whose majority more than counterbalances the minuteness of their individual shares.

Wealthy and industrious nations consume more than poor ones, because they produce more, generally re-consuming their capital frequently in the year. Besides, they consume unproductively the greater proportion of their revenue, no matter how it may be derived.

OF THE EFFECT OF CONSUMPTION GENERALLY.

The invariable effect of consumption is the destruction of value, and consequently of wealth, for a product consumed is a value lost to the world for ever. The after consequences, however, depend on the character of the consumption.

If the consumption be productive, a creation of new value, equal, inferior, or superior to that consumed, arises; if the converse, the general result is the gratification of some want, but the production of no value whatever.

Consumption, therefore, may be regarded as an exchange of value, either for some fresh value, generally of a superior character to that destroyed, or for the gratification of some personal desire. The latter branch of consumption, it may be remarked, requires no talent in the consumer, but the former requires a combination of labour and skill—what we have heretofore spoken of as industry.

OF THE EFFECT OF PRODUCTIVE CONSUMPTION.

Productive consumption has been defined. The value employed in its operation is called *capital*. The merchant, manufacturer, and cultivator purchase the raw material (which denomination comprises all products bought with a view to the creation of additional value), as well as productive agency, which they consume in the creation of some new utility. The immediate effect of this is entirely similar to that of unproductive consumption, that is, it creates a demand for the objects which they consume, operating upon their price and production, and causing a destruction of value. The ultimate effect, however, is different; no immediate satisfaction of any human want arises, no resulting gratification, excepting the result which accrues to the adventurer from the production of a fresh product, the value of which replaces that of the products consumed, and which generally affords him a profit in the bargain.

A saving of productive agency, whether it consist of industry, land, or capital, is equally real and effectual with the saving of a corresponding amount of raw material, an effect practicable in two ways; either by making the same productive means yield a greater agency, or by obtaining the same result from a smaller amount of means.

Such savings always operate to the benefit of the community; they reduce the charges of production; and in proportion as the economical process becomes more thoroughly known and generally practised, the competition between producers brings the price of the product gradually to a level with the charges of production.

OF THE GENERAL EFFECT OF UNPRODUCTIVE CONSUMPTION.

Unproductive consumption we have before defined to be such a one as is effected simply for the mere satisfaction of some want, or for the sake of enjoying some pleas-

ing sensation; and it has no ulterior effect other than the satisfaction of that want by the destruction of some existing value. It is the simple exchange of a portion of wealth for a corresponding amount of human gratification—nothing else. Wine cannot be drank and distilled into brandy at one and the same time; neither can an object consumed unproductively be a means of establishing a fresh demand, or serve to stimulate productive exertion. It is impossible that it should.

The sole object of our present inquiry, therefore, must be the degree of gratification arising from the act of unproductive consumption itself. The sole point, then, is to balance the loss accruing to the consumer by his consumption against the amount of gratification it produces him. The correctness with which the balance is struck between the two, will determine whether the consumption be judicious or otherwise. The most judicious kinds of consumption are, first, those which conduce to the satisfaction of actual wants, on which depend the health, well-being, and indeed existence of the human race; secondly, such as are the most gradual, and absorb objects of the best quality. The gratification of real wants is more important to mankind than that of artificial ones, for the luxury of comfort affords a more solid pleasure than the luxury of ostentation. Besides, it is less costly. In the second view, nations, as well as men taken individually or collectively, are wisest when they direct their consumption only to those products that are most frequently used, and less liable to wear and tear; as good houses and furniture, for example.

The pleasures which may be considered as among those of the shortest duration are excessively injudicious, even though they may be more pungent while they last.

There are also other kinds of judicious consumption,—the collective consumption of numbers for instance, when a cook dresses a dinner for ten with the same facility that he had formerly dressed one for two, and lastly, on other grounds, such kinds of consumption are judicious which are entirely consistent with moral rectitude, while the contrary are always be attended with public as well as private suffering.

Among the most prominent in the list of injudicious consumption are those things which produce disgust and displeasure instead of the desired gratification. Excesses of all kinds, intemperance, and war when undertaken for the mere purpose of vengeance, may be quoted as examples.

OF INDIVIDUAL CONSUMPTION.

The consumption of individuals is such as is made with the object of satisfying the wants of individuals or families, which wants are principally those of food, raiment, and lodging. They are supplied with these wants out of the respective revenues of each family, no matter how derived. The wealth of an individual or family declines or increases in proportion as its consumption equals its revenue, exceeds it, or falls short of it. The entire amount of individual consumption added to that of the government for public objects, forms the total of national consumption.

OF PUBLIC CONSUMPTION.

1. *Of the nature and effect of Public Consumption.*—The satisfaction of the wants of individuals associated together as a community, and considered as a nation, is the object of national, or public consumption. These wants, when viewed with those of individuals, are of a novel character, and arise from the circumstances accruing from such an association. The United States buys and consumes the service of the President and his various subordinate officers, as well as those of the judges that protect the rights and interest of its several members, and the soldier who defends it from outward injury. How it derives the values with which it purchases these agents will be considered directly.

Government exacts from a tax-payer the payment of a given thing in coin. To meet this demand the tax-payer sells a portion of his products and pays over the proceeds to the tax-collector. Another set of officers are employed in buying with that coin other necessaries for the support of the government and its soldiery. Up to this point no value is consumed, for the proceeds of this money still exist in the shape of stores and supplies. In the end, however, it is consumed, and then the values which have accrued are annihilated. The sum of money itself, however, must not be understood to have been destroyed—that has only passed from one hand to another, and still exists. The same course of conduct obtains with all other kinds of public consumption.

2. *Of the leading objects of National Expenditure.*—These are generally of what have been termed *immaterial* products, or, in other words, products destroyed as soon as created—the services or agency of human beings, or of other objects whether animate or otherwise.

It consumes the personal service of all its officers, whether civil, judicial, or military, and the agency of land and capital.

When government maintains and carries on establishments of productive industry, and they produce more than their expenses, then these institutions furnish a part of the national revenue, and are by no means to be considered as a portion of national charge. Such, however, is rarely the case.

3. *Of the charge of Civil and Judicial Administration.*—The charge of both of these kinds of administration is made up in this country of the specific allowances of magistrates and other officers. In others some allowance is made for the pomp and parade which may be necessary in the execution of their duties. Here, however, every thing is more simple.

Causes entirely of a political nature, as well as the nature and forms of the government, have an influence in apportioning the salaries of its officers as well as its other expenses. The salaries of inferior officers depend not only on their individual importance, but on the general plan of the government, and the services of such men are dear or cheap in proportion not only to what they actually cost, but likewise in proportion as they are well or illy executed. A duty badly performed is highly bought, no matter how little be paid for it; it is also dear when it is superfluous or unnecessary. On the other hand, a public duty may be cheap, however liberally paid, for there is real economy in procuring the best of every thing, even at a higher price. Integrity, too, has its value; like talent, it cannot be obtained without paying for it.

4. *Of Military and Naval charges.*—War is invariably considered as a national curse, although nations are sometimes compelled to engage in it. The soldier at such a time, and indeed at all times, is an unproductive labourer, but in time of war a destructive one. The vast increase of national expenditure during war over the same in time of peace, ought always to deter nations from engaging in combat, and never, except by the express will of the people, which would never be given could they know, as in time they will, their real interests. A national military and naval establishment ought to be reduced to as low an ebb as possible, and such troops retained as can only be made effective after long training and exercise. For the rest, nations ought to rely on their militia and the excellence of their internal polity, for it is next to impossible to conquer a people, unanimous in their attachment to their institutions, as is the case with those of the United States.

5. *Of the charges of Public Instruction.*—It has always been a question in political economy, whether the public were interested in the cultivation of the sciences, and, if so, whether it ought to be at the expense of teaching them?

Every advance of science is succeeded by an increase of social happiness, for man is necessarily dependent on the fixed laws of nature for his subsistence. The better those laws are understood, the better will be his situation. The superiority of enlightened over barbarous nations, in wealth and influence, are sufficient proofs of this fact, and the immense growth of America in so short a space of time may and ought to be attributed in a great degree to the universality of its educational system. The public are undoubtedly interested in the mental cultivation of all its citizens.

6. *Of the charges of Public Benevolent Institutions.*—Individual distress has no title to public relief, except when it is a necessary consequence of the existing institutions of society, and only then when it can be shown that the social system itself affords no means of prevention or cure. Institutions of the kind, however, exist, and are, in fact, kinds of social banks to which every one contributes a portion of his income, that he, himself, may claim a benefit in case of accident or misfortune. Some of these establishments are supported by their power of production, and when their product exceeds their outlay, they are no longer charges upon society. This, however, rarely occurs. The principal benefit they do society is the fact, that they partially relieve the poorer classes from supporting the aged and infirm, and thereby allow population to increase more rapidly than it otherwise would.

7. *Of the charges of Public Works.*—These are generally heavy, consisting of rent, of the interest of the capital employed in their erection, and of the annual charge for their maintenance. Some of these items may be curtailed—rent, for instance, or the charges of maintenance when they are at all productive. Roads and canals are costly examples even under the most judicious management; but the business facilities they afford society fully compensate for their cost. Public works of no real utility are only items of national luxury, and are as indefensible as private prodigality. They never compensate for the loss or the misery they often occasion.

OF THE ACTUAL CONTRIBUTORS TO PUBLIC CONSUMPTION.

Sometimes a portion of the objects of public consumption are furnished by private individuals, but the mass of the resources of a government are drawn directly or indirectly from its people. The government, however, from the sale of public lands, or by leasing them, and thus forming a revenue for its own support, may maintain itself in part; it can never do so entirely. Neither is it right that it should, for it is but fair that the people of a nation should pay for the protection, tranquillity, and safety they enjoy, both in person and property, under a well-balanced administration. The products thus obtained are generally taxes, the nature of which we shall consider hereafter.

OF TAXATION.

Taxation, as has been seen, is the transfer of a portion of the products of a people from their hands to those of the government. Its object is to provide funds. The name of the tax is unimportant, for whether it be called an aid, custom, subsidy, or gift, it is still a burden imposed on the people, considered as individuals, by the government for the purpose of supplying the consumption it may think proper to direct at their expense.

The object of taxation is not the commodity, but its value. Its being paid in coin, goods or personal service is an accidental circumstance more or less advantageous, as the case may be, to the government or the individual. The essential point is the value, which, the moment it leaves the tax-payer, is lost to him, and when it leaves the hands of the government is lost to the world eternally. Taxation serves to deprive the payer either of the gratification he might have in consuming his product, or of preventing its increase, for that part which is lost cannot produce to him again. Taxation, of course, then, tends to lessen, instead of increasing the wealth of a nation, and when pushed to an extreme, impoverishes the individual without enriching a state. History furnishes thousands of examples of this fact.

The best kinds of taxes are, 1. Those which are most moderate in their ratio; 2. Such as are attended with the fewest vexatious circumstances; 3. Such as fall equally on all classes; 4. Such as do the least injury to production; and, 5. Such as are most favourable to the formation of a healthy national morality.

Taxation is either direct or indirect—direct when a specific portion of an individual's revenue is absolutely demanded; or indirect when the demand is made for a specific sum on each act of consumption of any object to which individual revenue may be applied. The latter is the easiest collected and least felt.

Taxation in kind is the specific appropriation of a portion of the gross product to the public service.

OF NATIONAL DEBT.

The distinction between an individual borrower and a government in the same situation is this, that the first seeks for capital for the sake of beneficial employment, and the latter for barren consumption and expenditure. A nation rarely borrows except to satisfy some unexpected demand, or to meet some equally unexpected emergency. The loan in either case may prove effectual or otherwise. At any rate, the whole sum borrowed is so much value lost to the world, while the national revenue continues burdened with the interest yearly accruing on it.

National loans of all kinds are attended with the disadvantage of converting capital, which would otherwise be employed in production, into a means of barren consumption, and in countries where the credit of the government is low, of elevating considerably the interest of capital. Public prosperity can never be advanced by borrowing, except where the capital, so obtained, is employed in safe and certain modes of successful production, which can rarely if ever be the case.

ZOOLOGY.

THE branch of Natural History termed ZOOLOGY, is that which treats of the beings composing the *Animal Kingdom*. The general aspect of these, and the characters by which they may be ordinarily distinguished from plants, are under the observation of every one, and they need not here, therefore, be dwelt upon. It is only when we descend the scale, and arrive at the lowest and simplest of each kingdom, that the characters upon which we have been accustomed to rely successively disappear, and we meet with several tribes which it is very difficult to assign with certainty to either natural division. Thus, there are many animalcules in which no structure characteristic of the Animal Kingdom can be discovered; and yet they exhibit an activity of motion, evidently influenced by the sensations they experience, which shows them to be far removed from plants. It is when the characteristic structure of animals, and the manifestations of sensibility and power of spontaneous movement disappear together, as is the case in the sponge, that the naturalist is the most perplexed in regard to the place he shall assign to such beings; and he can only solve the question, by ascertaining whether the *general resemblance* is the greatest to beings of distinctly *animal* or of distinctly *vegetable* character. By this criterion, the sponge will hereafter be found to deserve a place in the Animal Kingdom.

The differences of structure which are most universally found to separate animals from plants, are those which are connected with the mode in which food is assimilated (or converted into the materials of their own fabric) by the beings of the two kingdoms respectively. Thus, it may be constantly noticed that plants imbibe their nourishment either through their external surface or by prolongations of this into roots and leaves. On the other hand, animals nearly always possess an internal cavity, the *stomach*, into which the food is received, and where it undergoes a preparation; and the absorption of it into the system takes place by vessels distributed on the walls of this cavity. Plants require nothing but a regular supply of water, with carbonic acid, ammonia, and a small quantity of saline matter dissolved in it; and the conditions of their growth generally afford them a constant supply of these, which they can imbibe by means of their roots and leaves, without moving from the place in which they are once fixed. But animals can only be supported by materials previously organized, all their food being derived from vegetable or animal substances; this is nearly always in a solid state, and has to be reduced to a fluid form in order to be imbibed into the tissues.

The life of every animal presents a number of facts for observation; and these may be separated from each other according to their character. Thus, we might consider their *structure* only—the department of science which is termed *anatomy*. Or we might examine their *actions* or *functions*—in fact, the history of their lives—which is termed *physiology*. In pursuing either of these, however, we might restrict our inquiries to a single animal, though it would not be advantageous to do so. The objects of the zoologist are different. He sees that the several beings included in the Animal Kingdom may be regarded not only in their individual aspect, but in their relations to each other; that they form parts of one vast plan, as harmonious in itself as that of a beautiful building made up of a vast number of subordinate parts; and that, while the diversities of form and aspect seem almost infinite, they are evidently subordinate to certain general principles, which produce not only the manifest conformity, but the apparent departures from it. The grand aim of the scientific zoologist being to discover this plan, he employs *classification* as a means by which to facilitate his acquaintance with the vast number of beings that claim his attention.

CLASSIFICATION.

On looking at the variety of animal forms around us—such as we are familiar with as inhabitants of this country, or as natives of other climates collected for our observation—the mind naturally associates together those which have the greatest general resemblance, and separates these (although differing in some degree among themselves) from those with which they have greater dissimilarity. It is by pursuing this plan, from one stage or degree of resemblance and difference to another, that classifications are formed; and these will be correct according to the amount of knowledge upon which they are founded, respecting not only the external form but the internal structure of the objects they include.

Experience teaches that the offspring of any kind of animal is similar to its parents, though slight variations may be often traced between them; but a succession of beings having this general conformity is called a *race*. Now, the first object which the naturalist has to determine is, whether two races, such as the Negro and European races of man, or any two breeds of dogs, *might have* had a common origin. If he finds reason to believe that their differences are not greater than may be accounted for by the influence of accidental causes, and especially if he finds one race ever producing the form of another, he considers them as springing originally from a common stock, and as of one *species*, but if he cannot thus account for their differences, he regards them as of different species. This division of all the existing forms of animals into *species* is that on which the naturalist has to found all his subsequent classification; and it is necessary to take great care to avoid errors arising from variations in the forms of animals at different periods of their existence.

A number of species, differing from each other in trivial points, but having a strong general resemblance, are said to belong to one *genus*. The genera most

nearly allied are united into one *family*; several families into an *order*; and several orders into a *class*. The class, therefore, contains a very large number of species, many of them differing widely from each other, but all agreeing in some prominent and important character. And the classes composing the Animal Kingdom are arranged under four groups, on account of their correspondence in certain general particulars, and their difference in others: these are called *sub-kingdoms*. This is the alphabet of the science; and when this has been acquired, the student will proceed to his grammar, which consists of such a knowledge of the principal divisions of the animal kingdom, as will enable him to read the language of nature with understanding, so as to learn from the simple *name* much respecting the structure and character of the particular specimen, of which he would otherwise be ignorant.

PRIMARY DIVISIONS OF THE ANIMAL KINGDOM.

In considering the primary subdivisions of the Animal Kingdom, it is desirable to view them at first in their most simple aspect, and to regard merely the points of agreement among all the beings contained in each group, and their most striking differences from the members of other groups. The subordinate differences among the forms contained in any one of the primary groups, will be subsequently attended to. Following the arrangement of Cuvier, which in this respect is unexceptionable, we divide the animal kingdom into four sub-kingdoms—VERTEBRATA, ARTICULATA, MOLLUSCA, and RADIATA. The principal characteristics of these will now be pointed out.

The VERTEBRATA derive their name from the peculiarity of their skeleton, which essentially consists of a back-bone or spinal column, formed of a number of separate pieces, so united as to combine great strength with flexibility. These are termed *vertebræ*. Each is perforated with a large aperture; and, when all are united, a continuous tube is formed, in which is lodged the *spinal marrow*, a very important part of the nervous system (this is quite different from the *marrow* of other bones, which is an oily substance, subservient to their nutrition). At one extremity, the spinal column is extended into a large bony structure, the *skull*, which is especially designed for the protection of the *brain* (a large nervous mass, which may be regarded as an expansion of the spinal marrow) and of the organs of sense connected with it. At the other extremity it is contracted into a *tail*, the size and prolongation of which are usually greater in proportion to the small size of the skull. Connected with this spinal column are a series of *ribs*, which pass off from it on each side, and generally meet again in a breast-bone, enclosing a cavity (that of the chest), in which are contained some of the organs of nutrition. Appended to it are two pairs of *members* or *extremities*, which are usually the instruments of locomotion. Although these are very differently formed in the different classes, they are essentially the same in all. The arms and legs of man, the four legs of a quadruped, the wings and legs of a bird, and the fins of a fish, are all exactly alike in their position, and in the elements of which they are composed. The skeleton of the Vertebrata is *internal*, being clothed with the muscles by which its various parts are moved; and, from what has been said, it is evident that it is particularly destined for the protection of the nervous system, which, from the high place of this group in the scale of animal beings, is the organ of the greatest importance in the whole structure. Vertebrated animals are endowed with all the *special* senses—sight, smell, hearing, and taste—the organs of which are situated in the head; besides the *general* sense of touch, which is common to the whole body. They have all *red* blood, which is propelled through the system by a muscular heart. The mouth is furnished with two jaws, which are placed one *above* or *before* the other; there are never more than two, and they open sideways as in the Articulata. They are usually armed with teeth, which are in structure very analogous to bone.

The Vertebrata are characterized by a higher degree of *intelligence* than is possessed by any other group. The animal powers of sensibility and spontaneous motion are also greatly developed; and in accordance with these, a complete symmetry or correspondence between the two sides of the body is observable externally. But this symmetry does not extend to the organs of vegetative life, which are irregularly disposed in the cavities which they occupy.

In the ARTICULATA, the skeleton is *external*, enveloping not only the nervous system but the entire body, with the muscles which move it; these, as is well seen in the crab or lobster (which are the largest animals of this group), being attached to the interior of the firm casing. This skeleton is formed of a number of pieces or *segments*, jointed or *articulated* together—whence the name of the group. The centipede is a very characteristic illustration of this structure. The legs, as well as the body, are here seen to be enclosed in a firm envelope, of which the pieces are connected together by a flexible membrane; and the segments of the body are nearly alike along its entire length. But in the higher classes of this sub-kingdom, where the movement is performed entirely by the legs, as in Crustacea, or by the legs and wings, as in Insects, the segments of the body to which these are attached are firmly united together, in order to give their muscles a fixed point from which to act. But, in the lower classes, such as the leech and worm, where the extreme flexibility of the body, and the change of its dimensions, are the only means of locomotion (no members being present), the whole envelope of the body is so soft, that the division into segments is scarcely perceptible. The nervous system of the Articulata is not by any means so highly developed as that of the Vertebrata; in general, the organs of taste and vision are all that can be detected in them; those of hearing and smell being possessed only by a few of the higher tribes. The number of legs, when these are present, is often very great; they are never less than six. More than one pair of jaws usually exist, and they open laterally. The blood is white, and only in the highest classes is propelled by a powerful heart. The Articulata have their whole structure adapted to great activity of locomotion, and to the performance of *instinctive* actions of a high character. The class in which this is most evident—that of Insects—is by far the largest in the whole animal kingdom. The body, which is usually of small size, derives its principal bulk from the organs of *animal* life, especially the muscles which move the extremities; and the *lateral symmetry* is even more remarkable in them than in the Vertebrata, extending in part to the organs of nutrition as well as to those of sense and motion.

The group of MOLLUSCA must be described more by its negative than its positive characters. The body, as the name imports, is here soft, and destitute of any distinct skeleton. It is enveloped in a loose elastic skin, which is termed the *mantle*, and the outer surface of this has often the power of secreting a shell. But this shell is by no means adapted to the form of the animal; it has no regular series of joints for the purpose of facilitating the movement of the body, and it has no prolongations for giving protection and support to locomotive appendages. Moreover, of two species closely allied in general structure, it is often present in one and absent in the other, as in the snail and slug; and, when present in both, often differs much in form; so that it cannot be regarded as a part of the structure essential to our idea of a molluscous animal. That idea is principally founded upon the softness of the body, the high development of the organs of digestion, nutrition &c.—in fact, of the

system of *vegetative* life, which constitutes the bulk of the body; and, on the contrary, the low development of the powers of sensation and locomotion, and the organs of *animal* life. Many of them are entirely fixed to one spot during all but the very earliest period of life; and in the lowest species there is a tendency to aggregation into a compound structure, like that which is seen in the zoophytes. The number of Mollusca possessing *active* powers of locomotion is comparatively small; and of those which are not entirely fixed, the general character is *sluggishness*. The blood is generally white; and is often propelled by a powerful heart, and distributed through a complex system of vessels, even where the animal seems almost inert. Where any correspondence between the two sides of the body exists, it is usually restricted to those parts which are concerned in the functions of animal life; especially the head, on which the organs of special sense (when they exist) are placed.

The division RADIATA includes the lowest members of the animal kingdom, and those, therefore, which most nearly approximate to vegetables. There is a great tendency in the animals of this group to associate into compound structures, in which each individual has a certain degree of connection with the rest. Thus are formed those assemblages which, from their general resemblance to plants, are commonly called *Zoophytes* (animal-plants). But as, in investigating the characters of a tree, we study the separate flowers and leaves, so, in studying the zoophytes, we consider the individual polypes which form them. These polypes, in common with the higher kinds of radiated animals, which are formed to exist separately (such as the star-fish), are distinguished by the *circular* arrangement of their organs around a centre, in which their mouth is placed; and from this arrangement the name of the group is derived. There is thus a repetition of similar parts; and, as in most other instances where this is the case, a great power of reproducing those which have been lost. In many of the Radiata there is no distinct skeleton; in others a very firm support exists, almost always partaking of the circular arrangement of the soft parts. The sea-anemone is a good example of the lower forms of this group; the star-fish, or sea-urchin, of the higher: very few species belonging to it possess much sensibility or power of locomotion. In many instances there are no distinct blood-vessels, but the nourishment is conveyed to the tissues by direct absorption from the external surface and from the walls of the stomach.

SUB-KINGDOM—VERTEBRATA.

Setting off with the idea of a *vertebrated* animal as one possessing an internal bony skeleton, essentially composed of a jointed spinal column, containing the spinal marrow, and expanded at one extremity into a bony case for the reception of the brain, having usually members or appendages for locomotion, which never exceed *four* in number, endowed with all the five senses, and in general with considerable activity, having red blood, and altogether a more complex organization than the lower classes possess, as well as a higher degree of intelligence—we next proceed to consider upon what principles this extensive group may be subdivided into others, which, agreeing in all these particulars, shall yet differ in other important characteristics.

The ordinary observer would readily establish three subdivisions or classes, upon the three well-marked types of form which he perceives to be adapted to existence in the three different elements. He sees that one large group is entirely confined to the water; that the form of its body is peculiarly adapted for motion in that medium; that its members are constructed for most advantageous propulsion in it; and that it is incapable of existing, at least for any length of time, out of it. This group he calls by the name of FISHES; and he naturally associates with it some of a higher class, which resemble it in external appearance and mode of life. Another large group he observes to be formed to pass a great part of its life buoyed up only by the air; that the form of its body, the construction of its members, and the peculiar covering with which these are invested, specially adapt it for this peculiar mode of support, and for rapid motion through the element it inhabits; and that it is incapable of existing for more than a few minutes under water. This is the class of BIRDS; and with it, also, the ordinary observer associates a portion of a superior class, which is adapted in part to a similar mode of existence. A third group would consist of animals possessed of four legs, adapting them to a residence on the earth, and to motion on its surface; these would also be found to agree in their incapability of living beneath water like fishes, or of rising into the air like birds. But further examination of these *quadrupeds* would disclose some important differences in structure and vital actions, which separate them into two great divisions, very widely apart from each other. It is soon observed that some are *warm-blooded*, maintaining a constant and elevated temperature, while the others are *cold-blooded*, their bodily heat varying with that of the atmosphere, and in general being but little above it; that the former are covered with hair or something analogous to it, while the latter are coated with scales; and that the former produce their young alive, or are *viviparous*, and nourish them afterward by suckling, while the latter rear them from eggs, or are *oviparous*. Hence this group is subdivided by the naturalist into two, of which one—that of MAMMALIA—is superior in its general organization to birds, while the other—that of REPTILES—is intermediate between birds and fishes. The scientific characters of these groups will next be considered.

FISHES are oviparous vertebrata, inhabiting the water, and respiring that element by means of *branchiæ* or gills, which are filamentous prolongations of the surface, into which the blood is propelled, in order to be brought into relation with the air contained in the surrounding water. The heart only contains two cavities; one of these receives the blood which returns from the system, and the other propels it through the gills, from which it is conveyed by the blood-vessels to the body at large. They are in general cold-blooded, but few of them maintaining a temperature above that of the surrounding medium. Living habitually in an element which is nearly of the same specific gravity with their bodies, fishes have no weight to support, and have only to propel themselves through the water. Accordingly we find their structure adapted for great freedom of motion, rather than for firmness and solidity; progressive motion is chiefly accomplished by the lateral action of the spine, which is endowed with great flexibility. The vertebræ, instead of being articulated by a flat surface, as in the Mammalia, or by a ball-and-socket joint, as in serpents, have each of their surfaces concave, and these glide over a bag of fluid, which is interposed between each pair of vertebræ. The tail is flattened vertically; and it is by its movement from side to side that the fish is urged forward as a boat by a sculler. The *pectoral* fins, which answer to the hands of man, and the *ventral* fins, which represent the feet, serve rather as *steering* than as *propelling* organs, and they also assist in raising and depressing the animal in the water. In a large proportion of this class, the skeleton is cartilaginous only; and in a few of the lowest the vertebral column is not divided into distinct portions, but forms one continuous tube of gristle, or even of membrane only. The surface of the body of fishes is almost always covered with scales; and these are sometimes quite bony, and fitted closely together, especially where the internal skeleton is soft.

REPTILES are also oviparous, cold-blooded vertebrata

but in their adult state they breathe air, which is introduced into *lungs* or internal cavities; and they mostly are formed to live on land—those which inhabit the water being obliged to breathe at the surface. Their heart possesses three cavities, one of which receives the blood from the lungs, and another from the system at large; the pure and impure blood are mixed in the third cavity, and the fluid is propelled by it partly to the lungs and partly to the body. Thus only part of the blood expelled from the heart is exposed to the influence of the air at each contraction; and this deficiency is accompanied by a general inertness of the other functions. Their motions are chiefly confined to crawling and swimming; for though a few at times can run and leap very quickly their general habits are sluggish, their sensations obtuse and their digestion slow. Hence they can exist for a long time with a very feeble exercise of these functions, under circumstances that would be fatal to animals in which they are performed with greater activity. In cold and temperate climates they pass the whole winter in a state of torpidity. There is greater diversity of form and structure among the members of this class, than in any other division of the vertebrated series. The *tortoises*, *lizards* and *serpents* appear so different, that a common observer would separate them widely; and yet they not only agree in all the foregoing characters, but pass into each other by links of transition so gradual that it is difficult to classify them. There is one group which, in its adult condition, bears a general correspondence with reptiles, and has been commonly associated with them; but which only arrives at this condition by passing through a kind of metamorphosis, like that of insects: this is the *frog* tribe, which includes several animals bearing the form of lizards and serpents, but differing, from them in having a soft naked skin, instead of a scaly one, and in passing the early part of their lives—that which, in the frog, is called the *tadpole* state—in a condition like that of fishes in all essential particulars. These differences have been regarded by some naturalists as establishing their title to rank as a distinct class, to which the term Amphibia has been given.

Birds are, like fishes and reptiles, oviparous vertebrata, and, like the true reptiles, they breathe air during the whole of their existence; but they are warm-blooded, having a heart with four cavities and a complete double circulation, by which all the blood returned from the system is transmitted to the lungs, before being distributed to it again. This high amount of oxygenation of the blood is accompanied by great activity and energy of all the organic functions, acuteness of the senses, and rapid and powerful locomotion. The class is further distinguished by the position of the body upon two legs only, and by the modification of the anterior members for wings; by the covering of the body with feathers, or something analogous to them; by the deficiency of teeth, in place of which the jaws are furnished with a horny covering or bill; and by various other characters of less importance. There is a peculiar conformity in the general structure and aspect of all the members of this class, with which scarcely any other animals are liable to be confounded. Birds have been not inappropriately termed the insects of the vertebrated classes.

The Mammalia agree with birds in possessing a complete double circulation and warm blood; and with reptiles in breathing air, and generally living on the surface of the earth; but they differ from all other vertebrata, not so much in producing their young alive (which is the case in a few species of reptiles and fishes), as in their subsequent nourishment of them by suckling—from which circumstance the name is derived. This class is placed at the head of the animal kingdom, not only as being the one to which man belongs, but also because it is that which enjoys the most numerous faculties, the most delicate sensations, the most varied powers of motion; and in which all the different faculties seem combined to produce a more perfect degree of intelligence; the one most fertile in resources, most susceptible of perfection, and least the slave of instinct. Although principally adapted to motion on the ground, we find one tribe possessed of the power of rising into the air like birds, and another formed to inhabit the water like fishes; but both these agree with other Mammalia in all essential characters, and differ very widely from the classes with which their habits seem to associate them. To the Mammalia is confined the protection of the body by hair or fur; the nearest approach to it being in the hair-like feathers of a few species of birds. But the presence of this covering is by no means universal in the Mammalia.

Class I.—Mammalia.

The Mammalia are universally regarded as constituting the highest group in the animal kingdom; not only from being the one to which man belongs (so far, at least, as his bodily structure is concerned), but also as possessing the most complex organization, adapted to perform the greatest number and variety of actions, and to execute these with the greatest intelligence. The contrast is here extreme between the *reasoning* and the *instinctive* powers. When we compare the sagacity of a dog, and the great variety of circumstances in which he will display an intelligent adaptation of means to ends, with the limited operations of the insect, over which the judgment and will seem to have no control, we cannot help being struck with the difference. The one is *educable* in the highest degree next to man; the other could not be made to change its habits by the most prolonged course of discipline. In ascending the animal scale, we observe the instincts gradually becoming subordinated to the reasoning powers; and this may be particularly noticed among the members of the class under consideration, which exhibit much variety in this respect.

If we regard intelligence as the chief characteristic of the Mammalia, we should perhaps rest upon the principal varieties in the degree in which this is possessed by the several subordinate groups, as the groundwork of our division of the class into orders. But for the sake of convenience the naturalist seeks for other characters, and more particularly aims to establish his classification upon such as are external and easily recognised. Such a classification will be *natural*, that is, will most nearly associate together the animals that have the greatest general resemblance, and will most widely separate those which have the least, in proportion as the characters which are selected for the purpose may be regarded as indicating the general conformation of the several animals. In this respect, the structure of the extremities, and the arrangement of the teeth, are found to be the most valuable.

From the general structure of the extremities, we may learn much of the habits of the animal, and the adaptation of its whole organization to a particular mode of life. These, for example, would be at once determined by an inspection of the wing of a bat or the flapper of a whale. Hence we shall not be far wrong if we throw into distinct groups all the Mammalia possessing one or other of these modes of conformation. But among those which are adapted to walk upon land, we must seek for some slighter differences; and such we may in the first place look for in the organs of touch, since on these will depend much of the address of the animal, and a number of differences connected with the amount of its intelligence. The degree of perfection of the organs of touch is estimated by the number and mobility of the fingers, and the greater or less extent to which their extremities are enveloped by the nail or hoof. When the fingers are partly absent or consolidated together, and a hoof envelops all that portion which touches the ground, it is

obvious that the sensibility must be blunted, while at the same time the extremity becomes incapable of prehension or grasping. The opposite extreme is where a thin nail covers only one side of the extremity of the finger, leaving the other possessed of all its delicacy; and where several such fingers exist, of which one can be opposed to the rest, so as to render prehension more perfect, and to perform a great variety of actions.

Another important series of characters is furnished by the teeth, which are varied in structure and arrangement according to the nature of the food; and it is obvious that, as to each kind of food the means of obtaining it must be adapted, certain forms of the extremities and of the teeth will be found together. Not only will the correspondence extend thus far, but to the whole interior structure of the animal also. The organs of the senses, and the digestive system—the one employed in obtaining the food, and the other in assimilating it—will in particular exhibit this adaptation; and thus we should find that the structure of the whole animal is so far connected with that of its teeth and extremities, that it might be predicted from the inspection of them. The extended application of this general fact to the determination of the characters of the animals whose fossil remains are so abundant in many parts of the crust of the earth, is the labour which will chiefly render the name of Cuvier immortal.

A primary division of the class Mammalia, however, may be founded on a character more important than any of the foregoing. As already mentioned, the animals of this group are distinguished from most others by producing their young alive—that is, having nearly their adult form, and being capable of executing spontaneous movements, and, to a greater or less degree, of seeking their own nutriment, from the time of birth; and they differ from all others in affording their young a subsequent nourishment secreted from their own bodies. But there are several among them, which produce their young in a state so immature, having so little of the form of the species, and so nearly motionless, that they can be scarcely called alive; and it is only after having been for some time nourished by suckling, that they attain a degree of development corresponding to that at which other young mammalia are born. Now, it is a general law that, the higher the grade of development a being is ultimately to attain, the more it requires to be assisted in the early stages of that development by its parent; and accordingly, the animals in which the intimate connection between the parent and the offspring is separated at the earliest periods, are those which attain the lowest permanent condition. In this case, the inferiority in the general organization of the mammalia thus produced, to that of the others, is sufficiently evident to the naturalist; and it is manifest in their low amount of intelligence, as well as in their bodily structure, which presents many points of affinity with birds and reptiles. We may accordingly divide the class Mammalia into two sub-classes, the truly *Viviparous* and the *Ovo-viviparous** Mammalia. The first comprehends by far the largest proportion of the whole, and nearly all the best-known animals. The latter contains comparatively few.

The truly Viviparous Mammalia may then be subdivided, according to the structure of their extremities, into the *Ungulated*, or hooted, and the *Unguiculated*, or clawed. Hoofed animals are necessarily herbivorous, inasmuch as the conformation of their feet precludes the possibility of their seizing a living prey; and they have flat-crowned grinding teeth for triturating their food. These teeth have irregular ridges on their surface, occasioned by the slower wearing of their harder portions; and by these, aided by the lateral motion of the jaws, tough vegetable substances are reduced to a pulp. Animals with unguiculated fingers are susceptible of more variety; their food is of different kinds; but it may at once be known from the form of the grinders, and from the degree of mobility and delicacy of the fingers. In some, the grinders are formed, like those of the hoofed animals, to triturate vegetable substances by elevated ridges; and in these the extremity has the least power of varied movement, the habits of the animals assimilating to those of the Ungulata. In others, the grinders are very narrow, and are formed with sharp points and edges, cutting like the teeth of a saw; these are adapted for dividing animal flesh, and the jaws are fitted together like the blades of a pair of scissors, having no action but a vertical one. In others, again, the summits of the grinders are raised, not into cutting edges, but into conical points; and they are thus adapted for breaking down the hard envelopes of insects, upon which such animals prey. Finally, in mammalia which are adapted to a variety of food, but which employ rather the soft and pulpy than the tough and stringy parts of plants, the summits of the grinders (which are covered entirely with enamel) are raised into flattened knobs or tubercles, adapted rather for crushing and bruising than for grinding or cutting. This is the case in man and most of the monkey tribe. Thus, by the form of the grinders, the nature of the food may be at once known.

In front of the grinders or *molar* teeth, we find in all the tribes that subsist entirely or in part on animal food, and in some of the vegetable-feeders also, a single pointed projecting tooth on each side, which is termed *canine*, from its large size and prominence in the dog. It is very large in all the truly carnivorous animals, and it enables them to lay a firm hold of their prey. It is also large, however, in some animals which are chiefly herbivorous, as the boar; and in these it seems chiefly intended as an organ of offence and defence. Between the canines, and occupying the front of the jaws, are the *incisors*, or cutting teeth, the purpose of which is nearly the same in all animals which possess them, namely, to divide the food that is to be introduced into the mouth. When they are altogether absent, the food is obtained by the tongue. In the truly Viviparous Mammalia there are never more than six incisors in each jaw.

I. The variations in the form and arrangement of the teeth, taken in conjunction with the differences in the structure of the extremities, enable us to subdivide the *Viviparous* Mammalia into ten orders. In the first place, they may be separated into the *Unguiculated*, containing eight orders, and the *Ungulated*, containing two only. Of the former group, some have all three kinds of teeth, whilst others are deficient in one or more of them.

A. The *unguiculated* animals having three sorts of teeth may be divided into the six following orders:—

1. Bimana.—This contains man only, who is characterized zoologically by the adaptation of his frame to an erect posture, supported upon his posterior extremities only, and by possessing *hands* (that is, feet with opposable thumbs) on the superior extremities only.

2. Quadrumana.—This order includes the apes, monkeys, &c., which have hands on all four extremities.

3. Cheiroptera.—In this order, known as the bat tribe, the anterior extremities are formed into wing-like organs, which enable the animals to rise into the air like birds.

4. Insectivora.—The animals of this tribe, which includes the hedgehog, mole, &c., have the peculiar adaptation of their teeth to insect food, just now described.

5. Carnivora.—In this very extensive group, of which the cat tribe may be taken as an illustration, the teeth manifest, in the most remarkable manner, the adaptation to devour animal flesh.

* This term is perhaps not altogether scientifically correct, but to employ any other would involve explanations unsuited to the character of this work.

6. Cetacea.—This order, properly restricted to those members of the whale tribe which feed on animal substances, follows very naturally on the aquatic forms of the Carnivora; since its digestive system exhibits the same general character, although the adaptation of the extremities for swimming prevents them from showing the same form.

The two other orders of Unguiculated Mammalia are adapted partly to vegetable, and partly to animal food. They are—

7. Rodentia.—In these the toes differ but little from those of the Carnivors; but the jaws are deficient in true incisors, their place being supplied by the canines, which are brought very much forward (so that a wide interval exists between them and the molars), and are adapted to gnawing. This order includes the beaver, rat, hare, &c.

8. Edentata.—This order is so named from the absence of front teeth, sometimes also of canines, and even of molars. The extremities of their toes are nearly included in large nails, which approach in character to hoofs. To this order belong the sloth, ant-eater, armadillo, &c.

B. The *Ungulated* Mammalia form two orders only—those which *ruminate* (or chew the cud), and those which do not. The latter differ much among each other, but are associated into one order:—

9. Pachydermata.—In some of these the toes are still partly separated, in others they are entirely united. The food is mostly vegetable; all three kinds of teeth are sometimes present; in some the canines, and in others the incisors, are deficient. Besides the elephant, horse, hog, &c., this order properly includes certain aquatic forms, which have been commonly associated with the Cetacea, but which are strictly herbivorous, and approach very nearly to the hippopotamus.

10. Ruminantia.—This order, containing the ox, sheep, deer, &c., is a very distinct one, and is characterized by its cloven feet, the absence of incisors in the upper jaw, and the complex arrangement of the stomach, by which rumination is effected.

II. The sub-class *Ovo-vivipara*, is easily divided into two orders—the one having a pouch, or *marsupium*, in which the young are received and nourished for some time after their birth, and the other being destitute of it.

11. Marsupiata.—The animals of this order, which includes the opossum, kangaroo, &c., differ considerably among each other in their food and habits; and the arrangement of their teeth, or their *dentition*, varies accordingly. They have mostly three kinds of teeth, the incisors more than six in number, and their feet are unguiculated, with an opposable thumb, in some instances, on the hind foot.

12. Monotremata.—This is unquestionably the group which approaches most nearly to oviparous animals. It contains only two genera, in one of which the teeth are altogether absent; and in the other nearly so, the jaws being covered with a horny bill. In addition to five claws on each foot, the males have a peculiar spur on the hind ones, like that of a cock.

The foregoing arrangement, founded entirely on external characters, does not give an altogether accurate representation of the relative intelligence of the different orders. If this be taken as the guide, we should first arrange the Viviparous Mammalia into a *Zoophagous* (or animal feeding) and a *Phytophagous* (or vegetable-feeding) series, of which the former will rank highest on the whole, although the highest of the latter may surpass its lowest forms.

The *Zoophagous* subdivision will include the Bimana, Quadrumana, Carnivora, Insectivora, Cheiroptera, and Cetacea.

To the *Phytophagous* belong the Pachydermata, Ruminantia, Rodentia, and Edentata.

These last approach most nearly of the *Vivipara* to birds in the structure of their brains; but a still lower type is exhibited by the *Ovo-vivipari*, which are unquestionably the lowest of the Mammalia in point of intelligence.

Order I.—Bimana.

If we regard the possession of intelligence as the peculiar characteristic of the class Mammalia, we can have no hesitation in selecting the order Bimana, to which Man alone belongs, as the *type* of the group, being the form most unlike that of any other groups on which this class borders. It has been already pointed out, that there is an important connection between the high development of the bodily structure and of the intelligent powers of this class, and that peculiarity which distinguishes it from all others, namely, the prolongation of the period during which the young is dependent on its parent for support. And this prolongation is greater in the human species, in proportion to the whole length of life, than in any other; and it has evidently a direct connection with the ultimate high development of the mind and body of the offspring, and also a most important indirect influence on the social condition of the human race. Thus man, presenting in the highest degree the characters which have been stated as distinctive of the Mammalia, is rightly placed at the head of the class, although, as will presently appear, he is in many other animals in particular portions of their organization.

The order Bimana includes only the single genus *Homo* or *Man*. Man is the only one of the carnivorous animal to which the erect position is natural, and in which there is an essential difference in the organization and function of the two pairs of extremities. In those of the monkey tribe whose form approaches most nearly to his, the erect posture is not natural but constrained; and none of those agile movements so peculiar to the group can be exhibited, unless the body is supported in front as well as behind. All the extremities of these animals are alike formed as organs of prehension; in the Carnivora, all are alike organs of prehension and support; in the hoofed animals, all are organs of support alone; in man, the anterior or upper extremities are entirely for prehension, and the posterior or lower entirely for support. When we examine these more particularly, we observe that each pair is adapted to its respective use in a higher degree than the extremities of the monkey or any other animal. The foot of man is broad, and its surface expanded; and the leg bears vertically upon it, the heel resting upon the ground. In the monkeys it is a sort of oblique continuation of the leg, as the hand of the arm, and supports the body chiefly by its powers of prehension. The whole structure of the body is adapted to being exclusively supported by the feet. The legs are so long, that man could not, if he wished it, walk on all fours; his short and nearly inflexible foot, and his long thigh, would bring his knee to the ground; whilst his widely-separated arms, and his shoulders, which are but loosely attached to the trunk, would ill support the fore part of his body.

But by the adaptation of his whole frame to the erect posture, his upper extremities are left at entire liberty, while his organs of sense are most favourably situated for observation. The hand of man is adapted to a far greater variety of purposes than that of the monkeys, in which it is most perfect. Its power consists chiefly in the size and strength of the thumb, which can have its tip brought into opposition with that of any of the fingers; and all these are capable of being moved separately. In none of the monkeys can the thumb be opposed to the fingers with any degree of force, and in many their tips cannot be brought into contact; so that, though admirably adapted for clinging round bodies of a certain size, such as the small branches of trees, their hands can neither seize very minute objects nor support large ones. To the hand of man some have attributed his superior

lity; but it may be safely said that he owes this to his mind and its instruments conjointly. The hand would be useless without the mind to direct it; and mankind, if handless, would soon be reduced to a very subordinate kind of existence, if not speedily extinguished altogether.

Man, possessed of so remarkable a means of executing that which his mental ingenuity devises, is less provided, in regard both to acuteness of sensibility and to muscular power, than many other mammalia. His swiftness in running is inferior to that of other animals of his size. The smallness of his face, compared with that of the cranium, shows that the portion of the nervous system connected with the external senses is less developed in him than in most other animals. Accordingly, he is surpassed by many in the acuteness of his sensibility to light, sound, &c. But he stands alone in the power of comparing his sensations and drawing conclusions from them. Moreover, although none of his senses are very acute in his natural state, they are all moderately so, which is not the case in other animals; and they are capable (as is also his swiftness of foot) of being much improved by practice, especially when circumstances strongly call for their exercise.

This improvability is one of the most remarkable characteristics of the bodily as well as the mental constitution of man. It is to a gradual advance in both, that the civilized races now enjoy so much of comfort, and of means of still further elevation. In the processes by which these are attained, we observe a remarkable difference between the character of man and that of other animals. The arts of which these are capable are limited and peculiar to each species; and there seems to be no evidence of a power of invention, or of construction for any purpose, beyond that to which the original and instinctive powers are adapted. Hence it would appear that there is no proof of any species or race among the lower animals ever making an advance towards an improvement or an alteration in its condition; and where a particular adaptation of means to ends, of actions to circumstances, is made by an individual (as is often the case where some amount of intelligence or rationality exists), the rest do not seem to profit by it.

Man is as much distinguished, then, from the lower animals, by his mental as by his corporeal endowments. Yet they are not of a *kind* altogether different from that which we may elsewhere see. In common with the inferior tribes, he possesses strong instinctive propensities, which are kept under control, however, in a well-balanced mind. But when the reasoning powers are undeveloped, as in early childhood and idiotcy, the exclusive sway of the instincts is obvious. The more violent passions and emotions are nearly akin to these; and whilst they give great activity to the operations of the mind, it is requisite that they should be duly restrained by the intellect and will. This power of internal regulation is one of the most striking characteristics of the human mind above that of animals, which possess like it reasoning faculties, often to no mean extent, and are actuated by emotions and moral feelings. One of the most important aids to the use and development of the human mind, is the power of producing articulate sounds, or language; of which, as far as we know, man is the only animal in possession. There is no doubt that many other species have certain powers of communication among individuals; but these are probably very limited, and of a kind very different from a verbal language.

The more we study the physical and mental constitution of man, the more are we led to the belief, that it is in the adaptation of the whole to a great variety of circumstances that its great perfection consists. There seems scarcely any condition in which he cannot support himself. He is capable of sustaining the lowest as well as the highest extremes of temperature. His diet is naturally of a mixed kind; but he can support himself in health and strength on either animal or vegetable food exclusively. At the same time, it is by the demands which his peculiar condition makes upon the exercise of his ingenuity, that his mental powers are first called into active operation; and, when once aroused, their development has no assignable limit.*

Order II.—Quadrumana.

The order Quadrumana, which takes its name from the peculiar conformation of the extremities of the animals composing it—all four of them having one of the toes opposed to the rest, like the thumb of man to his fingers—are remarkable for their facility in climbing, which they gain by the *grasping* power conferred upon them by the possession of *four hands*. Their anatomical structure refutes the common idea, that the upright position is natural to them; and it is certain that, though they may be taught in a state of captivity to walk erect like men, they usually support themselves by their anterior as well as their posterior limbs. It may be observed, that those species which approach the nearest to man rest upon the outer side of the foot only, and not upon its sole, when imitating his position; and that they are very insecure in it. And to those which are intermediate between the higher Quadrumana and the succeeding orders, the maintenance of the erect position without support, for any length of time, is impossible. It might be supposed that the possession of "four hands" is a character which raises the animals possessing it above two-handed man; but a little reflection will show that this is not the case, since the hand even of the highest Quadrumana is very inferior to that of man in complexity of structure and in the variety of movement to which it is adapted, whilst that of the lower shows but a slight advance upon the foot of the Carnivora. A corresponding series of gradations may be traced in the aspect of the face; for while, at one end of the series, the muzzle (at least in the young animal) is not much more prominent than it is in some races of man, at the other it nearly resembles that of other mammalia. Nevertheless, throughout the order, a certain degree of resemblance to man may be perceived, in the gestures as well as in the general aspect of these animals. All of them, like man and the Carnivora, possess three sorts of teeth; the canines, in the full-grown animal, are much more developed than in men; and there are intervals between them and the other teeth, which are not present in his jaws, but exist in all other mammalia.

Monkey.

The Quadrumana may be divided into three families—the Simiadæ, or Monkeys of the Old World; the Cebidæ, or American Monkeys; and the Lemuridæ, or Lemur tribe, which supply the place of monkeys in Madagascar and some parts of Africa and India. This restriction of distinct types of structure to different portions of the surface of the globe, is not a little remarkable; and it may be traced even in the subordinate divisions.

The Simiadæ include all the animals of the Old World known as apes, monkeys, and baboons—names which are commonly bestowed according to the development of the tail, the apes having none, the monkeys having a long one, and the baboons a short one. All these have ten molar teeth only in each jaw; and they have the partition between the nostrils very slender, so that the apertures are close to one another, as in man. On the other hand, all the Cebidæ are possessed of a tail, which is an extremely important organ to them,

* For a detailed inquiry into the characters of the different races of mankind, see PHYSICAL HISTORY OF MAN.

having great prehensile powers; they have *twelve* molar teeth in each jaw; and the partition between the nostrils is thick, so that the apertures are wide apart, as in the lower animals. The thumb of the hand, or fore foot, is not opposable; and it is entirely wanting in some of the genera. The LEMURIDÆ are distinguished from the monkeys, partly by the greater prolongation of the muzzle, the possession of a large bushy tail, (which is not, however, prehensile,) of opposable thumbs on all the feet, and of a crooked and pointed claw on the first hind finger. In their teeth, they present an approach to the type of the Insectivora.

1. The SIMIADÆ must be regarded as the types of the Quadrumanous order; and amongst these the *Apes* manifest, in the most striking manner, the peculiar characters of the group. These are distinguished from the other subdivisions, in part by the absence of a tail, but also by the want of the cheek-pouches and of the callosities, or hard spots on their haunches, destitute of hair, which the monkeys and baboons possess; and further, by the predominance in length of the fore feet or arms over the hinder ones. The most remarkable species of this group are the *chimpansee* and *orang-outang*; the former a native of equinoctial Africa, and the latter of the peninsulas and islands of Eastern Asia. Contrary to the general opinion, it is in the first of these that the greatest number of points of resemblance to man are to be found. Both these animals attain considerable size when full grown; probably in their native climate the former rising to five feet, and the latter to seven; but no living specimens of those sizes have ever been seen in this country. In both, there is a remarkable difference between the young and the adult form of the skull—the young bearing the greatest resemblance to that of man, while in the adult, the muzzle is so much prolonged, and the canine teeth are so much developed, as to give the face much more the aspect of that of the baboon. This difference, together with a change in the colour of the hair, has caused specimens of the orang-outang, at different ages, to be accounted distinct species. The character of the animal also changes, being mild and gentle when young, but having a good deal of baboon-like ferocity when come to its full development. In the *Gibbons*, or long-armed apes, the length of the anterior members is so great, that they touch the ground when the animal is in a semi-erect attitude; these present an approach to the monkeys, in the possession of callosities on the buttocks by some of the species.

The *Monkeys* of the Old World are distinguished (in addition to the characters which separate them from the Cebidæ) by the possession of cheek-pouches, callosities, and a tail, which separate them from the apes; the tail is longer than in the baboons, the muzzle less protuberant, and the aspect less ferocious. The group contains, however, some species which present an approach to the apes, and others which form a transition to the baboons. The true Monkeys are also remarkable for the shortness of the arms in proportion to the legs, which causes some species to walk on all-fours with difficulty, climbing being their usual mode of locomotion; but, by common observers, they are still more noticed for the beauty of their colouring, their activity of movement, and gentleness of demeanour. Their character is much changed, however, by confinement. They are found in almost all the tropical countries of the Old World, and particular genera have a peculiar local distribution. Many of them live in societies, chiefly inhabiting the woods, but committing great devastations on any cultivated ground in the neighbourhood. In several species the aspect of the head is extremely grotesque, as are also the attitudes of the animal. The number of species is altogether considerable. Their food seems to be rather vegetable than animal; and in one genus this is distinctly indicated by the structure of the teeth and of the stomach. One genus, restricted to Africa, is destitute of thumbs on the anterior extremities, and the deficiency is partly supplied by the great development of the tail, which is not, however, prehensile, as in the American monkeys.

The *Baboons* have usually a short tail, or none at all; but there is much variation in this respect. They are rather distinguished from the apes and monkeys by the protuberance of the muzzle, and the ferocity of aspect which is partly dependent upon this; the canine teeth are generally large and strong. The Baboons have also a large bag connected with the organ of voice, by the resonance of which the power of their loud and discordant cries is greatly increased. In a state of captivity, the Baboons exhibit less docility than any others of the order. They are by no means devoid of intelligence; but they do not seem capable of being steadily attached by kindness, and generally exhibit an alternation of moody sullenness and violent outbreaks of passion. Their resentment of injuries is often manifested for a long time afterwards.

2. The Monkeys of the New World, composing the family CEBIDÆ, differ from those of the Old, not only in the number of their grinders and the disposition of the nostrils, already mentioned, but in the entire absence of the cheek-pouches and callosities, and also in the conspicuous character, and the importance as a member, of the tail, which is usually prehensile in these monkeys, and capable of being twisted round branches so firmly as entirely to support the animal. In general, the thumbs of the anterior members are not opposable; and they are sometimes scarcely developed at all. The Cebidæ are generally of smaller size than the Simiadæ, none of them attaining nearly the dimensions of the chimpansee, orang-outang, or mandril; they are also less malicious, more easily tamed, and susceptible of a more constant attachment; but they seem to possess less intelligence. They are found in very large numbers in the woods of South America, where they chiefly subsist on vegetable food, to which their teeth show a peculiar adaptation. The largest of them are the *Myceti*, or howling monkeys, which derive their tremendous powers of voice from a sort of hollow drum connected with the larynx (somewhat resembling that of the baboons), which is peculiar to them among the Cebidæ. They are shaggy animals, about the size of a fox. The *Ateles*, or spider-monkeys, are remarkable for the length and prehensile power of their tails, and for the absence (in some species entire, in others nearly complete) of the thumb; whence they are called four-fingered monkeys. A large number of other genera, including many species, might be enumerated; some of these are remarkable for their nocturnal habits; and others for their carnivorous propensities.

3. The third family of Quadrumana, that of LEMURIDÆ, has in many respects the general aspect of the American monkeys; but the muzzle is much prolonged resembling that of insectivorous or carnivorous animals, the teeth, also, are modified for animal food, presenting sharp tubercles, locking into each other; and the grinding motion of the lower jaw is reduced, so that its action possesses more of the scissors-like character of that of the animal-feeders. The four thumbs of these animals are well developed and opposable; the claw-like aspect of the nail of the first hind finger has been already noticed as one of the most easily recognised characters of the family. The canines in the lower jaw have the character of additional incisors; and the first molars resemble the ordinary canines. The total number of teeth in each jaw is eighteen, as in the American monkeys. The *true Lemurs* are distinguished by their very large and handsome tails, which are elevated when the animals are in motion, and not trailed after them. They average the size of a large cat, but have longer limbs. They are nocturnal or twilight animals, passing the day in sleep, rolled up in the form of a ball; at night they rouse them-

selves, and spring with the greatest activity in search of their food, which principally consists of fruits. These are entirely confined to Madagascar, where at least thirteen species are known to exist, differing from each other but little except in colour. On the other hand, the *Galagos*, which are found in the neighbourhood of the river Senegal are pre-eminently insectivorous.

This group is connected with the Cheiroptera by a very remarkable animal—the *galeopithecus*, or flying-lemur, which so much resembles the bats, as to have been placed with them by many naturalists. It is, however, a *lemur* in all its essential characters, but it has its limbs connected by thin skin, which they stretch out, as the framework of an umbrella supports its covering. By this singular structure the animal is supported in the air, as by a parachute; but it has not the power of sustaining a continued flight, though it can leap a distance of a hundred yards with a gradual descent. Like the bats, it feeds on insects, and sleeps with its head downwards, suspended by its hind legs. It is a native of the Indian archipelago.

Order III.—Cheiroptera.

The order Cheiroptera (formerly arranged by Cuvier as the first family of the order Carnaria) is perhaps the most distinctly circumscribed group of the whole class Mammalia; for all the animals composing it agree in the possession of a pair of wings, formed by an extension of the skin over the very elongated fingers of the fore legs, and connected also with the hind legs, by which they are adapted to raise and sustain themselves in the air, and also to propel themselves through it by regular continued movements, in precisely the same manner as birds. Now, although in other groups we may observe a tendency towards the same adaptation, it is never carried farther than to give to the animal possessing it the power of partially supporting itself in the air, so as to prolong its leaps, as is the case with the flying-squirrel, the flying-lemur, and flying-opossum. None of these animals can really *fly*, like bats and birds.

We see in the bats a very interesting modification of the whole character of the mammal, to enable it to lead the life of a bird, just as in the whale tribe we see a similar adaptation to the life of a fish. The insectivorous bats bear a strong analogy to the swallow, in the character of the food itself as in the mode in which they obtain it—by the rapid pursuit of insects on the wing; the chief difference in habit being the time at which they respectively go forth in search of their prey.

The whole structure of the Cheiroptera is obviously adapted to the fulfilment of the object which is the distinguishing character of the group. All the bones of the upper extremity, as well as those which give attachment to its muscles, are very largely developed. The member itself, although consisting essentially of the same parts as in man, has its aspect greatly changed by the extraordinary prolongation of the finger bones, upon which chiefly the skin of the wings is stretched. This skin is extremely thin, and is generally devoid of hair on both sides. It extends not only between the fingers, but from the last finger to the posterior extremity, and from this to the tail, where one exists. This expansion of the tail probably serves as a rudder, enabling the animal to change its course rapidly in pursuit of its insect prey—an idea which is supported by the fact, that in the bats which feed on vegetable substances, or on animals which require less activity of pursuit, this part is either wholly wanting or is much circumscribed in extent and power.

The four fingers of the anterior extremity being involved in the expansion of the membrane, only the thumb is left free; this is of moderate length, and is furnished with a crooked nail, which is of great use to the animal in climbing and making its way along the ground. The toes of the hind feet are short, and furnished with claws, by which the bats suspend themselves from the trees or walls on which they rest, hanging with the head downwards. They walk with slowness and difficulty when placed on the ground; the wings are folded up; and they rest upon the hind feet, and upon the claw of the thumb, by which they crawl forwards, pushing on first one side and then the other. But they can climb up perpendicular surfaces with considerable agility. The expanded skin of the wings appears to be endowed with a sensibility of a peculiar kind, enabling the animals to perceive their proximity to solid bodies without the assistance of sight. That they have a very accurate perception of this kind was long ago shown by the experiments of Spallanzani, who found that bats deprived of sight, and, as far as possible, of hearing also, were still capable of directing their flight with security and accuracy, finding their way through passages only just large enough to admit them without coming in contact with the sides, and even avoiding numerous small threads which were stretched across the room in various directions—the wings, never, even by accident, touching them. It is probably through the vibrations of the air, which will differ according as the wing strikes it in the neighbourhood or the absence of any solid body, that the knowledge of the proximity of such is communicated to the delicate and expanded organ of touch. The use of this curious power to animals intended to execute rapid and varied movements in the dark, and among trees, buildings, &c., is sufficiently evident.

This tendency to a great extension of the skin is manifested in other parts of the body. In many bats, especially of the insectivorous kind, the external ear is enormously developed; being, in the long-eared bat of this country, nearly as long as the body. In the frugivorous bats, it is of ordinary size. The organ of smell, too, in many of the insectivorous bats, is furnished with curious leaf-like appendages, formed of the integument doubled, folded, and cut into the most curious and grotesque forms. The group in which these are most remarkable, is one which avoids the light of day even more than others; the animals composing it exist almost constantly in the darkest recesses of caverns; and it is probable that, by this peculiar conformation, they gain increased power and delicacy of the sense of smell, which in part compensates for the inutility of the organs of vision.

The families composing this order may be arranged under two principal divisions, which are strongly connected with each other in regard to the nature of their food, the conformation of their teeth and digestive system, and the peculiarities of structure which are connected with the mode in which food is obtained. One of these groups, which may be regarded as typical of the order, is insectivorous; the molar teeth are furnished with pointed tubercles, as in the order Insectivora; and the stomach and digestive system are evidently adapted to animal food. The other group is probably omnivorous, like many of the monkeys—feeding chiefly on fruits, but pursuing small birds, or large insects, that may be obtained without much difficulty; their molar teeth have flattened crowns, adapted for bruising and grinding their food; and the complex structure of the stomach and intestinal canal shows its adaptation to a vegetable diet. The proportional length of the intestine, in specimens of these two groups, is a remarkable illustration of this difference of adaptation. In the great bat of this country, belonging to the former group, it is only twice the length of the body; while in the frugivorous *pteropus* of the tropics, it is seven times.

The insectivorous group may be distributed into four families:—1. Rhinolophinæ: in these, the nose-leaf is of complicated structure, and is membranaceous; the index or forefinger has but one joint; the wings are

large and broad. 2. PHYLLOSTOMINÆ, which have the nasal appendage simple and fleshy, and an index-finger of two joints. 3. VESPERTILIONIDÆ, which are destitute of nasal appendages, and have a single joint in the fore-finger. 4. NOCTILIONINÆ, which are also destitute of nasal appendages, but have two joints in the index-finger.

1. To the first of these families, the RHINOLOPHINÆ, belong the greater and lesser *horse-shoe bats*, which are found in the darkest and most secluded retreats of Great Britain; their name is derived from the peculiar form of the anterior nasal appendage. The family contains many other genera and species, most of which are inhabitants of the Old World.

2. To the second family, the PHYLLOSTOMINÆ, belongs the celebrated *vampire*,-of the blood-thirsty propensities of which such marvellous stories have been told. The wound inflicted by its teeth is very small; but its tongue is endowed with a peculiar power of suction, by which a considerable amount of blood may perhaps be drawn. There are no well-authenticated accounts of the death of any animal having been occasioned by this creature; and the story of its fanning its victim with its wings to keep him cool, and render his sleep more profound, is probably a fiction of the imagination. Some of these bats have the tail very short, and in others it is altogether absent. They appear to feed in part upon succulent fruits; but there is one genus, the extreme shortness of whose intestine indicates that it must derive its food from animal matter almost exclusively. One of these has been taken in the act of sucking blood from the neck of a horse. The vampires are confined to South America; but other members of this family inhabit the eastern hemisphere. Many of them attain considerable dimensions; the body being equal in size to that of a magpie, and the wings, when expanded, measuring between two and three feet across.

3. The third family, VESPERTILIONIDÆ, is by far the most numerous, and includes most of the bats of temperate climates. At least thirteen species exist in this

Long-eared Bat.

country, the largest of which is the mouse-coloured bat, the expansion of whose wings measures fifteen inches; but this is of rare occurrence. A more common one is the noctule, or great bat, which is but little smaller; this is often met with in considerable numbers, seeking its retreat sometimes in the hollows of trees, at others under the roofs and eaves of houses. Probably the most abundant is the long-eared bat, which is easily distinguished by the character implied in its name. Its ears are folded downwards during hybernation or profound sleep. It is easily tamed when in confinement, and may be brought to considerable familiarity, so as to eat from the hand. It has an acute and shrill but not loud cry.

4. The bats of the fourth family, NOCTILIONINÆ, are almost exclusively confined to tropical countries. The number of species belonging to this group is very large, but few of them present any important peculiarities.

5. The frugivorous or omnivorous group contains but one family, the PTEROPINÆ. This is widely diffused throughout warm climates, and contains some of the largest species of the order. It is not improbable that the fabulous harpy may have had its origin in some of these. None of them have the tail much developed, and in many it is entirely absent. The *pteropus Javanicus* is a very characteristic example of this family. It is probably the largest of the bats—its expanded wings measuring five feet across. It is extremely abundant in the lower parts of Java, and uniformly lives in societies. They suspend themselves from trees during the day; and, from their motionless aspect and contracted bodies, they might be mistaken for parts of the tree, or for fruit suspended from its branches. When night comes, they begin to move, and go in search of food to the forests, villages, and plantations, in all of which they do great mischief, attacking indiscriminately almost any kind of fruit, of which they devour a large quantity. In their turn, they are eaten by the human inhabitants of some of the countries where they abound, who consider them as delicacies. The flesh of the common roussette of the Mauritius has been compared to that of the hare and partridge.

The Cheiroptera, inhabiting temperate climates, all remain in a torpid state during the winter. Some of them make their appearance, however, in mild days; but as casual revivals during the season of repose are injurious to them, they usually betake themselves to places of which the temperature is not readily affected by external vicissitudes. The office of this group in the economy of nature, is evidently to assist birds in restraining the too rapid multiplication of insects, and to keep down the luxuriance of tropical vegetation.

Order IV.—Insectivora.

The order Insectivora forms a group which is intermediate between the Cheiroptera and the Carnivora. Like the greater part of the first-named of these orders, the animals composing it are formed to live upon insect food; their molar teeth are beset with pointed conical tubercles, adapted to crush the hard envelopes of their prey; and they are, for the most part, like the bats, nocturnal animals—like them, too, passing the winter of temperate climates in a state of torpidity. But they are completely destitute of the wing-like expansions which enable those animals to rise into the air in search of their prey; it is *their* function to seek it upon the ground, or even by burrowing beneath it. Hence, in their general organization, they more resemble the Carnivora; but they retain the clavicle (collar-bone) of the higher orders, which in the Carnivora is reduced to a ligament, and this affords, in the burrowing species, a very important attachment to the powerful muscles by which their anterior members are put in action.

The teeth in this order are extremely variable, and cannot be so safely followed as guides to classification as the general structure and habits. All the animals belonging to it possess the peculiar conformation of the molars already described; the front molar, however, is usually of a form adapted for cutting, like those of the Carnivora; but posterior to this, there are generally three with conical tubercles. The disposition of the incisors and canines is very variable; in some species they are long, and in others short, and the forms of all the teeth are often so much changed that it is difficult to assign them to their respective classes.

This order may be divided into four families, which are characterized by their habits as well as by their external form and internal structure. 1. TALPIDÆ, or *Mole* tribe. These are pre-eminently subterranean, and are distinguished by their extraordinary habits of for

long and complicated burrows under ground, passing their whole lives in these retreats, in which they are born, feed, breed, hybernate, and die. 2. Soricidæ, or *Shrews*. These are a sort of carnivorous mice, which, though they do not actually burrow, retreat during the winter, and in their ordinary repose into holes; they feed, however, on the surface or in the water, several of them being partially aquatic, diving with facility after aquatic insects, and remaining without difficulty a long time under water. 3. Erinaceadæ, or *Hedgehogs*. Here we have still hybernating animals, but instead of burrowing or descending into deep excavations, they conceal themselves at or near the surface, where they find their food. The hair is converted into spines of considerable firmness. 4. Tupaiadæ, consisting of a single genus, the *Tupaia*. These partake of the character of the Insectivorous Quadrumana, living in trees, which they climb with the agility of a monkey or a squirrel.

It is remarkable that, as far as yet known, no species of this order exist in South America or Australia. In the former continent their place seems to be supplied by the Edentata, of which many species are similar in their food and habits; and in New Holland they are replaced by numerous small Marsupialia, having the same general adaptation of their structure to insect food and to an underground residence.

1. Of the Talpidæ, the common English *mole* is a very characteristic example. The whole structure of this animal is beautifully adapted to the subterranean life which it leads, and to the mode in which it seeks its food. A very short arm, attached to a large shoulder-blade, supported by a stout clavicle, and provided with enormous muscles, sustains an extremely large hand, the palm of which is always directed either outwards or backwards. The hand comes to a sharp edge below, and though the fingers are scarcely perceptible, the nails which terminate them are long, flat, strong, and sharp. This forms a most admirable spade, by which the earth is at the same time dug away and thrown behind the animal. The sternum (breast-bone) possesses, in common with that of bats and birds, a ridge or keel, for the attachment of the large pectoral muscles which are necessary to endow the anterior member with the required power. To pierce and raise up the ground, the animal employs its pointed head, of which the muzzle is greatly prolonged, and terminated by a little bone which serves as a borer. This prolonged snout is also used as an organ of prehension, for by it the food is seized and conveyed to the mouth. The hinder part of the body is feeble, and the animal advances above ground so awkwardly as to convey the impression of pain; but when placed in its gallery, or in a tube of the same size, it pushes itself forwards by its hind feet with great activity. The arrangement of the hairs composing the fur is such, that they will lie smooth in any direction; by which provision, the surface is prevented from offering any impediment to the motion of the animal either forwards or backwards.

The mole has been supposed to be deficient in the sense of sight, the eyes being so small, and so hidden behind the hair, that their existence was long denied; it has been ascertained, however, to be tolerably sharp-sighted. (There is a species inhabiting the south of Europe, very closely resembling the common mole, which is certainly blind; the eyelids of which are totally closed.) The sense of smell is extremely acute, and its organ largely developed; it is probable that to this almost entirely the mole is ordinarily indebted for the perception of its food, of its enemies, and of its mate. At the same time it appears to be assisted by that of hearing, which is certainly acute, although aided by no external ear. The burrows of the mole are of a beautifully complicated construction, and are formed with the utmost art. Its food chiefly consists of earth-worms and the larvæ of beetles. When hungry, however, it will attack mice, lizards, frogs, or small birds, that may fall in its way; and it is said that if two moles are confined together, they will fight until one is vanquished, and that the victor will then devour his fellow. Besides these forms of animal matter, vegetable substances, especially the roots of plants and the smaller roots of trees, are found in the stomach of the mole; but it may be doubted whether it eats these as food, or whether it does not simply tear them for the purpose of extracting the larvæ and worms which may be entwined among them.

Much controversy has taken place as to whether moles are on the whole injurious or beneficial to the agriculturist; some parties maintaining that they injure crops of various kinds by the destruction of their roots, and dig up and scatter the plants in ploughing their superficial furrows, besides rendering the ground dry and sterile by their subterranean roads; whilst others point to their destruction of earth-worms and grubs, and to the lightening of the soil produced by their operations, in proof of their beneficial character. The truth probably lies between the two extremes; the animal being neither prejudicial nor useful to the extent attributed to it by its enemies and friends respectively; but pretty certainly counterbalancing its mischief by the good it effects.

2. In the Soricidæ, or *Shrews*, all the feet are formed for running. These animals are usually small, but are very numerous and widely diffused. The fur is short, soft, and silky, and the tail long; so that the common shrew bears a strong general resemblance to a mouse, except that the snout is long and slender. The general habits of this family have already been mentioned.

3. The Erinaceadæ, *Urchins* or *Hedgehogs*, are remarkable not only for their covering of spines, but for the great development of the muscular envelope of the body immediately beneath the skin (especially on the back), which in most other animals is scarcely perceptible. By this they are enabled to roll themselves into a ball, presenting a panoply of sharp spines to their enemies. These are not only strong enough to resist attacks, but are sufficiently elastic to enable the animal to throw itself down upon them from considerable heights. So that, although destitute of all means of attacking its enemies or of defending itself by force, and not able to seek safety in flight, the hedgehog is endowed with a safeguard more secure and effectual than the teeth and claws of the wild-cat or the fleetness of the hare. In its natural state the hedgehog is nocturnal, remaining coiled up in its retreat by day, and moving about all night in search of food. Its run is quick and shuffling, and as it were by starts. Insects, worms, slugs, and snails, form the usual food of the hedgehog, but it will also devour frogs, toads, mice, and even snakes; and has been known to feed on eggs and vegetable substances. It is easily rendered familiar with man and with other animals. Other species of this family connect it with the previous and succeeding groups, the spines not differing so much in size and strength from hares, and the power of rolling up the body being absent.

4. The last family, that of Tupaiadæ, or *Banxrings*, is a very remarkable one. It is confined to the Indian archipelago, and has not been long known to exist. Their teeth chiefly resemble those of the urchins, with a slight tendency towards the lemurs; and, like this last group, their eyes are large and prominent. They are covered with hair, which is soft and glistening, but not fine in texture, and have a long bushy tail. Contrary to the habits of other Insectivora, they ascend trees with the agility of a squirrel; from which animal, however, their pointed muzzle renders them easily distinguishable, even at a distance. They are readily tamed

running freely through the house, and coming of themselves at every meal for fruit or milk.

Order V.—Carnivora.

The animals composing the order Carnivora are, like the four previous orders, separated from the other Mammalia possessing distinct fingers by the presence of three kinds of teeth; and from those orders they are distinguished by characters which point them out as especially formed for the pursuit and destruction of large animals. They possess in the upper and lower jaw six incisor teeth; a large, strong, and pointed canine tooth on each side; and molar teeth, which are evidently formed for cutting and tearing rather than for bruising or grinding. The form of these teeth varies, however, in the different genera, in accordance with their several habits. These molars consist of three kinds: the anterior, immediately following the canines, which are always more or less pointed, and are termed *false molars;* the next class, formed especially for cutting the flesh upon which the animals feed, are termed *carnivorous teeth;* and the posterior are tuberculated, with flattened summits.

The proportion which these different classes bear to each other in number and development, accords with the degree of the carnivorous propensity of the animal, and furnishes important characters in the subdivision of the order. The more the surface of the molar teeth is raised into points and edges, and the more the action of the jaws is restricted to the scissors-like movement by which these edges are made to meet and pass each other, the more purely carnivorous is the regimen of the animal: this is well seen in the Cat tribe. On the other hand, the more the molar surfaces are flattened, and the greater the lateral grinding motion of which the jaws are susceptible, the greater is the probable admixture of vegetable food: this is seen in the bears. The general structure of the body, and especially that of the extremities, is modified in a corresponding manner, in accordance with the habits and propensities of the animal. In all, the toes are furnished with claws, which are peculiarly sharp in the cats, and are in them kept ready for use within a sheath, from which they can be projected at the will of the animal. The stomach of the Carnivora is very simple in its form, and the intestines are short, in accordance with the easily digested character of their food.

The whole bony and muscular system exhibits a similar modification. Thus, whilst the powerful yet active and flexible movements of the purely carnivorous animals are adapted only to the pursuit and destruction of living prey, the more sluggish habits of most of the Bear tribe, their peculiar mode of progression, and the modified structure of the skull, the teeth, and the limbs, are all equally applicable to the mixed nature of their food. The difference in the conformation of the extremities, and in the mode of using them, is very striking in these two antagonized groups. In the former, the ends of the toes only touch the ground, the heel being considerably raised into the air; in this way, the limbs can be used to much greater advantage in running and springing: the animals possessing this conformation are termed *digitigrade* Carnivora. In the latter, the whole foot rests on the ground—a structure more favourable to the maintenance of a firm position, but preventing great activity of progression: these are called *plantigrade* Carnivora. There is a third very remarkable variety of conformation in the extremities of this order; and this is exhibited in the Seals. Here the anterior as well as the posterior feet are formed for swimming, being spread into fin-like paddles; and the whole arrangement of their organs is admirably adapted to the pursuit and capture of their scaly prey.

The Carnivora may be subdivided into five families each containing a well-known form. 1. Felidæ, or *Cat* tribe. In these the destructive power is most highly developed. They are characterized by their short powerful jaws, their retractile claws, and the peculiar adaptation of their teeth for cutting. They have but one small flattened molar tooth above, and no corresponding one below. 2. Canidæ, or *Dog* tribe. These, like the cats, are digitigrade; but their claws are not retractile; and they have two flat tuberculated molars behind the great flesh-cutter. 3. Mustelidæ, or *Weasel* tribe. These are mostly semi-plantigrade, a portion of the sole touching the ground. They are distinguished by their long narrow bodies, and by the presence of only one tuberculated molar. 4. Ursidæ, or *Bear* tribe. These are the only true plantigrade Carnivora. Most of them possess several tuberculous teeth. 5. Phocinæ, or *Seal* tribe. These are at once distinguished by the adaptation of their form and structure to a residence in the water; and of their teeth for holding the slippery surface of fish, and crushing them before they are swallowed.

1. The *Cat* tribe includes a large number of animals very closely resembling each other in structure and aspect—so closely, indeed, that many of the species can only be distinguished by their size, and by the markings of their skin. They all agree, too, in the mode of catching their prey, which is to steal upon it unawares, and seize it with a sudden spring, in which they expend their energy, often slinking off when once baffled. It is very difficult to subdivide the family, on account of the strong general resemblance of its members. Most of them are sufficiently well known to render any peculiar description of them unnecessary. It may, however, be remarked, that some species are found in almost all tropical and temperate countries, and that those of different parts of the globe *represent* each other in a remarkable manner. Thus, the *lion* and *tiger* are inhabitants of Africa and tropical Asia; in America they are replaced by the *puma* and *jaguar*, which are confined to that continent. In the same manner, we find the *panther* and *leopard* spread over tropical Asia and Africa; the *ounce* inhabiting the Asiatic mountains; the *caracal* in Turkey and Persia, and the *lynx* of Northern Europe. These are represented by the *ocelot* in South America, the *lynx* of Canada (differing from the European species), and other less known species. The Felidæ, like the noble falcons, will only eat the flesh of animals they have themselves killed, except when in a state of domestication or confinement, or when compelled by hunger.

Lion.

2. The family of Canidæ includes a much larger number of different forms, some of which approximate to the Cat tribe, and others to the weasels and bears. This tendency to variation from a typical form is most remarkably shown in the races of the common dog, which are believed to have all had the same origin, although the commencement of most of them is entirely unknown. The animals of this family agree in their greater or less adaptation to a mixed diet. Although animal flesh naturally constitutes the principal food of all, they do not attack living animals with a degree of boldness proportional to their strength, and many of them feed upon carrion, sometimes even when it is much putrefied. The *wolves*, *foxes*, and *jackals*, are the animals which most nearly approach the dog; and with the first of these it is regarded by many naturalists as being really identical.

The *Hyænas* constitute a group remarkably distinct from the true Canidæ, and yet bearing enough of their

characters to require to be associated with them. They are more purely carnivorous than the dog tribe, and approach in the deficiency of tuberculated molars to the cats. But they differ from these, not only in general aspect, which is much more nearly allied to that of the dog, but also in the absence of the retractile power of the claws, and in their propensity to feed on carrion. The teeth are peculiarly adapted for crushing bones, and their jaws are shorter than those of the dog, but longer than those of the Felidæ. In many other points of structure, the hyænas are intermediate between the two groups. They are peculiarly ferocious animals, combining the persevering *doggedness* of the one tribe with the furious bloodthirstiness of the other. Their habits are nocturnal—more so than those of most other Carnivora. Hyænas are now chiefly confined to Africa and the south of Asia; but there is no doubt, from the abundant remains of them which are preserved to us, that they must have formerly lived in large numbers in this country, and in other parts of Europe. With the Hyænas may be associated the *Civets*; and the *ichneumon* of Egypt, which restrains the multiplication of crocodiles by feeding on their eggs.

3. The Mustelidæ are the most *bloodthirsty* of all the Carnivora; but they are not so much adapted for devouring *flesh* as are the Felidæ. These animals, on account of the length of the body and the shortness of the limbs, which permit them to pass through very small openings, are called *vermiform*. All the members of this family are semi-plantigrade; and they thus conduct us to the truly plantigrade Carnivora. The *weasel* of this country is a very characteristic example of the family; it is one of the most sanguinary of any, but confines itself chiefly to small animals, destroying large numbers of mice, rats, moles, &c. The *ferret*, which is an allied species, is bolder, having been known to attack man; and the *polecat* is a great enemy to the farm-yard, game-preserve, and warren. All these animals have a strongly and disagreeably odorous exudation from a pouch under the tail; but it is most disgusting in the last. The *Otters* constitute an aquatic form of this family, having the same general aspect and dentition with the weasels, but being readily distinguished from all other genera of the family by their webbed toes and horizontally flattened tail. They subsist on fish.

4. The true plantigrade Carnivora, constituting the family of Ursidæ, participate in the comparative slow motion and nocturnal life of the Insectivora; and like them, too, the species which inhabit cold countries pass the winter in a dormant state. In the *Bears*, the cartilage of the nose is elongated and movable, somewhat resembling that of the Shrews. These animals possess a great facility, from the structure of the sole, of rearing themselves up on their hind feet; and this may be especially noticed in such as are, like the bears, fruit-eaters, becoming carnivorous only from necessity; they are thus enabled to climb trees in search of food. The bears are the largest of the family; and some species of them are pretty widely diffused over the globe. The *raccoons*, which resemble bears in miniature, with the exception of the greater length of the tail, are confined to the new world.

The *Badgers*, *Taxels* or Badgers of America, and the *Wolverines*, form a tribe connecting the Bears with the Mustelidæ. The *badger*, for example, is only semi-plantigrade, and has a dentition very like that of the weasels and otters, but adapted for a less carnivorous regimen. But it has the tardy gait and nocturnal habits of the other plantigrades; it does not, however, become torpid in winter. All these animals, like the weasel tribe, have the power of emitting a fetid odour at will.

5. The last family, that of Phocidæ (the Amphibia of Cuvier), is sufficiently distinguished from all the rest by the peculiar adaptation of the animals composing it to a marine residence. Their feet are so short, and so enveloped in the skin, that they are of little use in progression on land. In fact, the seal employs them only when clambering, wriggling itself forward along a plane surface by the action of the abdominal muscles. The intervals between the toes are occupied by membranes, so as to convert the feet into oars. The body is lengthened, and the spine very flexible, as in the Cetacea and Fishes; and the animals are covered with a short close fur, sitting flat upon the skin. All these adaptations combine to render them able swimmers; and they pass the greatest part of their time in the water, which they only quit to bask in the sunshine and to suckle their young.

Of the two genera, the *Seal* and the *Morse*, which this family contains, the former presents the least departure from the general type of the order, being adapted, as to its teeth and digestive organs, for animal diet; the latter group is chiefly herbivorous.

Order VI.—Cetacea.

In the order Cetacea, or *Whale* tribe, the adaptation of the mammiferous structure to the life of a fish is most remarkably displayed. The whole body is formed for an exclusive residence in the water. The posterior extremities are no longer present, as in the seal, to assist in progression on land; nor are the toes of the anterior furnished with claws. The trunk is prolonged into a thick tail, which terminates in a horizontal cartilaginous fin, by the vertical movement of which the propulsion of the body is effected. The head is very large, and is connected with the body (as in fishes) by so short and thick a neck, that no diminution of its circumference is perceptible; and the cervical vertebræ, which are still (as in all Mammalia) seven in number, are very thin, and partly united together. The bones of the arm and fore-arm are very short; and those of the hand are flattened, and enveloped in a tendinous membrane, which reduces them to the condition of fins. Hence their whole aspect is that of fishes, except that they are not covered with scales, and that they have the tail-fin expanded in the contrary direction. The object of this last provision is to enable them more readily to come to the surface to breathe, which they are obliged frequently to do. The largest species can remain, however, for an hour under water. Their blood, like that of other Mammalia, is warm; and to prevent the animal temperature from being rapidly lowered by the conducting power of the water, they are furnished with a thick coating of fat over the whole body. There are never any external ears, nor hairs upon the body. In these general characters, some other whale-like animals, now separated from the true Cetacea, agree; but they differ in being adapted for vegetable food, while the true whales are all animal-feeders, and are, therefore, properly associated with the Carnivora, to which they make a near approach through the seal. It is evident that the want of claws should not exclude them from this division of the Mammalia, since these are rendered useless by the adaptation of the animal to an exclusively aquatic residence. Some of them, which feed upon large marine animals, seize their prey with their jaws, whilst others, which derive their support from the smaller kinds, engulf them, with a large quantity of water, in their capacious mouths.

The true Cetacea are further distinguished from those herbivorous forms which are now associated with the Pachydermata, by the remarkable conformation from which they receive the name of *Blowers*. As with their prey they necessarily take in a great volume of water, a means of getting rid of this is required, and it is accordingly transmitted through the nostrils, and expelled by a strong muscular action through a narrow aperture pierced at the summit of the head. It is thus that these animals produce the jets by which they are observed

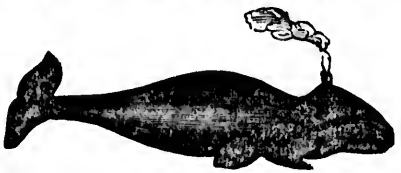
at a great distance. Their nostrils, being continually bathed in water, are not adapted to a delicate perception of odours; and their organs of hearing, being deficient in the external ear, and otherwise formed on a lower type, are also probably incapable of very acute perception of sound. But what is deficient in these respects seems to be compensated by a very high degree of sensibility of the general surface; and there is reason to believe that, by this diffused sense, whales are enabled to take cognizance of what passes in the water at a considerable distance, through the medium of the vibrations excited in the fluid.

In subdividing this order, the *dentition* does not afford much assistance, for the teeth are frequently absent altogether; and among the species which possess them, they often exhibit great differences, when the animals are closely allied. Where they exist, they are mostly small, numerous, and of a conical form, similar to each other. These animals do not chew their food, but swallow it whole. The stomach is usually of a rather complex form. The order may be divided into two families, according to the relative size of the head and body. In the first, DELPHINIDÆ, or the *Dolphin* tribe, the head is not out of the usual proportion; in the second, the BALENIDÆ, or *Whale* tribe, it is immoderately large.

1. The DELPHINIDÆ have teeth throughout both jaws, all simple, and nearly always conical. They are the most carnivorous, and, in proportion to their size, the most cruel of their order. The common *dolphin* has its snout prolonged into a kind of beak. It is extremely agile in its movements; and a number are often seen sporting together on the surface of the water. Nearly allied to the dolphin is the *porpoise*, which has a short muzzle. This is one of the smallest of the Cetacea, not exceeding four or five feet in length, and is very common in various parts of the Atlantic, assembling in vast herds. Allied to the porpoise is the *grampus*, which has large conical teeth, and is the most powerful of this family, attaining the length of from twenty to twenty-five feet. It is a cruel enemy to the whale, which it attacks in troops. Other species of this family are known on our coasts by the names of *white whale*, *bottle-nose*, *narwhal* or *sea-unicorn*, &c. This last animal is remarkable for the enormous development of a single tooth or tusk, commonly reputed to be a horn, whence the name commonly given to the species. In the general form of the head and body it agrees closely with the porpoises; but it possesses no other teeth than this tusk, which projects forwards, apparently from the centre of the upper jaw, to the length of ten feet. The animal really possesses, however, the germs of two tusks, of which only one is generally developed. That on the left side usually attains its full growth, while the other remains permanently concealed within its socket.

2. The remaining Cetacea, constituting the family BALENIDÆ, have the head so very large as to constitute one-third, or even one-half, of the entire length; but neither the cranium nor the brain participate in this disproportion, which is entirely due to an enormous development of the bones of the face. This family contains several remarkable and important animals, among which the following may be noticed:—The *catodon*, or spermaceti whale, receives its technical name from possessing teeth in the lower jaw only; these are of considerable size, and lock into cavities in the upper jaw when the mouth is closed. The superior portion of the enormous head consists almost entirely of large cavities, separated and covered by cartilages, and filled with an oil that concretes in cooling, and is known by the name of spermaceti. This is commonly, but erroneously, reputed to be the brain of the animal; the cavities which contain it, however, are very distinct from the true cranial cavity, which is rather small, and lies at the posterior portion of the head. Cavities containing spermaceti are found in various parts of the body, even ramifying through the external fat or blubber, and these communicate with those in the head. This whale is extensively distributed through various seas, but chiefly abounds towards the antarctic region. It sometimes attains the length of seventy feet.

The *balæna*, or Greenland whale, equals the catodon in size and in the proportional length of the head, which is not, however, so much enlarged in front. Instead of teeth, the mouth is provided with a number of vertical plates, terminating in fringes, which are composed of a sort of fibrous horn, and may be regarded as a kind of prolongation of the gum. These fringed plates, commonly known as whalebone, serve to retain, by straining from the water, the minute animals on which these enormous beings subsist. Their food consists partly of fishes, but chiefly of soft mollusca, acalephæ, &c. The blubber is of immense thickness, and furnishes a large quantity of oil—a hundred and twenty tons being sometimes obtained from a single individual. The whalebone also is an important object of pursuit. This animal was formerly not very uncommon in our seas, but has now retired to the far north, where its number, in consequence of the attacks of man, is constantly diminishing. The *rorqual*, an allied species, attains to still greater size, having been seen of the length of a hundred feet.



Whale.

Order VII.—Rodentia.

The order Rodentia bears a striking contrast to the last in the size as well as habits of the animals composing it, which are, for the most part, very diminutive, but they are very widely diffused, and are often extremely numerous. One species or another is found in every part of the world except New Holland, and sometimes their numbers are so great as to render them very destructive to vegetation. Some of the order are the most gentle of the Mammalia, while others are so ferocious that, if their size and strength were proportional, they would be extremely formidable. This order contains also some of the species most remarkable for their instincts, as the beaver. Generally speaking, the Rodentia are the most prolific of the Mammalia, the period during which they go with young being shorter, and their litters more numerous.

But though the animals differ much from one another in size and external appearance, the order is a very natural one; all the species contained in it being remarkable for the peculiar adaptation of their teeth to gnawing hard vegetable substances, and of the stomach and intestinal canal to the digestion of them. The mouth of a rodent animal is at once recognised by the two long teeth which project forwards from each jaw, working against one another, and separated from the molars by a wide interval. These are usually regarded as incisors; but they are really the canines, the direction of which has changed in consequence of the absence of the incisors. In the hare, the small true incisor teeth may be seen behind them. These gnawing teeth have enamel in front only; so that, their posterior edges being worn away faster than the anterior, they constantly retain a sloping or chisel-like edge. They continue to grow at the root as fast as they wear away at their points; so that, if either be lost or broken, its antagonist in the other jaw, having nothing to wear it down, becomes developed to an enor

mous extent. The mode in which the lower jaw is articulated to the skull, allows of no horizontal motion except backwards and forwards; and the flat-crowned molar teeth have enamelled ridges arranged transversely, so as to be in opposition to the horizontal movement of the jaw, and the better to assist in trituration. In a few of the genera, the structure of the molars more approaches that of the Carnivora.

The form of the body of the Rodentia is generally such that the hinder parts exceed those of the front, so that they leap rather than run. In some of them this disproportion is as excessive as in the kangaroos. The inferiority of these animals to those of the orders already considered, is perceptible in many details of their organization; the brain is less complex in structure; the forearm loses the power of rotation, its two bones being often united; and the eyes are directed sideways, showing their tendency to retreat from their enemies rather than to pursue them. In some the clavicles (collar-bones) are nearly or entirely absent; the anterior extremity being then usually deficient in strength.

The Rodentia may be divided into seven families, the technical distinctions between which are founded upon minute particulars in the structure of the cranium and of the lower jaw. 1. Sciuridæ, or *Squirrel* tribe, comprehending a large number of light and agile animals, chiefly distinguished by their long bushy tails, and by their adaptation to a residence in trees, and to live upon their produce. 2. Muridæ, or *Rat* tribe. 3. Castoridæ, or *Beaver* tribe, including the voles, lemmings, &c. 4. Hystricidæ, or *Porcupine* tribe. 5. Caviidæ, or *guinea-pig* tribe. 6. Chinchillidæ, the *Chinchilla* tribe. 7. Leporidæ, the *Hare* tribe. The rodents of the fourth, fifth, and seventh families are destitute of the clavicle, which those of the three first and the sixth possess.

1. Of the family Sciuridæ, the common *squirrel* of this country may be taken as a characteristic illustration; and its form and habits are sufficiently well known to render particular description unnecessary. It lives entirely upon vegetable food, in search of which it leaps with great agility from branch to branch. In taking these leaps, when it is once thrown off by an effort of its long and powerful hind legs, it is in a measure sustained by the horizontal spreading of its limbs and bushy tail, the hairs of which are directed laterally, so as to resemble a feather. In the *pteromys*, or flying-squirrel, this sustaining power is much increased by an extension of the skin of the flank between the fore and hind legs, which serves as a parachute. The *marmots* are allied to the squirrels in the number and structure of their teeth, which are partly adapted, however, to insect food. In other respects they are almost the reverse of squirrels, being heavy, with short limbs and a moderate-sized tail, and living on the ground, or even in burrows beneath it. More allied to the squirrels in the size of their tail and active habits, but differing in their dentition, are the *Dormice*, the structure of whose teeth shows them to approximate with the next family. They chiefly subsist on vegetable food; but some species of them attack small birds. All the members of this family pass the winter in cold climates in a state of lethargy, which is most profound in the marmots and dormice.

2. The family of Muridæ contains the smallest and at the same time the most numerous of the Mammalia. No undomesticated animals are better known than mice and rats. Of the common *mouse*, Cuvier thus concisely speaks—"known in all times and in all places." The house *rats*, abundant in this country, are almost as universally diffused; but the time of their introduction into many parts of the globe can be distinctly traced. The *brown* (commonly, but erroneously, called the Norway) *rat* made its first appearance in Paris about the middle of the eighteenth century, and in England not many years earlier; it is believed to have originally come from Persia. The brown rat is now speedily replacing the *black* or *old English rat*, which is becoming rather a rare animal in England, and which, from its smaller size, is an unequal match for the usurper. There is reason to believe, however, that even this is not a native of England, and that it was introduced from France about the middle of the sixteenth century. From Europe these two rats (which infest vessels equally with houses) have been sent to America, the islands of the Pacific, and many other places, in some of which they have now become a serious inconvenience. The only strictly indigenous British species of Muridæ are the *harvest-mouse*, and *long-tailed field-mouse*, both of them very beautiful little animals, and very interesting to the naturalist, although highly injurious to the agriculturist. A great number of species exist in various parts of the world, which do not differ widely from each other.

3. Of the Castoridæ, the *beaver* is probably the type; but this family contains many genera having a close resemblance to the rats. The beaver is distinguished from all other rodents by its horizontally flattened tail, which is of a nearly oval form, and covered with scales. The hind feet are webbed, by means of which and the tail, these animals obtain considerable swimming powers. They chiefly subsist on bark and other hard substances, and can fell trees of considerable size, of which they use the bark and twigs as food, employing the stems in the construction of their remarkable habitations. The flattened tail is employed by them as a kind of trowel, with which they plaster the walls of their houses. The beavers are connected with the previous family by the *Arvicolæ*, or *Voles*, many of which bear a strong general resemblance to rats, but differ in their dentition. Most of them are in some degree aquatic in their habits; such is the common *water-rat* of this country, the food of which, like that of the beaver, is (contrary to the general opinion) almost exclusively herbivorous. To this group also belong the *lemmings* or Scandinavian rats, which are remarkable for their occasional migrations in immense bodies. They are stated to advance in a straight line, regardless of rivers and mountains; and while no insurmountable obstacle impedes their progress, they devastate the country through which they pass. Most of this family lay up a winter store of food, upon which they subsist in the intervals of sleep, and do not go abroad during that season.

4. The animals which are characteristic forms of the family Hystricidæ are recognised at the first glance by the stiff and pointed quills with which they are armed, somewhat similar to those of the hedgehogs, but usually much larger. Besides the *Porcupines* and their allies, however, to which this description more particularly applies, this family contains several forms which connect it with the two preceding. The name porcupine is corrupted from the French *porc-epin*, a term expressive of the pig-like aspect and grunting voice of these animals, as well as of their spiny covering. They live in burrows, and have very much the habits of rabbits. The best known species inhabits the south of Italy, Sicily, and Spain. It is nearly the largest of the Rodentia, measuring almost three feet in length. There is an American genus nearly allied to the true porcupine, which has a long prehensive tail, like that of the opossums, and lives in trees.

5. The next family, that of Caviidæ, contains the largest-sized animals of this order, although, when compared with ordinary quadrupeds, they would be termed small. They are naturally restricted to tropical America, where they replace the hares and rabbits of cold climates. But the *guinea pig* is now extremely common in Europe, and is quite domesticated. The *capybara* is an inhabitant of the sides of nearly all the great rivers of South America, and is the largest known animal of the order

being about three feet in length, and of the size of the Siamese pig. It has a large thick and blunt muzzle, is destitute even of the rudiments of a tail, and is scarcely covered with bristly hairs. Its semi-aquatic habits are

The Capybara.

shown by the webbing of the feet. By this structure it can both swim and dive with much activity. Upon land it makes but little progress, running badly, and generally diving in the water to avoid danger. It lives in small societies, and seems to be a nocturnal feeder. Another of the Caviidæ is the *agouti*, which is an inhabitant of the Antilles and tropical America. It is about the same size as the European hare; but, in regard to its food, and its manner of feeding, it rather resembles the squirrel, preferring nuts to herbage, and sitting upon its haunches while eating.

6. The animals of the small family Chinchillidæ were until recently known only by their skins, which constitute an important article of commerce. In their general organization they seem intermediate between the cavies and rabbits, but differ from both of them in possessing clavicles. They are all natives of South America, chiefly inhabiting the range of the Andes, and they live socially, in extensive burrows.

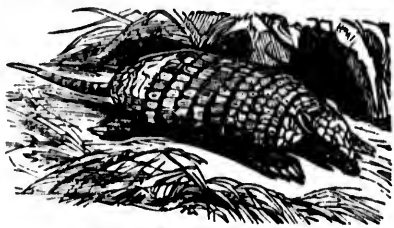
7. The Leporidæ constitute the last family of the Rodentia, and are distinguished from the rest by the presence of two small incisors behind the rodent teeth. The form and habits of the typical genus, *Lepus*, are sufficiently well known in the *hare* and *rabbit* of this country. A large number of species exist in the different parts of the northern hemisphere, and some are inhabitants of the Arctic regions. There is one species in England, in which the brown fur, that forms its summer coat, changes to white at the approach of winter. The hare is a ruminating animal, though without the peculiarly complex stomach of the Ruminantia.

Order VIII.—Edentata.

The animals composing the order Edentata cannot be described by any general positive characters which separate them from other groups; for there is a considerable dissimilarity in the entire structure and habits of the different species. The chief point of agreement among them is a negative one—the absence of incisor teeth, and the termination of the extremities in long claws. These claws are usually four in number, and partially embrace the extremities of the bones from which they are prolonged, so that each forms a kind of pointed hoof; and we have thus an approximation towards the unguiculated division of the Mammalia. The order may be separated into two distinct groups; one consisting of the Edentata-proper, and containing the Ant-eaters, Armadillos, &c., all of which are insectivorous; the other, denominated Tardigrada, from the slowness of movement of the animals composing it, and containing the Sloths.

1. The true Edentata are distinguished, like other insectivorous Mammalia, by their pointed muzzle. This is particularly remarkable in the *Ant-eaters*, which are peculiar to the warm and temperate regions of South America. They are destitute of any teeth; but possess a very long thread-like tongue, which they insinuate into ant-hills and the nests of the termites (or white ants), whence these insects are withdrawn by being entangled in the viscid saliva that covers it. Their fore-nails, strong and trenchant, enable them to tear open these nests, and also furnish them with an effective means of defence.

Most of the other true Edentata are burrowing animals, and are covered with a dense armour, composed of hard scales arranged in a *tesselated* manner, or fitted together like stones in a pavement. Between the different bands of these, there are narrow rings of membrane, which allow the body to bend. They have claws adapted for digging, seven or eight cylindrical molars on each side, and a tongue but little extensible. Of these animals the *Armadillos* are the chief, and are the forms best known. They subsist partly on vegetables and partly on insects and carcasses. Some of them appear to prefer putrefying animal matter; and many are nocturnal feeders.



Poyou, or Six-banded Armadillo.

2. The animals belonging to the family Tardigrada are at once known from the true Edentata by the peculiar shortness of the muzzle. The name of the family is derived from that commonly applied to the animals composing it. In the *Sloths*, according to Cuvier, "nature seems to have amused herself with producing something imperfect and grotesque." And if we consider the peculiarities of their organization in reference to the ordinary habits of mammiferous animals, this appears to be true. Both the fore and hind legs, by their form and proportions, and the manner in which they are joined to the body, are quite incapacitated from acting in a perpendicular direction, and of supporting the body from below; so that, when the animal is placed on the floor, his belly touches the ground. Moreover, he has no soles to his feet, and his claws are very sharp, long, and curved backwards; so that he has no firm support, and can only move forwards by laying hold of some fixed object, and dragging himself on by his hooked claws. But when placed on a branch, his aspect is altogether different. In the wild state, the sloth passes his whole life on trees, and never leaves them but through force or accident, or to pass from one to the other, which, in the densely tangled forests of South America, where alone it exists, is not frequently necessary. But, though appointed to spend its whole life in trees, it is not adapted to live *on* the branches, like the squirrel or monkey, but *under* them. It moves suspended from them; it eats suspended from them; it sleeps suspended from them. And, when its structure is considered in its adaptation to this extraordinary position, it is seen to be most admirably devised to meet the wants of the animal. The muscular system seems capable of prolonged action without effort; and this may perhaps be aided by the peculiar disposition of the arteries already noticed as possessed by the lori. The sloth remains upon a tree until it has stripped it of every leaf, and then it proceeds to another. It has been observed that, in the more open places, where the trees are

less contiguous, the sloths take advantage of windy weather to effect their transits, when the boughs are blown together and commingled. The peculiar conformation of these animals ought, therefore, no more to excite our pity and compassion, than the circumstance of fishes being destitute of legs. Their elevated habitation removes them out of the reach of the carnivorous animals, by which the race might otherwise be extirpated.

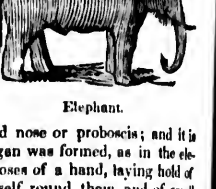
There have been found in South America—the country to which the existing Edentata are almost confined—remains of some enormous extinct animals, belonging evidently to the same group. Of one of these, the *megatherium*, nearly the whole skeleton has now been studied, by comparing different imperfect specimens; and there can be little doubt that it belonged to a gigantic animal intermediate between the sloths and ant-eaters. Its haunches must have been more than five feet wide; and its body fourteen feet long and eight high. Its feet were a yard long, and terminated by gigantic claws. Its whole structure seems to have been adapted to digging the earth in search of the succulent roots which probably constituted great part of its food. Another extinct animal of the same description is known by little else than its claws, and fragments of bones and teeth. From the form of the claw, the *megalonyx* (as it has been named) was at first supposed to be a carnivorous animal; but Cuvier satisfactorily proved it to belong to the Edentata. It seems nearly allied to the megatherium. Remains of tesselated bony armour have also been found, which indicate the former existence of a large animal allied to the Armadillos, to which the name *glyptodon* has been given; and other remains of gigantic ant-eaters have lately been discovered in the same locality.

The Edentata terminate the series of the *unguiculated* or *clawed* true Mammalia; and, as has been just seen, there are some among them with the claws so large, and so enveloping the ends of the toes, and these reduced to so small a number, as to approximate to the nature of hoofs. Nevertheless, they have still the faculty of bending their toes round various objects, and of grasping with greater or less force. The entire absence of this faculty characterizes the *hoofed* animals. They use their feet only as supports, and the fore-arm has not the power of rotation, its two bones being frequently consolidated into one, or one of them greatly enlarged at the expense of the other, like those of the leg of man and of most Vertebrata. The hoofed animals in no instance possess clavicles, and they are entirely vegetable feeders. Their forms and mode of life present, therefore, much less variety than is found in the unguiculated animals, and they can hardly be divided into more than two orders—those which ruminate and those which do not. The former constitute a very natural and easily circumscribed group, the animals which compose it bearing a strong general resemblance to each other, and being easily distinguished from other groups. The latter contains a number of different forms, the connection of which with one another by any very important peculiarities common to all is not very obvious. On account of the general thickness of their skins, they are called PACHYDERMATA.

Order IX.—Pachydermata.

The order Pachydermata, consisting of hoofed animals which do not ruminate, may be divided into three groups, each of which shows a tendency towards some other order. The first of these, PROBOSCIDEA, containing only the *elephant* and its extinct congeners, approaches in several particulars to the Rodentia. In both we find two large front teeth developed at the expense of the rest, and the grinders are formed of parallel plates of enamel and bony matter. There are also many points of resemblance in the form of the bones, and more particularly in those of the extremities. For the elephant has not a complete hoof, but five toes to each foot, which are very distinct in the skeleton; but being enveloped in a callous skin, which surrounds them all, the only external indication of their separate condition is in the nails at their extremities. The second group, that of TRUE PACHYDERMATA, contains those which have four, three, or two toes to their feet. Those in which the toes make even numbers, as the SUIDÆ, or *Pig* kind, have feet somewhat cleft, and approximate to the Ruminantia in various parts of the skeleton, and even in the complication of the stomach. Of the others, which have not cloven feet, some approach the Proboscidea, with which they are connected by forms now extinct, but of which the bony remains are sufficient to determine their character. The third group of Pachydermata, the SOLIDUNGULA, consists of quadrupeds with only one apparent toe, and a single hoof to each foot, as in the *horse*. These also, in their general form and manner of life, approach the Ruminantia, with which they are particularly connected by the camel and an animal now extinct. Another group should also probably be associated with this order, holding the same rank in it as the Amphibia or Seal tribe among the Carnivora. This is the small family of aquatic herbivorous animals, termed MANATIDÆ, which were placed by Cuvier among the Cetacea, but which differ from the true whales in several important particulars, and are found to be closely connected with the hippopotamus by links now extinct.

1. The first group, PROBOSCIDEA, contains only one living genus, the *elephant*, of which the *mammoth*, which has become extinct within a comparatively recent period, is an allied species.



Elephant.

Another extinct animal of this group is the *mastodon*, which, in the conformation of its teeth, appears to have some affinity with the hippopotamus. All these animals agreed in possessing a pair of enormous tusks or front teeth, and a very elongated nose or proboscis; and it is probable that this last organ was formed, as in the elephant, to answer the purposes of a hand, laying hold of large objects by coiling itself round them, and of small by means of the finger-like organ at its extremity. The magnitude of the sockets necessary to hold the tusks, renders the upper jaw so high, that the nostrils, which are prolonged through the trunk, are placed in the skeleton near the top of the face. By means of its trunk, the elephant not only lays hold of its food, but sucks up its drink, which it makes to fill its capacious nostrils, and then discharges, by bending its trunk, into its mouth. By this admirable organ, the shortness of the neck, rendered necessary by the weight of the head, is fully compensated. The cavity for the brain by no means corresponds with the external form of the skull; for, in order, as it would seem, to give a larger surface for the attachment of the muscles of the trunk, the outer layer of bone is widely separated from the inner, and between the two are a number of large bony cells.

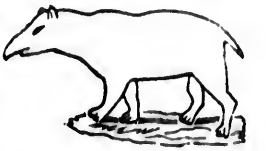
In none of the Proboscidea has the lower jaw of the adult any front teeth. The arrangement of the grinders differs in the various species; but in all they are composed of alternating plates of hard *enamel* and softer *bony* matter, cemented together by a third substance, which is termed the *cortical*. These grinders are in constant progress of renewal; but they succeed each other, not by rising from below upwards, as in man, but by being pushed forwards from behind, in proportion as the tooth before each is worn away. There is never more than one *perfect* molar on each side; but in proportion to the age of the animal there may be two, three, four, or more of the front ones being the worn-down remains of

those at first formed. It is stated that the molars are thus renewed eight times. The tusks, however, are only changed once; but, like the cutting teeth of the Rodents, they are constantly being renewed at the roots. Two species of elephants exist at the present day, both of which inhabit tropical climates, one in Asia the other in Africa. Remains of the mammoth are chiefly found in the north of America and of Siberia; and, from a nearly perfect specimen, which was discovered frozen in the ice near the mouth of the River Lena, it appears that this species was adapted to live in cold climates—the skin being densely covered with hair of two kinds. The habits of the elephant are sufficiently well known to render it unnecessary here to dwell on them. Its food is entirely vegetable; and, in its undomesticated state, it consists chiefly of the leaves and young branches of trees, and of the long herbage of the ground, both of which it gathers with its trunk. The tusks serve not only as weapons of offence and defence, but to root up small trees and tear down cross branches, either to obtain their leaves, or to make a passage for the bulky body of the animal through the tangled forest.

2. Of the true Pachydermata the first family is that of SUIDÆ, the *Pig* kind. It is characterized by the peculiar thickness of the skin, and by the presence of four toes on each foot. They have three sorts of teeth in each jaw; the canines are usually long, and project forward as tusks; the anterior molars are more or less narrow and conical, whilst the posterior are tuberculated. The food is principally vegetable, but admits of considerable variation. The domesticated pig is well known to be quite an omnivorous animal. In the true pigs, the foot has two toes furnished with large hoofs, and two much shorter ones that scarcely touch the ground. The *wild-boar*, which abounds in some parts of the continent of Europe, is well known to be a very ferocious animal; and the domesticated race which is derived from it often exhibits indications of the same character. One of the most curious animals of this tribe is the *babyroussa*, a native of the Indian archipelago; the upper canines of which are very long, and grow spirally upwards and backwards. These serve as defensive weapons of a very powerful description, inflicting severe lacerations by an upward stroke of the head.

With the family of Suidæ is probably to be placed the *hippopotamus*, or river-horse, which seems in many respects intermediate between the pig and the elephant; whilst its aquatic habits, and the conformation by which it is adapted to these, approximate it to the Dugongs. Only one species is known, which is now confined to the rivers of middle and south Africa. But for its short, thick, and very blunt muzzle, it might be compared to a gigantic pig; the body is extremely massive, and the legs so short that the belly almost touches the ground; and it is destitute of any covering but a few weak and scattered bristles. The canine teeth are long; the upper ones straight, and the lower curved backwards, so that they rub against each other. Although ferocious, or rather courageous, when attacked, these unwieldy inhabitants of the waters are in their nature shy, and feed entirely on roots and other vegetables, seeming to prefer those which are partially decomposed by the action of the water.

3. The second family of true Pachydermata, to which the name of TAPIRIDÆ, or the *Tapir* tribe, may be given, resembles the first in the thickness of its skin, but differs in the arrangement of the toes, of which there are only three on each hind foot, and sometimes also in front, without any central cleft. There is considerable variation in regard to the teeth; but the whole family is exclusively herbivorous. No members of it exist in Europe at the present time; but fossil remains of very large species are abundant in some localities. The *tapir* of America is about the size of a small ass, with a brown and almost naked skin, a short tail, and fleshy neck that forms a crest at the nape. It is common in humid places and along the rivers, and its flesh is eaten. The nose assumes the form of a short fleshy trunk—the rudiment, as it were, of that of the elephant. Other species have been recently discovered of a larger size; one of which has the bones of the nose still more elongated, approaching a very remarkable fossil genus, the *palæotherium*. This seems to have been an animal nearly allied to the Tapirs; remains of several species, varying in size from a rhinoceros to a small sheep, have been found in the gypsum quarries of Paris, the fresh-water deposits of the Isle of Wight, and other places.



Form of Palæotherium.

To this family belongs the *rhinoceros*, which is remarkable for its large size, and for the kind of horn, composed of a solid fibrous substance, resembling agglutinated hairs, which is supported on an arch formed by the nasal bones. Several species exist in different parts of the tropical portion of the Old World. They are naturally stupid and ferocious, frequenting marshy places, and subsisting on herbage and the branches of trees. In some species a second horn exists behind the first. The upper lip is generally elongated, and has some power of prehension. Rhinoceros' bones have been disinterred in many parts of Europe.

4. The third group of Pachydermata, the SOLIDUNGULA, contains only one family, that of the EQUIDÆ, or *Horse* tribe. Though there is only one apparent toe and single hoof to each foot, there are appendages beneath the skin which represent two lateral toes. The well-known animals of this tribe, the *horse*, *ass*, *zebra*, *quagga*, *onagga*, and *dzegguetai*, are commonly regarded as belonging to but one genus; but the first of these is probably to be separated from the rest, from the circumstance of its tail being wholly clothed with long hair, whilst that of the rest has long hair only towards the tip. On this point, however, there is much uncertainty, arising from our ignorance as to the original stock of the horse. In all the instances in which we at present know horses to exist in a wild state, the race appears to have been originally derived from a domesticated stock. This is certainly the case with regard to the wild horses which now spread over the plains of South America, all of which are descended from those first introduced there by the Spaniards.

All the animals just named agree in their dentition. There are six incisors to each jaw, which, during youth, have their crowns furrowed by a groove, and six molars on each side, above and below, with square crowns, marked, by plates of enamel which penetrate them, with four crescents. The males have, in addition, two small canines in their upper jaw, and sometimes in both; these are always wanting in the females. Between the canines and the first molar there is a wide space, which corresponds with the angle of the lips, where the *bit* is placed, by which alone man has been enabled to subdue these powerful quadrupeds. None of the species of this family are indigenous to America.

5. The animals associated in the family *Manatidæ*, may be considered as Pachydermata still more adapted than the hippopotamus to an aquatic residence. In their teeth and general organization they bear a close correspondence to this order; and the fish-like form which they exhibit is scarcely a greater variation than is seen in the order Carnivora. The posterior extremities of

these animals are entirely wanting, as in the true Cetacea. The type of this family is the *manati*, which grows to the length of fifteen feet, and frequents the mouths of the African and American rivers. It is called sea-cow, and its flesh is eaten.

Order X.—Ruminantia.

The order Ruminantia is perhaps the most natural and best determined of the whole class, for all the species which compose it seem constructed, as it were, upon the same model, the camels alone presenting any considerable exceptions to the general characters of the group. The first of these characters is the entire absence of incisor teeth from the upper jaw; whilst the lower appears to possess eight; of these, however, the two outer ones are really canines which have taken the form of incisors, so that the number of the true incisors is six, as in the other viviparous Mammalia. The molars are almost always six in number, both above and below, and have their crowns marked with two double crescentic ridges of enamel, which aid in triturating the food. The feet are each terminated by two toes and two hoofs, which present a flat surface to each other, appearing as though a single hoof had been cleft; hence the names that have been applied to these animals, of cloven-footed, &c. Behind the hoof there are always two small spurs, which are the vestiges of lateral toes.

The name of the order intimates the singular faculty possessed by these animals, of masticating their food a second time, or "chewing the cud." This faculty depends on the structure of their stomachs, which are four in number. The food which is cropped by the incisor teeth is swallowed almost without mastication, and is moistened in the stomach: and, after being compressed into little pellets or *cuds*, is returned to the mouth to be rechewed while the animal is at rest. When this operation has been performed, the food is transmitted to the true digestive stomach.* This remarkable provision has a very interesting adaptation to the general structure and characters of these animals. The Ruminantia, taken as a group, are timid, and destitute of powerful means of defence against their foes. They rather seek their safety in flight when attacked. Their food, consisting chiefly of the grasses of various kinds, requires to be thoroughly masticated before it can be properly digested. When feeding on the pastures they frequent, they are liable to many alarms; and if they were compelled to spend a considerable time in masticating their food before swallowing it, they would often be in danger of starvation, by being obliged to leave their pasture before their wants were supplied. But by their power of subsequent rumination, they are enabled to dispense almost entirely with the first mastication, and to feed with comparative quickness. They convey a store of food into the first stomach or paunch, as the monkey into its cheek-pouches; and then, retiring to a secure place, they prepare it for digestion at their leisure.

The whole structure of these animals corresponds with the account just given of their habits. Their legs are long in proportion to their body, and the spinal column is very flexible; both which conditions are favourable to great activity of motion. They are endowed with a very acute sense of smell, which seems to be their guide in the selection of their food. Their ears are placed far back, and are very movable; and these are well adapted to catch sounds from behind, so as to warn the animals of danger while feeding. The eyes are placed at the sides of the head, and the pupil is in the form of a horizontal oblong; so that the range of vision along the surface of the earth is very great, and the animals can easily look behind them when pursued. Their means of defence consist in the use of their horns to gore the enemy, and of their hind feet to kick it; but it is only when peculiarly courageous that single animals of this species will act on the offensive, or stand on the defensive, against others of proportional size and strength.

The Ruminants, of all animals, are those which are most useful to man. They supply him with a large proportion of his animal food. Some serve him as beasts of burden; others furnish him with their milk, their tallow, leather, horns, and other useful products.

The great resemblance which exists among the very numerous members of this order, renders the distribution of them into families, each characterized by some important peculiarity, a matter of some difficulty. These subdivisions are, probably, best erected upon the character of the horns, which are possessed by the males of all the species in their natural state, excepting such as (like the camel) connect this order with other groups. The horns are essentially bony prominences from the fore part of the skull. In some Ruminants, commonly termed *cattle*, such as oxen, sheep, goats, and antelopes, these prominences are covered with an elastic sheath, formed as it were of agglutinated hair, which continues to increase by layers during life. It is to the substance of this sheath that the name of *horn* is commonly applied, while the bony support is termed the *core*; this grows during life, and never falls. In the *giraffe*, again, the bony prominences are covered with a hairy skin, which is continuous with that of the head; and here, too, the bony part of the horn is permanent. But in the *deer*, these prominences, which are covered for a while with a hairy skin (commonly termed the *velvet*), like the other parts of the head, have at their base a ring of bony tubercles, which periodically enlarge, and compress the nutritive vessels of the horns. These accordingly die, and fall from the skull; and the animal remains defenceless. Others, however, are reproduced, generally larger than before, which are destined to undergo the same fate. These horns, periodically renewed, are usually styled *antlers*.

The Ruminants with horny sheaths to the bony prominences, may be divided into three families. Antelopidæ, or *Antelope* tribe, characterized by the lightness of their forms and the activity of their movements, and by the solidity of the bony core. Caprinæ, or *Goat* tribe: in these the bony core is partly occupied with cells, and the general form approaches that of the Ox tribe; but the horns are directed upwards and backwards. Bovidæ, or *Ox* tribe: these have the horns directed upwards and forwards; the form is robust, and the movements heavy. The division of the Ruminants in which the horns are periodically cast off, constitutes only one family, that of Cervidæ, the *Stag* tribe. Another family, including only the giraffes, and named Camelopardæ, is characterized by the shortness and permanence of the horns, which are covered with a skin. Of the Ruminants without horns there are two distinct families —the Moschidæ, or *Musk Deer*, which are remarkable for their elegance and lightness, and differ but little from the rest of the order save in the absence of horns; and the Camelidæ, or *Camel* tribe, which in their dentition and in the structure of the extremities, exhibit a transition to the Pachydermata.

1. The family Antelopidæ, remarkable for the slenderness of form and swiftness of foot of the animals composing it, contains above seventy well-ascertained species, bearing a strong general resemblance to each other. Most of these are natives of Africa; a few species, however, inhabit Asia; a still smaller number exist in America; and one only, the *chamois*, now remains in Europe. Among these numerous species we meet with forms that remind us of the other families o

* For a more particular description of this process, and the organization by which it is effected, see the article Animal Physiology

the Ruminantia—the ox, goat, stag, &c. They generally associate in large herds, which migrate together in search of pastures. A species well known to the colonists of South Africa is the *spring-bok*, which occasionally visit their cultivated lands, during seasons of drought, in innumerable herds, causing devastation wherever they pass. The antelopes may probably be regarded as the types of the Ruminantia, exhibiting the peculiar characters of the order in the most remarkable degree. They are extremely vigilant and timid: and the speed of the swiftest species surpasses that of every other mammiferous animal. Those which are adapted to live on rocks and mountains exhibit the most remarkable agility, and fearlessness of those dangers which their

Spring-bok Antelope.

habits would seem to involve; they walk with perfect composure along the giddy brinks of the most awful precipices, climb and descend with wonderful care and precision, and leap up or down to the smallest surface that will contain their collected feet, with perfect firmness; and yet they are so fearful of any supposed enemy, that it is difficult to get within gunshot of them.

2. The family of Capridæ is connected with the last by many antelopes which, like the chamois, approach the goats in form. It includes only the *goats* and *sheep*. The original stock of the domestic breeds of the former appears to be indigenous to Persia, where it inhabits the mountains in large troops. The goats of Angora, Thibet, &c., celebrated for the fine quality of their hair, are no more than varieties of the common species. The *ibex*, which inhabits the mountains of the old world, and especially the Caucasian chain, is distinguished by the size and strength of its horns. It is said that this animal fearlessly precipitates itself down precipices, always falling on its horns, the elasticity of which secures it from injury. The *sheep* appear to have extremely little real difference from the goats: a large number of races exist, the relation of which to each other is uncertain; and there is doubt as to the original stock of the whole. Of the domestication of this animal we have an earlier record than of any other.

3. The species of the family Bovidæ, or *Ox* tribe, are comparatively few. They are all large animals, with a broad muzzle, heavy and massive body, and stout limbs. Of the original stock of the domestic ox, we have no certainty, since, as in the case of horses, the existing races of wild-cattle are probably all descended from those which have been at some period subservient to man. Of all the animals which have been reduced to his service, the ox is, without exception, that to which he is most indebted, for the extent and variety of its means of usefulness. The universal utility of the animal appears to have been very soon detected; and we find, consequently, that its domestication soon followed that of sheep, and that it is mentioned in the most ancient records as a servant of man, long before either the horse or dog are noticed.

Among the undomesticated species of this family which have all a strong general resemblance to each other, and are the most powerful and savage animals of the whole order, may be noticed the European *bison*, which was formerly spread over Europe, but is now restricted to Lithuania and the Caucasian region; the American bison, commonly called *buffalo*, which inhabits all the temperate parts of North America; the *Indian buffalo*, of which there are several different races (in one, the horns include a space of ten feet from tip to tip), of which some have been domesticated; the *Cape*

Cape Buffalo.

buffalo, an extremely ferocious animal, with large horns, first directed downwards so as nearly to cover the forehead, inhabiting the woods of Caffraria; and the *musk-ox*, a species inhabiting the coldest regions of North America, with short legs, and long hair reaching the ground, which diffuses more strongly than the rest the musky odour common to the whole genus, and which is particularly noticeable in the European bison.

4. The family Cervidæ, or *Stag* tribe, includes, like that of antelopes, a large number of species differing but little among each other, very widely diffused over the earth's surface, and easily separated from others by the character of the horns. With the exception of the reindeer, however, the female is destitute of horns, save in a few rare individual cases, analogous to those in which the hen assumes the plumage of the cock bird. The substance of the horns, when completely developed, is that of a dense bone, without pores or internal cavity; their figure varies greatly according to the species, and even in the same individual at different ages. These animals are extremely fleet, and live mostly in forests, where they feed on grass, the leaves and buds of trees, &c.

5. Of the family Camelopardæ, only one species was for a long time known to exist; but there are probably two, or even three, kinds of giraffe, all of which are natives of Africa, frequenting chiefly the borders of the deserts. Its remarkable form, depending chiefly on the great length of its neck and fore legs, is familiar to every one. In its general structure, however, it closely resembles the deer; differing from them in the permanence of the horns. It has also some points of affinity to the camels; especially in the length of its neck, the existence of callosities, or hard surfaces, on the breast and knees, and the absence of the small spurious hoofs. It is the tallest of all animals; its head being frequently raised eighteen feet from the ground. Its disposition is gentle, and it feeds on leaves; browsing upon the young branches at a height much above that which any other animal can reach, and drawing them towards its mouth by its prehensile tongue. It lives in small troops of five or six individuals, and is very timid, although capable of powerfully defending itself by kicking. Not

withstanding the length of its neck, the number of vertebræ which this part contains is no greater than in other Mammalia.

6. The Moschidæ, or *Musk-deer*, are completely intermediate between the true *Deer* and the *Camel* tribe, which last connects the Ruminantia with the Pachydermata. They resemble the ordinary Ruminants in the lightness and elegance of their forms, and in the nimbleness of their movements; and differ chiefly in the absence of horns, and in the projection of the canine tooth on each side of the upper jaw, as in the camels. The name of this group has been derived from the common Musk, the males of which secrete the odoriferous substance so called. This species is almost without tail; and the hairs which completely cover it are so coarse and brittle that they might also be called spines. It is confined to the mountainous region between Siberia, China, and Thibet, from which most of the Asiatic rivers descend. Its habits are nocturnal and solitary, and its timidity extreme. The other musk-deer inhabit the warmer parts of Asia and the eastern archipelago; they have no musk-pouch. They are the smallest and most elegant of the Ruminantia, and are active and gentle in their habits.

7. The Camelidæ, or *Camel* tribe, approximate to the preceding order, and especially to the whole-hoofed division of it constituting the Horse tribe, more than do any other Ruminants—to such a degree indeed, that some naturalists prefer associating them with that group. They have always canines in both jaws, and two of the incisors have also the same pointed shape. The animals of this family are much less elegant in form and graceful in action than the other Ruminants; but their organization is, equally with theirs, most perfectly adapted to the circumstances in which they exist. The family contains two groups, the *Camels* and *Llamas;* the former are restricted to the Old World, and the latter correspond to them in the New.

In the true *Camels* the two toes are united below by a kind of horny sole, almost to their points, which terminate in small hoofs; and there is a soft cushion beneath the foot, by which it bears upon the sandy surface over which it is formed to move. Two species are known, one called the *Bactrian* or *two-humped camel*, and the other the *Arabian*, or *one-humped*. Both are completely domesticated. The first is employed chiefly in Central Asia, the latter in Arabia, North Africa, Syria, Persia, &c. The two-humped camel is the larger and stronger, being capable of sustaining above one thousand pounds' weight, and is best adapted for rugged ground; the other is the most abstemious, and the best

Dromedary.

fitted for the sandy desert. The *dromedary* is merely a lighter variety of it, possessed of greater fleetness and power of endurance. The flesh and milk of the camel serve as food, and the hair for the manufacture of cloth, to the people who possess it. Their humps, principally composed of fat, are provisions of super-abundant nutriment, which are gradually absorbed and disappear on the occasion of a scarcity of other food, as is observed at the end of a long journey. By resting on their callositics, they are enabled to repose on a scorching surface, and their stomachs are adapted to contain a supply of water sufficient for several days.

The *Llamas* of South America are much smaller than the preceding; they have the two toes quite separate, and are without humps. They were the only beasts of burden possessed by the Peruvians at the time of the conquest. They can only make short journeys, and the largest of the four species known cannot sustain more than one hundred and fifty pounds. Remains of a fossil species have been lately found, which must have equalled the camel in stature.

Order XI.—Marsupialia.

The two remaining orders of Mammalia, the Marsupialia and Monotremata, are now usually regarded as constituting a distinct sub-class, termed *Ovo-vivipara*, intermediate between the truly viviparous Mammalia and the oviparous Birds and Reptiles. Their most obvious peculiarity is the production of their young at a very early period of development, in a state incapable of motion, and barely exhibiting the rudiments of limbs; so that it is not until a long time after their birth that they acquire a condition parallel to that of a new-born animal of one of the higher orders, and they much more resemble the half-formed chick in an egg which has been but a few days incubated. In accordance with the lower grade of this important function, we find a general inferiority of the whole organization to that of the truly viviparous Mammalia, and approaches, in many points of structure, to birds and reptiles. The skeleton, the nervous system, the arrangement of the large blood-vessels, and the larger number of the incisor-teeth (which in the higher sub-class never exceed six), all show indications of this approximation; and this is also indicated in the deficiency of intelligence, which is manifest in their physiognomy as well as in their actions.

Of these two orders, that of Marsupialia is the one which exhibits the least departure from the general type of the Mammalia, and it is that, too, in which the provision for the continued nourishment of the young by its parent is the most remarkable. The new-born imperfect offspring attaches itself to the teats of the parent, in remains fixed there until it has acquired a degree of development comparable to that with which other animals are born. The skin of the abdomen of the parent is so disposed as to form a pouch in which these imperfect young are protected, and into which, long after they can walk, they retire for shelter on the apprehension of danger. It is from the pouch (*marsupium*) that the order takes its name, this being its distinguishing peculiarity. It is remarkable that, notwithstanding the general and usually very striking resemblance of the species to each other, they differ so much in the teeth, the digestive organs, and the feet, that, if we rigidly adhere to these characters, we should find it necessary to separate them into distinct orders.

The geographic range of this order is extremely peculiar. With the exception of the Opossum group, which inhabits America, its species are at present almost confined to Australia and the neighbouring countries, where they constitute, with the Monotremata, almost the only mammiferous animals.

The Marsupialia may be divided into families according to the nature of their food. Some of those inhabiting Australia are altogether carnivorous, and display considerable ferocity. The *Opossums* have a mixed diet; they are remarkable for possessing an opposable thumb, like that of Quadrumana. Another group is more formed to live in trees, where they feed upon insects and fruit; to this belongs the *petaurus*, or flying-opossum,

which is formed upon the same plan with the flying-lemur The Kangaroos, of which several species exist,

Great Kangaroo.

resemble the Ruminantia in food and habits. They are remarkable for the enormous length of their hinder feet, whence their generic name, *Macropus* (long-footed), is derived. The hind legs and tail are also very largely developed; while the fore legs and feet are very small. From this great inequality in the size of the limbs, they advance on all-fours very slowly; but they can make immense leaps with the hind legs, the tail probably assisting them. These are furnished with one large nail, almost like a hoof, which is a powerful weapon of offence and defence; for, supporting itself upon one leg and its tail, the animal can inflict a very severe blow with the leg which is at liberty. It will sometimes grasp its enemy with its fore paws, while it kicks it with its hind foot; but this it will only do when attacked, for it is naturally a very gentle animal. The largest species is sometimes six feet in height, having the bulk of a sheep, and weighing 140 pounds. Its flesh is used as food by the New Hollanders, and is described as being a little like venison.

Order XII.—Monotremata.

The order Monótremata is a very extraordinary one. It contains but two species, the *echidna* or spiny ant-eater, and the *ornithorhynchus* or duck-billed platypus; and these are found nowhere else than in New Holland and Van Diemen's Land. These were included by Cuvier (who regarded the absence of teeth as the chief character) among his Edentata; but zoologists have now generally agreed that the peculiarities of their structure and physiology fully entitle them to rank as a distinct order, even more dissimilar to the other Mammalia than are the marsupial quadrupeds just considered. Until recently, indeed, it was much doubted by many, whether they could be included among the class Mammalia at all, since their organization did not appear at all adapted for the nourishment of the young by suckling, which is the essential character of the group. The lips of both animals, in adult age, are of horny consistence, resembling the bills of birds; in the echidna they are prolonged into a narrow beak, and in the ornithorhynchus they form a wide flat bill like that of a duck. Moreover, the presence of glands for the secretion of milk appeared doubtful. But the late researches of Mr. Owen have shown that the lips, in the young state of these animals, are much softer and more flexible, and that mammary glands certainly exist; so that the question may now be regarded as decided.

The name and character of the order are derived from the fact of the excretory openings at the posterior part of the body being united into one, as in birds; and this is a point of very remarkable affinity with that class, which is borne out by their general organization. There is a sort of clavicle (collar-bone) common to both shoulders placed before the ordinary clavicle, and analagous to the *furcula* (merry-thought) of birds. Each foot possesses five claws; and, besides these, the males have a peculiar spur on the hinder ones, like that of a cock.

The *Echidna* is characterized by the slenderness of the prolonged muzzle or bill, which contains an extensible tongue, like that of the ant-eater. The feet are short, very robust, and adapted for digging. The whole upper part of the body is covered with spines, bearing some resemblance to those of the hedgehog; and when apprehensive of danger, and unable to escape from it by burrowing, the echidna can erect its spines, and roll itself into a ball.

The habits of the *Echidna* in a state of nature are but little known; for they do not exist in any large number, and they burrow so rapidly in the ground, that even when one is discovered it is not easily got hold of. To lift it from the ground, requires more force than would be supposed; for it firmly fixes itself to the earth in an instant, and but a few moments elapse before it is so far down, that its back is level with the surface. It feeds upon insects, principally ants, which it captures by its long extensile tongue; and this appears to be furnished with a glutinous secretion which causes them to adhere to it.

The *ornithorhyncus* (so named from its *bird*-like *bill*), is an animal of such extraordinary aspect, that the specimen first brought to this country, at the end of the last century, was supposed to have been *made up*, by the attachment of the beak and feet of a bird to the body of an otter-like quadruped. It was not until other specimens had arrived, and had been submitted to most careful examination, that naturalists were satisfied of the real existence of such an animal. Since that period, its true place in the scale, depending upon the mode in which it produces and nourishes its young, has been a most fertile source of controversy; but the question may now be regarded as set at rest by the inquiries of Mr. Owen, already alluded to.

The whole organization of this singular animal is evidently designed to adapt it for seeking its food in the water, and for chiefly inhabiting that element; and what is known of its habits fully confirms this view. It burrows in the banks of rivers, and seeks its food in precisely the same manner as the duck. River insects, small shellfish, and water-plants, appear to constitute its nourishment. The animal is very timorous, and, if alarmed while at the surface of the water, dives down head foremost, and does not ascend at the same spot.

CLASS II.—BIRDS

Birds have been denominated, and not inappropriately, the Insects of the vertebrated series. As in the animals of that class, we find the whole structure peculiarly adapted to motion, not in water, nor supported by solid ground, but in the elastic and yielding air. It is true that there are some birds whose wings are so slightly developed, as not to be able to lift them off the ground; and there are others whose natural element seems to be the water, through which they are more adapted to move than through the element above. But in looking at the general character of a group, the naturalist has to put out of view these exceptional cases, and to consider the structure and habits of the mass.

It is impossible to conceive of any more beautiful adaptation of structure to conditions of existence than that which is exhibited in the conformation of the bird with reference to its intended mode of life. To make a vertebrated animal capable of soaring through the air, sometimes moving with a swiftness which, in proportion

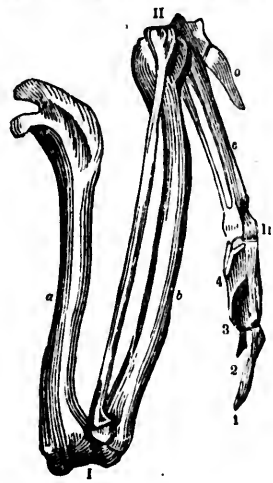
to its size, far surpasses that of any other beings but insects, and at others sustaining itself on the wing almost without motion for a considerable period, is a problem which human ingenuity, even with an unlimited command of materials and of power of construction, would almost certainly fail of solving—so many are the conditions necessary to be fulfilled, the slightest failure in any one of which would have marred the result. It is only after attentively studying the structure of these animals, as presented to our view by an all-wise Creator, that we become aware of the complex nature of these conditions, and of the variety of adaptations necessary to fulfil them.

In regard to the place of the class in the vertebrated series, this is easily determined to be between the Reptiles and Mammalia. Like the former, its members are oviparous, and, like the latter, they possess a complete double circulation and warm blood. In order to adapt the vertebrated animal to its aërial residence, it is obviously necessary that the body should be of as low specific gravity as possible, that is, should be as nearly as can be of the same weight with an equal bulk of air. It is further necessary that the surface should be capable of being greatly extended, and this by some kind of appendage that should be extremely light, and at the same time possessed of considerable resistance. The great degree of muscular power required for support and propulsion in the air involves the necessity of a very high amount of respiration, for which an express provision also exists in insects; and as the general activity of the vital processes depends greatly upon the high temperature which this energetic respiration keeps up, a provision is required for keeping in this heat, and not allowing it to be carried away by the atmosphere through which the bird is rapidly flying.

The first and third of these objects—the lightening of the body and the extension of the respiratory surface—are beautifully fulfilled in a mode which will be found to correspond with the plan adopted for the same purpose in insects. The air which enters the body is not restricted to a single pair of air-sacs, or lungs, placed near the throat, but is transmitted from the true lungs to a series of large air-cells disposed in the abdomen and in various other parts of the body. Even the interior of the bones is made subservient to the same purpose, being hollow and lined with a delicate membrane, on which the blood-vessels are minutely distributed. In this manner, the respiratory surface is immensely extended, and, by the large quantity of air introduced into the mass, its specific gravity is greatly diminished. There is another provision in the conformation of birds, having reference to the same objects. The ribs are connected to the breast-bone by bony instead of cartilaginous arches, and are fixed in such a manner, that a state of fullness is that which is natural to the chest and its contents, while that of emptiness is forced. And thus the body almost always contains as much air as its cavities can hold.

The other two objects—the extension of the surface and the retention of the heat within the body—are also accomplished in combination, by a most beautiful and refined contrivance, to which there is nothing parallel in the whole animal kingdom, namely, the covering of feathers. Like hair or scales, feathers are to be regarded as appendages of the cuticle or outer skin; and the apparatus by which they are formed does not differ in nature, although more complicated, from that which secretes hair. The feather consists chiefly of the *quill* and *vane*; by the former it is attached to the body, and the latter gives the expanded surface. The vane consists of a number of small *lamina*, or separate plates, which are formed between folds of membrane that serve as a kind of mould to them; and they are afterwards connected to the stem of the feather. When perfectly formed, they are connected by minute barbs at their edges, which hook into one another and thus give the necessary means of resistance to the air. The substance of which feathers are formed is a very bad conductor of heat; and when they are lying one over the other, small quantities of air are included, which still further obstruct, by their non-conducting power, its transmission. Thus the two chief objects are fulfilled—power of resistance and slow conducting properties being combined with lightness and elasticity.

The general adaptation of the bony frame-work to give effect to the purposes for which this remarkable covering is constructed, will next be considered. In



Jer Falcon's wing.

the accompanying wood-cut, I. represents the elbow-joint; II. wrist-joint; III. finger-joint; *a*, humerus or arm-bone; *b*, bones of fore-arm; *c*, bones of hand; 1, 2, 3, 4, rudiments of fingers; *o*, rudiment of thumb, or winglet. The feathers which form the wings are inserted into the skin covering the anterior extremities, which correspond to the arms of a man. In the bones of these may be recognised the chief parts which are elsewhere found; but those which form the hand, being only intended for support, and having no prehensile powers, are much consolidated together, but at the same time elongated. The quills adhering to the hand are called *primories*; from their greater distance from the centre of motion, they have the most powerful effect, and they are therefore constructed in the strongest manner; those attached to the fore-arm are called *secondaries*; and weaker feathers attached to the humerus are called *tertiaries*; while those that cover the shoulder are termed *scapulars*. These distinctions are very important in dividing the principal groups into subordinate sections.

The anterior extremities of birds being thus solely adapted to sustain them in flight, the posterior are necessarily modified for their support on the ground. These are usually placed rather far back, and the spine has a position more inclined than horizontal, so as to be balanced upon them. The trunk is supported on the thighs by very powerful muscles; and there is another series which pass from the lower part of the spine to the toes, turning over the knee and heel, in such a manner that the flexion of these joints shall shorten them: by this contrivance, the simple weight of the body flexes the toes, and birds are thus enabled to sleep perched on one foot. Most commonly the feet possesses four toes of which one is directed behind and three in front. This posterior toe opposed to the rest is not, however

analogous to the thumb of Quadrumana, which is only represented in birds by the spurs of the Fowl tribe. In some birds two of the toes are disposed behind, and two in front; in others the posterior toe is deficient; in others, again, it is brought forwards. The number of joints in the posterior toe is but two; in the external it is five.

The upper part of the skeleton of the trunk is peculiarly adapted to give power to the wings. The *sternum* or breastbone is made to project forwards with an elevated ridge or keel, to which the strong muscles which depress the wings are attached; and from the depth of this, the powers of flight may be in some degree judged of: in the ostrich tribe, where the wings are not sufficiently developed to raise the bird off the ground, it is quite flat. The shoulder-bones are connected with the sternum and with each other in a much stronger manner than in other vertebrata. The two *clavicles*, or collar-bones, are united together on the central line, forming the *furcula*, or merry-thought; and the use of this is to keep the shoulders apart, notwithstanding the opposing force exerted by the action of flying. It is generally

Sternal apparatus of the Common Hurrier;
a, furcula; *b*, keel of sternum.

firm, and its angle open, in proportion to the power of flight. Besides this, we find the sternum connected with the shoulder by two bones termed *coracoid*, which in man and the other Mammalia are scarcely developed, being merely short processes from the shoulder-blade, which do not reach the sternum.

In order to give as great firmness as possible to the centres of motion of the wings, the trunk of birds has but little flexibility; the vertebræ being firmly jointed to one another, and the ribs united to the sternum by bony prolongations of the latter, instead of by cartilages. But this want of flexibility of the trunk is counterbalanced by the length and flexibility of the neck. The number of cervical vertebræ (which in the longest-necked Mammalia is never more than seven) is very considerable, varying from twelve to twenty-three, the highest number being present in the Swan tribe. These are so jointed together that the head can be turned completely round (the position assumed when at rest) or moved in any direction. The jaws or mandibles of birds are not furnished with teeth; but are covered, like those of the Chelonia, with a horny envelope, which sometimes projects considerably beyond them, and forms the *bill*. This is occasionally furnished with little projections, which in some degree supply the place of teeth; but it is only in the birds of prey that these are supported by any corresponding projections of the bone beneath.

The reduction of the food is entirely performed in the stomach. The digestive process is extremely powerful in birds, and the demand for food very frequent. The gullet, before entering the stomach, is dilated into a large cavity, termed the *crop*, in which the food is stored up as in the cheek-pouches of monkeys, and from which it is transferred by little and little to the true stomach. This is composed of two parts, the *proventriculus*, or membraneous stomach, the walls of which are beset with glands; and from these a secretion is formed, by which the food is moistened. It is then transferred to the second division, termed the *gizzard*, which is furnished with thick fleshy walls; and by the muscular action of these it is ground down to a pulp. Gravel is swallowed by some birds, for the purpose of augmenting the triturating power of this organ. The gizzard is most powerful in birds which feed on grains, as the common fowl. In those which subsist on animal food, or on soft herbage, its muscles are reduced to extreme tenuity, so that it is scarcely distinguishable from the proventriculus. The dilatation of the craw is sometimes wanting. In parrots and pigeons it is an important organ in the nutrition of the young. It is furnished with numerous glands, which become developed in both sexes during the period that they alternately perform the duty of incubation; the function of these is to secrete a milky substance, with which a part of the food swallowed by the parent is impregnated, and this is then disgorged for the supply of the young.

The development of the senses of birds varies in different tribes according to the mode in which they are adapted to obtain their prey. The sight is almost always extremely acute, and is the chief means of seeking food. The powers of vision in the rapacious birds are probably the greatest. A hawk has been known to distinguish a lark, coloured like the clod of earth upon which it is sitting, at twenty times the distance at which it would be perceived either by a dog or man. The rapacious birds seem more remarkable, however, for their *length* of sight; those which, like the swallow, capture insect prey on the wing, must have a *quickness* of sight of which we can scarcely form a conception, since, while flying at the rate of three miles in a minute, they are constantly on the watch for their victims. The sense of smell does not seem to be in general highly developed in birds; even the vultures would seem to become cognisant of their food, at least as much by sight as by scent. The sense of hearing seems to be in general tolerably acute, especially in the nocturnal birds of prey, some of which possess—what the rest want—an external cartilaginous ear. The tongue of birds does not appear to serve as an organ of taste, except in a few species. It is employed in various ways as a means of obtaining food. The sense of touch appears to be generally very obtuse; but in such as the duck, which search for their food in mud, where neither sight nor smell can be of much avail, the bill is covered with a skin abundantly supplied with nerves of sensation, in order that the animal may feel about for its hidden sustenance.

Of all the endowments of this interesting class, none is more striking, or ministers more to the pleasure and delight of man, than their varied powers of *song*. It may safely be affirmed, that one, at least, of the reasons for which so much strength of voice has been given to the feathered creation is, that it may serve for mutual recognition and companionship, which would otherwise be difficult between individuals of so small a size, when separated by distance or intervening foliage; for this power has been bestowed upon the birds which make their habitation among trees, much more universally, and to a much greater extent, than upon any other part of the class. To this order of INSESSORES, or perching-birds, indeed, the *musical intonation* of the voice seems almost exclusively confined. The assertion that the song of birds is peculiarly an expression of love at the breeding season, is certainly erroneous; the use of the faculty is by no means confined to that season, and probably indicates general pleasure and contentment; the voice will consequently be most exercised at the time of

courtship, as well as during the period of incubation, when the male solaces the partner of his cares with his melody. For a combination of power, sweetness, variety, richness, and compass, the nightingale is generally regarded as entitled to the first place among singing-birds; but the vocal achievements of the mocking-bird, which can imitate "to the life" the song of every other bird, and the voice of almost every animal which it hears, while at the same time it possesses a rich and peculiar song of its own, are yet more extraordinary. Many birds which have no song, possess a remarkably expressive voice, obviously adapted to communicate their wants or desires; the common crow is an instance of this.

Not only do birds resemble insects in their general structure and mode of life, but also in the peculiar development of the instinctive powers. Under the direction of these, the place for their nests appears to be selected; their materials collected; the nests themselves built, and the young reared in them; the migrations are performed; and many curious stratagems are employed to obtain food. These it is sufficient thus to indicate in general terms; since it is well known that the habits of birds have something peculiar in each species, yet that in all the individuals of each species they are as precisely alike as their circumstances will admit. Nevertheless, there is observed in birds a degree and kind of adaptation to varying conditions, which insects do not possess, and which display an amount of *intelligence* superior to what is found in that class. And in the domesticability of many tribes of birds, we see an obvious approach towards that higher form of attachment to man, which is exhibited by many species among Mammalia.

There is a more striking conformity in the entire class of birds to one general type, than is probably seen in any other group of equal extent in the whole animal kingdom. The instances of any remarkable departure from it are very few; the chief is that exhibited in the Ostrich tribe, in which the development of the wings is very small. In no other instance are either of the extremities wanting; and thus birds never exhibit the irregularity occasionally presented by fishes, reptiles, and even Mammalia.

Owing to this general conformity of type, the subdivision of the class is a matter of some difficulty, since it is not easy to say what characters should be regarded as of most importance, and what are but secondary. And this difficulty extends also to the smaller subdivisions; in separating which, characters that appear very trivial are often necessarily employed from the want of others. The following orders may probably be regarded as constituting groups of species having a positive resemblance to each other, and a well-marked dissimilarity from the rest.

The Natatores, or Swimming-birds, are known by the union of the toes with a web, so that the surface by which the foot acts upon the water is greatly extended. The legs are short, and placed behind the point of equilibrium. The body is closely covered with feathers, and coated with a thick down next the skin. It is in this order that we find the nearest approach to reptiles which birds present.

The Grallatores, or Waders, are known by the length and slenderness of the legs, which are bare of feathers to a considerable height, by the elongation and straightness of the toes, the length of the neck and beak, the slenderness of the body, and the considerable development of the wings.

The Cursores, or Runners, were included in the last order by Cuvier, chiefly, it would seem, on account of the length of the legs. But these members, instead of being slender, are very strong, being the only locomotive organs; and the wings are very slightly developed, and not capable of raising the bird into the air. This last character is quite sufficient to separate the group from all others.

The Rasores, or Scratchers, receive their name from an action common to many of them, and particularly observable in our ordinary poultry. The character of the order is chiefly derived from the structure of the feet, which are furnished with three toes, united at their base by a short membrane, and with one behind, higher than the rest; and these are armed with short, blunt, and robust nails, for the purpose of scratching up their food.

In the first of these orders, the habitation is, more or less exclusively, aquatic; in the second, marshy places are chiefly frequented; and the third and fourth contain birds essentially adapted to live on the ground, and to seek their food without rising into the air. In the remaining orders, the habitation is more or less aërial.

The Scansores, or Climbers, pass most of their time in trees, clinging to the branches by means of their feet, which are specially adapted to that purpose. The external toe is turned backwards, as well as that which was posterior in the Rasores, so that they have two toes in front and two behind. This conformation prevents them from walking readily on the ground; and, their powers of flight not being usually great, they are not so active as the Insessores.

The Raptores, or Birds of Prey, constitute a group sufficiently well marked by the robustness and muscularity of the whole body, the strength of the legs, and of the bill and talons. The former is strong, curved, sharp-edged, and sharp-pointed; and all of the toes—three before and one behind—are armed with long, strong, and crooked claws.

There now remains a very extensive group of birds, presenting no very marked differences among its members, and not readily defined by any striking characters which separate it from the rest. Accordingly, it is usually made to constitute but one order, that of Insessores, or Perching-Birds. The principal character in which all these agree, is the slenderness and shortness of the legs; the feet have three toes in front and one behind, and the two outer ones are united by a very short membrane; they are all slender, flexible, and moderately long, with long and slightly curved claws. These feet are readily distinguishable from those of the other orders: they are destitute of the webbed expansion possessed by the Natatores; they have not the robust strength and destructive talons which characterize the Birds of Prey; nor do they present the very extended toes which enable the Waders to walk safely over marshy soils, and tread lightly on the floating leaves of aquatic plants. They are adapted to enable the bird to *rest* on the branches of trees, but not to *cling* to them; and, accordingly, the birds of this order pass a large proportion of their time on the wing.

Of all these orders, the Cursores present the nearest approach to the Mammalia in their conformation and mode of life; but it is among the Incessores that we find most developed those characters which have been mentioned as distinguishing the class—power of flight, beauty of plumage, and melody of voice. These, therefore, as the types of the class, will be first considered.

Order I.—Incessores.

This order, composed of the Perching-Birds, is the most numerous and varied of the whole class. Its character seems principally negative; for it embraces those birds which are neither swimmers, waders, climbers, rapacious, or gallinaceous. Nevertheless, by comparing the different tribes it includes, a great general resemblance of structure becomes apparent; and such insensible gradations are perceived between those that at first appear most unlike, that it is difficult to establish the subdivisions of the group. The foot, as the name denotes, is especially formed for grasping or perching—a peculiarly

evinced by the situation of the hinder toe, which is invariably placed on the same level or plane as those in front. The length of the tarsus or shank (that which appears the lowest division of the leg, but is really the higher part of the foot) is moderate, and often very short in comparison to what is seen in other orders; and, as these birds never seize their prey by their claws, these weapons are never retractile. The perchers are thus distinguished from the birds of prey properly so called; from the climbers they are separated by having three toes directed forwards; while the situation of the hind toe enables them to be readily known as neither gallinaceous, wading, nor swimming birds. Their food is various, but in general mixed, consisting of insects, fruit, and grain; those in which the beak is stout and strong feed more upon grain, some of them, however, even pursuing other birds; and those which have a very slender bill feed on insects, or on the juices of flowers. The proportional length of the wings and their powers of flight, are as various as their habits. In general the females are smaller and less brilliant in their plumage than the male; they always live in pairs, build in trees, and display the greatest art in the construction of their nests. The young come forth from the egg in a blind and naked state, and are wholly dependent for subsistence, during a certain period, upon parental care.

The *larynx*, or organ of voice, is always of complex structure in the members of this order, which contains all that are commonly known as singing-birds. There are few that do not either sing, or utter some peculiar note or chatter analogous to song, during the season of courtship; and even of those which in general utter only monotonous cries, or of which the notes are harsh, some are frequently capable of being taught to speak, to whistle airs, or to imitate other sounds.

The families composing this order may be distributed under four large groups or assemblages, characterized by the respective forms of their bills. The Conirostres have a stout beak, more or less conical, and with regular edges. The Dentirostres have the upper mandible notched, as in the Raptores, towards the point; but this notch only exists in the horny covering, and not in the bone. The Fissirostres have a short, broad, horizontally-depressed beak, so formed that the gape of the mouth is extremely wide; it is slightly hooked, but without any tooth at the edge. The Tenuirostres have the bill very slender and elongated; it is sometimes straight, and sometimes curved.

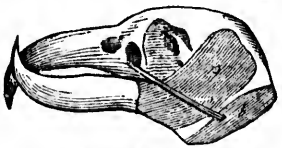
I. Conirostres.—The Conirostres are to be regarded as containing the types of the order, the species belonging to it having the most varied faculties. They feed indiscriminately upon insects and vegetables, and are therefore termed omnivorous. Their feet are so constructed that they can walk upon the ground with nearly the same facility as they perch upon branches. The families included in this tribe are the Corvidæ, or Crows; Sturnidæ, or Starlings; Fringillidæ, Finches; Bucerotidæ, Hornbills; and Loxiadæ, Crossbills.

Of the family Corvidæ, the common *Crows* are the most characteristic examples, and may be regarded as combining the general characters of the class in a greater degree than any other birds. In every climate habitable by man these birds are found; they are constructed for powerful and continued flight, as well as for walking firmly upon the earth; they feed indiscriminately on animals or vegetables, and, when pressed by hunger, do not refuse carrion: their smell is remarkably acute. They are bold but wary, live in common societies, and possess great courage; when domesticated, they possess a power of imitating the human voice nearly equal to that of the parrot; and, like it, show signs of greater intelligence than is found in the rest of the class. Under the general term *Crow* are included the raven, which is the largest of European perching-birds, and which is bold enough occasionally to carry off poultry; the corby crow, which is very destructive to eggs and young game; the rook, which chiefly feeds on insects, and especially devours the grubs of the Coleoptera, though it occasionally eats grain if its proper food be scarce; the hooded crow, which feeds upon molluscs, &c., on the sea-shore; and the jack daw, which is a very vigilant enemy of predatory birds. The *magpies* are nearly allied to the crows; as are also the *jays*, which live principally, however, in woods, and feed on acorns, &c. The Sturnidæ are best known by the European *starling*; the family seems like a smaller race of crows, which they greatly resemble in manners and structure, but are much weaker.

The Fringillidæ, or *Finches*, are the smallest of this group of perching-birds, and are readily known by the shortness and strength of their conical bills. They subsist generally on grain. The number of species is very great; and some among them are everywhere diffused. The sparrows, chaffinches, linnets, goldfinches, bullfinches, and larks, are the kinds best known in this country.

The Bucerotidæ, or *Hornbills*, are readily distinguished at first sight by the enormous size of their bills, which are swollen or enlarged at the base into protuberances resembling horns or knobs, which are sometimes as large as the beak itself. The form of this excrescence varies much with age; and in very young individuals there is no trace of it perceptible. It is not solid, except in one species, but composed of a fragile network of bony fibres. The use of this curious appendage is unknown. The Hornbills are gregarious noisy birds, of large size, and are peculiar to the Old World. They subsist on all sorts of food, devouring tender fruits, chasing mice, small birds, and reptiles, without disdaining carrion; and they breed in the hollows of lofty trees.

The family of Loxiadæ, or *Crossbill* tribe, contains a large number of genera, of which the common crossbill can scarcely be regarded as a characteristic illustration, the peculiarity from which it takes its name not being possessed by more than a few other species.



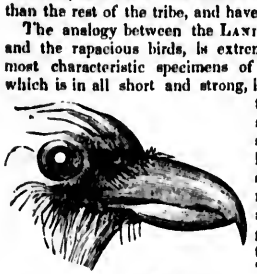
Bill of Crossbill: *a* and *b*, muscles which move it.

This peculiarity consists in the strong curvature of the mandibles, so that their tips pass each other; and not always on the same side; by this extraordinary bill the bird is enabled to extract the seeds from pine-cones with astonishing facility, and it is confined to localities in which these are to be obtained. The species common in Western Europe has of late years become more abundant than formerly in the British Isles, where it was previously chiefly known as an occasional straggler.

II. Dentirostres.—This group is the most allied of all the Incessores to the Birds of Prey. As its name imports, the species it includes are distinguished by a distinctly notched bill, and they are the greatest destroyers of insects among the Perchers. With very few exceptions, they either live entirely on insects, or resort to fruit only when insufficiently supplied with their favourite nourishment. The mouth is protected on each side by bristles, which defend the soft parts during the struggles of the prey; and the feet are generally adapted more for perching than for walking. The form of the beak varies in different species; in the shrikes, for example, it is stout and compressed, while it is flattened or depressed in the fly-catchers, which lead towards the Swallow tribe. This group includes the following families:—Laniadæ, or Shrikes, which most prominently manifest the peculiarities of the group. Merulidæ, or Thrushes, in which there is less restriction to peculiar kinds of food: Syl

VIADÆ, or Warblers, chiefly peculiar for the small size, delicate structure, and vocal powers, of the species it contains. AMPELIDÆ, or Chatterers, distinguished by the enormous width of their gape. MUSCICAPIDÆ, or Fly-Catchers, which are more exclusively confined to insects than the rest of the tribe, and have small and weak legs.

The analogy between the LANIADÆ, or *Shrike* tribe, and the rapacious birds, is extremely evident. In the most characteristic specimens of the family, the bill, which is in all short and strong, is abruptly hooked at the end, and the notch so deep as to form a small tooth more or less prominent on each side; by this conformation the bird is enabled to take a firm grasp of its food, and to tear it in pieces. The claws, also, are usually strong and sharp. Like many of the falcons, the shrikes will sit for hours watching for their prey, which consists of small birds, and, in the less powerful species, of insects; and will suddenly dart down upon such as come within their reach, seize it with their feet, and carry it home to be devoured at leisure. They not only pursue small birds, but successfully defend themselves against larger ones, even attacking them when they intrude in the vicinity of their nests. Many species feed also upon frogs and other small terrestrial animals. This family contains a large number of species, distributed through all quarters of the globe. They have the same general structure and habits, differing only in subordinate particulars. Some, which are superior in power of flight, pursue insects on the wing; others subsist entirely on soft caterpillars, which they search for among the foliage of high trees; and others prowl about among bushes and underwood, preying upon insects and young or sickly birds, and in the breeding season destroying great quantities of eggs.



Bill of Shrike.

The MERULIDÆ, or *Thrushes*, have an arched and narrow beak, but the point is not hooked, and the lateral tooth is not so marked as in the shrikes. Nevertheless, the transition from one form to the other is very gradual. This family is inferior to the shrikes, therefore, in the peculiar organization adapted to rapacious habits, but they possess a greater variety of powers. It is in this family that we find the birds most distinguished for the sweetness, compass, and versatility of their song. They are not confined to animal food, but live much on fruits and berries.

Of this family the common *thrush* (mavis or song-thrush), the *blackbird*, and *fieldfare*, are well known and also characteristic examples. These, as well as the *missel-thrush*, *redwing*, *ring-thrush*, &c., are closely allied species of the same genus, of which the other species are distributed over the whole globe. The *mocking-birds*, on the other hand, which probably stand unrivalled for their powers of voice, are restricted to America: some of them approximate to the shrikes in their habits. A few species of this family have somewhat aquatic habits.

The chief peculiarity which runs through the numerous family of SYLVIADÆ, or *Warblers*, is the very small size and delicate structure of the species which compose it. Excepting the Humming-Birds, we find among these elegant little creatures the smallest birds in creation. The diminutive golden crests, the nightingale, the white-throat, and the wood-wren, are examples of this family well known to the British naturalist; as are also the robins, stone-chats, wagtails, tit-larks, and tit-mice. Its different groups are spread over all the habitable regions of the globe, and appear to have a peculiar function in the economy of nature, being specially designed to keep down the multiplication of the innumerable minute insects which lurk within the buds, the foliage, or the flowers of plants. The small size of these insects causes them to escape the notice of the thrushes and the larger insectivorous birds; whilst their habits prevent them from being seized by the swallow and such as capture insects only on the wing. The Sylviadæ are for the most part migratory birds; appearing in spring, when the insect world is called into life and activity by the renewal of vegetation, and disappearing in the autumn, when their services are no longer required, and when their supply of food diminishes or ceases altogether.

Of the family of AMPELIDÆ, or *Chatterers*, the most characteristic examples belong to tropical America, and only one is found in Europe—the *wax-wing*. The birds of this family are distinguished from all the other Dentirostres by the enormous width of their gape, which in many extends beyond the eye, and in some is nearly as wide as in the goatsucker. This bill is not defended by bristles, however, at its corners; and the absence of these indicates that its wide opening is *not* for the purpose of catching insects on the wing, as in the swallow tribe. The chatterers live almost entirely on soft berries and small fruits, which they swallow whole; and this food naturally requires a very wide passage. They are perpetually hopping among fruit-bearing trees, and scarcely ever come to the ground. The species which may be regarded as the types of this family are very little known, being inhabitants of the deepest and most secluded forests of tropical America. They are oftener heard than seen; their notes being peculiarly loud, and uttered morning and evening from the deepest recesses of the forests. Many of them are clothed in a very rich and brilliant plumage, which rivals that of the humming-birds.

The MUSCICAPIDÆ, or *Fly-catchers*, are a family hardly less numerous than that of the warblers; and are composed, like that group, entirely of small birds. This family is more purely insectivorous than any other of the order, few of the species belonging to it ever partaking of fruits. These birds have a bill flattened at its base; and the sides of the mouth are defended with stiff bristles, to confine the struggles of their prey. The members of this family are distributed through the temperate and tropical portions of the Old World, and the temperate parts of the New. Between the tropics, however, they are replaced in America by the tyrant-shrikes and fly-catching warblers, both which groups are unknown in Africa and India. The *fly-catchers* of Europe are small birds, about the size of a sparrow. One species is common in Britain, usually arriving about May. It has been observed to take its station on the top of a stake or post, from whence it springs forth on its prey, catching a fly in the air, and hardly ever touching the ground, but returning to the same stand for many times together.

III. FISSIROSTRES.—The group of Insessores thus designated is a comparatively small one; but it is very distinct from all others in the beak, which is short, broad, horizontally depressed, slightly hooked, and very deeply cleft, so that the opening of the mouth is extremely wide. The birds possessing this kind of bill are adapted for capturing insects on the wing, receiving their prey in full flight into their mouths, which remain open for that purpose; and the victim is secured by a gluey exudation within, and a strong fence of bristles on the outside, which also serves to protect the soft parts of the head from its struggles. Although such is the typical or characteristic form of the bill in this group, it is not always seen. In some species the bill is stronger and longer; and these also are distinguished by having the external toe nearly as long as the middle one, and attached to it until nearly its end; to these the name of *Syndactyli* was given by Cuvier, who associated them into a separate group. The Fissirostres as a whole are peculiarly distinguished by having the powers of flight developed to the highest degree. All the energies of

their nature seem concentrated in this one perfection; for their feet are always very short and weak, and serve but for little else than to rest the body after flight. They may be separated into diurnal and nocturnal, like the birds of prey.

This group may be divided into the five following families:—Hirundinidæ, or Swallow tribe; Caprimulgidæ, or Goatsuckers—both these present, in a remarkable degree, the organization which has been described as characteristic of the order; the remaining families have a longer and narrower bill, and are syndactylous—Meropidæ, or Bee-eaters; Halcyonidæ, or King-fishers; Todidæ, or Todies.

The Hirundinidæ, containing the swifts and swallows, are diurnal birds, remarkable, like the diurnal Raptores, for their close plumage, the extreme length of their wings, and the rapidity of their flight. The *swifts* possess these characters in the highest degree, and surpass all other birds in the power of sustaining a rapid flight for a long time. They are distinguished from the swallows by having the hind toe directed very much forwards; and all four toes are armed with strong crooked claws, which give to the bird such a firm grasp, that it can sustain itself by the side of perpendicular rocks or buildings with great facility. In some species, the tail feathers are very stiff, as in the woodpeckers, and serve as an additional support. They spend their time almost entirely in the air, and pursue insects in flocks, sometimes at a great height, uttering discordant screams. They nestle in the holes of walls and rocks. The *swallows* are less capable of sustaining a continued flight than the swifts, as is shown by their weariness after or during migration, on which occasions they have been seen to alight flat upon the sea. Several species exist in Europe, and many more in other parts of the world. Among them may be mentioned a small species inhabiting the Indian archipelago, which forms its nest of a species of sea-weed, which it macerates in its stomach and then arranges in layers. These *edible birds' nests*, as they are commonly termed, are highly prized as delicacies in China, and constitute an important article of traffic with that country.

The Caprimulgidæ, or *Goatsuckers*, are nocturnal birds, and have the same light soft plumage which characterizes the owls. Their eyes are large, and their gape still wider than that of the swallows, so as to be capable of engulfing the largest insects. They come forth in the twilight and return to rest before morning; but in their other habits they much resemble the swifts, with which, indeed, they are closely connected by intervening species; *i.e.*, while there are goatsuckers which fly by day, skimming over the surface of ponds in small flocks, precisely in the manner of swallows, there is also a swift which only flies at night.

The family of Meropidæ, or *Bee-eaters*, is confined to the warm regions of the Old World; only one species being known as having occasionally strayed to Britain. They have long and pointed wings and short feet, and fly in the manner of swallows. The European Bee-eater annually visits Italy, in flocks of twenty or thirty, and may be seen skimming over the vineyards and olive plantations, especially pursuing bees and wasps. It is remarkable that they are never stung by these; they seize the insect, and at once crush it by the snap of their powerfully compressive beak.

The Halcyonidæ, or *King-fishers*, are remarkable for the great length of the bill, and the extreme shortness of the feet. Their habits are sedentary, much resembling those of the fly-catchers; but their food is more various. The common British species partly lives on small fish, which it takes by precipitating itself into the water, either from the branch on which it had perched, or by suddenly arresting itself during rapid flight, poising for an instant, and then plunging. It returns to its perch to gulp its prey, first killing it by repeatedly beating it against a bough. The Todidæ, or *Todies*, are small American birds, resembling the king-fishers in their general form and may be regarded as representing them in the New World.

IV. Tenuirostres.—This group, it has been well remarked, "is among the most interesting of the animal world. Deriving their subsistence, for the most part, from the nectar of flowers, we never fail to associate them in our idea with that more beautiful and perfect part of the vegetable creation, with which, in their delicacy and fragility of form, their variety and brilliancy of hues, not less than by their extracting their nourishment from vegetable juices, they appear to have so many relations." This tribe is confined exclusively to the torrid zone and southern hemisphere. The length and slenderness of the bill are its distinguishing characteristics. It is not by this, however, but by the long filamentous tongue, that the juices of flowers are sucked up; and to protect this important organ, the peculiar conformation of the bill seems chiefly intended. The tongue is often simply forked; but is sometimes divided into so many slender filaments, as to resemble a painter's brush. The feet are very short and delicate. All these characters are presented in the greatest perfection by the Trochilidæ, or Humming-birds, which are the types of the group. In the Cinnyridæ, or Sun-birds, the feet are more lengthened. The Promeropidæ, or Hoopoes, have the tongue short. The Paradisiadæ, or Birds of Paradise, are separated by the strength of the feet. And the Melithreptidæ, or Honey-suckers, have the bill notched.

The Trochilidæ, or *Humming-bird* tribe, so celebrated for the metallic lustre of their plumage, and particularly for the gem-like brilliancy of some of their feathers, have, within their long slender beak, a tongue capable of protrusion like that of the woodpeckers, and divided almost to the base into two filaments. These filaments are *not* tubular, as they are sometimes described, but are flattened. It is not improbable that the tongue may serve for catching insects, as well as for sucking the juices of flowers; since it is unquestionable that, like others of the order, the humming-birds are partly insectivorous. When hovering over flowers, these birds balance themselves in the air by a rapid motion of the wings, like many flies; and it is by this movement that the *humming* sound is produced, from which they take their name. The flight of these birds, the smallest of the order, is so rapid as frequently to elude the eye. They live solitarily; defend their nests with courage, attacking with their needle-like bills the eyes of intruders, which makes these minute creatures truly formidable; and fight with each other desperately.

This family is exclusively confined to America; and, with few exceptions, to the southern part of that continent and the adjacent West Indian islands. More than one hundred and seventy species are at present known; and others are constantly being discovered. The smallest of them, when plucked, are less than a large humble-bee; and one only, which is much larger than any others as yet known, nearly equals the common swift in size. This bird is also one of the dullest coloured, and its general resemblance to the swifts is very manifest.

The Cinnyridæ, or *Sun-Birds*, represent the humming-birds in the eastern continent. They are closely allied to the Trochilidæ in general structure and in the mode of obtaining their food, but their tongue is not so deeply divided. They are small birds, and the males have the most brilliant colours, rivalling those of the humming-birds, during the breeding season; but the garb of the female, and of the male at other times of the year, is much more dull. The Promeropidæ, or *Hoopoes*, are also restricted to the Old World; one species, the common hoopoe, annually visits Europe, in company with the bee-eaters and other swallow-like birds.

The PARADISIDÆ are among the largest of the Tenuirostres, and seem to live, like the rest of the order, chiefly upon soft vegetable substances. They are confined to New Guinea and the neighbouring islands, and for a long time no specimens were obtained but such as had been deprived by the natives of their legs, whence it was at one time supposed that they were destitute of limbs, and supported themselves entirely upon their airy plumes. The extraordinary development of their feathery appendages is well known; but of the purpose these serve in their economy, no plausible account has been given. The very restricted locality of these birds, and the savageness of the people who inhabit it, have prevented naturalists from obtaining much knowledge of their habits. They are partly supported upon insects.

The MELIPHAGIDÆ, or *Honey-Suckers*, are distinguished from all the preceding families by their notched bill; their tongue is terminated by a bunch of delicate filaments, and the hind toe is so strong and robust that it serves as a support to the bird during the process of feeding. This group is chiefly confined to Australia, where its members abound in great variety of form, and where they find a never-failing support in the luxuriant vegetation of that country.

The members of the family CERTHIADÆ, which consists of the Tree-creepers, Nuthatches, &c., strongly resemble the scansorial birds in their habits, but they more closely approximate to the Tenuirostres, and especially the Meliphagidæ, in general structure. Like those, they are of small size; the foot has three of the toes directed forwards, and the bill is more slender and delicate than that of the woodpeckers. The *Tree-creepers* bore into trees, however, and rest upon their tail in climbing, much as do the woodpeckers, but they rather seek for their food in the natural chinks of the trees, or among the mosses and lichens which cover the branches. The *Nuthatches* have a stronger bill, which is straight and pointed, like that of the woodpeckers. They use it, however, rather to scale off the bark than to perforate it, and they do not support themselves upon the tail. They feed not only upon insects but upon various seeds, and are celebrated for the instinct of fixing a nut in a chink while they pierce it with the bill, swinging the whole body as upon a pivot, to give effect to each stroke. The British species is about the size of a robin, its note loud, and its disposition remarkably fearless.

Order II.—Raptores.

The rapacious birds constitute a well-marked group, which may be compared with that of the Carnivora among Mammalia. In comparison with the Insessores, their number is but few; for had it been otherwise, they would soon have extirpated the whole race. They usually breed but slowly, leading solitary lives, and never appearing in numerous collections. Most of them are large and powerful birds; and, what is an exception to the general rule, the female is larger than the male, but her plumage is usually of a duller aspect. There are few of this family which do not show great strength of wing; but the power and swiftness of flight that are possessed by the different species, vary with their habits. As among the carnivorous Mammalia, we find some species adapted to pursue and bring down living prey; and these are endowed with the greatest activity and strength of movement. Others feed upon the carcasses of animals that have met their death in various ways, in search of which they have to perform long journeys: these are endowed with great power of wing, but their swiftness is less. The least degree of these faculties among the raptorial birds, exists in those which feed upon decomposing animal matter, or which hunt after such small game as it requires neither swiftness nor power to seize.

Rapacious birds are all remarkable for their strong hooked bill and large acute talons. The force of these is indicated by the size of the muscles of the legs and thighs; and the foot is usually but of moderate length, that its power may not be lost by being diffused over too large a space. It is by the talons that the prey is usually struck first; and, when secured by the feet, it is torn open by the bill. For this purpose there exists in the typical Raptores a strong and sharp tooth-like projection from one or both of the mandibles, which is of material assistance; but in such tribes as feed on carrion or small animals, it is nearly or entirely deficient.

This order is usually divided into two series—the *diurnal* and *nocturnal* Birds of Prey; the former containing the falcons, eagles, vultures, &c., and the latter the owls. As the falcons, vultures, and owls, however, constitute three distinct families of equal rank, it will be preferable thus to consider them. They are chiefly distinguished from each other by the presence or absence of the tooth on the bill, already adverted to; by the degree in which the neck is clothed with feathers or destitute of them; by the size of the eyes, and the presence or absence of a fringe of feathers around them; and other minute characters, the relation of which with the chief peculiarities of the several families will be more obvious when they are particularly considered.

The FALCONIDÆ, or *Falcon* tribe, exhibit the perfection of the order, and correspond very closely in their general habits, and the adaptations of structure to them, with the Feline tribe among the Carnivora. Their bodies are of moderate size; their forms light but powerful; their flight graceful; and their courage very great. They are technically distinguished from the vultures, to which (being both diurnal birds of prey) they are most nearly allied, by the bill being toothed, as well as shorter and sharper; and by the acuteness and strong curve of their talons, which, like those of the Cat tribe, are retractile. The members of this family are almost universally diffused over the earth's surface.

The Falconidæ have been commonly divided into the *noble* and *ignoble*; the latter not being susceptible of being trained to the (so called) noble sport of falconry. The noble division comprehends the *Falcons-proper*, which are distinguished from the rest by the size of the tooth on the mandible, and by the power of their wings, which are long and pointed. They are the most courageous of all the family in proportion to their size; and are especially adapted to pursue and bring down their prey while it is on the wing. The *Eagles* may be considered as ranking next to the falcons. They are the largest and most powerful of the whole group, and pursue and destroy quadrupeds as well as birds. They are distinguished from all other Raptores by having the legs and feet feathered quite down to the toes. The *Hawks*, *Kites*, *Ospreys*, and many other tribes, are well known forms of this family.

The birds of the family VULTURIDÆ, or *Vulture* tribe, are on the whole much larger than those of the previous family, but they are much less courageous. The beak is lengthened, and curved only at the end, and it is not in the least toothed. The power of their talons by no means corresponds with the stature of these birds, and they make more use of their beak than of their claws. Hence they are not adapted for a contest with a courageous victim, and rather seek carrion already decomposing, to which they are attracted—whether by the sight or by the smell is still a disputed question. On this they gorge to repletion; and, in order that the parts of the bird which come most in contact with this offensive food should not be soiled and matted together (as they would be if covered with feathers), the skin of the head, and frequently also of the neck, is destitute of covering. The legs, too, at their lower part, are covered with scales, and not with feathers, as in the eagle.

The Vultures are most abundant in hot climates, where they perform important services, by removing decomposing carcasses, which would otherwise be a source of offensive and noxious exhalations. They are sparingly scattered over the south of Europe; in Egypt they are more numerous; and in tropical America, although the species are fewer, the individuals are much more plentiful.

The family of STRIGIDÆ, or *Owl* tribe, including all the nocturnal birds of prey, is characterized by the large proportion of the head to the body, and by the size of the eyes, which are surrounded by a fringe of feathers. Their soft downy plumage, too, may at once be distinguished from the firm and sharply-cut feathers of the diurnal Raptores. All these peculiarities have reference to their habits. The cavity of the brain is not proportionally larger than in other birds; and the space between it and the exterior of the skull is occupied by large cells, which communicate with the ear, and probably assist the sense of hearing. The size of the eyes, again, has an evident relation to the small amount of light in which they are usually to be employed; the pupils are so large that the birds are dazzled in full day, and hence in part arises the stupid appearance which they exhibit. The fringe which surrounds them probably has for its object to prevent the interference of light from the sides, above, or below, and to enable them to concentrate their whole power of sight upon the object directly before them—as when we look through the hand contracted into a tube at some object which we desire to see more distinctly. This fringe is most remarkable in the *Barn Owl* and its *allies*. In the owls which are partly diurnal

Barn Owl.

in their habits, this circular fringe is hardly perceptible. The owls seek their prey, not by power of flight, but by stealing upon it unawares; hence the movement of their wings should be as noiseless as possible; and this object is peculiarly answered by the downy character of the whole plumage, and by a particular arrangement of the barbs of the feathers at the edge of the wings. The external toe, as in the osprey, can be directed backwards as well as forwards. Their period of activity being twilight, or during moonlight nights, that of their repose is during the day; and, if then disturbed, they make the most ludicrous gestures, which seem principally intended, however, to enable them to get a clear view of the object which annoys them. Owls are feared by all smaller birds, which do not hesitate, however, to attack them during the day. Their food is wholly animal; consisting of mice, frogs, and other small terrestrial vertebrata, small birds, fish in some instances, and insects.

Order III.—Scansores.

The peculiar disposition of the toes in the birds of this order, two being placed behind, and all four arising nearly on the same level, gives them great facility in climbing the branches of trees, but proportionally impedes their progression on level ground. By this character they may be readily distinguished from all other birds, notwithstanding many and striking variations in the form of the bill and wings. The nests of this order are generally less skilfully constructed than those of the Insessores; and the birds often employ for this purpose the hollows in decayed trees: one family is remarkable for depositing its eggs in the nests of other birds. Their flight is ordinarily but moderate. Their nourishment consists of insects and fruits; and the species feeding upon each may be distinguished by the greater or less robustness of the beak. This order may be divided into the four following families:—1. PICIDÆ, or *Woodpeckers*, which may be regarded as the types of the order, presenting its peculiar characters in the highest degree. 2. CUCULIDÆ, or *Cuckoos*. 3. RAMPHASTIDÆ, or *Toucans*. 4. PSITTACIDÆ, or *Parrots*. This last family is separated from the rest by so many peculiarities as almost to constitute a distinct order.

1. The PICIDÆ are chiefly characterized by their long, straight, angular bill, the end of which is compressed into a wedge, adapted to perforate the bark of trees. The tongue is also of peculiar conformation, being worm-like in its shape, barbed at its point, and capable of being suddenly thrown out to a great length. By this mechanism the bird can introduce it into holes and crevices, or even under the loose bark of trees infected by those peculiar insects which it is its province to destroy, and these they obtain, not only by transfixing them with the barbed point, but by causing them to adhere to it by means of a viscid glue with which it is covered. The feet of these birds are short but very strong; the nails are broad and crooked. As an additional and powerful support in their rapid and perpendicular ascent up the trunks of trees, their tail-feathers are very firm, and terminate in points; so that this member, being pressed against the bark, is of assistance to the bird in maintaining its perpendicular attitude. The species of this family are extremely numerous, and are generally distributed over the globe, with the exception of Australia.

2. The CUCULIDÆ, or *Cuckoo* tribe, are a numerous and diversified race, spread over all the temperate regions of the globe. They are principally distinguished by the short and slender make of the feet, of which one of the back toes can be occasionally brought forwards. The beak is of mean length, slightly arched, and compressed at its sides. Most of this family are migratory, and scarcely any build nests of their own. They fly rapidly, and subsist upon insects and fruits. The common cuckoo has long been celebrated for its habit of depositing its eggs in the nests of other birds, generally insectivorous species; and, what is more extraordinary the foster parents, often of species inferior in size, bestow as much care upon the young cuckoo as upon their own proper nestlings, even though the rearing of this involves the destruction of their own young. For, if other eggs are hatched with that of the young cuckoo, the latter speedily ejects the rightful tenants from the nest, and receives all the attention of their parents. If it were not for this, it must speedily perish for want, from the frequency and urgency of its demands for food, and its incapability of assisting itself, up to an advanced age. The cuckoo feeds principally on caterpillars, and

also devours cherries and the smaller fruits; it is sometimes seen to pursue insects on the wing. It is an unsocial bird, seldom congregating with its species, except at the time of migration.

3. The RAMPHASTIDÆ, or *Toucan* tribe, are easily recognised by the enormous size of the bill, which is nearly as large and long as the body itself, but internally very light and cellular; its edges are toothed, and both mandibles are arched towards the tip. The tongue is narrow and elongated, and laterally barbed like a feather. Their feet are formed more for grasping than climbing; accordingly, they always live among trees, and proceed by hopping from branch to branch. So light and elegant are their movements, that in the living bird, in its natural situation, the disproportionateness of the bill does not attract observation. Its large size is to give a more extensive distribution to the nerves of smell, for the purpose of enabling the birds to discover their food, which consists chiefly of the eggs and young of other birds, and also to enable them to obtain it, by dipping it into the deep hanging nests which abound in their natural abodes, for which purpose its surface is endowed with considerable sensibility, enabling it to feel the contents of these nests. The size of the bill prevents their swallowing their food in the usual manner, and they accordingly throw it into the air and catch it in the throat as it descends, a habit practised by many other birds also, in which the tongue is unusually short, or of a form unfit to assist in swallowing. Toucans are mostly large-sized birds, and clothed with brilliant plumage. They are peculiar to the warm regions of America, where they live in small flocks, different species often associating together. They nestle in the trunks of trees.

4. The PSITTACIDÆ, or *Parrots*, constitute a family which is very widely diffused through the torrid zone in both new and old continents, and is scarcely found beyond it. It contains a large number of species, each of which has its peculiar locality, the short wings of these birds not enabling them to traverse large tracts of sea. They correspond with the other Scansores in little else than the structure of the foot, and this is formed rather for grasping than for climbing. It is also used for conveying food to the mouth, a peculiarity nowhere else seen but in the goat-suckers. Their beak is stout, hard, and solid, curved and pointed very much as in the diurnal birds of prey, which they may perhaps be regarded as connecting with this order. They subsist, however, upon vegetable food at all ages, and have a peculiar provision for supplying their young, analogous to that which will be described as possessed by the pigeons. Their jaws are set in motion by a greater variety of muscles than are found in other birds. Their tongue is thick, fleshy, and rounded; and their larynx, or organ of voice, is more complicated than in other birds—by which peculiarities they gain their facility of imitating the human voice as well as other sounds. Their voice, in a state of nature, however, is loud and harsh. They use their crooked bills in clambering upon trees, and nestle in hollow trunks. They subsist upon the succulent parts of vegetables, especially bulbs and fruits. They are distinguished from the rest of the scansorial birds by their intelligence and docility, qualities in which some species are unsurpassed by any members of the class.

Order IV.—Rasores.

This order, corresponding with the *Gallinaceæ* or poultry tribes, consists of birds with bulky bodies, and essentially formed to live upon dry ground. They are the most easily domesticated of the whole class; they furnish men with a considerable amount of savoury and wholesome food, and their fecundity is very great. The majority of them are at once known by their strong thick legs, long necks, short wings, and large ample tails; and the heads of many, especially of the males, are ornamented with elegant crests. The form of the bill is well seen in the common cock; the upper mandible is vaulted, and, at the same time, destitute of any notch; the whole is short and strong, having a peculiarly horny appearance. The wings are muscular, but their feathers have rounded ends; and the breast-bone presents a much smaller surface for the attachment of the muscles than in the previous orders, so that the power of flight is comparatively small. Their food, with few exceptions, is entirely vegetable, and their chief support is derived from the seeds and grains of various plants. Many of them eat also the green portions, and are in this respect nearly peculiar among birds. Almost all of them have a large crop and an extremely muscular gizzard.

The Rasores are mostly social birds, and are readily domesticable. In general they deposit and hatch their eggs on the ground, in a rudely constructed nest of straw, but some of them, which reside in forests, build in trees. Each male usually associates with many females; he takes no part in the construction of the nest or in rearing the young, and these are generally numerous and able to run about and provide for themselves the moment they quit the shell. When this is the case, the male is larger and more gaily adorned than the female. But in the few species which associate in pairs, such as the ptarmigan and partridge, the sexes nearly or quite resemble each other, both in size and colour.

From the strong resemblance which subsists among all the birds of this order, the division of them into families is difficult. The following may be regarded as the most natural distribution of them into groups:—1. PHASIANIDÆ, *Pheasant* and *Fowl* tribe, distinguished by the shortness of the hind toe, the presence of spurs on the legs, and the beautiful development of the tail. 2. CRACIDÆ, or *Curassow-birds*, a tribe of poultry restricted to America, the legs of which are destitute of spurs, and the hind toe so much developed, as to give considerable power of perching. 3. TETRAONIDÆ, *Partridge* tribe, having a very short hind toe, and also very short tails. 4. COLUMBIDÆ, the *Pigeon* tribe, which are much isolated from the rest, and may be regarded as in some respects allied to the Insessores. From the well-known character of most of these birds, the description of the families need not be detailed.

1. The whole of the PHASIANIDÆ, with the exception of the turkey, are restricted to the Old World. The characters by which they are known from the other families, are those which peculiarly distinguish the order; hence there can be no hesitation in regarding this family as its type. It is in the hotter parts of Asia that the most brilliantly coloured birds of this family present themselves in the greatest numbers. The *peacock*, for example, abounds in the forests of India; and the wild specimens even surpass the domestic ones in brilliancy. The *turkeys* are the only representatives of this group in the New World, whence they were brought by the early discoverers, and are now quite naturalized in Europe. The *guinea-fowl* is originally a native of Africa, where it lives [illegible] in the neighbourhood of marshes. Its noisy and querulous disposition renders it incommodious in poultry-yards, although its flesh is excellent. Of our common fowls, the original stock, like that of most domesticated races, is obscure; but it was probably a species of *gallus*, inhabiting Java or Sumatra. The *pheasants* were originally brought from the banks of the Phasis in Asia Minor; several very handsome species abound in different parts of Asia.

2. The CRACIDÆ, or *Curassows*, which are restricted to America, offer a remarkable contrast, in their plain colours, to the brilliant plumage of the Asiatic race which occur in nearly the same parallels of latitude.

They are equally capable of domestication with the *fowls*; and their flesh is of excellent quality.

3. The TETRAGONIDÆ, or *Grouse* tribe, also differ strongly from the Phasianidæ, in the comparative dullness of their plumage, as well as in the extreme shortness of the tail. The *grouse* are formed to inhabit cold climates, and are found in Europe, Asia, and North America. The largest species, commonly known as the *capercailzie*, is the largest of the true poultry, surpassing the turkey in size. It particularly feeds on pine shoots. These birds strut with outspread tail, in the manner of the turkeys; and are polygamous. The *ptarmigan* live in pairs, and do not strut in this manner; the more generally diffused species become white in winter; there is one species peculiar to Britain, however—the moor-fowl or red grouse—which does not change. Nearly all the grouse have the toes and legs more or less covered with soft feathers; a character which disappears in the *Perdrix*, an extensive group, scattered in nearly all parts of the Old World, but unknown in the New. In the *Quails*, we have the miniature resemblance of partridges, but the tail is so short as to be nearly imperceptible.

4. The family of COLUMBINÆ, containing a large number of elegant and lovely birds, appears as much isolated from the rest as the Parrots are from the Scansores. Although it is particularly numerous, and spread over every part of the world, there is no difficulty in distinguishing its members from all other birds. One of their chief peculiarities is the *double* dilatation of the crop, which expands on each side of the gullet; and the young are fed with grain disgorged from this receptacle by the parent, and impregnated with a secretion which it forms. These birds live invariably in pairs; they nestle in trees, or in the holes of rocks, and lay but few eggs, though they breed often. This family includes the whole of the well-known tribe of *Pigeons* and *Doves*. Some of the tropical species are of considerable size, and of very rich plumage.

The *passenger-pigeon* of North America breeds in such immense numbers, as to darken the air for a considerable period when the flock takes to flight, and to destroy all the herbage where they settle.

Order V.—Cursores.

This order contains a small number of species, differing so considerably from one another, that almost every one may be regarded as belonging to a different family, and yet all agreeing in one characteristic—the non-development of the wings, and the enormous size and power of their legs—by which they seem justly separated from all other orders of birds. They may be regarded as in many respects intermediate between the Rasores and Grallatores; but they also present many remarkable points of approximation to the Mammalia. The most obvious of these are the loss of the powers of flight, and the dependence on the legs alone for locomotion; and the deficiency (most conspicuous in the cassowary) of barbs upon the feathers, so that they much resemble hair. In their internal structure, moreover, similar approximations exist: thus the ostrich has the rudiment both of a diaphragm and urinary bladder, which organs are wanting in other birds, whilst all Mammalia possess them.

Although destitute of the powers of flight, wings exist in an undeveloped or rudimentary state; and it has been observed that, when the ostrich is running, its small anterior members execute analogous motions, which seem to assist it. Their muscles, however, requiring but little strength, the sternum has no prominent keel, but is flat, as in man; whilst, on the other hand, the muscles of the posterior extremities are of enormous size and power. Only five genera are at present known to exist in this order; and of one more, which seems now extinct, remains are preserved to us which indicate its existence two centuries since.

The *struthio*, or ostrich, is a well-known bird in the tropical parts of the eastern hemisphere; its feathers do not differ so widely from those of other birds as do those of the cassowary, being furnished with barbs; but these do not adhere to one another, so that no continuous resisting surface is formed. Still the wings present sufficient expanse to assist the bird in running; which movement it executes so swiftly that scarcely any animal can overtake it. The *rhea*, American ostrich, or nandou, is about half the size of the African ostrich, and more thinly covered with feathers. Two species exist, one inhabiting the central parts of South America, where it is as abundant in some localities as the ostrich in Africa; and the other in Patagonia, where it is rare. The nandou is easily tamed when young, and its flesh is eaten: it has been observed to swim with facility.

The *casuarius*, or cassowary, has wings shorter than those of the ostrich, and quite useless in aiding progression. Besides the peculiarity of the feather, which has been already mentioned as giving it the appearance of hair, there is another, consisting in the great development of the *accessory plume*, so that two or even three equal stems appear to grow from the same quill. In its general form and aspect it much resembles the ostrich, but differs in the structure of its digestive organs. The head is surmounted by a bony prominence, covered with horn. The skin of the head and neck is bare of feathers, and of a bright blue and flame colour; it is furnished with wattles, like those of the turkey-cock, which change colour under the same circumstances. It lives on fruit and eggs, but not on grain. It is an inhabitant of the Indian archipelago, and is the largest-bodied of birds, next to the ostrich.

The *dromaius*, or emu, is a native of New Holland, and is closely allied to the cassowary; but its plumage is more dense, from its feathers being more barbed.

The *apteryx* of New Zealand appears, of all birds, to have the wings reduced to the most simple rudiments; and it presents, at the same time, many points of approximation to the Mammalia. It has a complete diaphragm, and no air cells exist in its abdomen; nor are any of its bones hollow. The bill is long and slender; the rudiments of wings are terminated by a sharp hook, which seems to be an important organ of defence; the feet have three toes in front, and the rudiment of a fourth behind, the claw of which is alone externally visible. The size

The Apteryx.

of this bird is about that of a domestic fowl, and its colour a deep brown. It runs with rapidity, and defends itself vigorously with its feet. It is nocturnal in its time of action, and subsists on insects. Its native name is *kivi-kivi*, derived from its cry.

With this group is probably to be associated the *dodo*, now known to us only by some very imperfect remains, and by the paintings and descriptions of naturalists nearly two centuries since, when it seems to have existed in the islands on the eastern coast of Africa, especially Madagascar; though no traces of it can now be found there.

Order VI.—Grallatores.

The Grallatores, Waders or Stilt-birds, derive their name from their habits and conformation. Their long legs raise up their bodies as it were upon stilts; and, thus elevated, they frequent the banks of rivers and lakes, marshes, the shores of estuaries; and, whilst resting with their feet upon the land, derive their nourishment chiefly from the water—some feeding exclusively upon small fishes, aquatic molluscs, worms, small reptiles, and water insects—whilst others are of more terrestrial habits and food. Such as are more especially aquatic have a short web to their toes. Their wings are long, affording them the power of changing their habitation with the seasons, which most of them enjoy. During flight, they stretch out their long legs behind, to counterbalance their long necks; and the tail is always extremely short, its function as a rudder being transferred to the legs. They mostly construct or choose their nests upon the ground; and the young are enabled to run about as soon as hatched, except in those species which live in pairs. The Waders are remarkable for their power of preserving a motionless position upon one leg for a considerable time.

The Waders may be grouped together under four families, principally characterized by the form of the beak:—1. Ardeidæ, the *Heron* tribe, in which the beak is long, thick, and stout, and has usually cutting edges, as well as a point. 2. Scolopacidæ, the *Snipe* and *Woodcock* tribe, in which the bill is long, slender, and feeble. 3. Rallidæ, the *Rail* and *Coot* tribe, in which the bill is less slender; but the chief character is derived from the extreme length of the toes. 4. The Charadriadæ, or *Plover* tribe, in which the bill is of moderate size, and the back toe either entirely absent, or not long enough to reach the ground.

1. The family of Ardeidæ includes the Cranes and Storks, besides the true Herons. By the *Cranes* this order is connected with the last, for nearly all of them are large birds, with short powerless wings; their necks long and frequently naked, and their habits more terrestrial than those of any of their congeners. They feed almost exclusively upon vegetables: and have a muscular gizzard. Most of them live in warm latitudes; and those which frequent Europe migrate southwards in the autumn and return in the spring.

The *Herons* differ from the cranes in being decidedly carnivorous; they are known by a larger and more pointed bill, and by the greater length of their legs. Their stomach is a large undivided sac, but slightly muscular. As a whole, they are the most beautiful of all the Waders; not so much, however, on account of the colours of their plumage, as from the elegant crests and prolonged feathers which ornament nearly all the species. They build in societies, usually in trees in the neighbourhood of banks of rivers; but generally feed and live solitarily. They are chiefly supported by fish, for which they watch in some concealed situation, transfixing them as they pass, with their long and sharp bills. The *storks* are less aquatic in their habits than the rest of the family, nestling by preference on towers and chimney-stacks; each pair returning to the same place in the spring, after having passed the winter in Africa. The common white stork of Europe is held in much popular respect, owing to its utility in destroying snakes and other noxious animals; but in England, almost every one that shows itself is shot, whence the species is very uncommon.

2. The Scolopacidæ, or *Snipe* tribe, characterized by their long, slender, and feeble bill, which only enables them to bore in the mud in search of worms and small insects, have all nearly the same conformation, the same habits, and the same distribution of colours; so that it is difficult to distinguish among them. They are also remarkable for the delicacy of their legs, and the smallness of the hinder toe. They run with vast celerity, and

Stilt.

have considerable powers of flight; and they have also the faculty, in part, both of swimming and diving. The females are usually larger than the males, and lay their eggs on the ground, in little or no nest. Their geographic dispersion is as wide as their locomotive powers are great. The shores of every part of the world abound with *sandpipers* and *curlews*; whilst snipes, woodcocks, &c., frequent the inland waters and marshy grounds. The *stilts* surpass all the rest of this family, and probably therefore all other birds, in the length and slenderness of their legs.

3. The Rallidæ, or *Rail* tribe, are furnished with very long toes, for traversing aquatic herbage; and they are even useful in swimming, especially in some species in which their surface is extended by a border of membrane. They are also distinguished by the form of the body, which is very thin and narrow—a structure adapted to their habits and mode of life, since they live for the most part in the thick and tangled recesses of the reeds and aquatic vegetables which clothe the sides of rivers and morasses. Their wings are short, or of moderate length, and their flight feeble; but they run with considerable swiftness. They are for the most part solitary and timid birds, hiding themselves at the least approach of danger, but quitting their semi-aquatic retreats morning and evening, to feed in more open spots. The flesh of these birds is delicate; and, as they live chiefly upon aquatic seeds and vegetable aliment, they may be regarded as aquatic Gallinaceæ. By the peculiar form of their bodies, and their powers of running, they are able to make their way through dense masses of reeds and high grass, with so much facility, as to escape even after being desperately wounded. The females are mostly larger than the males, and exceed them also in brightness of colouring. The *rails*, *coots*, and *crakes*, are the chief British species of this family, and are sufficiently characteristic of it.

Flamingo.

Under the family Rallidæ has been classed a remark

able bird, the place of which is rather doubtful. This is the *flamingo*, which is perhaps rather to be considered as one of the duck tribe, with an inordinately long neck and legs. The front toes are webbed to their ends, and the hind toe is extremely short. The mandibles are suddenly bent downwards, about the middle of their length; and they are roughened at the edges, like those of the ducks, to which the fleshiness of the tongue also shows an alliance. They feed on mollusca, insects, the spawn of fishes, &c., which they seize by means of their long neck, turning the head downwards, to use to advantage the crook in the upper mandible. They construct their nests in marshy situations, placing themselves astride of them during the act of incubation, being incapacitated by the length of their legs from sitting on them in the usual manner.

4. The CHARADRIADÆ, or *Plover* tribe, are less aquatic than most of the other families. The legs are long, and the back toe is either quite absent, or so short as not to reach the ground. They live only on sandy and unsheltered shores, or on exposed commons, congregating in flocks, and running with great swiftness. The bill is usually of moderate strength, enabling these birds to penetrate the ground in search of worms, to obtain which they have the habit of patting with their feet, which causes the worms to rise. The species in which the bill is more feeble, frequent meadows and newly ploughed land, where this food can be obtained with greater ease; those which have stronger bills subsist additionally on grain, herbage, &c. Of the plovers several species exist in Britain; and others are distributed through most other countries. Some chiefly frequent the sea-coast, and others the upland moors. The *Lapwings* are nearly allied to the plovers, and, like them, are migratory, passing the winter in warm latitudes; they are peculiar to the eastern hemisphere. They are very noisy birds, screaming at every sound they hear, and defending themselves with courage against birds of prey. They derive their name from the stratagem by which they lure away intruders from their nests; they drop their wings in flight, appearing as if wounded, and thus induce their pursuers to follow them to a considerable distance.

Order VII.—Natatores.

The Swimmers are, of all the orders of birds, the most easily recognisable by the structure and position of their oar-like feet. This peculiarity, which occasions that awkwardness of gait on land which every one may observe in ducks and geese, is extremely favourable to those birds whose business "is in the great waters." The body is boat-shaped, and the neck is very long in proportion, for the purpose of reaching prey beneath the water when the bird is floating on the surface. The thick downy covering is rendered impervious to water by the abundant application of the oily secretion. The bones of these birds are not hollow, like those of the rest of the class, but are filled with an oily marrow. In this, and in other points, their structure approximates to that of reptiles. Their circulation is less energetic than that of the other orders, and is capable of being considerably retarded in diving birds, by the obstruction of the respiration, without injury.

As the water is the element on which these birds are formed to move, so does it also supply them with food. Some of them live on aquatic plants and submarine insects, but the greater proportion prey upon fish and those innumerable swimming and creeping things which subsist in the sea and cover its shores. In general, several females associate with one male, and the young are hatched in a condition which renders the co-operation of both parents for their support unnecessary, being able to take to the water and swim about in search of food, the instant they are liberated from the egg-coverings.

This order may be divided into five families—1. The ANATIDÆ, or *Duck* tribe; 2. The LARIDÆ, or *Gulls;* 3. The PELICANIDÆ, or *Pelicans;* 4. The COLYMBIDÆ, or *Divers;* 5. The ALCIDÆ, or *Penguins*. The three first are distinguished by the length of their wings, which enables them to fly well, while in the two latter these members are so short that they seem perfectly useless for any other purpose than that of fins.

1. The ANATIDÆ are distinguished by a thick bill, which is horny only at its extremity; the remainder of the mandibles being invested with a soft skin, which in other birds is found only at their hinder part. This skin in the ducks is extremely sensitive, and by it the animals take cognisance of the food contained in the mud, into which they plunge their bills. The edges of the bill are roughened, either by plates or small teeth arising from it; and the tongue is large and fleshy. These birds live more in fresh waters than in the sea; and many of them (such as geese and swans) are exclusively vegetable-feeders. The ducks, on the other hand, subsist in part upon animal diet; and one tribe of them, the mergansers, feed almost exclusively upon fish. Under the general designation of *ducks*, *geese*, and *swans*, all the birds of this family may be arranged; and as these typical forms are so well known, it is unnecessary to dwell longer on it, although the habits of many species are extremely interesting. This family is very extensively diffused over the earth's surface, and supplies man with an important amount of food, and with the greater part of the *down* which contributes so greatly to his comfort and luxury.

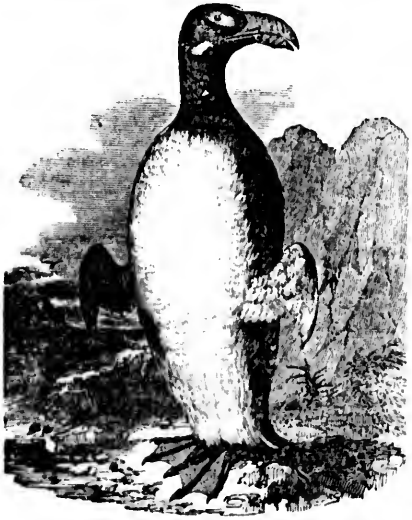
2. The LARIDÆ, or *Gull* tribe, more resemble the higher orders of birds in their general structure, but are deficient in that which constitutes the perfection of the order—the power of swimming and diving. The wings are very long, and their powers of flight considerable. The feet, although webbed, are so constructed as to enable them to walk with ease along the shore in search of food; the legs are slender, and sometimes so long as to resemble those of the waders; the hind toe is very small, and sometimes wanting. Many of the birds of this tribe have a tendency to associate in flocks. In consequence of their capability of protracted flight, they are met with at a greater distance from land than most others; many species are almost constantly on the wing, and brave the most violent storms. They seem to devour almost every description of animal and vegetable food. This family includes, with the *Gulls*, the *Skuas*, *Terns*, *Petrels*, and also the *Albatross*, which is the largest of all aquatic birds, and in its general habits may be described as a sort of marine vulture. It is extremely voracious, and devours almost any thing that falls in its way. Though its wings are powerful, its flight is by no means lofty. No species of it exists in the northern part of the Atlantic; but it is very abundant beyond the Tropic of Capricorn, and is one of the great enemies of the flying-fish.

3. The PELICANIDÆ, or *Pelican* tribe, are characterized by having the hind toe united to the rest by one continuous membrane: notwithstanding this conformation, which renders their feet perfect oars, they are almost the only Natatores which perch upon trees. All of them fly well, and have short legs. They are a large, voracious, and wandering tribe, living for the most part on the ocean, and seldom approaching land but at the season of incubation. The *Pelicans* themselves are remarkable for the length of the bill, which is armed with an abrupt hook at the end; the width of the gape is excessive; and the skin hanging from the lower jaw, and forming the throat, is so extensible as to dilate into a pouch capable of holding a large quantity of fish. The *Cormorants* are allied to these, and are remarkable for being not only voracious but docile, so that they have been trained for fishing, as hawks for fowling. These are very widely distributed over the earth's sur-

The Pelican.

face, while the pelicans are restricted to the warmer latitudes. The *Frigate-birds* are nearly allied to the Cormorants, but differ from them in the excessive spread of wing (which renders them the most powerful flyers in this order—perhaps not being surpassed by any other bird), and in the form of the tail and bill. They feed upon fish, especially flying-fish, both darting at it themselves, when near the surface, and obtaining it from other birds, whom they compel to drop their prey. The *Gannets* are allied to the frigate-birds; but the wings are less extended, and the powers of flight inferior. Some species are termed *Boobies*, from the stupidity they exhibit when attacked. A species about the size of a goose is very common in the British seas, and breeds especially on the Bass Rock, in the Firth of Forth. The Gannets take their prey by hovering in the air at some little distance above the surface, and then dropping down upon any fish that they may see rising within their reach. The air-cells are very largely developed, especially under the skin of the breast, which is almost completely separated by them from the muscles beneath; and it is probable that they may serve as an elastic cushion, to break the force with which the body of the bird would otherwise impinge on the water.

4. The Colymbidæ, or *Divers*, may perhaps be regarded as intermediate in structure between the Duck tribe and the next family. They are all marine birds,



The Great Auk

with a lengthened, strong, straight bill. The wings are in generally remarkably short; and the feet placed so far behind the point of equilibrium of the body, that they will not allow the birds to walk upon land even so well as ducks; but they can pursue the fishes upon which they feed, even beneath the water, with great swiftness. They are few in number, and are chiefly confined to the seas of northern regions.

The Little Auk.

5. The Alcidæ, or *Auk* tribe, exhibit the most remarkable adaptation of the structure of the bird to an aquatic life, with which the entire order presents us. This is best seen in the *Penguins*, whose wings are very small, and covered with mere vestiges of feathers, which resemble scales; so that they serve as admirable fins or paddles, but are totally useless for flight. The feet are placed very far back, so that when upon land the bird stands nearly erect. Having no power of flight, and not being able to run, the penguin may be overtaken with ease upon land; but once in the water, it distances its pursuers, swimming with the ease and rapidity of a fish, and springing several feet over any obstacle that may impede its course.

CLASS III.—REPTILES.

The class of Reptiles, which is the next to be considered, presents us with more diversity of form among its separate orders than any other division of the vertebrated sub-kingdom. Scarcely any animals are more unlike in external aspect than tortoises and serpents; yet we shall find that these extreme forms are connected with each other by a gradual series, and the internal differences are not so great as to prevent their association into one class, distinguished by characters which are common to all. These characters are—their low power of maintaining heat, or cold-bloodedness, arising from the imperfect aeration of their blood, of which only a portion is sent to the lungs at each impulse of the heart (see article Physiology); their oviparous reproduction; the respiration of air exclusively during the whole period of life, no metamorphosis taking place in this class; and the protection of the skin by hard scales or plates. By the first two they are distinguished from Mammalia and Birds, and by the others from Fishes and Amphibia.

The deficiency in the oxygenation of the blood, combined with the slowness and feebleness of the circulation, is connected with general inactivity of the nutritive functions, as well as with obtuseness of sensation and sluggishness of locomotion. It is a curious result of the feeble exercise of these functions, that, as in Amphibia, they may be suspended for a considerable time

without apparent injury to the animal; and that parts separated from the body retain for a long period much of that low degree of vitality which they usually exhibit in connection with it. Although at present Reptiles appear to perform a comparatively insignificant part in the economy of nature, especially in temperate climates, where their numbers are few and their powers feeble, we learn from the records of geology, that there was a period in the earth's history, long antecedent to the creation of Birds and Mammalia, when gigantic animals of this class not only constituted the chief tenants of the earth, but extended their dominion over the waters of the sea.

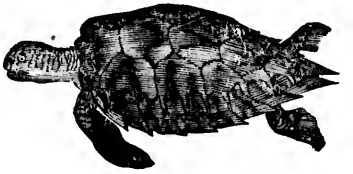
The three well-known forms, *Tortoises*, *Lizards*, and *Serpents*, may be taken as the types of three orders into which this class may be subdivided, namely, the Chelonia, Sauria, and Ophidia. But, in order to embrace some of the fossil species, which present us with other types of structure, it is desirable to create another order—the Enaliosauria—intermediate between the Turtles and Crocodiles; and this last tribe, though possessing the general form of lizards, so far differs from them in the covering of the body (which consists of large plates instead of scales) as well as in some points of internal organization, that a distinct order, Loricata, has been formed for it. These five orders may then stand thus:—1. Chelonia, including the *Turtles*, *Tortoises*, &c.; 2. Enaliosauria, to which the *Plesiosaurus*, *Ichthyosaurus*, and other fossil remains belong; 3. Loricata, comprehending the *Crocodiles*, *Alligators*, &c.; 4. Sauria, including the remainder of the *Lizard* tribes; 5. Ophidia, the *Serpents*.

Order I.—Chelonia.

The order Chelonia differs the most of any of these from the general form of the group. The shell in which the body is enclosed, and into which, in some species, the head, legs, and tail, can be completely withdrawn, would seem a perfectly new organ, to which nothing corresponding exists among vertebrated animals. And the fin-like extremities of the aquatic species remind us more of fish than of other reptiles. The shell, however, is composed of the usual bones of the skeleton, modified only in their form. The upper piece, termed the *carapace*, is usually more or less arched, and is composed of a bony expansion of the ribs, which are consolidated into a firm structure, adhering to each other along their edges, and are covered with horny plates, secreted from the skin like hair or nails. The lower plate, or *plastron*, is formed by a peculiar development of the sternum or breastbone, which, instead of being prolonged forwards into a keel, to give attachment to large muscles, as in birds, is extended laterally for the protection of the subjacent parts.

Most of the Chelonia are deficient in weapons of offence, being destitute of teeth, claws, or other sharp instruments. The jaws are covered with a horny substance, resembling that of the bills of birds; but their surfaces are usually rounded, so as to be more adapted to bruise than to bite. The shell, however, serves as a most effectual means of passive resistance. In the land species it is usually high-arched, and firmly united, so as to bear a very great weight without injury; and the feebleness of the power of motion in these animals is thus compensated. But in the aquatic species it is generally more flattened, so as to oppose less resistance to the water. Some of these have the power of swimming with considerable rapidity, and are altogether more active in their habits than the rest of the order. In these, the shell affords a much less complete protection to the body, and its parts are more loosely united, so that it possesses some degree of flexibility.

Among the families into which the Chelonia are subdivided, it will be convenient to notice first the Chelonidæ, or *Turtles*. These are distinguished by the incompleteness of their shelly covering, and by the peculiar modification of the feet for swimming. The ribs, by the union of which the carapace is formed, are separate from one another around its margin, and the pieces which compose the plastron do not form a continuous plate, but leave great intervals, which are occupied only by cartilage. All the feet are much elongated, particularly the anterior pair, and are flattened so as to serve for oars or paddles. The toes are seldom at all separated, the whole foot being enveloped in the same skin, closely set with hard plates. They live almost entirely at sea, feeding chiefly upon marine plants, and they only come to the shore to deposit their eggs. The œsophagus (gullet) of these animals is lined with long cartilaginous processes, all directed towards the stomach; these seem to have for their object the prevention of the return of the food, which is swallowed together with a large quantity of water; and, when the stomach afterwards ejects the superfluous fluid, these spikes prevent the food from being regurgitated with it.



Green Turtle.

The most important species of this group are the *chelone midas*, or green turtle, so much valued as an article of food; the *chelone imbricata*, or hawk's-billed turtle, the plates upon whose carapace furnish our tortoise-shell; and the *sphargis*, or leathery turtle, which has the shell covered by a thick leather-like skin. They are all chiefly found in warm latitudes.

The Emydæ, *Fresh-water Turtles*, or *Mud Tortoises*, are intermediate in form between the family just described and the Land-tortoises. The character by which they may be most constantly separated from the marine Turtles, is the distinctness of their toes, which are terminated by claws; but a web still exists between the toes, which assists them in swimming, and also prevents the feet from sinking into mud. Rivers, ponds, and running streams, are the haunts of these animals, of which one species is common in the south and east of Europe, and is fattened for food in Germany and Russia, where it is considered a delicacy. The food of the Emydæ consists of mollusca, aquatic insects, small fish, carrion and vegetables. The species at present existing seldom attain any great size, their shells varying from one and a half inch to a foot in length; many of the fossil species are much larger. In several of the Emydæ the carapace and the plastron are but loosely united; and the pieces of the latter are movable upon one another. This is the case in the *Terrapins*, or Box-tortoises, which are able to draw the head and limbs completely into the shell, and to close the latter by folding the anterior, and in some instances the posterior, division of the plastron against the carapace.

The family of Testudinidæ, or *Land-tortoises* is distinguished by the highly arched carapace, and, still more, by the short clubby feet, of the animals composing it. Their armour is harder and thicker in proportion to their size, and also more firmly united together, than that of the aquatic species. The neck and legs are short, and are capable of being drawn entirely within the shell; so that the whole structure of the animal is adapted for passive resistance. The feet, shaped very much like those of the elephant, are adapted for walking on firm ground only, as the surface they present is very small.

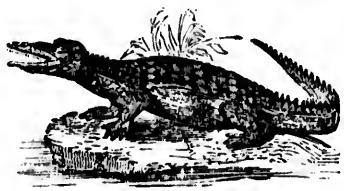
They are subdivided into toes, of which there are five on the fore feet and four on the hind; and these are furnished with short conical claws, well adapted for digging. These animals are of the most inoffensive character possible. They feed only upon roots and vegetables, and upon the worms and slugs that infest these; during the summer they live in woods or among herbage; and they pass the winter, in cold climates, beneath the earth, where they burrow and sleep. They are generally dispersed in all the warm and temperate latitudes; but they do not naturally extend to Great Britain, although individuals that have been introduced have lived to a great age in this country. The commonest species is the *Testudo Græca*, which is an inhabitant of most of the continent of Europe, as well as of many parts of Asia and Africa; it especially abounds near the shores of the Mediterranean. It seldom attains above a foot in length, or weighs more than three pounds. The flesh forms an article of food in Greece. In the East Indies are found species which attain to a much greater size. An individual in the possession of the Zoological Society of London, measures 4 feet 4½ inches along the curve of the back, the breadth of the shell being 2 feet 1 inch, and the weight of the whole animal 285 lbs.

Order II.—Enaliosauria.

The order Enaliosauria has been founded upon two extraordinary fossil genera, the *Ichthyosaurus* and the *Plesiosaurus*. Of these little else than the bones has been preserved to us; and it is therefore impossible to speak with certainty in regard to many parts of their organization. The character by which they are especially connected with the Chelonia is the flattening of the extremities into fin-like paddles, resembling those of turtles. They must have been, therefore, marine animals, endowed with scarcely any power of movement on land; but, although in many points analogous to fish, it is nearly certain that they breathed air like reptiles in general, and that they must have occasionally come to the surface to respire. Moreover, from the remains found in proximity with them, it may be surmised with probability that they fed upon marine animals alone, especially upon the various forms of Cephalopoda, which were particularly abundant at the epoch of their existence.

The general form of the *Ichthyosaurus* (or fish-lizard) appears to have been not unlike that of a crocodile, with the substitution of fins for feet. The head is lengthened into a narrow pointed muzzle, and the jaws armed with sharp and formidable teeth; and it had eyes of enormous size, which must have given it an extraordinary aspect, and probably enabled it to see by night. The skeleton of the commonest species (*I. tenuirostris*) usually measures 3½ feet in length; but portions of another kind have been found, which must have belonged to animals of above 20 feet. It is probable that the skin was destitute of scales, like that of the Amphibia; and, from recent inquiries, it appears that it possessed a sort of cartilaginous fin upon its back, like that of many Cetacea. This animal may thus be considered as presenting a very remarkable combination of the characters of other classes. Its remains, which are found in the lias and oolitic formations, are more abundant in England than in any other country in Europe.

The *Plesiosaurus* was distinguished by the extraordinary length of its neck, which, in the commonest species (*P. dolichodeirus*), occupies nearly half the entire length. The head is very small in proportion, and the tail is short, stout, and pointed. The cervical vertebræ exceed in number those of any other animal known; and in their conformation, have a good deal of resemblance to those of the body of a snake. It is the conjecture of Mr. Conybeare, by whom the first scientific investigation of the characters of this strange creature was made, that it breathed air and had frequent need of respiration, it generally swam upon or near the surface of the water, arching back its long neck, like the swan, and plunging it downwards at the fishes that passed within its reach. The greater length of its extremities would enable it to move on land with somewhat less difficulty than the Ichthyosaurus; and it might have very probably lurked in shallow water along the coast, where it could find shelter from its enemies, and a place of ambush from which to dart out its long neck upon its own prey. Its length seems generally to have been about ten feet.



Crocodile.

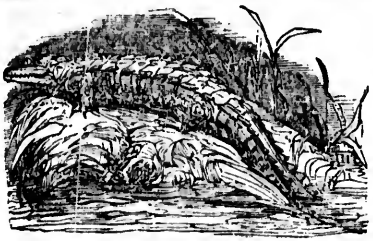
Order III.—Loricata.

The order Loricata, including the Crocodiles, Alligators, and Gavials, may be regarded as in many respects intermediate between the fresh-water Tortoises and the true Lizards. The body is enclosed in a sort of plate-armour, of which the separate portions are closely fitted together, and are capable of great resistance. Another character by which they are distinguished is the flattening of the foot, which is furnished with a kind of web between the toes, like that of the Emydæ: in the true lizards no such provision for aquatic habits is found. This order includes the most bulky reptiles at present known to exist. Some of them attain the length of thirty feet, and a circumference of seven or eight; so that, with the exception of the elephant, the rhinoceros, and the hippopotamus, there is no terrestrial animal exceeding these dimensions.

Although capable of moving on land, however, the greater number of them prefer the water, and show their chief activity in it. Besides the expansion of the foot, they are adapted for swimming by the lateral compression of the tail, which thus acts as a large and powerful fin. The crocodiles and their allies are all inhabitants of the rivers and fresh waters of warm climates; and they are all purely carnivorous. They destroy their prey by holding it beneath the surface of the water until it is drowned; the position of their nostrils, and the arrangement of the air-passages, being such that they are themselves enabled to breathe during the process. They cannot swallow under water, however, and their habit is to hide their prey in holes on the bank, until it has become putrid, and then to devour it at their leisure.

The conformation of the neck is such, that the head cannot be moved very far from side to side, though its play in the vertical direction is not limited. The animal finds it difficult, therefore, to turn itself round upon land; and thus a sure means of escape presents itself in those rare cases in which it leaves the water in pursuit of human prey. The tail, however, is very flexible from side to side, and is of great importance in propulsion. It also serves as an important weapon, for it is armed, like the back, with very strong upright plates, which form sharp ridges or crests in their centre; with this weapon the crocodiles can inflict terrific wounds upon their enemies. This group is entirely confined to the countries bordering on the equator. The animals which compose it may be considered in three subdivisions—the *Crocodiles*, chiefly inhabiting the Nile and other African rivers; the *Gavials*, found in the Ganges and other Asiatic rivers; and the *Caymans* or *Alligators*, confined to the New World.

The characteristic differences of these three divisions are best marked in the form of the head. The *Gavials*



Alligator.

have the muzzle exceedingly prolonged and narrow, somewhat resembling in form the beak of the spoonbill. In the true *Crocodiles* it gradually widens from the point towards the eyes; and in the *Caymans* the snout is much more rounded, and the head is broader in proportion to its length. These last appear less adapted to aquatic habits than the Crocodiles and Gavials, for the feet are not webbed to nearly the same extent as in the latter, and the ridge which increases the surface of their hind legs is wanting in the Alligators. With these exceptions, however, the general conformation of all, as well as their mode of life, is very similar.

Order IV.—Sauria.

The order Sauria comprehends all the animals commonly known as Lizards. They are intermediate between the Loricata and Serpents, for they have a lengthened body, terminating in a tail, like the former; but this, instead of being enclosed in large shields or plates, is covered with small scales, as in the latter. Moreover, they have usually four legs; but in some species one pair disappears, and in others they are all concealed beneath the skin, so that the body presents a snake-like aspect. In this group are found some of the most active, and certainly the most beautiful, of the Reptile class. Many of them are tinctured with the most brilliant colours, and as they are called into the greatest activity in the bright sunshine, nothing can surpass the splendour of their ever-changing hues. These colours bear an interesting relation to the habits of the animal, having a general resemblance to that of the places they frequent; thus tree-lizards are almost always of bright colours, in which green predominates; ground-lizards, brown, more or less speckled; and those which live in stony places are of a grayish hue.

The greater part of the Sauria are carnivorous, feeding upon other animals of inferior size and strength to themselves, and almost always preferring living prey. Many of them pursue nothing but insects; others lie in wait for small birds. The Iguanas, however, feed almost wholly upon vegetables. Many of them are possessed of very great agility upon land; some of them can ascend perpendicular walls, and even run along the ceiling with their backs downwards; none of them are inhabitants of the water, though a few occasionally resort to it. The activity of the smaller insectivorous lizards, when in pursuit of their food, is exceedingly curious and interesting. They watch with all the caution of a cat, and dart upon their prey with the quickness of lightning. Their movements are effected chiefly by means of their feet, and in the higher tribes exclusively so; but in those species in which the legs are short and the feet very small in proportion to the length of the body, progression is greatly assisted by the lateral motion of the trunk, which works its way along somewhat in the manner of that of the serpents.

The order Sauria may be subdivided into five families —1. The Lacertinidæ, characterized by the small head and thick neck, but particularly by the very long slender forked tongues of the animals composing it. This group includes the common lizards of this country, and most of the Saurians whose habits are peculiarly active. 2. The Iguanidæ, having the same general form, but short thick tongues. This group includes some of the largest of the Sauria, both recent and fossil. 3. The Geckotidæ, which are all nocturnal animals. These have not the attenuated form of the previous families, but are flattened, especially on the head. Their legs are short, and their movements comparatively tardy. Their colour is usually very sombre; and they are reputed, but without foundation, to be venomous. 4. The Chameleonidæ, whose tongue is of immense length, but obtuse at its point. The feet and tail are both peculiarly adapted for climbing; the former having two of the toes opposable to the rest, and the latter being round and prehensile. Their movements are very slow, except when the tongue is darted out to secure its insect prey. 5. The Scincoidæ, or Serpent-lizards, which are recognised by the shortness of the feet, the non-extensibility of the tongue, and the equality of the tile-like scales which cover the whole body and tail.

1. The Lacertinidæ are the most agile, most innocent, and most beautiful of the Saurians. Though they share, in common with the others, the dislike in which the animals of the class of reptiles are held by most persons, they never injure man, and are in some cases of considerable service to him. The larger ones live on the ground, usually preferring the shelter of underwood or of stones, and some frequenting marshy situations; whilst the smaller kinds resort to trees in search of their insect food, and, in the liveliness of their colours and the rapidity of their motions, bear no inconsiderable resemblance to birds. Two small species inhabit this country —the *lacerta agilis*, or sand-lizard, a beautiful little animal, which is sometimes of a brown and sometimes of a greenish hue; it is found on sandy heaths, and occasionally seen basking on the sunny sides of green banks. A more common one, however, is the *lacerta vivipara*, which inhabits most districts of England, and even extends into Scotland; it is also one of the few reptiles found in Ireland. It frequents heaths and banks, and may be seen on the watch for its insect prey, during the warm parts of the day, from the early spring until summer has far advanced. Its name is derived from a peculiarity which it shares with the viper—its eggs are retained and hatched within the body, so that the young are produced alive.

Some gigantic fossil bones have been discovered, which seem to be the remains of enormous Saurians, allied in structure to the Lacertidæ of the present time. From the proportional length of the head of one of these, which is nearly the sole part preserved, this lizard must have been at least seventy feet from head to tail.

2. The family of Iguanidæ approaches pretty closely to the true lizards in many of its general characters; but it contains several most extraordinary forms, widely differing from each other. The true Iguanas are confined to America; but some genera of this order are found over the greater part of the tropical zone.

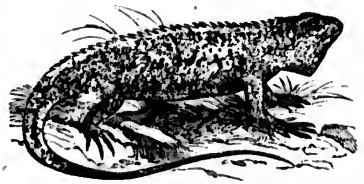
Flying Dragon.

Among these may be noticed the genus *Draco*, the animals included in which are distinguished at the first glance from all other saurians, by the possession of a pair of wing-like appendages to the sides of the body. These are formed by extensions of the skin, supported by the false ribs, which are greatly prolonged. They can be folded up or extended at the will of the animal, but they cannot be made to strike the air and to elevate the animal like a bird or bat. They serve rather as a kind of parachute, on which this little dragon, not many inches long, flutters from branch to branch in search of its insect prey; and also as a support to it when shooting, like the flying-squirrel, from tree to tree. These animals, the only living representatives of the fabulous dragons of the olden time, are found in the woods of tropical Africa and Asia, especially in the Indian archipelago.

This is perhaps the proper place to notice the very extraordinary fossil, to which the name *pterodactylus* has been given. In its general character it was certainly a lizard; but it seems to have been adapted to raise itself and fly in the air, like a bat or bird. The membrane of the wing was not extended, however, over the whole bony apparatus of the limb, but only one finger, which was enormously developed to support it. It is ranked by Cuvier among the most extraordinary of all the extinct animals that had come under his consideration; and the one which, if we saw them all restored to life, would appear most strange, and most unlike to any thing that exists in the present world. In the form of its head and the length of its neck, it resembled birds; but it had the bones and teeth of a lizard; its wings approached those of bats in form and proportion; and its body and tail resembled those of ordinary Mammalia.

In general external form, the pterodactyles probably most resembled a vampire bat; but in most of the species, the snout was elongated like that of a crocodile, and armed with conical teeth. Their eyes were of enormous size, apparently enabling them to fly by night. From their wings projected fingers, terminated by long hooks, like the curved claw on the thumb of the bat. These must have formed powerful members, with which the animals were enabled to climb, or creep, or suspend themselves from trees. With regard to their food, it has been conjectured that they preyed upon insects; and the number of fossil remains of insects in the strata in which they are found, proves that such a source of aliment was within their reach. The head and teeth of two species, however, are so much larger than would be required for the capture of insects, that they may have possibly fed on fishes (as there were at that epoch few or no small land animals), darting upon them from the air after the manner of many sea-birds.

From this account of the pterodactylus, it is evident that it is a most remarkable connecting link between the classes of birds and reptiles. That it is to be associated with the latter can scarcely be questioned; but if, as has been recently stated, the covering of the skin was more analogous to hairs or feathers than to scales, its affinity to birds must have been extremely strong.



Iguana.

The true Iguanas are confined to the New World, and frequently attain considerable size. They have a kind of spine or crest along the back, and a hanging pouch under the throat, which seems analogous to the dewlap of oxen; this pouch can be inflated, but under what circumstances is not exactly known. They have also in some degree that power of changing the hue of the skin, which is so remarkable in the chameleon. They are very agile, the legs being long in proportion to the body, and their food is almost exclusively vegetable. Some of them attain the length of five or six feet, of which the tail constitutes a large proportion. Their flesh is much esteemed as food; and, in the countries where they abound, they are sought for with this object. They are extremely tenacious of life. When attacked, they assume a formidable, though not a dangerous, aspect. They open their mouths, vibrate their tongues with rapid motion, inflate their throats, and erect their crests, while their eyes glance with great brilliancy. All this, however, is a demonstration for defence and not for attack. They are never known to combat with any animals but those of very small size.

Some gigantic fossil remains, allied in conformation to the Iguana, indicate the former existence of animals of similar character, which attained enormous bulk. The chief of these was the *iguanodon*, of whose bones fragments have been found in Tilgate Forest. The teeth are so precisely similar to those of the iguana in the principles of their construction, as to leave no doubt of the near connection of this gigantic saurian, which must have probably attained a length of at least seventy feet, with the herbivorous lizards of our own time. The examination of these teeth discloses some remarkable mechanical contrivances, adapting them to the function of cropping tough vegetable food, such as that afforded by the plants found imbedded with it.

The third family, the GECKOTIDÆ, consists of a large number of animals bearing a strong resemblance to each other in general characters. They are all nocturnal, and pass the day in obscure places; their eyes are large, and their pupil contracts under the influence of light, like that of cats, into a very small aperture. Their flattened form and broad head give to them a very striking and peculiarly disagreeable appearance, which is aided by their sombre and somewhat toad-like hue; hence, although timid and harmless, they are always regarded by the vulgar as having a venomous character, but without the least foundation in truth. Most of them possess claws at the extremities of the toes, and these are capable of being retracted like those of the Felinæ. They appear more useful to their possessor in climbing, however, than in securing their prey, which consists principally of insects. The Geckos are found in most warm countries in both hemispheres. They frequent buildings; and some species have a peculiar organization of the feet, by which they can climb smooth perpendicular walls, or even run beneath ceilings. They are often useful in clearing houses of musquitoes and spiders; but it is said that articles of food over which they have passed acquire poisonous properties, in consequence of an acrid exudation from the feet. It is difficult to know how much credit to give to such statements; equally positive ones, which are entirely destitute of foundation in fact, being circulated in this country in regard to the toad.

The CHAMELEONIDÆ, or *Chameleon* tribe, are few in number; but they present so many anomalies of organization, that it is necessary to separate them from all the other saurians, and to rank them as a distinct family. They are characterized, in the first place, by the structure of the feet, which are adapted for climbing, like those of the scansorial birds (such as the parrot), having two of the toes opposed to the other three. The tongue also affords a remarkable character; it is fleshy, and capable of enormous elongation; the extremity is thickened or club-shaped, and is furnished with a viscous secretion at its extremity. It is by this organ that the

chameleon entraps its insect food; for, by suddenly darting out the tongue, the insect is glued, as it were, to the end, and instantaneously conveyed to the mouth. This is the only part of the body that moves quickly; the

Chameleon.

limbs are often quite motionless for hours. When the chameleon walks, it advances with the greatest circumspection, and there seems a want of power to combine the actions of the different members. But when once attached to a branch or twig by the grasping of its feet, it seems to have little disposition to quit its hold.

The peculiar conformation of the eyes of the chameleon adds much to the general singularity of its aspect. They are large and prominent, but so much covered by the scaly skin of the orbits, that there only appears a small hole in the middle opposite the pupil. It is no uncommon thing to see the animal directing its eyes in two different ways at once; one eye looking forwards, for example, the other backwards, sideways, or upwards. This power must be very useful in compensating for the fixity of the body itself, so as to give information of the proximity of food in any direction. The powers of abstinence possessed by this singular race are very great, and hence most probably arose the fable of their living on air. They do not appear inclined to take food in confinement; and have yet been seen to shrink but little during many weeks of almost entire abstinence.

The chameleon has been most remarkable, however, for its power of changing colour, which was known to the ancients, and is commonly supposed to be peculiar to it; but, as already stated, other animals possess it in a greater or less degree. Much exaggeration has prevailed, as might be expected, in the descriptions of this phenomenon. All the colours of the rainbow, as well as white and black, have been represented to be assumed by it. Its natural hue, when at rest and in the shade, seems to be a bluish gray; from this it easily changes to a brownish gray or into a green. Sometimes the colour fades to a pale gray, and sometimes it deepens to a dark brown; but these are the extremes. The phenomenon has been variously accounted for. Of late, it has been generally supposed that the hue of the skin depends upon the degree in which the colour of the blood is combined with that peculiar to the membrane; and that it is altered by a change in the quantity of blood sent to the surface, which is increased by the distension of the lungs occasionally practised by this animal. But the recent inquiries of Milne-Edwards have shown that this is only a partial cause; and that the change is principally owing to an alteration in the relative position of two layers of colouring matter which the skin contains, so that they may be displayed singly or in various degrees of combination.

The last family of the Saurian Reptiles—the Scincidæ, or *Skink* tribe, conducts us so gradually towards the Serpents, that it is difficult to know where to draw the line of demarcation between them. They are recognised by the shortness of the feet, the roundness of the body, and the equality of the tile-like scales over the whole surface: their tongue is not capable of extension. They have all more or less of a snake-like form; and in some of them only two feet are developed. The true *scincus* probably approaches to the general saurian type more closely than the rest of the group. It is furnished with four short but strong feet, and runs with considerable agility. The *seps* has a more serpent-like body than the skink, and the feet are smaller and wider apart. These gradually become simpler in structure in various species; the number of toes being reduced, until the feet seem like simple hooks protruded from the body. The *chalcis* is another snake-bodied, small-legged saurian, which, in some peculiarities of its conformation, approaches a different group of serpents. In the *bipes*, the anterior pair of feet is not developed; and in the *chirotes*, the posterior pair is wanting. In both these, the general conformation of the body, and the habits, so far as known, correspond with those of the common blindworm, which is ranked among the Ophidia.

Order V.—Ophidia.

The animals composing this order are at once distinguished, not only from all other Reptiles, but from all other Vertebrata (except certain fishes of the *eel* kind), by the entire absence of members or appendages for locomotion. Although no trace of these is ever perceptible externally, there are some species bordering upon the saurians, in which rudimentary legs can be detected; and these approximate, therefore, towards the lizards in their own tribe, just as the two-legged, long-tailed lizards approach the serpents in theirs. Although apparently so different from other reptiles, Serpents are to be distinguished from lizards by little but the absence of extremities; since, in the possession of teeth, and in the scaly covering of their bodies, as well as in their general interior organization, they closely correspond with them. The elongated form of their bodies reminds us of the Worm tribe among the Articulata, which they may be regarded as representing among the Vertebrata, just as the class of birds represents that of insects; and they correspond with them in another very curious particular—the periodical exuviation of their skin. All serpents pass the coldest part of the year in a state of torpidity; and it is on emerging from this that they slough or cast their skin. This is first detached round the head, and is gradually pushed off by the animal, being turned inside out like the finger of a glove.

The progression of serpents on the surface of the land is accomplished in two ways; sometimes the whole body creeps along the ground, the scales on its under side serving (like the minute bristles of the earth-worm) as so many points of resistance to a backward movement, when the trunk is elongated, after being contracted; and sometimes it is bent upwards into a series of arches, by which the tail is brought near the head; and when these are straightened, the head is thereby projected forwards. In crawling along the ground, they are much assisted by the points of the ribs, which do not meet again in a sternum, but bear upon the ground, and serve as so many short feet, having a certain power of movement in themselves by means of the intercostal muscles. Most serpents can swim when placed in the water; and there is one group which is pre-eminently aquatic, and is distinguished by its vertically-flattened tail. So closely do the members of this group resemble certain species of the eel tribe, that it is not always easy to determine to which a specimen belongs, until its respiratory organs have been examined. The great flexibility of the body is partly due to the very large number of vertebræ (from 200 to 300) composing the spinal column, each of which is united to those before and behind it by a very beautiful ball-and-socket joint. A large group of serpents is distinguished by the possession of venomous teeth, or *poison fangs*, in addition to the ordinary teeth. These are sharp, long, and tubular; they are connected at their roots with a gland by which the poison is secreted; and

this is instilled into the wound through the tube in the tooth.

As in the case of other reptiles, we find that serpents only attain their full development in warm climates, having very little proper heat of their own. The species inhabiting the temperate zone are not nearly so remarkable, either for size, brilliancy of colour, or poisonous properties, as those which exist between the tropics. The order may be divided into five families. 1. The COLUBERIDÆ, consisting of the *Boas*, *Pythons*, *Colubers*, and other non-venomous snakes not belonging to the subsequent orders. 2. The CROTALIDÆ, containing the *Rattlesnake*, *Viper*, and all the venomous species. 3. The HYDROPHIDÆ, or *Water-Snakes*. 4. The AMPHISBÆNIDÆ, or *Double-walkers*. 5. The ANGUINIDÆ, or *Slow-worms*. These last approximate the Lizards, in the possession of rudimentary legs under the skin, as well as in other points of their organization.

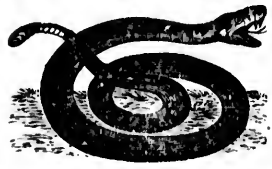
The COLUBERIDÆ are particularly distinguished by the power of dilating the opening of the jaws to an enormous extent, so as to permit of animals being swallowed which are much larger than the diameter of the serpent itself. This is accomplished by the separation of the jaw-bones into various pieces, which are very movable on one another and on the skull. The most remarkable species of this family, which is the most numerous of the order, are the *Boa Constrictors** of the New World and the *Pythons* of the Old; these, when full grown, attain the length of from thirty to forty feet, and

Boa Constrictor.

in thickness nearly equal a man's body. They do not fear to attack any animal; and, if they can once coil themselves round it, crush it by the enormous combined power of their muscles, in spite of all its means of resistance and defence. Their power is much increased by coiling the tail round a tree, so as to give a point of support from which the muscles may act more efficiently; and it is in this manner that they commonly wait for their prey. When they have seized and entirely destroyed it by crushing, in which process all the principal bones are broken, they begin to swallow it. This process lasts some time; and when it is complete, the position of the mass in the alimentary tube is at once known by the external protuberance. The process of digestion takes some days or even weeks for its performance, according to the size of the prey; and during that time the monster lies in a very inactive state, only issuing forth to seek a new victim when the digestion of the last has been for some time finished. The hair, horns, and other least digestible parts, are usually disgorged during the process. The Boas are distinguished from other serpents by the presence of two projecting bones near the vent, which are called *claspers*, and which may be regarded as the rudiments of posterior extremities.

* The name *Boa Constrictor* is commonly applied to the immense serpents of the East Indies; but only those of the western hemisphere possess the characters which the naturalist now assigns to the genus Boa.

The *Colubers*, strictly so called, are usually of comparatively small size; but their habits are the same in proportion. The common snake of England attacks small quadrupeds, frogs, birds, &c., in precisely the same manner that the boa seizes its larger victims. It is fond of marshy situations, and takes to the water readily, inflating its lungs so as to render itself buoyant. The flexibility of body, which is their means of obtaining support, is greater in the non-venomous serpents than in the Crotalidæ, which have another mode of procuring it. This is shown by suspending a coluber by its tail; it can bend its body so as to bring its head to the point at which it is held; this the venomous serpents cannot do. All the smaller species of this family are perfectly harmless to man, and may be handled without fear. Many of them are remarkable for the brilliancy of their colours, and others for the extreme regularity of their markings.



Rattlesnake.

The CROTALIDÆ, or *Venomous Serpents*, do not differ much in external characters from the preceding family; but the character of their teeth is quite sufficient to distinguish them. The poisonous properties of the different species vary considerably; in general they are more severe in the serpents of warm climates than in those of temperate regions. Cases of death from the bite of the British viper are very rare, and are generally to be attributed in part to some previously existing derangement of the system. There are many serpents in the torrid zone, however, whose bite is fatal to man and other large animals in a few hours, and to small animals much sooner.

European Viper.

This family contains two principal series—the *Rattlesnakes* and the *Vipers*. The former are generally regarded, but probably incorrectly, as the most venomous of all serpents. The rattle at the end of the tail, which is their distinguishing characteristic, is formed of several separate pieces of a dry horny substance, one of which is received within another. They are quite loose, and receive no nourishment after they are once formed. A new piece is said to be added every time the skin is cast, which usually takes place twice a year. The sound made by the rattle is not great in the ordinary motion of the serpent, and cannot be heard at more than two or three yards' distance. Several species of *Crotalus* are described, varying in length from four to eight feet. They are all natives of America. Their ordinary food consists of birds, squirrels, and other small animals. It was once supposed that they possessed the power of charming or fascinating these animals, so as to draw them by degrees to enter their throats. This is certainly an error; but it is equally certain that most animals are so terrified at the sight of the rattlesnake as to lose the power of escape and to become an easy prey when it darts upon them.

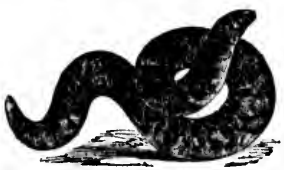
The *Vipers*, being destitute of the peculiar characteristic of the Rattlesnakes, are more like the Colubridæ their forms, however, are less elegant, their colours less

splendid, and their movements less active. In general, they are remarkable for the dark lurid tints of their covering. The most celebrated species of this group is the

Horned Viper.

cobra di capello or *spectacle-snake* of the East Indies. Its first name, given to it by the Portuguese, signifies hooded snake, and is derived from the power of dilating the skin behind the head, when irritated, so as to give the appearance of a hood or cowl. The common English appellation is bestowed in consequence of a mark, in the shape of a pair of spectacles, behind its head. This is one of the most deadly serpents of the East. An equally, if not still more, venomous snake, however, exists in some of the West Indian islands. The bite of the venomous serpents varies in its consequences according to the state of health of the bitten subject, the depth and number of the wounds, the time which has elapsed since the animal last made use of its fangs, and consequently the amount of poison which has penetrated into the system.

The HYDROPHIDÆ, or *Water-Serpents*, are comparatively few, and are limited in their geographical range. They are mostly found in the seas and rivers of the East Indies, and in some localities they are by no means uncommon. They are chiefly known by the very decided vertical compression of the tail and hinder part of the body, which may thus be compared to the tails of fishes; hence they swim with considerable facility, occasionally coming to the surface to respire. They possess poison-fangs, and are more dangerous than crocodiles or sharks to persons entering the water where they abound. One species exists in the rivers and canals of India, and attacks animals which come to bathe or drink, as well as devotees while performing their ablutions; others are confined to the sea, where they feed upon fish. It is stated that they will occasionally make their way into boats. Their colours are generally bright.



The Amphisbæna.

The AMPHISBÆNIDÆ, or *Double-Walkers*, are a still smaller group, intermediate in some respects between the true serpents and the slow-worms. They derive their name from the power of moving either backwards or forwards with equal facility. The two extremities of the body are so much alike, that they would not be distinguished by a superficial observer, the eyes being so very small as sometimes to appear wanting; the whole body is of nearly equal diameter. This group is restricted to the warmest parts of South America. Notwithstanding the common idea of its venomous properties, it is quite harmless, and subsists on ants and other small insects. It has not the power of separating the bones of the jaws, which distinguishes the true serpents.

The ANGUINIDÆ may almost be called either lizards or serpents, so remarkably do they combine the characters of the two orders. In one species the rudiments of hind legs form a visible projection near the vent; and in another the anterior ribs are connected by a cartilage, which is the rudiment of a sternum. The common *slow-worm* or *blind-worm* of this country has received its second name from the supposed absence of eyes; this is an absurd error, however, as the eyes, though small, are very brilliant. It is a perfectly harmless animal, feeding on insects, slugs, &c. It is said to swallow frogs, birds, and mice; but this is impos as the bones of its jaw do not separate in the middle, d its swallow is consequently small and not dilatable. When alarmed, it throws the whole of its muscles into contraction in a peculiar manner, and is then very brittle, so that it frequently loses its tail by various accidents; in the course of a year, however, this member is replaced. There is a larger species of this family existing in America, which attains the length of two feet, and from its extreme fragility is called the *glass-serpent*.

The Serpents are connected with the Amphibia by the curious genus *Cæcilia*, or naked serpent, which will be described as a member of that class.

CLASS IV.—AMPHIBIA.

The animals composing the class Amphibia were included by Cuvier and many other zoologists under the general designation of Reptiles. There seems, however, sufficient reason for separating them into a distinct group of equal rank. They may be regarded as intermediate in their structure, and in their habits and mode of life, as well as in many of their forms, between Fishes and true Reptiles; and they bear a still more remarkable relation to these classes, in that change which many of them undergo at a certain period of life, by which they become transformed from the nature and habits of the former to those of the latter class, by a metamorphosis analogous to that of insects.

The class we are now considering offers us the only instances of animals possessing two sets of respiratory organs, one adapted to breathe air and the other to aerate the blood by exposing it to water. In most of the species composing it, lungs and gills do not exist at the same time, at least in a state of activity; the latter gradually disappearing as the former are developed. But in a few species the gills are retained during the whole of life, even after the lungs are capable of aerating the blood. These are, then, the only true amphibious animals; but the term AMPHIBIA may be very properly applied to all such as undergo this kind of metamorphosis, breathing by gills alone at the commencement of life, and afterwards acquiring lungs by which air can be respired.

The general peculiarities of the Amphibia may be thus stated:—Like fishes and reptiles, between which they are intermediate, they are oviparous and cold-blooded, but their skin is soft and naked, being destitute of scales or plates. Most of them undergo a metamorphosis which has reference to a change of condition, from the form of a water-breathing fish to an air-breathing reptile; and, when they have attained their perfect condition, they closely resemble true reptiles in general character. In many species, however, little change is seen from the time that the animal emerges from the egg to its adult age. With the exception of the frogs, they have much the form of lizards (among which several of them were formerly classed), and have generally four feet and a lengthened tail.

The class, which contains but a small number of different genera, may be best subdivided into orders chiefly according to the degree to which the metamorphosis proceeds. Thus, in the first, ANOURA, embracing the *Frogs* and *Toads*, the gills are entirely lost in the

fect state, and the tail also disappears. In the Urodela, including the *Salamanders*, *Water-Newts*, &c., the gills disappear in the perfect state, but the tail is retained. The Amphipneusta, to which the *Proteus* and *Siren* belong, retain their gills during the whole of life; the tail continues to form a large part of the body, and in some instances only two legs are developed. In the Abranchia, an order which consists only of two little-known genera, no gills have been found at any period of life, but the body and tail are evidently formed for swimming. And in the Acoua, including only one genus, the *Cæcilia*, the body is altogether destitute of feet, and has a serpent-like form.

Order I.—Anoura.

The principal subdivisions of the first order are the Ranidæ, or *Frog* tribe, and the Bufoidæ, or *Toad* tribe. The former frequent water, and are adapted for swimming in it; the latter are usually found at a distance from water, and are much less adapted for active movements of any kind. The metamorphosis of both these is attended with the same general phenomena; and as the animals themselves are so well known, a description of this process will be a sufficient account of those which inhabit Britain. It is one very easily observed, for, by obtaining a little water containing young tadpoles, the whole process may be made to go on under our eyes, and the young naturalist is earnestly recommended to watch it for himself.

The spawn, soon after its deposition in pools, consists of a transparent gelatinous mass, enveloping a number of little black dots, which are regularly distributed through it, and which are the eggs. Those are abundantly found in stagnant pools in the month of April, being usually deposited (in this country) at the end of March, and hatched about a month afterwards. When the tadpole first emerges, it is seen to present, in every respect, the appearance of a fish. It has a large oval head, and an elongated tail, flattened vertically, by the vibrations of which it swims actively through the water. The gills are found hanging in tufts on each side of the head; and, if examined with a microscope, the motion of the blood through them may be very beautifully seen. The circulation may be observed, also, with great facility, in the fin-like expansion on the upper and under edge of the tail. Very soon, however, the gills are withdrawn, as it were, into the head, being covered over by a fold of skin, analogous to the operculum, or gill-plate of fishes. The little creature, which at first seemed to derive its subsistence from the fluid absorbed within the body and on its surface, now seeks its food amidst softened or decomposing vegetable matter; and, to give greater power of movement, the surface of the tail is considerably increased.

The tadpole now undergoes but little change in its external form for a considerable time, but increases rapidly in bulk. The first appearance of limbs is seen in a little tubercle or knob which projects at the back of the head: this is the rudiment of the hind leg. It soon acquires somewhat the form of the perfect limb, the toes budding, as it were, at the extremity; but it still continues very short, even in proportion to the diminutive size of the animal. Meanwhile, the fore legs are also budding out in the same manner, and gradually assume their distinct and ultimate form. During this process, the development of the body goes on at the expense of the tail, which is gradually removed by absorption, so that the hinder part of the body becomes rounded. The gills disappear by a similar process.

The little animal has now undergone its complete development, and having, at the same time, become capable of respiring air by true lungs, and of moving freely on land by means of its hinder legs, it comes to the shore to feed on small insects and worms,

Frog.

which are henceforward to constitute its nutriment. Such multitudes of these newly perfected little beings are often found in damp weather enjoying their new scene of existence, as to have given rise to many stories of showers of frogs having descended from the sky, which are still believed in some parts of the country. They now grow with great rapidity during the remainder of the year; but on the approach of winter they retire to the mud at the bottom of the water, where they congregate in large masses, remaining torpid until the return of spring.

The Bufoidæ, or *Toads*, are a perfectly harmless and inoffensive race, although certainly not inviting in their general aspect. The idea of their venomous character is altogether unfounded. The body is of a dull hue, its shape awkward, and its movements appear difficult, but it is by no means deserving of that disgust which it has inspired in some naturalists as well as in the popular mind. Unpossessed of any power of active defence, or of rapid escape from its enemies, the dullness of its colour serves to shield it from observation. Its eye bears a remarkable expression of mildness and patient endurance, rather fitted to excite pity and compassion than disgust or repugnance. It issues forth from its concealment at twilight in search of food; and this consists of insects, worms, slugs, &c., the inordinate increase of which it is very useful in repressing. It seems to prefer that which is actually alive and in motion. When about to feed, it remains motionless, with its eyes turned directly forwards upon the object, and the head inclined towards it; and in this attitude it remains until the animal moves, when, by a stroke like lightning, the tongue is thrown forward upon the victim, which is instantly drawn into the mouth. So rapid is this movement, that it requires some little practice, as well as close observation, to distinguish the different motions of the tongue. This organ is folded back upon itself, as in the frog; and the under surface of the tip is imbued with a viscid mucous secretion, which adheres to the prey. This is generally swallowed alive; and its motion within the stomach may often be perceived for some time afterwards.

The toad, like the rest of the Amphibia, becomes torpid in winter; but, instead of returning to the water, like the frog, it chooses for its retreat some retired and sheltered hole, or a space among large stones. Like the other Amphibia, too, it is endowed with great tenacity of life, and can exist for a very long time deprived of food and almost of air. The knowledge of this fact has occasioned a disposition to give too ready credence to the various wonderful accounts which have been circulated, at different times, of toads being found alive, completely enclosed in solid rock or in the heart of trees. It is not at all unlikely that a toad which has retired to a hollow in a tree in the autumn, may find itself so far enclosed in the spring as to be unable to escape; and that, through the opening, it may obtain the requisite supply of air, and even of food. In process of time new wood may be deposited around it, so that the cavity shall be completely moulded upon its body; and the opening will be gradually diminished. Still, a very small aperture will be sufficient to admit air, moisture, and minute insects, by which it may be supported for many years, being a long-lived animal; and in none of the cases on record does there seem to have been such a minute examination of the cavity as to disprove the idea that a connection with the external air still existed. In a similar manner it is fair to explain most of the accounts of toads found in stones, &c.

Order II.—Urodela.

The animals of the order Urodela bear so strong a general resemblance to lizards, that they were united with that group by Linnæus, and are still popularly regarded as such. The *Salamanders* and their allies, however, are easily distinguished by the smoothness and softness of their skin, which is entirely destitute of those scales which all lizards possess. Moreover, they undergo a metamorphosis similar to that of the frogs, except that the change of form does not proceed to the same extent. Like the Anoura, this order may be subdivided into two families, of which one, that of the TRITONS, is of aquatic habits even in the adult state, like the frogs; while the other, that of the true SALAMANDERS, bears more analogy with the toads in its aspect and habits.

Of the TRITONS several species exist in this country, and are known under the names of *Evat*, *Eft*, *Newt*, &c. The largest is about six inches in length: it is not at all uncommon in ponds and large ditches, where it lives upon aquatic insects and other small living animals: it even devours the smaller species of newt. The eggs are laid in the spring, upon aquatic leaves, which are folded together by the animal; and the young tadpole, when it comes forth, bears considerable resemblance to [illegible] of the frog. The gills, however, are in larger tufts, and they afford a most advantageous opportunity for observing the circulation. The anterior legs are the first developed; and even after they have arrived at nearly their full growth, the gills are very large, and actively performing their functions. The lungs are, however, gradually developed; and, towards the end of autumn, the gills are absorbed, and the animal breathes air only. Still it does not quit the water, but remains an inhabitant of that element, coming occasionally to the surface to breathe.

The *Salamander* is a land animal, of the same general character with the water-newt, but possessing a rounded instead of a flattened tail, and a surface somewhat warty, like that of the toad. It discharges, when alarmed, an acrid secretion from the tubercles in the skin, which is said to be poisonous to small animals. In other respects it is quite harmless, and is not possessed of any remarkable properties. The eggs of the salamander are hatched within the body, so that the young are produced alive, and the progress of the metamorphosis has been considerable before it sees the light. Nevertheless, it at first inhabits the water, and, when it has finally quitted it, frequents damp in preference to dry situations. No species exists in Britain, but the salamanders are pretty extensively diffused over other parts of the globe.

Order III.—Amphipneurta.

The animals belonging to the order Amphipneurta exactly resemble salamanders, the development of which has been checked just at the period of their transformation from aquatic to air-breathing animals. They retain their gills during their whole life, and acquire lungs in addition, by the partial metamorphosis they undergo. The legs bear but a very small proportion in their degree of development to the tail; and in some instances only one pair is formed. The first-discovered animal of this order was the *proteus*, an inhabitant of the underground lakes of Carniola and Styria, and of the passages between them. So strongly does this resemble the larva of a salamander, that it was at first believed by naturalists to be such; and it was only after the discovery of others of the same character, that its true nature was understood. Unlike most other animals, it appears to suffer injuriously from light; for not only does it prefer dark places, but even dies if it be exposed to open day for any length of time without the power of hiding itself. The siren is an animal of similar character, inhabiting the North American rivers, where it feeds upon earth-worms, aquatic insects, &c., in search of which it burrows in the mud. Only the anterior pair of feet is developed, and there is no rudiment of the other. The body has very much the form of that of the eel; and sometimes it attains the length of three feet.

Order IV.—Abranchia.

The order Abranchia contains only two genera, and these both peculiar to North America, the *menopoma* and the *amphiuma*. They are not known to undergo any metamorphosis, but breathe by lungs during the whole period of life, and have never been seen destitute of legs. These are, however, very short, and seem almost useless appendages to the body, which is shaped like that of an eel. It is not improbable that, as in the salamander, the egg may be hatched within the body of the parent, and that the young may not come forth until it has passed through its tadpole state.

Order V.—Apoda.

The order Apoda contains but one genus, the *Cæcilia*, blind-newt, or naked serpent. This was placed by Cuvier among the Serpents, from the snake-like form of the body, which is destitute of any rudiment of legs. But, in the absence of scales on the skin, as well as many anatomical characters, it rather corresponds with the Amphibia, forming, however, a most interesting transition to the next class. It is not known to undergo any metamorphosis. Its name was conferred by Linnæus on account of its supposed blindness. The eyes are exceedingly small, and are nearly hidden under the skin, and it is believed that, in some species, these organs are altogether wanting. These animals frequent the rivers and marshy grounds of many tropical countries: further information in regard to them is much needed. They are said to burrow in the ground, and to live very much in the manner of earth-worms. As far as is known, they are perfectly harmless.

From this sketch of the class AMPHIBIA, it will be seen that, in a scientific point of view, it is one of the most interesting in the whole animal kingdom. Though of little direct benefit to man, it is certainly as harmless as any tribe. And thus, although the forms of many of the species offend against our notions of beauty, and their love-songs give them the character of "horrible musicians," the aversion and prejudice with which they are ordinarily regarded would be justly replaced by the pleasure of intelligent curiosity.

CLASS V.—FISHES.

The animals of this class are the only Vertebrata which, in their adult state, are formed for respiring beneath the surface of the water they inhabit. The whale tribe, which so much resemble them in external aspect and in mode of life, are all air-breathing animals, and they are as certainly drowned by being prevented from taking in air at the surface, as are any species which ordinarily live on land, though, by their peculiar conformation, they are enabled to sustain the want of it for a longer time. The same is true of frogs, salamanders, and other reptiles, which pass a large part of their time under water. But with fishes, the reverse is the case. In these, as in the Mollusca, the blood receives its necessary purification by being exposed to the air contained in the surrounding fluid. This is done by its transmission to a series of delicate filaments, constituting the *gills*, each of which consists of two minute blood-vessels (one to convey the blood from the heart and the other to return it) enclosed in a delicate membrane, through which the chemical changes between the blood and the air take place. But these filaments do not hang loosely in the water, as in the greater part of the Mollusca. They are attached to bony or cartilaginous arches, which are arranged in pairs behind the head, and are more or less

protected by a special covering; and there is a provision which ensures a proper change of the fluid in contact with them. The cavity in which they lie is connected with that of the mouth, and water is constantly taken in by that opening, and forced by muscular action over the surface of the branchiæ or gills, passing off through the apertures which are seen behind the head.

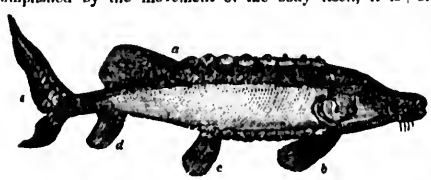
The quantity of air contained in water is very minute, and if the fish have need of a larger supply, it takes it in at the surface from the atmosphere. This is often seen in the summer, when the increased temperature renders the organic functions more active, and occasions a greater demand for air. It may also be seen when the quantity of water is limited, so that all the air is soon exhausted from it. Fishes that are kept in such water, and are prevented from coming to the surface, are *drowned* as truly as an air-breathing animal would be under similar circumstances. Hence the desirableness of frequently changing the water in which gold-fish are kept, and of exposing as large a surface of it as possible to the atmosphere, that absorption from it may supply the air removed by the animal. The death of a fish out of water is attributable chiefly to the clogging together of the filaments of the gills, so that the air cannot act upon them, and the drying up of those which, being at the surface, are in contact with the air. Hence, if the branchial arches are kept separate, and their filaments be preserved in a moist state, respiration will go on. There are some fishes in which this is naturally effected by a peculiar contrivance, and in others it may be artificially accomplished.

But there is another way in which the atmosphere acts injuriously upon fishes. Not only from the gills, but from the whole surface of the body, a very rapid evaporation of fluid takes place in dry air; so that the weight diminishes considerably, and the tissues are incapable of performing their proper functions. Hence, if it be desired to keep fishes alive in air as long as possible, they should be surrounded by moist grass, or some other substance which will effectually saturate with dampness the air in their neighbourhood.

Whilst the respiratory organs of fishes immediately indicate their adaptation to pass the whole of their lives in the water, the conformation of almost all of them exhibits an adaptation to rapid and energetic movement in that element. The form of the body is such as to oppose the least resistance to progression, while it is also such as to confer great propelling power. It is usually flattened in a vertical direction; and the surface is extended by a finny prolongation of the spine above, and of corresponding rays below, and by the expansion of the tail in the same line. In this manner, a very large lateral surface is produced, while the resistance to forward movement is very small. The propulsion of the fish is chiefly effected by the movement of the whole body and tail from side to side, which operates in precisely the same manner as the oar of the sculler; and this is facilitated by the great flexibility of the spine, the bones of which are so united together as to move with the slightest possible effort.

But though the propulsion of the fish is chiefly accomplished by the movement of the body itself, it is usually aided by lateral fins, which answer to the legs and arms or wings of higher Vertebrata. Besides the fins which have been already spoken of as existing on the central line of the body, above and below (of which the one running along the back is called the *dorsal* fin and the one under the body the *anal*), there are generally found two *pairs*, of which one, corresponding to the anterior extremities of other Vertebrata, is always situated near the head, and is called the *pectoral*; while the position of the other, corresponding with the posterior extremities of land animals, and called the *ventral*, is extremely variable. Sometimes the ventral fins are placed far back, in the usual position of hind legs; and sometimes they are fixed far forwards, even anteriorly to the pectoral. The pectoral fins are usually connected more intimately with the spinal column than the ventral. These fins are composed of a membrane stretched over a set of bony or cartilaginous rays, which may be regarded as representing the bones of the hand or foot. The bones which connect them with the spine are very short, and are hidden under the flesh; so that the chief movement of the fins is, as it were, at the wrist and ankle joints. It is chiefly by their vibrations that the animal is raised or depressed in the water, and they also assist in changing its direction from side to side. The forward position of the ventral fins is chiefly noticed in those species whose habits involve a considerable variation of their depth in water. Sometimes one, and sometimes both pairs of these fins are absent; in the latter case the fish is said to be *apodal* or footless. In other instances the pectoral fins are enormously developed, like the wings of birds, and even enable the animal to rise out of the water and to skim for a short time along its surface.

The *swimming-bladder* is an organ usually supposed to be peculiar to this class. In the highest forms in which it exists, however, its correspondence with the lungs of air-breathing animals is very evident; and there is little doubt that air is taken into it from without, for the purpose of respiration. In its lower or rudimentary condition, however, its office is more doubtful, especially where it is entirely closed. It is usually believed to contain air, and to serve as a means of regulating the specific gravity of the animal, the swimming-bladder being compressed when the fish desires to sink, and allowed to expand when it desires to rise. In this manner it would seem that gold-fishes are enabled to ascend and descend in the water, without any muscular effort visible to those who watch them. But it is remarkable that this organ is sometimes absent in a species nearly allied to one in which it is present; and that the want of it does not seem to make any difference in its powers. As a general rule, it is more constantly present in river fishes than in the inhabitants of the sea; and it is most frequently absent in those which live habitually near the bottom of the water.



Fish.

a dorsal fin; *b*, pectoral fin of one side; *c*, ventral fins, *d*, anal fin; *e*, caudal fin, or tail.

The surface of the body is generally covered with numerous scales, which vary considerably in form and size in different species. Each scale is composed of several plates, of which every one extends on all sides beyond the one on its exterior; hence the appearance of numerous concentric lines on all sides, which mark the stages of growth, the larger plates being the latest formed. They thus resemble the shells of mollusca in their mode of increase. Each scale is attached to the skin of the fish by its anterior edge, which is covered by those in front of it, whilst its posterior edge overlaps the scales behind it. This arrangement is not universal, however; for the scaly covering is sometimes formed by a series of bony or even enamel plates, united to each other by their entire edges. Such an arrangement was very common in the fishes existing at the time of the coal formation, but is now much more rare.

When we consider that more than two-thirds of the

earth's surface is covered with water, often to a very great depth, and that, as far as is known, the whole of this element is habitable by fishes (each stratum having some particular species formed to exist in it), little doubt can be entertained that they form the most numerous class of vertebrated animals. Their numbers are kept up by their extreme fertility. The cod-fish has been ascertained to lay not much fewer than four millions of eggs at a single deposit; and in other species the number may even be greater. Their voracity is also extreme. Almost all of them are adapted to devour and digest animal food, some of them living chiefly on crustaces, molluscs, and other invertebrate inhabitants of the ocean; and others having it for their especial function to keep down the inordinate multiplication of their own kind. Some of these attain a considerable size. The pike has been found nineteen feet long; and there is evidence of one having lived for 267 years. The sun-fish has reached the length of twenty-five feet; and some rays and sharks have exceeded forty feet.

The classification of Fishes proposed by Cuvier is probably the best that, in the present state of our knowledge of this group, can be adopted. It is obvious that, from the peculiarities of the habitation of these animals, and the very imperfect manner in which the depths of the ocean, over a large part of the earth's surface, have yet been explored, a great number of existing species probably yet remain to be discovered. And it is also certain that the number of species formerly existing in the waters, and of which we have at present but very scanty remains, was considerable, and that their forms often differed widely from those familiar to us. Hence, when these shall have been more completely investigated, it is not improbable that this classification must be greatly modified in order to include them.

The primary division of the class is into the *Osseous* and *Cartilaginous* Fishes, the former having a hard bony skeleton, and the latter having one of less firm consistence, possessing but little calcareous matter. The former group is divided into six orders, which are principally characterized by the structure and arrangement of the fin rays. These are distinguished as either consisting of a single piece—in which case, whether stiff or flexible, they are said to be *spinous*—or as consisting of a number of jointed pieces, divided at their extremities, when they are called *soft* or *articulated*.

1. Acanthopterygii, or *spiny-finned*. In this order, which contains the greatest number of ordinary fishes, there are spinous rays in the first or anterior part of the dorsal fin, and sometimes these have no connecting membrane. The anal fin has also its first rays spinous, and there is generally one such ray in the ventral.

The three next orders are all *soft* or *jointed-finned*, and come, therefore, under the general designation Malacopterygii. They are distinguished from each other by the position or absence of the ventral fins.

2. Malacopterygii Abdominales. In these, the ventral fins are attached to the abdomen behind the pectorals. They are a very numerous order, and include the greater part of the fresh-water fishes.

3. Malacopterygii Sub-Brachiati. In this order the ventral fins are brought forwards under the pectorals, and the fish, which are chiefly marine, enjoy a considerable power of ascending and descending in the water.

4. Malacopterygii Apoda. These are fishes in which the ventral fins are always wanting, as are not unfrequently the pectoral also.

The two remaining orders of Osseous Fishes are separated from the rest by other peculiarities.

5. Lophobranchii (Tuft-Gilled). In these, the gills, instead of hanging in regular fringes, like the teeth of a comb, from the branchial arches, are disposed in tufts, and the gill-covers open less freely than in the preceding orders.

6. Plectognathi. The members of this order, though retaining many of the characters of the Osseous Fishes, exhibit an evident transition to the Cartilaginous, both in the less complete ossification of the skeleton, and by the union of the bones of the upper jaw to each other and to the head. The opening of the gill-covers is still smaller than in the last order.

The *Chondropterygii*, or Cartilaginous Fishes, cannot be considered either superior or inferior to the others, but form, as it were, a parallel series with them. Some tribes exhibit the lowest organization which exists in the class, while others present many points of affinity to Reptiles. The different parts of the skeleton, which, in the Osseous Fishes, are united by distinct joints, here frequently form one continuous piece. This is most remarkable in the head, which is composed of a single piece, in which, however, the principal parts found in the bony fishes may be distinguished by various ridges, furrows, and holes. This group contains three orders, distinguished from each other by the conformation of the mouth and the arrangement of the gills.

7. Chondropterygii Branchiis Liberis (Free-Gilled Cartilaginous Fishes). In these, consisting chiefly of the Sturgeons, the gills hang freely, and are covered with a gill-lid having a single wide opening, as in Osseous Fishes.

In the other two, the gills are attached at the outer edge, and there is a separate opening for the escape of the water that passes over each arch. These, which are termed Chondropterygii Branchiis Fixis, or Fixed-Gilled Cartilaginous Fishes, are distinguished from each other by the conformation of the mouth.

8. Selacii, or *Sharks* and *Rays*. Here the jaws are not united into a ring.

9. Cyclostomi (Round-Mouthed). These have a round fleshy lip, by which they adhere to their prey, obtaining their food by suction, and this is supported by a cartilaginous ring, formed by the union of the jawbones. It is in the fishes of this order that we find the vertebrated structure in its lowest form.

Division 1.—Osseous Fishes.

Order I.—Acanthopterygii.

The Spiny-finned Fishes are divided by Cuvier into fifteen families, the most important of which will now be noticed.

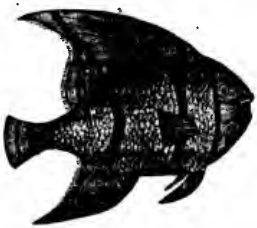
Perch.

Percidæ, the *Perch* tribe. These are very numerous in the waters of all warm climates, some species inhabiting the rivers, and others the open sea. Their bodies are oblong, and covered with hard or rough scales; and the gill-covers are toothed at the margin. They are mostly *thoracic*, or have the ventral fins under the pectoral. Some, however, are *jugular*: that is, have the ventral fens placed upon the throat, farther forwards than the pectorals; and some are *abdominal*. Their teeth are very minute, and set close together in numerous rows. Their flesh is in general agreeable and wholesome. This family includes all the fish known as Perches, of which some species are found in almost all the rivers in the world, and a large number of marine fishes used as food on different shores.

Triglidæ, the *Gurnard* tribe. These bear a general resemblance to the Perches; but have the head peculiarly armed with spines or hard scaly plates. In several species the pectoral fins are very much extended; but in

Dolphin.

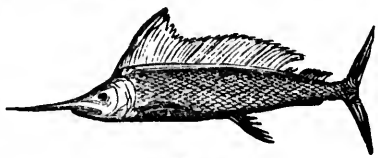
none except the flying-fish are they sufficiently powerful to raise the animal out of the water. Many species of this tribe are found in the temperate seas. The most interesting of all is the *dactylopterus*, or *flying-fish*. This has a kind of supplementary pectoral fin on each side, formed of a membrane stretched over finger-like processes, which in the gurnards are unconnected. By the impulse of these on the surface of the water, the flying-fish can raise themselves to the height of several feet into the air, and can suspend themselves above the surface for a few seconds, often skimming lightly over it for a considerable distance; but they cannot sustain themselves in the atmosphere for any length of time. They are gregarious fish; and it is when a shoal of them is chased by the *coryphæna* (commonly but erroneously termed *dolphin*) or some similar enemy, that the most remarkable leaps are taken. They not unfrequently fall upon the deck of a large vessel that may be passing among them. The finger-like processes are usually prolonged beyond the fins, and appear to possess an amount of sensibility unusual in such parts.



Chætodon.

The family SQUAMIPENNES is so named because the soft and even the spinous parts of their dorsal fins are so covered with scales as not to be distinguished from the rest of their bodies. The most interesting genus is the *Chætodon*, of which several species, remarkable for the beauty of their colours, abound in tropical seas. One of these, the *C. rostratus*, which has a very prolonged snout, has the faculty of shooting insects with drops of water projected from the mouth, and it then seizes them as they fall. This power is the more extraordinary, as, according to the laws of the refraction of light, the place of the insect will appear to the fish different from the reality, the rays passing from a rarer to a denser medium; and the drop must not, therefore, be projected in the line in which the insect *appears* to be, but somewhat below it. This little fish, which is a native of India, is often kept in glass vases by the residents there, as gold-fish are in this country, for the purpose of affording amusement by its dexterity.

The next family, SCOMBERIDÆ, or the *Mackerel* tribe, is one of very great importance to man. It comprises a large number of genera, a vast collection of species, and numberless individuals. The aspect of the common *mackerel*, with its spindle-shaped, beautifully-coloured, smooth, and small-scaled body, is well known. It very rapidly dies out of water, and soon becomes tainted. Mackerel has been supposed to be a migratory fish, on account of its appearing on our shores in immense shoals at particular epochs. But it may be caught all the year round on our coasts, which shows that it does not wholly desert them, as is done by the really migrating tribes. The fact is, that it passes most of the year in the open sea, and that its object in approaching the shore is to deposit its spawn; after which, those that have escaped being entrapped by the ingenuity of man, return to their former quarters. The extent and importance of the mackerel-fishery of Britain, especially in the south and east, are well known. The *tunny* is an allied species, attaining a much greater size, and also valuable as an article of food. This frequents the Mediterranean, and is occasionally seen on our own shores. It sometimes attains the length of fifteen or even eighteen feet. To this order belongs also the *xiphias*, or *sword-fish*, distinguished by its long pointed beak. This



Sword-Fish.

is a most powerful offensive weapon, and with it this fish attacks the largest inhabitants of the ocean. By its high dorsal fin, and expanded tail, it is able to impel itself forwards with great force; and when attacking a large animal, it makes a violent dart against it, quite transfixing it with its sword. It has been known in this manner to drive its beak into the timbers of a ship, and, not being able to withdraw it, to break it off and leave it. The sword-fish abounds in the Mediterranean, but is less frequent in the Atlantic. It is very palatable as food; and often attains the length of fifteen feet. The *dory*, of which one species is highly prized by epicures, is another fish of the same family. It is remarkable for the filamentary prolongations from its dorsal fins. And lastly may be mentioned the *coryphæna*, commonly known as the *dolphin*. This is a large and splendidly coloured fish, which darts through the water like a radiant meteor, exhibiting an extraordinary play of colours when brilliantly illuminated. It has long been celebrated for its change of colour when dying. It swims with great rapidity, and is very voracious, committing great havoc among the flying-fish and others of like size. The influence of light on the colour of animals is remarkably shown in the far superior brightness of the Indian *Scomberidæ*, when contrasted with the blackish hue of those of northern seas.

The fishes of the family PHARYNGINÆ LABYRINTHIFORMES, are characterized by a very peculiar structure, from which they derive their designation. The membranes of the pharynx (or back of the mouth) are divided into small irregular leaves, containing cells among them, which the fish can at pleasure fill with water; and, by ejecting a portion of this water, it moistens its gills, and may thus continue its respiration out of its proper element. By means of this apparatus, which resembles that possessed by the land-crabs, these fishes are enabled to quit the pool or rivulet which constitutes their usual element, and move to a considerable distance over land. Such a provision is especially desirable in tropical climates, where shallow lakes are often dried up by a continued drought, and their inhabitants must perish if not enabled to migrate. The people of India, who often witness the appearance of these fishes where they were known not to exist, believe that they fall from heaven. Some of them are able not only to traverse plane grounds, but can climb steep banks or even trees in the course of

their journeys. Of these the most curious is the *anabas*, commonly known as the *climbing-perch* of Tanquebar, which climbs bushes and trees in search of its prey, a species of land-crab, by means of the spines on its back and gill-covers.

The members of the family Gobiidæ, or *Goby* tribe, are known by the thinness and flexibility of their dorsal spines. Many of them are remarkable for producing their young alive, the eggs being hatched within the body of the parent. This is the case with the *blenny*,

Blenny.

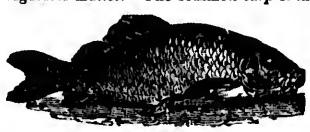
of which several species frequent the British shores, living in small troops among the rocks. They are remarkably tenacious of life, being capable of being kept a good many days in moist grass or moss, but they are of little value as articles of food. The true *Gobies* are chiefly remarkable for the *nest* which they construct among the sea-weed for the protection of their young, which was observed by the ancients. They prefer a clayey bottom, in which they excavate canals, and in these they pass the winter.

The next family Pectorales Pedunculati, derives its name from the peculiar structure of the pectoral fins, which have a kind of wrist formed by the elongation of the bones to which they are attached. This conformation gives these fishes a very strange appearance, and enables them to leap suddenly up in the water in pursuit of their prey, and even to leap over the mud. In many of them the skeleton is semi-cartilaginous. One of the most curious is the *lophius* or *fishing-frog*, of the British seas, which is met with chiefly on muddy shores. It derives its name in part from its wide gaping mouth, and in part from the peculiar manner in which it angles for its prey. It has some curious appendages to its head, which terminate in long, round, and rather brilliant filaments, having a resemblance to worms. The animal lurks in the mud, and puts these appendages in vibration; they are mistaken for worms by small fishes, which they attract, and these are gulped down the capacious swallow of the lophius. To such an extent is this voracity carried, that the *angler* (as it is sometimes called) is often an article of value for the live fish which it has in its stomach, although its own flesh is worth but little. There is an allied genus, the *chironectes*, of which a species abounds on the north coast of Australia. When the tide ebbs far back in the dry season, these frog-fishes are so abundant, and capable of taking such vigorous leaps, that those who have visited these places have taken them at first sight for birds. The fishes of this genus can inflate their large stomachs with air, in the manner of the Tetrodons.

Order II.—Malacopterygii Abdominales.

This order, consisting of soft-spined Fishes which have the ventral fins under the abdomen, contains five families, all of which are highly interesting to the naturalist.

1. The Cyprinidæ, or *Carp* tribe, are all fresh-water fishes. They have the mouth shallow, the jaws feeble, and very often without teeth, but the pharynx is strongly toothed. They are among the least carnivorous of fishes, feeding chiefly on seeds, the roots of plants, and decomposing vegetable matter. The common *carp* is imported



Carp.

into England from the warmer parts of Europe; it thrives better in ponds or lakes than in rivers, it feeds on insects and worms, as well as on vegetables, and it is very tenacious of life, so that it is easily transported from place to place.

2. The family Esocidæ, or *Pike* tribe, contains the

Pike.

most voracious fresh-water fishes, as well as several important marine species. They are distinguished by the absence of fatty matter in the dorsal fin (which exists in the Salmon tribe), and by the position of this opposite to the anal fin. The *pike* is very destructive of the smaller fishes in the ponds and rivers in which it exists, and sometimes attains a considerable size, weighing between thirty and forty pounds. The *gar-fish*, or *sea-pike*, is an allied species, frequenting the British shores and stretching into the Arctic regions. Some of this kind have been known to attain the length of eight feet, and to bite very severely; hence they may be considered as the sharks of northern seas. To this family belongs the most common of the flying-fish, though, as already stated, it is not the only one which deserves the title. The *exocœtus* is at once distinguished from the rest of the family by the immense size of its pectoral fins, by the impulse of which upon the water it is enabled to rise into the air; but it can scarcely be said to *fly*, since it is unable to do more, without again dipping into the water, than partially to sustain itself, and to direct the movement to which the impetus was given at the moment of quitting the water. Nevertheless, the common flying-fish can leap more than two hundred yards in distance, and upwards of twenty feet in height. They are not unfrequently found upon the decks of large vessels, across which they had endeavoured to pass. This power appears to be conferred upon them to enable them to escape from the pursuit of the Coryphæna; but, in avoiding one enemy, they put themselves in the way of others, for voracious birds watch for them and seize them as they rise into the air. They furnish an excellent article of food, and are very abundant in the neighbourhood of some tropical islands; individuals have occasionally appeared as stragglers on coasts of Britain.

3. The Siluridæ are distinguished from all the rest of the order by the want of true scales; having only a naked skin, or large bony plates. The fishes of the genus *Silurus* inhabit the rivers of warm countries; they have a strong spine in front of the dorsal fin, which can be laid flat on the shoulder, or perpendicularly erected so as to become a formidable weapon; and the ragged wounds inflicted by it are reputed (but probably erroneously) to be poisonous. One species, belonging to the sub-genus *Malapterurus*, an inhabitant of the Nile and of the rivers of Central Africa, has electric properties similar to those of the torpedo and gymnotus.

4. The fishes of the order SALMONIDÆ, known as *salmons* and *trouts*, are very extensively, indeed almost universally, diffused over the globe, some of them being confined to fresh-water, and others passing a part of their lives in the sea, but resorting to rivers to deposit their eggs. They are distinguished by the fatty deposition in the dorsal fin, from part of which the spines often disappear. All of this family are clouded with dusky patches when young, as occurs in all the species of Cats. Many remain permanently spotted. The flesh of most of them is esteemed as food. The *salmon* inhabits the seas of comparatively cold regions, ascending the rivers for the purpose of spawning at seasons varying with the climate. The efforts which they make to overcome difficulties in the ascent are very great; they will not only swim against powerful streams, but will leap up cascades of considerable elevation, and find their way to the brooks and small lakes of lofty mountains. They return to the sea after this operation is accomplished, and are followed by the young produced from the eggs they have deposited. These, in their turn, ascend the rivers for the same purpose, and are understood to resort to those in which they were produced. The *trout* appears to vary much in size and colour, according to the climate and other conditions of its residence, so that it is difficult to distinguish species from mere varieties.

Salmon.

5. The CLUPEIDÆ, or *Herring* tribe, is one of the most important families in the whole class, for the amount of food it supplies to man. The fishes belonging to it resemble the Salmonidæ in many characters, but differ in having no fatty matter in the dorsal fin. They chiefly inhabit the seas of the temperate zone. The *herring*, which periodically visits our shores in such immense shoals, was formerly supposed to migrate from Arctic seas; but this is now ascertained to be a mistake, the fish being almost unknown there, and often appearing on the southern shores of Britain before the northern. The fact is rather that the herring, like the mackerel and many other fish, usually lives in the open ocean, and resorts to the nearest coast to deposit its spawn. There are many well-known species, differing but little from the herring, which frequent separate localities. Thus, the *pilchard* is caught especially on the coast of Cornwall and other shores to the southward of those on which the herring most abounds. The *sardine* is taken on the west coast of France and in the Mediterranean, where the herring never appears. The *sprat*, *white-bait*, *shad*, and other British species, belong to the same family; as does also the *anchovy*, well known for its rich and peculiar flavour, which is abundant in the Mediterranean. Other species inhabit the American, African, and Indian seas and rivers, but they are less abundant than those already mentioned.

Order III.—Malacopterygii Sub-Brachiati.

The soft-rayed Fishes, which have the ventral fins brought forwards beneath, or even in advance of, the pectoral, are divided into three families, one of which is equally important to man with the last, if not more so. This is,

Cod.

1. GADIDÆ, the *Cod* tribe. The fishes of this genus are easily known by the softness of all their fins, and by having the ventrals inserted under the throat, and pointed. The greater number live in cold or temperate seas, and furnish a most important article of food, their flesh being wholesome, easy of digestion, and agreeable to the palate, and their numbers (owing to their extraordinary reproductive power) extremely abundant. The *cod* is nearly the largest of the family, but is usually surpassed by the *ling*, which is commonly from three to four feet long: both of these are especially valuable for their excellence when salted. The *haddock* is a smaller species, nearly allied to the cod; for eating in the fresh state, it is perhaps the most delicate of the whole family. Many other species are useful to man, occurring in large numbers in particular localities. Such are the *whiting*, the *coal-fish*, the *pollock*, the *haak* (of which some species frequent high southern latitudes), the *burbot* (which ascends rivers), the *rockling*, and many others. Besides their use as food, these fish are valuable on account of the oil obtained from their large livers, which is very serviceable in the arts.

2. The second family is that of PLEURONECTIDÆ, the *Flat-fish* or *Flounder* tribe. The form of these fish is peculiar, not only for the extreme flattening of the body, but for its deficiency in symmetry. The two flat surfaces—one of which (in the ordinary position of the fish during life) is above, and the other below—are in reality the two *sides* of the fish, differing in several important respects. Both the eyes are placed on the upper side; and its colour is usually much deeper than the other. The body, from the head backwards, partakes a little of the same peculiarity. The two sides of the mouth are not equal, and the pectoral fins rarely so. On the other hand, the dorsal fin, which runs along one of the lateral edges, corresponds with the anal, which occupies the other, and with which the ventrals are sometimes united. So that, when we look at the fish in its usual position, its body appears more symmetrical than it really is. These fishes are destitute of air-bladder, and they frequent the bottom of the sea, from which they seldom rise far. The colour of their upper surface usually corresponds closely with that of the ground on which they lie; and thus they escape the observation of their enemies, and are unnoticed by the small fishes on which they prey. Individuals are occasionally found, however, in which both sides are alike; these are called "doubles;" it is usually the dark side which is doubled. The fishes of this family are found along the shores of almost all countries, and are, generally speaking, wholesome and agreeable as food. The form and aspect of the different species exhibits little variation. The *flounder*, *turbot*, *brill*, *plaice*, *dab*, and *sole*, are the chief species of our own coasts; the *hallibut* is a very large species, attaining the length of six or seven feet, and weighing 500 lbs., occasionally taken in the British seas; and other species inhabit the Mediterranean.

Flounder.

3. The DISCOBOLI, so named from having their ventral fins formed into a sucker or disk, are the last family of this order. By this curious provision, the fishes belonging to this family have the power of attaching themselves to rocks and other hard substances, and thus remain and find their food in situations where every other species would be swept away by the current of water.

Eel.

Order IV.—Malacopterygii Apoda.

The fishes in which the ventral fins are wanting form but one natural family, the Muræniдæ, or *Eel* tribe. They are all lengthened in form, have the spine extremely flexible, the skin thick and soft, and the scales almost invisible. In most of them the external gill-apertures are very small, and open very far back; by which arrangement they are enabled to keep the gills moist for a long time when out of water, whilst the roundness and flexibility of their bodies facilitate their motion upon land. Many of them inhabit rivers, whilst others are exclusively marine. The *eel* is the kind most abundant in Britain. The *conger* is a marine eel, frequenting the European seas; it is one of the largest of the family, being from four to six feet long, and as thick as a man's leg. The *gymnotus*, or *electric eel*,

Gymnotus.

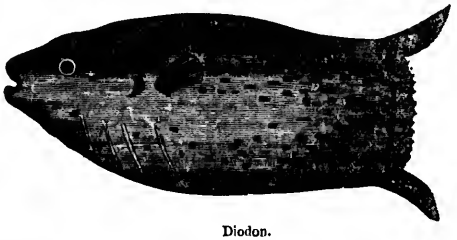
is a native of the South American rivers. It attains the length of five or six feet, and communicates shocks so powerful that men and horses have been stunned by them. This power seems voluntary, and can be sent in a particular direction, or even through the water, the fish in which are killed or stunned by its shocks. By giving these it is greatly exhausted, and requires rest and nourishment before it can renew them.

Order V.—Lophobranchii.

This order is a very small one, containing but one family, of which the genera are few. Their appearance is very peculiar. The tufted gills are covered by a large operculum; but this is bound down by membranes on all sides, so that there is only one small hole for the water to escape. The body is covered, not with small scales, but with shields or plates, which often give it an angular form. In general they are of small size, and almost without flesh. The *syngnathus* possesses a long tubular snout; it is peculiar for the protection which it affords to its young, which resembles that provided in the marsupial Mammalia. The eggs are conveyed into a sort of pouch under the body of the male, and are hatched there, the young fry afterwards finding their way out. Some of these are found in the British seas, as are also the *hippocampi*, commonly called sea-horses, from the resemblance of the upper part of the body (especially when the dead specimen bends in drying) to the head and neck of a horse in miniature. Their tail is prehensile, and they climb or hold on to the stalks of marine plants, by its means. Some of this family are almost destitute of fins, having none but the dorsal.

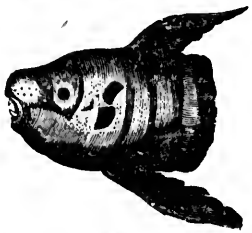
Order VI.—Plectognathi.

This order, the last of the osseous Fishes, approaches the cartilaginous in many points of its organization; principally, however, in the slow ossification of the skeleton, and the imperfect structure of the mouth. They derive their name, as already stated, from the union of the upper jaw to the skull; so that its motion is obtained, not from a distinct joint, but by the mere flexibility of the half-ossified cartilages. The gill-lid is concealed under the thick skin, with only a small opening; the ribs are scarcely developed; and there are no true ventral fins. This order contains two families.



Diodon.

1. The Gymnodontes, or Naked-Toothed Fishes, are distinguished by having the jaws covered with a substance resembling ivory, arranged in small plates (which are reproduced as soon as destroyed by use), and really representing united teeth. They live on crustacea and sea-weed, and their flesh is not palatable. Some species are reputed to be poisonous, at least at particular seasons. The most remarkable species of this family are the spinous globe-fishes, *diodon* and *tetraodon* (their technical names being derived from the apparent division of their jaws into two and four tooth-like pieces respectively), which have the power of blowing themselves up like balloons, by filling with air a large sac which nearly surrounds the abdomen. When thus inflated, they roll over with the belly upwards, and lose all power of directing their course; but they are remarkably defended by spines over their whole surface, which are erected as they are inflated. They are mostly inhabitants of warm seas, but a specimen is occasionally drifted to our coast. The *sun-fish* has a body of somewhat similar form, but incapable of inflation; the tail is so short that it looks like the anterior half of a fish cut in two in the middle. Some species attain an immense size. One which is occasionally taken on the British coast has been known to weigh 300 lbs., and others are much larger.



Sun-fish.

2. The second family, Sclerodermi, contains fishes which are remarkable for their very hard and granulated skins. They have a prolonged muzzle, with distinct teeth. Their skin is covered with scales in some species, and in others very rough, like a file, whence they are commonly termed *file-fishes*. They are principally inhabitants of warm seas, living near rocks or on the surface of the water, their brilliant colours sparkling in the sunshine like those of the Chætodons.

DIVISION II.—CHONDROPTERYGII OR CARTILAGINOUS FISHES.

The skeleton of these fishes is not entirely devoid of calcareous matter, but this is disposed in separate grains, and does not form fibres or plates. Hence the hardest portions of the framework remain quite flexible. The freedom of motion of the spinal column, which is characteristic of fishes in general, is here still further increased, in many species at least, by the continuation of the sac containing gelatinous matter (which in the osseous fishes was simply interposed between each pair of vertebræ) through the whole column, the bodies of the vertebræ being pierced in the centre so as to form a continuous tube. This division contains two subordinate groups: in the first, the gills are attached by one edge only, hanging in fringes as in the osseous fishes; in the second, they are so attached to the skin by the second edges, that the water cannot escape from their intervals except by holes in the surface. Accordingly, instead of having a single pair of large apertures, with a valve-like cover, or *operculum*, behind the head, they have as many apertures on each side as there are arches of gills. The first series contains but one order, and the second the other two.

Order VII.—Chondropterygii Branchus Liberi.

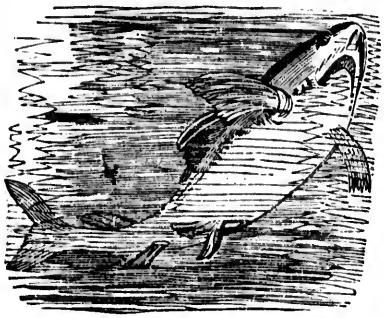
This order contains only one family, the STURIONES, or *Sturgeon* tribe. In many of its characters, as well as in the disposition of the gills, it is intermediate between the Osseous Fishes and the Shark tribe, which may be regarded as the types of the Cartilaginous division. Sturgeons are chiefly river fish, and from their large size, vast numbers, and the quantity of food and other important products they afford, are extremely valuable to man. The common sturgeon of the British shores is about six feet long, and its flesh is somewhat like veal. The rivers falling into the Black and Caspian Seas, however, produce several other species, of which the largest not unfrequently attains the length of fifteen feet, one individual being recorded as having weighed 3000 lbs. The roe of the sturgeon furnishes the caviar so much esteemed in Russia; and its air-bladder furnishes isinglass.

The section of CHONDROPTERYGII BRANCHUS FIXIS is divided into two orders, the first having teeth, and the second having the mouth formed into a sucker.

Order VIII.—Selachii.

This order only comprises one family, that of *Sharks* and *Rays*. A great metamorphosis here takes place in the condition of the bones of the mouth, those which are commonly termed the jaws, in which the teeth are fixed, being very different in position and character in osseous fishes, and the true jawbones not being here developed. This tribe is distinguished from other fishes by many peculiarities: in several members of it the young are produced alive, the eggs being hatched within the body of the parent; and in others the eggs are enclosed in a peculiar horny casing, which has often long tendril-like appendages, that coil round and attach them to other bodies. This is the case with the eggs of the common *dog-fish* of our coast, vulgarly known as *sea-purses*. The Sharks much resemble ordinary fishes in their form, having the gill-openings on the sides of the neck, and the eyes on the sides of the head, in both of which respects the Rays differ from them. The *dog-fish* of the British coasts differs but slightly from the true sharks, and is, in its way, equally voracious.

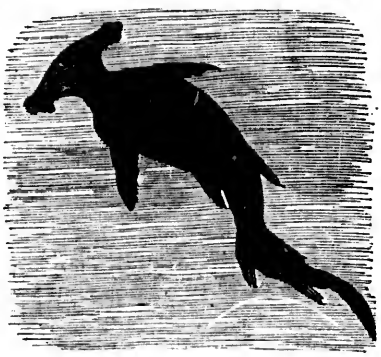
The *white shark* is the most celebrated species of the tribe, being, from its size and voracity, the terror of mariners in the seas it inhabits. It frequents warm latitudes, but has occasionally visited the British shores. It has been known to attain a length of thirty feet, and the opening of the jaws in the largest individuals is sufficient to admit with ease the body of a man. The mouth is placed on the under surface of the head, from



White Shark.

which circumstance the fish cannot bite whilst in the act of swimming forwards, so that a dexterous person has been known to defend himself from its attack.

A remarkable genus allied to the Sharks is the *zygæna*, or *hammer-headed shark*, so named from the projection



Hammer-headed Shark.

of the head at each side in the form of a double-headed hammer, with an eye in the middle of each extremity. The *pristis*, or saw-fish, is another interesting genus. Its general form and character is like that of the sharks, but the snout is extended like the blade of a sword, with strong and cutting tooth-like spines on both edges. With this formidable weapon the fish, which sometimes attains the length of from twelve to fifteen feet, will attack the largest whales, and inflict dreadful wounds. To the shark tribe also belongs the *angel fish* of our own coasts, which forms the link to the rays in its general structure and aspect. The eyes are situated on the back or upper surface of the head; the body is broad and flattened horizontally, and the pectoral fins widely expanded. It commonly grows to the length of seven or eight feet; its appearance much belies its name, being (according to our ideas of beauty) one of the ugliest of fishes, but its flesh is by no means unpalatable.

The *Rays* are less numerous than the Sharks, and abound rather in temperate than in tropical seas. They are characterized by the extreme horizontal flattening of the body, in which, however, there is not (as in the Pleuronectidæ) any want of lateral symmetry. The two sides are expanded horizontally, and unite with the

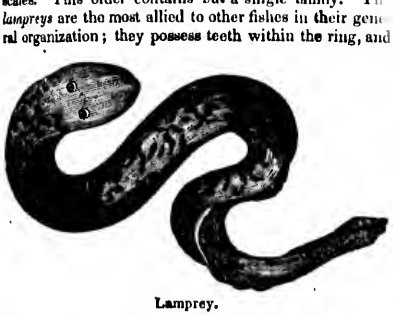
expanded and fleshy pectoral fins to form one continuous surface. The eyes are placed on the back or upper surface, whilst the mouth, nostrils, and gill-openings, are below. To this group belong the *rays* and *skates*, *thornbacks*, and other species; but the most interesting of all is the *torpedo*, or **electric ray**, sometimes found on the Channel coast of England, but more abundant in

Torpedo.

the Mediterranean. The electric apparatus is of very similar structure with that of the *gymnotus*, and it is disposed in the space between the pectorals and the head and gills. The shocks given by this fish, though smart, are not so benumbing as those of the gymnotus; their use in its economy are not apparent, as the animal can obtain its prey without them. The flesh of the rays is wholesome, and that of most species agreeable as food. The skin of some of them is employed in the arts for polishing, and, from that of others, shagreen is made.

Order IX.—Cyclostomata.

The third order of the Cartilaginous Fishes, and the last of the class, is one which contains comparatively few species, and these exhibiting but a very low degree of organization. They take their name from the adaptation of the mouth to the purposes of suction, by its transformation into a round fleshy disk, having the oral opening in the centre, and the margin supported by a ring composed of the cartilaginous jaws united together. The spinal column loses its distinct division into vertebræ, the space elsewhere occupied by their bodies being traversed from end to end by a cylindrical membranous tube filled with a mucilaginous fluid; and this, in the higher species, presents cartilaginous rings at intervals, which are the rudiments of vertebræ; whilst, in the lower, there is no vestige of these bodies, and the whole structure is reduced to the level of that of the Annelida. The pectoral as well as the ventral fins are absent; and the skin is soft and mucous, with scarcely a vestige of scales. This order contains but a single family. The *lampreys* are the most allied to other fishes in their general organization; they possess teeth within the ring, and



Lamprey.

with these they tear the bodies of the animals to which they attach themselves. There is a marine species two or three feet long, and other smaller ones which inhabit rivers. The *myxine* or *hag* is destitute of eyes, and is altogether of lower organization than the lamprey; but the species that differs most in its general characters from the rest of the class is the *amphioxus*, or lancelet. This is a very small animal, about an inch long, sometimes found lurking under stones in pools left by the ebbing tide. It is destitute of almost every one of the characters which have been mentioned as peculiar to vertebrated animals; and, nevertheless, can scarcely be classed anywhere else than with this family.

SUB-KINGDOM—ARTICULATA.

From the Vertebrata, we might pass, in descending the animal scale, either to the Mollusca, or the Articulata, both of which exhibit some points of approximation with them. In both we meet, as in the Vertebrata, with very highly organized, as well as very simply constructed beings. In both we find animals much superior to the lowest Vertebrata; and in both, also, we find species which are in many respects below the highest Radiata. It is the necessary consequence of a *natural* arrangement, which aims at grouping together the different forms of living beings according to the type or plan on which they are constructed, that such should be the case. Neither of these two sub-kingdoms can be regarded as in all respects superior to the other. The high development of the locomotive power in the Articulata strikingly contrasts with its usually slight possession by the Mollusca. On the other hand, the digestive and nutritive systems in the Mollusca are much more complex, and attain a higher organization; so that the heart, for example, of the Tunicata is as powerful in its action on the circulating fluid as that of the highest Articulata. On the whole, however, the Articulata should be regarded as ranking above the Mollusca in the animal scale, since it is in the *animal* powers that the former have the superiority.

The general character of the series has been already stated as being the jointed or *articulated* character of the skeleton or hard portion of the structure, and the enclosure of the whole body in this. Nothing can be found in the Mollusca at all approaching in character to the shell of a lobster or the horny case of the beetle. It is the peculiarity of the skeleton in the Articulata, that it not merely encloses the body, but is prolonged over the appendages for locomotion, where they exist; and the portions of it which cover these are also jointed, for the sake of conferring upon them the requisite flexibility. This structure is more apparent, however, in some cases than in others. In the lowest animals of this series, where there are no appendages for locomotion, and where all movements are effected by the body itself, this is endowed with great flexibility, and the whole envelope is so soft that the division into segments can scarcely be recognised. This is the case, for example, in the leech and earthworm. The articulated character is most apparent in the Centipede tribe, where the segments are all of nearly equal size, and where each possesses a short pair of legs, which are themselves also articulated. But in the highest classes of this sub-kingdom we again lose the appearance of the division into segments, from an opposite cause—the consolidation of several rings into one piece. In proportion as the locomotive power is more intrusted to the extremities, so does it become unnecessary that the trunk should possess much flexibility; and in the same proportion does it become necessary that the portion of it from which arise the muscles of those extremities should be very firmly framed. Accordingly, the part of the body behind the head, which is called the *thorax*, and from which the legs and wings of Insects, and the principal walking legs of Crustacea have their origin, very commonly appears as if composed of one piece, although it is really made up of three or more

segments, each one of which gives origin to a pair of members.

The Articulata are almost invariably of small size; and the bulk of their bodies is made up, not by their digestive and nutritive apparatus, but by the muscles which move it. It is only in those which approach the Mollusca in the vegetative nature of their existence, that we find any considerable dimensions attained. As the Mollusca are an essentially aquatic group, so are the Articulata principally adapted to atmospheric respiration; and the most active among them can even quit the surface of the ground and mount up into the air. We find their respiratory apparatus constructed, therefore, upon an opposite plan. Instead of the blood being sent into external prolongations of the surface—the gills—to meet the air contained in the surrounding fluid, the air is introduced into the body to meet the blood, this being distributed on the sides of cavities or tubes into which it enters. In Insects these tubes have a very complex and beautiful distribution through the body.

The Articulata exhibit a peculiarity in the nervous system, which often enables the real character of doubtful animals to be distinguished. A double cord runs along the centre of the *lower* surface of the animal, studded with knots or *ganglia* at regular intervals, which are so many centres from which the nerves pass off to the different segments. The head, also, has its ganglia, in which the double cord terminates anteriorly. Where the members, however, are not uniformly distributed along the whole body, but are concentrated to one part, as in Insects, Arachnida, and the higher Crustacea, we observe a corresponding concentration of the ganglia in that region. The degree of this concentration indicates the elevation of the animal in the series.

The following classes must be arranged in the articulated series, though in some of them the characteristic structure is very indistinct:—

Annelida, or *Worm* tribe. In these the body is prolonged, without any distinct appendages for locomotion. The habitation is usually aquatic, though sometimes terrestrial. The division into segments is not very distinct, the entire skin being soft.

Myriapoda, or *Centipede* tribe. These have also a prolonged body, but it is provided with legs; and the articulation of the covering both of the body and legs is very distinct.

Insects, which are distinguished in their perfect state by the possession of one or two pairs of wings; by the restriction of the legs, which are never more than six in number, to the thorax; and by the division of the trunk into three portions, the head, thorax, and abdomen, which are usually very distinct from one another. They are also distinguished by their remarkable metamorphosis, commencing from a form which resembles that of the Annelida.

Arachnida, the *Spider* and *Scorpion* tribe, which differ from insects in having the head and thorax united, in undergoing no metamorphosis, and in having eight or more legs.

Crustacea, which have a hard envelope, principally composed of earthy matter, and which are adapted for aquatic respiration. Many of them have the form of insects; but their legs are never less than ten in number.

The foregoing constitute a tolerably regular series, into which we must also introduce the Entozoa, which seem to exhibit the characters of the Worm tribe in their most degraded condition, and the animals composing which are parasitic upon or within others; the Rotifera, or *Wheel-Animalcule* tribe, of which some approach the Polypifera and Polygastrica, while others approximate the Crustacea; and the Cirrhopoda, or *Barnacle* tribe, which bear a strong general resemblance to the Mollusca, but unquestionably belong to this series.

CLASS VI.—INSECTS.

The class of Insects is perhaps the most interesting in the whole animal kingdom, both in regard to the number, variety, beauty, and complexity, of the different forms which it contains, the vast assemblages of individuals of the same species which not unfrequently make their appearance together, and their consequent importance in the economy of nature.

The true Insects are distinguished from the Crustacea by their peculiar apparatus for atmospheric respiration; from the Arachnida by having but six legs (eight being the number in that class), and by the division of the body into three parts; and from the Myriapoda by the limited number of legs and segments, the latter seldom exceeding thirteen. In the perfect Insect it is sometimes difficult to distinguish the division into segments; they may generally be seen, however, on the lower side of the body, especially on the abdomen. But in the larva or caterpillar state they are never obscure, and their number is very constant, being almost always thirteen, one forming the head. Of the twelve segments of the body, three in the perfect insect form the thorax, or division succeeding the head, while the remaining nine constitute the abdomen. It is more common for one or two segments to be apparently deficient (being consolidated with the rest), than for any increased number to be present.

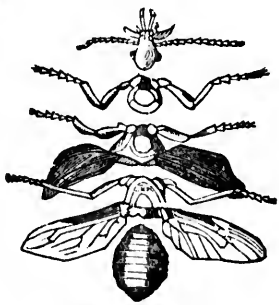
The *metamorphosis*, or complete change of form, which may be seen in the greater number of insects during their development, has attracted much attention from the earliest ages to the present time. The *larva*, which afterwards changes to a beetle, a butterfly, or a wasp, bears no resemblance whatever to the perfect or *imago* form and is in fact allied, in almost every particular of its conformation, to a class far beneath. Moreover, it has to go through an intermediate form—if any thing still more remarkable—that of the *pupa* or *chrysalis*, in which there is an almost complete cessation of activity, but in which preparation is being made for the exit of the perfect insect at its final change. The alteration of the entire character of the animal is no less remarkable than its change of form. In the *larva* condition, its whole energies seem to be concentrated upon the nutritive functions; the voracity is extreme, and the increase in the weight of the body is very rapid; while, in the perfect insect, the body undergoes little increase of size, but it is provided with powers of active movement, and these are principally destined to enable it to seek its mate, for the purpose of propagating its race.

The *larva*, when it first emerges from the egg, bears but a very small proportion to its subsequent bulk. According to Lyonnet, the comparative weight of a full-grown caterpillar of the goat-moth to that of the young one just crept out of the egg, is as 72,000 to 1. During its increase, it throws off its skin several times, like the Crustacea. The larvæ in the different tribes vary extremely as to the degree of their development: in some orders they are extremely imperfect, not even possessing legs; while in others they correspond with the perfect insect in almost every particular except the presence of wings.

After attaining its full growth in the larva condition (the bulk of the body in this state often much exceeding that of the imago), the insect undergoes a very remarkable change, ceasing to take food, and apparently losing all appearance of vitality. In this state it is termed the *pupa* or chrysalis. Many larvæ enclose themselves in a silken cocoon, or in some other kind of envelope, before undergoing this change; and remain in it during the whole period of inactivity, which is sometimes many months in duration. Others bury themselves in the ground; and others, again, suspend themselves in the air. The pupæ of different orders of insects vary, like the larvæ, both in form and in degree of torpor. Some have the whole body enclosed in a horny case, without

vestige of members, and are totally inactive, except when disturbed; while others present the general form of the perfect insect, but appear as if the body and limbs were separately bandaged and laid in close apposition; while others retain all their limbs free, and suffer no diminution in their locomotive powers or in their appetite for food. These, indeed, can scarcely be said to pass into the pupa state at all, their condition being only indicated by the gradual development of the wings. This development is equally taking place beneath the envelope of the pupæ that are enclosed and inactive.

The perfect insect or imago, when it emerges from its pupa case, exhibits in all respects the *form* which is characteristic of the species, and, in general, the *size* also; few growing much after they have attained this condition, and many scarcely eating at all. As already mentioned, the twelve segments forming the body of the larva, may still be recognised here, but very much changed in their character. The three anterior ones are often soldered, as it were, together; forming but one strong sheath for that portion of the body from which the wings and legs proceed, and this sheath affords firm attachment for the powerful muscles which move these organs. Those which constitute the abdomen, however, retain much more of their original aspect. The head is now quite distinct from the body, and connected with it by a neck, which is often very narrow. From each of the segments of the thorax a pair of legs proceeds; and the second and third usually give origin to a pair of wings each. Where, however, only one pair of these organs exists, they proceed from the second segment. The segments of the abdomen never show any vestige of legs. The accompanying diagram represents the chief parts of the perfect insect; the three segments of the thorax are separated from each other to show the organs attached to them.



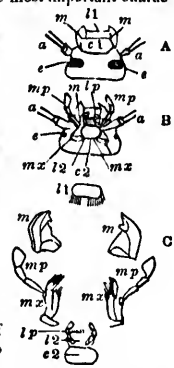
Segments of Insects.

The especial function of the perfect insect is the continuance of the species; and the wings enable it to seek its mate, and to obtain a situation fit for the deposition of its eggs, which are always laid in the neighbourhood of whatever substances will supply the larvæ with nourishment, although it most commonly happens that the imago does not feed upon them. Many insects, such as the *silk-worm* moth and the *ephemera* or May-fly, die soon after having fulfilled this object, to which they proceed very soon after their last change.

However extraordinary is the metamorphosis of insects, it is by no means *unique*, as was formerly supposed. The change of the tadpole into a frog, is an exact parallel to it; for the tadpole is for the time a fish, resembling that class in its entire organization, just as the maggot is for the time a worm. Moreover, we shall hereafter see, in some of the lower classes, a change which is fully as remarkable. When the larva is very imperfect, and the pupa inactive, so that its change to the form of the perfect insect is very striking, the metamorphosis is said to be *complete*; but if the larva is more advanced, and the pupa differs little from it and from the perfect insect, the metamorphosis is termed *incomplete*.

Insects, in their perfect state, are distinguished beyond all other animals for their power of locomotion, and for the perfection of their instinctive actions. In estimating their power of locomotion, the space traversed is of course compared with the length of the body; and thus it is seen that, rapid as is the flight of many birds, that of most insects far surpasses it. The senses of insects appear to be acute. They have generally large eyes, formed, in fact, by the union of a great number of small ones—often several thousand; and although these are fixed, yet, from their being directed at various angles to each other, a great range of vision is obtained. It is believed that insects possess the power of hearing, and also of smell; though no distinct organs for receiving such impressions have been satisfactorily determined. That they have a delicate sense of touch in some part of the body, even where the general envelope is firm, cannot be questioned; and, from observations made upon the social insects, such as bees and ants, there is reason to believe that they communicate with each other by this sense.

The different organs on the head of insects, furnish, by their varieties of conformation, important characters in classification. It will, therefore, be necessary to describe these in some detail. The most important characters, upon which, in fact, the primary subdivision of the class is founded, are drawn from the structure of the mouth; in one large group it is furnished with *mandibles* or jaws, adapted for biting and bruising; while in the other, it is provided with a *haustellium* or proboscis, adapted for suction. Hence the first group is termed MANDIBULATA, and the second HAUSTELLATA. These organs are, however, but different modifications of the same elements.



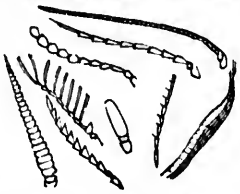
* Different parts of the mouth of a beetle.

In the mouth of the Mandibulata, six principal pieces may be readily distinguished. Of these, four are arranged in two pairs, which work against each other laterally; a fifth piece is above the upper pair, and a sixth below the lower. The two lateral pairs are the jaws; of which the upper pair is distinguished by the name of *mandibles*, and the lower by that of *maxillæ*. The mandibles are usually the largest, and are very powerful organs; sometimes they are provided with sharp or toothed edges, working against each other like those of a pair of scissors; and sometimes with hooked points, more formidable, for the size of the animal, than the teeth of the tiger. These are the principal organs by which the food, of whatever description, is usually obtained; but in the bees and wasps, of which some species are adapted to obtain their nourishment by suction, they are the instruments by which their curious edifices are built up. In a word, as has been well remarked, they supply the place of trowels, spades, pick-axes, saws, scissors, and knives, as necessity may require. The *maxillæ*, or under pair of jaws, are of similar construction, but usually smaller and less powerful. The pieces which are applied above and below to the spaces left between the jaws, are termed *lips*; the upper one being particularized as the *labrum*, and the lower one as the *labium*.

* A, upper side; B, under side; C, parts separated: *a a*, antennæ; *e e*, eyes; *l1*, upper lip; *m m*, mandibles; *m x*, maxillæ, *m p*, maxillary palp; *l2*, labium; *l p*, labial palpi: *c 2*, chin or mentum.

Various modifications of these parts are seen in the different orders of insects, but their existence may always be detected under some form or other. The most remarkable alteration in the structure of the mouth is that which we find in the Lepidoptera or Butterfly tribe. Instead of cutting jaws, we observe a tubular appendage or trunk, which is often of considerable length, and coiled spirally beneath the head, but capable of being unrolled when its point is required to descend into the corollæ of flowers. This tube is composed of two long narrow filaments, which are in fact the *maxillæ* excessively drawn out; these filaments are channelled on the sides at which they approach one another; and by the adhesion of the edges of these channels, which lock together by means of minute teeth, a complete tube is formed. In this mouth, therefore, all the parts except the maxillæ would seem at first sight to be wanting; but they may be detected by a careful examination, and the rudiments of the upper lip, of the mandibles, and of the lower lip, as well as of the *palpi* (organs to be presently described), may be distinctly demonstrated. In other instances, an entirely different modification of the same parts may be observed, which will be noticed in the proper place.

The head of the perfect insect is usually furnished with three pairs of jointed appendages, all of which are probably instruments of sensation. The first of these are termed *antennæ;* they are affixed to the sides of the head, and usually between the eyes and the mouth. The number of joints in them, and the forms they present, vary in the different tribes of insects, as also does their size, within very wide limits. Sometimes they are three or four times as long as the whole body, and sometimes they are scarcely to be perceived; sometimes they are simple thread-like organs, gradually tapering from the base to the point; sometimes they swell out towards the extremity; and often they possess side branches or appendages of various forms. These different characters are extremely useful in classification. The *palpi*, or feelers, are organs which are not dissimilar in general character, but are usually of much smaller size, consisting of seldom more than six joints; of these, one pair is attached to the *maxillæ*, and the other to the *labium*, and they are called *maxillary* and *labial palpi* respectively.



Variously formed Antennæ.

The uses of these organs are involved in some obscurity. There is good reason to believe that all of them are organs of touch; and this sense is probably sometimes most acute in the antennæ, and sometimes in the palpi. There is also reason to believe that the sense of hearing is in some way connected with the antennæ, and a curious modification of the joint at the base seems to be particularly appropriated to this function. It has also been thought that the antennæ minister to the sense of smell.

The *wings* of insects are the organs most peculiar to them; nothing at all analogous being developed in other articulated animals. They consist of a double layer of membrane, prolonged from the skin which covers the body, and partaking of its characters. This membrane is supported by a frame-work of harder structure, composed of ribs, which go by the name of *veins* or *nerves*. These terms must not be supposed to imply any analogy of structure with the organs they designate in higher animals; they are rather drawn from the analogous parts in the leaves of plants.

There is scarcely any organized substance upon which insects are not adapted to prey. In regard to the food of individual tribes of insects, it may here be stated generally, that some are purely carnivorous, devouring only prey which they have themselves killed. Others eat carrion, and even keep it until its decomposition is advanced. Others are herbivorous; some feeding only upon particular species of plants, while others are not restricted, but feed upon almost any vegetable substance. Others again are omnivorous, and will attack almost any thing that falls in their way. The excessive multiplication of insects, which would result from the enormous number of their eggs, and from their rapid growth, is prevented by the influence of other tribes of animals, as well as by the wars of their own tribes against each other. The destruction of the larvæ of some insects by those of others is often enormous, and far exceeds in proportion the diminution in their numbers effected by higher tribes. There are no classes of animals formed to exist on land, however, of which part do not derive a great proportion of their food from insects; and thus, if man does not interfere with the economy of nature, a balance is maintained, which is rarely disturbed. But if these higher tribes be destroyed (as, for example, if a rookery be dispersed), insects will then multiply inordinately, and will become a pest to the country.

Insects are distributed abundantly over all the portions of the globe yet trodden by man. Even in the coldest regions which he has yet explored, they present themselves to his notice during the brief summer; and no severity of the winter appears capable of destroying their vitality, although it reduces them to a state of complete torpidity. It is in tropical regions, however, that the largest and most brilliant species are usually found.

With these general remarks, we are now prepared to consider the principal subdivisions of this important class in more detail. These subdivisions are principally formed upon the character of the wings; since it is found that the structure of these organs affords a good general index of that of the body in general. But it cannot be trusted to alone. For, while certain orders may be included under the general designation *Aptera* or wingless, and another is termed *Diptera* or two-winged, we find wingless and two-winged insects in all the other orders.

Winged insects may be distributed among the eight following orders, of which the first four are Mandibulate, while the rest possess a mouth formed for suction, and are termed Haustellate.

1. Coleoptera (*Beetles*). In these the two anterior wings are converted into a horny or leathery substance, and enclose the posterior when folded.

2. Orthoptera (*Grasshopper, Cockroach*). In these the anterior pair of wings is composed of a substance more resembling membrane.

3. Neuroptera (*Dragon-Fly, White Ant*). Both pairs of wings are membranous, and the nerves form a close network by their interlacement.

4. Hymenoptera (*Bee, Wasp, Saw-Fly*). Both pairs of wings are here also membranous; but the veins have larger areas between them. The tail is possessed of a sting.

5. Homoptera (*Cicada, Lantern Fly*). In this order the four wings are of the same consistence, often somewhat parchmenty; and, when folded, they incline at an angle like the roof of a house.

6. Heteroptera (*Bugs*). The anterior pair of wings is horny or leathery, but generally tipped with membrane; both pairs are horizontal or but slightly inclined.

7. Lepidoptera (*Butterflies and Moths*). These have four membranous wings, covered with minute scales.

8. Diptera (*Gnat, Fly*). These have but two wings, and are in many respects parallel to the Hymenoptera.

Besides these, there are some small orders intermediate between the principal groups. Thus a separate order, Trichoptera, has been formed to include the

case-worm flies, which are intermediate between LEPIDOPTERA and NEUROPTERA. The order STREPSIPTERA, again, comprehends a small group termed *wasp-flies*, intermediate between the LEPIDOPTERA and DIPTERA.

The APHANIPTERA, the order to which the flea belongs, are entirely *apterous* or wingless, and parasitic; but undergo a metamorphosis, by which they show an alliance with the Diptera.

The Wingless Insects, which do not undergo any metamorphosis, may be distributed into two classes—1. PARASITA (*Louse*); and, 2. THYSANOURA (*Sugar-Louse, Spring-tail*). These connect true Insects with the Myrispoda.

These orders will now be considered more in detail.

Order I.—Coleoptera.

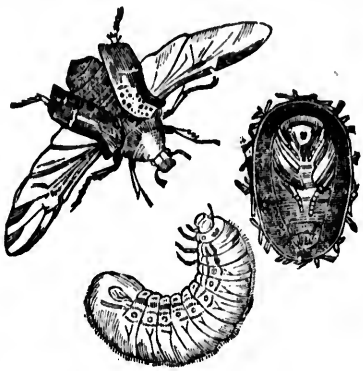
This order comprehends all insects which have the anterior pair of wings converted into wing-cases or *elytra*, and which undergo a complete metamorphosis. These wing-cases are of horny consistence, and are opaque, or nearly so. When expanded, they are of little or no use in flight; and, when closed, they meet along the back, in a straight line, which is called the suture. The second pair of wings constitute the true organs of flight; they are of large size, and of membranous texture; and, when unemployed, they are shut up in several transverse folds, and are entirely concealed beneath the elytra. The mouth is formed for mastication, and possesses two horny mandibles. The head is provided with two antennæ, of variable form, and of which the number of joints is usually eleven; these often differ considerably in the two sexes. The eyes are large and protuberant, especially in the carnivorous species, and in those, the slowness of whose habits makes them need quick powers of sight for the purpose of avoiding their enemies.

The body exhibits a well-marked division into thorax and abdomen. The former consists, as usual, of three segments; but the first of these is so largely developed at the expense of the rest, as to appear almost to constitute the thorax in itself. The abdomen usually consists of only six or seven segments; the remainder of the nine which properly form this part being consolidated in the last.

Although the characters already mentioned are applicable to by far the greatest number of insects included in this order, nearly all of them are subject to exceptions.

Thus, there are some species in which the organs of flight are altogether wanting, as in the female of the glow-worm; others which have elytra, but no wings; others, again, in which the elytra adhere together along the suture; others, in which they overlap; others, in which they do not meet; and others, in which the wings are longitudinally folded. It is well for the student to be aware that such exceptions exist in almost every large natural group, however definite its characters may generally be. In none of these instances is there an exception as to more than one or two of the characters; the remainder conform to the usual type. The most universal is that of the metamorphosis, which, being *complete*, distinguishes this order from others approaching it in the structure of the mouth or in the character of the wings.

The *larvæ* are worm-like in their aspect; the head is usually horny, and the rest of the body soft. There is generally a pair of short jointed legs attached to each of the three first segments, representing those of the perfect insect. Those which possess legs are usually active in their habits; but there are others which, leading a retired life, and being born in the midst of their food (such as the nut weevil), are destitute of legs. The larvæ of the carnivorous species have in general the most robust legs; and in some of the herbivorous species these are replaced by fleshy prominences, or pro-legs. A pair of these



Rose-beetle, in its different shapes.

generally exists on the last segment of the abdomen. Previously to undergoing its change, the larva often forms a case for itself of bits of earth or chips of wood, united by silken threads or gluey matter. The *pupa* or chrysalis is inactive, sometimes even for years, and takes no nourishment; but the form of the future beetle is plainly perceived, the different parts being encased in distinct sheaths.

There is much difficulty in forming a simple natural classification of this immense tribe, on account of the great number of distinct species it includes, and their strong general resemblance to one another. Hence it is often necessary to resort to characters of great minuteness as the groundwork of the system; and it sometimes happens that, by the adoption of such a plan, tribes which are in reality closely allied in general structure, are placed in different groups, and others are brought together which are generally dissimilar. No better system has yet been proposed, however, than that of Latreille, who took as the basis of his classification the number of joints in the *tarsi*, or divisions of the foot. He thus formed the four following sections:—

1. PENTAMERA (or five parted), in which the tarsi of all the feet are five-jointed, the fourth being of ordinary size.

2. HETEROMERA (or differently-parted), in which the four anterior tarsi are five-jointed, and the two posterior four-jointed.

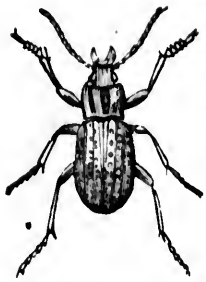
3. TETRAMERA (or four parted), in which all the tarsi have four distinct joints. It has lately been observed, however, that the fifth joint exists in these, although it is very minute, and concealed in one of the others.

4. TRIMERA (or three parted), in which only three ordinary-sized joints exist in the tarsi—a fourth of small size, however, being also present. Hence these two last sections may be more correctly denominated Pseudo-Tetramera and Pseudo-Trimera.

Each of these sections contains several families, of which the most important will now be noticed.

Section I. PENTAMERA.—1. The first family of this section is composed of Beetles exclusively carnivorous, hunting after and devouring other insects, and carnivorous even in the larva state. These *Carnivora* are characterized by the possession of six palpi, and by the termination of the jaws in a sort of claw or hook. Some of them are aquatic; others terrestrial. In many species there are no wings under the elytra. The terrestrial carnivora have legs fit only for running; their body is elongated, and their eyes are prominent.

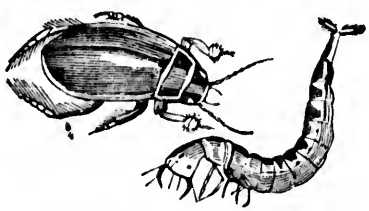
To this division belongs the tribe of *Carabidæ*, which is of very great extent, above two thousand species



Carabus Clathratus.

having been brought together by a single collector. Their bodies are of very firm consistence, whereby they are enabled to creep under stones, and through fissures, and are also prevented from being injured by the insects they attack. They prowl about on the surface of the ground, under stones, &c., beneath the bark of trees, or in the moss growing at their roots, in search of their insect prey, which principally consists of the herbivorous species. Some of them are nocturnal in their habits, feeding upon Cockchafers and other species of herbivorous beetles that fly abroad by night. The habits of the family are not exclusively carnivorous, however, for some species generally found in corn-fields are clearly ascertained to feed upon growing grain. Many larger species of this tribe are provided with a very curious means of defence; being enabled to exhale a very fœtid odour, and to discharge from the abdomen, to a considerable distance, an acrid fluid capable of producing considerable irritation. In the *bruchinus*, this fluid is so highly volatile, that, immediately on coming in contact with the air, it becomes a bluish vapour of very pungent scent, and makes a sort of explosion; hence the species possessed of this power have been termed Bombardier Beetles. They mostly live in societies.

The *aquatic* Carnivora form a tribe far less numerous than the terrestrial species, and are characterized by the peculiar modification of the lungs, which adapts them for swimming, these members being flattened and fringed with bristles, so as to serve as oars. They pass their larva and perfect states in water; quitting it, however, in order to undergo their metamorphosis into pupæ. The larvæ have the body long and narrow, with a strong head armed with powerful mandibles, and they are of very active carnivorous habits. They breathe by organs adapted for aquatic respiration, but the perfect insect can only breathe air, and it is obliged to come to the surface occasionally for that purpose. The *dytiscus*, the principal genus of this tribe, is common in fresh and placid



Dytiscus Marginalis—Larva and Imago.

waters, such as lakes, pools, or ditches. Its larva feeds upon other aquatic larvæ, such as those of dragon-flies, gnats, &c., and moves quickly through the water, striking it by its expanded tail. The pupæ may be found buried in the adjoining banks.

2. The next family is that of Brachelytra, which possess but four palpi, and are distinguished, as their name imports, by the shortness of the wing-cases. The family consists of only one genus, *Staphylinus*, of which one of the largest species is known by the name of devil's coach-horse, and is frequently to be seen running about garden walks. These insects run and fly with equal agility They are very voracious, but do not feed upon living prey, deriving their nutriment from dead and decaying animal matters, especially fungi, &c., in which they chiefly reside. They are also found in profusion under heaps of putrescent plants. They all possess the faculty of emitting a powerful odour, which seems to serve as a means of defence; and this is, in some instances, of peculiarly fœtid character. The larvæ feed on the same substances, and frequent the same situations, as the perfect insect. This group leads, in many respects, towards the Earwig tribe, with which the next order commences.

3. The family Serricornes is distinguished by the toothed or serrated form of the antennæ. Like the last, it possesses four palpi; but the elytra completely cover the body. Some of this family, having the body of solid consistence and oval in form, have the head buried, as it were, in the thorax, which advances on its two sides nearly as far as the mouth. In this way are formed the *Buprestis*, distinguished for the splendour of its colours, many of its species having spots of golden hue upon an emerald ground, whilst in others azure glitters upon the gold. These brilliant species belong to tropical climates, which these insects appear especially formed to inhabit, our native species flying with the greatest activity in warm weather. They live among trees; and if an effort be made to seize them, they counterfeit death, and fall to the ground. The beetles belonging to the allied genus *Elater* are commonly called skip-jacks; for, when laid on their backs, being unable to raise themselves on account of the shortness of their feet, they spring perpendicularly in the air, so as to alight upon their feet. This is effected by a violent backward blow of the head against the surface on which they are lying. The larva of an English species is known to the farmer as the wire-worm, which does much injury by devouring the roots of the corn. A species of elater inhabiting the West Indies and South America, has two brilliantly luminous spots upon the front of the thorax; and a portion of its abdomen which is uncovered during flight is also illuminated.

Another interesting genus of this family is the *Lampyris*, to which belong the glow-worm of this country, and some of the fire-flies of warmer regions. The body of these insects is very soft, especially the abdomen; and it is from the two or three last segments of this part of the body, that the phosphorescent light for which they are so remarkable is emitted. Its intensity is evidently dependent in a great degree upon the state of the animal; if the insect be irritated it is increased, but if its powers are depressed or exhausted it is lessened. It seems to be sometimes withdrawn simply at the will of the animal. In the glow-worm (*L. noctiluca*) it is only the female that is luminous; and she is destitute of wings and elytra, which the male possesses. They are only active by night; and as the male is known to be attracted, like moths, by lights in houses, it is probable that the phosphorescence of the female is given for the purpose of signalizing her position to him. In most of the tropical species, both sexes are furnished with wings.

4. The next family of Pentamerous Coleoptera is that of Clavicornes, characterized by the club-shaped form of the extremities of the antennæ. These are partly terrestrial and partly aquatic; they feed for the most part on animal matter, at least in the larva state. The terrestrial ones seem to prefer substances which are in a state of decay; they creep slowly, and are mostly of a dark colour—black or bronzed. One of the most interesting genera is the *Necrophorus*, or burying-beetle, so named from its habit of excavating the ground beneath the dead bodies of small quadrupeds, such as mice or moles; when they have interred the carcass, they deposit their eggs in it, and the larvæ when hatched feed upon the flesh.

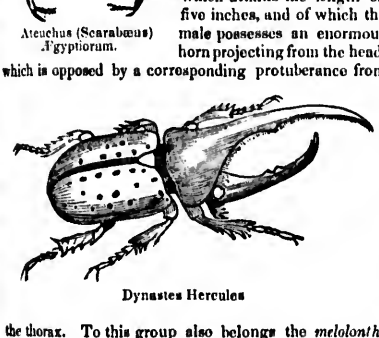
5. The Palpicornes also possess antennæ with a

club-like termination; but these are never longer, and usually shorter, than one of the pairs of palpi. Nearly all of these are aquatic, and have their legs formed for swimming. The most remarkable genus is the *Hydropaulus*, of which a large species, *H. piceus*, an inch and a half long, oval, of a brown-black colour, and highly polished, is common in the ponds and ditches of this country. It swims and flies well, but walks badly. The eggs are laid in a sort of cocoon spun by the female and coated with a gummy matter which is impervious to the water on which it floats. The larvæ, which have a worm-like body, with six feet, the head armed with strong mandibles, are very voracious, feeding upon tadpoles and the young fry in fish-ponds, and upon small fresh-water Mollusca.

6. The last family of the Pentamerous section, the Lamellicornes, is of very great extent, and one of the most striking of the whole Beetle tribe, in respect to the size of the body, and the variety in the form of the head and thorax in the different sexes; and often, also, in those species which in their perfect state live upon vegetable substances, in respect to the brilliancy of the metallic colours with which they are ornamented. But the majority of the other species, which subsist on decomposing vegetable matter, are of an uniform brown or black colour; though some are not inferior in brilliancy to the preceding. All have wings, and they crawl but slowly along the ground. None of them are aquatic. Their food consists of dung, manure, tan, and particularly (in some species) of the roots of vegetables; whence these insects, especially in their larva state, often occasion great loss to the cultivator. This family receives its name from the peculiar conformation of the antennæ, which terminate in a mass formed of the three last joints; these are flattened into plates or lamellæ; and sometimes arranged like a fan or the leaves of a book, sometimes in the manner of a comb, and sometimes enclosing each other. The family is distributed into two principal sections, the *Scarabæi* and the *Lucani*.

Of the *Scarabæi*, one subdivision, including the sacred beetle of the Egyptians, feed principally upon the excrements of various animals, and they enclose their eggs in balls of the same (whence they have been called Pilularii), which they roll along with their hind feet (several often being in company), until they reach the hole in which they are to be deposited. A most remarkably formed species is the *dynastes hercules*, a native of Brazil, which attains the length of five inches, and of which the male possesses an enormous horn projecting from the head, which is opposed by a corresponding protuberance from the thorax. To this group also belongs the *melolontha vulgaris*, or common cockchafer, which is most destructive to vegetation both in its larva and perfect condition, feeding on the roots in the one case and on the leaves and young shoots in the other. The larva lives for three or four years beneath the ground, becoming lethargic in winter but actively voracious in summer. Their excessive multiplication is usually prevented by birds; but if these be kept away, they increase very rapidly, and become a complete pest to the cultivator. The perfect insect sometimes makes its appearance in such swarms as to devastate an entire forest.

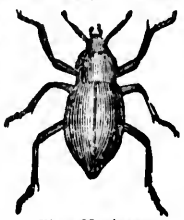
Ateuchus (Scarabæus) Egyptiorum.



Dynastes Hercules

The *Lucani* or *Stag-Beetles* derive their common name from the peculiar form of the mandibles, which are very large, curved, and toothed, like stag-horns. The *L. cervus* is one of the largest British insects, the males being two inches or more in length. This species flies about in the evening in the middle of the summer, especially round the oaks, upon the wood of which the larva feeds, remaining in that state for several years before undergoing its final transformation. Some of the exotic species of this group are very large and splendidly coloured.

Section II. Heteromera.—The Coleoptera of the second section entirely feed on vegetable substances; they are all terrestrial, and most of them frequent dark places. In the first family, the Melasoma, the body is of an ashy-brown or black colour, and for the most part the wings are absent, the elytra being united along the suture. They live for the most part in the ground, beneath stones, or in the sand—often, also, in low and dark parts of buildings, such as cellars, stables, &c. This tribe of insects is very tenacious of life; individuals have been known to remain alive for six months without food, and stuck on a pin. To this family belong the *blaps mortisaga*, a beetle often found in dark and dirty places about houses; and the *tenebrio molitor*, of which the larva is known under the name of the meal-worm, living in corn and flour, and the perfect insect frequents bakehouses, corn-mills, &c., where it may often be found in the evening.



Blaps Mortisaga.

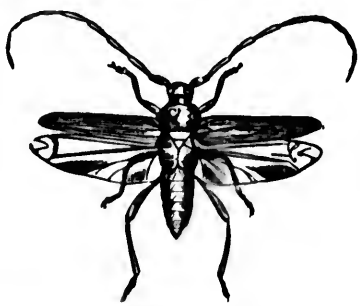
In the family *Trachelides* the head is triangular or heart-shaped, and carried on a kind of neck, which separates it from the thorax. The body is soft, the elytra being flexible, and sometimes very short. The majority live in the perfect state upon different vegetables, devouring the leaves or sucking the honey of the flowers. Many, when seized, depress the head and contract the feet, as if they were dead. Their colours are often very brilliant. This is well seen in the *cantharis vesicatoria* or blistering-fly, which is of a shining green metallic hue; this insect is most abundant in Spain, but appears about midsummer in France, and is found most abundantly on the ash and lilac, of which it consumes the leaves. Its larva lives in the earth, and feeds upon the roots of vegetables.

Section III. Tetramera.—All the insects of this section are likewise vegetable-feeders. The perfect insect is found upon the flowers and leaves of plants; the larvæ are often produced in their interior; and, when thus hatched in the midst of their food, their legs are commonly very imperfect. Very often the true legs are almost entirely absent, and their places supplied by fleshy tubercles. The first family, that of Rhyncophoræ, or the *Weevil* tribe, is distinguished by the prolongation of the anterior part of the head into a kind of muzzle. The number of species in this family is very great, nearly 4000 have been reckoned. Many of them are extremely destructive; especially the *calandra granaria*, or corn-wevil, which commits great havoc in granaries. To this tribe belongs one of the most splendid of all

beetles, the *curculio imperialis*, well known as the diamond beetle, a native of South America, in some parts of which it abounds. There are small species belonging to our own climate, which are scarcely less brilliant when magnified in a good light.

The second family of the Tetramerous Coleoptera has received the name of Xylophagi (Wood-eaters) on account of the peculiar habits of the beetles composing it. They usually live in wood, which their larvæ pierce in every direction; and, when abundant in forests, especially those of pines and firs, they destroy the trees in a few years, and sometimes in enormous numbers. They are destitute of the prolonged muzzle of the last order, and have short antennæ, thickened towards the tips. One of the most important species is the *bostrichus typographus*, so named from the figure of its burrows, which has at different times ravaged the forests of Germany. It devours the soft wood beneath the bark, which is most essential to the vegetative processes, both in the larva and perfect state, and thus causes the death of the tree. It was reckoned that a million and a half of pines were killed by this species alone in the Hartz forest, in 1783; and that as many as 80,000 insects were ordinarily engaged in the destruction of each tree.

The beetles of the family *Longicornes* are distinguished by the great development of the antennæ, which are always at least as long as the body, and often longer. The larvæ mostly reside in the interior of trees or under the bark, and are destitute of feet, or have them very small. They are furnished with robust mandibles, and do much injury to trees, especially those of large size, by burrowing deeply into them. They are vegetable-feeders in their perfect state also, and do great injury to plants, some attacking the leaves and others the roots. Many of them produce a slight creaking sound, by the friction of the joint which unites the thorax to the abdomen. Many of these are brilliantly coloured, especially the tropical species. Some of them are remarkable for exhaling an agreeable musky odour. This is the case with an English species, the *callichroma moschata*, which is about an inch long, entirely green or shaded with blue, and is very common upon willows.



Callichroma Moschata.

Section IV. Trimera.—The beetles of this last section are mostly of small size, and they are not very common. Their habits are various, a portion feeding upon fungi, and the remainder chiefly upon aphides. To the latter section belongs the genus *coccinella*, of which several species are known in this country under the name of lady-birds or lady-cows. They sometimes appear in great profusion, and have created much alarm. It is erroneous to suppose, however, that they do any injury to vegetation; for, on the contrary, they are of great benefit to plants, by feeding on the aphides which infest them; and this they do both in the larva and perfect states.

Order II.—Orthoptera.

The order Orthoptera comprehends all insects that have the mouth armed with jaws fitted for mastication, and two pairs of wings; of which the anterior encase the others, the posterior being membranous, and folding longitudinally during repose. In many respects they resemble the Coleoptera; and they are closely connected with that order by the Forficulidæ, or *Earwig* tribe, which partake of the characters of both. But they differ from the Beetles in the softer covering of their bodies; in the partially membranous character of the anterior pair of wings, which seem intermediate between the horny elytra of Beetles and the membranous wings of other insects, and which do not meet along the back when closed; and in the fan-like manner in which the posterior wings are folded up beneath them, which is permitted by the straight direction of their veins. They differ also in their metamorphosis; for, while that of the Beetles is complete, that of the Orthoptera is only partially so; for the larva and pupa closely resemble the perfect insect in form, walking and feeding in the same manner, and differing in but little else than the absence of the wings and wing-covers, which are gradually developed in the latter.

This order comprises numerous well-known insects, often of large size and splendid colours; such as grasshoppers, locusts, walking-leaves, as well as cockroaches and earwigs. Some of the largest of known insects belong to it; a few species attaining a length of eight or nine inches, and an equal expansion of wings. Comparatively few of this order are inhabitants of temperate regions; it attains by far its greatest development, both in number, size, and colour, between the tropics. All the known Orthoptera are terrestrial, both in their perfect and two previous states. Some are purely carnivorous, and others are adapted to a mixed diet—the Cockroaches, for example, being capable of feeding on almost any organized matter, while the great majority feed upon plants. Hence, from their large size, and the quantity which each individual can devour, they are among the most destructive of all the insect tribes, when they appear in large numbers. This is particularly the case with the locusts in warm countries, the ravages of which not unfrequently cause famine and pestilence, both among men and beasts.

The Orthoptera are divided into two principal families. In the first, that of Cursoria, the legs are all alike, and adapted for running. They have generally the wing-covers and wings resting horizontally on the body. In the second, the *Saltatoria*, the thighs of the hind legs are much larger than the rest, by which they obtain great powers of leaping. In some of these, the wings meet at an angle when folded, like the two sides of a roof. The males have the power of making a sharp creaking noise, which is very loud in some species.

1. The Cursoria contain three well-known forms—the *Earwig*, *Cockroach*, and *Mantis*. Of these, the first approaches more closely than the rest to the Coleoptera; but have a peculiar character of their own in the forceps with which the posterior part of the body is provided; these are used as weapons of offence and defence. The *Blattæ*, or Cockroaches, are intermediate between them and other Orthoptera. These well-known insects are now pretty generally diffused over temperate climates, although most of the species are believed to have been originally natives of tropical regions. Their wings are small in proportion to the weight of their bodies; and in cold climates are seldom enough developed to lift them from the ground. The females are generally almost destitute of these organs.

The Mantidæ are purely carnivorous insects, of which none are natives of this country. They differ much from the Blattæ in the form of the body; which,

instead of being flattened and ova., is narrow and elongated. The first pair of legs is enormously enlarged, and forms a very powerful organ of attack. They frequent trees and plants; and the forms and colours of their wings and bodies are often so adapted to those of the leaves and twigs which surround them, as to give them remarkable power of eluding observation. Hence these have been called walking-leaves. One species, the *mantis religiosa*, is regarded by the natives of the countries it inhabits with superstitious reverence, on account of its occasionally assuming the attitude of prayer. This is, however, the position in which it lies in wait for its prey; the front of the thorax being elevated, and the two fore-legs held up together, like a pair of arms, prepared to seize any animal that may fall within their reach. They are extremely voracious insects; and, if kept together without food, will fight, the victor devouring its conquered adversary.

Mantis Religiosa.

2. The family SALTATORIA consists of numerous species allied to the well-known *Crickets*, *Grasshoppers*, *Locusts*, &c. Besides the peculiarities already mentioned, they are remarkable for the deposition of their eggs in the ground, which is generally accomplished by means of a long horny ovipositor. The mode in which the sound is produced varies in different species.

The first division of the Saltatoria, termed *Achetidæ*, includes the species known as *Crickets*. These are essentially inhabitants of the ground, in which many of them burrow; few have any power of active flight. The greater number of them, like the common house-cricket, are nocturnal.

The next subdivision of the Saltatoria, the *Gryllidæ*, is distinguished by the roof-like position of the wing-covers, when they are closed; they also possess very long thread-like antennæ. This group contains the *Grasshoppers* and their allies, which, although bearing a general resemblance to locusts, differ from them in the inferior robustness of the body and the delicacy and slenderness of the appendages.

The last section consists of the various species of migratory locusts, forming the tribe *Locustidæ*. These are formed for a more active life than the preceding, being able to leap much farther, and to sustain a longer flight. Their powers of devastation, also, are enormous; for they are produced in vast numbers, and live in societies, so as speedily to destroy the vegetation of the spot on which they have settled. Thence they take their flight in great swarms to adjoining districts; and so great is the number of which those swarms consist, that it is not speaking figuratively to say that the sky is darkened by their passage.

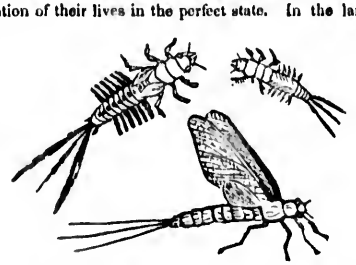
Order III.—Neuroptera.

The Neuroptera resemble the Coleoptera and Orthoptera in the structure of the mouth, but differ from them in the conformation of the wings. The anterior as well as the posterior pair are here membranous and transparent. In both, the veins form a very beautiful and minute network, subdividing and uniting again, so as to divide the whole surface into a large number of cells, which very much exceed in number those of the wings of any other tribe of insects. The posterior wings are usually as large as the superior, or sometimes even larger: if narrower, they are generally longer.

The body of the insects of this tribe, which contains the well-known *Dragon-flies*, *May-flies*, *Ant-lions*, and *White Ants* or *Termites*, is generally prolonged, and destitute of any very hard integument. They are of intermediate size, none exceeding in dimensions the largest dragon-flies of this country, and none exhibiting the minuteness of some Hymenoptera and Coleoptera. They differ in the character of their metamorphosis as well as in their adult structure; for in some the metamorphosis is complete, the larva undergoing a marked change of form; in others there is not much difference, except in the absence of wings, between the larva and the perfect insect. By these differences the order may be subdivided into two groups, in the first of which the pupa is active, while in the second it is quiescent, except just before the assumption of the perfect state. The first of these groups may be farther divided into those which have terrestrial larvæ, such as the *Termitidæ*, and those which are aquatic in their preparatory states, such as the *Libellulidæ*, or Dragon-flies, and the *Ephemeræ*, or Day-flies. These pass the first two stages of their lives in water, respiring by means of peculiar organs placed at the sides or extremity of the abdomen. In other respects their larvæ and pupæ nearly resemble the perfect insect. They creep out of the water to undergo the final metamorphosis.

1. The LIBELLULIDÆ are well-known insects, being easily distinguished by the slender form of their bodies, their varied colours, their large gauze-like wings, and the rapidity of flight with which they pursue other insects upon which they feed. They have a large head, of rounded form, furnished at its sides with two very large eyes. The eggs are deposited upon aquatic plants, and the larvæ are produced in water, in which they remain until their last metamorphosis.

2. The EPHEMERIDÆ derive their name from the short duration of their lives in the perfect state. In the larva

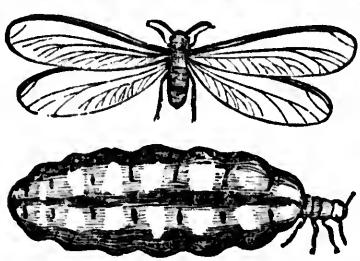


Ephemera Vulgata.—Larva, Pupa, and Imago.

condition they exist for two or three years; in this and the pupa state they reside in the water, burrowing in the banks. In this condition, the abdomen is furnished on each side with a row of plates, which appear to serve as gills for respiration, and also to act as paddles. The pupa differs from the larva in possessing rudiments of wings, which are covered over with scales. At the moment of their last change they quit the water, and appear, after casting their skin, in a new form; but, by a singular exception to what is elsewhere observed, they have to undergo another moult before they are fit for propagation. They generally appear at sunset in the fine days of summer and autumn, along the margin of

the streams, &c., in which they have been developed. They take no food after their final change; and as the propagation of the race is then their only object, they die almost as soon as it has been performed, often in a few hours after their exit from the water.

3. The TERMITIDÆ, or White Ants, are terrestrial, active, and carnivorous or omnivorous, in all their stages. In several points of their structure they approach the Orthoptera; whilst in their habit of living in societies they resemble the Hymenoptera. Unlike the social tribes among the former, however, the neuters or sexless individuals in these communities officiate only as soldiers; and those which are here denominated workers are in reality the larvæ, which closely resemble the perfect insect, except in the absence of wings. These insects commit the most extraordinary ravages, the numbers in each colony being almost incalculable, and their voracity extreme. Their nests are sometimes concealed below the surface of the earth, or in the interior of trees, timbers, &c.; and through these they bore galleries in such a manner, that, though the outer surface is left untouched, they fall to pieces on the slightest violence. Sometimes the nests are elevated to several feet above the surface of the ground, and have a pyramidal roof. When arrived at their perfect state, the Termites quit their habitation, and fly abroad during the evening or night in great numbers; they lose their wings before the morning, and some of them, falling to the ground, become the prey of birds, reptiles, &c. The females, however, are sought by the workers, who imprison them in royal chambers (as they have been termed) in the centre of the nest.



Queen in the winged state, and when filled with eggs.

The abdomen subsequently attains an enormous size from the quantity of eggs it contains; and these, when laid, are carefully tended by the workers and defended by the soldiers.

4. Of the division of Neuroptera, in which a more complete metamorphosis occurs, the family of MYRMELEONIDÆ is one of the most remarkable. Their larvæ have received, from their peculiar habits, the name of *ant-lions*; they excavate conical pit-falls in fine sand, and bury themselves at the bottom, their long mandibles only appearing above the surface; and by these any luckless insect that happens to fall down the hole is immediately seized and killed.

The remaining families of this order need not be here particularized.

Order IV.—Hymenoptera.

In the membranous character of their four wings, the insects of this order resemble the Neuroptera; but they cannot well be mistaken for them. The anterior wings are usually much larger than the posterior; the veins or nervures are much fewer in number than in the Neuroptera, and do not form a close network by their ramifications, as in that order. In some of the minute species the wings are almost, or even entirely, destitute of nerves. Another character furnished by the wings consists in the connection of the anterior and posterior during flight, by means of a series of minute hooks along the front edge of the latter, which catch the hinder margin of the former, so as to produce one continuous margin on each side.

The principal character of this order, however, is derived from the structure of the mouth; for, although considered as mandibulate insects, the Hymenoptera are much better fitted for imbibing their nourishment by suction than for obtaining it by mastication, their maxillæ being much prolonged and channelled, and even uniting at their base into a tube, so as to form a kind of proboscis. This is well seen in the bee. The Hymenoptera are also peculiarly distinguished by a prolongation of the last segment of the body in the females, into an organ which is in one division of the order a *sting*, and in the other an *ovipositor*, or instrument for depositing the eggs, usually possessing the power of boring a hollow for their reception.

The Hymenoptera are further remarkable for the great development of their instinctive faculties and of their locomotive powers. It is in this order that we find the most remarkable examples of contrivance, and skilful adaptation of means to ends; but this adaptation results, it would appear, not from an exercise of *intelligence* on the part of the animals themselves (as in man and the higher Vertebrata), but from their blindly following out a plan laid down for them by the Almighty Designer. This inference may be deduced from the *invariability* of the operations performed by different individuals among the same species, so that a history of the life of one is equally applicable to all. The adjustment of instinctive actions to each other is nowhere more remarkable than in the case of the *social* insects, which are chiefly restricted to this order. The Bees, the Wasps, the Ants, the Saw-Flies, the Ichneumons, and the Gall-Flies, have attracted the attention of the observer of nature from the earliest period.

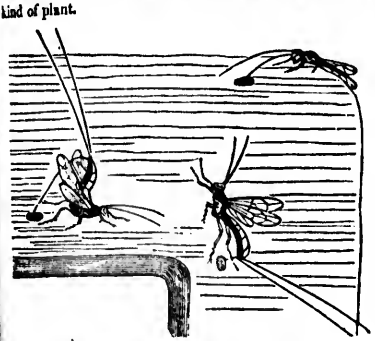
The insects of this order undergo a complete metamorphosis, the larvæ being amongst the most imperfect of those of any tribe. In the greater proportion of the order they are destitute of feet, and resemble little worms. These are dependent upon the instinctive care of the parent for support; which is either provided for by the deposition of the eggs in situations where the future grub will be certain of an ample supply of food, or by the active exertions of the parents, which convey to the young the food they have themselves collected for them, or by similar exertions on the part of a race destitute of a peculiar sex (hence termed *neuters*), on whom this charge more especially devolves. When arrived at their full growth, and after undergoing several previous moultings, the larvæ are transformed into inactive pupæ, in which all the limbs of the future insect are visible, encased in distinct sheaths, and folded on the under surface of the thorax. During this part of their existence they take no food. In their perfect state, these insects, for the most part, take but little nourishment; and this almost exclusively consists of the nectar of flowers. Many of them, however, such as the Wasps, attack and destroy other insects; but these are often destined, not for their own support, but for the nourishment of the young. This order is of considerable extent, being inferior only to the Coleoptera; and it has been estimated as containing one-fourth of the whole insect population. It attains its greatest development in warm climates; for of the numerous species inhabiting this country, the greater part are of very small size. None of the species, however, attain any great dimensions very few exceeding or attaining two inches in length, or three in the expansion of the wings. The duration of their lives, from the hatching of the egg to the final change, is believed never to exceed a year.

This order may be primarily divided into two sections, the TEREBRANTIA, in which the female is furnished with a saw or borer for the deposition of the eggs; and

the ACULEATA, in which the abdomen of the females (and neuters) is armed with a sting connected with a poison reservoir. In the former, the antennæ vary considerably in the number of their joints; in the latter, there are always twelve in the female and thirteen in the male. The Terebrantia may be again divided into the PHYTIPHAGA, in which the larvæ feed upon vegetable matter; and the ENTOMOPHAGA, in which they in general feed parasitically upon living insects. The Aculeata are in like manner divided into the PRÆDONES, or predaceous tribes, which do not collect pollen, and in which the larvæ feed upon other insects stored up for them, or upon fluids provided by the neuters; and the MELLIFERA, in which the larvæ feed upon honey or pollen-paste stored up for them. The adult forms of all these are distinguished by certain technical peculiarities, which it would be tedious here to specify.

Section I. TEREBRANTIA.—The principal family of the Phytophagous Terebrantia is that of TENTHREDINIDÆ, or *Saw-Flies*, so named from the saw-like character and action of the ovipositor. With this instrument, they make a succession of small holes in the branches or other parts of trees, in each of which an egg and a drop of frothy fluid are discharged, the latter of which closes the hole.

The family of CYNIPIDÆ, or *Gall-Flies*, placed on account of its structure in the Entomophagous division of the Terebrantia, is nearly allied in habits to some among the last group. The ovipositor does not seem capable of boring a hole by itself; but, being armed with teeth at its extremity, it can enlarge slits already existing, for the deposition of its eggs. The fluid accumulating in the wounded parts forms excrescences or tumours, which are commonly termed *galls*, *nut-galls*, or *gall-apples*. Their form and solidity vary according to the parts of the plants which have been attacked, and the species of the insect, of which each is restricted to a particular kind of plant.



Pimpla Manifestor engaged in oviposition.

The family of ICHNEUMONIDÆ may be regarded as peculiarly characteristic of the entomophagous division. The female deposits her eggs, by means of her sharp-pointed ovipositor, only in the bodies of other insects, chiefly the larvæ of caterpillars, on which the young may feed when hatched. Some of them have a very long ovipositor, which is used to insert the eggs into the bodies of caterpillars that live beneath the bark, or in the crevices of trees; whilst those which have this instrument short, place their eggs in or upon the bodies of caterpillars or pupæ to which they can obtain easier access. They do not confine themselves to these situations, however; but employ for the same purpose the eggs or pupæ, still preferring the larvæ when they can find them. The young Ichneumons, when hatched as footless grubs, sometimes in considerable numbers in the body of one larva, devour only the fatty parts, which are not absolutely necessary to life; but when ready to undergo their metamorphosis, they either pierce through the skin and escape, or else kill their victim, and perform their changes within its body.

Section II. ACULEATA.—The Hymenoptera of this division may usually be distinguished from the Terebrantia by the mode in which the abdomen is united to the thorax. In the *Borers*, it is in general closely jointed to it—a structure which is evidently necessary for providing the ovipositor with the requisite strength; whilst in the stinging Hymenoptera, it is usually connected by means of a peduncle or footstalk, which is often, as in some of the Wasp tribe, of great length and extremely slender. The predaceous division of this section contains several families, of which the most important only will be noticed in detail.

The CRABRONIDÆ, LARRIDÆ, BEMBECIDÆ, SPHEGIDÆ, SCOLIIDÆ, and MUTILLIDÆ, may all be considered under one general description. They form a group which may be termed that of *Fossores* or Diggers, from their peculiar habits; and they are commonly known as *Sand* and *Wood Wasps*. They are solitary in their mode of life, and consequently no neuters exist among them. In general, the females excavate cells in the ground, or in posts, timbers, &c., in which they deposit, together with their eggs, various larvæ, or perfect insects, and (in some species) even spiders, which are destined for the support of their progeny when hatched. Occasionally the insects composing this store are first stung to death; but sometimes they are only slightly stung, and are finally killed by the larvæ when hatched. In this manner they are rendered powerless; whilst their bodies are prevented from decomposing. The perfect insects are generally very active, and fond of the nectar of flowers, especially those of the umbelliferous tribe. They delight in the hottest sunshine, flying and running over sandbanks exposed to the mid-day sun, and keeping their wings in constant agitation; some of the tropical species are among the largest of the order, and their sting is very severe. The sand-burrowers excavate their nests by means of powerful brushes with which their legs are furnished; while the wood-burrowers use for this purpose their strong bread mandibles, which are provided with tooth-like projections.

The next family, that of FORMICIDÆ, is composed of the well-known and singularly interesting tribes of Ants, which are distinguished from all the Hymenoptera previously described, by their habit of residing under ground in numerous societies, and by the existence of *neuters* among them, by which class the labours of the community are chiefly performed. The males and females, which constitute but a small proportion of each community, are alone furnished with wings; the former are the smallest. The neuters are somewhat smaller than the males, and mostly resemble the females in conformation; but the thorax is much narrower and contracted in the middle, not having to give attachment to wings. The nests of Ants are differently constructed in the different species, but in all are very curiously and regularly arranged. The males and females leave them as soon as they have acquired their wings, and go forth together into the air. The males soon die, without entering their former abode; of the females some return, and deposit their eggs in the original nest, whilst others go off to a distance and become the foundresses of new colonies. They lose their wings at this period, sometimes stripping them off with their own feet, in other instances being deprived of them by the neuters.

The neuters not only construct the nest, but most carefully tend the young grubs, supplying them with food, moving them on fine days to the outer surface of the nest to give them heat, and carrying them back again at the approach of night or bad weather, and defending them when attacked by enemies. The winged

ants having all perished at the commencement of the cold weather, the neuters only survive the winter. Some of the neuters are larger and rather differently formed from the rest, and appear to be the chief defenders or soldiers of the community. A most remarkable instinct is observed in some species, that of making war upon colonies of smaller ants, carrying captive the larvæ and pupæ of the neuters, and keeping them in slavery when hatched. Ants are well known to be extremely fond of saccharine matters, and they seem greatly to relish the fluid which exudes from the bodies of Aphides and Coccidæ. Some species of ants collect Aphides, and keep them, as it were, in pastures, which they connect with their nests by means of galleries excavated along the stems and branches of trees; and they protect the eggs of these insects in their own nests, especially in bad seasons.

The foregoing are a few of the chief facts relating to the economy of this tribe, on which many volumes have been written; and it may be safely asserted that there is none whose habits are calculated to afford more of interest and entertainment to those who seek acquaintance with them, either by the recorded observations of others or by their own.

The family of Vespidæ, or *Wasps*, is distinguished from the other Hymenoptera by their wings being folded when at rest, throughout their entire length. In general these insects are social, the communities, however, being small. In such cases, there are neuters which are not destitute of wings. There are also some solitary species (whose habits resemble those of the Fossores, whilst their general structure is more conformable to that of the Social Wasps) among whom no neuters exist. The nests of the solitary species are formed of earth; they are sometimes concealed in holes of walls, in the earth, or old wood, and sometimes they are fixed to plants. The parents store them with caterpillars or spiders, which they have previously wounded with their stings. These nests contain a succession of cells, in each of which a single egg is deposited.

The best known of the Social Wasps, such as the common species of this country, construct their nests with bits of wood, bark, &c., which they separate with their jaws, and reduce to a pulp; and this, when expanded and dried, forms a paper-like substance. With this are built layers of hexagonal cells, one row being joined to the under side of another. The top row is attached, in some species, merely to the under side of a branch, or to the top of a slight hollow, by which it may be in some degree protected; but in others the whole comb is enveloped in a covering, formed by several layers of the same paper-like substance, with one or more apertures. Wasps feed, in their perfect state, upon insects, meat, fruit, &c., and nourish their young with the juices of these substances. A Brazilian species stores up an abundant provision of honey.

The Hymenoptera belonging to the *melliferous* or honey-collecting division of the Aculeata, are known by the peculiar conformation of the hind feet, of which the first joint is compressed and extended into the form of a square plate, and provided on its inside with brush-like tufts: these organs are employed for the purpose of collecting and carrying the pollen of flowers, which is employed for the nourishment of the young. All of these insects are commonly known by the name of Bees; but the tribe contains two families; in one of which all the species are solitary, and are of only two kinds—males and females; whilst the others mostly live in societies, but are chiefly distinguished from the former by certain peculiarities in the structure of the mouth.

Of the solitary Bees which construct nests for themselves, there are many curious varieties, some of which go under the names of Mason, Carpenter, and Upholsterer Bees, from the material with which they work—the first agglutinating bits of sand or gravel, the next excavating wood by means of their powerful jaws, and the last constructing their cells of portions of leaves. The habits of all of these may be studied in detail with extreme interest.

Of the social species there are two principal groups the Humble-Bees, or Wild-Bees, and the Hive-Bees. The common Humble-Bees of this country live in curious underground habitations, in societies usually of fifty or sixty, but sometimes of 200 or 300 individuals.

Queen-Bee.

Drone.

It is in the Hive-Bees that the arts of construction are exhibited in the most elaborate degree. Their societies consist of but one female, commonly termed the queen, several hundred males, which are known as drones, and about twenty thousand working bees or neuters. It is by the latter that all the labours of the hive, the construction of the combs, the collection of food, both honey for the adults and pollen for the larvæ, and the nourishment of the grubs, are performed. The accompanying figures exhibit the relative sizes and aspects of these three orders. The wax of which the comb is constructed is secreted by the insects themselves, in little scales, which work out from between the segments of the abdomen. These are taken up and kneaded by the jaws, and applied in the proper place. The drones are killed at the end of summer; but the queen and great part of the workers remain; and when, in the summer, they increase so much as to over-people the hive, colonies are sent forth with young queens, in search of another habitation.

Neuter Bee.

Order V.—Homoptera.

The insects contained in this order present many curious anomalies of structure and habit, and depart more widely from the general type than is the case in almost any other division of the class. Hence it is difficult to assign any general characters which shall include them all. It is in the structure of the mouth that there is the greatest agreement. This is adapted for suction, the tongue being elongated and channelled into a gutter, and being surrounded by delicate lancet-like organs which pierce the tissues of plants. All the insects of this group subsist on vegetable juices; and some of them, from the amount of damage they commit, are very injurious to the cultivator. Some of the females are furnished with an ovipositor, provided with several toothed saws; and with this they make incisions into the leaves or stems of plants, into which they introduce their eggs. The anterior pair of wings is usually similar to the posterior in consistence, both being composed of a firm membrane: that which chiefly distinguishes the Homoptera, however, from the Heteroptera, is, that the substance of the anterior pair, whatever be its nature, is the same throughout, and that, when folded, they are roof-like.

This order may be divided, like the Coleoptera, into sections, according to the number of joints in the tarsi. These sections are only three in number; in the first, Trimera, the tarsi are three-jointed; in the second,

DIMERA, they are but two-jointed; and in the third, MONOMERA, they have but one joint.

Section I. TRIMERA.—The three-jointed division of the Homoptera includes three families, of which two, the CICADIDÆ and FULGORIDÆ, are very interesting. The CICADIDÆ are the largest of the order; one species measuring between six and seven inches in the expanse of its wings. Their peculiar characteristic consists in their musical powers. By a peculiar apparatus situated beneath the abdomen, they are enabled to produce a continued sound, nearly monotonous, but of considerable power. In some species the sound is so loud and shrill as to be heard at the distance of a mile.

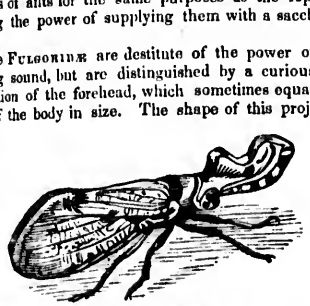
The family of CERCOPIDÆ, also belonging to this section, consists of insects of small size, but which are remarkable for the grotesqueness of the forms which many of them assume; some inhabit this country, and are known by the name of cuckoo-spits and frog-hoppers; but the most singular species are confined to the tropics. The curious appendages represented in the

Bocydium Globulare.

Bocydium Cruciatum.

accompanying figures of a Brazilian species, result from an extraordinary development of the first segment of the thorax. The insects of this family are often beautifully varied in their colours; they are constantly found amongst plants, and on trees, upon the juice of which they subsist, in all their stages. Of the best-known species of this country, the larva and pupa invest themselves with a frothy secretion, whence the vulgar name is derived. Some of this tribe are employed by certain species of ants for the same purposes as the Aphides, having the power of supplying them with a saccharine fluid.

The FULGORIDÆ are destitute of the power of producing sound, but are distinguished by a curious prolongation of the forehead, which sometimes equals the rest of the body in size. The shape of this projection



Fulgora Laternaria.

differs extremely in the various species, which are very numerous. It is in it that the luminous property of the *lantern-fly* is said to exist; but the luminosity of this insect, of which one species is a native of Brazil and Guiana, whilst another inhabits China, is doubted by many naturalists. If it really exists, it probably only shows itself at particular seasons.

Section II. DIMERA.—Of the Dimerous Homoptera, the most remarkable family is that of APHIDÆ, commonly known as *Plant Lice*, which is extremely obnoxious on account of the injuries committed by its members against almost every kind of vegetable. The Aphides live in great numbers upon the surface of the plant, and suck the juices by means of their proboscis, from the young shoots, leaves, stems, and even roots. They thus greatly weaken its vigour, and often distort young shoots and leaves; some species cause little gall-like excrescences by the irritation they produce. From two horn-like processes at the posterior part of the body, a saccharine secretion exudes, of which ants are very fond; and it is either this fluid dropped on the adjacent leaves, or the extravasated sap flowing from the wounds made by the insects, which is known under the name of honey-dew. In many of the species of this family a large proportion of the individuals never acquire wings, in which case the pupa is not to be distinguished from the mature larva or imago states, whilst at certain parts of the year, other individuals of the same species and of both sexes acquire wings. The wingless Aphides, which may be seen in the spring and early summer, are all females capable of producing fertile eggs, and from these are reared the winged males and females which are seen later in the season. Their rapidity of production is enormous, nine generations having been obtained within three months. The young are sometimes produced alive, whilst in other cases (according to the season and other circumstances) eggs are deposited. Many of the *blights* so injurious to the gardener and the agriculturist, consist really of Aphides, although, from the minuteness of the insects themselves, they often escape observation.

Section III. MONOMERA.—The third section contains but one family, that of COCCIDÆ, sometimes called *Scale Insects*. These, although ordinarily of very small size, are amongst the most injurious to vegetation of any tribe. Their powers of propagation are excessive, and when they once gain possession of a plant or young tree, its death is almost certain, the minute size of the larvæ rendering it impossible to exterminate them. They furnish, however, some very important products. The bodies of many species are very deeply coloured through their whole substance, and yield dyes of great value, the richness of which seems to depend upon the nature of the plant on which they feed. The species employed by the ancients was a native of the Levant; but that which furnishes the *cochineal* so highly valued at the present time, was originally confined to Mexico, where it feeds on the cacti; it has, however, been introduced, along with its proper food, into Spain and Algiers, and also into the hot-houses of this country. About 800,000 lbs. weight of cochineal are annually brought to Europe, each pound of which contains about 70,000 insects. The lac of the East Indies, which is extensively used in the composition of varnishes, the making of sealing-wax, &c., is the product of another species of Coccus.

Order VI.—Heteroptera.

These insects bear a close general resemblance to those of the last order; as in them, the structure of the mouth, which is wholly adapted for suction, indicates that their nourishment consists solely of the juices of plants or animals; but they are at once known from them by the character of the anterior pair of wings, which are coriaceous at the base, and membranous towards their point, and which fold nearly horizontally, partly lapping over each other. By far the greater number of them feed upon the juices of plants, but some of them prey upon other and weaker insects, and a few species (of which the numbers, however, sometimes multiply to a great extent) suck the juices of larger animals. The majority of this order are found in tropical climates, and the species which inhabit these regions are mostly ornamented with a great variety of beautiful colours and markings, often vyeing with the most splendid of the Beetle tribes. Many species, however, are of aquatic habits, and they are all of an obscure black colour. Nearly all the terrestrial species have the power of emitting, when suddenly alarmed or touched, a powerful odour, which is of a pleasing character in some species, but in others (as the common bedbug) very disgusting

Others seem to eject a poisonous fluid into the wound they make for the purpose of suction. In some species the wings are altogether undeveloped, or the upper pair is wanting. The insects of this order continue active, and require food, during all the stages of their existence. They may be divided into two sections, distinguished by their residence—the Geocorisa, or Land Bugs, and the Hydrocorisa, or Water Bugs.

The first section contains a large number of families, nearly all of which bear a considerable resemblance to that which includes the common Bugs, the Cimicidæ. Some of the tropical species attain considerable size, being described as of the bulk of a cockchafer, and they are much dreaded by the inhabitants of the regions they infest. Many of the Geocorisa, however, are vegetable feeders, and it is among these that the most brilliant colours are exhibited. Some of them, belonging to the family Hydrometridæ, are distinguished by their power of moving on the surface of standing or running waters.

Of the true Water Bugs, there are two families only. The Notonectidæ live almost entirely in the water, where they feed upon other aquatic insects; these they seize by means of their fore legs, which are formed as claws. The two hinder pairs have a fringe of bristles along their edge, by which the surface with which they strike the water in swimming is greatly increased. Their general form is extremely well adapted for rapid progression in water; and, from the peculiar aspect of the body, they have received the name of *boat-flies*. The insects of this family swim on their backs, a peculiarity to which their name refers; and the arrangement of all their organs has reference to this position. When stationary at the surface of the water, as is much their custom in still hot weather, they very quickly obtain intelligence of the approach of danger, by means of their eyes, which are so placed as to be able to see both above and below; and then, by a single stroke of their paddles, which are ordinarily stretched out at full length, they descend out of sight. Their motions are very quick in the element they chiefly inhabit, while on land they are scarcely able to walk. They fly well. The larvæ and pupæ differ from the imago only in their smaller size, and in the deficiency of wings. The Notonectidæ carry down a supply of air for respiration beneath the wings. The Nepidæ are in most respects similar in structure and habits to the insects of the last family. Their motions, however, are much slower.

Order VII.—Lepidoptera.

The order Lepidoptera, characterized, as formerly stated, by the downy covering of the wings (which is composed of minute scales, arranged with great regularity upon the membrane itself), contains some of the most beautiful forms of the whole class, as well as some of the largest. The number of species it comprehends is probably as great as that of any other order except the Coleoptera, and may probably rank as about one-fifth or one-sixth of the whole class.

All the insects of this order belong to the well-known forms of *Butterflies* and *Moths;* and there is so much general resemblance among them, that the difficulty of classifying them is often considerable. The possession of scales upon the wings is not altogether peculiar to them; for they are found on the wings and bodies of other insects. But it is only in these that the wings are covered with such complete layers of them. The scales are generally of somewhat oval form, terminating at one end in a kind of stalk, by which they are attached to the membrane of the wing; and on this they are arranged in rows, overlapping each other, like tiles on a roof. They may be easily rubbed off with the finger; and the bare membrane is left, which is then seen to correspond with the wings of other insects. The number of scales covering the wings of the silk-worm has been estimated at about 400,000. It is entirely to the scales that the colours of the wings are due; and sometimes these are so brilliant, as to be almost painful to look upon, if a strong sunlight is reflected from the surface. In some species the wings are partially, or even almost entirely destitute of scales.

The Lepidoptera, in their perfect state, are formed to exist entirely upon fluid nutriment, which they suck up by means of a long trunk, which is usually coiled up spirally under the head. This trunk is not an organ altogether peculiar to them, however; for it is constructed out of the lower pair of jaws or *maxillæ*, which are very much prolonged; each is channelled on the side nearest the other, and furnished with very closely set teeth along its whole edge; when the edges are brought together, and the teeth lock into one another, a perfect tube is formed by the junction of the channels in the two, and through this canal these beautiful insects suck up the juices of flowers. All the other parts of the mouth usually possessed by insects, may be detected in that of the Lepidoptera, but in a different state of development. The antennæ are variable in size, and always composed of a great number of joints. The eyes are usually large, and contain a considerable number of facets.

The curious phenomena of the metamorphosis are presented to our notice more remarkably, perhaps, in this order than in any other. All the beings commonly known as *Caterpillars*, are the larvæ of Lepidoptera. They are produced from eggs of various forms and curious markings (sometimes almost resembling Echini), which have been deposited by the parent upon the leaves that are to serve as the food of the larvæ when hatched.

The three first segments of the body have each a pair of simple, short, and jointed feet, which are the rudiments of those of the perfect insect. Behind these are a variable number of temporary appendages, called pro-legs, which are thick, short, fleshy limbs, armed at their extremity with a great number of minute hooks, and furnished with powerful muscles. There are usually five pairs of these—four of them succeeding the true legs, and another arising from the last segment of the body. Those possessing pro-legs on nearly every segment, crawl upon all the feet at once, after the manner of the Myrapoda; but those which have only a small number of pro-legs, adopt a different method. They seize fast hold of the objects on which they are stationed with the six true legs at the fore part of the body, and then elevate the intermediate segments into an arch, until they bring the pro-legs behind close to the others; they then disengage the true feet, and retaining hold with the pro-legs, thrust the body to its full length, and then recommence the same manœuvre. These are called Loopers or Geometers. Many of them resemble, in their forms and colours, as well as in their mode of standing fixed for a great length of time by their hind legs only to twigs, and small pieces of stick.

The greater number of caterpillars are vegetable

Caterpillar and Chrysalis of the Magpie Moth.

feeders, and are mostly confined to the leaves; and the correspondence between the development of the leaves and flowers of plants on the one hand, with that of the caterpillars and butterflies which are respectively to feed upon them, cannot but strike every one as a beautiful instance of creative foresight. But there are some caterpillars adapted to feed on flowers (such as come forth early in the year); and others attack seeds, roots, and even the woody portion of the stem. Moreover, there are a few which live in this state upon animal matter, such as wool, hides, leather, and fat. Many can digest a considerable variety of alimentary materials; while there are others that can only find support on some one kind, the leaves of some particular species of plant, for example.

The habits of Caterpillars are extremely various. Some burrow into the substance of leaves, in which they excavate galleries; others envelop themselves in the membrane of the leaf itself. Many construct cases or sheaths, either fixed or portable, by agglutinating various substances together; and there are some which live in societies, living together under a tent of silk which they spin in common, and which serves to defend them from the inclemency of the weather. They usually throw off their skin four times before undergoing the transformation into the chrysalis state. For this they prepare by spinning a *cocoon*, in which they are enclosed during the greater part of that epoch. Some construct this entirely of silk; others attach together portions of leaves or particles of earth by silken threads. These threads are formed by a glutinous secretion from glands which seem analogous to the salivary glands of other animals; and these being forced out through a small opening at the end of the lip, hardens as it dries in the air. There are some caterpillars which form no cocoon, but which are contented with suspending themselves by the attachment of the hinder part of the body to some solid support, or by a silken thread coiled around them. The *chrysalis* or nymph has the whole body enclosed in a tough envelope, under which, however, the form of the parts of the future insect may be discerned. At the moment of the final transformation, it discharges from its intestine a red liquid, which softens one end of the cocoon, and allows the exit of the moth. Generally one end of it is weaker, or even fitted by the arrangement of the threads for the escape of the insect.

The *Butterfly*, when it throws off its last envelope and comes forth into the air, of which it is henceforth to be one of the gayest inhabitants, is not altogether perfect, although capable of very soon becoming so. The wings appear at first very slightly developed, and hang loosely by the sides; and it is not until the animal has injected their tubes with air, by taking several full inspirations, that they become expanded so as to serve for flight. From that period, the body is supported by them during by far the greatest proportion of their active state.

The order of *Lepidoptera* is usually divided into three sections, which are different alike in their conformation and habits. These are—1. The Diurna, or *Butterflies*, which may be at once recognised by the vertical position of the wings during repose; 2. The Crepuscularia, or *Twilight-Moths*, commonly known as *Hawk-Moths*, in which the wings are horizontal in repose, and the antennæ thick or club-shaped; 3. The Nocturna, or true *Moths*, whose wings are also horizontal or inclined in repose, but whose antennæ are more slender, tapering gradually from the base to the point.

Section I. Diurna.—The first section corresponds with the Linnæan genus *Papilio*, which is now, however, very much subdivided. The butterflies are distinguished from other Lepidoptera by the brilliancy of their colouring, and by the beauty of the under as well as of the upper side of the wings. Their caterpillars have generally sixteen feet, and their pupæ are nearly always destitute of any silken envelope, and are attached by the tail. The antennæ of Butterflies are sometimes knobbed at their extremities, sometimes of the same thickness throughout, and sometimes taper gradually from base to point. This section may be divided into three families, according to peculiarities in the metamorphosis.

Section II. Crepuscularia.—The section of Crepuscularia, or *Hawk-Moths*, corresponds with the Linnæan genus *Sphinx*, which derived its name from the peculiar attitudes (resembling that of the sculptured sphinx of antiquity) into which the larva sometimes throws itself. Although the Lepidoptera arranged under this division, on account of their similarity of structure, are mostly twilight-fliers, it is not the case with all; for there are some which come abroad in open daylight, and suck the juices of flowers with their long trunks, while the sun is brightly illumining their wings. These species are observed to be more brilliantly coloured than the rest. In most of the Sphinges the body and wings have a dull brownish-gray aspect, like that of many owls, whose habits are similar. The wings are more downy in appearance than those of the Butterflies, as if the scales did not lie so closely upon each other. The larvæ of the Crepuscularia have always sixteen feet, and their pupæ are either enclosed in a cocoon or bury themselves in the earth. The Hawk-Moths make a loud humming noise in their flight.

One of the most remarkable of this group is the death's-head moth (*acherontia atropos*,) recognised by the

Acherontia Atropos.

skull-like patch on the back of the thorax. This emits a squeaking kind of sound, sometimes rather loud, but upon the mode in which it is produced entomologists are not agreed. In consequence of the peculiar aspect of its body, the sudden appearance of this insect in large numbers has been popularly regarded as ominous of evil. It is a great enemy to bees, and enters their hives undefended, devouring the honey, and alarming the inhabitants so that they seem to keep aloof from it.

Section III. Nocturna.—The group of nocturnal Lepidoptera is by far the largest of the order. In general aspect, Moths and Sphinges are somewhat alike, but they may be at once distinguished by the form of the antennæ, which, in the latter, gradually taper from the base to the point. Many of them have no distinct trunk, and in some species the females are almost or altogether destitute of wings. In general, these organs assume a horizontal or inclined position, and are connected in the same manner as in the Sphinges. Sometimes they can be rolled round the body, and in a few instances they fold longitudinally like a fan. The greater part of these Lepidoptera fly by night, and their colours are usually dull. Their caterpillars vary as to the number of legs from ten to sixteen, and their pupæ are of rounded form without those angular projections usually seen in those of other families, and almost always spin a cocoon. The large number of species belonging to this section, and the general similarity of their form, make their classification a matter of much difficulty. They have been divided into ten families, of which a few of the most important will be particularly noticed.

The tribe of Bombycidæ consists of Moths allied to that of the common silk-worm. The pupæ are enclosed

in cocoons of pure silk, frequently of very firm texture; and are rarely subterranean. The prevailing hues of these Moths are gray or fawn colour; and many of the larger species have the wings ornamented with eye-like spots. This tribe contains the largest species of Lepidoptera. The *Saturnia pavonia major*, found in France, has been seen to attain the breadth of five inches; and the *S. pavonia minor*, or emperor moth, attains in this country the breadth of three inches and a half. It is believed that the silk formerly obtained from China and India proceeded from the caterpillars of this genus. Many of them are remarkable for the contrivances they adopt for security in the chrysalis state; and among the most so is the *S. promethea*, an American species, which, previously to spinning, draws together the sides of a leaf (within which it afterwards forms its cocoon), and fastens its stalk to the stem by a strong silken web. The genus *Bombyx* is an extremely important and interesting one, as it is by the caterpillar of the *B. mori* that all the silk now employed in Europe is produced. The larva feeds especially upon the mulberry, although it may be grown upon other plants; but as the silk produced by the former is preferable, that tree is grown to a great extent in Italy and the south of France, where the breeding of silk-worms is carried on. The quantity of nutriment they require is enormous in proportion to their original size, but probably not greater than that consumed by other caterpillars. The care bestowed upon them, however, draws attention to the fact. The larva is reckoned to weigh, when first hatched, about one-hundredth of a grain; previously to its metamorphosis it increases to ninety-five grains, or 9500 times its original weight. It is reckoned that, for the larvæ proceeding from *an ounce* of eggs, nearly *two thousand pounds* of leaves are requisite. The caterpillars of another species of Bombyx are very remarkable for their curious habits. They live in societies on the leaves of the oak; and spin, when young, a kind of silken tent, divided within into cells. They may be seen to issue from it in the evening in procession. One of them advances at the head, and seems to act as a guide; two then follow; next three; then four; and so on, each rank containing one more than the preceding one. Hence they have been called processionary caterpillars. Each spins a separate cocoon; but they are united in regular apposition, laid side by side against each other.

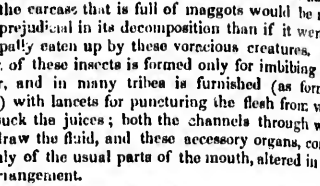
The family of TINEIDÆ contains those little moths which are so injurious to woollen stuffs of every kind, as well as to furs, skins, feathers, and other objects of natural history, upon which their voracious larvæ feed. They use the same materials also for the construction of their movable cases or sheaths, which they enlarge with the increasing size of their bodies, both by adding to their extremities, and by slitting them along and inserting a new piece, so as to increase their diameter. In these tubes they undergo their metamorphosis, after closing the orifice with silk.

The FISSIPENNÆ are distinguished from all other Lepidoptera by the division of the membrane of the wings into branches or rays, of which each pair has from two to six. These are most beautifully fringed at their edges, and much resemble the feathers of birds. The rays are composed of the nerves, without any of the usual intervening membrane, which seems to be transformed into the fringe. These insects (commonly known by the name of Plumed Moths) are of small size: some of them are diurnal and brightly coloured; others are twilight fliers, and of a duller aspect. Some species have the power of folding up their wings, one ray against another, somewhat like a fan; so that when closed they present the appearance of a single broad ray.

Order VIII.—Diptera.

The Two-Winged Insects constitute one of the most extensive orders of the whole class, not only in regard to the number of distinct species, but also from the swarms of individuals of the same species. Many of them, also, have been constant attendants upon man in all ages. They do not attract attention from their size, however, for there are few that exceed an inch in length; nor is it on account of their beauty, for the majority of them are of dull colours; their forms, too, are rarely elegant, and the transformations of many are unknown. They owe the notice they have attracted chiefly to their habits, and especially to those which affect man and the domestic animals, both in their perfect and early states. However annoying these are, it must not be forgotten that other Diptera are of extreme service, by cleansing the surface of the earth of vegetable and animal impurities; the carcass that is full of maggots would be much more prejudicial in its decomposition than if it were not principally eaten up by these voracious creatures. The mouth of these insects is formed only for imbibing fluid matter, and in many tribes is furnished (as formerly stated) with lancets for puncturing the flesh from which they suck the juices; both the channels through which they draw the fluid, and these accessory organs, consisting only of the usual parts of the mouth, altered in form and arrangement.

The Diptera all undergo a complete metamorphosis, as far as the structure of the larvæ is concerned; these



Stratiomys Chameleon—Larva, Pupa, and Imago.

being generally cylindrical footless grubs, no representatives of legs being found except in a few species. But in many there is no proper transformation into the pupa state, the skin of the larva, which hardens, contracts, and shortens, becoming, as it were, the cocoon for the chrysalis. The body is detached from its interior, leaving the organs peculiar to the larva, such as the parts of the mouth, adherent to the inside of the skin. Shortly afterwards, the enclosed being assumes the form of a soft and gelatinous mass, without any of the parts of the future insect being visible; some days subsequently, however, these organs become distinct, and the insect has then assumed the real state of pupa, though without having yet thrown off its larva skin. When ready to escape, it scales off the anterior end of its case like a cap. Many larvæ, however, do throw off their skins when assuming the pupa state, and some spin a regular cocoon. The duration of life in the perfect state is usually very short.

In subdividing the order, we first separate from it a small but remarkable group, which forms the transition to the more aberrant orders of the class, especially the Aphaniptera. Some of them are entirely destitute of wings, and yet in their general structure correspond with the Diptera. They are distinguished from all other insects by their curious mode of reproduction. Not only are the eggs hatched within the body of the parent, but the larvæ are retained there, until they have been transformed into pupæ, in which state they come forth into the world. Hence the group has received the name of PUPIPARA.

The remaining Diptera constituting by far the largest proportion of the class, may be divided into four sections. In the first, NEMOCERA, the antennæ are composed of more than six joints, whilst in all the remainder, the antennæ are short, having apparently more than three distinct joints. In the second, NOTACANTHA, the last division of the antennæ is really composed of two; the proboscis does not project much from the mouth, and is furnished with only two lancets. In the third, TANYSTOMA, the antennæ have really only three joints, the last being usually terminated by a *seta* or bristle. And in the fourth, the ATHERICERA, the antennæ are only two or three jointed, and the proboscis is withdrawn into the mouth.

Section I. NEMOCERA.—To the Nemocera belong the two families of CULICIDÆ and TIPULIDÆ, the former known as the *Gnat* tribe, the latter as the *Harry-long-legs*. The former are distinguished by their beautifully tufted antennæ. Gnats are well known to abound chiefly in damp situations; the reason being that their larvæ are inhabitants of the water. In this state they are very active, swimming with great agility, and often descending, but coming to the surface to breathe, which they do head downwards; the respiratory orifice being at the end of the tail. When the final transformation occurs, the skin of the pupa, which is being cast, serves as a kind of raft, which prevents the perfect insect from being immersed in water. The musquitoes which infest many countries, especially in warm latitudes, differ but little from the common gnats. They sometimes appear in such swarms, especially in marshy districts, as to be kept off only by fire.

Section II. NOTACANTHA.—The second section of the Diptera contains three families, STRATIOMIDÆ, BERIDÆ, and CŒNOMYIDÆ, which do not attract much attention, although some of the insects contained in them are very abundant. They are mostly small, but gaily-coloured insects, and are most numerous in moist situations, in which the larvæ are generally produced. They mostly feed upon vegetable rather than animal juices.

Section III. TANYSTOMA.—The insects composing the third division have usually a more perfect mouth than those of the other sections; and they are also remarkable for the structure of the head of the larvæ, which possess two claw-like appendages, by which they attach themselves to the substances from which they derive their support. Many of the perfect insects are eminently carnivorous or insectivorous, so are also some of the larvæ. To this group belongs the family of TABANIDÆ, the Gad-Fly tribe, to which belong the largest Dipterous Insects, pre-eminently distinguished for the tormenting powers which the different species possess, by piercing the skins and sucking the blood of various quadrupeds, and even of man himself.

Section IV. ATHERICERA.—The insects of the fourth tribe of Diptera are principally vegetable-feeders in their perfect state, only a few being carnivorous, or feeding on other insects; but their larvæ are generally extremely voracious, and will devour almost any kind of soft animal matter. This section includes the Flies strictly so called, the Bot-Flies, and many other tribes.

The first family, that of SYRPHIDÆ, bears an extremely close resemblance to the humble-bees and wasps, in the nests of which some species of them deposit their eggs; others lay them among Aphides, which fall an easy prey to the larva when it is hatched. The perfect insects are very partial to flowers, preferring the Compositæ; and they delight to hover immovably over certain spots, to which they will return, if disturbed, a considerable number of times. Above a hundred species inhabit Britain. In a few species, the larvæ are aquatic, and the posterior part of the body is prolonged into a respiratory tube, whence they have received the name of rat-tailed larvæ. The imago of one of these closely resembles in size and colour the male of the hive-bee.

The form and habits of the family MUSCIDÆ, or *Fly* tribe, are generally known; the family is an extremely numerous one, above 1700 species having been recorded as existing in Europe, of which about half are indigenous to this country; and there are probably at least as many more which have not been described. The strong general resemblance which exists among all the species, makes it very difficult (especially when their small size is considered) to discriminate them readily. The larvæ of these insects, commonly known as *maggots*, are soft, vermiform, footless grubs, possessing on the head a couple of retractile hooks, by which they can cling to the substances on which they feed. They devour various substances, both animal and vegetable, living, recently-dead, or far advanced in putrefaction. The eggs are deposited by the female, as in other instances, in the neighbourhood, or in the very substance, of the food which is adapted for the support of the larva, however little to its own liking.

The ŒSTRIDÆ, or *Bot-Flies*, are a family very remarkable in regard to their structure and habits. The perfect insects resemble large meat-flies in form, are very hairy, and generally have these hairs coloured in rings, like humble-bees; but they are seldom seen, the duration of their lives being very short in this condition. Their chief peculiarity consists in the absence of any proper mouth in the imago (in which respect there is an analogy with the Strepsiptera), and in the peculiar habitation of the larva. This is always found in living animals; its situation, however, varying with the species, of which almost every herbivorous mammal has one or more peculiar to it. The egg is deposited by some in situations where the larva may burrow into the flesh, where it occasions inflammatory tumours, the fluids contained in which afford it nourishment. In other cases, the eggs or larvæ, existing upon spots which the animal is in the habit of licking, are conveyed by the tongue into the mouth, whence they pass into the stomach. There they remain until full-grown; and then they quit the body (as do also those that inhabit the flesh) and fall to the ground, beneath the surface of which they undergo their transformations. The larvæ of one species, which inhabits the sheep, are found in the cavities in front of the bones of the skull and higher parts of the nose. Man is subject to the attacks of one or more species, which do not, however, infest this country.

The Pupiparous division of the Diptera contains two families, the HIPPOBOSCIDÆ and NYCTERIBIIDÆ, the habits of all the species of which are parasitic. The former, sometimes termed *Forest-Flies*, are of small size, covered with bristles, and sometimes destitute of wings. They are known by the French under the name of Spider-Flies. They reside upon quadrupeds and birds, running with great agility, and often sideways, burying themselves among the hair or feathers. That which is parasitic on sheep is known as the *tick*. The minute species infests the hive-bee; and this is remarkable not only for being destitute of wings, but of eyes also. In the other family, that of NYCTERIBIIDÆ, the general form more nearly approaches that of the spiders. It contains but few species, all of which are parasitic upon bats, and are commonly termed *bat-lice*.

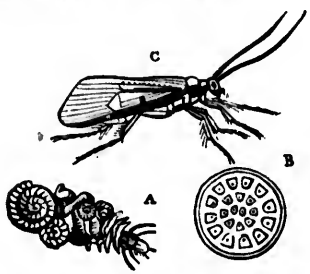
Order IX.—Trichoptera.

This order is a very small one, and consists but of one tribe, the PHRYGANEIDÆ, which have been commonly associated with the Neuroptera. But there seems good reason for ranking them as a separate order, connecting the Neuroptera with the Lepidoptera, for they resemble the latter in the distribution of the nerves of the wings and in the hairy covering with which both the wings and bodies are beset, as well as in many other characters.

The larvæ, well known under the name of *caddice-worms*, reside in cylindrical cases, open at each end, to

which they attach various matters, as bits of stick, weeds, pebbles, or even small living shells, by the assistance of silken threads, which they spin from the mouth in the same manner as caterpillars. These cases they bear about with them, protruding the three first segments, with their legs, when they creep forwards, and withdrawing these upon the slightest alarm: they never quit the cases of their own accord. Different species appear to prefer different materials for the construction of their cases, but they have the power of employing almost any which fall in their way, when those they prefer are deficient. The food of some of the larvæ is vegetable, but others prey upon smaller aquatic larvæ, such as those of Neuroptera.

When about to assume the pupa state, the larvæ fix their cases to some solid substance beneath the water, and close the two extremities with a kind of grating, that admits of the passage of water through the tube, which is necessary for respiration. When nearly arrived at their perfect form, they make their way out by the pair of hooked jaws with which they are then furnished, and swim about with great activity by means of the two hind legs, crawling also upon the four first.



Phryganea Grandis.
A, Larva in its case; B, Grating; C, Imago.

Order X.—Strepsiptera.

This is a small order, containing only a single group of insects; but these are so anomalous in structure that it is not merely impossible to associate them with any other order, but it is even difficult to assign their proper place in the class. As they possess less of general interest than of curiosity to the scientific naturalist, they need not here be treated of.

WINGLESS INSECTS.

Besides the foregoing orders, which constitute the true Insects, three others must be included in the class, on account of the correspondence in their general structure, although they present only one or neither of the two characters which have been stated to distinguish it—the presence of wings in the perfect state, and the metamorphosis. These three orders are, the Aphaniptera, or *Flea* tribe, which have the rudiments of wings, and undergo a metamorphosis; the Parasita, or *Louse* tribe, which is entirely destitute of wings, and undergoes no metamorphosis, but agrees with the true Insects in having only six legs; and the Thysanoura, including the *Spring-tails*, in which there are appendages to the abdomen, representing the legs of the posterior segments, so that these may be regarded as approaching the Myriapoda.

Order XI.—Aphanipters.

This order contains only one family, the Pulicidæ, or *Flea* tribe, all of which are insects of minute size, and, like the Diptera (to which they are perhaps most nearly allied), of suctorial habits. Their larvæ come forth from the egg in the form of minute worms, possessing considerable activity, and feeding upon animal matter, a provision of which seems to be formed for them by the parent. They afterwards enclose themselves in a small cocoon of silk, which is often covered with dust, and in this they undergo their change into the pupa state. In their perfect state, the rudiments only of wings are visible, in the form of little scales, attached to the second and third segments of the body, in which there is no proper distinction of thorax and abdomen.

Order XII.—Parasita.

The insects of this order, the *Louse* and its allies, are regarded with the greatest disgust by the common consent of civilized man, because their presence on the body is an indication of a gross want of cleanliness of habit. Most of the lower animals, however, are infested with one or more species, from the attacks of which they are not able to defend themselves; and man is subject to a peculiar disease which seems very much to favour their production. Their generations succeed each other very rapidly. The Parasita are almost entirely destitute of eyes.

Order XIII.—Thysanoura.

In the insects of this order there is a remarkable diversity of structure, especially in regard to the mouth. Some of them possess as complex an oral apparatus as the mandibulate insects, while in others there is scarcely a perceptible opening. The same is the case with regard to the eyes; these organs being fully developed in some, and almost rudimentary in others. The order contains two families. In the first, the Lepismidæ, the abdomen is furnished on each side with a row of movable appendages, like false legs, and is terminated by long jointed bristles, of which three are more remarkable. These little insects leap very well; some frequent stony places, while another is found in sugar, and is known as the *sugar-louse*. In the Poduridæ, the appendages to the sides of the abdomen are wanting; but the extremity of it is prolonged into a forked tail, by which these insects can execute very surprising leaps; this, when in inaction, is applied against the belly. From this conformation they are popularly known under the name of *Spring-tails*.

Podura Villosa.

CLASS VII.—ARACHNIDE.

The class of Arachnida, including the *Spiders* and their allies, was for a long time confounded with that of Insects, and has been only recently separated. The characters which they present are perfectly distinct from those either of Insects on the one hand, or of Crustacea on the other; nevertheless they present numerous relations with both those groups.

The Arachnida may be distinguished from Insects by the absence of any division between the head and thorax; and the compound mass thus formed is termed the cephalo-thorax. Again, Insects in their mature state are always provided with six legs and no more; the Arachnida have eight of these members. Moreover, the eyes are not compound, but more resemble those of higher animals. From Crustacea they are separated by the softness of their bodies (in which respect, however, they are approached by certain Macrourous Decapoda termed Spider-Crabs), but still more completely by their exclusively atmospheric respiration. The organs by which this function is performed vary in different tribes. In the *Acari*, or Mites, and their allies, they resemble the trachem of insects, and are distributed through the body; while in the Spiders, Scorpions, &c., they consist of rounded cavities, or air-sacs, into which the air is admitted by spiracles situated on the abdomen, and which are

lined by a membrane plaited into numerous folds, which resemble gills, and lie in opposition like the leaves of a book. On this character is founded the subdivision of the class into *pulmonary* and *tracheary* Arachnida.

The majority of the Arachnida feed upon insects, which they seize alive, or upon which they fix themselves, and from which they suck the juices. Others live as parasites upon the bodies of vertebrated animals. There are some, however, which are only found in flour, cheese, and upon various vegetables. These last, which mostly belong to the tracheary order, exhibit an affinity to Insects not only in their structure but in their metamorphosis; for they undergo great changes after they come out of the egg, an additional pair of legs being often developed; while in the others nothing else than a moult or casting of the skin occurs.

Order I.—Trachearia.

The Trachearia, being the most nearly allied to Insects, are naturally the first to be considered. This order contains several remarkable forms, of which the one best known is that of Acaridæ, or Mites, the majority of the species of which, however, are very minute, or almost microscopical. They are very extensively distributed; some being wanderers under stones, leaves, the bark of trees, in the ground, or upon articles of food; while others subsist as parasites upon the skin and in the flesh of different animals, often greatly weakening them by their excessive multiplication. There are some species which infest insects, especially the carrion beetles. Some of this tribe much resemble spiders in form and habits.

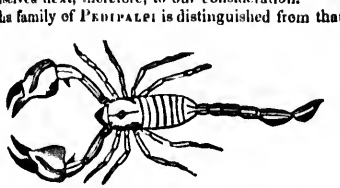
Acarus Domesticus magnified. (Mite.)

Besides the *Acari*, which form the principal part of this order, there is a curious group, which has received the name of *Pseudo-Scorpions*, owing to their possession of a pair of large claws terminating in forceps, which, like those of the true scorpions, are formed by an excessive development of the organs which in insects are termed palpi. There is also a very curious family, which some naturalists have separated into a distinct order, the *Pycnogonides*; these are distinguished by the absence of all special respiratory organs, and in their aquatic habits bear a strong resemblance to Crustacea. They are found among marine plants, and under stones on the beach. Their motions are remarkably slow; and they are said to live chiefly upon the animals of Bivalve Mollusca.

Order II.—Pulmonaria.

In this order, the respiration is performed by means of air-sacs contained on the under-side of the body, and opening externally by stigmata; sometimes these apertures are eight in number, four on each side, but sometimes four, or even only two. This diminution appears to indicate a gradual elevation in the character of the apparatus; leading us from the diffused condition in which it exists in Insects, to the more concentrated form it presents in higher animals. The Scorpions possess eight breathing-pores; and thus approach nearer to the Tracheary Arachnida than do the Spiders. They offer themselves next, therefore, to our consideration.

The family of Pedipalpi is distinguished from that of Araneidæ principally by the great development of the palpi, which form extended arms, terminated by a pincer or claw. The entire body is clothed with a hard skin. In the *Scorpions*, which constitute the principal part of this family, the abdomen is very much prolonged, forming a sort of tail, which is terminated by a sting furnished with a venomous secretion. The wound of this sting, although very painful, does not seem to be ordinarily dangerous. A small species inhabits this country; but it is between the tropics that the Scorpions attain their greatest development. They usually live on the ground, hiding themselves under stones or other bodies, among ruins, where such exist, and dark and cool places generally, even the interior of houses. They run quickly, and curve the tail over the back. They can turn it as an arm of offence or defence.

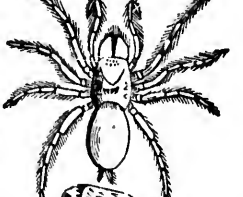


Scorpio Occitanus.

Besides the Scorpions, there is included in this family the tribe of *Tarantula** Spiders, which seem intermediate in several respects to the Scorpions and true Spiders.

The other family of the pulmonary Arachnida consists only of the Spiders of various kinds, and is designated Araneidæ. In these, the palpi are not developed to any thing like the same degree as in the Scorpion tribe; they rather resemble feet; but the jaws are armed with sharp and hooked fangs, and are perforated near their points, for the emission of a poisonous secretion provided for the destruction of their prey. Nearly all of them are provided with organs, situated at the hinder part of the body, for spinning a very delicate silken thread; but the use to which it is to be applied varies in different species. In some it forms webs in which are entangled the insects on which they feed; in others, it is employed to make a delicate silken tube, which lines their habitations; and in others, it is chiefly used for the fabrication of a sort of cocoon with which the eggs are surrounded. The instruments by which this thread is produced are little teat-like protuberances, termed *spinnerets*, of which four usually exist at the posterior extremity of the abdomen. Each of these, when highly magnified, is found to be perforated at its extremity by innumerable orifices of extreme minuteness, through which is forced out a glutinous fluid, secreted by glands within. This fluid soon hardens by exposure to the air; and thus each thread, delicate as it may seem, is composed of several hundreds, of extreme minuteness, coiled together, so that it possesses great strength in proportion to its diameter.

The Spiders are all extremely voracious in their habits, feeding only upon prey which they have themselves killed. When they have got an insect between their claws, either by entrapping it in their web or by their stealthy mode of pursuit, they plunge their poisoned mandibles into its body, and the bite is usually soon fatal. Sometimes, however, the insect has strength enough to resist its enemy, and to prevent the infliction of the fatal wound; and, as a prolonged struggle might be very injurious to the spider, on account of the softness of its body, it generally retires from the contest if not speedily successful. Where its prey has been entangled in its web, however, the spider still further encloses it by a silken thread, and then retires until the insect has lost its strength by ineffectual struggles, when it soon despatches its victim.



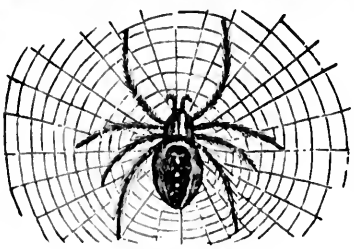
Mygale Fodiens.

The Mining Spi-

* These are not the animals known in the south of Europe under the name of Tarentula, receiving their designation from the city of Tarentum; the latter are true Spiders.

ders, found in the South of Europe, construct, in dry shelving situations exposed to the sun, subterranean cylindrical galleries, often two feet deep, and so tortuous, that the traces of them are lost. These they line with a silken tube, forming at its entrance a movable lid, composed of silk and earth, attached to the silken lining by a sort of hinge; and this is adapted, by its size, situation, and weight, to close the opening so precisely, as scarcely to allow its entrance to be distinguished from the neighbouring soil. When the spider enters its retreat, or passes out of it, the door shuts of itself. The Mygale spins a sort of cocoon round its eggs, enclosing a hundred or more; they are hatched within it, and the young undergo their first changes before quitting it.

The *Clotho* is remarkable for the curious habitation which it constructs for its young. It spins a kind of circular cocoon or tent, which it attaches to the under side of stones or to crevices in rocks by seven or eight points, leaving festoons between these, the edges of which are free. At first this consists of only two folds, but others are gradually added; and beneath them all a lining of peculiarly soft texture is constructed for the reception of the eggs. The young remain in this for some time after they are hatched, and are supplied by the parent with food. The *Argyroneta* forms a winter retreat for itself beneath the water. It spins an oval silken chamber, open at the bottom like a diving-bell, which it attaches by cords to water-plants. It then carries down successive bubbles of air beneath its body, by crawling down their stems; and these bubbles it transfers to its bell until it has filled it. It then takes up its abode in this cell, where it remains for the winter, first closing the mouth of the bell. The *Epeiræ* are among the most remarkable for the strength of their webs; some of the exotic species, which are remarkable for the variety of their forms, colours, and habits, spinning nets which are



Epeira Diadema.

sufficiently strong to catch small birds, and even to annoy man when he happens to come in the way of many together.

CLASS VIII.—CRUSTACEA.

The animals composing this group may be regarded as representing in the sea the insects and spiders of the land. Indeed, they were associated with those classes by Linnæus, in his class of Insects. But they are separated from both by very important characters. Their chief distinction is in the breathing apparatus, which is adapted to aquatic and not to aërial respiration. Instead of the system of branching tubes which we find in Insects, or the lung-like cavities which are a more concentrated form of the same structure in the Arachnida, the Crustacea are furnished with fringes of gills like those of the Mollusca or Fishes, into which the blood is sent, as it were, out of the body, to meet the small quantity of air contained in the surrounding water. In the highest order of this class, the gills do not hang loosely from the body, but are enclosed in a cavity, having two orifices, through one of which a constant stream of water is introduced, which is ejected through the other by a curious mechanical contrivance. And in a few species of this order, there is a special provision for keeping the gills moist when the animal leaves the water out of which it can live for a considerable period. The best known of these are the Land-Crabs of the West Indian Islands.

It is not only by their aquatic respiration, however, that the Crustacea are distinguished, but also by the calcareous nature of their integument. The shell, as it is commonly termed, is a secretion from the surface of the true skin, just as are the shells of Mollusca from their mantle. There is this important difference, however, between the two, that, while the latter is merely adapted to enclose loosely and to protect the general mass of the body, so that the locomotive appendages, when put in action, must be made to project beyond it, these being themselves unsupported by any hard skeleton, the former accurately fits not only the trunk but the extremities also, and, as in the other Articulata, is composed of a number of rings, more or less regular in form, and accurately jointed together by an intervening membrane.

As no addition to the edges of these rings would increase their diameter, some other means must be provided for enabling the size of the shell to keep pace with the increasing bulk of the body. This is effected by the periodical *exuviation*, or throwing off of the old shell, and the formation of a new one. This change is preceded by evident illness on the part of the animal, which retires to its hiding-place at the time. The part of the shell enclosing the trunk splits usually at its under part, in such a manner as to allow the body to escape; but the shell of the legs and claws remains entire, though the fleshy parts are entirely withdrawn from their interior. This is the more remarkable, as the bulk of the claw is much greater than the diameter of the joint through which it is thus made to pass: and often the disproportion is extreme. When the shell has been thus thrown off, the animal is entirely unprotected, and it carefully conceals itself from its enemies. Its soft skin is soon covered, however, with a sort of mucous exudation, which contains a large quantity of calcareous matter, and speedily hardens. The re-formation of the shell is facilitated by a store of carbonate of lime previously laid up in the stomach, where it forms the concretions commonly known as *crab's-eyes*; these disappear at this period, being absorbed, and then excreted on the surface of the skin.

The power possessed by the Crustacea of repairing injuries, is very remarkable in beings of such high organization. In the process of exuviation, it is not uncommon for a part of a claw to be lost; and this is speedily replaced by a new one. The second joint from the body is that at which the fracture most commonly occurs; and it is probably the only one from which the new growth can issue. For, if the claw be broken off below that point, the animal itself effects the removal of the upper portion, either simply casting it off by violent muscular contraction, or striking it against some hard body. The same is the case when the claw has been accidentally lost in some other way; and, accordingly, it is by no means uncommon to witness a great disproportion in the size of the two members, one being much smaller than natural, from its having been only recently produced.

The number of legs possessed by the Crustacea is greater than that of perfect insects, being never less than four pairs, besides the pair of claws which may be considered as metamorphosed legs. It is in the crab, lobster, crayfish, &c., that we find this small number; and these belong to the highest order, the Decapoda, or ten-footed Crustacea. In front of these are some curious organs termed feet-jaws, being intermediate in structure between

these two kinds of appendages; in some of the lower Crustacea these become true legs. And from the posterior part of the body there hang down certain appendages, which are also true legs in the lower orders. In fact, the lowest Crustacea approach very closely to the Myriapoda in their general form and structure, differing chiefly in their aquatic mode of life; the segments of the body are nearly equal, and are each furnished with a pair of legs. On the other hand, among the Decapoda we find an approximation to the form both of insects and spiders—the lobster representing the one, and the crab the other. In the lobster we have a regular division into *head*, *thorax*, and *abdomen*, as in insects; and it is to the thorax alone that the locomotive appendages are attached, as in the perfect state of the insect. There is no rudiment, however, of wings. As in the insect, we find that, where the force is concentrated in one part of the body, and the general movement is effected chiefly by the members, the segments of that part are consolidated; and, accordingly, the thorax of the lobster seems, until carefully examined, as if composed of a single piece. The segments of the abdomen, however, are movable on each other; and their motions assist in progression, the flattened tail serving as a fin by which the water is struck. In the crab, the head, thorax, and abdomen, are all consolidated into one mass; but the division into segments is still evident on the under side.

As in all other Articulata, the eyes of the Crustacea are compound. Their external coating is thrown off with the shell; and this, when examined with the microscope, is seen to exhibit the division into minute lenses with beautiful distinctness. By its transparency the cast shell may be at once distinguished from one in which the animal has died. It is interesting to find this structure preserved in great perfection in a curious fossil tribe of this class, the *Trilobites*, the compound structure of whose eyes, mounted as they are upon short foot-stalks, is at once distinguishable with a magnifying glass, proving them to have been articulated animals, even if no other evidence existed to that effect.

Owing to the great varieties of structure which this class includes, its division into orders appears very complex. Thirteen are established by M. Milne-Edwards, the characters of which will now be generally stated. As many of them, however, contain but a few species, of which little is known, a more detailed account will be given of those only which possess more universal interest.

The class Crustacea may be separated in the first instance into two divisions. In one of these, including the great bulk of the class, the mouth is furnished with organs specially destined for the prehension or division of the food. In the other, there are no special organs for the purpose, the bases of the neighbouring legs serving the purpose of jaws. This *second* division contains but one order, the Xyphosura, and this contains but one genus, the *Limulus*, or King-Crab, which will hereafter be noticed in detail. The *first* division is then separated into two groups—one, the Maxillosa, having the mouth furnished with jaws; the other, the Edentata, having the mouth prolonged in the shape of a sucker. These two groups are precisely analogous to those of Mandibulata and Haustellata among insects. The Edentata are divided into three orders, according to the form of the extremities:

Araneiformes, in which the extremities are rod-like, long, and adapted for walking.

Stphonostomata, in which the extremities are not adapted for walking, are partly formed into plates, and partly adapted for prehension.

Lernéiformes, in which the extremities are but little developed, and the body presents great variety of form. Most of these are parasitic upon other animals, especially fishes, to which they cling by means of hooks in which their rudimentary extremities terminate.

The Maxillosa, containing by far the larger proportion, as well as the most highly organized forms of the class, are again distributed into four sections. 1. Podophthalmia, in which the eyes are mounted upon foot-stalks, and are movable. These have almost always branchiæ, properly so called; their feet are partly ambulatory, partly prehensile; and the thorax is covered with a *carapace* or shield (like the upper shell of the turtles), which is formed by the great development of one of the rings, overlapping the rest. 2. Edriophthalmia, in which the eyes are *sessile*, or not mounted on a pedicle. The branchiæ are not separate organs, being united with the extremities; these are almost always seven on each side, and adapted for walking. There is no carapace. 3. Branchiopoda, in which there are no gills, but the anterior pairs of legs are flattened into plates, which are subservient to respiration. 4. Entomostraca, in which there are no branchiæ, or any apparent organs to supply their place. The eyes are sessile, and commonly united into a single mass. These groups are again subdivided into nine orders, as follows:—

1. The Podophthalmia consist of the Decapoda, in which there are five pairs of thoracic extremities, and which have the gills enclosed in a special respiratory cavity; and the Stomapoda, which have six or eight pairs of thoracic extremities and external branchiæ.

2. The Edriopthalmia contain three orders—the Amphipoda, in which the thoracic members are subservient to respiration, and the abdomen well developed, and furnished with six pairs of limbs; the Læmodipoda, in which the abdomen is not developed; and the Isopoda, in which the abdomen is well developed, and its members, which are similar in form to the rest, subservient to respiration. It is this order which most resembles the Myriapoda.

3. The Branchiopoda contain two orders—of which one, the Cladocera, has a carapace in the form of a bivalve shell, with five pairs of thoracic members; whilst in the other, the Phyllopoda, there is no carapace, and the extremities, which are formed for swimming, are more numerous, varying from eight to twenty-two.

4. The Entomostraca are also divided into two orders; the Copepoda, which have the body divided into distinct rings, but without carapace, and the appendages to the mouth in considerable numbers; and the Ostrapoda, in which the body is without annular divisions, and entirely enclosed under a large shield having the form of a bivalve shell, the extremities being in very small number. In some members of this division, we find a very close approximation to the higher Rotifera.

Order I.—Decapoda.

It is in this order that we find the highest general organization, the largest size, and the most varied habits; it is the one most useful to man, and most interesting to the naturalist. The lobsters, crabs, cray-fish, prawns, shrimps—in fact, nearly all the species that are ever used as food—belong to it. Their growth is slow, but they ordinarily live a long time. Their habits are mostly aquatic; but none of them are killed at once by being withdrawn from the water; and some of them pass the greatest part of their lives in air. They are naturally voracious and carnivorous; the first pair of legs is usually transformed into a pair of powerful claws, by which they seize their food, and convey it to the mouth. This order contains three families; the Brachyoura, or short-tailed Decapods, to which the name of *Crabs* is commonly given; the Macroura, or long-tailed, such as the Lobster, Cray-fish, &c.; and the Anomoura, in which the abdomen is prolonged, but destitute of a shell, so that the tail is soft, and which inhabit the shells of Mollusca, in which they seek protection.

As illustrations of the structure and habits of the Brachyoura, the common *Crabs* will suffice; but a pe-

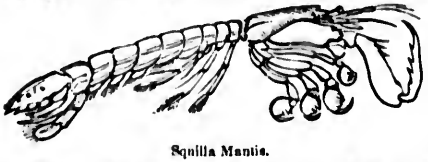
cular tribe, that of the *Land-Crabs*, should be specially mentioned. These often live at a considerable distance from the sea, and even burrow under ground. Their gills are kept moist by a kind of spongy structure in the interior of the cavity which encloses them, and from this a sufficient amount of fluid is secreted, to prevent them from being dried up. Some species, though living on land, are confined to damp situations. Others, however, ordinarily inhabit elevated regions, and migrate towards the sea once a year to deposit their spawn.

The Macrodra are distinguished, not only by the length of their tail, but by having it expanded at the extremity into a pair of fin-like processes, which afford valuable assistance in swimming. This family is a very extensive one, and contains the largest species of the whole class.

The Decapods of the family Anomoura are commonly known by the name of Hermit-Crabs, from their remarkable habit of seeking protection in the empty shells of molluscs. The shells they seem to prefer for this purpose are those belonging to the family Trochoidæ. The abdomen or tail is inserted into the upper part of the cavity, of which, after a time, it assumes the perfect form, so that when withdrawn it presents all the markings of it. The thorax and head occupy the lower part of the spire; and the mouth is closed by one of the claws, which is usually larger than the other, and serves as an operculum when the animal is withdrawn. When they outgrow the habitations they have selected, they quit them and go in search of others; and they try one shell after another, by slipping the tail into it, until they have found one whose size and form suit them.

Order II.—Stomapoda.

This is a much less extensive order; and the species it contains are entirely marine, and mostly confined to tropical climates; on which account comparatively little is known of them. Some of them have powerful claws,



Squilla Mantis.

which they use for seizing their prey in the same manner as the Orthoptera among insects; so that these have received the name of Sea Mantes. The accompanying figure shows one of the most characteristic forms of the order, which is abundant in the Mediterranean. The gills are there seen to be affixed, in separate tufts, to the abdominal appendages.

Order III.—Amphipoda.

This is an extensive order, in regard both to the number of species contained in it, and the amount of individuals which are sometimes seen collected together. The greater number of them are marine, but some are found in brooks and reservoirs; all, however, are more or less aquatic in their habits. They are of small size, and swim and leap with agility. The best known British species is the *Sand-hopper*, which burrows in the sand, and which, unlike the greater part of the order, seldom enters the water.

Order IV.—Læmodipoda.

Of this small order, one of the most interesting and characteristic species is the *Cyamus*, commonly called the Whale-Louse, from its infesting the Cetacea as a parasite. Sometimes these creatures are so abundant on the surface of whales, that the individuals they infest may be recognised at a distance by the white colour these parasites impart to them.

Cyamus Balænarum.

Order V.—Isopoda.

These Crustacea not only resemble Myriapoda in external form, but in many parts of their internal structure. The greater number live in water, but many species, such as the common Wood-Louse, are inhabitants of the land. Having no special apparatus, however, for keeping the respiratory surface moist, they can only exist in damp places. The *Oniscus*, or Wood-Louse, frequents dark and concealed places, such as cellars, caves, chinks in walls, or hollows under stones. It feeds upon decaying vegetable and animal matter, and only comes forth from its retreat in damp weather. It has the power of rolling itself completely into a ball.

Order VI.—Cladocera.

The Crustacea composing this and the three following orders are of very small size, so that the details of their structure can only be examined with the microscope. They mostly inhabit fresh waters, and are in almost constant motion. A characteristic example of this order is the common *Daphnia Pulex*, or Water-Flea, which may be found during the summer in almost every pond, and is recognised by its very rapid and sudden movements, resembling the leaps of the animal after which it is named. These are principally executed by a pair of large branched antennæ, which serve as oars.

Order VII.—Phyllopoda.

To this order, which is characterized by the prolonged form of the body, and the flattening of the extremities, which adapts them for swimming, belongs a large number of species, whose movements are generally very regular and equable. The *Branchipus*, one of the most characteristic examples, is found, often in great numbers, in small puddles, and most abundantly after heavy rain.

Branchipus Stagnalis.

The eggs are capable of being dried up without injury, and are hatched soon after being moistened

Order VIII.—Copepoda.

The animals of this and the next order are commonly termed *monoculous*, from the two eyes being united into one mass. In their general habits they agree with the former. The *Cyclops* is an interesting species, very common in the ponds and ditches of this country. The female has an oval sac on each side of the tail, in which the eggs are carried. She is able to produce ten broods in the course of three months, and as these are speedily able to reproduce themselves, it has been calculated that in a year, 4,442,189,120 young may be the progeny of one individual. The majority of the animals of this order swim with the back downwards, darting about with great agility, and moving backwards or forwards with equal ease. In the absence of animal matter, on which they usually feed, they attack vegetable substances.

Cyclops Vulgaris, magnified.

Order IX.—Ostrapoda.

In habit and general character, the animals of this order, of which the common *Cypris* of our ponds is an example, closely resemble those of the last, but their bodies are enveloped in a sort of bivalve shell. They swim, like the *Daphnia*, by means of the prolonged antennæ, which spread at their extremities into tufts of filaments.

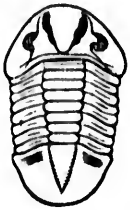
The animals of the division Entomata are nearly all parasitic. In their general organization they are the most imperfect of all Crustacea, some of them approaching the higher Entozoa whilst others have a resemblance

to the lowest Arachnida. The various species of these orders, which need not be more minutely particularized, infest, more or less, almost all marine animals.

There now only remains the remarkable order *Xyphosura*, separated from all the rest by the absence of any special organs for conveying food into the mouth. It receives its name from the sword-like prolongation of the carapace, which is used as a weapon by the natives of the regions in which the animals exist. The *Limuli*, or King-Crabs, as they are commonly termed, are peculiar to the East Indies (abounding in the neighbourhood of the Molluccas) and the coast of America. They sometimes attain the length of two feet. Their legs are very short, not extending beyond the margin of the shell. The anterior ones seem to assist in conveying food to the mouth; and the posterior are modified for respiration.

Limulus Polyphemus.

Near the *Limuli* should probably be placed the remarkable group of *Trilobites*, which are at present only known in a fossil state, but which were very abundant in former epochs of the earth's history. There can be no doubt, from the character of the animals with whose remains it is found, that the Trilobite was an inhabitant of the water; and as its integument was evidently hard and articulated, it must have been a Crustaceous animal.



Asaphus Expansus.

Same rolled up.

CLASS IX.—MYRIAPODA.

The class Myriapoda is the lowest in which we meet with articulated members, or distinct jointed legs, as well as with an articulated body. These are intermediate in their conformation between the more highly organized legs of insects and the simple bristle-like appendages possessed by some of the Annelida; and this is exactly the place to which we should refer the animals of this class, from a regard to their general structure. For, on looking at the form of their bodies, we observe that they are distinguished by an uniformity in the character of the segments, nearly as great as that which prevails in the Annelida; so that an *Iulus* might almost be likened to an earthworm provided with a stiffened integument, and with slender legs: whilst, on the other hand, the adaptation of the respiratory organs to breathe air with regularity and energy, the increasing complexity of the apparatus of mastication, the possession of distinct eyes, and many other characters, indicate their affinity with Insects—in which class, indeed, some naturalists comprehend them.

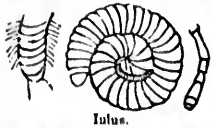
Cyclops Vulgaris, magnified.

Most persons are familiar with the common forms of this class—the *Centipedes* (hundred legs) and the *Millepedes* (thousand legs); and a minute description of them is therefore unnecessary. On examining any of these animals, the following points will be observed. The covering of the body is firm, and of a somewhat horny character, resembling that of many insects. The division into segments is very distinct; a flexible membrane being interposed between each pair of firm rings or plates. This is obviously required by the condensation of the skin; since, if it were otherwise, the body would not have the power of bending in any direction. The legs are covered by the same kind of integument, and are jointed in a similar manner; each terminates in a single claw or hook. No division of the body into distinct regions, like those which are so evident in the true Insects, can be observed; but, on the contrary, the segments are nearly equal along its whole length, and each is provided with one or two pairs of legs. The first segment, or head, is furnished with eyes formed upon the same general plan as those of insects; and also with a pair of long jointed antennæ, which are probably organs of touch. On the side or under surface of the animal may be seen a row of minute pores, a pair usually existing on each segment, which are the apertures for the admission of air to the respiratory organs. The different parts of the nervous system are repeated in a similar manner, a pair of ganglia being found in every division of the body.

The Myriapoda may be divided into two orders, the Iulidæ, or *Millepedes*, and the Scolopandridæ, or *Centipedes*.

Order I.—Iulidæ.

The Iulidæ, consisting of animals bearing a general resemblance to the *Iulus*, or common Millepede, are the most nearly allied to the Annelida, both in external form and in the arrangement of the several organs. The *Iulus Terrestris*, or Galleyworm, is a species often found concealed under stones, or beneath the bark of decaying timber. Its body is long and cylindrical, and is composed of between forty and fifty hard rings, which, except at the head and tail, differ but little from one another. Each segment gives origin to two pairs of small legs, which arise close to the middle line along the under surface of the body. These are scarcely large or strong enough to support its weight, so that the animal moves but slowly, and seems rather to glide or crawl than to walk. When at rest, the body is rolled up in a spiral form, and the feet, being concealed in the concavity of the spire, are protected from injury, whilst the firmness of the rings of the body enables them to resist considerable pressure.



Iulus.

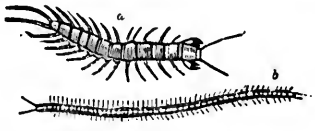
The mouth of the *Iulidæ* is furnished with a pair of stout horny jaws, moving horizontally, and furnished with sharp toothed edges; and by means of these, they are enabled to divide with facility the portions of decayed vegetable matter upon which they usually feed. These animals are very harmless to man, not being possessed of any poisonous organs; and they may be regarded as positively benefiting him, by the removal of substances the decay of which would be noxious. The common *Iulus* of this country seldom much exceeds an inch in length, but there is a South American species (*I. maximus*) which attains the length of seven inches.

Order II.—Scolopendridæ.

The animals composing the order Scolopendridæ may be distinguished from the Iulidæ by the greater development of the legs, by the diminution in their number and in that of the segments, and by the flattened form of the body.

Of the carnivorous propensities of the Scolopendridæ the structure of the mouth affords sufficient evidence. It is provided not only with a pair of horny jaws resembling those of insects, but with a pair of strong sharp

claws, formed by an enlargement of the second pair of legs, which are perforated at the tip with a minute aperture through which a venomous fluid is probably instilled into the wounds made by them. Small insects seized in these claws are seen to die very speedily, and in warm countries the bite of a large species of Centipede is a source of great irritation to man, being reputed more injurious than that of the Scorpion, though it is seldom fatal. The application of ammonia is the most effectual remedy for the pain, as well as for the constitutional effects of the bite. The last pair of legs undergoes some modification in this order; being directed backwards, so as to form a kind of double tail; and not being used for walking except when the animal is moving backwards.



a, Lithobius Forcipatus; *b*, Geophilus Longicornis.

The European species of this order seldom exceed two or three inches in length, but they present themselves by no means unfrequently. Like the Iulidæ, they frequent dark places, hiding themselves under stones, the bark of trees, in the ground, and especially in over-ripe fruit which is likely to attract insects. In tropical climates, however, they attain a much larger size, and abound still more. Centipedes of the length of fifteen inches have been brought to this country; and it is stated by Ulloa, that at Carthagena they have been seen exceeding a yard in length and five inches in breadth; and that the bite of these is mortal. It is doubtful, however, whether this statement may be relied on.

CLASS X.—ANNELIDA.

The class of Annelida is the lowest in which the articulated structure is distinctly manifest. It is composed of animals having a worm-like body, without true jointed legs; and marked by transverse lines that divide it into a succession of rings or segments, which, except the first and last, differ little from each other but in size. Many of them are remarkable for the red colour of their blood; and, on account of this character, they have been regarded as approaching nearer to the vertebrated subkingdom than any other class of articulated animals. This is not universally observed, however, for in some species the blood has a greenish tint, and in others it is nearly colourless, as in invertebrata in general. The body is usually soft and flexible, the rings being possessed of little firmness, and no internal skeleton of any description being present. It is not only flexible, but capable of great alteration in its dimensions, as may be seen in the common earth-worm or leech.

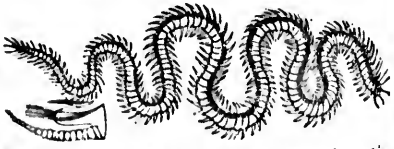
The greater part of this class are solely inhabitants of the water, and are provided with external appendages for exposing the blood to its influence, which are analogous in function to the gills of fishes, but which are often distributed over the whole surface, and are also concerned in locomotion. It may be regarded as the *regular* form of these animals to possess such appendages upon every segment. But not unfrequently the body is enclosed in a tube, and then the gill-tufts are collected in the neighbourhood of the head, where they may be protruded from its opening. The earth-worm and a few other species are adapted to live on land, and they have a series of air-sacs arranged along the interior of the body on each side, opening externally by a small orifice, of which a pair may be seen upon each segment.

The first segment, which may be termed the head, contains the mouth, sometimes provided with a formidable apparatus of jaws; and it is also generally furnished with eyes, and with variously shaped tentacula, which are apparently instruments of touch. The last segment is occasionally destitute of the appendages with which the rest are provided, and these are replaced by a sucker, which is of great assistance in locomotion.

The class is subdivided into orders by the differences in general conformation and habits exhibited by the tribes which compose it; and especially by the character and distribution of the respiratory organs. The first order, Dorsibranchiata, includes those which have the branchial appendages or gill-tufts disposed regularly along the body, sometimes extending its entire length and sometimes restricted to the segments about the middle. This order has been also denominated *Errantia*, from the active habits of the animals comprehended in it. In the next, Tubicola, we find worm-like animals inhabiting fixed and permanent residences like the Mollusca. Sometimes they are enclosed in shelly tubes, formed by an exudation from their own surface, and sometimes in casings constructed by the agglutination of foreign substances. The disposition of the gill-tufts around the head is the principal character which distinguishes the animals themselves from those of the first order. In the third order, Terricola, the body is destitute of all external appendages, except some minute and almost imperceptible bristles; for the respiratory organs are here developed internally, the animals being formed to crawl upon the ground instead of swimming through the water. And in the last, Suctoria, the body is destitute even of these bristles, but is furnished with a sucker at each end of the body. The two latter groups were regarded by Cuvier as forming one order.

Order I.—Dorsibranchiata.

Of the foregoing orders, the Dorsibranchiata appear, on the whole, to possess the most complex structure, as well as the most varied faculties, and they also exhibit the most characteristic forms of the class. The head is almost always distinct from the body, and furnished with highly-developed organs of sensation, as well as with complex instruments of mastication. These marine worms do not attain any considerable dimension upon our own coasts, rarely exceeding a few inches in length; but in tropical climates some species are found of comparatively gigantic proportions, having their bodies composed of 400 or 500 segments, and occasionally measuring four feet from one end to the other. Their general form will be seen in the accompanying figure, which represents the *Syllis Monilaris*; and the enlarged view of one of the lateral appendages will show the parts of which it consists. In the centre there is a tuft of delicate bristles, which may be regarded as the chief organ



Syllis Monilaris, with an enlarged representation of one of its appendages.

of respiration, the blood being sent into them to be exposed to the air contained in the water; above and below there are separate bristles, much more elongated, of which the lower one has a jointed character, these are instruments of locomotion, and may be regarded as rudimentary legs. The arrangement of these

parts differ much, however, in the various tribes of this order.

Among the more interesting forms of this order may be mentioned the family NEREIDÆ, or Sea-Centipedes, of which many species inhabit our own coasts, but much larger ones are found in tropical seas. They have no venomous power, but are extremely voracious; and are often furnished with a complex apparatus for seizing their prey and reducing it to fragments.

The *Aphrodita* is an animal well known on our coasts under the name of *Sea-Mouse;* numbers are often cast up by a gale of wind. The body is flattened, and shorter and broader than that of other Annelida. The back is covered by two longitudinal ranges of broad membranous scales, under which the gills lie concealed. The most common species of Sea-Mouse are about six or eight inches long, and two or three broad. A great part of the body is covered by bristles of brilliant lustre, and of colours which vary with the light; so that the animal is scarcely surpassed in beauty of colouring by any other. The *Arenicola piscatorum*, known to fishermen by the name of *Lob-worm*, is another species common on our coasts, and is eagerly sought as a bait. It burrows, like the earth-worm, in the sand; and the place of its excavations may be known by the little heaps which it casts up. The branchial tufts are confined to the centre of the body, where they form on each side a series of bunches, which are remarkable, during the life of the creature, for their beautiful red colour, derived from the crimson blood which circulates copiously through them.

Order II.—Tubicolæ.

Comparatively little is known of the structure of the animals of the order Tubicolæ, which never attain to such great dimensions, and do not offer to the naturalist the same facilities for examination. The structure of the casings which they form, however, has been fully investigated. One of the commonest of these is the shelly tube exuded by the *Serpula*. This is formed of calcareous matter resembling that of the shells of Mollusca, and apparently secreted from the surface of the body in a similar manner. These tubes, which are often very greatly contorted in form, are generally found encrusting the surface of stones or other bodies which have been immersed for any length of time at the bottom of the sea; they are closed at one end, which tapers to a point, and the wide end is open.

Serpula Contortuplicata, taken out of its tube.

The animal forming this shell has its branchial filaments all assembled round the head, where they form a pair of most elegant fan-like appendages, which usually possess very brilliant colours. At the base of each tuft is a fleshy filament; and one of these, on the right or left side indifferently, is always prolonged and dilated at its extremity into a flat disk, which fits to the mouth of the shell, and serves to close it when the animal is withdrawn into the tube.

The *Sabella* is an animal very much resembling the Serpula; but it constructs its tube by agglutinating particles of clay or fine sand. The *Terebella* forms a similar tube, by cementing together minute shells and fragments of larger ones, together with particles of sand, gravel, &c.; and some species live in aggregate groups, so that the clustering together of their tubes forms solid masses, which may go on increasing to a considerable size. In none of these cases is the shell or tube to be regarded as part of the animal; it is merely its habitation. The Annelide forms no muscular attachment to it, and its body can be easily drawn forth from its interior.

Order III.—Terricola.

The order Terricola includes very few genera, of which the *Lumbricus*, or common *Earth-worm*, is the chief. They live in general beneath the surface of the ground, either perforating the dry soil, or burying themselves in mud, where many of them lead a semi-aquatic life. When the Earth-worm is boring, it insinuates its pointed head between the particles of earth, among which it penetrates like a wedge; and in this position, the anterior part of the body is fixed by spines or bristles curved backwards, which prevent it from slipping. The hinder parts are then drawn forwards by a longitudinal contraction of the whole animal—a movement which the spines do not oppose. This swells out the anterior segments, and forcibly dilates the passage into which the head had been already thrust. The spines upon the hinder rings then take a firm hold upon the side of the hole thus formed, and prevent any backward movement; the head is again forced forward; and, by a repetition of the process, the animal easily makes its way through substances which it would at first have seemed impossible for it to penetrate.

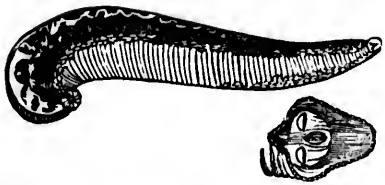
The burrowing of Earth-worms is a process exceedingly useful to the gardener and the agriculturist; and these animals are far more beneficial to man in this way than injurious by devouring the vegetables set in the soil. They give a kind of under-tillage to the land, performing the same below ground that the spade does above for the garden, and the plough for arable land, and loosening the earth so as to render it permeable to air and water. It has lately been shown that they will even add to the depth of the soil, and create mould where none existed before. This they do principally by the exercise of their digestive process. They take a large quantity of the soil through which they burrow into their intestinal canal; from this they extract the greater part of the decaying vegetable matter it may contain, and reject the rest in a finely divided state, forming what are known as worm-casts. By the accumulation of these, a field which was manured with marl has been covered in the course of eighty years with a bed of earth averaging thirteen inches in thickness.

It is commonly supposed that the Earth-worm may be multiplied by the division of its body into two pieces, of which each will continue to live. This does not appear to be the case. If it be divided across the middle when in motion, each will continue to move for a time but only the piece which bears the head will be found alive after a few hours. This forms a new tail, and soon shows little sign of the injury. But if the division be made near the head, the body will remain alive, and will renew the head; and the head with its few attached segments will die. The *Naides*, however, have a much greater amount of reproductive power; for they may be cut into many pieces, of which each will become a perfect animal; and it is stated that a separation takes place spontaneously, but to a much greater extent.

Order IV.—Suctoria.

The order Suctoria contains the common Leech and its allies, which are all animals of aquatic habits, but not all agreeing in its blood-seeking propensities. Most of the tribe, however, live at the expense of some other animal.

The structure of the mouth of the leech is very interesting. It is situated in the middle of the cavity of the anterior sucker; and three little cartilaginous bodies, usually called *teeth*, but more properly *jaws*, are seen to be disposed around it, in such a manner that the three edges form three radii of a circle. Each of these has two rows of very minute teeth at its edge; so that it resembles a small semicircular saw. It is imbedded at its base in a bed of muscle, by the action of which it is



Leech, with the anterior sucker and teeth enlarged.

worked in such a manner as to cut into the skin—a sawing movement being given to each piece separately. It is in this manner that the tri-radiate form of the leech-bite is occasioned; each ray being produced by a separate little saw. The lacerated character of the wound is very favourable to the flow of blood, which is further promoted by the vacuum created by the sucker. The greater number of the *Leech* tribe are inhabitants of fresh water; some, however, are only found in the sea; and there is one terrestrial species, a native of Ceylon, which appears to be more voracious than any other, and to be one of the greatest pests of that fine island.

CLASS XI.—CIRRHOPODA.

The animals composing this class have so many characters in common with the Mollusca, that they have been generally regarded as belonging to that sub-kingdom. The body and its appendages are themselves quite soft; and the skin has the loose spongy muscular character which corresponds with the *mantle* of Molluscs. From its surface is secreted a shell, composed of several pieces, but not differing in general aspect from multivalve shells belonging to that division. Further, the shells are either themselves firmly united at their base to some solid masses, or they are attached by a foot-stalk; so that the conditions in which the animals exist closely resemble those to which we observe the Mollusca peculiarly adapted.

On the other hand, when we examine the animal itself, we find that it is perfectly symmetrical in its form—a character nowhere existing among the Mollusca which are enclosed in shells. Its body is prolonged and exhibits a tendency to division into segments; and from each of these there arises a pair of appendages on each side, which possess something of a jointed structure. These *cirri*, as they are termed, are long tapering arms, fringed with cilia, or little hair-like filaments; and they have gills at their base. Further, the mouth is furnished with lateral jaws, which no Mollusca possess; and the nervous system consists of a double cord, with a pair of ganglia in each segment of the body, precisely as in the other Articulata. The most interesting proof, however, that the Cirrhopoda belong to this division, is derived from the history of their development. On their liberation from the egg, they present a form much more analogous to that of the lower Crustacea than to that of the adult animal, which they only acquire after a series of metamorphoses. They are furnished with antennæ and eyes, and move freely through the water; but when they become fixed they lose also these organs of sense. The shell is not formed of simple layers, like that of the Mollusca, but is traversed by a complex series of canals, through which nourishment is conveyed to it.

The Cirrhopoda are divided into two principal groups —the *pedunculated* and the *sessile*. The latter, of which the common *Balanus* or *Acorn-shell* is an example, have the base of the shell fixed immediately to rocks. In the former, such as the well-known *Barnacle*, the shell is attached by a peduncle or footstalk, which consists of a tube of leathery consistence, and is often of considerable length. In both groups, the animals, not being able to go in search of food, obtain it through the currents produced by the action of their cilia.

The shell of the common *Barnacle* consists of five pieces, of which two are large valves, somewhat resembling those of a mussel; two smaller pieces are jointed to these near the point; and one unites the valves along the back edge. These cover the whole of the mantle. Barnacles are abundant in all seas, and fix themselves, in preference, to wood; so that a piece of timber which has been for a short time floating in the ocean is almost sure to be partly covered with them; and ships' bottoms, if not protected by copper, are rendered so foul as greatly to impede their sailing.

Group of Anatifa, attached to a ship's bottom.

The *Balanus*, or Acorn-shell, has more of a globular shape, with a narrow mouth, and is composed of a certain number (varying in the different species) of plates of a triangular form, so disposed, that an addition to the edges of each shall preserve the general proportions of the shell, while increasing its cavity in all its dimensions in accordance with the growth of the animal. In this arrangement we recognise the same plan as that adopted in the shell of the echinus. The animal closely resembles the barnacle. The mouth of the shell is guarded by an *operculum*, consisting of two or more valves, which close it more or less completely. The rocks, piers, &c., on many parts of the coast, are covered with these animals; and small species of them also attach themselves to shells of various kinds.

CLASS XII.—ROTIFERA.

The class Rotifera is one composed entirely of animalcules which can only be distinctly seen with the microscope; and it takes its name from the wheel-like organs with which most of them are provided, whence they are commonly known as Wheel-Animalcules. It is only within a very recent period that the complex structure of these beings has been understood, and that they have been separated from the animalcules of simpler organization. It is on account of the prolonged form of their bodies, the position of the mouth and eyes at one extremity, the occasional marking of transverse lines indicating a division into segments, and most of all by the character of the nervous system, when that can be detected, that the Rotifera are ranked in the articulated sub-kingdom. Unquestionably, they bear more general analogy to that than to any other; but they must not be considered as characteristic specimens of it.

The structure of the common wheel-animalcule, *Rota*

fer vulgaris—which may be found in many collections of stagnant water, especially such as have been long and freely exposed to the atmosphere—will afford a good illustration of that of the class. The body exhibits a prolonged form when fully extended; but, as the integument is very elastic, it may be drawn up into a circle or made to assume a great variety of shapes. At one end it is furnished with a pair of projections, which are surmounted by circular fringes of cilia. It is by the vibration of these cilia that the currents are produced in the water around, which give an appearance as of the continual revolution of wheels. Between the wheels a sort of head extends forwards, on which a couple of red spots may be observed, which are believed to be eyes. The mouth is situated at the base of this central projection. At the opposite end the body is prolonged into a sort of tail, furnished with three prongs; and by this the animal fixes itself when working its wheels for obtaining food.

The delicate membrane which covers the body has two series of muscular fibres disposed within it; one set running longitudinally from end to end; the other transversely, so as to form rings around the body. By the contraction of the former the body is shortened; by that of the latter its diameter is decreased, and it is consequently lengthened. This is the same kind of apparatus as that by which the form of the leech and worm tribe is altered. The transparency of the integument allows the contained organs to be distinctly seen; and these are perceived to have regular membranous walls of their own, and to be altogether distinct from the general substance of the body. The most curious of these is the gizzard, or set of jaws (as it may perhaps be termed) in which the food is ground down before it is transmitted to the true stomach. This is placed in the fore part of the body, and principally consists of a hard framework in two pieces, each of which bears two teeth. The two frames are moved by powerful muscles, and worked in such a manner that the teeth are made to interlock and to separate alternately, so as to tear all the food which is transmitted into the stomach. From the stomach there passes backwards a long straight intestine, which terminates near the posterior part of the body.

These animalcules feed chiefly upon others of smaller size and simpler character. The currents set in motion by the cilia are very powerful, and draw in whatever small bodies are within their scope; and the animal seems to select from these what is adapted to afford it nutrition. Sometimes it folds in its wheels, and moves along a solid surface by the suckers with which its head and tail are furnished, in the same manner as a leech; and sometimes it remains altogether inert for a considerable period. One of the most remarkable points in its history is its power of being revived by the application of moisture, after having been entirely dried up. This experiment, however, does not always succeed.

The Wheel-Animalcules are propagated by eggs, the development of which within the body of the parent may be very distinctly seen, on account of the transparency of the latter. These eggs are large and not very numerous, seldom more than four; but they rapidly arrive at maturity, and are soon capable of producing others. It has been calculated that, from a single individual, more than a million may be produced in ten days. In some of this class, the eggs are borne for some time on the outside of the body, attached to its posterior part, as in the *Cyclops* and other minute Crustacea, to which the general structure of the higher species of Rotifera shows them to be nearly allied. Other species connect this class with the higher Polypifera.

CLASS XIII.- ENTOZOA.

This class derives its name from the peculiar condition in which the animals composing it exist, most of them being inhabitants, during their whole lives, of the bodies of other animals, generally those of higher organization, from the juices of which they derive their nourishment. Many of them possess a distinct worm-like form, the body being much prolonged, and exhibiting a division into segments, and the mouth being situated at one extremity. These, therefore, evidently belong to the Articulated series. There are others which, in the absence of all distinct organs, and also in the circularity of their form, seem to approximate more to the Radiata. Some species, formerly located in this class, are now known to be low kinds of Crustacea.

A division of the Entozoa into two sections has been proposed, founded upon the general peculiarities of their structure, which it may be useful here to adopt. In the first and highest of these, there is a distinct intestinal tube, with an orifice at each end; and traces of a nervous and muscular system, more or less developed, may be detected. This division evidently approximates to the Annelida. It includes, among many other species, the *Filaria*, or Guinea-Worm, which burrows in the flesh of man and other animals in warm climates; if undisturbed, it will often continue its operations for a considerable time without much uneasiness; but, if disturbed, it sometimes occasions the most excruciating pain. When it shows itself externally, it is extracted very slowly, for fear of breaking it, in which case the remainder would retreat, and continue to exist; it grows to the length of several yards. The *Ascaris lumbricoides*, or Round Worm of the intestines, also belongs to this group. It infests not only man but many of the lower animals, and often occasions severe disease and even death. It derives its second or specific name from its resemblance to the earth-worm. The short active Thread-worms, sometimes infesting the lower part of the intestine, are another species of the same genus.

In the lower division of the class, there is no distinct alimentary canal; the cavities for the reception of food, as well as those for other purposes, being, as it were, channelled out of the soft, almost homogeneous, tissues of the body. Some of these still preserve the worm-like form. Such are the so-called eels in vinegar; and the curious little parasites which have been recently discovered to infest the muscles of man. To this group also belongs the *Tænia Solium*, or Tape-Worm, in which we find a remarkable repetition of organs. The body is distinctly divided into joints or segments, which sometimes amount to several hundred: the whole animal occasionally attaining the length of ten feet. These segments are all connected by the nutritive canal, which runs from one end to the other; but the reproductive apparatus is repeated in each division. The head is small and possesses four mouths, surrounded by a double circle of small hooks. Its existence is essential to the life of the body, the latter dying if it be broken off; but if some of the joints remain attached to the head, it continues to grow and form new ones. In this repetition of parts, we see a tendency towards the type of the Polypifera.

One of the most simple of all the Entozoa is the common *Hydatid*, or Acephalocyst (headless bag), which seems to consist of nothing but a globular membranous bag filled with a limpid colourless fluid. It exhibits no motion or indication of sensation, when stimuli of any kind are applied to it; and it is often difficult to distinguish it from the tissues in which it is found. Its power of reproduction, however, by the formation of *gemmæ*, or buds between its layers, shows it to be entitled to the rank of an independent being; the young Hydatids are thrown off internally or externally according to the species.

Among the animals associated with this group, though not conforming with it in their residence, is the *Planaria*, a very interesting genus, of which some species inhabit fresh water, and others are marine. The body is flat,

and three or four times as long as broad. Within its soft tissue are channelled out not only a complex digestive cavity, but also a system of vessels which absorb fluid from its walls and convey it through the system and a reproductive apparatus. The stomach opens, not by a mouth at one end, but by a sort of sucker projecting from the middle of the body; and through this the Planaria imbibes the juices of various aquatic animals which it attacks, mastering even active little worms by twisting its body round them. The most curious part of their economy consists in their power of reproducing parts that have been lost, and of repairing injuries, which seems almost as great as that of the Hydra among Polypes. They may be divided into three parts, of which the former shall contain the two minute spots which are believed to be eyes, the middle one the sucker, and the posterior one the reproductive apparatus; and in a short time each part will develop itself into a new individual, perfect in all its parts. It may be partially split longitudinally from either extremity, so that two heads or two tails will be formed, uniting at the middle point, but each being complete in itself.

SUB-KINGDOM—MOLLUSCA.

The range of animal forms comprehended in this division of the Animal Kingdom is so great that it would be difficult to include them by any definition applicable to them all. The highest class approaches Fishes in many points of its organization; while in the lowest we not only lose sight of some of the characteristic peculiarities of the group, but we find a near approximation to the higher Polypifera In all the Mollusca, the body itself is of soft consistence, as its name imports, and is enclosed in a soft elastic skin, lined with muscular fibres, which is termed the *mantle*. This skin, in many instances, is not applied closely to the body, but forms a membranous bag, having apertures (which are sometimes prolonged into tubes) for the entrance and egress of water; and through these the respiratory organs, which are situated within the cavity, are regularly supplied with the pure fluid necessary for aerating their blood; and the mouth, when it is not capable of being projected beyond this cavity, is supplied with food by the same stream.

The Mollusca possess in general a very complicated digestive and circulating apparatus; but the organs of sensation and voluntary motion are comparatively undeveloped. The great bulk of their bodies is made up of the stomach and intestines, the liver and other glands connected with the alimentary canal, the respiratory apparatus, and the ovary for the production of germs (which is usually very large); and the muscular system, which in the Articulata forms so large a proportion of the whole structure, is here frequently reduced to a few scattered fibres, and in but few instances attains any complexity and power. A considerable number of Mollusca are formed for an existence as completely stationary as that of the Zoophytes, and are dependent for their nourishment on the supplies of food casually brought within their reach by the waves and currents of the ocean. A few, however, have powers of locomotion which enable them to search actively for it themselves; but the greater number wander sluggishly, like the snail, from place to place, devouring with voracity such supplies as they meet with, and being capable of fasting for long intervals when none come in their way.

It is from the surface of the mantle that the calcareous matter is exuded which forms the shell, in those species which possess such a protection; its particles are held together by a sort of glue, which exists in much larger proportion in some species than others. In very hard and brittle shells, if the calcareous matter be removed by the action of an acid, the animal matter that remains appears in the form of separate flakes. But in many other shells thus treated, the animal portion retains its form after the removal of the lime; and there are a few in which the (so-called) shell consists only of a substance like horn, without any intermixture of calcareous particles. Such a substance appears to be formed by the young animal before the true shell is secreted; and it is also the first that appears when the animal is repairing the effects of an injury to the old one. It is this that constitutes what is commonly termed the *epidermis* of shells—a covering possessed in their natural state by all that are not enveloped in a fold of the mantle, but which is commonly removed when the shell is preserved, as it impairs the beauty of the exterior. The shell is most solid and massive in those species which lead an inactive life; and is usually light and thin, or altogether deficient, in those whose powers of locomotion are greater. Its thickness often varies greatly among different individuals of the same species, according to the roughness or tranquillity of the waters they inhabit.

As the shells of Mollusca are the parts of their structure by which they were best known, it was natural that the first attempts at classification should be founded on their peculiarities. Accordingly, Linnæus arranged them into *Univalves*, *Bivalves*, and *Multivalves*, according to the number of pieces of which the shell is composed; and this classification, from its simplicity and the apparent facility of its application, has been very generally adopted. But, as will hereafter be seen, it is only within certain narrow limits that the character of the animal can be known by the structure of its shell; and, by the Linnæan classification, animals are brought together which are widely separated, and others are placed in distinct classes which are closely allied. Again, such a classification is totally inapplicable to the very numerous shell-less Mollusca, some of which approach so closely to those bearing shells (as for instance the *Slug* to the *Snail*), that scarcely any essential difference exists. It is obvious, then, that although the characters derived from the shell may often be valuable in enabling us to recognise the remains of particular animals, classification must not be founded on them, but on the general conformation of the animals by which they are produced.

Following this principle, the Mollusca may be divided, first, into those having *a head*—that is, a prominent part of the body on which the mouth is situated, with organs of sense in its neighbourhood—and those which are *acephalous*, or headless. Among the former we perceive three very distinct types of structure.

The Cephalopoda, or *Cuttle-Fish* tribe, have feet or tentacula arranged in a circular manner around the head. In this group we find the nearest approximation to the Vertebrata.

The Pteropoda constitute a small but interesting class, characterized by the possession of a pair of winglike expansions of the mantle, and by the great symmetry of their bodies. These expansions serve as fins, by which they swim through the water with great velocity.

The Gasteropoda are the most extensive group of the whole. The two former are confined entirely to the sea; among these we find species adapted to live in fresh water, and even on land. They have but one muscular expansion or foot, and this proceeds from the under surface of the body, as may be well seen in the Snail.

In each of these orders we observe a considerable variation in regard to the relative size and even the existence of a shell; for while there are some species in all of them which are entirely destitute of this protection (such being called naked Mollusca), there are others which possess it in a slight degree, having it generally concealed in a fold of the mantle, while in others it completely envelops the body, when they desire to withdraw

themselves under its protection. In the different species of Snail and Slug, all agreeing closely in general structure, every variety of this kind may be seen.

In the headless Mollusca, on the other hand, we find two very distinct groups; in the first of which the shell is constantly present, while in the second it is as invariably absent. The general structure of the latter is much inferior to that of the shell-bearing class, and it approaches more nearly in several of its characters to the Polypifera.

The highest class of Acephalous Mollusca is named Conchifera, from the constant occurrence of a shell, which is nearly always formed of two pieces, or *bivalve*.

The lowest is denominated Tunicata, the shell being replaced, as it were, by a leathery or cartilaginous envelope or tunic, which encloses the whole body.

CLASS XIV.—CEPHALOPODA.

The class of Cephalopoda, which is so named from the arrangement of the feet or locomotive organs around the head, must be regarded as the highest among the Mollusca in respect to the complexity of its organization, and it is the one which approaches most nearly to vertebrated animals. In the general form of their bodies, and in their adaptation to a rapid motion through the water, many species bear a considerable resemblance to Fishes, and are, indeed, commonly reputed as such. The name of the class expresses the character which distinguishes it from all others. On the head, which is furnished with eyes resembling those of higher animals, and also with organs of hearing, and perhaps also of smell, are disposed in a circular manner the curious appendages, which have received the names of *feet* or *arms*, and to which either term may be justly given, as they are organs of prehension as well as of locomotion. These are usually eight or ten in number; but in the true *Nautilus* they are much more numerous, amounting to nearly a hundred.

The mouth, which is situated in the centre of the circle of arms, is provided with a pair of firm horny mandibles or jaws, of which one is sharply pointed, and overlaps the other when closed, so that the whole very much resembles the bill of a parrot. This beak encloses a large fleshy tongue, roughened with horny prickles; and the œsophagus leads to a muscular stomach, which much resembles the gizzard of birds. All the Cephalopoda are aquatic, and consequently breathe by gills. These are disposed symmetrically on the two sides, and are covered in by the mantle. This envelope includes the whole body, but there is an opening in which it gives passage to the head. Through this opening the water enters to the gills, and it is expelled through a tubular prolongation of the mantle termed the *funnel*, which also serves as the excretory canal for other fluids.

Most of the Cephalopoda possess something analogous to the shells of other Mollusca, although it often exists in a form and position which might almost prevent its being recognised as such. The only species at present known in which the body of the animal is enclosed within it, as in the shells of Gasteropoda, are the *Nautilus* and the *Argonauta* (Paper-Nautilus). In the former of these the shell is spiral, and is divided by transverse partitions into chambers, in the last or outermost of which the animal lives; and when it wishes to enlarge its shell, it prolongs the mouth of it, which widens as it is prolonged, and throws a new partition across the bottom. The shell of the Argonaut has no such chambers, and the animal, when hiding within it, occupies the whole of its cavity. In the common *Sepia* (Cuttle-Fish), on the other hand, the shell is reduced to the form of an oval plate, commonly known as the *cuttle-fish bone*, from which pounce is derived, that may be picked up on almost every shore; and this is enclosed within a fold of the mantle, and lies upon the back of the animal. In some of the more slender and flexible species even this is nearly wanting; all that remains of a shell in the *Loligo* (Squid) being a narrow horny plate, somewhat resembling a feather in shape, whence it is termed the *pen*.

The arms of all the Cephalopoda are covered with very curiously constructed suckers, by which they are enabled to take firm hold of any thing to which they are applied These act by excluding the air, and thus producing a vacuum, exactly upon the principle of the boy's leather sucker. In this manner they are enabled to master animals which it would have been supposed entirely out of the power of their soft unprotected bodies to combat successfully. They are generally agile as well as voracious; and prey upon almost all other classes of marine animals. Their special articles of food, however, are Fishes and Crustacea; and they are probably the only animals which are able to restrain the inordinate multiplication of the larger members of the latter class. The firm armour of the crab or lobster, and its powerful claws, are no protection to it against these soft-limbed cuttle-fish, which wind their arms round their bodies, and, fixing every part by means of their suckers, tear apart the divisions of the shell by means of their hard parrot-like bills. So firmly do these suckers adhere, that, while the muscular fibres remain contracted, it is easier to tear away the substance of the limb than to release it from its attachment.

The Cephalopoda which are unprotected by an external shell, are furnished with a curious means of escaping from their enemies. This is the secretion of a dark fluid, which, when emitted by the animal, tinges the water around to such a degree that it can escape in the cloud it has made. The fluid is usually stored up in a bag communicating with the funnel through which it is ejected under the influence of alarm. This ink-bag, as it is termed, is collected from the species inhabiting the Indian seas; the ink forms a valuable pigment, known to the artist as *sepia*, the name of the animal which furnishes it.

The class of Cephalopoda may be subdivided into two orders. In the higher division, which approaches the nearest to vertebrate animals, the *branchiæ* or gills are two in number, and the order is termed Dibranchiata, while in the one most closely allied to the Gasteropod Mollusca, the branchiæ are four in number, and the order is therefore termed Tetrabranchiata.

Order I.—Dibranchiata.

The Dibranchiate order includes all the best-known forms of the class. It is divided into two tribes, in one of which there are but eight arms, while in the other there are ten, of which, however, two are different from the rest. The first of these, termed Octopoda, may be considered as the highest in point of general organization; the second, termed Decapoda, presents many points of approach to the Tetrabranchiate order, both in the increased number of arms, and in the presence of an inner circle of short tentacula, as well as in several internal characters. The *Sepia*, or common Cuttle-Fish, is a characteristic example of the Decapod family. Some species of it abound in almost all seas. It has two long slender arms, which are furnished with suckers only at their extremities; and by these the animal is said to fix itself, as by anchors, when exposed to a rough sea or strong current. They are probably employed also in seizing prey, which is brought by them within the range of the others.

To this group we are probably to refer the *Spirula*, a little chambered shell, the animal of which is very imperfectly known; and a large number of fossil chambered shells, known as *Ammonites*, *Belemnites*, &c.; the animal of which was probably analogous to the Sepia,

including the shell, like the bone of the cuttle-fish, within the body.

The Octopoda, which form the highest family of the Dibranchiata, have but eight arms, without tentacula; and they are destitute of lateral fins, so that they depend entirely upon the arms for their movement through the water. Accordingly it is found that these are very large and powerful, and that the body is proportionally short. The arms are generally united at their bases into a kind of circular fin, by the motion of which the animal can swim backwards with great energy. The common *Octopus*, or *Poulp*, of European shores, has the arms six times the length of the body, and each furnished with 120 pairs of suckers. It can leave the water, and creep over the beach; taking hold of the ground before it by the extension of its arms, and then dragging the body towards the point at which the suckers are attached.

A very interesting species of the Octopod group is the *Argonauta Argo*, commonly called the *Paper-Nautilus*, from the whiteness and delicacy of its shell. As the animal has little in common with the true Nautilus, it would be much better if the latter designation were entirely abandoned, and the term *Argonaut* substituted for it. The shell is not chambered, but possesses one spiral cavity, into which the animal can withdraw itself entirely; this, however, has no muscular attachment to it, whence it has been supposed by many naturalists that it was only a parasitic inhabitant, which had taken up its abode within it, and that the shell, from its resemblance to that of Carinaria, was formed by a Gasteropod mollusc allied to that genus. It has been lately proved, however, by the interesting experiments of Madame Power, that the shell increases regularly with the growth of the animal, which possesses the power of repairing it when injured: so that no doubt can exist that the Argonaut is the original constructor of it.

Of the eight arms of the Argonaut, six taper gradually towards the extremities; but two are expanded into wide membranous flaps. From very early times, this animal has been reputed to swim on the surface of the water, using its arms as oars, and spreading these expanded

Shell of Argonaut, with animal in the reputed position.

membranes as sails to the wind. But it is now known, by accurate observation of the living animal, that this is altogether a fiction (though an interesting one); and that the expanded arms are spread over the sides of the shell, meeting along its keel or edge, and almost completely enclosing it. It is by these, indeed, rather than by the surface of the body itself, that the calcareous secretion is poured out for the enlargement or separation of the shell. By the action of the arms, the Argonaut swims backwards in the same manner as other Octopoda, and it can also creep along the bottom of the sea.

Order II.—Tetrabranchiata.

From the remains preserved in a fossil state, the Tetrabranchiata appear to have formerly existed in our seas; but the only living representative of them is the *Pearly Nautilus* (*N. Pompilius*). In the animal which forms and inhabits the well-known chambered shell found on most tropical shores, we observe many differences from the usual type of organization in the Cephalopods. The arms are very numerous, amounting to nearly a hundred; they are unprovided with suckers; and they are short and slender, resembling closely the tentacula of many Gasteropods.

The head of the *Nautilus* supports a large fleshy disc, upon which it is believed that the animal crawls upon the bottom or sides of the ocean, as a snail upon its foot. The animal frequents deep waters; and, though it is occasionally found at the surface, it sinks upon the least alarm, so that it has been very rarely captured, although the empty shell is so common. This power of rising and falling in the water appears in some degree connected with the structure of the shell, and with the mode in which its chambers communicate with the body by a membranous tube which passes through all the partitions, and is called the *siphuncle*. But of the mode in which this operates no very satisfactory account has yet been given.*

A large number of fossil shells, analogous to that of the Nautilus, and hence called *nautilites*, are found in various strata, from the oldest limestones and sandstones of the Silurian system, to those covering the chalk.

CLASS XV.—PTEROPODA.

The Pteropoda are a small but remarkable class of Mollusca, distinguished by the adaptation of their structure for active locomotion in water only. Their general organization is higher than that of the Gasteropods; and they are particularly distinguished by the possession of a pair of fin-like organs, which are attached to the anterior part of the body, and are evidently adapted for propelling it rapidly through the water. The body is uniformly symmetrical; that is, its two sides precisely correspond—a condition obviously favourable for rapid movement. It is from the wing-like character of these lateral appendages that the name of the class is derived.

The dimensions of the animals composing this class are uniformly small; but the number of individuals which associate together in shoals is often enormous, so that the sea appears literally alive with them. Some of them are possessed of a shell, whilst others are unprovided with such a protection. Wherever it exists it is very light and delicate; and it seldom covers more than the posterior part of the body. In one beautiful little Mollusc, the *Cymbulia*, it is of a slipper form, the wings or fins issuing from the large opening. The head is usually prominent, possessing eyes and sensitive tentacula; and the interior organization is of very complex nature.

One of the best-known genera of this group is the *Clio*, which abounds both in the arctic and antarctic seas, and is a very important article of food to the whale. The aspect of this animal will convey a good general idea of that of the whole class. The Clio is itself eminently carnivorous, and in its whole organization is fitted to seize and prey upon the yet more minute inhabitants of the deep.

The *Clio Borealis* is well known to the whale-fishers and others as *whale's food*; this species swarms in the arctic seas, and when the weather is calm, these little animals may be seen floating in myriads upon the surface. According to Cuvier, the sea is sometimes so covered with them, that the whales cannot move their

* See Dr. Buckland's Bridgewater Treatise for an attempted explanation. This is deficient in its application to all those cases in which the siphuncle is a shelly not a membranous tube, as in the *Spirula*, *Ammonite*, &c.

mouths without engulfing thousands of these small Mollusca. An analogous species, the *C. Australis*, ap-

Clio Borealis

pears equally abundant in the polar regions of the southern hemisphere.

CLASS XVI.—GASTEROPODA.

It is in the animals of this class that we find the characters of the Mollusca most prominently displayed, namely, the high development of the nutritive apparatus, with very feeble powers of locomotion. In all the more perfect forms, which are usually carnivorous, a distinct and prominent head exists, furnished not only with *tentacula*, or feelers, but also with eyes, and with what appear to be rudiments or organs of smell and hearing. In this part, we usually perceive that *symmetry* or correspondence between the two halves, which has been spoken of as characterizing the *animal* organs in general; whilst in the posterior part of the body, which is made up of the organs of vegetative life, this symmetry is seldom to be discerned. They have the power of crawling from one place to another, by means of the expanded muscular disc or foot with which they are furnished; and as this foot proceeds from the belly or under surface of the animal, the class receives the name given to it. The mode in which it is used may be well seen by placing a snail or slug on a piece of glass, and looking at it from the under side. Many of those which inhabit the water can swim with considerable rapidity; but this power is chiefly possessed by those species which have no shell, or but a very slight one, and can bend their bodies in any direction.

The general character of the shelly structure, where it exists, is the same as in the Conchifera. It is in general composed of one piece, and called a *univalve*; in some instances, however, it is a *multivalve*: and in many species there is a small *operculum* or lid to the mouth of the shell, which may in some degree be regarded in the light of a second valve. The body is attached to the interior of the shell by muscles which can withdraw it or project it at the will of the animal; and the operculum can be drawn down upon the mouth with considerable force. It is the habit of some species (as the Limpet and Haliotis) to attach themselves, by the expanded surface of the foot, to rocks, &c.; these are able to draw the shell closely down upon the rock, with great muscular power, just as the Conchifera draw together their valves; a short interval existing, however, when the animal is not alarmed, for the admission of water or air to the cavity of the shell. A very slight irritation will cause the animal to draw the shell close down on the rock, from which it is then very difficult to detach it.

The shell is formed, as in other Mollusca, by an exudation from the mantle; and is enlarged at intervals, in accordance with the increasing size of the animal. In some, the addition of an entire new interior layer, projecting beyond the old one, is made at every such period, as in the Conchifera; but in others the new matter is secreted only at the edge of the previous shell, and is joined on, as it were, to it; in these the line of addition is usually marked by a prominent rib on the exterior, but the interior is beautifully smoothed off.

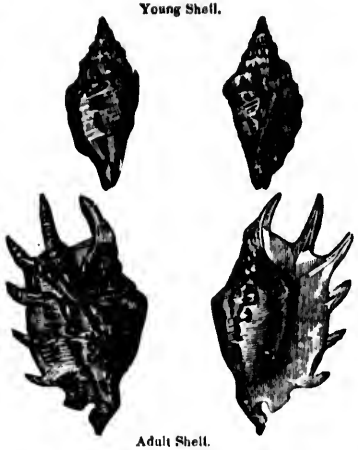
The forms of the shell in this class vary extremely; but those which appear most widely separated may be shown to be connected by intermediate links. The open cone of the *Limpet* may be regarded as one of the simplest forms; in an allied genus, the *Pileopsis*, we find the point prolonged, and somewhat rolled upon itself; and by various links of this kind, we are brought to the regular spiral of the snail. From this we may return to the long straight form by the *Scalaria*, in which the coils of the spire touch each other only by their ribs; and by the *Vermetus* and *Magilus*, in which the commencement only of the shell possesses a spiral form, the remainder being prolonged into a straight tube. When the shell is spiral, and the point and mouth are not in the same plane, a sort of central pillar is formed, like that round which a spiral staircase is constructed. This is called the *columella*; and it is usually grooved at its lower part, for the passage of water to the respiratory organs, which are placed within the shell.

The margin of the shell is not unfrequently fringed with spines, as in the *Murex*; these are formed, like similar appendages in the Conchifera, by prolongations of the mantle; and the dissimilar number of them in different specimens has caused the establishment of many species, which, now that the habits of the animal are better known, prove to be but different forms of the same. For it has been ascertained that the animal has not only the power of forming new spines, but of removing old ones, especially such as would interfere with the continued growth of the shell. The edge of the mantle is applied against their bases, and a kind of absorption of shelly matter seem to take place—a notch being formed, which causes them to be easily broken off. Various analogous changes are produced by a similar action in other shells, the portions first formed being wholly or partially removed. Sometimes the walls of the older portion are thinned, for the purpose of lightening the shell; and in other cases the top of the cone is altogether removed, a groove having been formed around its interior, which renders it so weak as to be easily broken off: in these last cases, the animal previously withdraws itself from the part that is thus to be separated, and throws a new partition across, by which the top of the shell remains closed after the division. A shell thus deprived of its apex is said to be *decollated*.

Murex Tenuispina

It is not only by such removals that the form of univalve shells undergoes a great change. Sometimes additions are made to them, which completely alter their figure, so that two individuals of different ages would be scarcely supposed at first sight to belong to the same tribe. But in all these cases the form of the young shell may be traced in that of the adult. The preceding figures of the *Pteroceras* show this change in a moderate degree; in other genera it is much more remarkable. In another group of shells, of which the common *Coury* is an example, a still more curious alteration takes place. In the

Young Shell.



Adult Shell.

Pteroceras Scorpio.

young shell the edge is sharp, and the mouth or opening of considerable breadth. This state continues as long as the shell is increasing in size; but when it has arrived at adult age, the outer lip is thickened, and brought so near the other as to leave but a narrow chink between them. At the same time, a prolongation of the mantle on each side deposits a new layer of shelly matter on the outside of the previous one; and as the two prolongations meet along the back (the line of their junction being usually evident on the shell), this additional coat, which is very hard and *porcellanous* in its texture, encloses the whole previous shell.

Young Shell.

Adult Shell.

Cypræa Exanthema.

The *operculum* is principally confined to the aquatic Gasteropods. It is sometimes of the same texture as the shell itself, and sometimes horny. It does not always close the entire mouth of the shell, but it is sometimes made to fit it, at all stages of growth, with the most beautiful accuracy. Some of the land species also possess an operculum; but in general they are destitute of it, and they form during hybernation a temporary closure to the mouth of the shell by a viscid secretion, which hardens into a thin plate, and includes within it a bubble of air. Behind this, a second and even a third similar partition is occasionally found, as in the common snail.

The subdivision of this extensive class into orders, may be best effected by arranging the different tribes according to the character and position of the respiratory organs. The following are those adopted by Cuvier

1. Pulmonia. These are terrestrial species, adapted to breathe the air by means of a pulmonary sac or air-cavity, the orifice of which they can open or close at will. Many have no shell.

2. Nudibranchiata. These, as well as all the succeeding orders, are aquatic, being adapted to respire water by gills, like other Mollusca. The animals of this order have no shell, and they carry their branchiæ, which present various forms, on some part of the back.

3. Inferobranchiata. These are similar in many respects to the preceding, but the branchiæ are situated under the margins of the mantle.

4. Tectibranchiata. In the greater part of the animals contained in this order, the branchiæ are situated upon the back or on the side, and are covered in by a fold of the mantle, and this fold usually includes a shell more or less developed.

5. Heteropoda. This is a small order, characterized by the peculiar form of the foot, which is not spread out horizontally, but compressed vertically into a sort of fin. They carry their branchiæ, the tufts of which are generally protected by a shell, upon the back.

6. Pectinibranchiata. The animals of this order, to which belong all the spiral shells, except those of the Pulmonea, are so named from the comb-like form of their gills, which are usually situated in a cavity behind the head, corresponding with the respiratory sac of the Pulmonea. This is by far the most numerous order of the whole.

7. Turbulibranchiata. These have many affinities with the last order, but the shell is spiral only at its apex, where it is commonly fixed to (or rather enclosed by) other bodies, and is prolonged in the shape of a tube more or less regular.

8. Scutibranchiata. In these, also, there is a considerable resemblance to the Pectinibranchiata in the form and position of the gills; but the shells are very open, scarcely in any degree spiral, and cover the body and gills like a shield; and they also differ essentially in their mode of reproduction.

9. Cyclobranchiata. These molluscs have their gills disposed in little tufts under the margins of the mantle, much as in the Inferobranchiata; but they have shells which are spread out over the body, and differ from that order in the mode of reproduction.

Order I.—Pulmonea.

Although the greater part of the Molluscs of this order live on land, some are aquatic; but these, like the aquatic air-breathing Insects and Vertebrata, are obliged to come occasionally to the surface to breathe. They all feed chiefly upon vegetables, and many of them exclusively so; but some are extremely voracious, and will devour almost any organized matter that falls in their way. They are diffused through all climates, particular species being restricted to each. Those without a shell, commonly known as Slugs, constitute the family Limacina. In the common *Slugs*, as in most of the terrestrial species of this order, we observe a prominent head, with four tentacula, and at the end of the longer pair the eyes are situated. These tentacula can be drawn inwards, by a process resembling the inversion of the finger of a glove. On the back there is a kind of shield or disc formed by the mantle, which sometimes encloses a small shell. This shield covers the pulmonary sac, the opening of which is on its right side, and the head can be withdrawn beneath it. The *Testacella* is a kind of slug which has the disc of the mantle at the posterior extremity, and this always contains a small shell. This animal, which feeds largely on earth-worms, is abundant in the south of France, and has been introduced into the gardens of this country, where it is multiplying rapidly.

The *Snails* and their allies, constituting the family HELICIDÆ, are closely allied to the Slugs in organization; differing in but little else than the possession of a shell into which the body may be withdrawn. The common garden-snail of this country, and the *Helix pomatia*, or edible snail of France and Italy, are well-known examples of this family. More striking ones are to be found, however, in tropical climates; where some species of the genus *Bulimus* attain to great size, the eggs being as large as a pigeon's. In some species the direction of the coils of the shell is opposite to what it is in other spiral shells; such are said to be *reversed*. A European species of this genus is one most remarkable for the decollation of its shell. Another large snail of tropical climates, as the *Achatina*, which feeds on trees and shrubs, chiefly on the western coast of Africa, and in the West Indies. Several of its species are distinguished by the beauty of their colours.

The aquatic Pulmonea have only two tentacula. From the necessity of coming to the surface to breathe, they can only live in water of inconsiderable depth; and they chiefly inhabit ponds and shallow streams, or the banks of rivers. Some, however, live on the sea-shore. The *Planorbis*, the shell of which is quite flat, having all its coils upon the same level, is a very common genus in this country; as is also the *Lymnæa*, which feeds upon seeds, as well as the softer parts of plants, and the stomach of which has a very muscular gizzard.

Order II.—Nudibranchiata.

The animals of this order, which might be designated Sea-Slugs, are all marine; and being adapted to breathe water at any depths, and also, in many instances, to swim with facility, they are often found at a great distance from land. When they swim it is usually in a reversed position, the foot being turned upwards; this is made concave by muscular action, so as to serve as a kind of boat, the buoyancy of which keeps the animal at the surface without effort. This order is a very numerous one, and some of its species attain a considerable size; but, from their habits, little is known of them.

Order III.—Inferobranchiata.

The few Molluscs contained in this order differ but little from the last, except in the position of their gills, and their incapability of swimming. They are, therefore, confined to the sea-shore; where they subsist, as do the Nudibranchiata, upon sea-weeds and other aquatic plants.

Order IV.—Tectibranchiata.

This order begins to show an approximation towards that disposition of the gills which characterizes the great bulk of the class; the animals composing it are marine, and live chiefly on the shore or on floating sea-weeds. A very characteristic example of the order is the *Aplysia*, commonly termed Sea-Hare, which is abundant on many parts of the British coasts. Its vernacular name is probably derived from the peculiar form of the superior pair of tentacula, which are flattened and hollowed, like the ears of a quadruped. The head has a very distinct neck. The branchiæ consists of leaflets arranged in a complex form, and situated on the back, beneath a fold of the mantle, which also encloses a flat horny shell. The digestive apparatus is very complicated; consisting of a membranous crop like that of birds, a gizzard having cartilaginous walls, and a third stomach beset with sharp hooks in its interior. These animals feed on sea-weed. They are very sluggish in their movements; but have a peculiar means of defence, consisting of a deep purple liquid, which they can discharge from the edge of the mantle when alarmed, and by which the surrounding water is discoloured, so that they cannot be discerned.

Order V.—Heteropoda.

This is a very small order; but the animals contained in it differ remarkably from all other molluscs. At the edge of the vertical muscular plate, which has been mentioned as occupying the position of the foot in the other Gasteropods, is a small conical sucker, by which the animal can attach itself, and which represents the expanded disc of other orders. The gills are placed on the back, and close behind them are the heart and liver, which seem, as it were, external to the body. In one of the few genera which the order contains, these parts are protected by a small shell, whilst in another there is none. The body, consisting of a semi-transparent gelatinous substance, enclosed in a muscular envelope, is elongated, and generally terminated by a compressed tail; this body can be distended with water. The animal swims in a reversed position, the fin-like foot being uppermost, and the shell depending below. They are limited to warm latitudes: one species of the Carinaria inhabits the Mediterranean, and occasionally appears on particular coasts in large numbers; whilst others are peculiar to the tropics, where most of the allied genera also exist. The shell of the Carinaria is interesting, on account both of its extreme delicacy and fragility, and on account of the strong resemblance which that of the Argonaut or Paper-Nautilus bears to it.

Order VI.—Tectinibranchiata.

This order is not only by far the most numerous in the whole class, but contains the animals which may be regarded as its most characteristic examples. They have all two tentacula and two eyes, sometimes raised on stalks, as in the snail. The mouth is prolonged into a sort of proboscis; and the tongue is furnished with little hooks or recurved spines, which enable it to wear down the hardest bodies by slow and oft-repeated action. The cavity in which the gills are fixed occupies the last whorl of the shell; and in some of the order there is a tubular prolongation of the mantle, termed the *siphon*, for the purpose of conveying water into this cavity, so that the animal can breathe without leaving its shelter. By the presence or absence of this organ, and by the form of the shell, which here appears to bear a sufficiently constant relation with that of the animals, this large group may be arranged under the following families:—1. TROCHOIDÆ, in which there is no siphon, and which have the mouth closed by an operculum. Of this the common periwinkle is a characteristic example, though very small in proportion to tropical species. 2. CAPULOIDÆ, which have a wide open shell, very much like that of the limpets, without operculum or notch in the margin for the passage of a siphon. 3. BUCCINOIDÆ, which have a spiral shell, and a canal at the end of the columella for the passage of the siphon; this is sometimes extremely prolonged, as in the Murex; and the genera exhibiting this character are all carnivorous in their habits. To this family belong the animals forming the greatest number of marine univalve shells preserved in cabinets.

Order VII.—Tubulibranchiata.

The Molluscs of this order construct an irregularly tubular shell, which so much resembles that formed by certain Annelida, as to be scarcely distinguishable from it. They are very few in number.

Order VIII.—Scutibranchiata.

This order is also a small one, containing but two principal genera, which do not differ widely from the limpets, except in the disposition of the gills. The shells are very open, without an operculum, and the greater number are not in any degree spiral. In the *Haliotis*, the shell is slightly twisted; and from a faint resemblance it is thought to bear to the ear of a quadruped, it has been called the Sea-Ear. This animal, in its living state, is one of the most beautiful of Gasteropods, on account of the variety and richness of its colours. Its shell, when the surface is polished, possesses a pearly lustre, with resplendent metallic hues. It is consequently much sought for as an ornament.

Order IX.—Cyclobranchiata.

The general form of the *Limpets*, which principally compose this order, is well known; and the peculiarity in the position of their gills has already been mentioned. Closely allied to the limpets in general structure, but differing remarkably in the formation of the shell, are the *Chitons*, of which some small species inhabit our shores, but which attain to much greater size between the tropics. Their shell is composed of a number of plates arranged behind one another with great regularity, and connected by a very complex series of ligaments and muscles, which reminds the naturalist of those which unite and move the different segments in the articulated animals.

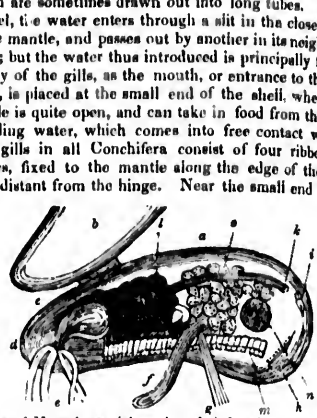
CLASS VII.—CONCHIFERA.

This class is nearly synonymous with that of *Bivalves* in the Linnean arrangement, since all the animals which construct bivalve shells belong to it; but it also contains a few species whose shells are *multivalve*, and some others in which there appears at first sight an entire departure from the usual form. The molluscs belonging to this class are, in common with the Tunicata, destitute of a head; that is, the mouth is not situated upon a prominent part of the body, nor assisted in its choice of food by organs of special sensation in its neighbourhood, but the entrance to the stomach is buried between the folds of the mantle. Hence these two groups were associated by Cuvier into one class, to which he gave the name of ACEPHALA, or Headless Molluscs; but there is quite sufficient reason for separating them, on account of the superior organization of the group at present under consideration.

The part of the structure of these animals which is best known, is the *shell*. This is composed of particles of lime, exuded from the surface of the mantle, in combination with a gluey secretion, by which they are united together. If one of the valves of a bivalve shell be examined, it will be seen to consist of a number of layers, of which the outer one is the smallest, each inner one projecting beyond the one which covers it. This is more evident in such shells as that of the oyster, in which the layers adhere loosely together, than in others in which they are more compact. The shelly matter is thrown out at intervals from the surface of the mantle; and as the animal enlarges at each interval, the new layer extends beyond the old one. In this manner, a constant relation is preserved between the size of the animal and that of its shell; and the addition of the newly-formed portions, not to the edge only, but to the interior of the whole previous shell, strengthens the latter in proportion to its increase in size.

The valves are connected together in various ways. In the first place, they are jointed by a *hinge*, which is in some instances so firm and complicated that it holds them together when all the soft parts have been removed. This hinge is sometimes formed by the locking of a continuous ridge on one valve into a groove in the other, and sometimes by a number of little projections or *teeth*, which fit into corresponding hollows in the opposite valve. In the neighbourhood of the hinge (sometimes outside, sometimes inside, or both) is fixed the *ligament*, which is composed of an elastic animal substance; this answers the purpose of binding the valves together, and at the same time of keeping them a little apart, which may be regarded as their natural position. When the animal wishes to draw the valves closely together, it does so by means of the *adductor* muscle, which is fixed to the interior of both valves at some distance from the hinge, and of which the insertion can be easily traced by a somewhat rough depression of the interior surface of each valve. In some Conchifera, this muscle is single, and in others it is double, the two parts being even at opposite ends of the valve. Upon this character it has been proposed to found the primary division of the class into orders; but the classification thus formed is not a natural one, inasmuch as it brings together kinds which have little resemblance, and widely separates others which are closely allied.

In order to describe the general structure of the Conchifera, it will be advantageous to select some particular illustration; and the common *mussel* is well adapted to this purpose. On opening such a shell, it is seen that the two valves are lined by a membrane which corresponds with the tunic or *mantle* of the Tunicata. This is divided into two halves along a considerable part of the edge of the valves, but is united near the large end. In some Conchifera, as will be presently noticed, the two halves of the mantle are separated along their whole extent; whilst in others, as in the Tunicata, they are completely closed, with the exception of the two orifices for the ingress and egress of water, which are sometimes drawn out into long tubes. In the mussel, the water enters through a slit in the closed part of the mantle, and passes out by another in its neighbourhood; but the water thus introduced is principally for the supply of the gills, as the mouth, or entrance to the stomach, is placed at the small end of the shell, where the mantle is quite open, and can take in food from the surrounding water, which comes into free contact with it. The gills in all Conchifera consist of four ribbon-like fringes, fixed to the mantle along the edge of the shell most distant from the hinge. Near the small end of the



Interior of Mussel; *a*, right valve; *b*, left valve; *c*, hinge; *d*, stomach; *e*, tentaculæ; *f*, foot; *g*, byssus; *h*, branchial orifice; *i*, vent; *k*, termination of intestine; *l*, liver; *m*, gills; *n*, adductor muscle; *o*, ovarium.

shell is seen the stomach, with the short tube leading to it, the orifice of which is furnished with four tentacula or feelers. To the right of this is seen the long and complicated intestinal tube, with the liver lying in separate masses amongst its folds. And nearer the large end, the cavity of the shell is chiefly occupied by the ovarium, in which the eggs are formed. Close to this is the powerful adductor muscle, by which the valves can be drawn together with considerable force. The intestinal tube is seen to terminate near the opening of the posterior (or right-hand) extremity of the shell, which discharges its contents, and serves for the exit of the respiratory current.

The foregoing description will apply, with slight variations, to the structure of almost all Conchifera; but we have now to notice two organs, which are absent in some, and in others more largely developed than in the present instance. From the lower part of the shell, passing out between the separate edges of the mantle, is seen the *foot*, a fleshy muscular organ, somewhat resembling the tongue of higher animals, and not containing any hard support, or being protected by any envelope. This foot, which is the only special locomotive organ possessed by the Mollusca of this class, serves a great variety of purposes, sometimes enabling the animal to leap with considerable agility along a hard surface, sometimes being used to bore into the sand or mud, and sometimes serving only to affix the animal to some firm support. From the base of this foot there proceeds, in the mussel, a band of hair-like filaments, forming what is called the *byssus*. These sometimes exist in great abundance, and serve, by being fixed by their extremities to the shore or bottom of the sea, to anchor the shell, and yet to allow the animal considerable freedom of motion within certain limits. Frequently the byssus is altogether absent.

The Conchifera have usually more power of locomotion than the Tunicata. Some of them, however, as the oyster, are attached to one spot during all but the earliest period of their lives. Others adhere by the byssus, or by the foot, by which they obtain a certain range; and others are free during the whole of their lives, swimming and leaping with considerable agility. In these movements some of them appear to be directed by powers of sight, and in these are perceived small red spots at the edges of the mantle, which are believed to be eyes. They do not appear to have much choice of food, nor are they provided with any other means of obtaining it than the ciliary action, which introduces constant currents of water into the mouth. In general they do not attain any great size, but they are on the whole larger than any Molluscs except the Cephalopoda; and a few species attain considerable dimensions —a *Pinna* having been known four feet long, and a *Tridacne* (Giant Clamp-shell) having been known to weigh 600 lbs. They are distributed over the whole globe principally frequenting the shores or shallows. Each region has certain species peculiar or most abundant in it, and there are few which are not limited to one hemisphere. The temperate zone appears as favourable to the development and multiplication of some species as the torrid zone to others; but the largest kinds are only found in warm latitudes.

In the subdivision of this class into orders, the degree in which the two lobes of the mantle adhere along the margin of the shell, is the character chiefly rested on; the presence or absence of the foot, and of the byssus, also, are important characters; and along with these the structure of the hinge should be attended to. On those grounds, the five following orders are established by Cuvier:—1. Ostracem, the *Oyster* tribe, in which the two halves of the mantle are separated the whole way round, or the foot absent or very small: they are usually fixed by the shell to solid bodies. 2. Mytilacem, the *Mussel* tribe, in which the mantle remains open in front (at the end where the mouth is situated) and closed behind, an aperture being left for the egress of the fluid. They have a foot strong enough to crawl by, and commonly affix themselves by a byssus. 3. Chamacem, or *Clamp-shells*; in these the mantle is closed, with the exception of three apertures, two of which are for the ingress and egress of water, and the third for the passage of the foot, which is here usually more powerful. 4. Cardiacem, or *Cockle* tribe, in which the mantle is not only closed, but extended at the respiratory apertures into tubes of greater or less length. The foot is very strong. 5. The Inclusa, in which the mantle has only one opening for the passage of the foot; at the posterior end it is prolonged into tubes of great length, that can be extended far beyond the shell, as in the common *Solens* or Razor-Shells.

Order I.—Ostracem.

The Ostracem, of all the orders, exhibit the nearest approach to the Tunicata, both in the absence of the foot, the entirely fixed condition of the body, and in the low grade of their organization in general. The shell itself is usually fixed by adhesion to other masses; in a few, the animal is attached by a byssus; and some species, which are unattached, have a slight power of changing their place, by suddenly closing their valves and squirting out the water that was between them. In the true *Oysters* there are no teeth in the hinge, which is held together by the ligament only. Several species exist, some of which are as abundant in tropical regions as the common Oyster of temperate seas is on the shores of Britain. Their continued abundance, notwithstanding the large quantities constantly being consumed, is less surprising when we reflect upon their astonishing fertility, as many as 1,200,000 eggs having been detected in a single individual. The *Pectens* have a hinge like that of the Oysters, but differ in having the surface of the valves raised up into ribs, and in having two angular projections, commonly termed *ears*, by the sides of the hinge. Many of them are very elegantly coloured, and they are the most active of the whole order, being entirely unattached, and swimming with greater quickness than would have been expected from their imperfect means of locomotion.

The foregoing tribes of Ostraceæ, and many more which might be enumerated, are distinguished by the presence of only one adductor muscle; in the remainder of the order, as in most other Bivalves, there exists a second. Among these may be first mentioned the *Etheria*, which is a sort of fresh-water oyster. The *Aviculæ*, which furnish the greater number of the pearls, so highly prized as ornaments, are called *Pearl Oysters*, from their general resemblance to the same tribe. The valves are extended into ears or wings, on each side of the hinge; and these are frequently very long on one side. The pearl is produced from the same substance as that which lines the shell, and which is commonly known as mother-of-pearl. It seems usually to result from some irritation of the mantle, which causes it to excrete an unusual quantity of pearly matter at one spot; and grains of sand, or other small particles, which, by getting between the membrane and the shell, seem to have caused such an irritation, are often found in the centres of pearls. Sometimes, again, pearls are found at points where the shell has been pierced by a boring animal; and it has been proposed to cause the formation of pearls by perforating the shell; but the pearls so produced seldom have that regularity in their form which is as important to their value as is their size. Pearls are also produced within many other shells. The *Pinnæ*, or Wing-shells, approach the Mussels in many respects; they are remarkable for the length and silky character of the byssus by which they attach themselves to rocks, and which is collected in the Mediterranean for the manufacture of gloves and other articles, for which it is well adapted by its strength and durability.

Order II.—Mytilaceæ.

The order Mytilaceæ is well represented by the common *Mussel*, which has been already described. The various species of this group are extensively diffused; and from their abundance in particular localities, and their palatability, they serve as important articles of food. Belonging to this order are some remarkable *boring* shells, which have the power of penetrating hard rocks, and making deep holes, which are enlarged as they advance, in accordance with the growth of the animals, and which, therefore, they cannot quit. By what means they accomplish this is unknown. The flattened form of the shell is a sufficient proof that it is not by mechanical action, as in some of the boring shells of the order Inclusa. The *Anodon* is a fresh-water mussel, closely allied in general conformation to those inhabiting the sea, but differing remarkably in the absence of teeth in the hinge, whence the name of the genus is derived. The *Unio* is another fresh-water genus, having a more complicated hinge. It is remarkable for the pearly aspect of the lining of the valves, and for producing small pearls, sometimes in considerable abundance. These are not so pure in their colour, however, as those of the Avicula, and are but little esteemed. Some species of Unio are common in the lakes and rivers of Britain, but the greater number are peculiar to North America; many of these are remarkable for their size and colour. There are some marine Mytilaceæ allied to the Unios, one of which burrows in coral.

Order III.—Camacem.

The order Camacem includes but a comparatively small number of species, most of which are peculiar to tropical climates. The most remarkable is the *Tridacna gigas*, or Giant Clamp-shell, of the Indian Ocean. When young, this animal attaches itself to rocks by means of its tendinous foot, which serves as a sort of byssus; but when its shell becomes so massive that it is in no danger of injury, it detaches itself, and the groove of the shell

is fille. *ap.* These animals, with their shells, sometimes attain the weight of many hundred pounds. Smaller specimens are often brought to this country; the valves being used to receive water from small fountains, &c.; and, on the continent, they are employed as reservoirs of holy water in the churches. The foot has a structure so tough, that, to separate the shell attached by it, it is necessary to chop it with a hatchet like a cable.

Order IV.—Cardiacea.

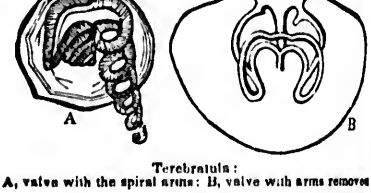
In the animals of the order CARDIACEA, or *Cockle* tribe, we usually find greater activity than in any others of the class. The foot now comes to be a very important organ, possessed of great muscular power, and capable of being applied to a variety of uses. Many of these animals bury themselves in sand or mud; and it is in these that we find the respiratory orifices prolonged into tubes. In the common Cockle, however, these tubes can scarcely be said to exist, the orifices not being prolonged beyond the shell. Its foot is very large, and can be bent nearly double in the middle; by doing this, and then suddenly straightening it, the animal is enabled to take considerable leaps. The hinge is very beautifully constructed; and the two valves lock closely together. The *Trigonia*, a very interesting genus, abundant in former ages of the globe, but now restricted to the shores of New Holland, seems allied to the cockle in the structure of its hinge and shell, in the size of its foot, and in its general organization, although its mantle is divided into two lobes along the whole margin of the valves, as in the oyster. This is an instance of the impropriety of basing our classification on any single characters. There are other Cardiacea which obviously conduct toward the next order. Such is the *Tellina*, of which the valves, when closed together, gape at the posterior extremity; and through this passage there pass out two long tubes which terminate in the branchial orifices and funnel. These tubes have an elastic structure, and can be entirely drawn within the shell. These long tubes are seen also in the *Venus* and its allies, of which one species is remarkable for the long spines which guard its posterior end; and also in the *Mactra*, and the animals allied to it. In some cases the tubes are united along their whole length, and appear to be single; but they are always in reality double. All these animals are in the habit of burying themselves in sand or mud, or in stones; and the tubes serve to introduce fresh water from the entrance of their burrows.

Order V.—Inclusa.

In the order Inclusa we usually find the valves, when joined together, presenting more or less of a cylindrical form, as in the common Razor-shell. A hollow is left at each end, and from one the foot is projected, through a passage in the mantle, while the other gives exit to the respiratory tubes, which are often prolonged to a great length. The animals live almost uniformly buried in sand or mud, in rocks or wood. The *Solen*, or Razor-shell, is a very characteristic example of the order, which contains, however, some forms that depart very widely from it. The foot, which can be projected from the lower end, is firm and pointed, and serves as an admirable boring instrument, by the use of which the animal can burrow in the sand with great rapidity, sinking very deep when alarmed. The *Mya* approaches, in the form of its shell, and in its general organization, to the previous family; but some of its species also closely approximate the Solens. The *Pholas* is a very interesting genus, the animal of which nearly resembles that of the Solen, while the shell is formed of several pieces, and would thence be called a *multivalve*. There are two principal portions, and a variable number of accessory pieces. Some species of this genus bore in mud, others in rocks, and a few in wood. Their action seems purely mechanical. They fix themselves firmly by the powerful foot, and then make the shell revolve; the sharp edges of this commence the perforation, which is afterwards enlarged by the rasp-like action of the rough exterior; and though the shell must thus be constantly worn down, yet it is replaced by a new formation from the animal, so as never to be unfit for its purpose.

We now come to some very remarkable forms of this order, in which the bivalve character of the shell gradually disappears, being replaced by a new structure of which no examples have been yet seen. The *Teredo*, or Wood-worm, as it is commonly termed, is an animal of the same general organization as the Pholas; but its valves are smaller in proportion to the body, and its tubes still more prolonged—at least when the animal may be regarded as full grown. By means of the mechanical action of its valves, it perforates timber, in the same manner as the Pholas penetrates stone. As it advances, the respiratory tubes are prolonged, so that their orifice remains at the entrance of the burrow, which is very small in proportion to the cavity formed by the animal as it increases in size. This orifice is furnished with a pair of valve-like shelly plates, termed *palmulæ*; by the action of which a current of water is driven towards the body of the animal, in order to serve for its respiration, and at the same time for the supply of its food. The gallery is lined by a calcareous exudation from the surface of the tubular prolongation of the mantle, which forms a kind of secondary shell. The Teredo is an animal extremely destructive to timber, especially in warm climates, from which it seems to have been originally introduced into the sea-ports of Europe. In other genera the valves are lost in the shelly tube, so that the ordinary structure of the class is no longer apparent.

Besides the orders now described as composing the class Conchifera, there is a very curious group which should also be included in it, although established as a separate class by many naturalists. This is the group of BRACHIOPODA, containing only three genera at present known, namely, *Terebratula*, *Lingula*, and *Orbicula*; but formerly of much greater comparative importance. These animals have all bivalve shells, differing in no essential particular from those of the Conchifera in general. The two former genera are attached, however, by a footstalk proceeding from an opening in one of the valves near the hinge, to solid substances; and in this respect they have an affinity with the Tunicata. The Orbicula is attached, like an oyster, by one of its valves. They bear considerable resemblance to the Tunicata, also, in the structure of the nutritive system—the digestive apparatus, heart, gills, &c. But in the complexity of the muscular apparatus provided for giving motion to the valves, they much surpass the highest of the other Conchifera. There are not only several muscles provided for the closure of the shell, but another set to open it—an organization which no other Bivalves possess. The most peculiar part of their structure, and that from which they



Terebratula:
A, valve with the spiral arms: B, valve with arms removed

derive their name, consists in the presence of two very long arms or tentacula, between the origin of which the mouth is situated. These can be projected to a consi

durable distance from the shell, or drawn in and coiled up spirally within it. They do not appear, however, to seize upon prey; but rather, by means of the cilia with which they are fringed, to create currents which may bring food to the mouth. In the Terebratula, these arms are affixed at their bases to a very curious framework within the shell, the use of which is uncertain; but it is believed to aid, by its elasticity, in separating the valves from each other. This framework is most complex in the species in which the arms are shortest. The species of Brachiopoda at present known, live at great depths in the ocean; and many of their peculiarities seem to have reference to that particular condition. They are distributed through all latitudes.

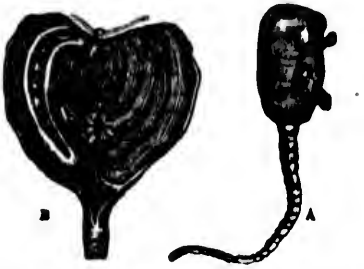
CLASS XVIII.—TUNICATA.

The lowest and simplest of the molluscous classes is that to which the name of Tunicata has been given, in order to mark the peculiar structure of the animals composing it. They bear a general resemblance to the animals which form bivalve shells, but are of inferior organisation. They are peculiarly distinguished from them, however, by the entire absence of any shelly envelope; and by the possession, instead of it, of a *tunic* or external coat, of greater firmness than the rest of the structure, which surrounds the whole body and affords it protection, besides being the medium of its attachment to the fixed substances upon which these animals usually rest. This external tunic is extremely variable in colour, consistence, and form. Sometimes it is dark, and of leathery toughness; sometimes even cartilaginous; and in many species it exudes a glutinous matter, by which particles of sand, gravel, comminuted shells, &c., are attached together, so as to form an additional envelope, which possesses great firmness. Sometimes, on the other hand, the whole body is extremely soft and delicate in its structure, and the tunic is a thin transparent membrane, the colour of which depends upon the intensity of the light transmitted through it.

The greater number of the animals of this class are attached, during the principal part of their existence, either to each other or to solid bodies. In a few species, a number of individuals are united by a stem which contains vessels establishing a connection among them all; so that they closely resemble the compound Polypifera. More commonly, however, the Tunicata live in societies, each individual being distinct from the rest, but a number adhering together to form one mass, which is often enclosed in a common envelope. In other instances, each animal is completely separate from the rest, although a number are found in the same locality. Where this is the case, the animals are severally fixed to rocks or other solid masses, either by the adhesion of the tunic itself, or by a sort of footstalk prolonged from it.

The *tunic* is always provided with two orifices; these are sometimes placed near each other, and are sometimes at the opposite extremities of the body. One of these orifices serves for the entrance of water into the cavity of the mantle, the other for its exit. The great bulk of the body may be considered as a respiratory chamber, that is, a cavity lined with a membrane upon which the blood is plentifully distributed, in order that it may be exposed to the action of the air contained in the water introduced into it. Accordingly, a continual current of water is maintained by the action of the *cilia* (minute, constantly vibrating, hair-like filaments) which clothe the lining membrane; and this current also serves to supply food to the inactive creature which produces it. The true mouth, or entrance to the canal that leads to the stomach, is situated at the bottom of the *branchial sac* or respiratory chamber; and part of the water introduced into the latter passes into the stomach, and after traversing the intestinal canal, and parting with whatever nutritive materials it contained, is ejected from the second orifice of the tunic, with the stream that has merely passed over the respiratory membrane.

In these actions nearly the whole life of the Tunicata appears to consist. Those which are adherent to rocks have no power of changing their place when once attached; and those which float in water, either singly or adherent to one another, seem to have no means of locomotion, except what they derive from the currents just described. The only other movement ordinarily noticed, is the contraction of the whole sac, which takes place when the animal is irritated in any way, the water contained in it being violently ejected.



Ascidia Australis: A, external aspect; B, internal structure.

The accompanying figure will give a general idea of the structure of one of these animals. On the right hand it is seen in its natural condition, with its attached footstalk; the two projections on the right side are short tubes terminating in the orifices by which water is introduced and expelled. On the left hand is shown the interior of the sac, which has been laid open; it is seen to be nearly empty, the intestinal canal on the left side occupying but a small proportion of the cavity; and the membrane lining it is disposed in folds, which are traversed by blood-vessels, so as to expose the greatest extent of surface to the action of the water, by the air contained in which the vital fluid is purified. The orifice by which the water enters this chamber is called the *branchial* aperture, because it leads chiefly for the admission of water to the *branchiæ* or gills; and that through which it passes out is called the *anal* or vent.

The division of this class into orders is not satisfactorily based upon the relative position of these orifices, which have a close relation with the whole life of two groups of animals. In the Ascidiæ, the two orifices approach more or less closely, and the body is either immediately fixed to some solid mass, or attached to it (as in the example just referred to) by a footstalk. In the Salpæ, on the other hand, the two orifices are situated at the opposite extremities of the body, which usually has an elongated form. They seldom attach themselves to fixed objects, but float freely amidst the waters. Without any special means of locomotion, they are continually changing their place, by means of the currents of water they produce; for, the fluid being drawn in at one end and expelled at the other, they advance in the direction to which the branchial orifice points. The Salpæ are usually of much more delicate structure than the Ascidiæ. Some of the more interesting species of each group will now be noticed.

Order I.—Ascidiæ.

Although some of the Ascidiæ present a nearer approach to the animals forming bivalve shells, than do any

of the Salpæ, it can scarcely be doubted that the group as a whole is inferior; and in it only do we find instances of that connection of several individuals by a common stalk, through which blood passes from one to the other, which indicates an approach to the Polypifera, especially to the order Ascidioida. In these compound Ascidiæ, a curious phenomenon is witnessed, which resembles the movement of fluid that will be described in one of the compound Polypes, the *Sertularia*. The stem which supports them contains two large vessels, which send off branches into the footstalks that support the several individuals. The branch from one trunk goes at once to the heart of each ascidia, which is but a simple bag, formed by a dilatation of the tube, having muscular walls; and that from the other is connected with the vessels which return from the intestinal tube and respiratory membrane, which are supplied with branches proceeding from the heart. The blood may be observed ascending for a time towards the heart through the first of these trunks, passing thence to the general structure, and returning to the footstalk by the second. But, after a short time, the current is reversed, and the blood ascends through what was before the returning trunk, and descends through the heart. In a short time, the flow is again reversed; and this change is repeated with great regularity, just as in the Sertularia. Although this alternation may be best observed in these compound Ascidiæ, in which the direction of the flow through the stem and branches may be clearly traced, there is reason to believe that it is common to the whole group of these curious animals.

Order II.—Salpæ.

The Salpæ are most abundant in tropical climates, and possess a greater delicacy of organization than the Ascidiæ, being generally almost or completely transparent. Most of the species belonging to this group are also remarkable for their luminous properties. In no species does there appear to exist such an internal connection as has been described in the lowest Ascidiæ; but scarcely any of them are entirely solitary. They generally associate together in masses of considerable extent, adhering either by their whole external surface, or by little projections from it, which seem formed for the purpose of attaching them to each other. Sometimes these masses assume the form of long bands, composed of salpæ adhering together side by side, all lying in the same direction. In others, again, the form of a star is presented, by an arrangement similar to that of the Botryllus. One of the most interesting of all, however, is the *Pyrosoma*, in which a number of these stars are piled, as it were, on one another, so as to form a cylindrical tube, which is closed at one end. The orifices of all the animals composing it are disposed in the same direction; so that water is constantly being drawn in on the exterior and expelled from the interior of the tube; as it can only pass out at one extremity, a current of sufficient force is produced to occasion the steady movement of the aggregate mass in the contrary direction. The luminosity of the Pyrosoma, the length of which varies from five to fourteen inches, is extremely vivid.

SUB-KINGDOM—RADIATA.

The general fact, that, in every complete natural group, there are some members which exhibit most plainly its characteristic peculiarities, whilst there are others in which these cannot be distinctly traced, or are altogether obscured, is nowhere more evident than when we compare together the different classes which are associated into this sub-kingdom. For whilst in some we find the *radiated* arrangement of parts almost invariably preserved, and, if left at all, only slightly departed from, we can only trace it indistinctly in others, and in others, again, it cannot be at all perceived. Thus, when we examine a Star-Fish, a Medusa, or a Sea-Anemone, we observe that they all have a circular form, that the mouth is in the centre of one of the surfaces, and that the several parts arranged round these are but repetitions of one another; and an internal examination would show the contained organs to have the same character. If from these we pass to certain other species of the same groups, we should find the external form slightly modified, being prolonged or shortened in one particular direction, and the disposition of the interior organs no longer radiated. Again, in the Sponges, all trace of a circular arrangement of parts disappears. Yet these, and other groups in which the radiated type is equally absent, must be associated with the classes more characteristic of it, on account of their general conformity of structure, and in some instances their very close alliance with them.

Moreover, in comparing the different forms of this group, we see exemplified another general principle, namely, that the *aberrant* members of it—those which depart most widely from its regular type—connect it with other groups. For, among the species in which the radiated arrangement is obscure, we find some that conduct us towards the Mollusca, and others that lead us to the Articulata; whilst in the Sponges and Corallines we have an evident approximation to the vegetable kingdom. So close, indeed, is this approximation, that there are many beings of which the true character is yet in doubt; they live, and grow, and multiply, very much in the manner of plants, and it cannot be ascertained with certainty whether the feeble motions they exhibit are to be regarded as spontaneous or not.

The great diversity, not only in form, but also in degree of organization, that exists amongst the Radiated classes, prevents much being stated of their general characters that shall be applicable to all of them. Thus, although the skeleton is external in some species, as the Sea-Urchin and Star-Fish, it is internal in others, as the Corals and some of the Jelly-Fish. Although most of them have a distinct mouth and stomach for the reception of aliment, others imbibe it, like plants, only by absorption through their exterior. Although some exhibit a high degree of sensibility, others are so apathetic as scarcely to manifest any feeling of injury when severely wounded.

The class Polypifera, containing the coral-forming animals, may perhaps be regarded as the most characteristic of the group. These animals usually associate themselves together into compound masses, of which every part is capable of existing independently of the rest, and each polype exhibits in itself the radiated structure, which cannot be detected in the entire mass; but all have a certain degree of connection with each other, which may be compared to that existing among the different buds of a tree. Even the species which do not form solid structures, such as the Sea-Anemone, remain almost constantly attached to the same spot.

The Acalephæ, commonly termed Sea-Nettles, or Jelly-Fish, have no such tendency to aggregation, and they never attach themselves to solid bodies, but wander at large through the ocean. By these characters, and by their extreme softness, these animals are readily distinguished.

The Echinodermata also live solitarily, and have the power of free movement, except in a few species which approach the Polypifera; but they are readily distinguished from the Acalephæ by the density of their texture, and especially by the roughness of the integument, which is usually beset with prickles or spines, as in the Star-Fish and Sea-Urchin.

In the two following classes, no distinctly radiated structure can be seen:

The Polygastrica, which are ordinarily known as Animalcules, are beings of extreme minuteness and gene

tal simplicity of structure. In the absence of distinct organs for the various purposes of the economy, they correspond with the lower Radiata, but they differ in the extreme activity of their movements. A separate division of the animal kingdom might almost be formed for them alone, so difficult is it to assign them any place in the ordinary scale. Some of them exhibit a tendency to associate into compound structures, like the Polypifera.

The Porifera, or *Sponge* tribe, are of all animals those which approach nearest to plants, in the absence of the characters peculiar to the kingdom in which they are placed, and in the want of definiteness of form. Certain movements exhibited by them, however, and their close affinity with some of the Polypifera, render it proper that they should be classed among animals.

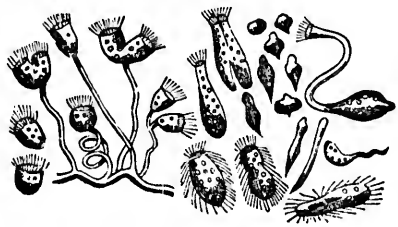
CLASS XIX.—POLYGASTRICA.

This class includes the greater part of those minute beings termed *Animalcules*, which have been, from the time of the discovery of the microscope, such fertile sources of wonder and delight, both to those who have themselves observed them, and to those who have heard from others of their marvels. Previously to that epoch, it was not suspected that beings existed of such minuteness as to be invisible to the eye, much less was any idea entertained of the extreme smallness of many species; and still more improbable and absurd would the statement have been deemed, that such beings are not of rare occurrence, but abound in every drop of stagnant water, and even exist in the whole mass of the ocean. Yet such has been shown to be the fact, and every improvement in the powers of the microscope has enlarged our ideas of the extent of animal life in the fluids of the globe; so that the philosopher is now ready to admit no limit to the possible minuteness of living beings, but looks to still further improvements in the microscope as a means of extending his acquaintance with them, and not as likely to set any bound to his inquiries.

Animalcules may be obtained without difficulty for microscopic examination during the warmer part of the year, by skimming the surface of ponds, especially those in which the water exhibits a red or green tinge, or in which it is covered with duckweed, or with the slimy film which may often be noticed. Many curious species frequent these situations; but the commoner ones may be obtained with even less difficulty, by placing soft vegetable matter, of almost any description, in vessels with water, and exposing the mixture to the sun and air for a few days. As soon as decomposition begins actively to take place, Animalcules may be detected in the fluid, and in a short time they often crowd it most densely. These are generally at first of a simple kind; but new species soon prevail, and those first seen disappear. Different kinds of vegetable matter seem to favour the development of the different species; and there are some Animalcules that can be produced in no other way than from an infusion of some particular substance. Asparagus stems that have been boiled will favour the production of Animalcules, with perhaps as much readiness as any vegetable matter; hay, chopped straw, the leaves of plants, and other common ingredients, may also be advantageously employed.

In the class Polygastrica are included all the most minute species of true Animalcules, and some among the larger ones; but as a whole, the beings composing it are smaller than the Rotifera, and far smaller than those of any other class. The largest among them are but with difficulty seen by the naked eye, and of the dimensions of the smallest the mind can scarcely form an adequate conception, although they may be numerically stated. The class takes its name from the belief entertained by the celebrated Prussian naturalist, Ehrenberg (who has devoted almost his whole life to the study of the microscopic forms of existence), that the animals composing it may be characterized by the possession of many distinct stomachs or digestive sacs. There is some doubt upon this question, however; that which can actually be seen will be presently stated; and it will be preferable to enter no further into the question in this place.

The bodies of these Animalcules are of very soft consistence, and very transparent; so that they resemble flakes of very thin jelly. Their forms are extremely variable; and, in some species, the same individual at different times alters its shape so completely, that it could scarcely be recognised. Indeed, many mistakes have occurred from this cause. The softness of the tissues of the Polygastrica is also seen when, in swimming, they encounter an obstacle, there seems scarcely any limit to the change of form to which many will submit, in order to pass the obstruction. They are not all so flexible, however; for in some species the body is enclosed in a siliceous sheath of very great delicacy, which gives support and protection to the still more delicate structures it contains. It is the accumulation of such sheaths that has given rise to the collections of Fossil Infusoria (as they have been termed), which will be hereafter noticed. Sometimes the whole body is contained within the sheath; whilst in other instances a sort of trunk or foot may be projected from its opening.



Various forms of Animalcules.

The bodies of the Polygastrica are usually fringed with cilia, by the vibrations of which they are assisted in their own movements, and also in the acquirement of their food. Sometimes these cilia are disposed along the whole extent of the edges of the body; in other instances they surround the mouth only, and from that part they are seldom absent.

For some time after the discovery of the Infusoria, it was supposed that they must obtain their nutriment by absorption through the substance of their bodies, for no mouth, stomach, or alimentary tube could then be discerned. But, by placing them in water, through which very small particles of colouring matter (such as indigo or carmine) were diffused, it was perceived that these particles are introduced into the interior of the body, and are collected in cavities hollowed from the general mass. And, subsequently, the improved powers of the microscope have enabled an entrance to the interior of the body or mouth to be discovered in almost every instance, and a second orifice in a considerable number of species. The mouth is commonly furnished with a border of cilia, and sometimes with a set of projecting bristle-like teeth, which are used in laying hold of smaller Animalcules, on which the possessor of this apparatus feeds. The introduction of food into the cavity of the body in those species which are destitute of this appendage, may be best watched by diffusing colouring particles through the water in which the Animalcules are swimming. They are seen to be drawn into the mouth by the vortex or whirlpool occasioned by the action of the cilia; and soon after entering it, they are observed to be united together into little round balls, as if they had been compressed in a small spherical cavity. These balls are sent one after

the other into the general cavity of the body, where they seem to lie in the midst of a soft gelatinous pulp, and in which they perform a slow revolution—the foremost ones escaping at intervals from the second orifice, whilst new ones are being pushed in from the mouth behind.

This is all that can as yet be certainly stated in regard to the digestive apparatus of the Polygastrica; since the opinion of Ehrenberg, that the whole body is occupied by a series of small distinct globular cavities or stomachs, connected by an intestinal tube, is not adopted by other naturalists. Nothing will therefore be said of his classification of these Animalcules, which is principally based upon characters furnished (according to his idea) by the arrangement of the stomachs.

The largest species of the Polygastrica probably never exceed 1-20th of an inch in length; the smallest at present known are about 1-2000th of a *line* in diameter; but there is no reason to suppose that this is by any means the limit of minuteness. They usually multiply by spontaneous division, the body of the parent splitting into two or more parts, each of which soon becomes a perfect being, capable of going through the same process. From observations which have been made upon the species in which these changes are most rapidly effected, it has been calculated that, under the most favourable circumstances as to food, temperature, &c., a hundred and forty million millions may be produced in four days—a degree of fertility which assists in explaining the almost universal diffusion of these Animalcules, and their sudden appearance in countless swarms.

Our ideas of the vast amount of animal life existing in this class have lately received a considerable extension by the discovery that their remains, minute as they are, not unfrequently accumulate into masses of great extent. It is only of those species in which the bodies are covered with an envelope containing earthy matter, that the remains can be thus preserved; and the substance formed by their aggregation seems to be an impalpable powder, such is the minuteness of each particle.* Such substances have long been known under various names. One is the Tripoli, or Rottenstone, used in the arts for polishing metals. Another is the siliceous meal which has been used in Sweden, on account of its supposed

Fossil Remains of Animalcules, forming Tripoli.

nutritious qualities, mixed in bread with flour and the inner bark of trees, in times of scarcity. Both these, as well as many other substances, consist entirely of the siliceous shields or envelopes of Animalcules, closely allied to, if not identical with, species at present existing; and the quantity of animal matter which is dried up in the latter, and which may be determined by the effect of heat (this dissipating the animal portion and leaving the siliceous particles unchanged), is sufficient to account for its nutritious properties.

* Of the larger species more than 190 millions are estimated to weigh only a grain.

CLASS XX.—ECHINODERMATA.

The class of Echinodermata, comprehending those well-known animals, the *Asterias* (Star-Fish), and *Echinus* (Sea-Urchin), takes its name from the prickly skin with which most of the tribes it includes are provided. But this is not an universal character; for some of the species which border upon other groups, have a skin destitute of any appearance of spines. There is a little difficulty, however, in distinguishing the animals of this class from all others, for in nearly the whole of them the radiated structure, or the arrangement of parts in a circular form, is very evident; and they are the only animals among the Radiata which have the power of moving from place to place, and have at the same time an integument firm enough to resist pressure.

Although the character and degree of organization in the different subdivisions of this class may be regarded as about the same, the form of the organs, and the mode in which they are arranged, are very different, so that it will be better to describe each group separately. The class may be distributed into three orders; the Stellerida, including the Star-Fish and their allies; the Echinida, including the Echinus and its allies; and the Holothurida, a group less commonly known, and differing much from the others.

Order I.—Stellerida.

The common *Asterias*, or Star-Fish, which may be taken as a type of the order Stellerida, is covered with a tough leathery skin, beset with prickles. The animal has the form of a star, with five or more rays springing from a central disc. In the middle of one side of the disc is situated the mouth, and this side, according to the usual habits of the animal, must be considered the lower one. The mouth opens into a globular stomach, which sends out prolongations into the several rays, but there is no intestine in this animal, nor any second orifice to the digestive cavity, so that the indigestible parts are rejected by the mouth, as in the Sea-Anemone.

Asterias: upper surface.

If the tough prickly skin be removed, it is seen that it is supported by a series of bony plates, beautifully jointed together. Along the under side of each ray, the plates exhibit a series of perforations, through which there issue, in the living state, a large number of minute tubes, which may be occasionally seen projecting on the outside. These tubes are termed the *feet*, on account of the use to which they are subservient. Every one of them is connected, on the interior of the shell, with a small vesicle or bag, which is capable of being distended with water by a system of vessels adapted to the purpose, and of contracting so as to force its contents into the tube. The tube consists of a delicate elastic membrane, covered with two layers of muscular fibres, the one circular, the other longitudinal, and furnished with sucker at its extremity. When distended with water, the tube projects from the body; and, if the sucker be then applied to any movable substance, it will be drawn towards the body by the elasticity of the membrane, when the distending force is relaxed. Although each sucker is small and weak, the combined efforts of many give the animal considerable power, not only of drawing prey towards the mouth, but of moving its own body from place to place.

The order Stellerida includes a large number of forms, having a general resemblance to the *Star-Fish*, but differing much in the relative proportion of the body and rays. Thus, in some species, the arms seem to make up the entire animal, no central disc being present, save that formed by their union. In others, the arms appear simply appendages to the central disc, to which the stomach and other important organs are confined. In some instances, the arms send off lateral appendages; and these occasionally again subdivide, so that a branch-like structure is produced, such as we find in the *Comatula*.

A very remarkable tribe, included among the Stelle-

rids—once a group very important in its numbers, and in the extent of its diffusion through the sea, but now presenting only two or three comparatively small species—is that known under the name of *Crinoidea*, or lily-like animals. These are formed much upon the plan of the Comatula, but they are attached by a jointed stalk to solid substances, usually to the bottom of the sea. They thus remind us of the Polypifera, which they seem to connect with the Echinodermata. This group contains two principal subdivisions—the *Encrinites* and the *Pentacrinites*. The former are distinguished by the roundness of their stems, the joints of which being flat and perforated in the centre, are known under the name of wheel-stones, or St. Cuthbert's beads. The latter have pentagonal stems. The former seem to have been the most ancient.

Order II.—Echinida.

In the Echinida we find the body usually of a somewhat globular shape, and enveloped in a firm shell, composed of a very regular series of plates jointed together. In the Echinus, the shell of which is commonly known as the Sea-Egg, we observe two orifices situated at the poles, as it were, of the globe. The larger of these orifices is the mouth: at the smaller one the intestinal tube terminates. The mouth, as in the star-fish, is generally directed downwards. It is furnished with a very curious apparatus of teeth, which are worked by powerful muscles, attached to projections of the shell, that may be seen on the inner margin of the mouth; and their points can even be protruded beyond the mouth, so as to lay hold of prey brought to them by the long tubular feet. By the action of the teeth, the food is ground down before it passes into the intestinal tube, which is here of considerable length, and takes a couple of turns round the shell before its terminntion. Round the second orifice of the shell are disposed the ovaria, which are very largely distended with eggs at some seasons, and are eaten under the name of *the roe of the sea-egg*.

It is the exterior organization of these animals, however, that presents us with the greatest sources of interest. On looking at the Echinida in their living state, we see that most of them are covered with spines of considerable size, instead of with such small prickles as the Asterias bears. Moreover, these spines are seen to be movable at their bases, and their power of motion is due to their peculiar connection with the shell. Each spine is spread, at its root, into a cuplike form, and the hollow of this cup fits upon a little knob or tubercle projecting from the surface of the shell, so that a complete ball-and-socket joint is formed. The spines are connected to each other, and held on the shell by the skin which covers the latter, and which is attached around their roots; and it is by the contractions of this skin that they are moved.

On looking at the exterior of the shell of an *Echinus*, it is seen that the tubercles are arranged with great regularity, and that the larger ones are confined to particular rows of plates, which are hence called *tubercular* plates. Between these are smaller plates, commonly bearing smaller tubercles, and perforated with a number of minute holes, for the passage of the tubular feet; these are called *ambulacral* plates. The tubular feet, like the spines, are much longer than in the star-fish. They are always capable of being projected beyond the spines; and, taking an attachment by the suckers at their extremities, they can cause the shell to roll, as it were, upon the points of these. In some species, the spines are five or six inches long, whilst the diameter of the body is much less. The tubular feet often escape notice on account of their transparency; and the animal appears to be walking upon its spines, when it is merely resting upon them as fulcra, and drawing itself forwards by these curious organs. It is to be remembered that the body will weigh much less in water than in air, and thus may be supported upon spines of great delicacy.

Shell of Echinus; *a*, tubercular plates; *b*, ambulacral plates.

The structure of the shell itself, and the mode of its increase, are not among the least interesting parts of the history of this animal. The shell is composed, as already stated, of a large number of plates disposed with great regularity, and accurately fitted together. These plates are usually of an hexagonal shape, but where large and small ones join, there is of course some modification. Now, it is obvious that a shell of globular form can only be regularly increased in all its dimensions by the equal growth of every part of it. This addition is provided for by the interposition of a thin layer of membrane, from which the shelly substance may be deposited between the edges of all the plates; and this membrane also answers the purpose of forming a connection between the skin covering the shell and the organs of nutrition within.

These animals are generally found on sandy shores, and especially in little nooks secluded from the direct influence of the waves. Some of them excavate hollows in the sand by means of their spines, and one species even works its way into solid rock. Their food is of a mixed quality. Fragments of shells, Crustacea, and other marine animal products, are found in their stomachs, as well as portions of sea-weed. They obtain their prey whilst lurking in their hollows, by allowing their tubular feet to play loosely in the water around; and when any small animal touches the sucker at the end of one of them, it is soon secured by the assistance of others, and drawn within the range of the powerful teeth.

It is not in every species of Echinida that the globular form is so well marked as in the Sea-Egg. There are many in which the shell is more or less flattened, and in which one or both the apertures of the alimentary canal are out of the centre. In these the dental apparatus is either absent or comparatively feeble.

Order III.—Holothurida.

In the last order of Echinodermata, the Holothurida, we find the characters of the class remarkably blended with those of Articulated animals. The body is not enveloped in a hard shell, but in an elastic skin, destitute of spines or prickles. It retains, in some species, the globular form, but in many it is very much prolonged, so as to be almost cylindrical, and thus to resemble that of the Worm tribes; and it is occasionally even marked by transverse bands, indicating a division into segments. Still, however, a distinctly radiated conformation may be seen around the mouth; and some of these animals look as if a star-fish were set as a head on the body of a large worm. In the general conformation of the internal organs they correspond with the Echinida; but they are in some respects more complex, and the respiratory organs are constructed upon the plan of those of the Articulata. They thus form a very interesting link of connection between the Radiated and Articulated subkingdoms.

The skin of most of the Holothurida is so very elastic that they can change their size and form in a remarkable degree. They are capable, too, of swimming with considerable rapidity, and some of them crawl like slugs upon solid surfaces. Small species are occasionally found in British seas; but on some tropical shores they are very abundant, and grow to the length of eighteen or twenty inches. They are sometimes eaten by the poor on the Neapolitan coast; but in the Malay archi-

pelago they are regularly sought, and conveyed to the Chinese market, where, under the name of *trepang*, they fetch a high price.

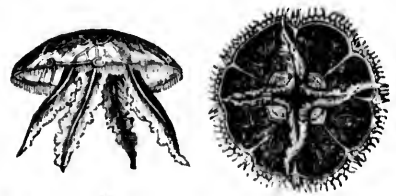
CLASS XXI.—ACALEPHÆ.

The name of the class next to be described, the Acalephæ, is derived from the stinging power possessed by nearly all the animals composing it. The word is the Greek term for *nettles;* and by the designations *sea-nettles, stung-fishes*, &c., these animals are popularly known; as well as by another, also expressive of a character by which the group is distinguished—*jelly-fish*. It is rather difficult to give any description of the structure of the class that shall include all the members of it, so much do they vary among each other. They all differ from the Polypifera in being unattached to solid bodies, and in having the power of freely moving through the sea; and they differ from the Echinodermata in not being covered with a dense integument. Their extreme softness is one of their most remarkable characters. Some of them attain considerable size, yet with an almost entire absence of any hard support or framework; indeed, it is only in a few species that any such exists.

The tissues of the Acalephæ are so soft, that they seem almost like masses of jelly; whence originated their common name. They consist of a sort of network of animal filaments, the interspaces between which are filled up with water; and so large a proportion does this bear, that it drains away when the animal is kept out of its element for a short time, leaving but a thin film of membrane behind it.

The arrangement of the mouth, stomach, and other organs, is subject to great variation in the different subdivisions of this class, and we here encounter the very remarkable fact, of the existence of animals of complex structure and varied powers, which do not possess any regular mouth, but imbibe their food like plants by root-like filaments. Owing to the difficulty of examining the structure of beings which can be so imperfectly preserved, however, the organization of many of the more curious species is as yet very imperfectly understood, and it will be better to confine ourselves here to the consideration of those most certainly known.

One of the commonest forms of this class is the *Medusa*, which is often seen floating in vast numbers on calm sunny days at a little distance from the shore. The animal consists of a large umbrella-shaped disc, from the under surface of which hang down four broad and long tentacula. Both disc and tentacula exhibit a very beautiful assemblage of colours, like those of the rainbow, when the rays of the sun are reflected from their surface. On the under side of the disc is seen the mouth, situated in the centre, and surrounded by the origins of the tentacula. This is the entrance to a stomach, which lies in the middle of the disc, and is surrounded by four ovarial chambers,



B A

Medusa: A, under surface, showing the mouth in the centre, surrounded by the tentacula, and the ovarial chambers exterior to the origins of these; B, side view, showing the tentacula hanging down in their natural position.

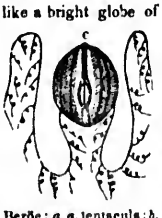
having separate external orifices. The animal may be compared, in some degree, to a Sea-Anemone detached from its base, and swimming with its mouth downwards. The membrane of the disc extends much beyond the stomach and ovarial chambers (which may be described as occupying the part corresponding to that included between the metallic stretchers of the umbrella), and this broad free margin is endowed with muscular powers, and performs a series of regular undulations, by which the animal is propelled through the water.

The extreme softness of the tissues of these *Medusæ* is an obvious reason why they should not expose themselves to the rough surface of the ocean, where they would be beaten to pieces by the waves—or to the proximity of the shore, from which they would soon receive fatal injury. Although so soft, however, they have the power of mastering prey of much firmer structure, and hard Crustacea, as well as other marine animals of high organization, supply them with food.

The *Medusa* shares in another property possessed by most of the class, that of luminosity or phosphorescence. It is chiefly to the smaller tribes, accumulating in immense numbers, and so transparent as to escape notice by day, that the occasional phosphorescence of the sea is due. This very beautiful phenomenon may be seen not unfrequently on the shores of Britain; but it is most splendid in warmer seas, especially in the Mediterranean. In the midst of the diffused luminosity, caused by the glow of innumerable multitudes of small Acalephæ, and even of animalcules far smaller, the larger ones shine out like stars in the milky-way. The cause of this beautiful appearance is ill understood. It has been ascertained to exist in a secretion formed from the surface, which can be washed off, and can thus communicate the phosphorescence to various fluids, in which it seems to remain until decomposition has taken place. The light is rendered more brilliant, when exhibited by the animal itself, by any thing which irritates it; and this fact is observed in the case of most luminous animals.

An interesting species, allied in general form to the Medusa, but differing from it in a remarkable particular, is the *Rhizostoma* (root-mouth). No mouth is seen in the centre of the inferior side of the disc, but the stomach sends canals into the substance of the tentacula, which terminate in a number of minute pores at the extremity of those organs. By these small pores, as by the roots of plants, nourishment is absorbed into the system, for the ends of the tentacula fix themselves like suckers upon the surface of the animal they have grasped, and imbibe its juices. These and other Acalephæ which move through the water by the undulations of their membranous disc, are included in the order PULMONIGRADÆ. All the Acalephæ of this order exhibit a very regular disposition of their parts around a centre, so as to be truly *radiated* animals. Some of them attain a diameter of two or three feet.

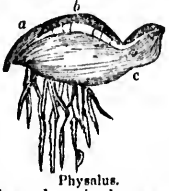
Another interesting species of this class is the *Beröe pileus*, a small animal not unfrequently found on the coast of Scotland. When at rest in the water, it looks like a bright globe of jelly, about half an inch in diameter. An opening is seen at each pole of the globe; one of these is the mouth, and at the other the alimentary canal, which runs straight across the body, terminates. Its surface is marked by eight bands, running, as it were, from pole to pole; these bands seem to be of firmer texture than the rest of the body, and on them are placed the rows of cilia, which can act either together or separately, so as to give every possible variety of motion to the body. Hence this animal, and others resembling it, are said to belong to the order *Ciliograda*. The Beröe usually swims, by means



Beröe: *a, a*, tentacula: *b*, mouth; *c*, termination of intestine.

of them, mouth forwards, through the water, and thus a current of water is driven into the stomach, without any further effort on the part of the animal. But it is provided with other means of obtaining its food, in two long tentacula, which arise from the posterior part of the body, and are furnished with a number of lateral filaments; these can all be withdrawn and folded into two cavities, excavated, as it were, in the substance of the body, and are easily unrolled when required for use.

A very common form of this class in some climates is the *Physalus*, known to sailors as the Portuguese Man-of-War. This is distinguished by its large air-bag, surmounted by a vertical membrane or crest, which usually floats above the surface of the water, and is acted upon by the gentle breeze, in the same manner as the little sail of the Velella. The animal organs placed below are very obscure in their character. No distinct stomach can be perceived; but the tentacula are dilated at their roots into chambers, of which each may perhaps be regarded as a digestive cavity. Some of the tentacula are very long, and hang down in the water to the depth of fifteen or twenty feet when the animal is floating. They possess considerable stinging power, and probably serve to entrap the food upon which the shorter tentacula, with their sucker-like extremities, then affix themselves, for the purpose of taking up nutriment by absorption. These Acalephæ have been termed *hydrostatic*, from the power they possess of rising or falling in water, by increasing or diminishing the bulk of the air-bag; but by what means they effect this change is not known. In some species comprehended with the *Physalus*, in the order Physograda, several small air-bags exist, instead of a single large one. These are usually fixed to the same stalk, like currants upon their stem, and this rises out of the apparatus of tentacula, &c., of which the animal may be said really to consist.



Physalus.

The Acalephæ inhabit all climates, but the larger forms are to be seen in tropical seas.

CLASS XXII.—POLYPIFERA.

The animal character of the beings composing the class Polypifera was formerly doubted, as that of the Sponges is at present. The structures which they form, known as Corals, Coralines, &c., have often so much of the plant-like aspect, and sometimes also of an apparently woody structure, that, even in recent times, naturalists have been deceived into a belief in their vegetable nature.

Another popular error in regard to this group, is the attributing the formation of coral to *insects*, and the supposition that it is their habitation, constructed under the same circumstances as the comb of Bees, or the pyramids of the Termites. Now, the real fact is, that the masses of *coral, madrepore*, &c., as well as the *sea-fans* and other similar structures, with many smaller and more delicate ones, of which some are ranked among the *sea-weeds*, and others commonly known as *corallines*, are the *skeletons* of the animals by which they are produced, and are to be regarded as parts of the living structure, so long as the flesh which clothes or lines them retains its vitality.

If, for example, the stem of the common *red coral* be examined when clothed with its living flesh, its surface is seen to be scattered over with polypes, the structure of each of which bears some resemblance to that of the sea-anemone; but these, so far from being independent of one another, like so many sea-anemones attached to the same rock, are connected by a system of vessels which traverse the flesh, and bring them all into communication. Nevertheless, any one of these would live if detached from the rest, and would gradually produce others, until a new structure is formed, similar to that of which it was a part. Moreover, if a piece of the gelatinous flesh be stripped from the stem, *this* will be competent to form both new polypes and a new skeleton.

Such compound beings, then, of which the polypes only form a part (like the leaves or flowers of plants), are not improperly termed Polypifera or Polype-bearing Animals. But there are many kinds of Polypes, which have no tendency to this kind of aggregation, and which are never found but in a solitary state. Such are the *Sea-Anemones*, and the *Hydra* or fresh-water Polypes. And various degrees of intimacy of connection between the polypes of compound structures may be traced in different species; some of these will be hereafter noticed.

The class may be divided into four orders, characterized by four distinct types of structure: in each of these we shall find polypes existing almost or altogether independently of one another; and species closely allied to these, in which they are intimately associated. As the distinguishing characters of these orders cannot be understood without a knowledge of the structure of the polypes belonging to each, it will be better to proceed at once to the description of them, the amount of popular information on the subject being small. We shall begin with the one generally accounted the simplest.

Order I.—Hydroida.

The *Hydra*, or fresh-water Polype, is a minute animal, often found in great abundance, clustering round aquatic plants in stagnant pools. It seems to consist only of a kind of bag, constituting its stomach, round the mouth of which is disposed a circle of long arms or *tentacula*, whilst the opposite end is prolonged into a foot, terminated by a kind of sucker, to which the animal attaches itself. The changes of form in this polype are very remarkable. The body has sometimes the shape of a long cylinder, whilst at others it is contracted into a sphere, the arms having shrunk alike into small projections around the mouth. This appearance is generally presented when the stomach is replete with food.

Hydra.

The *Hydra* is an extremely voracious animal; and, although little able to move from place to place, it secures an abundant supply of food by its long arms, which serve as so many fishing-lines. When any aquatic worm or insect touches one of them, it is entrapped by it, and other arms are speedily brought to its assistance; so that, by the simultaneous contraction of the whole, the prey is conveyed to the mouth, even if strong enough to make powerful resistance. Not unfrequently it can be seen to move about violently within the stomach for some little time; but the powerful digestive secretion speedily begins to act upon it, and its soft parts are dissolved, the hard ones being usually ejected by the mouth. When this solution has been performed, the fluid which results from it is seen to be distributed by a kind of circulation through the walls of the stomach and the arms.

Nothing in the history of the Hydra is so remarkable as its power of being multiplied by division, and of repairing the effects of other rough treatment. In regard to this, there really seems no limit. Not only can the body reproduce the arms, the mouth re-form the tail, and the tail the mouth; but, from a minute fragment, the perfect Hydra is reproduced, so that an individual cut up into forty or fifty pieces, will be converted into as many separate polypes. Two bodies, also, may be grafted together by the side, the tail, or in any other way; and

monsters with two heads, two tails, &c., may be easily produced. It was, in fact, on account of this tenacity of life and tendency to reproduction as a consequence of injury, that the name Hydra (after the fabulous monster of ancient times) was given to this little creature when first discovered about a century ago. The power of any one part to perform the functions of the rest, is remarkably shown by the fact, that the polype may be turned inside-out; so that what was before the lining of the stomach becomes the external integument, and *vice versa*, without its comfort being perceptibly impaired.

The Hydra is not known to subdivide spontaneously, however, but it propagates itself by a process resembling the budding of plants. A little knob first projects from the side of its body, this enlarges, and from the top of it are seen to spring a number of small processes, which are the arms. In the centre of these an opening appears, constituting the mouth of the young polype, which gradually assumes the form of its parent, and begins to catch prey for itself. Still, however, the cavity of its stomach communicates with that from which it was at first prolonged; but the passage is gradually narrowed, and at last obliterated. When quite independent, the young polype detaches itself from the parent, and has no further relation with it. Several of these buds may spring from the same polype at once, provided it be well supplied with food, and the temperature be warm; and a second generation may even show themselves upon the first, whilst still continuous with the parent structure.

The entire substance of the Hydra is soft, and no part seems possessed of greater firmness than the rest. In some other species, however, we find a tendency to the consolidation of the exterior into a kind of horny tube or sheath; and when a number of polypes are associated together, a compound structure is thus produced. In these compound structures the cells are connected by stems and branches, in the same manner as the buds of a plant, and through the base of each cell there is a canal lined by an extension of the lining membrane of the polype, and uniting with the channels which pass through the whole structure. Thus, all the polypes are brought into connection with each other, and with the general mass or polypary.

Portion of Sertularia: *a*, *a*, polype-cells withpolypes; *b*, *b*, ovaral vesicles.

These polyparies, formed by the association of hydraform polypes, are among the most graceful and elegant of all the structures with which this class presents us. They are of minute size when compared with the massive productions of other tribes; and the uniform absence of stony deposit gives them a degree of flexibility which adds much to their gracefulness. There are few shores on which some forms of them may not be picked up. They are commonly mistaken for seaweeds.

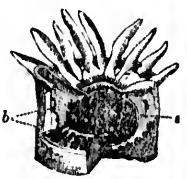
The polypes, being enclosed in cells, do not share in the function of reproduction, for which a special apparatus is evolved. A set of horny vesicles (*b*, *b*), usually much larger than the polype-cells, are developed at intervals from particular parts of the stem and branches; and it is in these that the reproductive bodies or gemmules are formed. Each vesicle is provided with a lid, which falls off when the gemmules are mature and ready to swim forth; and the vesicle itself afterwards shrivels and drops away, like the seed-vessel of a plant that has shed its seeds. The whole of this process very much resembles the fructification of mosses, in the mode in which it is carried into effect.

The forms of Polypifera allied in structure to the Hydra, compose an order which may be termed that of HYDROIDA, or *Hydraform* Polypes. This order is pretty uniformly distributed over the globe; not abounding more in tropical than in temperate regions. Scarcely any fossil remains of it are to be found.

Order II.—Hetiantho.da.

A common form of polype, apparently so different from the Hydra that the relationship between them would not have been suspected by an uninformed observer, is the *Actinia* or Sea-Anemone. There are probably no shores over the whole globe, except the very coldest, on which some species of this interesting creature are not to be found. The mouth is in the centre of the upper surface, and is surrounded by tentacula; and these are numerous and arranged in several rows. The under side forms a large sucker or disc; by this a very firm hold is taken of the rock or other surface to which the animal adheres. The stomach does not occupy the whole cavity of the body, by only the central portion; and the space between its wall and the outer integument is divided, by vertical membranous partitions passing directly from one to the other, into a number of radiating chambers, in which the germs of young *Actiniæ* are produced, and sometimes nearly matured. The tentacula are hollow, and their cavity is continuous with that of these chambers; at the extremity of each is a small aperture, through which water is occasionally taken in, and then ejected with considerable force. This process seems to be of the nature of the action of respiration in higher animals.

Actinia seen from above.



Section of Actinia; *a*, cavity of stomach; *b*, surrounding chambers.

The tentacula of the Sea Anemone can be contracted in the same manner as those of the hydra, and they are furnished with a sort of sucker at their extremities, by which they can draw towards the mouth any substance which comes in contact with them. Although each seems weak in itself, the combined action of many is sufficiently effectual for maintaining an ample supply of food. These animals are extremely voracious. Not being able to move from place to place in search of particular kinds of nutriment, they are adapted to digest almost any which comes within their reach. Shell-fish and small Crustacea appear to be their usual diet. These are swallowed alive, in spite of their struggles, but are soon destroyed by the powerful solvent action of the juices of the stomach. The hard portions are ejected from the mouth; and, in getting rid of them from its stomach, the Actinia often inverts the lining of the latter through its entrance, so as almost to turn its body inside out.

The powers enjoyed by the Actinia of reproducing different parts which have been removed, and of multiplication by the division of its body, are nearly as great as those already described in the hydra. It may be divided either vertically or transversely, and each part will in time supply what was deficient, and become an entire animal. This reproduction has taken place in

some instances from small fragments, but it does not appear that the same number can be reproduced by the subdivision of one, as in the hydra. We do not find here the same process of multiplication by buds, as in the hydra; but distinct germs, or *ova*, are formed in the radiating chambers which surround the stomach (hence called *ovarial* chambers), and from these, as from the eggs of higher animals, new beings like the parent are produced. The development of them may take place whilst yet within the body of the parent; and thus, as the young ones pass out from the mouth, it appears to cast them up from its stomach.

The sea-anemone is not the only solitary polype possessing the kind of structure which has just been described. Several other species exist, in which the same type is presented with various modifications.

There are some among them which form a stony deposit in the substance of their base, and in the membranous partitions between the radiating chambers. Of these one small species inhabits the British seas; it belongs to the genus *Caryophyllia*. A very beautiful corallino formation of this description is that produced by the *Fungia*, an animal allied to the sea-anemone, and inhabiting only tropical seas. It consists of a thick round plate, sometimes several inches in diameter, from one surface of which arise thin vertical plates, radiating very regularly from the centre to the circumference. This is, in fact, a single cell of a large solitary polype, and from it the structure of other corallino masses will be understood.

The cells of such solitary polypes are not always round, but are sometimes very much prolonged in one direction, so that the depression in the centre, marking the place of the mouth, towards which all the radiating plates are directed, becomes a long groove. These stony masses contain a considerable quantity of animal matter, by which the particles of carbonate of lime are glued together; and when a sufficiently fresh specimen of a stony coral is submitted to the action of an acid which dissolves these, the animal substance will retain its form

Mass of Astræa Viridis:
a, a, expanded polypes; b, b, polypes withdrawn into their cells; c, stony mass uncovered by flesh.

The number of stony corals formed by the compound Polypifera is very great; and, of the more massive kinds, a large proportion belongs to this order. Those which are to be ranked as the skeletons of animals allied in structure to the sea-anemone, are distinguished by a character very easily recognised. In each cell, however minute it may be, the arrangement of radiating plates, described in the *Fungia*, is seen; and from the presence of these thin plates, or *lamellæ*, the whole of this group of corals and madrepores have been designated as *lamelliform*. A lamelliform coral is, then, always formed by a polype similar to the sea-anemone (or *actiniform*); and thus, by attending to the mode in which the growth of the coral depends upon the structure of the animal, we obtain a valuable character, on which we can always rely.

The individual polypes belonging to such structures are connected by a gelatinous flesh enveloping the whole, which seems to answer to the membranous pith lining the stems of the compound Hydroida. It is by this flesh, rather than by the polypes themselves, that much of the stony mass is deposited, as may be seen by examining many species in which the intervals between the cells are considerable. The variety of aspect which these masses present is very great, but there is little difference, so far as is known, in the structure and habits of the individual polypes, which form part of the beings in their living state.

None but *stony* corals are formed by Polypifera of this order; but there are many of that description which do not belong to it, of which we shall hereafter speak. However, it is to this order that the greater part of those species belong which are concerned in erecting the massive structures known at present under the names of coral reefs and islands, as well as those which appear to have existed in still greater amount in former epochs of the earth's history, and to have given origin to the greater part of the limestone rocks which constitute so large a proportion of the crust known to us. This order may be denominated that of *Actiniform* Polypes, from the general resemblance of the animals composing it to the sea-anemone; or *Helianthoida*, from their similarity in aspect, when expanded, to the sun-flower.

Order III.—Asteroida.

The next order of Polypifera is one which brings us nearly to the form of the Sponge. In the compound groups we have been last considering, the polypes form an important part of the general structure, and in some instances each may be regarded as existing almost for itself alone, even where many are united by the connecting fleshy matter. But in the group to be next treated of, the polypes seem quite subordinate, and the general mass seems to have (as in the sponge) much more of the character of a single individual. In these structures we observe, too, that the hard basis or skeleton is seldom so distinct from the living tissue as in the lamelliform corals, the two often passing into each other by almost insensible gradations. The density of the skeleton varies considerably in the different species. Sometimes it is of a spongy character, as in the *Alcyonia*; sometimes of a stiff horny texture, as in the *Gorgonia*, or Sea-Fan; and sometimes of a stony hardness, as in the Red Coral.

The *Alcyonia* are found abundantly on many parts

Alcyonium:
A, portion enlarged, showing the polypes.

of the British shores, and are known to fishermen by the names of *dead-man's-hand*, *sea-fingers*, *sea-paps*, &c., from their flabby texture, and the peculiar forms they present. Their structure is spongy but they have

usually a more distinct envelope than the true Sponges, and this has sometimes a leathery character. Their interior is traversed by a series of canals, which ramify and inosculate with each other; and, on cutting into the mass, it is observed that nearly the whole tissue is composed of a network of these passages, separated by the animal fibrous tissue, which is sometimes condensed into a fabric of considerable firmness. The large canals have no direct external opening, however, but they terminate in prominences of the spongy mass, from which the polypes protrude.

The polypes themselves have some resemblance to to the sea-anemone, but they are usually much smaller and of more delicate structure. There are, however, some important differences, upon which the character of the order is founded. The tentacula, instead of being numerous, and arranged in several rows, are only eight in number, and form one circle. They are broad, and almost leaf-like, instead of being round and slender. The mouth is situated in the midst of them, and leads to the stomach, which occupies the centre of the body; around the stomach are the *ovarial chambers*, separated by radiating partitions, but only eight in number. The stomach opens into the canal upon the end of which the polype is placed, and all the fluid which enters the mass appears to be taken in through these mouths. The ovarial chambers also communicate with the canal beneath, indeed they may be said to be a continuation of it, for the partitions between them are prolonged downwards into the canal, forming plaits or folds of its lining membrane, in which the ova or germs are developed; so that these are produced from the general mass rather than from the polype, and the whole structure may be regarded as a higher kind of Sponge.

The polypes are capable of being drawn entirely within the protuberances on the surface of the *Alcyonia*, and even these projections become flattened when the animals are in a state of great contraction. In this condition they are often left by the tide, and if then placed in a glass of clear water, their gradual expansion may be watched. The protuberances from the surface first show themselves, and the polypes, one by one, appear at their summits, and slowly expand their tentacula, until the whole surface appears covered with delicate blossoms. The entire mass then not unfrequently swells to twice or thrice its original size. If any one of the polypes is irritated, it shrinks into its hiding-place, but those near it are not affected. If the irritation of the part be prolonged, however, those in the neighbourhood gradually show themselves influenced by it, and draw themselves in; and in this manner the whole mass may be ultimately affected. The same effects, however, may be produced by irritating a portion of the spongy substance intermediate between the polypes. From this it is evident, that sensibility to impressions is not confined to the polypes alone, but that the whole mass must be regarded as possessed of animal properties.

The *Alcyonia* grow in the same circumstances with Sponges, and their correspondence is further shown by the existence of crystals of silex in their tissue, which are not found in other polype-structures, the earthy matter in these being entirely calcareous. The different species of the Alcyonia, like those of the Sponges, may be distinguished by the form of the spicula preserved in the skeleton.

In other forms of this order we find the skeleton, or firm support, in a more concentrated form. Thus in the *Gorgonia*, a beautiful framework of horny matter, consisting of a stem and a minute network of branches, occupies the centre of the structure; and this is clothed with a soft flesh, through which the channels pass that connect the polypes together. This flesh is covered with a firm skin, in which a great amount of earthy crystals is deposited, so as to form a crust; and in this are the hollows or cells by which the polypes are protected. In the dead structures, with which we are familiar under the name of *sea-fans*, the dark horny flexible stem is seen to be covered in many parts with a brittle crust, often brightly coloured, which can be scaled off it and crumbled to powder. Between the two, in the living state, the fleshy coat existed; the inner part of it being in contact with the exterior of the horny stem, which was then soft and scarcely distinct from it, while the exterior part was consolidated by the earthy matter into the firm integument.

Pennatula

In the *Isis* we find less stony matter on the outside of the flesh, but a deposition of it at intervals in the stem, which thus obtains a jointed character, being flexible at the points at which the horny matter has not been consolidated. And in the *Red Coral*, the entire stem is converted into a very firm stony axis, which presents no indication of polype-cells, these being excavated only in the flesh that clothes it. The *Pennatula*, or Sea-Pen, is an interesting species belonging to the same group, and in some respects resembling the Red Coral; it has a stony axis, but this is flexible at the extremities; and it is not attached by a solid basis, but is carried about by the mercy of the waves. From the central axis, which is nearly straight, a regular series of lateral branches passes off on each side, like the barbs of a feather; and on these the polypes are situated. By the simultaneous movements of their tentacula, the animal (if it is to be called *one*) seems to have some power of directing its course, if not of propelling itself through the ocean. A small species, which is luminous at night, inhabits the British seas.

Single Polype of Pennatula.

There is one species in this order which differs from all the rest in the consolidation of the exterior rather than of the interior tissue; so that a stony *tube* is formed instead of a central stem. This is the *Tubipora Musica*, of which the skeleton is known as Organ-pipe Coral. The polypes are not here connected by any system of vessels or uniting flesh; each lives for itself alone, but a number (probably all produced from the same stock, and by offsets from each other) unite for mutual support in one structure. Each polype has a cylindrical form, and its exterior membrane is progressively consolidated into a stony tube, which is thus gradually increasing in length by new deposits at its upper end. At certain intervals the soft membrane (which is always projecting beyond the mouth of the tube) is flattened down into a sort of collar, which is consolidated likewise; and the collars of the neighbouring tubes coming in contact with one another, form a sort of floor or shelf, which greatly strengthens the mass. After this collar is formed, the tube is continued as before for another period, when a similar floor is again produced by the simultaneous action of the numerous polypes composing this beautiful structure.

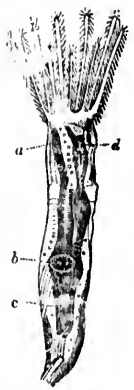
To this order the term of *Alcyonian* Polypifera (from the name of one of its principal groups) may be conveniently applied; it is also known by the designation of Asteroida, from the star-shaped form presented by the tentacula when expanded. Its most luxuriant kinds are natives of tropical seas; thus the *Alcyonium poculum*, or

Neptune's cup, which abounds in the neighbourhood of Singapore, is one of the most bulky species at present existing. But the smaller tribes abound in our own seas. No massive stony polyparies are formed by the animals of this order.

Order IV.—Ascidioida.

The last order of Polypifera far surpasses all the rest in the complexity of its organization; although so little distinguished from them in external form, that a cursory examination would not reveal the points of difference. In fact, many of the species belonging to it have been associated with the *Hydraform* Polypes, by naturalists of eminence; and it is only by means of a high and clear magnifying power that their true structure is capable of being ascertained. The stony character of the polyparies formed by others, has led them to be grouped with the *Actiniform* Polypes; and it is only within a very recent period that opportunities have been afforded for that examination of their living condition, upon which alone reliance can be placed.

The polypes of this order seem more independent of one another than they are in the associated groups of the others; but they are not known to exist in an absolutely isolated condition. A species lately discovered on the British shores, the *Bowerbankia densa*, will afford an excellent illustration of the structure of the separate polypes. These arise like buds from a sort of creeping stem, which connects them all, and which has the power of extending the structure by its own growth; but no communication has been observed between the interior of this stem and the stomachs of the polypes, like that which exists in the Sertularia. Each is enclosed in a horny transparent sheath, the upper part of which is so flexible, as to be capable of being drawn inwards by the action of muscles, thus closing the mouth of the cell.



Bowerbankia: a, œsophagus; b, gizzard; c, stomach; d, orifice of intestine.

The polype itself has, when protruded, the general form of the hydra; the mouth being surrounded by ten long and slender tentacula. There is this important difference, however, that in the Bowerbankia and all the other polypes of this order, the arms are fringed with cilia or little hair-like filaments; while in the Hydraform Polypes no such appendages exist. This difference is more important than it would at first sight appear, being connected with the whole economy of the animal. The hydra only obtains its food by grasping with its arms that which comes within their reach; but in the animals at present under consideration, the rapid vibration of the filaments, which seem to take place at the will of the polype, produces currents in the water, by which a regular stream is brought to the mouth; and this stream contains many nutritive particles, from which a selection, adapted to the highly organized digestive apparatus, may be made.

The mouth opens into a wide tube, which may be regarded in the light of the œsophagus or gullet of higher animals; and this terminates, at its lower end, in a narrow orifice leading to a globular cavity, which seems analogous to a gizzard, having thick muscular walls, lined with tooth-like processes. Here the food seems to be ground down, before being transmitted to the true stomach, a much larger cavity, situated below it, in which the process of digestion takes place. From the upper part of the stomach, not far from the first opening, an intestinal tube passes off by a distinct orifice; and this terminates on the outer side of the ring to which the tentacula are fixed.

The whole process of digestion may be distinctly watched in this beautiful little animal. The food obtained by the motion of the cilia passes into the mouth, and is propelled downwards to the first stomach or gizzard, by the successive contraction of the walls of the tube, as in the highest animals. After being subject to a brief trituration there, it is passed onwards to the principal stomach, where it remains a considerable time for digestion, being sometimes regurgitated, for a second trituration, to the gizzard. The matter to be rejected does not return, as in the lower Polypifera, by the mouth, but passes, in the form of little granules (no large substances being ever swallowed), into the intestine, where it accumulates into small pellets, which are gradually propelled to its outlet by the successive contraction of the tube. When they have been ejected from it, they are carried to a distance by the reflux of the current, which is constantly being driven by the action of the cilia to the mouth. No nervous system can be detected in these animals, yet its presence may be inferred from the existence of distinct muscular structure, of which different parts have to be put in action at the same time.

There is considerable variety in the structure of the Polypifera which have been associated into the group of which this is a specimen, some being more and others less complex; but they all agree in these two essential points—the possession of a second external orifice to the digestive cavity, and the presence of cilia on their arms. By these they are distinguished from all the other Polypifera. The latter of these characters has been embodied in the term *cilio-brachiata* (ciliated-armed), which is very appropriate. They have also been called Bryozoa, from their fancied resemblance to mosses; and Ascidioida, from their affinity to the *ascidiæ*, a group in the lowest class of Mollusca.

The polyparies formed by the animals of this group differ considerably from each other in the structure and arrangement of their parts. Frequently they have but a horny texture; sometimes, however, stony matter is deposited in the cells, and fills up the interspaces between them. A very common kind of compound structure is the *Flustra*, which grows in flat expanded surfaces, often encrusting sea-weeds and other marine bodies, but sometimes without any such attachment. This may be picked up on almost any of our shores; it is often mistaken for a sea-weed, but is distinguishable from it by its greater crispness and firmness of texture, and by the cells which may be observed to cover its surface. These cells are extremely minute, and are set closely together, so that a very large number, each when alive containing a polype, exists in each specimen. The polypes of this order are also reproduced by the formation of gemmules, somewhat resembling those of Sponges and Sertularia, but endowed with greater activity, and with apparently greater power of directing their movements. These are developed from the inner membrane of the cell, and gradually increase so as to fill up its cavity, and to cause the death of the contained polype. When they at last escape, they swim, like animalcules, with a great variety of movements; and seem to have a perfect control over the vibrations of the cilia with which they are covered, and by which all their motions are produced. When they at last fix themselves, they spread themselves out each into a gelatinous film, in the substance of which the outline of cell soon shows itself, and the polype, with all its complex parts, is developed by degrees. To this first-formed cell others are soon added.

The Polypifera of this order seem to attain their full development under a less constantly elevated temperature than that required by the Helianthoida. Stony corals are formed by them in many seas of the tempe-

rate zone, and the more delicate species abound on our own coasts. This fact is interesting when we compare the fossil with the recent corals, as will be presently done.

When we consider the vast extent of the coral formations, which are at the present time effecting a change on the surface of the globe that has been a fertile theme of astonishment and admiration, we cannot but be struck with the enormous amount of animal existence that must be concerned in producing them. Much error has prevailed on this subject, however; and in some points exaggerations have been produced through superficial observation. But here, as in almost every department of nature, the truth, as disclosed by a more careful examination, is far more wonderful than the showy covering in which the common love of the marvellous may have enveloped it.

It is generally stated that the coral masses, forming reefs or islands, are built up from the depths of the ocean. This is not strictly true; for it is well ascertained that none of the species which form the massive stony structures of which these are composed, can exist at a greater depth than from 80 to 120 feet. It is evident, then, that supposing the relative level of the land and sea to have been always the same as at present, these coral structures must be based on the summits of submarine mountains or ridges of hills, which rise from the bottom of the ocean, like corresponding hills and ridges upon the dry land; since deep water is almost always to be found in their neighbourhood. This is probably true to a certain extent. There is reason to believe that solid rock exists at no great depth beneath the surface of some of the islands; and there are many in which it forms part of them, a cone of rock rising out of the water, encrusted with a terrace of coral. Moreover, it may be stated as a general fact, that there is no part of those seas in which the temperature, depth of water, and other circumstances, are favourable to the operations of the coral-polypes, in which they are not constantly at work; and thus channels are being constantly rendered narrower and less deep, and harbours are being blocked up which were formerly accessible. But this takes place with less rapidity than is generally imagined.

The coral islands of the Pacific and Indian Oceans constitute a large proportion of the groups with which that vast area is scattered. In some instances they are considerably elevated above its level; but in general their surface is but little raised above it. As the polypes do not build above low-water mark, it does not become at once apparent how even this elevation is attained. It is to be remembered, however, that in the tropical ocean there is an almost constant succession of waves driven by the trade-wind from east to west. These, dashing against the windward side of the islands, break off blocks from the masses of coral, which they cast upon the summit. An accumulation of these blocks, consolidated by smaller fragments, and by the sand resulting from their constant friction, gradually produces a firm rocky superstratum. The surface of this, decomposed by the atmosphere, forms a sort of chalky soil, which is well adapted to the growth of many kinds of plants; and their seeds being drifted by the sea, or brought through the air by birds, take root in it, so as speedily to cover the island with a luxuriant vegetation. The growth and decay of successive crops gradually covers with a thick layer of mould the previous chalky soil; and this affords support to the most beautiful kinds of tropical plants, which the humidity of the insular atmosphere causes to flourish to a degree rarely seen on continents.

Several of the coral islands take the form of rings, containing large basins of water communicating with the sea, which are termed lagoons. These were probably erected on the craters of submarine volcanoes; of the existence of many of which, beneath the Pacific Ocean there can be no doubt. They first rise to the surface in the form of circular reefs; the windward side is gradually raised above the sea-level by the process already described; but an opening usually remains at the leeward side, through which the water that washes into the central basin may flow out. As the whole ring is gradually elevated, however, the source of this overflow diminishes, and gradually ceases, the channel is filled up by the growth of coral, and the lagoon is cut off from the sea. This basin, also, is at last filled up by the accumulation of fragments of coral, and by the growth of the more delicate species in its interior; and at last one nearly uniform surface is produced.

There is reason to believe, however, that in many instances the coral extends to a much greater depth beneath the surface than that in which the animals are known to live; and the question then arises, in what manner was it formed? A careful examination of the islands of the Pacific Ocean shows us that many of them, which rise considerably above the surface, are entirely composed of coral. Now, as the coral-polypes never build above the level of the sea, it is evident that some subterranean movement, probably of a volcanic nature, must have lifted these islands from the bed of the ocean. In some instances the height at which coral may be found is very great—not less than eight or nine thousand feet. It is not improbable, then, that as the bottom of some parts of the ocean is rising, that of others should be falling. If a coral island had been originally formed in the usual way, and had then gradually sunk in the water, the polypes would have continued to build it up to the surface; and thus almost any amount of thickness may be produced, by a corresponding slow subsidence.

One of the most extraordinary coral growths known, is the barrier-reef which stretches along the shores of New Holland, at a distance of usually more than a hundred miles from the coast. This is above a thousand miles long; and for several hundred miles has no break wide enough to give passage to a ship. It is scarcely conceivable that a submarine ridge of hill should exist, a thousand miles in length, and approaching everywhere within one hundred feet of the same elevation; for such a ridge is nowhere seen on the dry land. But it is easy to account for this remarkable structure, if we suppose that the ridge was formerly more or less elevated above the surface; and that its different parts gradually became encrusted and capped with coral as they were submerged, after which the growth would continue upon the same parts, until the whole, being thus depressed and covered, became the continuous mass which is now witnessed. That such depressions *are* taking place in some islands of the Pacific, is a fact substantiated, not only by the traditions of the natives, but by observations made since they have been visited by Europeans.

There are many instances in which the coral structures of comparatively recent origin have undergone a metamorphosis, which causes them to lose in some degree their original aspect. Large masses, when long exposed to the air, become changed into a solid, often somewhat crystalline, rock, in which the traces of organic structure are very indistinct, and with which the *mountain* or *secondary limestone* closely corresponds. This is observed in the Bermudas. Moreover, the coral sand often becomes agglutinated, by the percolation of water through it, into a very hard stone; it is in such a mass that the human skeleton, found on the shore at Guadaloupe, and now placed in the British Museum, is imbedded. This stone, when minutely examined, is seen to consist of a number of rounded grains, cemented, as it were, together; and it closely resembles the rock known to the geologist as *oolite*. Further, where shallow water exists around coral islands, the bottom is found to be covered with a layer of white mud, which is formed by

the decay of the animal matter that held together the particles of carbonate of lime in the stony corals, and these are consequently set at liberty in a finely-divided state, and fall to the bottom in a form which, if dry, would constitute *chalk*. Thus we may trace, very distinctly, the mode in which the three principal kinds of limestone rocks may have taken their origin in coral formation.

Now, the mountain limestone, as it is termed—a rock very abundant in Britain, extending over large areas beneath the coal-fields, and sometimes exhibiting a thickness of nearly 3000 feet—is in some parts evidently composed of accumulations of shells, stems of encrinites, &c. But in many others, the remains of corals are very distinct; and these are so blended with the neighbouring rock as to make it appear probable that the latter also was once in the state of coral, but was gradually changed by the process just described. Further, the collections of other animal remains are just such as we should expect to find on the margin of a coral reef or island existing at that epoch; and a similar process of fossilization is taking place on the shores of those existing at the present time; the imbedded series of animals being different. The great thickness of the beds of may be very well accounted for, in the same the depth of the coralline masses of recent

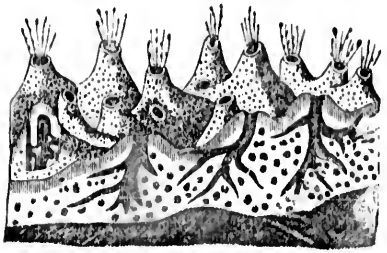
There are observed, in rocks of more recent appearances which still more clearly indicate too were originally formed by coral-polypes. often found only within narrow limits, as if they had been reefs or islands of small size. Thus we find a stone called coral-rag in Oxfordshire; and very distinct coral beds in the crag of the eastern coast of England. It is interesting to remark, that the remains of coral which are found in the older limestones, all correspond with those at present abounding near the equator, and exhibit the *lamelliform* character; while they are gradually replaced in the newer strata by species more allied to those at present existing in temperate climates. This is one of the many facts which tend to prove that this part of the earth had at some former period a much higher temperature than at present.

We see, then, that vast as are the works of the existing species of this class, they are probably far surpassed by the accumulations of former ages, which constitute, in some form or other, a large proportion of the solid rocks of our terrestrial surface. And thus we see the exemplification of a principle which has frequently come under our notice—that in the economy of Nature nothing is insignificant; and that the most gigantic effects may be produced by the multiplication even of the humblest among the living inhabitants of the globe.

CLASS XXIII.—PORIFERA.

Of all the beings usually known under the designation *Zoophytes*, the *Sponges* and their allies, constituting the class Porifera, appear to have the best claim to the title; since they present so complete an admixture of the characters of plants and animals, that it is difficult to say to which division of the organized world they properly belong. Like plants, they are fixed to one spot during the whole of their lives, subsequently, at least, to their first development, they seem to possess no sensibility, for they can be torn or wounded in any way without showing by their movements any indication of being affected by the injury; and they do not appear to have that power of executing voluntary motions which must be regarded as the distinguishing characteristic of animals. On the other hand, they present a structure which is not analogous to any thing found in plants, but is similar to that of beings undoubtedly belonging to the animal kingdom, with these beings they are connected by intermediate forms, presenting a regular gradation of increasing complexity of structure and variety of function; and there are certain movements, both in the adult and in the undeveloped Sponge, which are more analogous to those seen in higher animals than to any observed in plants. On the whole, however, the evidence for the animal character of the *Sponges* seems to preponderate; and they will be accordingly considered here. Still there is no doubt that, if they are included in the Animal Kingdom at all, the lowest place in the scale should be assigned to them.

The common *Sponge* is a sufficiently characteristic form of this class, to serve as the foundation of a general



Section of Living Sponge.

account of the structure which prevails in it. On looking at its exterior, we observe that it is covered by a number of closely set and minute orifices; and that larger openings are disposed at intervals among these. The former are termed *pores*, the latter *vents*. On cutting into the substance of the sponge, it is seen to consist of a sort of network or filaments, interlacing together in such a manner as to leave large channels and spaces of various forms, which communicate with each other. The large channels terminate in the vents; and on tracing any one of them into the substance of the sponge, it is seen to divide and send off ramifying branches, which at last lose themselves in the spongy network that lies around them; and this communicates with the pores on the external surface.

The interlacing fibres, of which the walls of the large canals, and the spongy tissue between them, are alike composed, entirely consist (in the common sponge) of a sort of horny animal matter, as is shown by burning a small portion of them. But in other species we find *spicula*, or needle-like crystals, of silex or of carbonate of lime, disposed among these, giving to the structure much greater firmness, but depriving it, more or less completely, of that elasticity which is so useful in the common sponge.

The substance known as *sponge* is, however, but the skeleton of the being; when alive, this fibrous network is clothed, within and without, by a thin gelatinous substance, very like the white of an egg. This lines all the passages, and covers the exterior; but it drains away when the sponge is removed from the water. In this the peculiar vital endowments of the being appear to reside. These are manifested, not only by its slow but regular growth, but by a curious circulation of fluid, constantly taking place within the mass. When a sponge is examined in its living state, beneath the water, a constant current is seen to issue from the vents; being made evident by the disturbance of the water, and by the movement of particles floating in it. It may also be ascertained that a constant flow of water takes place inwards through the pores; for small solid particles upon their edges are occasionally seen to be sucked in. No intermission can be detected, during the life of the sponge, in these currents, which evidently have for their object to

convey the nutritive matter contained in the water into the interior of the mass, and also to carry off the particles which are to be excreted, since thin films detached from the living tissue are seen to pass out from the vents along with the fluid ejected from them.

The relative position of the *pores* and *vents* differs much in the different kinds of sponge. Sometimes all the former are on one side, and the latter on the other. Not unfrequently the vents are placed on the summit of little conical prominences, which look like craters of a volcano; and the stream issuing from them, when seen under a microscope, may be likened to a miniature eruption. Sometimes the sponge assumes the form of a hollow cylinder, which hangs at one extremity from a rock; the pores are all upon the exterior surface, while the vents open into the interior cavity, and their united stream rushes out with considerable energy from the lower end of the cylinder.

Sponges may be multiplied, like plants, by artificial division, each portion becoming a new individual, but it does not appear that this is their natural mode of increase. They propagate by detaching little round gelatinous bodies, termed *gemmules*, from their living tissue; which in time develop the original form of the parent. These are produced in the network between the large canals, into which they find their way; when mature, they pass out of the vents in the current which sweeps through them, and by which they are conveyed to a distance. In these gemmules a peculiar motion, like that of animalcules, may be seen for some time; they swim hither and thither; at last they fix themselves, and begin to deposit the horny or earthy particles which are to form their skeleton; and the system of canals gradually shows itself in their substance. When once they have fixed themselves, they seem to lose all power of further movement, and remain during the rest of their lives attached to the same spot.

Some kinds of sponges are found on almost all shores; and some frequent deep water, whence they can only be obtained by dredging. It is in this manner that the common sponge is procured from the Mediterranean, the Grecian archipelago, and the other localities it frequents. Sponges are not confined to the sea, however; for there is a species which inhabits fresh water.

With the notice of this group we appropriately close the subject of Zoology.

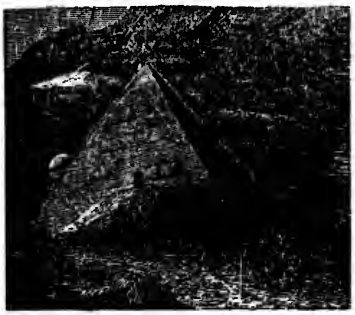
[BOOKS ON ZOOLOGY.

Among the various works which have been published on the subject of Zoology, few are entitled to confidence. The errors of the older writers are numerous, and some of them of a ludicrous character, as, for example, where Gerard, in his Herbal, gravely assures the reader that the Barnacle Goose grows upon a tree, germinating from a barnacle shell adhering to old water-soaked logs, trees, and other pieces of wood cast up by the sea, and called, from this wonderful circumstance, the "Goose-bearing tree." Many of the assertions in Goldsmith's Animated Nature are just as well founded; and yet the delightful style of Goldsmith commends his book to almost universal favour, and will long continue to do so.

In Natural History, Linnæus was the great reformer of the last century, as Cuvier was of the present. The minute classifications of the former gave precision to the science, and the researches of the latter in comparative anatomy have given it a simplicity, compactness, and certainty, which leaves nothing to be desired with respect to system. The following out of details will of course continue for centuries

The writings of Linnæus and Cuvier are the great classical works of the science. For popular use we commend to the reader the articles on Zoology in the Penny Cyclopædia and the British Cyclopædia of Natural History, and particularly the Pictorial Museum of Animated Nature, published in London, by Charles Knight, in two quarto volumes. It contains the most complete collection of well-figured animals attainable at a moderate price. The works of Wilson and Audubon are invaluable, but rather costly. Nuttall's Ornithology is a first-rate work, afforded at a moderate price. Most of the cheap compends of Zoology copy the errors of the old writers, and of course are of little value as authorities.—*Am. Ed.*]

ANCIENT HISTORY—EGYPT.



Great Pyramid of Cheops, in its present condition.

Ancient History usually commences with an account of the creation of the world, as narrated by Moses—the subsequent dispersal of mankind over the earth—the flood of Noah—and the re-settling of the human race in Asia, Africa and Europe, after that disastrous event. But to the annals of these early times it is unnecessary here to advert. We take up the history of antiquity at a period less remote, or from 2000 to 1000 years before Christ, when Egypt and the adjacent territories were illumined with the light of science and the arts.

It is important, at the outset of our sketch, to call attention to the fact, that the whole of ancient history refers to a limited cluster of countries on or near the shores of the Mediterranean. By a glance at the accompanying map, it will be perceived that Egypt, also the country of the Carthagenians, in Africa; Syria and Palestine, (including the country of the Phœnicians,) Arabia, the country of the Chaldeans, Babylonians, Medes, Persians and Assyrians, in Asia; and Greece, Italy, and other countries of the Gentiles, in Europe—all lie upon, or at no great distance from the Mediterranean. To the countries, therefore, adjacent to this inland branch of the Atlantic ocean, the knowledge of the ancients was chiefly confined, or at the utmost did not extend in an easterly direction beyond Hindostan, or the country of the Moguls. In consequence of this limited knowledge of geography, as well as the natural but very erroneous notion that the world was only a great stretched-out plain, the Mediterranean sea received the name it now bears, which signifies the *sea in the middle of the earth*—the central ocean round which the human race had been planted.

The world, as thus known to the ancients, may be described, in general terms, as a region extending from the 10th to the 50th degree of north latitude, and from the 1st degree west to the 70th degree of east longitude, and comprehending only limited districts of Africa, Asia and Europe—the whole composing a most insignificant portion of the globe. As far, however, as is learned from the records of sacred and profane history, it was in some spot within this anciently settled territory that science, learning, and the arts originated, and spread over the earth; and as thus forming the cradle of modern civilization, the region is invested with an interest due to its former greatness. Yet the political history of the empires and kingdoms which anciently flourished in this once favoured territory, is on the whole unworthy of lengthened study. Time is only thrown away in the vain endeavour to unravel the vague and offensive details of kingdom warring against kingdom, tribe against tribe, and each in its turn assailing and overpowering its more feeble neighbour. Thus, the Chaldeans in the south-east of Arabia were overpowered by their neighbours the Babylonians, the Babylonians by the Assyrians, the Assyrians and Egyptians by the Persians, the Persians by the Greeks, and the Greeks by the Romans while these latter, who had swallowed up the whole of their predecessors, were in their turn overpowered by barbaric hordes from the north of Europe, or by nearly equally savage tribes from the east. In this manner the bulk of ancient history is little else than a record of oppressions, conquests and crimes, and in the main exhibiting few facts which are of value either for amusement or instruction. Ancient history is indeed only interesting where it throws light upon the origin and progress of our religion, or upon the primeval state of learning, philosophy, and the arts; as a chronicle of mere wars and conquests, it is utterly valueless.

Whatever may have been the extent of knowledge in

letters, science, or the polite arts, gained by the ancient Chaldeans, Babylonians, or other Asiatics, it is generally understood that it fell short of what existed about the same period (2300 to 1000 years before Christ) among the inhabitants of Egypt, from which certain kinds of learning spread to Greece, from Greece to Rome, and from Rome over western Europe, including the British islands, and all other modern countries. By a clear line of descent, therefore, we trace the rudiments of modern civilization to Egypt, a land which is deserving of our notice, not only on this account, but on that of its magnificent remains of art, which till the present day astonish the mind of the traveller.

As thus interesting from their connection with modern civilization, or with our religion, we offer sketches of the history of Egypt, Palestine, Greece, and Rome, with some account of these countries, confining ourselves in the present instance to Egypt.

EGYPT—ITS HISTORY.

In point of local situation, Egypt possesses various advantages.* It lies in the north-east corner of Africa, in a salubrious part of that vast continent, presenting its northern base to the Mediterranean Sea, and bounded on the east by the Red Sea, which separates it from Asia. Through the whole land, from north to south, a length of 900 miles, flows the Nile, a fine large stream rising in the inland kingdom of Abyssinia, and, from certain periodic floods, of great use in irrigating and fertilizing the country. A large portion of Egypt consists of an alluvial plain, similar to our fertile meadow-grounds, formed by the deposits of the river, and bounded by ranges of mountains on either side. The greatest breadth of the land is 150 miles, but generally it is much less, the mountain ranges on either side often being not more than five to ten miles from the river. Anciently this territory was divided into three principal parts—Upper Egypt, or Thebais (from Thebes, its capital city), which was in the inner or southern part; Middle Egypt; and Lower Egypt, which included what was called the Delta, a low district of land on the shores of the Mediterranean, formed by the mouths of the Nile into the shape of the Greek letter Δ, or delta.

The history of the people who at one time inhabited this remarkable country is carried by their annalists to the very earliest ages; indeed, to a period far more remote than that ascribed by Moses to the creation of the world. When divested of fable, it appears that an Egyptian monarchy was established by Menes, or Misraim, in the year of the world 1816, and that it lasted till the year 3479, when it was destroyed by Cambyses, King of Persia. To Misraim succeeded a line of sovereigns of great power and fame, almost every one of whom seems to have delighted in rearing edifices of extraordinary magnitude and splendour. Extensive and beautiful cities, obelisks, pyramids, and temples, were erected without regard to the toil or resources of the people; and as their remains are till this day extant, and have been described by travellers, we are impressed with the most significant tokens of the taste and knowledge of the ancient Egyptians. Although each of the Egyptian monarchs was distinguished by his own peculiar name—as Moeris, Rameses, Sesostris, Pheron, Cheops, &c.—those who reigned for a considerable period, in lower Egypt especially, were designated Pharaoh, a title commonly used in Scripture to express the Egyptian rulers at the time. The Pharaoh who was noted for his oppression of the Israelites, and who flourished 1577 years before the Christian era, was properly called Rameses Miamum, while his son, the Pharaoh under whose reign the Children of Israel departed out of Egypt, and who was drowned in the Red Sea, was entitled Amenophis.

* Egypt is called Mazr by the natives.

The country thus governed, by a course of circumstances unknown to the present age, and which will most likely ever remain hid from our understanding, was among the first on the face of the earth which exhibited any demonstrations of refinement in taste. "This kingdom (says Rollin) bestowed its noblest labours and finest arts on the improving of mankind; and Greece was so sensible of this, that its most illustrious men—as Homer, Pythagoras, Plato, even its great legislators Lycurgus and Solon, with many more—travelled into Egypt to complete their studies, and draw from that fountain whatever was most rare and valuable in every kind of learning. God himself has given this kingdom a glorious testimony, when, praising Moses, he says of him, that 'he was learned in all the wisdom of the Egyptians.'" Such was the desire for encouraging the growth of scientific pursuits, that discoverers of any useful invention received rewards suitable to their skill and labour. They studied natural history, geometry, and astronomy, and, what is worthy of remark, they were so far masters of the latter science as to be aware of the period required for the earth's annual revolutions, and fixed the year at 365 days 6 hours—a period which remained unaltered till the very recent change of the style. They likewise studied and improved the science of physic, in which they attained a certain proficiency. The persevering ingenuity and industry of the Egyptians are attested by the remains of their great works of art, which could not well be surpassed in modern times; and although their working classes were doomed to engage in the occupations of their fathers, and no others, as is still the custom in India, society might thereby be hampered, but the practice of handicrafts would be certainly improved. The Egyptians were also among the first people who were acquainted with the processes of communicating information by means of writing or engraving on stone and metal; and were, consequently, the first who formed books and collected libraries. These repositories of learning they guarded with scrupulous care, and the titles they bore naturally inspired a desire to enter them. They were called the "Office for the Diseases of the Soul," and that very justly, because the soul was there cured of ignorance, which it will be allowed, is the source of many of the maladies of our mental faculties. As these repositories of the learning of the ancient Egyptians were all destroyed, and are only known from the records of historians, the work[illegible]eir sages and poets cannot now be shown; and [illegible] little else than the inscriptions on stones found [illegible]dst the ruins of pyramids and temples, that we are so much as aware of the nature of the characters employed in their writing. These characters were exceedingly curious, consisting chiefly of representations of animate and inanimate objects, each of which stood for some particular idea. The use of emblematic figures seems to have been, as it still is, common among uncultivated races of men, being the first approach towards literature; but the use of an alphabet, by which words are formed by combinations of different characters, was in early times confined entirely to the Egyptians, from whom the invention was communicated across the Mediterranean to Greece, by a person of celebrity called Cadmus, and from thence spread into other European nations. It is also understood that the Israelites, and other Asiatics, received their knowledge of letters from the learned inhabitants of Egypt. The use of rude emblematic figures was not abandoned by the Egyptians as letters became known, but continued chiefly to denote matters of a mysterious or religious tendency. These figures have received the name of *hieroglyphics*, and are of various kinds, more or less significant of the thing or idea intended to be expressed. For thousands of years the world remained in total ignorance of the manner of deciphering these hieroglyphics, for the Egyptians left no clue whereby to make the discovery; and it

was only in 1814 that, by the researches of some Frenchmen, a key to certain kinds was made known. It was found that, although the figures often signify the thing which they represent—for instance, the figure of a lion signifying that animal—yet that in many instances it does no such thing, but stands simply for the letter L, which is the initial letter in the word *lion*. The discovery of this mode of deciphering the Egyptian hieroglyphics, by reckoning only the initial letters in the names of the things represented, lays open a wide field for the investigation of learned and inquisitive travellers in the ancient territory of the Pharsohs.

The comparative intelligence of the Egyptians did not rescue them from the most debasing superstitions in their religious faith. They had a great number of ideal gods; among others, Osiris and Isis, which are thought to have been the sun and the moon. They also worshipped a number of beasts, as the ox or bull (under the name of Apis), the dog, the wolf, the hawk, the crocodile, the ibis or stork, the cat, &c.; and such was the reverence which they paid to these animals, that, in extreme famine, they chose to eat one another rather than feed on their imagined deities. The Egyptians had a belief, inculcated by their priests, that the souls of men, after death, passed into the bodies of clean or unclean animals, according to the deeds done in the body, and that at a distant period of time they returned to the body to which they originally belonged. A doctrine so extravagant led their kings to build enormous architectural edifices for the reception of their bodies, in order that they might, as they thought, repose in safety till they were again to be endowed with a living soul. In this fantastic notion we find a satisfactory solution of the mysterious practice of inhuming mummies in those huge pyramids, now reckoned among the greatest wonders in the world.

In the days of Egypt's ancient glory, it was dignified with two greater and many lesser cities. The two principal were Thebes, the capital of Upper Egypt, and a city of extraordinary extent and splendour; and Memphis, the capital of the middle district of the country. Memphis was built on the west side of the Nile, and has been succeeded by the comparatively modern city of Cairo, on the east bank of the river. On the site of Thebes and Memphis, and in their neighbourhood, are now found the greatest quantity of the ruins of ancient temples and other magnificent erections. In the present day Thebes receives the name of Said.

Like all other distinguished nations of antiquity, Egypt, after a lengthened period of extensive civil power, military glory, and dignified learning, suffered a series of reverses of fortune, and finally sank into a state of utter poverty and barbaric ignorance. The proximate causes of this disastrous event were the political distractions of the country, and the rise of a greater power in the vicinity—that of Nebuchadnezzar, king of Babylon. But in this, as in every other instance of national ruin in ancient times, the principal causes of the disaster were the ill-balanced condition of society, and the general ignorance of the people; the nation did not possess the elements of stability, and became an easy prey to a more powerful and savage neighbour. The country was overrun by Nebuchadnezzar and his hosts, 569 years before Christ, when an immense quantity of its movable wealth was carried off. About forty-four years afterwards, Egypt was again intruded upon by force of arms, and fell a prey to the conquering hordes of Persia under Cyrus, when many of its edifices were destroyed. It now became a distant colony of Persia, which maintained an authority over it for more than 200 years, at the end of which it was seized by Alexander the Great, a monarch of Greece, who shortly afterwards conquered the whole of Persia. Besides settling the government of the country, Alexander improved it in various ways—among the rest of his enterprises, building the city of Alexandria, which he called after his own name; and as it was placed on the sea-coast, at one of the mouths of the Nile, it speedily rose to be one of the largest and most opulent seaport towns in the world. Upon the division of the Persian empire some time later, Egypt fell to Ptolemy Lagus, one of Alexander's generals, who was succeeded by a race of princes distinguished by the name of Ptolemy, in addition to their other appellations; and hence the Ptolemies of Egypt who are spoken of in ancient history. The last royal descendant of this noble Grecian line was Cleopatra, a princess of great beauty and accomplishments; and at her decease, which she accomplished by suicide, the land of Egypt became a province of Rome, some of whose emperors endeavoured to revive in it a love of letters, and enriched it by various improvements. Subsequently, Egypt fell into a state of ruinous distraction, consequent on the troubles and decline of the Roman government, and was at last completely subdued by the Saracens, who introduced the religion of Mohammed, destroyed the libraries, and, as far as possible, the splendid works of art; so that, under their sway, every species of barbaric rudeness was made to supersede the ancient refined habits of the people. Since that dismal epoch, Egypt has, century after century, sunk deeper and deeper into a state of perfect neglect and ruin. In recent times it has been under the immediate rule of Mehemet Ali, nominally a pacha of the Sultan of Constantinople, and by whom, with considerable suffering to the poor inhabitants, certain improvements have been effected.

DESCRIPTION OF THE COUNTRY.

As already mentioned, Egypt consists of the long flat valley of the Nile, from Abyssinia on the south, to the shore of the Mediterranean Sea, and nominally consists of three divisions, the Delta or lower region, Middle, and Upper Egypt. It is said to contain 200,000 square miles, but only about 16,000 of these are susceptible of cultivation. In ancient times, the country was more generally fertile than in the present day, owing to the encroachment of the sands of the adjacent deserts, and the long period of desolation and mismanagement in which it has existed. Still, owing to the inundations, the lands are more than usually productive, and yield crops of wheat, barley, rice, millet, maize, flax, beans, cotton, tobacco, the sugar-cane, and other useful vegetables. Of fruits, the citron, lemon, pomegranate, apricot, banana or plantain, and the palm-date, flourish luxuriantly. The palm is cultivated to a large extent in the inundated and irrigated lands, and groves of it, yielding a delightful shade, are to be seen, consisting of several thousand trees. Another celebrated production of Egypt is the lotus, a species of water-lily, of great beauty, exhibiting broad round leaves, amid which the flowers, in the form of cups, of bright white and azure, expand on the surface of the waters. The roots of vegetables were used as food by the ancient Egyptians. There is also the papyrus, not less celebrated than the lotus, and which furnished a material used as paper, before the invention of that article; it is, like the lotus, an aquatic plant, growing to the height of eight or ten feet amid the swamps of the Nile. The filaments of the plant being separated and cemented together in pieces, formed sheets whereon writing was executed. (See article PAPER-MAKING.)

THE NILE.

The most remarkable natural object in Egypt is the Nile, which periodically overflows its low banks, and inundates the greater part of the country. The Nile is formed by the union of two streams in the upper country, the Bahr-el-Abiad (white river), and the Bahr-el-Azrek (blue river), in lat. 15° 40′ north. The former, rising in Abyssinia, to the south-west of lake Dembea, comes from the south-east, and was considered by Bruce

as the Nile. The latter, however, which comes from the south-west, and is supposed to rise in the Mountains of the Moon, in the centre of Africa, brings down the greatest mass of water, and is considered as the true Nile. In lat. 17° 40′ it receives the Tacazze from the east; enters Egypt in 24°, following nearly a northern course; and below Cairo (30° 15′ north) divides into the two main arms, as we have already mentioned. There were anciently reckoned seven principal mouths, by which its waters were poured into the Mediterranean; only those of Damietta and Rosetta are at present navigable; the others have been choked up. The distance from the confluence of its two head branches to the sea, is about 1500 miles; from its highest sources probably not far from 2500 miles. At certain points in its course, the Nile falls over a series of cataracts, or, properly speaking, descends a series of tumultuous rapids, for the fall is nowhere above two feet of sheer descent. The cataracts are not altogether a bar to navigation, as vessels which sail up the river may be drawn up by an extraordinary force. There are parties of Arabs who make a business of hauling boats up the cataracts. The Nile has also numerous islands in its course.

The grand phenomenon connected with the Nile, is its annual overflow of the banks which border it—an event looked for with as much certainty as the daily rising of the sun. These inundations of the Nile are owing to the periodical rains which fall between the tropics. They begin in March, but have no effect upon the river until three months later. Towards the end of June it begins to rise, and continues rising at the rate of about four inches a-day, until the end of September, when it falls for about the same period of time. Herodotus, the Grecian historian, informs us, that in his time a rise of sixteen cubits was sufficient to water the country. At present, twenty-two cubits are considered a good rise. The towns are generally built in such a situation and manner as not to be overflowed by the inundation, and in some parts of the country there are long raised causeways upon which the people may travel during the floods. It is only in cases of an extraordinary rise that any villages are destroyed. The inundations, instead of being viewed as a calamity, are considered a blessing, for they are the cause of inexhaustible fertility. After the waters have subsided, the earth is found covered with mud, which has been left there by the river. This mud, which is principally composed of argillaceous earth and carbonate of lime, serves to fertilize the overflowed land, and is used for manure for such places as are not sufficiently saturated by the river; it is also formed into bricks, and various vessels for domestic use. The whole valley of the Nile may be considered as an alluvial plain formed of the washed-down mud and sand of central Africa, and it is therefore to these inundations that Egypt owes its existence. The accumulation of soil has been estimated at about forty feet within the last four thousand years.

In Upper and Middle Egypt, there are immense numbers of canals on the left bank of the river. Mehemet Ali, the present pasha, has opened many of the old canals, which had been closed for centuries, and dug new ones; among the atter, the canal of Mahmoud, connecting the harbour of Alexandria with the Nile, near Fouah, forty-eight miles long, ninety feet broad, and eighteen deep, is a magnificent work. The Delta is bordered by a number of maritime lakes or lagoons, which at different periods have undergone considerable changes; some of them had been dried up, when, from various causes, their connection with the ocean, which had been interrupted, was again resumed, and the exhausted basins replenished with water. In the ancient Egyptian mythology, the Nile was revered as the tutelary deity of the country. His attributes are the crocodile, the sphinx, the hippopotamus, and the dolphin.

It might be supposed that in consequence of the annual inundations, Egypt would be a wet or moist country; but the very reverse is the case. The waters are speedily dried up and carried off as vapours by the winds, leaving the climate so remarkably dry that meat in the open air will not putrefy, but be dried or shrivelled up. Rain, snow, thunder, or any of the common atmospheric phenomena, are seldom or never seen or heard. In consequence of the dry arid heat during most part of the year, hot winds from the sandy deserts, and the mode of living of the people, ophthalmia, or disease of the eyes, is common, and many of the inhabitants are blind of one or both eyes. The principal winds blowing over the country are from the north, and are of great use in tempering the atmosphere and wafting vessels up the Nile against the current.

To the above account of the Nile, we add the following pleasing sketch by Mr. Bowring, as given in his interesting small work for youth, entitled "Minor Morals:"—"Among the Egyptians, the attachment is less to the soil than to the river—the river Nile, which is in their eyes, as it was in the eyes of their forefathers, a sort of divinity. They speak of their Nile with the intensity of personal affection—it is their daily benefactor; to it they owe their wealth, great or small—the verdure of their fields, their food, their drink, their clothing—for it produces the vegetables and the fish they eat; it gives the water with which they quench their thirst and cook their victuals; it causes the cotton tree to grow, of which they make their garments; it supplies their flocks and herds. There is not a woman on its banks who, from the time at which she is first able to carry a pitcher on her head or bear one in her hand, does not daily replenish it in the sacred and venerable stream. Its praise passes into proverbs, into their daily talk. I remember travelling to the Bahr el Yeressouff, and having alighted, I gave my horse to a poor Fellah woman; when, on remounting, I put a small coin into her hand, she said, 'May Allah bless thee as he blessed the course of the Nile!' A hundred times I had been told in Egypt, 'You will return hither. No one ever drank the waters of the Nile without being irresistibly impelled to drink them again.' And the water, though not clean, is delicious and healthful. The Egyptian Levantines have a saying, that 'What champagne is to other wines, is the Nile to other waters;' and there is also an Arabian proverb—'Had Mohammed drunk the waters of the Nile, he would have stayed on earth, and not have allowed himself to be conveyed to Paradise.' * * * There are between 5000 and 6000 boats constantly in movement on the two branches of the Nile, the Rosetta and Damietta branches; and from the point of their union up to Assouan. There is the first cataract, as it is called but it is not a cataract; it is merely a rapid, where the waters rush through the granite rocks—having, however, channels so large that during certain months of the year the boats can be hauled through, and proceed to Wadi Halfa, the second cataract. The boats are of all sizes, from the smallest *pont* to vessels which will convey 200 tons of goods. They are for the most part of coarse construction, carrying enormously large triangular sails, and are frequently overturned by the sudden gusts on the river."

The district of country west from the banks of the river is ordinarily called the Libyan desert or division, and that on the east the Arabian.

CLIMATE—NATURAL HISTORY.

In Egypt, the harvests follow each other at the distance of about six or eight weeks, according to the different kinds of grain, leaving time in most cases for a succession of crops wherever there is a full command of water. The cold season commences with December, and continues for about two months. Early in February spring appears, when the atmosphere acquires a delightful warmth, and the trees put forth their

blossoms. The period of summer may be said to commence in June, and to end at the close of September. The transition from the one season to the other is so imperceptible that it is scarcely possible to say when the one begins and the other ends. During these four months, the heat is intense; the fields to which the swelling river has not attained, are parched like a desert, and no green leaf is seen but such as are produced by artificial irrigation. Autumn, which is only marked by a slight diminution of temperature, commences about the middle of October, when the leaves fall, and the Nile retires within its channel; and till the approach of that season, which can only be called winter from its situation in the calendar, the face of the country resembles a beautiful and variegated meadow. Volney's description is thus a matter of fact, that Egypt assumes in succession the appearance of an ocean of fresh water, of a miry morass, of a green level plain, and of a parched desert of sand.

From the nature of the surface, and the universal aridity of the surrounding desert, Egypt is much hotter than most other countries under the same parallel. From March to November, the atmosphere is inflamed by a scorching sun and a cloudless sky, the average height of the thermometer being about 90°; during the other six months, it is about 60°. At sunset, the winds fall, and the nights are generally cool, and the dews heavy. Except along the sea-shores, rain is a phenomenon in Egypt. At Cairo, there are on an average four or five showers in the year; in Upper Egypt, one or two at most; nor are they considered as beneficial to the agriculture of the country. Thunder and lightning are still more uncommon, and are likewise completely divested of their terrific qualities. Showers of hail, sweeping from the hills of Syria, are sometimes known to reach the confines of Egypt; but ice is a commodity so extremely rare, that instances have occurred of its being sold at a high price.

In its geological features, Egypt presents great variety, including specimens of almost every formation, from the earliest to the most recent. Several granitic chains of hills stretch to a considerable extent. These contain vast quarries of syenite, from which the ancients drew the stupendous masses required for their colossal statues and obelisks. Between Assouan and Esna lies the sandstone, or middle district, which supplied blocks for the temples; and beyond it, the northern or calcareous district stretches to the southern angle of the Delta. This last chain supplied materials for the pyramids, and many public buildings. The limestone extends from Syene to the Mediterranean, and, in Lower Egypt, from Alexandria to the Red Sea, in the vicinity of Suez. Other valuable rocks are abundant in Egypt, and various precious minerals are found. In zoology, the camel, so emphatically named the ship of the desert, has long been domesticated in the country. The giraffe, or cameleopard, has been occasionally seen. A quadruped, called virrera ichneumon, is one of the most celebrated animals in the country. Amongst the ancients, it was venerated with a species of worship. Ichneumons are domesticated in Egypt, where they perform the duties of our domestic cat, in ridding the houses of the smaller animals. The names of the crocodile and hippopotamus are familiarly associated with Egypt and the Nile. The number of the latter animal is now declined, and he is seldom seen below the Cataracts. A species of lizard, called the monitor of the Nile; the common cameleon; the lizard; the sorex, or shrew; and, of the marmot tribe, a particular genus called the dipus, or jerboa; the goat, sheep, and the animals which figure in the Egyptian mythology, such as the dog, ape, buffalo, &c.; still belong to the zoology of the country. Of birds, the ostrich, the ibis, of which there are several species, and the Egyptian vulture, are most famous. With respect to fishes, the country presents nothing remarkable.

INHABITANTS.

The population of Egypt is composed of an extraordinary mixture of races, and of all shades of colour some claiming to be descendants of the ancient Egyptians, though utterly degenerated, others being from Arabian or Saracenic intruders, and so on to the number of a dozen distant races, also a variety of mixtures to whom no name can be assigned. The following is the common enumeration:—1. The race called Copts, the supposed descendants of the ancient Egyptians, and more certainly the feeble remnant of a once numerous Christian population. 2. The Fellahs, who compose the bulk of the labouring class, and who are supposed to be a mixture of ancient Egyptians, Arabians, and Syrians; they are rigid Moslems. 3. The Bedouin Arabs, the same in character, manners, and customs that they are everywhere, and apparently ever have been since the days of the patriarchs, regarding with disdain and proud independence all other classes of mankind, but more especially those of their own nation who have degraded themselves by taking up their abodes within walls. 4. Arabian Greeks, that is, the descendants of ancient Greek colonists, who have lost their ancient language, and speak a kind of Arabic. Many of them are mariners, but, in general, they pursue the inferior and handicraft trades. 5. Jews. To these must be added, as inhabitants of Egypt, 6. Syrian-Greeks and Maronites, who have, within the last century, greatly increased in numbers, and have proved successful rivals of the Copts and Jews as merchants and agents. 7. Armenians. 8. Turks. 9. Franks or Europeans. 10. Mamelukes. 11. Moggrelins, or Western Arabs. 12. Ethiopians and other Africans. The following is as near an approximation as can be obtained of the relative numbers of the different divisions of this motley crew:—Copts, 160,000; Arab Fellahs, 2,250,000; Bedouin Arabs, 150,000; Arabian Greeks, 25,000; Jews, 20,000; Syrians, 20,000; Armenians, 10,000; Turks and Albanians, 20,000; Franks, 4000; Mamelukes, 500; Ethiopians, &c., 7500; which amount in all to 2,667,000. Since this list was made up, the Mamelukes, a race of foreign mercenary soldiers, have been extinguished. As being dangerous to the state, or rather opposed to the introduction of European customs, they were utterly destroyed by order of Mehemet Ali.

The Arabs have been divided into three classes:—First, the wild independent Bedouins who occupy the desert; second, the pastoral tribes, who feed their flocks upon the borders of Egypt, and occasionally enter the cultivated provinces; and lastly, the peasants or Fellahs, who are devoted to agriculture and the arts. The latter, who form the bulk of the population, are described as a fine race of men in their persons, active in agricultural employments, and possessed of many good qualities. In their dress and household economy in general, though not strangers to comfort, they are so to every thing like luxury. Their food is very plain, and none but the higher orders, or those of dissolute lives, ever taste wine. The Arabs carry on the common trades of civilized life, but in a very unskilful and imperfect manner. We shall have occasion afterwards to speak of the general state of trade and manufactures in Egypt.

The Arabs have seldom more than two wives; in general only one. The women for the most part can neither read nor write; but the better sorts are taught embroidery and ornamental needlework, in which they mostly pass their time. The features of the Arab-Egyptian women are by no means regular. They are taller in general than our European women. Their hair is black and long, their skin of a disagreeable mulatto colour, and they stain various parts of their body with colouring matter. The tented Arabs still maintain their ancient character of proud independence, and in manners

ar customs are the same people they were 3000 years ..

After enumerating the various oriental races who inhabit Egypt, it need hardly be mentioned that Mohammedism is the prevailing religion. Generally speaking, those who profess Christianity know nothing of its doctrines or moral precepts, the practice of their faith being confined to a few unmeaning ceremonies, and the repetition of a few established phrases. The whole people, high and low, are in a state of intellectual darkness; in the towns there exist, among Jews, Franks, and Turks, a degree of comfort and some wealth, but in the country parts many of the inhabitants are in a state of deplorable wretchedness; and in some places they are seen almost entirely naked, having neither regular food nor clothing, and no lodging except in holes or mud-built hovels. When they have any thing to take, they are ground to the earth by taxation, and both person and goods are at the mercy of their despotic ruler and his inferior functionaries.

ALEXANDRIA.

On reaching the shores of Egypt from the sea, the first place usually touched at by the traveller is Alexandria, the capital of Lower Egypt or the Delta. It is situated on a low flat part of the coast, at some distance west from one of the main branches of the Nile. The two main branches of the river are to the east of Alexandria—the first in this direction being that on which is placed Rosetta or El Raschid, and that still farther east being that on which Damietta is situated. Between Alexandria and Rosetta is Aboukir Bay.

The Alexandria (or Iskandria) of the present day, is very different from its predecessor, founded by Alexander the Great, and destined by him to be the centre of his empire, and of the commerce of the world. According to Pliny, it was fifteen miles in circuit, and contained a population of 300,000 individuals. It shone in all the pomp of architectural magnificence, and contained streets of immense breadth, which intersected it from end to end. Its public edifices were of the most splendid description. At one period, it is said to have contained 4000 palaces, 4000 baths, 400 public edifices, including theatres or places of popular amusement, and 12,000 shops; with, as is believed, a population of 200,000 persons. Much of its grandeur perished when the Emperor Theodosius ordered all the heathen temples throughout the Roman dominions to be destroyed; but there still survived a magnificent library of several hundred thousand volumes, including all the Greek and Latin literature of which we now only possess fragments. This treasure has been irreparably lost to the world. It was burned to ashes by the ferocious Caliph Omar, in the year 635. (See HISTORY OF THE MIDDLE AGES.) By the desolating influence of Turkish rule, the appearance of Alexandria now is most melancholy and wretched, resembling, at a distance, according to one traveller, with its gray ruins and flat-roofed houses, a town newly laid desolate by an enemy. The streets are narrow, dirty, and irregular, and usually crowded with "half-fed, half-clad" human beings. The climate of the place is also materially altered. From having been once salubrious, it is now very unhealthy. "Still Alexandria," says Sir Robert Wilson, "must be pronounced the key of Egypt, although insulated by water and desert from the surrounding country, since in its harbour alone security can be found for shipping of any burden throughout the year." The modern town does not occupy the site of the old one, which lies to the south, and presents an immense field of confused ruins. Over a space of from six to seven miles in circuit, is spread an assemblage of broken columns, obelisks, and shapeless masses of architecture, which are interspersed with some more modern buildings, such as churches, mosques, and monasteries. Amid this scene of wide-spread devastation, a few objects rise conspicuous, the most remarkable of which is "Pompey's Pillar;" it is about ninety feet high, and consists of a pedestal, a very fine shaft, and a Corinthian capital, each being composed of one entire piece of granite. Vulgar belief ascribes the erection of this pillar to Cæsar, in commemoration of his triumph over Pompey, but this is now generally considered as erroneous. The most plausible conjecture is, that it was reared by a governor of Egypt, named Pompey, in honour of the Emperor Diocletian. The next remarkable objects are the two obelisks vulgarly called Cleopatra's Needles, one standing erect, and the other lying prostrate on the sand, and greatly injured by the abrasions of footsteps and the chippings of visiters. They are composed each of a single block of granite, nearly sixty feet in length, and entirely covered with hieroglyphics. This circumstance indicates an Egyptian origin, and it is conjectured that they were conveyed thither from Memphis; in reality, they are the obelisks of a Thotmes surcharged by a Rameses. Alexandria is beginning to exhibit some marks of renovation. Mr. Stephens, a recent traveller,* observes—"I contemplated the improvements: a whole street of shops, kept by Europeans, and filled with European goods, ranges of fine buildings, fine country-houses, and gardens growing upon barren sands, showed that strangers from a once barbarous land were repaying the debt which the world owes to the mother of arts, and raising her from the ruin into which she had been plunged by years of misrule and anarchy." The pasha has here his arsenal, fort, barracks for his army, also his fleet when not in active employment; and he has endeavoured to centre here a commerce that was formerly divided between several places. Alexandria is further likely to be improved, from being an intermediate station for the new line of intercourse between England and India by way of the isthmus of Suez and the Red Sea, from which it is about eighty miles distant. The Nile, a short way above Rosetta, when reached from Alexandria, is described by Mr. Stephens as being worthy of its historic fame. "I found it (says he) more than a mile wide; the current at that season (December) full and strong; the banks on each side clothed with a beautiful verdure, and groves of palm trees—the most striking feature in African scenery—and the village of Fouah, the stopping-place for boats coming up from Rosetta and Damietta, with its mosques, and minarets, and whitened domes, and groves of palms, forming a picturesque object in the view."

ROUTE OF THE NILE—CAIRO.

Egypt, as has been said, must be viewed simply as a strath or valley of a few miles in width, with the river Nile flowing through it; it is at least only on the banks of the river that the wonderful objects of ancient art are seen, which excite the admiration of travellers. Pursuing the course of the river above the point of its separation into two main branches, these remains come first into view on approaching Cairo, at the 30th degree of north latitude. Here the river consists of one beautiful broad stream, on the east or right bank of which stands Cairo; and also on a very narrow branch, on the west or left bank, the famed Pyramids of Gizeh are situated. The site of these structures is generally elevated above the level of the plain, and stretches as a rocky platform for about fifty miles parallel with the river. Cairo, or Kahira, is not close upon the Nile, but stands at the distance of about a mile from it, at the base of the rocky heights of Mokattam, and the large village of Beulac, on the river, is its harbour or port; here, likewise, are various manufacturing and other establishments, including

* Incidents of Travel in Egypt, Arabia-Petræa, and the Holy Land. "People's Edition." W. and R. Chambers.

a printing-office under the auspices of the pasha. As in the case of Alexandria, the modern Cairo is very different from the ancient city of that name, erected by the caliphs in the middle ages. It is a walled town, built in a picturesque eastern style, and is the seat of the court of Mehemet Ali, whose palaces are very extensive. The population of Cairo amounts to about 240,000, but with that of the environs it amounts to half a million.

A considerable traffic and retail trade are carried on in the town, and the place is distinguished as a seat of Arabic learning and Mohammedan theology. There are several splendid mosques, to which schools are attached.

There is now an English hotel, and an Italian locanda or lodging-house, in which European travellers reside. The town is now also under a strict police, established by Mehemet Ali, and all Europeans, in whatsoever costume, are perfectly safe from insult or injury. Old Cairo, the original town near this spot, and called by the natives Mezr-Anteekeh, is a suburb at the distance of two miles on the banks of the river, the intervening grounds being laid out in gardens and plantations. This ancient seat of population, which is now partially in ruins, and made a place of temporary summer resort by the citizens of Cairo, is believed to be as old as the sojourn of the Israelites in Egypt, and a house in it is shown as that in which the Virgin Mary lodged after she had fled into the country from Palestine. The modern town is said to have been erected in the year 980, at the Saracenic conquest, and called El Kahira, or the Victory. In the year 1175, it was visited by Saladin, who surrounded it with a wall for defence.

Mr. Stephens's account of his approach to Cairo, in sailing up from Alexandria, conveys a striking idea of the appearance of the city and its environs:—"Towards the evening of the fourth day, we came in sight of the 'world's great wonder,' the eternal pyramids, standing at the head of a long reach of the river directly in front of us, and almost darkening the horizon. The sun was about setting in that cloudless sky known only in Egypt; for a few moments their lofty summits were lighted by a gleam of lurid red; and as the glorious orb settled behind the mountains of the Libyan Desert, the atmosphere became dark and more indistinct, and their clear outline continued to be seen after the whole earth was shrouded in gloom. The next morning at seven o'clock we were alongside the Island of Rhoda, as the Arab boatmen called it, where the daughter of Pharaoh came down to bathe, and found the little Moses. We crossed over in a small boat to Boulac, the harbour of Cairo, breakfasted with Mr. T——, the brother-in-law of my friend, an engineer in the pasha's service, whose interesting wife is the only English lady there; and, mounting a donkey, in half an hour I was within the walls of Grand Cairo. The traveller who goes there with the reminiscences of Arabian tales hanging about him, will nowhere see the Cairo of the caliphs; but before arriving there he will have seen a curious and striking spectacle. He will have seen, streaming from the gate among loaded camels and dromedaries, the dashing Turk, with his glittering sabre, the wily Greek, the grave Armenian, and the despised Jew, with their long silk robes, their turbans, solemn beards, and various and striking costumes; he will have seen the harem of more than one rich Turk, eight or ten women on horseback, completely enveloped in large black silk wrappers, perfectly hiding face and person, and preceded by that abomination of the East, a black eunuch; the miserable santon, the Arab saint, with a few scanty rags on his breast and shoulders, the rest of his body perfectly naked; the swarthy Bedouin of the desert, the haughty janizary, with a cocked gun in his hand, dashing furiously through the crowd, and perhaps bearing some bloody mandate of his royal master; and perhaps he will have seen and blushed for his own image in the person of some beggarly Italian refugee. Entering the gate, guarded by Arab soldiers in a bastard European uniform, he will cross a large square filled with officers and soldiers, surrounded by what are called palaces, but seeing nothing that can interest him save the house in which the gallant Kleber, the hero of many a bloody field, died ingloriously by the hands of an assassin. Crossing this square, he will plunge into the narrow streets of Cairo. Winding his doubtful and perilous way among tottering and ruined houses, jostled by camels, dromedaries, horses, and donkeys, perhaps he will draw up against a wall, and, thinking of plague, hold his breath, and screw himself into nothing, while he allows a corpse to pass, followed by a long train of howling women, dressed in black, with masks over their faces; and entering the large wooden gate which shuts in the Frank quarter for protection against any sudden burst of popular fury, and seating himself in a miserable Italian locanda, he will ask himself, Where is the 'Cairo of the caliphs, the superb town, the holy city, the delight of the imagination, greatest among the great, whose splendour and opulence made the prophet smile?'

"One of my first rambles in Cairo was to the slave-market. It is situated nearly in the centre of the city, as it appeared to me, although, after turning half a dozen corners in the narrow streets of a Turkish city, I will defy a man to tell where he is exactly. It is a large old building, enclosing a hollow square, with chambers all around, both above and below. There were probably 500 or 600 slaves, sitting on mats in groups of ten, twenty, or thirty, each belonging to a different proprietor. Most of them were entirely naked; though some, whose shivering forms evinced that even there they felt the want of their native burning sun, were covered with blankets. They were mostly from Dongola and Sennaar; but some were Abyssinians, with yellow complexion, fine eyes and teeth, and decidedly handsome. The Nubians were very dark, but with oval, regularly formed and handsome faces, mild and amiable expressions, and no mark of the African except the colour of their skin. The worst spectacle in the bazaar was that of several lots of sick, who were separated from the rest, and arranged on mats by themselves; their bodies thin and shrunken, their chins resting upon their knees, their long lank arms hanging helplessly by their sides, their faces haggard, their eyes fixed with a painful vacancy, and altogether presenting the image of man in his most abject condition. Meeting them on their native sands, their crouching attitudes, shrunken jaws, and rolling eyes, might have led one to mistake them for those hideous animals the orang-outang and ape. Prices vary from twenty to a hundred dollars; but the sick, as carrying within them the seeds of probable death, are coolly offered for almost nothing, as so much damaged merchandise which the seller is anxious to dispose of before it becomes utterly worthless on his hands. There was one, an Abyssinian, who had mind as well as beauty in her face; she was dressed in silk, and wore ornaments of gold and shells, and called me as I passed, and peeped from behind a curtain, smiling and coquetting, and wept and pouted when I went away; and she thrust out her tongue to show me that she was not like those I had just been looking at, but that her young blood ran pure and healthy in her veins.

Cairo is surrounded by a wall; the sands of the desert approach it on every side, and every gate, except that of Boulac, opens to a sandy waste. Passing out by the Victory Gate, the contrast between light and darkness is not greater than between the crowded streets and the stillness of the desert, separated from them only by a wall. Immediately without commences the great burial-place of the city. Among thousands and tens of thousands of Mussulmans' headstones, I searched in vain for the tomb of the lamented Burckhardt; there is no mark to distinguish the grave of the enterprising traveller from that of an Arabian camel-driver. At a short distance

from the gate are the tombs of the caliphs, large and beautiful buildings, monuments of the taste and skill of the Saracens. From hence, passing around outside the walls, I entered by the gate of the Citadel, where I saw what goes by the name of Joseph's Well, perhaps better known as the Well of Saladin. It is 45 feet wide at the mouth, and cut 270 feet deep through the solid rock, to a spring of saltish water, on a level with the Nile, whence the water is raised in buckets on a wheel, turned by a buffalo."

PYRAMIDS OF GIZEH.

"Almost from the gates of Cairo (continues this writer) the pyramids are constantly in sight, and after crossing the ferry, we rode towards them. Approaching, the three great pyramids and one small one are in view, towering higher and higher above the plain. I thought I was just upon them, and that I could almost touch them; yet I was more than a mile distant. The nearer I approached, the more their gigantic dimensions grew upon me, until, when I actually reached them, rode up to the first layer of stones, and saw how very small I was, and looked up their sloping sides to the lofty summits, they seemed to have grown to the size of mountains. The base of the great pyramid of Cheops is about 800 feet square, covering a surface of about eleven acres, according to the best measurement, and 461 feet high [being 117 feet higher than St. Paul's at London]. Even as I walked around it, and looked up at it from the base, I did not feel its immensity until I commenced ascending; then, having climbed some distance up, when I stopped to breathe and look down upon my friend below, who was dwindled into insect size, and up at the great distance between me and the summit, then I realized in all their force the huge dimensions of this giant work. It took me twenty minutes to mount to the summit; about the same time that it had required to mount the cones of Ætna and Vesuvius. The ascent is not particularly difficult, at least with the assistance of the Arabs. There are 206 tiers of stone, from one to four feet in height, each two or three feet smaller than the one below, making what are called the steps. Very often the steps were so high that I could not reach them with my feet. Indeed, for the most part, I was obliged to climb with my knees, deriving great assistance from the step which one Arab made for me with his knee, and the helping hand of another above.

"It is not what it once was to go to the pyramids. They have become regular lions for the multitudes of travellers; but still, common as the journey has become, no man can stand on the top of the great pyramid of Cheops, and look out upon the dark mountains of Mokattam bordering the Arabian desert; upon the ancient city of the Pharaohs, its domes, its mosques, and minarets, glittering in the light of a vertical sun; upon the rich valley of the Nile, and the 'river of Egypt' rolling at his feet; the grand range of pyramids and tombs extending along the edge of the desert to the ruined city of Memphis, and the boundless and eternal sands of Africa, without considering that moment an epoch not to be forgotten. Thousands of years roll through his mind, and thought recalls the men who built them, their mysterious uses, the poets, historians, philosophers, and warriors, who have gazed upon them with wonder like his own."

On the summit is an area, about thirty feet square, consisting of six square blocks of stone irregularly disposed. Six millions of tons of stones are supposed to have been employed in the construction of the pyramid, and 100,000 men for twenty years are said to have been engaged in the erection of this the most stupendous mass of masonry in the world. The four angles of the pyramid correspond with the four points of the compass. The mass of the pyramid is not altogether solid. An entrance has been made, by which a series of labyrinthine passages and chambers have been discovered. "The entrance (says Stephens) is on the north side. The sands of the desert have encroached upon it, and, with the fallen stones and rubbish, have buried it to the sixteenth step. Climbing over this rubbish, the entrance is reached, a narrow passage three and a half feet square, lined with broad blocks of polished granite, descending in the interior at an angle of twenty-seven degrees for about ninety-two feet; then the passage turns to the right, and winds upwards to a steep ascent of eight or nine feet, and then falls into the natural passage, which is five feet high and one hundred feet long, forming a continued ascent to a sort of landing-place; in a small recess of this is the orifice or shaft called the well. Moving onward through a long passage, the explorer comes to what is called the Queen's Chambers, seventeen feet long, fourteen wide, and twelve high. I entered a hole opening from this crypt, and crawling on my hands and knees, came to a larger opening, not a regular chamber, and now cumbered with fallen stones. Immediately above this, ascending by an inclined plane lined with highly polished granite, and about 120 feet in length, and mounting a short space by means of holes cut in the sides, I entered the King's Chamber, about thirty-seven feet long, seventeen feet wide, and twenty feet high. The walls of the chamber are of red granite, highly polished, each stone reaching from the floor to the ceiling; and the ceiling is formed of nine large slabs of polished granite, extending from wall to wall. It is not the least interesting part of a visit to the interior of the pyramids, as you are groping your way after your Arab guide, to feel your hand running along the sides of an enormous shaft, smooth and polished as the finest marble, and to see by the light of the flaring torch chambers of red granite from the Cataracts of the Nile, the immense blocks standing around and above you, smooth and beautifully polished in places, where, if our notions of the pyramids be true, they were intended but for few mortal eyes. At one end of the chamber stands a sarcophagus, also of red granite; its length is seven feet six inches, depth three and a half, breadth three feet three inches. Here is supposed to have slept one of the great rulers of the earth, the king of the then greatest kingdom of the world, the proud mortal for whom this mighty structure was raised. Where is he now? Even his dry bones are gone, torn away by rude hands, and scattered by the winds of heaven. The interior of the pyramid is excessively hot, particularly when surrounded by a number of Arabs and flaring torches." To this account it may be added, that there is a well in the pyramid which is referred to by the Roman historian Pliny, as being eighty-six cubits in depth. It has been descended by a few enterprising travellers.

In one of the chambers of the great pyramid the annexed figure with hieroglyphics has been discovered; the hieroglyphics signify the word "Seamphis," the name of the builder, as it is believed, who lived about 2120 years before Christ.

To the celebrated Belzoni we are indebted for a knowledge of the interior of the pyramid of Cephrenes, brother and successor of Cheops, but any detail of his labours

would carry us far beyond our limits. Suffice it to say, that they were directed with remarkable skill, and a perseverance which no obstruction could arrest. It stands upon a rather higher elevation than that of Cheops, and is built of the same species of limestone, and jointed with the same kind of cement. Its base is 684 feet, and its height 456. The steps are much splintered and broken, but it can be ascended to a certain extent on the southern side without great difficulty. The opening of this pyramid presents to us a striking instance of discrimination and tact. Herodotus had declared that it contained no chambers, and modern travellers had taken this report for granted. The practised eye of Belzoni, however, detected certain indications of an entrance, and, after many days of labour upon the hard stone, he found himself at last in a chamber hewn out of the solid rock, from the floor to the roof, which last is of the same stone as the pyramid itself. In the sarcophagus were the bones of an animal, very generally supposed to be those of a sacred bull, an object of veneration among the ancient Egyptians. On the wall at the west end of the chamber he perceived an Arabic inscription, from which it has been inferred that the two larger pyramids had been explored, at the distance of many years, by some of the caliphs. The third large pyramid is that of Mycerinus; but it is much less, and not so important an object as the others. There is also a fourth large pyramid, although travellers are in the habit of speaking of the pyramids of Gizeh as only three in number. Those of Sakhara appear to be a continuation of the great cemetery to which those of Gizeh belong. Two of them only are very large, and they are all more dilapidated than those we have described; hence, a higher antiquity has been ascribed to them. With regard to the other Egyptian pyramids, they are, in their leading characters, nearly similar to those described, and the end for which they were constructed we infer was the same—that of receptacles for the dead, and chiefly for the bodies of kings and other royal personages. Some maintain that they were consecrated to the sun, others that they were used for astronomical observations, others for transmitting historical information, and so on.

Numerous ruined edifices and tumuli lie scattered about among the pyramids, and extend north and south along the left bank of the Nile as far as the eye can reach. The stone buildings supposed to be mausoleums, are generally of an oblong form, having their walls slightly inclined from the perpendicular inwards, the peculiar characteristic of ancient Egyptian architecture; flat-roofed, with a sort of parapet round the outside, formed of stones; rounded at the top, and rising about a foot above the level of the terrace. The walls are constructed of large masses of stone of irregular shape. The various chambers of these edifices were found to be profusely embellished with sculptures and bas-relief paintings, many of which were spirited and beautiful. In one of them were found the remains of several mummies, and in another the fragments of a figure as large as life. An important circumstance remains to be noticed. In each of these edifices there was discovered a well, from the bottom of which a passage led to a subterranean chamber. Caviglia cleared out one of these shafts, which was sixty feet deep; and in the chamber he found a plain but highly finished sarcophagus, nearly of similar dimensions with that in the pyramid of Cheops. This supplies a strong argument in favour of the hypothesis that the pyramids are tombs.

By far the most brilliant of Mr. Caviglia's discoveries, are those to which he was led in the laborious task of uncovering the great sphinx in front of the pyramid of Cephrenes. On the stone platform on the foreground, and centrally between the outstretched paws of the sphinx, was discovered a large block of granite which fronted east, and was highly embellished with sculpture in bas-relief. Two other tablets of calcareous stone, similarly ornamented, were supposed, with that of granite, to have constituted part of a temple, by being placed one on each side of the latter, and at right angles to it. One of them, in fact, was still remaining in its place. Of the other, which was thrown down and broken, the fragments are now in the British Museum. A small lion couchant, in front of this edifice, had its eyes directed towards the sphinx. There were, besides, several fragments of other lions, rudely carved, and the fore part of a sphinx, of tolerable workmanship. In front of the temple was a granite altar, with one of the four "horns" still retaining its place at the angle. From the effects of fire evident on the stone, this altar, it would seem, had been used for burnt-offerings. Inscriptions were found upon the digits of the paws, but of no moment.

Like every thing else in Egypt, this singular monument has been the subject of very opposite representation. The general accuracy of Dr. Richardson induces us to lay his account of it before the reader. "The breast, shoulders, and neck, which are those of a human being, remain uncovered; as also the back, which is that of a lion. The neck is very much eroded, and, to a person near the head, seems as if it were too heavy for its support. The head-dress has the appearance of an old-fashioned wig, projecting out about the ears like the hair of the Berberi Arabs; the ears project considerably; the nose is broken; the whole face has been painted red, which is the colour assigned to the ancient inhabitants of Egypt, and to all the deities of the country except Osiris. The features are Nubian, or what from ancient representation may be called ancient Egyptian, which is quite different from the negro feature. The expression is particularly placid and benign, so much so that the worshipper of the sphinx might hold up his god as superior to all the other gods of wood and stone which the blinded nations worshipped." As to the dimensions of the sphinx, the stretch of the back is about 120 feet, and from the top of the head to the base of the reclining figure about 40 feet. Such has been the drifting of the sands, that the whole figure is now covered, except the head and a portion of the dilapidated neck, as seen in the annexed cut. The French uncovered a part of the figure, but the sands have again drifted it up.

A few miles above the pyramids of Gizeh once stood Memphis, a city as large and flourishing as Alexandria, but now utterly destroyed, and the very ruins hardly distinguishable.

DISTRICT ABOVE CAIRO.

Pursuing the course of the Nile upwards, and passing various villages and ruined structures, the first place of importance which occurs is Beni Soueff, situated on the left bank in one of the richest and most extensive tracts

of corn land in Egypt, at the distance of 114 miles above Cairo. Penetrating a pass of the sylvan chain of mountains, at about fifteen miles west-south-west of this town, we enter the district of Fayoum. Medinet-el-Fayoum, the capital, is situated in lat. 29° 20′ north, long. 31° 1′ 30″ east, built from the materials, and partly on the site, of the ancient Crocodilopolis, the name of which was changed to Arsinöe, by Ptolemy Philadelphus, in honour of his sister. It contains about 5000 inhabitants, chiefly Moslems, with the usual proportion of mosques and baths. A canal from the Bahr Yousuf divides it into two parts, which are connected by five bridges. The principal remains of the ancient city lie to the north of the present town, occupying an area nearly two miles and a half from north to south, and two miles from east to west. Among the ruins are numerous fragments of statues, obelisks, &c. The town of Arsinöe was one of the most celebrated in Egypt, and so late as the time of the Romans contained a flourishing population. Fayoum is still reckoned the most productive part of Egypt, and all the country as far as Lake Mœris is well cultivated. This celebrated lake was of artificial formation in ancient times, and extended to several hundreds of miles in circumference. It was connected by canals with the Nile. Continuing the route up the Nile, at the distance of about seventy miles we arrive on the same or western bank, at a considerable village called Al Rairamoun, where Ali Pacha has established a sugar manufactory and a distillery. In the environs are extensive sugar plantations, and there is a saltpetre manufactory in the neighbourhood. About six miles to the south-west of this place are the remains of Hermopolis, an ancient town, whose representative is a large village called Oshmuncin. About a league to the south of it is the large and well-built town of Mellane; and ten leagues farther on, and near the western shore, that of Manfaloot, anciently a place of great trade. It is a sort of capital, and the see of a Coptic bishop. The adjacent country is very fertile, particularly in fruits. About two leagues farther up, on the eastern side of the river, are several pits, in which are deposited the mummies of crocodiles. But we have now entered the Said, or Upper Egypt, which properly begins with Manfaloot, which is a sort of frontier town on the left bank. The valley of the Nile is in this part about eight miles from mountain to mountain, and, above Manfaloot, a cultivated place, commences on the eastern side of the river. For many miles the left bank of the river is perforated with excavations, which, however, have not been explored.

DENDERA.

Proceeding upwards beyond Manfaloot, we pass in the distance of eighty or ninety miles various towns of less or more importance; among others, Siout and Girzah on the left, and the ruins of Ekhim on the right bank. On the face of a range of mountains near Siout, is a long range of tombs, the burial-place of ancient Egyptians, excavated as chambers in the solid rock, and still ornamented in their ceilings with coloured paintings of old date, and which, like other remains of art, have been preserved by the extreme dryness of the climate. These, and all other objects, however, are of inferior interest to those which begin to be disclosed on approaching a bend of the river near the 26th degree of north latitude. Here the view opens of the magnificent ruins of the temple of Dendera, and some miles farther on those of Thebes.

The ruins of Dendera are more than a mile in length, and half a mile in breadth. The grand object of interest is the temple, a very celebrated ruin, which, if cleared from rubbish, would present a front of 160 feet, with a height of 60 feet. The principal propylon—or, as we might call it, the gateway of the approach—is a truly magnificent object, forming a tall block of columnar architecture, covered with the most exquisite sculpture and hieroglyphics. The sculptured figures on the dilapidated walls of the temple bendings are equally beautiful. Some idea of the grandeur of these ruins may be gathered from the circumstance recorded of the French army during its campaign in Egypt. When the soldiers first beheld the ruins, they were so overpowered with their gigantic size and extraordinary beauty, that they exclaimed, as with the heart and voice of one man, such a sight more than repaid them for all the sufferings and dangers of the war. It is supposed to have been consecrated to the worship of Isis, who was the principal deity in the Egyptian Pantheon. The temple itself still retains all its original magnificence. Time has only rendered it more venerable and imposing in appearance.

THEBES.

Thebes, once the capital of Upper Egypt, and the most splendid city in the world, no longer exists; its site can now only be traced in four petty villages, Luxor, Karnac, Medinet Abou, and Gornoo, on both banks of the river—distance from the sea 850 miles. Thebes is famous as "the city of a hundred gates," the theme and admiration of ancient poets and historians, the wonder of travellers—"that venerable city," as Pocock eloquently remarks, "the date of whose destruction is older than the foundation of other cities, and the extent of whose ruins, and the immensity of whose colossal fragments, still offer so many astonishing objects, that one is rivetted to the spot, unable to decide whither to direct the step or fix the attention." These ruins extend about eight miles along the Nile, from each bank to the sides of the enclosing mountain, and describe a circuit of twenty-seven miles. The most remarkable objects on the eastern side are the temples of Karnac and Luxor; and on the western are the Memnonium, or palace of Memnon, two colossal statues, the sepulchres of the kings, and the temple of Medinet Abou. Almost the whole extent of eight miles along the river is covered with magnificent portals, obelisks decorated with the most beautiful sculpture, forests of columns, and long avenues of colossal statues. The largest of these temples, and of any in Egypt, is that at Karnac, on the site of the ancient Diospolis.

With respect to the magnificence and beauty of its several parts, this temple has been pronounced as having no parallel in the whole world. It has twelve principal entrances, each of which is composed of several propyla and colossal gateways, besides other buildings attached to them, in themselves larger than most other temples. The sides of some of these are equal to the bases of the greater number of the pyramids in Middle Egypt. One of the propyla is entirely of granite, adorned with the most finished hieroglyphics, and many of them have been furnished with colossal statues. The avenues of sphinxes that lead in several directions to the propyla, one of which was continued the whole way across the plain to the temple at Luxor, nearly two miles distant, correspond to the magnificence of the principal structure; and the body of the temple, which is preceded by a large court, consists of a prodigious hall or portico, the roof of which is supported by 134 columns, some 26, others 34 feet in circumference; four beautiful obelisks mark the entrance to the shrine, which consists of three apartments, built entirely of granite. The dimensions of this great edifice are about 1200 feet in length, and 420 in width. But the principal fane, grand and imposing as it is, sinks into nothing when compared with the extent and number of the buildings which surround it; the prodigious gateways of polished granite, covered with sculpture, and adorned with colossal statues; the subordinate temples which anywhere else

would be esteemed magnificent piles; and the avenues, which approach it from almost every point of the compass, miles in length, and guarded by rows of sphinxes of vast size, cut out of single blocks of syenite. The field of ruins at Karnac is about a mile in diameter. Probably the whole of the space was once, in the prouder days of Thebes, consecrated entirely to the use of the temple.

About a mile and a quarter above Karnac, are the village and temple of Luxor. This temple, though not of such vast dimensions as that of Karnac, is in a superior style of architecture, and in more complete preservation. The entrance is thought to surpass every thing else that Egypt presents, and the two obelisks are considered the finest in the world. But the objects which most attract attention are the sculptures which cover the east wing of the northern front. They contain, on a great scale, a representation of a victory gained by one of the ancient kings of Egypt over their Asiatic enemies. The number of human figures introduced amounts to 1500—500 on foot, and 1000 in chariots.

The disposition of the figures, and the execution of the whole picture, are equally remarkable, and far surpass all preconceived ideas of the state of art at the remote era to which we must attribute them. After passing several gateways, we enter what is conjectured to be the palace of the great Osymandyas. These ruins of Luxor and Karnac represent only one half of ancient Thebes. The temples of Medinet Abou are also splendid, and upon a grand scale. It was so placed as to be exactly opposite to that of Luxor, on the other side of the Nile, where the magnificent structure at Karnac was fronted by the Memnonium or temple of Dair; and hence all these grand objects formed so many stages or prominent points in the religious processions of the priests. Though the tabernacle of Jupiter dwelt at Karnac, the proper Diospolis, yet it was carried over the river every year, and remained a few days in Libya; and we find, from a general estimate, that there was a space of between nine and ten miles over which they might exhibit the pomp and parade of their superstition, both going and returning. Almost every part of the road through this immense theatre was lined with sphinxes, statues, propyla, and other objects calculated to inflame the ardour of devotion.

The Memnonium deserves particular notice. This celebrated relic of antiquity, the palace of king Memnon, or of the Pharaohs, faces the east, and is fronted with a stupendous propylon, of which 234 feet of its length are still remaining.

Every stone in the propylon appears to have been shaken and loosened, as if from the concussion of an earthquake. The passages which conduct to the chambers are so broken and filled up, as hardly to admit of examination. The walls are in various parts ornamented with sculptures, and other pictorial devices. One of the most striking is a battle scene. The various situations of victors and vanquished are represented in a very lively manner, and the whole sculpture, though but roughly executed, is full of fire. In the Memnonium there is still to be seen the statue of Osymandyas, or Sesostris, which is allowed to be the finest relic of art which the place contains, although shattered and broken. It is about twenty-six feet broad between the shoulders, fifty-four feet round the chest, and thirteen feet from the shoulder to the elbow. There are on the back hieroglyphical tablets, extremely well executed, which identify this enormous statue with the hero whose achievements were sculptured on the walls of the temple.

The above figure has sometimes been confounded with that of Memnon, so long celebrated for its vocal qualities. The latter, however, is one of the two statues usually called Shamy and Damy, which stand at a little distance from Medinet Abou, in the direction of the Nile. These, we are told, are about fifty-two feet in height. They rest on thrones, which are respectively thirty feet long, eighteen broad, and between seven and eight high. They are placed about forty feet asunder, are in a line with each other, and look towards the east,

directly opposite to the temple of Luxor. The southern one appears to be of one entire stone. The face, arms, and front of the body, have suffered so much, that not a feature of the countenance remains. The head-dress is beautifully wrought, as also the shoulders, which, with the back, are uninjured. The massy hair projects from behind the ears like that of the sphinx. The sides of the throne are highly ornamented with elegant devices. The colossus is in a sitting posture, with the hands resting upon the knees.

The gigantic statue which is placed on the north side, would appear, from various circumstances, to be that of the vocal Memnon, who was said to play a lively strain when the sun rose, and a melancholy one when he set. It presents the same attitude as its companion. These statues are placed on either side of an avenue leading to a place of worship, and evidently were followed by a series of other colossal figures, as the remains of some of them are still visible.

"The rambler among the ruins of Thebes (observes Mr. Stephens) will often ask himself, 'Where are the palaces of the kings, and princes, and people, who worshipped in these mighty temples?' With the devout spirit of religion that possessed the Egyptians, they seem to have paid but little regard to their earthly habitations, their temples and their tombs were the principal objects that engrossed the thoughts of this extraordinary people. It has been well said of them that they regarded the habitations of the living merely as temporary resting-places, while the tombs were regarded as permanent and eternal mansions; and while not a vestige of a habitation is to be seen, the tombs remain monuments of splendour and magnificence, perhaps even more wonderful than the ruins of their temples. The whole mountain-side on the western bank of the river is one vast necropolis. The open doors of tombs are seen in long ranges, and at different elevations, and on the plain large pits have been opened, in which have been found 1000 mummies at a time. For many years, and until a late order of the pasha preventing it, the Arabs have been in the habit of rifling the tombs to sell the mummies to travellers. Thousands have been torn from the places where pious hands had laid them, and the bones meet the traveller at every step. The Arabs use the mummy-cases for firewood, the bituminous matters used in the embalmment being well adapted to ignition; and the epicurean traveller may cook his breakfast with the coffin of a king. Notwithstanding the depredations that have been committed, the mummies that have been taken

away and scattered all over the world, those that have been burnt, and others that now remain in fragments around the tombs, the numbers yet undisturbed are no doubt infinitely greater; for the practice of embalming is known to have existed from the earliest periods recorded in the history of Egypt; and by a rough computation, founded upon the age, the population of the city, and the average duration of human life, it is supposed that there are from 8,000,000 to 10,000,000 of mummied bodies in the vast necropolis of Thebes.

Amid the wrecks of former greatness which tower above the plain of Thebes, the inhabitants who now hover around the site of the ancient city are perhaps the most miserable in Egypt. On one side of the river they build their mud huts around the ruins of the temples, and on the other their best habitations are in the tombs; wherever a small space has been cleared out, the inhabitants crawl in, with their dogs, goats, sheep, women, and children; and the Arab is passing rich who has for his sleeping place the sarcophagus of an ancient Egyptian."

Mr. Stephens, in the above quotation, inquires, "Where are the residences of the kings, princes, and people of ancient Egypt?" These are entirely gone. They were built of brick, and have long since been utterly destroyed, or buried in fragments beneath the drifting sands of the desert, or the accumulations from the Nile. The temples and pyramids having been erected of a stupendous size and of a solid material, have survived, while all the ordinary habitations of the people have disappeared.

EDFOU, ELEPHANTINA, PHILÖE.

The magnificent ruins of Thebes are not by any means the last object of interest in ascending the river. Passing Esneh, a town on the left bank, and an emporium of the trade with Abyssinia, we reach on the same side of the river, at about the distance of fifty miles from Thebes, the town of Edfou, composed as usual of a parcel of mud houses, bazaars, and a mosque. "At one corner of this miserable place (says Mr. Stephens) stands one of the magnificent temples of the Nile. The propylon, its lofty proportions enlarged by the light of the moon, was the most grand and imposing portal I saw in Egypt. From a base of nearly 100 feet in length and 30 in breadth, it rises on each side the gate in the form of a truncated pyramid, to the height of 100 feet, gradually narrowing, till at the top it measures 75 feet in length and 18 in breadth. Judge, then, what was the

temple to which this formed merely the entrance; and this was far from being one of the large temples of Egypt It measured, however, 440 feet in length and 220 in breadth, about equal to the whole space occupied by St. Paul's Churchyard. Its dromos, pronaos, columns and capitals, all correspond, and enclosing it is a high wall, still in a state of perfect preservation I walked round it twice, and, by means of the wall erected to exclude the unhallowed gaze of the stranger, I looked down upon the interior of the temple. Built by the Egyptians for the highest uses to which a building could be dedicated, for the worship of their gods, it is now used by the pasha as a granary and storehouse."

Fifty miles farther up we reach the boundary of Egypt and Nubia, at the town of Assouan or Syene. It is situated in lat. 24° 5′ 23″ north, long. 32° 54′ 49″ east. Its natural position, so well adapted for a frontier town, has rendered it at all times a place of importance. It was formerly a bishopric, but no Christians are now found here. Ruined churches and convents strike the eye of the traveller, but the Christian faith is unknown. Not only is it the last town in Egypt, but it is the last place in this direction in which the Arabic is spoken as the vernacular tongue. Here occurs the first Egyptian cataract in descending the Nile.

The present town of Assouan has been built a little to the north of a former town of Saracenic origin, the ruins of which are seen above it, and which was itself built upon the ruins of a Roman city. The whole town is encompassed with vestiges of buildings; the most interesting are about the old town, which occupies a strong and commanding position; the walls still remain, and though slight and of sun-dried brick, are very entire. They are flanked with towers at unequal distances. Many of the walls of the houses are also standing, but they are all unroofed. From the interior of many of them, passages lead down to the chambers of houses belonging to the ancient city, which are now under ground; of the old town a few insignificant ruins are all the remains.

Below the cataracts at this place occurs the small island of Elephantina, or, as it is called by the Arabs, Djeziret-zel-zabir, the flowery island; it is about 2000 feet in length, and 600 feet in breadth. The northern end is low and alluvial, well cultivated, and shaded with palm-trees. Here are the ruins of Roman fortifications, opposite to which, on the eastern bank of the Nile, are remains of Arabian works. There is an ancient quarry, from which large columns have been excavated; the marks of the workman's chisel and wedge are as fresh as if they were of yesterday. Some are lying blocked out and partly wrought, and a large sarcophagus is two-thirds cut out of the rock. There are a number of architectural remains, sculptures, and hieroglyphical tablets. This beautiful island is inhabited by Nubians, who are perfectly black, without having any resemblance in their features to the negro.

Above the cataracts, at the distance of about six miles south from Assouan, is the far more interesting though smaller island of Philöe, or Djeziret-el-birba, meaning the Temple island. "This island is entirely covered with temples in large groups, and in a high state of preservation; and from a rocky eminence at its southern extremity the whole of the ruins may be seen at once. On the south-west side are two large temples, adorned and connected by long colonnades, but manifestly of different ages; on the right is the small Temple of Isis with an isolated unfinished building, having no remains of the cella, nor any appearance of an interior cornice; and on the left are an obelisk, and long porticoes leading to a large temple of Isis, near a smaller one dedicated to Hathor or the Egyptian Venus, which Champolion has pronounced the best in the island. The great Temple of Isis, which is the southernmost of all, has two colossal pyramidal propyla. None of the existing monuments of Egypt is better calculated to convey an adequate idea of the magnificence by which they are characterized, than the portico of this temple, which consists of twelve

columns, four in front and three deep. The capitals, which are in pure Egyptian taste, represent varied forms and compositions of the palm branch, the domm leaf, and the lotus. These, as well as the sculptures on the columns, the ceiling, and the walls, have been painted in the most vivid colours, which still retain much of their original brightness. At the northern extremity of the island there are the remains of a triumphal arch, and other works of Roman architecture; and on the north-east side an unfinished temple, exhibiting many peculiarities of structure, and showing that the arts were not always stationary in Egypt. In a word, within the compass of this little island, Nubian cabins, Arab huts, Christian chapels, Roman fortifications and Egyptian temples, are crowded together in such a manner as to produce a painful sense of the lapse of ages, the transitory nature of empires, and the destructibility of human works, however colossal in magnitude or solid in construction."*

ETHIOPIA.

Few travellers proceed farther up the Nile than Philoe, as the journey through Nubia is less safe or agreeable than that within the Egyptian territory. Yet without a visit to the Nubian valley of the Nile, which extends to near the head branches of the river in Abyssinia, much of the ancient grandeur of this part of the world will remain unexplored. Nubia, which is at present a Turkish province subject to the pasha of Egypt, is frequently called by the name Ethiopia, from the black complexion of whose inhabitants the term Ethiopian came in early times to signify one who is black, or a negro. This country of Nubia, or Ethiopia, is understood by some historians to have enjoyed a degree of civilization and refinement in art, at a date even earlier than Egypt; and till the present day it possesses pyramids and other monuments of architectural skill, as wonderful, in the eyes of the traveller, as those in the lower divisions of the Nile.

One of the latest travellers who penetrated to this inner Ethiopian region, was Mr. G. A. Hoskins, who in 1835 published a large volume descriptive of his journey. At about the 17th degree of north latitude, he reached Meroe, an island formed by the forking of two upper branches of the Nile. This island is between three and four hundred miles long, and contains several distinct groups of pyramidal structures of extraordinary magnificence, but greatly damaged by the hand of barbarians; also some traces of the remains of the city of Meroe, once the capital of Ethiopia. "Never (says Mr. Hoskins) were my feelings more ardently excited than in approaching, after so tedious a journey, to this magnificent necropolis. The appearance of the pyramids, in the distance, announced their importance; but I was gratified beyond my most sanguine expectations when I found myself in the midst of them. The pyramids of Gizeh are magnificent, wonderful from their stupendous magnitude; but for picturesque effect and elegance of architectural design, I infinitely prefer those of Meroe. I expected to find few such remains here, and certainly nothing so imposing, so interesting, as these sepulchres, doubtless of the kings and queens of Ethiopia. I stood for some time lost in admiration. From every point of view I saw magnificent groups, pyramid rising behind pyramid, while the dilapidated state of many did not render them less interesting, though less beautiful as works of art. I easily restored them in my imagination; and these effects of the ravages of time carried back my thoughts to more distant ages. The porticoes on the east side of each pyramid soon attracted my attention, and I passed eagerly from one to the other, delighted to find in several of them monuments of sculpture and hieroglyphics, which, few as they are, have, I trust, given us the assurance of the locality, and will, I hope, throw some light upon the mythology and arts of the Ethiopians. There are the remains and traces of eighty of these pyramids; they consist chiefly of three groups. The principal and most imposing, at which I arrived first, is situated on a hill, two miles and a half from the river, commanding an extensive view of the plain. There are thirty-one pyramids in this group, of which the plans of twenty-three may be traced; while to the south-east is another group of thirteen, in some degree of preservation. There are three other groups, two consisting of two pyramids each, and the other of six; and at 5600 feet to the west of the chief group, may be traced the remains of twenty-five pyramids, but almost buried."

After mentioning the appearance and minor details of these remarkable structures, this author continues—"I have carefully described this interesting and magnificent cemetery; but how shall I attempt to express the feelings of the traveller on treading such hallowed ground? One who, in passionate admiration for the arts, had visited the chief galleries of Europe, gazed upon the breathing image of divinity in the Apollo of the Vatican, or the deep expression of the most poetical of statues, the Dying Gladiator of the Capitol; who had beheld and felt the pictorial creations of a Raphael and a Correggio, and, with delight, contemplated Grecian, Roman, and modern sculpture, could not be unmoved at finding himself on the site of the very metropolis where those arts had their origin. The traveller who has seen the architectural antiquities of Rome, and has admired the magnificent use that nation has made of the arch, making it the chief ornament of their baths, palaces, and temples, would be further deeply interested at finding here the origin of that discovery. These emotions would be felt with peculiar force by one who, like myself, had been fortunate enough to trace art through her earliest creations—from the splendid Gothic edifices of the north to the ruins of the eternal city—from Rome to Magna Græcia—from the magnificent temple of Neptune at Pæstum, to the still purer antiquities of Sicily, particularly at Girgenti, where nature and art seem to have vied with each other—from that interesting island to the Morea and the city of Minerva, where the knowledge of the arts, sown in the most genial soil, produced the perfection of elegance, chasteness, and magnificence. But the seeds of the knowledge of the Greeks were derived from Egypt; and the Egyptians received their civilization from the Ethiopians and from Meroe, where I now am writing. The beautiful sepulchres of that city afford satisfactory evidence of the correctness of the historical records. Where a taste for the arts had reached to such perfection, we may rest assured that other intellectual pursuits were not neglected, nor the sciences entirely unknown. Now, however, her schools are closed for ever, without a vestige of them remaining. Of the houses of her philosophers, not a stone rests upon another; and where civilization and learning once reigned, ignorance and barbarism have resumed the sway.

"These pyramids are of sandstone, the quarries of which are in the range of hills to the east. The stone is rather softer than the Egyptian, which, added to the great antiquity, may account for the very dilapidated state of most of these ruins, and also for the sculpture and hieroglyphics being so defaced. Time, and the burning rays of a tropical sun, have given them a brownish-red tint, in some parts nearly black. As the operation of many ages is required to make this change on a light-coloured sandstone, a further proof is afforded of the great antiquity of the monuments. The stones being small, and easily removed, it is fortunate that the chief group of pyramids is so far distant from the Nile; otherwise, like those on the plain, near the river, a great proportion of them might have been carried away as materials for the erection of more modern edifices.

* Encyclopædia Britannica, article Egypt.

"This, then, is the necropolis, or city of the dead. But where was Meroe, its temples and palaces? A large space, about 2000 feet in length, and the same distance from the river, strewed with burnt brick and with some fragments of walls, and stones similar to those used in the erection of the pyramids, formed, doubtless, part of that celebrated site. The idea that this is the exact situation of the city, is strengthened by the remark of Strabo, that the walls of the habitations were built of bricks. These indicate, without doubt, the site of that cradle of the arts which distinguish a civilized from a barbarous society. Of the birthplace of the arts and sciences, the wild natives of the adjacent villages have made a miserable burying place: of the city of the learned—'its cloud-capt towers,' its 'gorgeous palaces,' its 'solemn temples,' there is 'left not a rack behind.' The sepulchres alone of her departed kings have fulfilled their destination of surviving the habitations which their philosophy taught them to consider but as inns, and are now fast moulder-ing into dust. As at Memphis, scarcely a trace of a palace or a temple is to be seen. In this once populous plain, I saw the timid gazelles fearlessly pasturing. The hyænas and wolves abound in the neighbouring hills. This morning Signor B. met a man with the head of one which he was carrying in triumph to his village: he said that he had been attacked at once by three small ones when alone, and with no weapon but his lance. The small villages of Bagromeh, south of the ruins, consist of circular cottages with thatched conical roofs. The peasants have numerous flocks, which they send to pasture on the plain. On the banks of the river I observed cotton, dourah, and barley. Such is the present state of Meroe. It is an ample requital for my toilsome journey, to have been the first to bring to England accurate architectural drawings, &c., of all the remains of the ancient capital of Ethiopia, that city which will ever live in the grateful recollection of those who love the arts."*

Returning to Egypt, the description of the country may be concluded by a notice of those fertile districts in the desert at a distance from the Nile, and termed Oases.

THE OASES.

Oasis is a Coptic word signifying an inhabited place, and is usually applied to a fertile spot or island in the midst of a sandy desert. The Oases of Egypt are found at intervals in the middle of that vast plain of arid sand called the Libyan Desert. There are several of them, which are named, according to their size or situation, the Great, Little, Western, Northern, &c.

The Northern, or Oasis of Siwah.—This place, which is about 300 miles distant from Cairo, and about 100 from the Nile, is peculiarly interesting, from its being supposed to enclose the far-famed temple of Jupiter Ammon. The Oasis is about six miles long, and from four to five broad. It is pretty fertile, and contains about 8000 inhabitants. The capital is called Siwah. Besides the splendid remains of the temple, supposed to be that of Jupiter Ammon, are the ruins of other sacred places, and a number of sepulchral excavations.

Great Oasis.—This Oasis is formed of a number of fertile isolated spots, which lie in a line parallel to the course of the Nile, and to the mountains which bound the valley of Egypt on the west. It is about two days' journey from the nearest part of the valley of the Nile. The patches of firm land are separated from one another by deserts of twelve or fourteen hours' walk—so that the whole extent of this Oasis is nearly 100 miles, the greater proportion consisting of a desert. It contains many gardens watered with rivulets, and its palm groves exhibit a perpetual verdure. According to a more recent account, it contains Egyptian ruins covered with hieroglyphic inscriptions. The principal town is called El-Kargeh. Here are the remains of a temple beautifully situated in the midst of a rich grove of palm trees. Near El-Kargeh, there is also a regular necropolis or cemetery, containing 200 or 300 buildings of unburned brick, chiefly of a square shape, and each surmounted by a dome similar to the small mosques erected over the graves of sheiks. At distances of a few miles, some other remains of ancient temples are found. This whole oasis has always been and still is dependent on Egypt. None of the other oases of the desert present us with any object worthy of being dwelt upon.

* Travels in Ethiopia, by G. A. Hoskins, Esq. 1 vol. 4to. London Longman & Company, 1838.

ANCIENT EGYPTIAN SOCIETY AND ART.

The discoveries which have been made in modern times by travellers (chiefly French, Italian, and English) in Egypt, although disclosing the remarkable remains of pyramids, temples, and tombs, which have been above adverted to, do not give any just idea of the grandeur and opulence of the ancient Egyptian dynasties. We learn from Josephus, Diodorus, Herodotus, and other historians, that at one time Egypt and the adjoining provinces under its sway contained 20,000 (some say 30,000) populous cities, and as many as 7,000,000 of inhabitants. At that early period (2300 to 1000 years before Christ) the country was also more fertile, and much less encroached upon by sandy deserts than it now is. Besides depending on its internal resources, it drew great wealth from the territories which it laid under contribution; but its chief source of revenue was in manufacturing industry and commerce. Its artisans excelled in all manner of handicraft employments, and its merchants conducted an export and import traffic on a most extensive scale; in short, Egypt was long the Great Britain of its day—the most industrious and wealthy nation in the world.

It is interesting to know what was the constitution of Egyptian society in these days of ancient glory. It was that of castes similar to what still exists in India. According to the best authorities, the first or chief caste was that of the priests, to whom the king necessarily belonged, as a species of pope or temporal head; the second was composed of the soldiers and agriculturists: the third of the artificers, tradesmen, merchants, builders and professional men; and the fourth consisted of shepherds, fishermen, servants, and all other orders of common people. All the learning of a refined or metaphysical kind was confined to the order of priests, who were of various classes, each following its appointed duty; for example, each deity had its own order of priests. The judges and magistrates were also priests, as likewise were the sacred scribes, the officers who examined and set their seal on the sacrifices, the attirers of the statues of the gods, the keepers of the sacred robes, the doctors, the carriers of the sacred emblems in the processions, the bearers of the small statues, the preservers of the sacred animals, the sprinklers of water in the temples, the embalmers of bodies, the drivers away of flies from the countenances of the gods, and various other functionaries. Thus, the Egyptian priesthood, with the king at their head as a sort of deity, were a formidable body among the people, both from the power with which they were invested and their number; and it need hardly be mentioned that they appropriated to themselves by far the largest share of all the good things with which the land abounded, or which the industry of the nation introduced from foreign countries. The enormous sums which must have been lavished by them in the erection of temples and palaces are beyond all calculation; and when we consider that this vast expenditure went towards the adoration of crocodiles, bulls, dogs, storks, snakes, and other animals, or at least of a tribe of gods whom these creatures were imagined to represent, we are overwhelmed with the magnitude of the superstition, and look upon the ancient Egyptians, with all their

learning, as little advanced on the right road to civilization.

A nation, however, as has been a thousand times proved, may have attained considerable proficiency in learning and the arts, and yet be affected by the most ridiculous superstitions. The Egyptians, as appears from hieroglyphics, paintings, and records of various kinds, were adepts at mechanical expedients, and possessed almost all the elegances of refined living which are now common in an improved form in Europe. In the construction of their pyramids and other large buildings, no degree of labour for any length of time seems to have intimidated them. The huge blocks of stone, sometimes weighing 1000 tons each, were dragged for hundreds of miles on sledges, and their transport, perhaps, did not occupy less time than a year; in one case which is known, 2000 men were employed three years in bringing a single stone from a quarry to the building in which it was to be placed. Usually, the sledges were drawn by men yoked in rows to separate ropes, all pulling at a ring fixed to the block. Where it was possible, the blocks were brought from the quarries on flat-bottomed boats on the Nile. But the transport of these large masses was much more easily accomplished than the placing of them in elevated situations in the buildings. They were raised by the power of levers and inclined planes of immense trouble and cost. One of the largest is the lintel over the doorway leading into the grand hall at Karnac; it measures 40 feet 10 inches long, and five feet square. It is understood that slaves or captives furnished a large share of the moving force in these undertakings; but besides these there was a variety of classes of workers, each carefully trained in the performance of his own particular duty; for instance, in dragging the blocks, there were employed slaves to pull, guards to watch, task-masters to regulate the operations, men with jars to throw water on the ground before the sledges, and, lastly, a person whose duty consisted in marking the time to the cadence of a song to ensure a simultaneous draught. This practice of shouting or singing to mark time during work, as still customary among sailors, is of extremely ancient date, being alluded to in the book of Jeremiah, xxv. 30:—"He shall give a shout as they that tread out the grapes."

The most extraordinary of the customs of this remarkable people was that of embalming their dead bodies with a view to perpetual preservation in the tomb. The business of embalming was very dignified, and was aided by a host of inferior functionaries who made and painted coffins and other articles which were required. The bodies of the poorer classes were merely dried with salt or natron, and wrapped up in coarse cloths, and deposited in the catacombs. The bodies of the rich and great underwent the most complicated operations, wrapped in bandages dipped in balsam, and laboriously adorned with all kinds of ornaments. Thus prepared, they were placed in highly-decorated cases or coffins, and then consigned to sarcophagi in the catacombs or pyramids. Bodies so preserved have been called mummies, from the Arabian word *mumia*, or the Coptic word *mum*, signifying bitumen or wax. The quantity of mummies carried off in modern times to England, France, and indeed every European country, has been very considerable. The collection of them, and other Egyptian antiquities, in the British Museum, is very extensive.

MEHEMET ALI.—MODERN EGYPT.

Mehemet or Mahomet Ali, the modern reformer and pasha of Egypt, was born at Cavallo, in Roumelia, a part of European Turkey. His parents, who were of an humble condition of life, had a family of sixteen children, of whom he was the youngest; and being a greater favourite than his brothers and sisters, he in early life came accustomed to indulgences, and to be impatient of the control of superiors. His youth, it has been related, was partly spent in the service of a tobacconist, but leaving this employment, which was unsuitable to his genius, he entered the Turkish army as a common soldier, at a time when troops were raising in his native district. This was the sphere of life in which he was calculated to shine. Distinguishing himself as a soldier by his bold and skilful conduct, he soon attracted the attention of beys, pashas, and the sultan himself; and having attained a prominent position in the bloody wars that distracted Egypt under the Mamelukes, he rose to be Pasha, or Viceroy of Egypt, one of the highest posts of honour in the whole Turkish empire. On getting the command of that province, he speedily showed that he was no ordinary man. He established a regularly paid, disciplined, and armed military force, on the European plan, instead of the irregular bands of men serving as soldiers in Egypt. The remnant of the Mamelukes, that remarkable body of men, which since the days of Saladin had practically governed Egypt by overawing the viceregal authority, he annihilated, and thus became the uncontrolled lord of the land of the Pharaohs, Ptolemies, Cæsars, and Caliphs. By the strictness of his government, he rendered Egypt as safe to travellers as any ordinary civilized country. Agriculture, commerce, manufactures, all engaged his attention; and though his reforms were accomplished with a despotic hand, perhaps with no small degree of cruelty, his conduct deserves our approbation. He may be crafty, cruel, and treacherous, still he has prodigiously advanced the cause of civilization and improvement in Egypt, and opened the way for further and more important reforms.

Mehemet Ali has a family of several sons, the eldest of whom, Ibrahim Pacha, acts as commander-in-chief of his troops, and is understood to be of a less sagacious mind than his father. It is incontestible that Mehemet Ali has done much to further the advancement of civilization in modern Egypt, but the whole of his efforts have at the same time tended to personal aggrandizement, and to the complete subjection of the people to his will. In order to maintain his authority, he raises troops from amongst the male population by the most tyrannical means; and so much is this forced military service detested, that great numbers of young men mutilate themselves, by destroying an eye, or cutting off one or more fingers, in order to escape the conscription. Having been lately driven from Syria, with a prospect of being permanently confined to Egypt, it is likely that the pasha will relax the excessive military burdens of the people. In the meanwhile, his lust of conquest has led to the exaction of taxes to a degree altogether unheard of in any country laying claim to civilization. "His revenue," says Mr. Lane,* "is generally said to amount to about £3,000,000 sterling. Nearly half arises from the direct taxes on land, and from indirect exactions from the fellaheen (fellahs or agriculturists), the remainder principally from the custom-taxes, the tax on palm-trees, a kind of income tax, and the sale of various productions of the land [no one being permitted to export corn or cotton but himself]; by which sale, the government, in most instances, obtains a profit of more than fifty per cent. The present pasha has increased his revenue to this amount by the most oppressive measures. He has dispossessed of their lands all the private proprietors throughout his dominions, allotting to each, as a partial compensation, a pension for life proportioned to the extent and quality of the land which belonged to him. The farmer has, therefore, nothing to leave to his children but his hut, and perhaps a few cattle and some small savings.

"The direct taxes on land are proportioned to the natural advantages of the soil. Their average amount

* Account of the Manners and Customs of the Modern Egyptians. 2 vols. 1836.

is about 8s. per feddan, which is nearly equal to an English acre. But the cultivator can never calculate exactly the full amount of what the government will require of him: he suffers from indirect exactions of quantities (differing in different years, but always levied per feddan) of butter, honey, wax, wool, baskets of palm-leaves, ropes of the fibres of the palm-tree, and other commodities; he is also obliged to pay the hire of the camels which convey his grain to the government shooneh (or granary), and to defray various other expenses. A portion of the produce of his land is taken by the government, and sometimes the whole produce, at a fixed and fair price, which, however, in many parts of Egypt, is retained to make up for the debts of the insolvent peasants. The fellah, to supply the bare necessaries of life, is often obliged to steal, and convey secretly to his hut, as much as he can of the produce of his land. He may either himself supply the seed for his land, or obtain it as a loan from the government; but in the latter case he seldom obtains a sufficient quantity; a considerable portion being generally stolen by the persons through whose hands it passes before he receives it. It would be scarcely possible for them to suffer more, and live. It may be hardly necessary, therefore, to add, that few of the fellahs engage with assiduity in the labours of agriculture, unless compelled to do so by their superiors. The pasha has not only taken possession of the lands of the private proprietors, but he has also thrown into his treasury a considerable proportion of the incomes of religious and charitable institutions, deeming their accumulated wealth superfluous. He first imposed a tax (of nearly half the amount of the regular land-tax) upon all land which had become a *wuckf* (or legacy unalienable by law) to any mosque, fountain, public school, &c.; and afterwards took absolute possession of such lands, granting certain annuities in lieu of them, for keeping in repair the respective buildings, and for the maintenance of those persons attached to them, as nazirs (or wardens), religious ministers, inferior servants, students, and other pensioners." Mr. Lane subsequently mentions, that sometimes the poverty of parents causes them to sell their children to any one who will purchase them, which presents a shocking idea of the degraded condition of the humble order of modern Egyptians.

In pursuing his schemes of improvement and family aggrandizement, Mehemet Ali acts as a despotic monopolist in all matters relating to both agriculture and commerce. He not only dictates what article of produce shall be cultivated, but the price at which it shall be sold. According to Dr. Bowring, it appears that in 1834, the country produced about 500,000 quarters of wheat, 450,000 quarters of dourah, 400,000 of beans, 280,000 of barley, and 80,000 of maize. Of wheat, however, the produce sometimes rises to 1,000,000 of quarters. Dourah or Indian millet (*sorghum vulgare*) is used for bread by the fellahs or labourers. It is the same plant which is raised in the West Indies for food to the negroes, under the name of Guinea corn. Its price is 30 or 40 per cent. below that of wheat. The helbeh is a coarser seed, sometimes mixed with it. The average price of wheat is from 20s. to 27s. per quarter at Cairo, but in years of scarcity it rises to 60s. Egypt is generally an exporting country, but in 1837 it was forced to draw supplies from abroad. The cultivation of cotton was introduced by the pasha very recently, and succeeds well, the exports of this article in 1834 having been 300,000 cwts.; but as the government is the exclusive purchaser, and only gives what price it pleases, the fellahs would not raise it unless compelled by the despotic mandates of the pasha. He has endeavoured to extend the cultivation of sugar, has introduced improved sugar-mills, and brought persons from the British colonies to distil rum. He has also invited Armenians from Smyrna and the East Indies to teach his people how to cultivate opium and indigo, and prepare them for the market. There are about two millions of date trees in Egypt, each of which yields by its fruit from 8s. to 16s. per annum. A few attempts have been made to introduce the vine. Onions are still produced and consumed in prodigious quantities, as in the days of Herodotus. The pasha has established model farms, with improved ploughs, &c., but even his despotism cannot induce the people to abandon their ancient rude processes and implements.

The pasha is a great manufacturer. He has built large mills, and procured skilled workmen at a great expense from France, Italy, Germany, Belgium, and Britain, to conduct them. He has manufactories of cotton yarn and cotton cloth, woollens, carpets, ironware, muskets, cannon, bayonets, gunpowder, &c. All these establishments are believed to be attended with loss to his highness, and in some cases the loss is heavy. His spinning-mills for cotton are the most extensive of his manufactories. There are twenty-two of these, which, according to Dr. Bowring, produce about 210,000 rottoli of yarn monthly, of various qualities, from coarse to "very fine." The Cairo rottoli is, we believe, just equal to the British pound, while the Alexandrian rather exceeds two pounds. The former, we suppose, is the weight alluded to in this instance; but as the cost of this yarn to the pasha is said to be only L.5270, we suspect there is some mistake in the statement. The men are paid fixed wages, generally about twopence per day, and they are punished with the lash for bad work or misconduct. The pasha has three manufactories of arms, which turn out 1600 muskets and bayonets per month. The largest one is managed by an Englishman, who has five other Englishmen and a number of Arabs under him.

All travellers represent Mehemet Ali as a person of plain and affable manners in private life, and fond of his family. Dr. Bowring speaks of him as follows:—"Mehemet Ali was forty-six years old before he had learned either to read or to write. This he told me himself. I have heard that he was taught by his favourite wife. But he is fond of reading now; and one day, when I entered his divan unannounced, I found him quite alone, with his spectacles on, reading a Turkish volume, which he was much enjoying, while a considerable pile of books were by his side. 'It is a pleasant relief,' he said, 'from public business; I was reading some amusing Turkish stories' (probably the Arabian Nights); 'and now let us talk—what have you to tell me?' There is a great deal of sagacity in Mehemet Ali's conversation, particularly when he knows or discovers, as he usually does, the sort of information which his visitor is most able to give. He discourses with engineers about mechanical improvements—with military men on the art of war—with sea-officers on ship-building and naval manœuvres—with travellers on the countries they have visited—with politicians on public affairs. He very willingly talks of foreign countries, and princes and statesmen, and is in the habit of mingling in the conversation all sorts of anecdotes about himself, and the events connected with his history. His phrases are often poetical, and, like most Orientals, he frequently introduces proverbs and imagery. I heard him once say, speaking of the agriculture of Egypt, 'When I came to this country, I only scratched it with a pin; I have now succeeded in cultivating it with a hoe; but soon I will have a plough passing over the whole land.'

"Mehemet Ali's great pride is Ibrahim Pacha; a victorious leader is always an object of admiration among Mussulmans, and Ibrahim Pacha's career has been one of brilliant military success. His father is fond of talking of his first-born son and intended successor. 'I did not know him,' he said; 'I had not an unbounded confidence in him for many, many years; no, not till his beard was almost as long as my own, and even changing its colour,' said the pasha to me; but now I can thoroughly

trust him.' On the part of Ibrahim Pacha there is always the utmost deference to Mehemet Ali's will. 'I have been very happy in my children,' Mehemet Ali said to me one day; 'there is not one of them who does not treat me with the utmost deference and respect.'"

Notwithstanding the improvements in education carried into effect by Mehemet Ali, the more opulent classes in modern Egypt are exceedingly ignorant. We learn from Mr. Lane that "many of the tradesmen of Cairo can neither read nor write, or can only read, and are obliged to have recourse to a friend to write their accounts, letters, &c.; but those persons generally cast accounts and make intricate calculations, mentally, with surprising rapidity and correctness." General learning is confined within very narrow limits. Very few persons "study medicine, chemistry, mathematics, or astronomy. The Egyptian medical and surgical practitioners are mostly barbers, miserably ignorant of the sciences which they profess, and unskilful in their practice, partly in consequence of their being prohibited by their religion from availing themselves of the advantage of dissecting human bodies. But a number of young men, natives of Egypt, are now receiving European instruction in medicine, anatomy, surgery, and other sciences, for the service of the government. Many of the Egyptians, in illness, neglect medical aid, placing their whole reliance on Providence or charms. Alchemy is more studied in this country than pure chemistry; and astrology more than astronomy. To say that the earth revolves round the sun, they consider absolute heresy. Of geography, the Egyptians in general, and, with very few exceptions, the best instructed among them, have scarcely any knowledge; having no good maps, they are almost wholly ignorant of the relative situations of the several great countries of Europe. Some few of the learned venture to assert that the earth is a globe, but they are opposed by a great majority of the Oolama. The common opinion of all classes of Moslems is, that the earth is an almost plane expanse, surrounded by the ocean, which, they say, is encompassed by a chain of mountains called *Ckaf*." Such being the condition of general knowledge among the modern Egyptians, it does not surprise us to learn that they labour under the most ridiculous superstitions, and believe in the powers of magic. Mr. Lane represents the people, among whom he lived for some time, as of an overreaching and deceitful disposition; but accounts for these and other vices by the manner in which they are ground under a rapacious and tyrannical system of government. By a singular contradiction of character, "they are generally honest in the payment of debts. Their prophet asserted, that even martyrdom would not atone for a debt undischarged. Few of them ever accept interest for a loan of money, as it is strictly forbidden by their law."

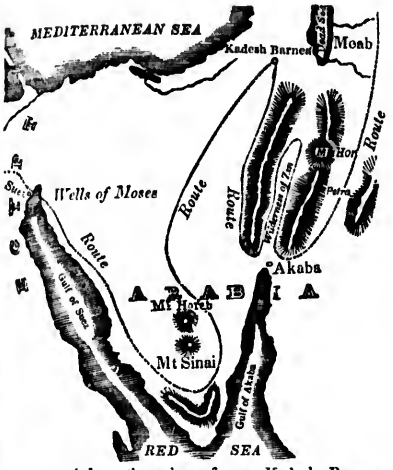
Oppressed as modern Egypt is, it is gratifying to reflect that it is improving in various respects in its condition. The pasha has introduced a number of intelligent Europeans into his military and civil services. Printing is now executed at Boulac, near Cairo, the press having there produced more than a hundred different books in the Arabic language, for the use of the military, naval, and civil servants of the government. A newspaper and an annual almanac are also regularly printed at Boulac. A considerable export and import trade is now carried on, the raw produce of the country being exchanged for the manufactured woollen, cotton, silk, and other goods of Europe. The cause of national regeneration is further advanced by the regular arrival of steam-vessels at Alexandria from Malta, bringing hosts of European travellers and persons who design reaching India by a journey from Cairo to Suez, and thence by steamboats down the Red Sea to Bombay.

Treasury of Pharaoh, Petra.

THE Jews are the most ancient race of mankind of whom we possess any regular or authentic history, or whose existence as a distinct people can be clearly traced from the primeval ages till the present day. According to the accounts given of them in Scripture, and in their history by Josephus, they were descended from Abraham, the tenth in descent from Noah, through his second son Shem. According to Josephus, Abraham, who was born in the 292d year (according to other authorities, in the 352d year) after the Deluge, "left the land of Chaldea when he was seventy-five years old, and at the command of God went into Canaan, and therein he dwelt himself, and left it to his posterity. He was a person of great sagacity, both for understanding of all things and persuading his hearers, and not mistaken in his opinions; for which reason he began to have higher notions of virtue than others had, and he determined to renew and to change the opinion all men happened then to have concerning God; for he was the first that ventured to publish this notion, that there was but ONE God, the Creator of the universe; and that as to other goda, if they contributed any thing to the happiness of men, that each of them afforded it only according to his appointment, and not by their own power. For which doctrines, when the Chaldeans and other people of Mesopotamia raised a tumult against him, he thought fit to leave that country, and at the command of God he came and lived in the land of Canaan. And when he was there settled, he built an altar, and performed a sacrifice to God." Abraham spent the chief part of the remainder of his life in Canaan; and dying at the age of one hundred and seventy-five years, was buried in the tomb of his wife Sarah, in Hebron. At his death, he left one legitimate son, Isaac, who had two sons, Esau and Jacob.

After the death of Isaac, his sons divided their inheritance, and Esau departing from Hebron, "left it to his brother, and dwelt in Seir, and ruled over Idumea." Jacob remained for a number of years in Canaan, surrounded by a family of twelve sons, one of whom, Joseph, as related in Scripture, became the cause of the removal of his father and brethren, and all belonging to them, into Egypt. The Hebrew emigrants were seventy in number, and formed at the first a respectable colony among the Egyptians. Jacob died after having been seventeen years in Egypt, and his body was carried by Joseph to Hebron, and buried in the sepulchre of his father and grandfather. Joseph also died in Egypt at the age of a hundred and ten, and at length his brethren died likewise. Each of the twelve sons of Jacob became the progenitor of a family or tribe, and the twelve tribes, personified by the term ISRAEL, continued to reside in Egypt, where they increased both in number and in wealth. Their rapid increase and prosperity soon excited the jealousy of the masters of the country; and from being in high favour, the different tribes gradually fell under the lash of power, and came to be treated as public slaves. The Egyptian rulers enjoined them to cut canals in connection with the Nile, to build walls and ramparts for cities, to make bricks, and to perform other laborious offices. "And four hundred years did they spend under these afflictions; for they strove one against the other which should get the mastery, the Egyptians desiring to destroy the Israelites by these labours, and the Israelites desiring to hold out to the end under them." From the description of their situation which is given in Genesis, and the affecting allusions to it afterwards in different passages of the Psalms, it appears that their tyrannical masters viewed them with the most unjustifiable hatred, contempt, and fear. Their sufferings were at last avenged by a direct interposition of Providence, which visited their oppressors with successive plagues, storm, vermin, and pestilence, till every living and growing thing in the land of Egypt was threatened with destruction, and the selfish rulers of the country were at last constrained by terror to release their injured bondamen.

The entire body of Israelites, guided by Moses, fled from Egypt in the year 1490 before Christ, at a time when Thebes, Memphis, and the other magnificent cities of that country, were in all their glory. Proceeding in a north-easterly direction from Rameses (near the site of modern Cairo), they went through the flat region of the land of Goshen (now a barren sandy plain) to the head of the Gulf of Suez, the western branch of the Red Sea. Here they crossed in a miraculous manner to the opposite shore, to a spot now called the Wells of Moses, where, according to the Scripture narrative, they sang their song of thanksgiving for their deliverance. The country in which they had now arrived was a portion of Arabia Petræa, consisting of a dismal barren wilderness, now called the desert of Sinai, from the principal mountain which rises within it. From the point at which the Israelites had crossed the Red Sea from Egypt, they were conducted by a most circuitous and tedious route towards the Promised Land of Canaan, once the residence of their fathers. Their route (see following map) lay along the eastern border of the Gulf of Suez to a point beyond Mount Sinai; then, turning



they proceeded northward as far as Kadesh Barnea; from that they turned again southward to near the head of the Gulf of Akaba; again, they bent their way northward through the wilderness of Zin to Mount Hor, where Aaron was buried. Being at this point refused a passage through the country of the Idumeans or Edomites, they retreated along the path by which they had entered the desert vale; and lastly issued upon the plains near the Gulf of Akaba, and compassing on the south the land of Moab, arrived at Gilgal in the Promised Land.* This painful and tiresome journey extended over a period of forty years, and was not completed till all the Hebrews who were above twenty years of age when they left the land of Egypt (excepting Caleb and Joshua) had died, and a new generation possessing greater courage and confidence in the Almighty had succeeded them. In the trackless wilderness through which they were led, their multitudes, as we learn from Scripture, could neither have traced their way nor procured subsistence, without a continued miracle. The hand of God brought for them streams of water out of the flinty rock; rained manna or bread from heaven; and gave a pillar of cloud to direct their journeys through the day, and a pillar of fire by night. He delivered the tables of a moral law, comprehending the ten commandments, to Moses their leader; and gave out a set of regulations for the ceremonies of worship, the establishment of a separate order devoted to religion and learning, and for the civil government of the nation. They had thus a regular polity and written laws, when most other nations knew only the law of the sword, or of savage animal superiority.

The country on the shore of the Mediterranean which was allotted as a settlement to this people, was at that time occupied by many warlike tribes, who had grown strong in its fertile plains and valleys; and the generation of the Hebrews who were conducted into it were compelled to fight for its possession. The struggle was not of long continuance. The armies of the Ammonites and Canaanites were defeated one after another in rapid succession; and the alarm which had deterred their fathers from making the attack, was now transferred to their enemies, who feared it. The old Israelites had said in the desert, "We are in our own sight as grasshoppers before these sons of Anak; hath the Lord brought us out of the land of Egypt to fall by the sword of this people?" But the new generation had a firmer confidence in the help which was promised them; and it was now the turn of their foes to shrink, "insomuch that their hearts melted, neither was their spirit in them any more, because of the children of Israel." The land was conquered in the year 1450 before Christ.

According to the account given in the 26th chapter of the book of Numbers, the Hebrew nation thus brought out of the land of Egypt and settled in Canaan, amounted to 601,730 souls, unto whom the land was divided for an inheritance, according to the number of individuals in the respective tribes. The tribes, and their fighting men above twenty years of age, were reckoned as follow:—Tribe of Reuben (the eldest son of Jacob) 43,730; Simeon 22,200; Gad 40,500; Judah 76,500, Issachar 64,300; Zebulun 60,500; Manasseh 52,700, Ephraim 32,500 (the tribes of Manasseh and Ephraim were both from Joseph); Benjamin 45,600; Dan 64,400, Asher 53,400; and Naphthali 45,400. Among these twelve tribes the land was divided. The tribe of Levi (to which belonged Moses, Aaron, and Eleazer the high priest), amounting to 23,000 males from a month old and upwards, received no share of the land; being set apart for the priesthood, the tenth or tithe of the general produce was assigned them as their perpetual inheritance. By making a special agreement with the other tribes that they should assist them against the common enemy, the two tribes of Gad and Reuben, and the half tribe of Manasseh, were permitted to appropriate land for their inheritance in Gilead and Bashan, on the Arabian side of the Jordan.

Previous to the settlement of the tribes in Canaan, they were called together by Moses to receive his parting address, for it was ordained that he should not enter the land along with them. The account of this memorable assemblage is given in the first chapter of Deuteronomy. Having first narrated the history of their tedious journey in the wilderness, and its objects, Moses proceeded to promulgate and explain to them, as their lawgiver, the statutes and commandments for their obedience, and the form of government, secular and spiritual, which they should adopt. Among other things, he recommended the erection of a capital city, where the great temple should be, and to which the whole people should repair three times a year, for the purpose of offering thanks to God for his former benefits, and entreating him for those they should require hereafter; also with the view of maintaining a friendly correspondance among the various tribes and orders of people. In obedience to this and subsequent injunctions, the Israelites built Jerusalem, and established the temple on Mount Zion within its walls. Moses, in concluding his lengthened address to the people of Israel, sang a song of praise to God, breathing a spirit of the most exalted piety (Deut. xxxii.), and bidding the sorrowing multitude adieu, proceeded alone to the top of Mount Pisgah, in the land of Moab, where he died. The place of his interment was concealed.

Moses was succeeded by Joshua as a leader, and by him the Israelites were conducted across the Jordan. The political government of the various tribes, after their conquest and settlement of Canaan, appears to have been republican, with military leaders called judges; but these acted by the direction of the priesthood, who were immediately counselled by the Deity within the sanctuary, the government of the Jews has thus been called a *theocracy*, or government by God. Their position, in the midst of hostile nations, required constant vigilance. In the book of Judges, we find them under the command of Gideon and other leaders. The instances of generous patriotism, of bravery, and of devout confidence in the God of their fathers, which are shown in the acts of several of the judges, render the record of their history one of the most interesting and romantic in the earth. Yet they were often reduced to the greatest distress.

* An account of Arabia Petræa, through which the Israelites travelled, is given in the latter part of the present sheet.

"Because of the Midianites," it is said, "the children of Israel made them dens in the mountains, caves, and strongholds; and when Israel had sown, the people of the east came up against them, and destroyed the increase of the earth, till they left no sustenance for Israel, neither sheep, nor ox, nor ass—for they came up as the grasshoppers for multitude; and the children of Israel cried to the Lord." From these calamities they were at times delivered by the devotion of some pastoral soldier among their tribes. Their songs of rejoicing on such occasions still more pathetically tell the disturbed state of the country, and present the troubles of its inhabitants for three hundred years (before Christ 1427 to 1112), while they formed a republic under their judges. It says much for this people, that in the midst of such a scene of unrest, they continued still to cultivate letters. The beautiful simplicity of the narratives given concerning the heroes of their country, is not to be equalled in any other remains of antiquity.

The epoch of kings succeeded that of judges. The reign of Saul, their first monarch, though the people were stronger by being united, was gloomy and troubled. David, who succeeded, was a soldier and a conqueror. He rendered the Hebrews formidable to the whole of their enemies, and gave them a regular and defensible position, expelling their old antagonists from every part of the country. He left an empire peaceful, respected, and strong; and, what was of as much importance, he selected from among his sons a successor who was able to improve all these advantages, and to add to the progress which his countrymen had already made in prosperity. Under Solomon, the name of the Hebrew government being able to protect its subjects in other countries, the people and their king began to employ themselves in commerce. Their trade was at first engrafted on that of Tyre, a people speaking a similar language with themselves, and like them, too (though certainly in a smaller degree), acquainted with the art of writing. We only find in Scripture an account of the state of commerce in Solomon's time; but there is no reason to suppose that after his day it was discontinued. It was, perhaps, no longer a matter of state; but the wealth of the country, which exposed it to continued pillage, and the number of prosperous Hebrews who were found in all parts of the earth (it would be idle to say that these were all brought away as captives), render it probable that, from the splendid reign of this monarch, they always continued to be addicted to commerce. It is indeed likely that they had been so before his reign, and that Solomon merely took commerce under the protection of the state; for there is no instance on record of any monarch all at once, and successfully, creating a national trade. However this may be, a greater contrast cannot be imagined than between the troubles of the time of the judges (only one hundred years before), and the peace, security, and enjoyment of this reign. "And the king made silver to be in Jerusalem as stones; and cedars made he to be as sycamore trees that are in the vale for abundance; and Judah and Israel were many; as the sand which is by the sea-shore for multitude, eating, and drinking, and making merry." The riches lavished upon the temple, which was erected in his time, are still the wonder of the east and west; and though the building itself may now be rivalled in extent by many of our parish churches, yet the gold, ivory, and other precious materials employed in its decoration, indicate a wealth which must, at that time, have been without a parallel. Both Solomon, and David his father, were men accomplished in learning, as well as in the arts of government; and the writings which they have left, if they show their own abilities, indicate not less a great attention to the cultivation of knowledge among the rest of the Hebrews.

After the death of Solomon, the country fell into the same divisions which had weakened it in the time of the judges. Each of the districts of North and South Israel was under a separate king, and the people were exposed both to the attacks of their enemies and to quarrels with each other. Their history is a succession of agitating conflicts for independence, and of unexpected and remarkable deliverances, of a similar nature to those of the earlier period, and they continued for about the same length of time (380 years); but they are marked by fewer of those traits of heroic devotion which distinguished the epoch of the judges. The backslidings, errors, and misgovernment of their kings, is the chief and painful subject which is presented to us; and though these are relieved at times by the appearance of such monarchs as Josiah, Jehoshaphat, and Hezekiah, yet the whole history of this period is overcast with the gloominess of progressive decline. By far the most delightful parts of it are those which relate to the lives of the prophets, who were raised up at intervals to warn the nation and its rulers of the fate which they incurred by forsaking the religion of their fathers. These inspired men sometimes sprang up from among the humblest classes of the community; one from "the herdsmen of Tekoa," another from "ploughing with twelve yoke of oxen;" several were of the priestly order, and one (Isaiah) is said to have been of royal lineage; but the works of all are marked with the same sacredness, force, and authority. They reprehend their countrymen, in the most eloquent strains, at one time for their idolatry, and at another for their hypocrisy; and their indignation is expressed with the same freedom and dignity against the vices of the highest and the lowest. It has become fashionable to trace the free spirit of our national tone of thinking to the historians and orators of Greece and Rome, which are taught in our schools; but any one who looks into the writings of the Hebrew prophets, and sees the boldness and energy with which the humblest of them threatens the nobles and princes of his country, or chastises the vices of the nation around him, will remark the pedantry of seeking, in volumes known only to the learned, for an effect which may be traced to books whose strong and pathetic eloquence has long swayed the affections of every peasant of the country. There is no subtlety of reasoning, no sporting with ambiguities in these writings; every thing is bold, decided, and powerful, appealing to great principles, and marked with high and energetic feelings. What a film of fancy-work are the metaphysical ingenuities of Plato, compared with the firm, broad, and uncompromising morality, the mild domestic charities, taught in the books of Psalms and Proverbs, or the pathetic and indignant remonstrances of the prophets against the backslidings of the "daughter of their people!"

At the end of the epoch of the kings (about 600 years before Christ), the land of Israel was swept by several powerful invaders, who carried off many thousands of the people into captivity. Little is known of the fate of those of the northern district, who are by some supposed to have been carried to India, by others to Tartary; but there are many interesting notices of the captives of Judah. These were carried to Babylon, a flat country intersected by rivers, to the eastward of their own. Here they seem to have been treated with kindness, and many of them even arrived at wealth and distinction. Nothing, however, could overcome their regret at being torn from the country of their ancestors—a feeling which is expressed with unrivalled beauty in the 137th Psalm, where the Hebrew captive looks back mournfully to the mountains and brooks of Judah, as he hangs his harp on the willows by the sluggish Euphrates, and refuses, with sorrow and scorn, to gratify his conquerors by singing the celebrated songs of his country in a strange land. It is a further proof of what we have said of the general intelligence and education of the Jews, that all the cou

querors who carried them off granted them high privileges in their new countries. Alexander, it is said, made them equal with his own Macedonians in the city which he founded; Ptolemy conferred on them similar privileges. We find the celebrated man of their nation (Daniel) chief minister of two successive monarchies.

After seventy years (during which there is little recorded of the people who were left in the country), permission was given to some of the chief Hebrews of the captivity to return with their people to Judea, and to establish there a government, conducted by their own countrymen, under the protection of the Persians. They were also allowed to rebuild the temple. Many families returned accordingly; and the Hebrews from this period enjoyed, as tributaries of this powerful monarchy, a peace of about 220 years, during which their country seems to have been quiet and prosperous. About 187 years before Christ, in consequence of their becoming involved in the quarrels of neighbouring powers, they were obliged to maintain a series of struggles in behalf both of their religious and national independence, more fierce and prolonged than we read of in almost any other nation. We are accustomed to admire the gallantry and perseverance of Wallace and of William Tell in behalf of their country; but Judas Maccabeus surpassed both, and with more brilliant success. The actions of one family of Jewish priests, belonging to a town (Modin) the site of which is afterwards noticed, might dignify the escutcheons of a whole aristocracy. Under them the Hebrews were again, for three reigns, an independent and even a powerful people.

The empire of the Romans was now extending itself to the east; and that power, being called in to aid the Hebrews on one occasion (about seventy years before Christ), seized the opportunity to establish its influence among them permanently. Their kings, the three Herods, and their other rulers, were now dependants of the emperor, and their country the tributary of Rome. On obtaining full possession of the country, the Romans divided Palestine (the region between the Mediterranean and the Jordan) into three tetrarchies or provinces—Judea, Samaria, and Galilee. It is creditable to the Romans, however, that while thus taking complete political possession of the ancient land of Israel, they in no respect interfered with the religion or other usages of the people, which they left under the direction of the sanhedrim and elders as of old. But notwithstanding this favourable arrangement, the Jewish nation was restless and unhappy; it was broken up into parties and sects, and some of these continually plotted schemes for a restoration of independence. The country was in this humbled and distracted condition when "Jesus was born in Bethlehem of Judea, in the days of Herod, the king." This most important of all events, which occurred in the reign of the Emperor Augustus, and marks the commencement of our era, made no difference politically in the condition of the Jewish people. During the continuance of Christ on earth, we do not read of any civil war in Palestine; but between thirty and forty years afterwards, serious insurrections broke out against the Roman authority, and the country was exposed to the greatest sufferings. In the year 70, Titus took Jerusalem by assault, burned the temple, and sold into slavery, or drove into exile, all the inhabitants who escaped death. About 110,000 Jews perished during the siege and at the destruction of Jerusalem.

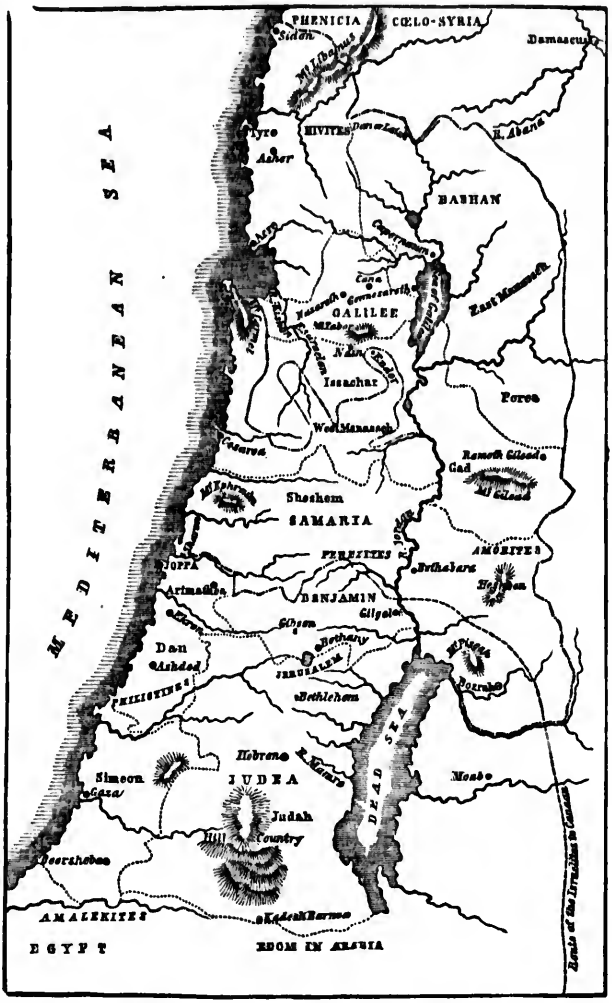
Reckoning from the settlement of Canaan by the Israelites till this last dire calamity, the Jewish nation existed in a regular form, though under various modifications, for 1560 years. Since they were first scattered over the face of the earth, in which condition they still exist, 1770 years have elapsed (reckoning till 1840), so that they have already been longer a scattered than they were a united people. By a late calculation, it is ascertained that the Jews now existing in different parts of Europe amount to 1,918,053; in Asia 738,000; in Africa 504,000; in America 5700; and in New Holland 50—grand total 3,218,000. Other estimates carry the number to 5,000,000 or even 6,000,000. In most countries they are still treated as strangers, and denied the rights of citizenship, though in manners, language, and general conduct, they do not differ from the common inhabitants. The government of the United States of North America was the first which placed them on the same political level with other citizens. More recently, the laws excluding them from civil privileges have been one after another abolished in the kingdom of the Netherlands, until they are now in all respects on an equality with the other people of that country. There is, we believe, evidence of the most incontrovertible nature, namely, statistical evidence, to show that crime has diminished among the Hebrews, as invidious distinctions have been thus done away with.

For a period of upwards of 200 years after the final dispersion of the nation, Palestine continued in a miserable condition. On the conversion of the Romans to Christianity, it became an object of religious veneration, as the scene of the ministrations of Christ and his apostles. The Empress Helena repaired in pilgrimage to the "Holy Land," viewed all the spots rendered remarkable by events in the gospel history, and built splendid temples, or other religious structures, on their sites. The Holy Land was now enriched by the crowd of pilgrims who came from all parts of the Christian world. The destinies of Judea, however, were changed by the invasion of the fanatical followers of Mohammed, in the sixth century, and soon fell under their sway. The caliphs, or Arabian monarchs, indeed, still viewed her holy places with reverence, and were induced to encourage pilgrimage, from the gain which it afforded. But when the Turks, an ignorant and barbarous race, poured in from the north, the same courtesy was no longer observed. They profaned the holy places, and committed outrages of every kind upon the visitants to the Holy Land. The pilgrims on their return related the dangers they had encountered. These representations kindled the religious zeal of the Christians in Europe into a flame, and a general ardour was awakened to "free the holy sepulchre from thrall." Now ensued a series of warlike expeditions, termed crusades, for the recovery of Palestine from the Mohammedans. After various successes and disasters, the crusades terminated in the middle of the thirteenth century, leaving the Holy Land still in the possession of a barbarous Mohammedan people. (See article HISTORY OF THE MIDDLE AGES.) In the year 1517, Palestine was annexed to the Turkish empire, and still remains a portion of Turkey in Asia. As such, it belongs to the pashalik of Damascus, and is (or was lately) under the jurisdiction of Mehemet Ali, the pasha of Egypt, by whose firm though precarious government it has been rendered much more safe to the visits of travellers than it was in past times. Its population now consists of a mixture of Turks and Arabs, chiefly the latter, with a small number of Jews and Christians.

PALESTINE.

Palestine, or the Land of Canaan, in which the Israelites settled after their protracted wanderings in the deserts, is a small country, forming part of Syria (which is a modern name for an indistinct portion of north Arabia), and lies on the shore of the Mediterranean Sea, between the 31st and 34th degrees of north latitude. With the whole of Arabia behind it, it may be described as a frontier border to that extensive pastoral region. Lying with the Mediterranean (anciently the Great) Sea on the west, it has Phœnicia on the north, Arabia on the east and south-east, and Idumea or Arabia Petræa on the south. The country has been called Palestine, as is supposed, from the Philistines, who were once its possessors,

let in the Scriptures, from various circumstances, it has received the appellations of "the Promised Land," "the Land of Canaan," and "the Land of Judea." In modern times, from its connection with the events which occurred within it upon the promulgation of Christianity, it is more generally called "the Holy Land."



Palestine extends from north to south a length of about two hundred miles, and fifty in breadth, and is, therefore, in point of size, of nearly the same extent as Scotland. The general character of the country is that of a hilly region, interspersed with moderately fertile vales; and being thus irregular in surface, it possesses a number of brooks or streams, which, for the most part, are swollen considerably after rains, but are almost dry in the hot seasons of the year. The longest and principal valley is in the centre, in a direction from north to south, and in this flows the river Jordan, which is the chief of the Judean streams. It arises from the outskirts of the mountains of Lebanon or Libanus on the north, flows into the lake of Tiberias, or sea of Galilee, and thence continues its course to the Dead Sea, from which there is no perceptible outlet, the water probably waning by means of evaporation. The present condition of Palestine scarcely corresponds with its ancient fertility. This is chiefly attributable to the devastating effects of perpetual wars, and some physical changes have also contributed to the destruction of agricultural industry. Yet, after all, so excellent would the soil appear to be, and so ample its natural resources, that Canaan may still be characterized as a land flowing with milk and honey. Its pastures are extensive, and of the richest quality; and the rocky country is covered with aromatic plants, yielding to the wild bees which hive in the hollows of the rocks such an abundance of honey, that the poor classes use it as a common article of food. Dates which are found springing up in the midst of the most arid districts, are also another important article of

consumption. If to these we add olive oil, an article so essential to an oriental, the ancient fertility of even the most barren part of Judea becomes easily accounted for. Delicious wine is still produced in some districts, and the valleys bear plentiful crops of tobacco, wheat, barley, and millet. Among other indigenous productions may be enumerated the cedar and other varieties of the pine, the cypress, the oak, sycamore, mulberry-tree, fig-tree, the willow, acacia, aspen, arbutus, myrtle, tamarisk, oleander, oshar, doom, the turpentine, almond, peach, chaste and locust trees; the mustard plant, aloe, citron, apple, pomegranate, and many flowering shrubs. Other indigenous productions have either disappeared, or are confined to circumscribed districts. Iron is found in the mountain range of Libanus, and silk is produced in abundance in the plains of Samaria.

Generally speaking, the climate is mild and salubrious. From May to August the sky is clear and cloudless, but during the night there falls a copious dew, which moistens the soil. Intensely cold nights, however, frequently succeed to very sultry days—a vicissitude more than once referred to in Scripture. Rain falls in sufficiency during the rest of the year, to which, in the absence of springs, the fertility of Palestine is mainly attributable. As the streams pour in impetuous torrents through the vales after heavy rains, it is unsafe to erect habitations on the plains, and such most probably is the reason why the towns and villages of Palestine are almost uniformly built upon elevated grounds.

Of the animals which prevail, or formerly prevailed, in Palestine, it is unnecessary to say much. The wild animals referred to in Scripture, such as the lion, wolf, leopard, &c., have almost totally disappeared. The fox is still common. Anciently the horse and ass were here celebrated for their beauty. The breeds of cattle reared in Bashan and Gilead were remarkable for their size, strength, and fatness; but this is far from being the case now. The vulture, falcon, jackdaw, nightingale, fieldlark, goldfinch, partridge, quail, and the quail of the Israelites, the turtle and ringdove, are found, and various kinds of land and water game are abundant. The Holy Land is infested with a frightful number of lizards, different kinds of serpents, vipers, scorpions, and various insects. Flies of every species are also extremely annoying. Ants are very numerous in some parts; one traveller describes the road from El Arisch to Jaffa, as, for three days' journey, one continued ant-hill. But these creatures, numerous as they are, are harmless in comparison to the locusts which overspread the country. These insects sometimes came in flights, which, on alighting, cover the land, and destroy every blade of herbage in their way. To oppose their destructive ravages, the inhabitants attack them with fire and branches of trees, and endeavour, by every other means, either to kill them in masses or to cause them to take to flight. It is not uncommon for an army of soldiers to be sent out to assist in slaughtering or expelling them from the land.

Travellers usually reach Palestine from Europe by sea, few daring to encounter the danger of the route from Egypt, through the land of Edom. Vessels from Malta or Alexandria regularly proceed to Acre, and from that port the traveller journeys to Jerusalem and other parts of the country. The most interesting route seems to be, in the first place, southwards, along the coast of Jaffa, Ashdod, Askalon, Gaza, &c., and then striking inland to Jerusalem, Bethlehem, and the Dead Sea; and proceeding afterwards, in a northerly direction, to Tiberias, Nazareth, and Lebanon; lastly, before leaving Syria, making a journey to the ruined city of Baalbec, and to Damascus. In visiting these and other places mentioned in Scripture, the traveller is scarcely so much shocked with the changes produced on scenery and localities, by the hand of warlike invaders, as by that of over-pious Christians. By the Empress Helena, and other individuals, convents, chapels, and churches, have been erected over almost every spot rendered sacred by the ministrations of our Lord, so that the original character of the principal places mentioned in the New Testament is altogether destroyed.

ACRE—MOUNT CARMEL.

Acre stands close to the sea, at the end of a bay, extending in the form of a bow, at the distance of twelve miles to the north of Mount Carmel, which is also on the sea-shore. It was originally called Accha, and is alluded to in sacred writ: of this name Acre is evidently a corruption. Its name is usually preceded by the words "St. Jean," in consequence of the place having been given by Richard of England to the Knights of St. John of Jerusalem: at one time it received the name of Ptolemais. The place was visited by the apostles, and particularly by St. Paul. It has been the scene of a variety of bloody contests, especially during the period of the Crusades, and was the last place from which the Christians were driven. The Turks ultimately laid hold of it with a numerous army, after a furious siege, when terrible outrages were committed. They were in possession of it from 1291, till compelled to surrender it to Mehemet Ali, who in his turn has been obliged to give it up to the Turks, by the warlike operations of the European powers in 1840. As Acre is reckoned the key of Syria, and has the best port, the French under Bonaparte made violent efforts to grasp it; they were, however, as is well known, successfully repelled. Acre is very strongly fortified, being newly enclosed with high walls, and is considered the strongest place in Syria. The houses are of stone, with roofs like terraces, the entrances to which are narrow, and many appear to communicate with each other. The streets are dirty, and so contracted that there is no more than room for a loaded camel to pass along; hence the air is very impure. The bazaars are mean, and the inhabitants miserable. The population is reckoned to be about 10,000

Mount Carmel forms a promontory, or majestic head land, on the Mediterranean. It runs from east to west, and rises about two thousand feet above the level of the sea, by which its base is washed. Near it runs Kishon, one of the rivers which are particularly alluded to in the sacred writings. Carmel is the most beautiful mountain in Palestine; is of great length, and in many parts covered with trees; and a part of its summit is pointed out as the place where Elijah prayed for rain, and saw the humid cloud rise out of the sea. On the 20th of July, the Christians proceed to perform acts of devotion in memory of the prophet. There was formerly a monastery here, but it is now abandoned.

Between this point and Jaffa we meet with the ruins of several ancient villages and towns, amongst which are those of Cesarea. "Perhaps there has not been," says Dr. Clarke, "in the history of the world, an example of any city that in so short a space of time rose to such an extraordinary height of splendour as did this of Cesarea, or that exhibits a more awful contrast to its former magnificence, by the present desolate appearance of its ruins." In fact, not a solitary inhabitant remains where once stood the proud city of Herod. Its theatre, its palaces, and temples, form a marble desert.

A large part of this now desolate territory—that is from Carmel to Jaffa, an interval of about sixty miles—is the plain of Sharon, celebrated in Scripture for its beautiful flowers and fertility, particularly its "rose," of which distinct mention is made. In the present day, though in a wild condition, it still yields pomegranates, oranges, figs, and other eastern fruits.

Jaffa, which is near the southern extremity of the plain of Sharon, and is the Joppa of Scripture, is situated on a conical mount overhanging the Mediterranean. Jaffa is one of the most ancient sea-ports in the world, but for all purposes of maritime traffic it is now nearly unfitted from the badness of its harbour. It was to this place that

Solomon ordered the materials of his temple to be brought by sea from Lebanon; here the prophet Jonah embarked for Tarshish; and here, in apostolic times, St. Peter restored Tabitha to life. The town is at present fortified, and the inhabitants amount to between four and five thousand, who are mostly Turks and Arabs. Latterly it has been greatly injured by an earthquake. Between Jaffa and El Arisch, the extreme point of the Holy Land in this direction, lie various places celebrated in the scriptural record. These are

ASHDOD, EKRON, GATH, ASKELON, AND GAZA.

At about an hour's journey south from Jaffa is Edzoud, the ancient Ashdod, standing on the summit of a grassy hill, but now in a decayed condition. The ruined village of Tookrair, situated also on the top of a hill, occupies the site of Ekron, which does not possess the smallest vestige of its former grandeur. Gath, a place of strength in the time of the prophets Amos and Micah, is now also either entirely gone or degenerated to a few ruins and a hamlet. Askelon, farther on to the south, and likewise situated on the summit of a hill at the distance of three miles from the sea, still, to external appearance, maintains something of its ancient character. Its position is strong, and its walls, which are of great thickness, and considerable height, are built on the top of a ridge of rock, winding round the town in a semicircular direction, and terminating at each end in the sea. But, alas! they enclose not a living being. How truly has been fulfilled the prophecy of Zachariah, "The king shall perish from Gaza, and Askelon shall not be inhabited." Gaza is truly without a king. It is now only a large village, situated a few miles south from Askelon, with a number of poor narrow streets. There is some trade, however, carried on in Gaza, particularly in cotton, and the inhabitants exceed 2000. This place was formerly of great magnificence and strength; for two months it baffled all the efforts of Alexander to take it.

Such are the chief places along the coast from Jaffa to the southern boundary of Palestine. We now take the route inland from Jaffa to Jerusalem.

JAFFA TO JERUSALEM.

About nine miles from Jaffa stands Ramla, or Rameli, the ancient Rama of Ephraim, and very probably the Arimathea of the New Testament. It is situated in a rich plain, and contains about 2000 families. Here there are several convents and mosques; and on a hill to the west of the town stands a venerable ruin, called the Tower of the Martyrs, a name probably derived from the martyrs of Sebastia, in Armenia, whose bodies have been here deposited. About a league from this is Lydda, still called Loudd, where St. Peter cured Æneas of the palsy. This place is now a poor village, with few inhabitants. The country which surrounds it, however, is of a rich and fruitful soil. Farther on is the Arab village of Bethhoor, supposed with much probability by Dr. Clarke to be the Bethoron of Scripture. We enter now into the country of Judea. It is very mountainous; "and its scenery," says Dr. Richardson, "brought strongly to my recollection the ride from Sanquhar to Leadhills, in Scotland; and to those," he continues, "who have visited this interesting part of my native country, I can assure them the comparison gives a favourable representation of the hills of Judea." He goes on to say, that the great difference lies in the contrast which the countries present in the character of their roads and inhabitants, those of Palestine being of the very worst description. Among the places of note which lie in the route to Jerusalem, is Modin, well known as the site of the city and tombs of the illustrious and patriotic Maccabees. It is still a place of strength and goes by the same name. As the road approaches Jerusalem, the vegetation becomes exceedingly scanty, and the country has a bare, rocky, and rugged appearance.

JERUSALEM.

Jerusalem—the city of Zion—the ancient capital of Judea, is situated on the western slope of a rocky hill, at the distance of about forty-five miles eastward from the shore of the Mediterranean. In the present day, it cannot be said to possess any resemblance to its condition in the period of its ancient glory, for the repeated sackings by Persians, Romans, Saracens, and other warlike intruders, also the changes it underwent at the period of the crusades, have obliterated all its original structures; and it now exhibits the external aspect of a Turkish city, with round-topped edifices and mosques, and environed with a wall for its defence. It is now only between two and three miles in circuit; and can be walked round in forty-five minutes. The town is built irregularly, somewhat in the form of a square, has pretty high walls, and six gates, which still bear Hebrew names. The houses are of sandstone, three stories high, and without windows in the lower story. This lifeless uniformity is only diversified here and there by the spires of the mosques, the towers of the churches, and a few cypresses. The population has been variously estimated at from 20,000 to 25,000. "It can hardly," says Mr. Carne, in his letters from the East, "exceed 20,000; 10,000 of these are Jews, 5000 Christians, and the same number Turks. The lower division of the city," he continues, "towards the east, is chiefly occupied by the Jews; it is the dirtiest and most offensive of all. Several of this people, however, are rather affluent, and live in a very comfortable style; both men and women are more attractive in their persons than those of their nation who reside in Europe, and their features are not so strongly marked with the indelible Hebrew characters, but much more mild and interesting. But few passengers in general are met with in the streets, which have the aspect, where the convents are situated, of fortresses, from the height and strength of the walls the monks have thought necessary for their defence. Handsomely dressed persons are seldom seen, as the Jews and Christians rather study to preserve an appearance of poverty, that they may not excite the jealousy of the Turks. The women, in their close veils and white dresses, look like walking corpses. The streets are unpaved, and filled either with heaps of dust or with mire. Nothing is to be seen but veiled figures in white, insolent Turks, and stupid or melancholy Christians." Weavers and slipper-makers are the only artisans. A multitude of relics, which are probably not all manufactured in the city, but are sent in also from the neighbourhood, are sold to the credulous pilgrims. Nevertheless, this city forms a central point of trade to the Arabians in Syria, Arabia, and Egypt. The people export oil, and import rice by the way of Acre. The necessaries of life are in profusion, and quite cheap, the game excellent, and the wine very good. The pilgrims are always a chief source of support to the inhabitants; at Easter they often amount to 5000. But few of them are Europeans. Jerusalem has a governor, a cadi or supreme judge, a commander of the [illegible] and a mufti [illegible] side over religious [illegible]. The citadel, which is pretended to have been the castle of David, is a Gothic building throughout. It is called the Pisan Tower, probably because it was built by the Pisans during the crusades. All the pilgrims go to the Franciscan monastery of the Holy Saviour, where they are maintained a month gratuitously. Besides this, there are sixty-one Christian convents in Jerusalem, of which the Armenian is the largest. They are supported by benevolent contributions, principally from Europe, and form the only place of residence for travellers.

Jerusalem is esteemed by Mohammedans as a holy city, though not to the extent it is by Christians; they

have here a temple or mosque, called the Mosque of Omar, which is on a scale of extraordinary magnificence, and contains a stone supposed to be of miraculous origin. Jerusalem, however, is chiefly of importance to the Turks, from the revenue which is derived from the Christian pilgrims. The spot to which all Christians first direct their attention, is that on which took place the crucifixion and burial of our Lord, now marked by

The Church of the Holy Sepulchre.

Mount Calvary, he spot on which the crucifixion of Christ took place, was originally a rising ground without the walls, but was afterwards enclosed within the city, altered entirely in its outlines, and made the site of a church founded by the Empress Helena. This Church of the Holy Sepulchre, as it is called, is about one hundred paces in length, and sixty in width. It is in the form of a circle, having a heavy dome or cupola, the frame of which is made of the cedars of Lebanon, and covered with a kind of stucco. It has a spacious and magnificent appearance, the Corinthian order of architecture prevailing. The present building is not altogether old. A fire, which occurred in 1808, destroyed a considerable portion of the edifice, and the present structure has been completed in the original style chiefly at the expense of the Greek religionists, who hence possess the best part of the edifice for their religious services, greatly to the distress of the Romish clergy. None of the Protestant churches takes any charge of the place. Carne gives us the following account of his visit to the church:—

"There was a guard of Turks in a recess just within the door, to whom every pilgrim is obliged to pay a certain sum for admission; but we were exempted from this tax. In the middle of the first apartment is a large marble slab, raised above the floor, over which lamps are suspended: this is said to be the space where the body of the Redeemer was anointed and prepared for the sepulchre. You then turn to the left, and enter the large rotunda, which terminates in a dome at the top. In the centre of the floor stands the holy sepulchre: it is of an oblong form, and composed of a very fine reddish stone brought from the Red Sea, that has quite the appearance of marble. Ascending two or three low steps, and taking off your shoes, you enter the first small apartment, which is floored with marble, and the walls lined with the same. In the centre is a low shaft of white marble, being the spot to which the angel rolled the stone from the tomb, and sat on it. You now stoop low to enter the narrow door that conducts you to the side of the sepulchre. The tomb is of a light brown and white marble, about six feet long and three feet high, and the same number in breadth, being joined in the wall. Between the sepulchre and the opposite wall the space is very confined, and not more than four or five persons can remain in it at a time. The floor and the walls are of a beautiful marble; the apartment is a square of about seven feet, and a small dome rises over it, from which are suspended twenty-seven large silver lamps, richly chased and of elegant workmanship—presents from Rome, of the courts and religious orders of Europe; these are kept always burning, and cast a flood of light on the sacred tomb, and the paintings hung over it, one Romish and the other Greek, representing our Lord's ascension, and his appearance to Mary in the garden. A Greek or Romish priest always stands here with the silver vase of holy incense in his hand, which he sprinkles over the pilgrims.

"Wishing to see the behaviour of these people, who come from all parts of the world, and undergo the severest difficulties to arrive at this holy spot, we remained for some time within it; and the scene was very interesting. They entered: Armenians, Greeks, and Catholics, of both sexes, with the deepest awe and veneration, and instantly fell on their knees; some, lifting their eyes to the paintings, burst into a flood of tears; others pressed their heads with fervour on the tomb, and sought to embrace it; while the sacred incense fell in showers, and was received with delight.

"In an apartment a little on the left of the rotunda, and paved with marble, is shown the spot where Christ appeared to Mary in the garden. Near this begins the ascent to Calvary, which consists of eighteen very lofty steps; you then find yourself on a floor of beautifully variegated marble, in the midst of which are three or four slender white pillars of the same material which support the roof, and separate the Greek division of the spot from that appropriated to the Catholics; these pillars are partly shrouded by rich silk hangings. At the end stand two small and elegant altars; over that of the Catholics is a painting of the crucifixion, and over the Greek is one of the taking down the body from the cross. A number of silver lamps are constantly burning, and throw a rich and softened light over the whole of this striking scene.

"The street leading to Calvary has a long and gradual ascent; the elevation of the stone steps is above twenty feet; and if it is considered that the summit has been removed to make room for the sacred church, the ancient hill, though low, was sufficiently conspicuous. The very spot where the cross was fixed is shown; it is a hole in the rock, surrounded by a silver rim, and each pilgrim prostrates himself, and kisses it with the greatest devotion. Its identity is probably as strong as that of the cross and crown of thorns found a few feet below the surface; but where is the scene around or within the city that is not defaced by the sad inventions of the fathers!"

The priests connected with these sacred places keep up a system of religious ceremonies, in some of which it would be impossible to say whether solemnity, fervour, superstition, ignorance, or sheer madness, most predominates. The ceremonies which take place during the season of Easter are ridiculous and absurd in the extreme. Upon Good Friday night the monks enact a sort of drama of the death of our Lord, in which they severally perform the various characters, such as Joseph of Arimathea and Nicodemus. They have a figure of Christ as large as life nailed to a cross, which they carry before them in solemn procession. No circumstance in the awful tragedy is omitted, from the singing of the hymn to the anointing of the body for burial, and its deposition in the sepulchre. The transactions of Easter day partake more of comedy than tragedy. It is a scene of superstitious riot and pitiful absurdity, which we think it unnecessary to describe. The reader may have some idea of it by imagining to himself what would be the consequences if bedlam were let loose upon the holy sepulchre. It is only doing justice, however, to those who have the keeping of the "place where our Lord lay," to observe, that some of the ceremonies are both solemn and impressive, without much admixture of absurdity. It is impossible, however, to read the exhibitions of Easter day and eve, without a painful misgiving as to every thing connected with the holy city.

Mounts Zion and Moriah.

On crossing the small ravine which divides the modern city from Mount Zion, the attention is attracted to three ancient ruins, covered with buildings comparatively modern—said to be, respectively, the house of Caiaphas, the place where Christ held his last supper, and the tomb or palace of David. The first of these is now a church, the services of which are performed by the Armenians: the second presents a mosque and a Turkish hospital while the third, a small vaulted apartment, contains only three sepulchres, formed of dark-coloured stone. This holy hill is equally celebrated in the Old Testament and in the New. Here the successor of Saul built a city and

a royal dwelling; here he kept for three months the ark of the covenant; here the Redeemer instituted the sacrament, which commemorates his death; here he appeared to his disciples on the day of his resurrection. The place hallowed by the last supper, if we may believe the early fathers, was transformed into the first Christian temple the world ever saw, where St. James the Less was consecrated the first bishop of Jerusalem, and where he presided in the first council of the church. Finally, it was from this spot that the apostles, in compliance with the injunction given them, went forth to teach all nations.

A shallow vale, called the valley of Millo, separates Mount Zion from Mount Moriah, on which the temple stood; this was originally an irregular hill, separated from Mount Zion and Acra, as well as from Beretha. For the purpose of extending the appendages of the temple over an equal surface, and to increase the area of the summit, it became necessary to support the sides, which formed a square, by immense works. In order to connect it with Mount Zion, it was necessary to throw a bridge across the valley of Jehoshaphat. According to Josephus, the execrable but magnificent monarch Herod rebuilt the second temple; but there is reason to suppose that he only added considerably to its extent. Its fate is well known: the prediction of our Saviour, that one stone should not be left upon another, was literally fulfilled. After the Caliph Omar took Jerusalem, buildings were erected on the spot where Solomon's temple stood, the rock was enclosed with walls, and, by subsequent additions and embellishments, it became the splendid mosque which we have already described.

Leaving the city at the gate of St. Stephen, the pilgrim is conducted to the spot nearly contiguous where it is supposed he suffered martyrdom. He is then shown the church of the sepulchre of the Virgin Mary, situated in the valley between the Mount of Olives and Jerusalem, founded by St. Helena. This is a small square building, flat on the roof, with a door on the south side, by which there is a descent into the interior by steps, having on the right hand a small chapel, with the tomb of St. Ann, the mother of Mary. On the left is another similar to the former, where Joseph, the husband of the latter, is said to have been interred. Although the authenticity of such assertions depends on the probabilities of tradition, yet the solemn stillness of the place, the sepulchral gloom, and, above all, the associations which are calculated to affect the mind on seeing every object about this city, combine to render a visit to this consecrated spot so deeply interesting, that a traveller of the least sensibility never can forget it.

Mount of Olives.

Passing along a small bridge thrown over the Kedron, the Mount of Olives next presents itself. About halfway towards the summit, there are several grottoes excavated labyrinthically in the rock. Higher up is another cavern, or subterraneous church, as it is now formed, consisting of several arched vaults, where the apostles composed the creed bearing their name; but this is almost filled with rubbish. About fifty yards farther, the spot is pointed out where Christ looked down upon Jerusalem in grief, and pronounced that ever memorable prophecy which has been so awfully and strikingly fulfilled. On the top of the Mount are the remains of a small church or chapel, in the octagon form, with a cupola, denominated the Ascension. This was built by Helena. Here there is shown the impression of the left foot or sandal of a man, which is ten inches in length and four in breadth, made on a rock or stone, said by the guides to be that of Christ, when his foot last touched the earth, though of course this is one of those modern inventions which prevail throughout the country.

Garden of Gethsemane.

The garden of Gethsemane, of all gardens in the world the most hallowed and interesting, is situated at the foot of the Mount, and near the brook Kedron. It is a piece of ground, about the third part of an acre in extent, surrounded by a coarse loose wall of a few feet in height. There are seven olive trees of enormous magnitude remaining, and separate from each other, said to have been in existence since the time of our Lord; they are highly venerated by the Christians, who consider any attempt to cut or injure them as amounting to an act of profanation. Should a Catholic be known to pluck any of the leaves, it subjects him to a sentence of excommunication from church privileges. Beads are made of the stone of the olive, and a string of them is the most sacred object that can possibly be presented to a traveller.

It was to this garden that Christ had occasion to resort with his disciples, to engage in devotional meditation, immediately before his death, and a view of it is calculated to impress the Christian mind with the deepest religious awe. At the upper end is the place where the apostles, Peter, James, and John, fell asleep during the passion of their divine Master, and, in the middle of the garden, the place where Judas betrayed him. Many other interesting places and grottoes are here pointed out, and among them is one which is supposed to be the scene of the agony and the bloody sweat.

Valley of Jehoshaphat.

After leaving the garden of Gethsemane, the traveller enters the valley of Jehoshaphat towards the south, on the eastern side of it. Among the first objects which are pointed out is the pit of Nehemiah, where the avenger of Israel discovered the sacred fire which had been concealed there during the Babylonish captivity. There is also shown the spot where Isaiah is said to have been sawn asunder. A little farther from the scene of the martyrdom, and on the same side of the valley, is the pool of Siloam, so particularly alluded to in Scripture, the water of which is of a brackish, disagreeable taste, and flows several miles distant under the city of Jerusalem, and is emptied here into a sort of basin enclosed by a wall. At a short distance from, and over against the pool, is the "Mountain of Offence," as it is termed, where Solomon committed acts of idolatry, by offering sacrifices to the gods of the Moabites and other nations. Near the foot of it, the Field of Blood is shown, where Judas hanged himself; and beyond it two massy pieces of antiquity, one of which is named the Tomb of Zechariah, and the other that of Absalom, formed in an extraordinary manner out of the natural rock, about eighteen feet in height, and ornamented with some columns of architecture, after the Ionic order, hewn in the same entire stone, supporting a cornice over which rises a pyramidal roof. The latter, since Absalom was not supposed to be buried in the valley, is conjectured to have been formed during the life of that prince. Such is the antipathy of the Jews to this monument, that it is their practice in passing to throw stones against it, as a mark of their reprobation of the unnatural rebellion of Absalom against his father. Near it is the sepulchre of Jehoshaphat, which gives the name of the valley. It is a cavern which is more commonly called the Grotto of the Disciples, from an idea that they went frequently thither to be taught by their divine Master. The front of this excavation has two Doric pillars of small size, but of just proportions. In the interior are three chambers, all of them rude and irregular in their form; in one of which were several gravestones, removed, we may suppose, from the open ground for greater security. Like all the rest, they were flat slabs of a long shape, from three to six inches in thickness, and evidently a portion of the limestone rock which composes the adjoining hills.

Chateaubriand is of opinion, that, except the pool of

Bethesda at Jerusalem, we have no remains of the primitive architecture of its inhabitants. The tombs in the valley of Jehoshaphat display an alliance of Egyptian and Grecian taste, mixed with the peculiar style of the Hebrews. In the valley of Jehoshaphat the Jews have a place of sepulture, which contains a number of gravestones, and to which those who reside in Jerusalem are in the habit of going in procession at certain seasons, for the purpose of observing a religious festival in memory of the dead. There still exists a strong desire in this people to mingle their dust with the ashes of their fathers, and many of them, as well as Christians, entertain the fantastical belief that the valley of Jehoshaphat is to be the scene of the final resurrection. With respect to its present aspect, Chateaubriand beautifully observes, "What with the sadness of Jerusalem, from which there ascends no smoke nor issues any sound—the solitude of the mountains, in which we perceive no living being—and the confusion of the tombs, all broken, shattered, and half open—one could almost believe that the trump of doom had already sounded, and that the dead had begun to rise in the valley of Jehoshaphat."

Besides the places already described in and about the city which tradition has hallowed, are the following:—Beneath the gate of Bethlehem is the spot where Bathsheba was bathing when David beheld her from the roof of his palace, and the present tower of the king is built upon the site of the ancient palace. A small distance within the gate of St. Stephen is the pool of Bethesda. It is one hundred and fifty feet long, and forty broad. The sides are walled with large stones joined together by iron cramps, and covered with flints imbedded in a substance resembling plaster. Here the lambs destined for sacrifice were washed, and here the Saviour said to the paralytic man, "Take up thy bed and walk." It receives a melancholy interest from the consideration that it is the only remnant which remains of Jerusalem as it appeared in the days of Solomon. A wretched street leads from this to the governor's palace, a spacious and rather ruinous building of Roman architecture. It contains some good apartments, the windows of which command an excellent view of the Mosque of Omar and its large area. In this palace the monks point out the room where Christ was confined before his trial; and at a short distance is a dark and ruinous hall, shown as the judgment-hall of Pilate. You then proceed along the street where Christ bore his cross, in which, and in the streets leading up to Calvary, are the three places, where, staggering under the weight, he fell. These are marked by three small pillars laid flat on the ground. The very house of the rich man also is here, and the spot where Lazarus sat at his gate. A pilgrim who comes to the city must set no bounds to his faith, as he is shown the place where the head of Adam was found, the rock on which the martyr Stephen was stoned, and the place of the withered fig-tree, with the milk of the Virgin Mary, and some of the tears that St. Peter wept on his bitter repentance.

In the neighbourhood of Jerusalem, the two chief places of interest are Bethany, lying in a northerly, and Bethlehem in a southerly, direction from the city.

BETHANY.

After leaving Jerusalem by the gate of St. Stephen, crossing the valley of Jehoshaphat, and passing the garden of Gethsemane and the Mount of Olives, the pilgrim arrives at the village of Bethany, situated about two miles from the city, where Jesus once resided, and where he appeared to his disciples after his resurrection. On the road, we meet with the village of Bethpage, now a heap of ruins. Bethany is both small and poor: it is, however, beautifully situated, and the view just above it is very magnificent. The cultivation of the surrounding soil is much neglected. The object which first strikes the traveller, is a ruinous castellated pile, which it is said Lazarus occupied. This, however, is only one of those oral legends, which, being manifestly of such a nature that the alleged fact could never have been ascertained, only affect the traveller with a painful sense of distrust, as he passes through this otherwise interesting country. Not far distant are the ruins of a building, said to have been the house of St. Mark. A little to the right are the vestiges of the habitation of Mary Magdalene. But by far the most interesting object is the tomb of Lazarus. The traveller first descends to a cave, probably from fifty to sixty feet under ground, and lands on a small quadrangular space, where there appears to have been a communication with a church adjoining, which is now built up and converted into a mosque. In the wall of this apartment there is an aperture of about three feet in breadth, formed by the raising of a large stone, as if by some convulsion of nature, and which conducts into an arched vault, said to be the spot where the body was laid. The vault measures about fourteen feet in length, ten in breadth, and eight in height. With respect to the identity of the tomb, Mr. Carne observes, "Its identity cannot be doubted—the position of Bethany could never have been forgotten—and this is the only sepulchre in the whole neighbourhood;"—reasoning which appears by no means conclusive.

BETHLEHEM.

Bethlehem, as being the birthplace of Christ, is one of the most interesting places in the Holy Land. The road leading to it is extremely rocky and barren, only diversified by some cultivated patches bearing a scanty crop of grain, and a profusion of wild flowers. On the way lie the ruined Tower of Simeon, who, upon beholding the infant Messiah, expressed his willingness to leave this world; the monastery of Elias, in which there is said to be a large stone, still retaining an impression of his body; and the tomb of Rachel, rising in a rounded top, like those erected to the memory of a Turkish sultan. Farther on is the well of which David longed to drink, and of which his mighty men, at the imminent risk of their lives, procured a supply. To distinguish this town from another of the same name of the tribe of Zebulun, the Bethlehem we now approach is usually distinguished by the addition of Ephrata, or by a reference to the district in which it is situated. It is a fine village, situated upon a mountain, and surrounded with gardens of fig-trees and olives. The houses are very humble, and flat on the roof, with stairs on the outside.

The principal buildings in Bethlehem are the convent and church of the Franciscans, which cover the supposed spot of the nativity. From the alteration of the surface caused by the building, this celebrated spot is now in a species of vault or subterraneous chapel, called the Chapel of the Nativity. Before the altar in this underground chapel, there are several massy silver lamps kept constantly burning; and the spot where it was said Christ was born, is marked with a star, formed of white marble, inlaid with jasper, and surrounded with a radiance or glory. On this there is encircled the following inscription:—

Hic de Virgine Jesus Christus natus est.
[Here Jesus Christ was born of the Virgin Mary.]

To the right of this is shown the place where stood the manger in which he was laid. It appears to be cut out of the natural rock, and lined with marble. Lamps of silver are always kept burning before it. A narrow passage leads from this chapel into that of the innocents who were slain by the command of Herod, where is a cell, in which, say the monks, St. Jerome made a translation of the Bible. A short distance from the convent is a grotto, where, according to tradition, the mother of Jesus concealed herself and child, whilst Joseph was making arrangements for their flight!

Four miles to the south of Bethlehem, in a most secluded situation in the midst of mountains, are situated

the celebrated pools or fountains of Solomon. These are three in number, of a quadrangular form, cut out of the living rock. About half a mile below, there is a deep valley, embosomed in high hills, where it is said the gardens of Solomon were laid out.

From the top of the church at Bethlehem there is a fine prospect of the surrounding country, extending to Tekoa on the south, and En-gedi on the east. In the latter place is the grotto or cave of Adulam, where David cut off the skirt of Saul's garment. Between this point and Jerusalem are several small detached towers, of a square form, built in the midst of vine-lands. These are for the accommodation of watchmen appointed to guard the produce from thieves and wild beasts, as alluded to by the evangelist St. Mark.

About twenty miles south from Bethlehem is Mount Hebron, with the town of that name, one of the oldest cities of Canaan, but now containing only 700 or 800 Arab families. The present inhabitants are the wildest, most lawless, and desperate people of the Holy Land. The principal mosque is said to contain the tombs of Abraham, Isaac, and Jacob; being in the possession of bigoted Mussulmans, no examination can be made of these supposed objects of antiquity.

CAVE OF JEREMIAH.

The central district of Palestine, northward from Jerusalem, contains a few objects of interest to travellers. The first which attracts their attention is the cave of Jeremiah, situated at a short distance from the gate of the Holy City. The bed of the prophet is shown in the form of a rocky shelf, about eight feet from the ground; and the spot is likewise pointed out on which he is understood to have written his book of Lamentations. At a little distance from the city stand the sepulchres of the kings, connected with which there still prevails some obscurity. But whoever was buried here, the place discovers so great an expense, both of labour and treasure, that we may well suppose it to have been the work of kings. It is approached on the east side by an entrance cut out of the rock, which opens into a court of about forty paces square. On the south side is a portico nine paces long and four broad, likewise hewn out of the living rock, and having an architrave running along its front adorned with sculpture. In the interior there are six or seven rooms in which stone coffins are exhibited.

BEER, LEBONAH, AND THE MOUNT OF GERIZIM.

The next object of importance which we meet with is a village supposed to be the Mickmash alluded to in Scripture. It is at present distinguished by the name of Beer, signifying a well, and adopted, most likely, from a delicious spring of water flowing through it; near to which are the ruins of a church, built in commemoration of the missing of Jesus by his parents, on their way home from Jerusalem, when it was discovered that he had remained in the temple with the expounders of the law. It was to this place, also, that Jotham had recourse in order to escape the fury of his brother. Beyond this hamlet, at the distance of about four hours' walk, is Leban, called Lebonah in the Bible, a village situated on the eastern side of a delicious vale. The road between these two places is carried through a wild and very hilly country, destitute of trees or other marks of cultivation, and rendered almost totally unproductive by the barbarism of the government. In a narrow dell, formed by two lofty precipices, are the ruins of monastery, being in the neighbourhood of that mystic Bethel where Jacob enjoyed his celestial vision. We next arrive at the well of that patriarch, the scene of the conference between our Saviour and the woman of Samaria. Over this fountain Helena erected a large edifice, of which, however almost nothing now remains. Near this is the narrow valley of Secasm, the Sychar of Scripture, overhung on either side by the two mountains Gerizim and Ebal, memorable as being the theatre on which was pronounced the sanction of the divine law. The Samaritans have, as is well known, a place of worship on Mount Gerizim, where at certain seasons they perform the rites of their religion. According to their version of the Pentateuch, it was here that the Almighty commanded the children of Israel to set up great stones covered with plaster, on which to inscribe the body of their law, to erect an altar to offer peace-offerings; and to rejoice before the Lord their God. In the Hebrew edition, Mount Ebal is said to have been the scene of these pious services—a variation which the Samaritans ascribe to the malice of the Jews. In the vicinity of the town is a small mosque, which is said to cover the sepulchre of Joseph, and to be situated in the field bought by Jacob from Hamor, the father of Shechem, as is related in the book of Genesis.

NABLOUS OR SHECHEM, AND SAMARIA.

Penetrating farther northwards, we arrive at a rich and fertile district, in which is situated Nablous, the ancient Shechem, and at present one of the most flourishing towns in the Holy Land. It has a very imposing appearance when viewed from the surrounding heights, and looks as if it were embosomed in a delicious paradise. The population, who are principally Mohammedans, have been estimated at 10,000, but this Mr. Buckingham thinks an exaggeration.

The Samaritans do not exceed forty in number. They have a synagogue, where divine service is performed every Saturday. Four times a year they go in solemn procession to the old temple on Mount Gerizim, on which occasion they assemble before sunrise, and read the law till noon. They have but one school in Nablous where their language is taught, though they take much pride in preserving ancient manuscripts of their Pentateuch in the original character. Mr. Conner saw, a copy which is reported to be 3500 years old, but he was not allowed to examine nor even to touch it. The events transacted in the field of Shechem render the localities contiguous to this city peculiarly interesting. Here stands the well of Jacob, and here the sons of the patriarch "drove their flocks a-field," and here they sold to the Ishmaelites their brother Joseph, the future all but potentate of the greatest kingdom then upon the face of the earth. Here, as of old, the shepherds graze their flocks upon the hills of Samaria, and the Ishmaelites come from Gilead, "bearing spices, and balm, and myrrh"—so enduring are the customs and manners of the east.

A few miles beyond Nablous, and about forty from Jerusalem, is situated the town of Samaria. This situation is extremely beautiful, and naturally strong, occupying the summit of a hill, encompassed all around by a deep valley. But the city which Herod adorned with princely buildings is now a mere village, small and poor, exhibiting only the miserable wreck of former greatness. Here John the Baptist was decapitated, and the Empress Helena erected a church over the place where he pined and suffered; but it has shared the fate of the rest of the city, being now a mere ruin. The prison where the holy blood of the desert-bred was spilled, is, however, pointed out by the Turks, who hold it in high veneration.

THE DEAD SEA.

This extensive sheet of water lies in an easterly direction from Jerusalem, and also from Bethlehem. In proceeding towards it from the latter place the traveller goes through a vale where it is said Abraham was wont to feed his flocks. This pastoral plain is succeeded by a range of mountainous and barren ground. Descending from this, two lofty towers rise from a deep valley, marking the site of the Convent of Santa Saba, a very an-

cient church. Its situation is dreary, being built amidst precipices on the brink of a deep and gloomy dell, where the brook Kedron flows.

In advancing, the country still presents a desolate aspect. The road at length seeks a lower level, and approaches the rocky border which bounds the valley of the Jordan; when, after a toilsome journey of ten or twelve hours, the traveller at last beholds the Dead Sea, and the line of the river; the landscape, however, is by no means grand or prepossessing. Two long chains of mountains run in a parallel direction from north to south, without breaks and without undulations. The eastern or Arabian chain is the highest; and when seen at the distance of eight or ten leagues, it resembles a prodigious perpendicular wall. Not one summit, not the smallest peak, is distinguishable; only slight inflections are here and there observed, as if the hand of the painter who drew this horizontal line along the sky had trembled in some places. The mountains of Judea form the range on which the observer stands as he looks down on the lake Asphaltites; it is less lofty and more unequal than the eastern chain, and also differs from it in its nature; exhibiting heaps of chalk and sand, which assume various bizarre forms. The Arabian side, on the contrary, presents nothing but bleak precipitous rocks, which throw their long and gloomy shadows over the water of the Dead Sea. Not a single blade of grass is to be found among these crags; every thing announces the country of a reprobate people, and well fitted to perpetuate the doom pronounced on Ammon and Moab. The valley embosomed in these two chains of mountains displays a soil similar to the bottom of a sea which has long retired from its bed—a beach covered with salt, dry mud, and moving sands, furrowed as it were by the waves. Vegetation is here in a deplorable state: there are a few dreary shrubs, with leaves covered with salt, and a bark which has a smoky smell and taste. Instead of villages, you perceive the ruins of a few towers. In the middle of this valley flows a discoloured river, which reluctantly throws itself into the pestilential lake by which it is engulfed. Its course amid the sand can be distinguished only by the willows and the reeds that border it; among which the Arab lies in ambush to attack the traveller, and to murder the pilgrim.

We now come to the lake itself, called in Scripture the Dead Sea; among the Greeks and Romans, Asphaltites; and among the Arabs, Bahr Lout, or the Sea of Lot. Considerable diversity of opinion has prevailed, both among the ancients and moderns, regarding the exact dimensions of this lake, which as yet are probably not accurately ascertained. Mr. Carne says, its length may probably be about sixty miles, and its average breadth eight. Mr. Banks, however, who took observations from several neighbouring heights, says, that its utmost extent does not exceed thirty miles. This discrepancy places the inaccuracy of travellers, with regard to their topographical descriptions of Palestine, in a very strong point of view. It is surrounded on the east by lofty hills, exhibiting rugged and frightful precipices; on the north it is bounded by the plain of Jericho, through which it receives the river Jordan. Other streams are discharged into it; and there being no visible outlet, while the banks are not overflowed, some have thought there is a subterraneous channel communicating with the Mediterranean: others readily account for the phenomenon, in the evaporation which necessarily takes place in a hot climate. This lake is clear and limpid, resembling the colour of the sea. Its waters are in general fatal to animal life, nor do vegetables flourish in their immediate vicinity. The fishes carried hither by the river Jordan, according to the concurring testimony of travellers, speedily perish; but the latest observers affirm that there are some small ones in the lake peculiar to itself, as also that a few inferior vegetables may be seen in it.

Travellers on bathing in the lake find their faces covered with a thin crust of salt, and the stones which the water occasionally covers, are encrusted with the same substance. From whatever cause, the water is different from that of other lakes or seas. On being analyzed, it is found to have a greater specific gravity, or power of buoying up bodies, than any other water. It holds in solution muriate of lime, muriate of magnesia, muriate of soda, and sulphate of lime; of all these there are 24 grains in 100 grains of water.

Great quantities of asphaltum, or mineral pitch, are always seen floating on the surface of the Dead Sea, and it is driven by the winds to the banks on the east and west; but the statement that a pestilential effluvium hovers over it is doubtful. Mr. Carne informs us that there is nothing of the kind. The neighbourhood of the lake abounds with volcanic products; and although eruptions have ceased for many centuries, earthquakes are still common in Syria and Palestine.

The Dead Sea is associated with that dreadful catastrophe recorded in Scripture, the destruction of Sodom and Gomorrah. With respect to the agents employed for executing the purpose of Divine vengeance, various conjectures have been hazarded—some suppose that the great cities were swallowed up by a volcano. The opinion of Chateaubriand, who had carefully examined several volcanoes, is decidedly opposed to this theory. The learned Frenchman inclines to the opinion of Michaelis and Busching, that Sodom and Gomorrah were built upon a bituminous mine; that lightning kindled this combustible mass; and that the cities were engulfed in this subterraneous conflagration. Malte-Brun ingeniously supposes that the stones of which the towns themselves were built might be bituminous, and thus have been kindled by the fire of heaven. These views appear very plausible, when taken in connection with the Mosaic account of the place, that the vale of Siddim, which is now occupied by the Dead Sea, was full of "slime pits," or pits of bitumen. There can be no doubt, however, that combustible matter descended from heaven upon the devoted cities of the plain, for the language of the Scriptural account is precise and explicit: "The Lord rained upon Sodom and Gomorrah brimstone and fire from heaven." According to Strabo, there were thirteen towns swallowed up in the lake Asphaltites; Stephen of Byzantium reckons eight; the book of Genesis, although it names five as situated in the vale of Siddim, relates the destruction of two only; four are mentioned in Deuteronomy, and five are noticed by the author of Ecclesiasticus. A considerable difference of opinion exists respecting the probable outlet of the waters of the Jordan, previous to the catastrophe which destroyed Sodom and Gomorrah, and created the Dead Sea on their site. Buckhardt and others allege, that the Jordan must have proceeded along the plain of Sodom, and pursued a course through the wilderness to the Gulf of Akaba, or eastern limb of the Red Sea; indeed no other probable outlet could be assigned. Other travellers who have scrupulously examined the district, and taken its levels mathematically, declare that the surface of the Dead Sea is several hundred feet below the level of the Gulf of Akaba, and much more below that of the Mediterranean. If this be the case, the land on which the Dead Sea rests, and also the present termination of the Jordan, must have been sunk at least 1000 feet on the occasion of the awful catastrophe which laid the "cities of the plain" in ruins, and covered them with a waste of bitter waters.

THE RIVER JORDAN.

The river Jordan, which flows into the Dead Sea at its northern extremity, rises at the foot of the mountains of Lebanon, and has altogether a course of 150 miles For the last two or three miles, it runs between perpen

dicular banks of sand, from five to ten feet high, and here the river is about thirty paces broad. A few miles from its mouth, on the right side, and at a short distance from the stream, is the site of Jericho, now consisting only of a few miserable huts and a watch-tower. At this point of the river is the spot where the Israelites crossed from the Arabian side into Palestine, under the command of Joshua. Passing up the vale of the Jordan, for a distance of ninety or one hundred miles, with the land of Gilead, as it is called, on the right, the traveller arrives at the Lake of Genesareth, near which are a number of places mentioned in the narrative of Christ's ministrations.

LAKE OF GENESARETH.

This sheet of water, which is an expansion of the Jordan, passes under various names from the sacred writers, such as the Sea of Galilee, Lake of Tiberias, and Lake of Geneser or Genesareth. The river Jordan enters at the northern and flows out at the southern extremity, and its course is visible all the way through. The range of mountains forming its eastern shore, is very lofty, and their steep and rocky sides are barren; the western shore, where the town stands, is lower; the hills are picturesque, and divided by sweet valleys clothed with verdure, but destitute of trees. With respect to the size of the lake, we must choose again among conflicting statements. It seems to be about fifteen miles in length and five in breadth. The waters are perfectly sweet and clear, and the fish are said to be of a delicious flavour.

It is almost unnecessary to remind the reader that this lake and neighbourhood were the scene of many important events recorded in the New Testament. Here, it will be remembered, Christ embarked in a ship, to go to different places about its borders, in the prosecution of his errands of mercy, and from which he instructed the multitude who had assembled on the shore.

Capernaum lies at the upper end of the lake, and is now called Talhewin, or Tel Hoom. It is nothing more than a station of Bedouins, but there are traces of its former importance. The foundations of a magnificent but now much dilapidated edifice can still be traced.

Tiberias, which makes a conspicuous figure in the Jewish annals, is situated on the western side, and is the only place on the sea of Galilee retaining any marks of its ancient importance. It is understood to cover the ground formerly occupied by a town of a much remoter age, and of which some traces can still be distinguished. Tabaria, as it is now denominated, has the form of an irregular crescent, and is enclosed towards the land by a wall, flanked with circular towers. It lies nearly north and south along the edge of the lake, and has its eastern front so close to the water, on the brink of which it stands, that some of the houses are washed by the sea. The whole does not appear more than a mile in circuit, and cannot, from the manner in which they are placed, contain above 500 separate dwellings. Here there are a mosque and two Jewish synagogues, also a Christian place of worship, called the house of Peter, which is thought by some to be the oldest building used for that purpose in any part of Palestine. The structure is of very ordinary description; but it derives no small interest from the popular belief that it is the very house which Peter inhabited at the time of his being called from his boat to follow the Messias. The population of the town does not now exceed 2000. Of these, about one-half are Jews; the rest are Mohammedans, with the exception of a few of the Christian creed. The warm baths, which have given celebrity to that neighbourhood, are still found at the distance of between two and three miles southward from the town.

MOUNT TABOR.

An almost uninterrupted ascent, in a south-westerly direction, conducts from Tiberias to Nazareth. On this route, we have on our left Mount Tor, or Tabor. This mount, which is classed in Scripture with Hermon, and is of a sugar-loaf shape, stands apart from the neighbouring mountains, is at one end of the great plain of Esdraelon. It may be ascended on all points, excepting towards the north, where it is rugged. There is not, perhaps, to be found, in the whole compass of the globe, one spot, from which a believer in the gospel can possibly enjoy a more sublime or glorious prospect, than from the summit of Mount Tabor. In the first place, there is presented to view an extensive plain, on one side of which, on the left hand, are the mountains of Samaria, towards Jerusalem; on the other, to the right, those about Nazareth, especially the memorable hill from which the Jews attempted to precipitate Christ. At the opposite extremity of this plain, is the top of Mount Carmel, washed by the ocean. In another direction, we see Hermon in its lofty dignity; Endor, and Nain, with the mountains of Gilboa; the valley of Jordan; the spacious plains of Galilee, with its sea of Genesareth, and its enclosure of mountains; Dothan, where Joseph was sold, with its rivers, valleys, and little hill; and the village of Saphet, anciently called Bethulia, on an eminence, and presumed to have been the point of elevation alluded to by Christ in his sermon on the mount, from which it is also remarkably conspicuous, and not at a great distance. Again, the sublime height on which he delivered this memorable oration; the route to Damascus; lastly, Mount Lebanon, towering with prodigious alpine dignity in the background.

Different opinions have been entertained by writers with regard to the extent of ground on the summit of Tabor, and the cultivation of it. Taking the whole into calculation, it may be nearly two miles in diameter. To the west, there are masses of scattered ruins. At one period, a governor of Galilee surrounded the top of it with walls, which is confirmed by the scattered fragments still to be seen. St. Helena, also, in prosecution of her zeal in the cause of Christianity, founded two monasteries, one to the memory of Moses, and the other of Elias. Various historical incidents are connected with this mountain. Here it was that Barak, descending with his ten thousand men from Tabor, discomfited Sisera and all his chariots. In the same neighbourhood, Josiah king of Judah fought in disguise against Necho king of Egypt, and fell by the arrows of his antagonist, deeply lamented. Vespasian reviewed his army in the same great plain. It has been a chosen place for encampments in every contest carried on in the country, from the days of Nebuchadnezzar, king of the Assyrians, down to the disastrous invasion of Napoleon Bonaparte.

NAZARETH.

A short way to the north-west of Mount Tabor is situated the village of Nazareth, on the western slope of a delightful valley, and encompassed by rocky mountains; the distance from Jerusalem is about one hundred miles. The place is properly named Nazareth of Zebulun. The inmates of a convent at the eastern extremity of the village, conduct travellers to a number of spots in the neighbourhood of scriptural interest, but greatly changed in their appearance in modern times. The first thing to which attention is directed is the church belonging to the convent, which is rather elegant, and is erected over the grotto or cave where Mary took up her abode. It has no other roof than that which is formed of the natural rock, and is in the shape of a cross.

Among many pictures which adorn this church, there is a pretended likeness of Christ.

The second object shown is the shop where Joseph worked; it is now used as a place of worship. Over the altar, he is represented with the implements of his trade

holding our Lord by the hand, as if in the act of imparting the knowledge of his vocation.

Thirdly, a chapel, in the centre of which is an enormous stone, about nine feet in length, and six in breadth, on which it is affirmed that Christ sat and ate with his chosen few.

Fourthly, the synagogue where Christ, agreeably to his practice, read to the Jews, from the sacred volumes, on the Sabbath.

Fifthly, near the town is pointed out a hill, from which, disregarding the sanctity of that day, they threatened to throw him, in consequence of the dissatisfaction which his addresses had given.

And, lastly, a well of the Virgin, which supplies the inhabitants of Nazareth with water. Mr. Carne says, the population may amount to about 1200, and are mostly Christians.

After crossing the plain of Esdraelon, we come to Mount Hermon, the dew of which is so beautifully alluded to by the Psalmist. Near this place stands Nain, which is so called from its pleasant situation, where the widow's son was restored to life. About two miles from Nain, is seen Endor, where the sorceress resided who was consulted by Saul, and in the vicinity are the mountains of Gilboa, where the forces of Israel were collected.

A few miles northward from Nazareth, is

CANA OF GALILEE.

This village, which was the scene of the earliest miracle performed by our Lord (the conversion of the water into wine at the marriage feast), is pleasantly situated on a small eminence in a valley, and contains 200 or 300 inhabitants. Many pots, answering to the description given by the Evangelist, are found lying about amongst the ruins; from which it would appear evident, that the practice of keeping water in large stone pots, each holding from eighteen to twenty-seven gallons, was once common in the country. Near the bottom of a field, which is said to be that in which Christ plucked the ears of corn upon the Sabbath, stands the Holy Mount, which has been so eminently distinguished as the spot from whence the multitudes were addressed. It has an elevation of from 200 to 300 feet.

The landscape, which stretches from the lake of Tiberias to the sources of the Jordan, is in many parts uncommonly fine, presenting luxuriant crops, thriving villages, and other tokens of security and comfort. The mountains that terminate the prospect are magnificent, some of them being covered with perpetual snow.

SAPHET, SEPHOURI, AND ZEBULUN.

The only town of consequence between the ruins of Capernaum and the alpine range of Hermon and Djibbel d Sheik, is Saphet or Zaffad, being one of the four cities consecrated by the religious veneration of the Hebrews. According to Burckhardt, it stands upon several low hills that divide it into quarters, the largest of which is occupied by Jews. The whole may contain 600 houses, of which 150 belong to the people just named, and nearly as many to the Christians. The summit of the principal eminence is crowned with an ancient castle, part of which is regarded by the descendants of Israel as being contemporary with their ancient kings. The Jews have here seven synagogues, and a sort of university for the education of their rabbis. Their attachment to this place arises especially from the traditionary belief, that the Messias is here to reign forty years before he assumes the government at Jerusalem. From Nazareth to Acre we proceed over a barren rocky tract of country; on the way we meet with Sephouri or Sepphoris, the Zippor of the Hebrews, and the Diocesarea of the Romans, once the chief town and bulwark of Galilee. The remains of its fortifications exhibit one of the works of Herod, who, after its destruction by Varus, not only rebuilt and fortified it, but made it the principal city of his tetrarchy.

Its chief celebrity is connected with the tradition that it was the residence of Joachim and Anna, the parents of the Virgin Mary. Constantine built a magnificent church over the spot where the devout couple lived. The vale of Zebulun divides the above village from the ridge of hills which look down on Acre and the shores of the great sea. This plain everywhere presents the most beautiful scenery. On the road, various ruins occur which exercise the ingenuity of the antiquarian traveller. All remains of the strong city of Zebulun have disappeared, and its admirable beauty, rivalling that of Tyre, Sidon, and Berytus, is now sought for in vain among Arab huts and heaps of rubbish. We shall now proceed in a westerly direction to the coast of the Mediterranean, to describe those points of interest lying to the north of Acre.

TYRE.

Tyre (now called Tsour), which is situated on the coast about twenty miles north from Acre, and anciently belonging to the Phœnicians, is renowned in Scripture as a mighty mercantile stronghold, encompassed with walls and towers. Perhaps, of all other maritime cities in the globe, this was the most highly renowned for riches and commerce, since its very merchants were declared to be as princes, and "every deck a throne." A most interesting description of the trades carried on within its walls has been transmitted to us in the 27th chapter of Ezekiel. It was not, however, merely in a commercial point of view that it was represented to the world at large as an object of wonder and admiration. Among the variety of trades exercised in this city, that of dyeing was most distinguished, on account of the beautiful purple tint which poets have celebrated as a chief ingredient in the magnificence of the vestments worn by the principal inhabitants. During the time of our Saviour, considerable importance must have been attached to the city, as it is frequently alluded to, with its neighbourhood. Tyre was besieged and taken by Alexander the Great, after whose death it began to recover, and maintain a commercial character. It afterwards submitted, first, to the Roman, and afterwards to the Mohammedan yoke, under the power of which it now remains. It was enclosed with walls, which originally must have been of great strength, furnished with towers, having holes or apertures for making observations, part of which still remain. In the present day it exists as a small decayed town at the outer extremity of a low sandy peninsula, and a recent traveller mentions that he saw only a single boat in its harbour.

SIDON.

Sidon, or Zidon, called by the Arabs Tsaida, is situated on the coast at about twenty miles northward from Tyre. It owes its name to the eldest of the sons of Canaan, and was comprehended under the "lot," or possessions, formally assigned to the tribe of Asher. It appears to have been higher in point of antiquity than Tyre, although both have been classed in the character of sisters, arising, most likely, from their contiguity, and publicly considered as a city of large extent and importance, since it has been distinguished in Scripture by the title of "Zidon the Great." The invention of the alphabet and arithmetic, making of glass, and skill in casting and sculpture, have been celebrated; and an unrivalled dexterity in hewing of wood will hand down the Sidonian name in the page of history to the latest period of time. The commercial pursuits of this people were also as lucrative as they were extensive; and it was likewise celebrated for its maritime enterprise.

Sidon is now a small town, rising gradually from the

sea-shore, very pleasantly situated, and surrounded with rich gardens. The climate is peculiarly mild: the streets are excessively narrow, many of them under archways as at Jerusalem: the inhabitants are estimated at about 7000, of whom 2000 are Christians, who have places of worship; the Jews, also, who may be calculated at 200, have a synagogue. Considering its small extent, the trade of this place is considerable, particularly in silk.

The next object of importance, in a northerly direction, is

MOUNT LEBANON,

"Whose head in wintry grandeur lowers,
Whiten'd with eternal sleet;
While summer, in a vale of flowers,
Is steeping rosy at his feet."

This mountain has received the appellation of Lebanon from the word *Leban*, signifying white, and, in all probability, from the snow which remains on its heights during the whole year. It has afforded many glowing images and beautiful metaphors to the sacred writers. Its cedars, alluded to in ancient prophecy, have in all ages been celebrated as fine objects. It may be further added that, uniting so many qualities for building, many of these trees were sent by King Hiram to Solomon for the erection of his temple. Lebanon is variously described as rising to 9600 and to 11,000 feet. At one spot is found a grove of cedars, and other parts of the mountain are beautified with thousands of rare plants.

THE DRUSES AND MARONITES.

The mountains of Lebanns and neighbourhood are inhabited by two races, differing in religion and manners, but similar in their love of independence, the Maronites and the Druses. The country of the former is called Kesraoun, the Castravan of the historians of the crusades. It reaches from the river Kebir to the Kelb. The Maronites, amounting to 120,000, dwell in villages and hamlets. The fervour and devotion which animate this people recall to us the ideas of the primitive church. An imposing superstition has consecrated a cedar forest which is said to have furnished the timber of Solomon's temple. Only twenty large cedars remain, and this old vegetable race verges fast to its extinction. Every year, on transfiguration day, the Greeks, the Armenians, and the Maronites, celebrate a mass on an altar of rough stones raised at the roots of these venerable trees.

The Druses, also 120,000 in number, live to the south of the Maronites. Their country has several subdivisions, differing from one another in their soil and productions. It is by religious peculiarities that this people is separated from the other inhabitants of Syria. They believe in one God, who, for the last time, showed himself in human form in the person of Hakem, caliph of Egypt, in 1030. Persuaded that all other systems of belief will finally be united in that which they profess, they regard them all with equal indifference, although the Christians have considered them as entertaining a marked contempt for the Mohammedan religion. Recent travellers have described the Maronites and Druses as an inoffensive primitive people.

In a northerly direction from Sidon, the only port of any consequence on the Mediterranean is Beirout.

BALBEC AND DAMASCUS.

Having reached Mount Lebanon, at the northern extremity of Palestine, travellers generally spend a few days in making a journey to Balbec and Damascus, both lying beyond the frontier of the Holy Land, but still of great historical interest. Balbec, the ancient Heliopolis, and once distinguished for its beautiful Grecian and Roman architecture, is now completely in ruins. These, however, are of the most magnificent kind, and consist of detached columns, façades of temples, and other elegant blocks of destroyed buildings.* Balbec is now uninhabited, except by wandering Arabs. Damascus, situated near the confluence of the rivers Abnia and Pharphar of Scripture (see map), is an ancient town in Syria, built in the eastern style, and, with the surrounding country, is again in the possession of the Sultan.

Damascus is enlivened by the bustle of commerce, and the passage of the caravans to Mecca. The great street which crosses it presents two rows of shops, in which the riches of India glitter along with those of Europe. Damascus is seven miles in circumference, and at present the population may amount to 100,000. The private houses in Damascus, simple in external appearance, exhibit in the interior all the splendour and elegance of a refined luxury; great magnificence is also displayed in the mosques, the churches, and the coffee-houses. The large mosque is a fine and spacious building, but no traveller is permitted to enter. The Chan Verdy, or Coffee-House of Roses, is considered as one of the curiosities of the Levant. Various places associated with events mentioned in Scripture, are pointed out in the city and neighbourhood. The street, still called Straight, is that where St. Paul is, with reason, said to have lived. It is as straight as an arrow, a mile in length, broad, and well paved. A lofty window, in one of the towers to the east, is shown as the place where the apostle was let down in a basket; and in the way to Jerusalem is the spot where his course was arrested by the light from heaven.

* For an account of the ruins of Balbec, see Lamartine's Travels in the East, page 113; People's edition.

ARABIA PETRÆA.

Arabia Petræa, or Arabia the Rocky, is the most northerly part of the peninsula of Arabia, and includes the territory lying between the Mediterranean and the two upper extremities of the Red Sea. These extremities form two gulfs—the Gulf of Suez, which is the largest, and the Gulf of Akaba. The Gulf of Suez is adjacent to Egypt, and between it and that of Akaba there is an angular tract of country, in which is situated the wilderness of Sinai. The whole of this territory, from the borders of Egypt to near the Dead Sea in Palestine, and from the Red Sea to the Mediterranean, is little else than an universal desert of rocky mountains and sandy plains, almost destitute of any settled human habitations, and inhabited only by roving bands of Arabs or Bedouins (children of the desert), whose hand is against every man, and every man's hand against them. Anciently, the country, which was called in its more northerly part the land of Edom or Idumea, was mostly fertile and productive, but by the encroachments of the sands of the deserts and the desolation which has otherwise spread over it, the land is generally barren, and mostly in the condition of a wilderness. Till this hour, the curse of God, as enunciated by the prophet Isaiah, rests upon it—"From generation to generation it shall lie waste; none shall pass through it for ever." With the exception of a few French and English travellers who have within the last twenty years passed through Idumea, from Akaba to Jerusalem, the prophecy has been fulfilled.

According to the accounts of recent travellers, nothing can exceed in rugged grandeur the desolate region of Sinai and Mount Horeb. Rocks piled on rocks to an immense height, precipitous cliffs, and bare desolate valleys, fill up the melancholy scene. On the face of Sinai, a fortified monastery is placed, for the accommodation of Christian pilgrims and travellers. The ascent of the mountain commences above the monastery, and

in this direction it was climbed by Mr. Stephens, who reached the top with some difficulty, and saw around him a terrific solitude, a perfect sea of desolation. "Not a tree, or shrub, or blade of grass, is to be seen upon the bare and rugged sides of innumerable mountains, heaving their naked summits to the skies. The level surface of the very top or pinnacle, is about sixty feet square. At one end is a single rock about twenty feet high, on which, as said the monk [my conductor] the spirit of God descended, while, in the crevice beneath, his favoured servant [Moses] received the tables of the law. The ruins of a church and convent are still to be seen upon the mountain, to which, before the convent below was built, monks and hermits used to retire, and, secluded from the world, sing the praises of God upon his chosen hill. Near this, also in ruins, stands a Mohammedan mosque—for on this sacred spot the followers of Christ and Mohammed have united in worshipping the true and living God."

The route from Sinai towards the land of Edom is by way of Akaba, a small fortified town at the head of the Gulf of Akaba, or Elanitic branch of the Red Sea. The journey is through a rocky desert, "with here and there (says Mr. Stephens) a fertile spot, near some fountain or deposit of water, known only to the Arabs, capable of producing a scanty crop of grass to pasture a few camels and a small flock of sheep or goats. There the Bedouin pitches his tent, and remains till the scanty product is consumed; and then packs up his household goods, and seeks another pasture-ground. The Bedouins are essentially a pastoral people; their only riches are their flocks and herds, their home is in the wide desert, and they have no local attachments; to-day they pitch their tent among the mountains, to-morrow in the plain; and wherever they plant themselves for the time, all that they have on earth, wife, children, and friends, are immediately around them. In fact, the life of the Bedouin, his appearance and habits, are precisely the same as those of the patriarchs of old. Abraham himself, the first of the patriarchs, was a Bedouin, and 4000 years have not made the slightest alteration in the character and habits of this extraordinary people. Read of the patriarchs in the Bible, and it is the best description you can have of pastoral life in the East at the present day.

"Akaba (continues this writer) is situated at the foot of the sandstone mountains, near the shore, and almost buried in a grove of palm-trees, the only living things in that region of barren sands. It is the last stopping place of the caravan of pilgrims on its way to Mecca, being yet thirty days' journey from the tomb of the Prophet, and, of course, the first at which they touch on their return. Except at the time of these two visits, the place is desolate from the beginning of the year to its close; the arrival of a traveller is of exceedingly rare occurrence, and seldom does even the wandering Bedouin stop within its walls; no ship rides in its harbour, and not even a solitary fishing-boat breaks the stillness of the water at its feet. But it was not always so desolate, for this was the Eziongeber of the Bible, where, 3000 years ago, King Solomon made a navy of ships, which brought from Ophir gold and precious stones for the great temple at Jerusalem; and again, at a later day, a great city existed here, through which, at this distant point of the wilderness, the wealth of India was conveyed to imperial Rome. But all these are gone, and there are no relics or monuments to tell of former greatness; like the ships which once floated in the harbour, all have passed away. Still, ruined and desolate as it is, to the eye of feeling the little fortress is not without its interest; for, as the governor told me, it was built by the heroic Saladin.

"Standing near the shore of this northern extremity of the Red Sea, I saw before me an immense sandy valley, which, without the aid of geological science, to the eye of common observation and reason had once been the bottom of a sea or the bed of a river. This dreary valley, extending far beyond the reach of the eye, had been partly explored by Burckhardt; sufficiently to ascertain and mention it in the latest geography of the country as the great valley of El Ghor, extending from the shores of the Elanitic Gulf to the southern extremity of the Lake Asphaltites or the Dead Sea; and it was manifest, by landmarks of Nature's own providing, that over that sandy plain those seas had once mingled their waters, or perhaps, more probably, that before the cities of the plain had been consumed by brimstone and fire, and Sodom and Gomorrah covered by a pestilential lake, the Jordan had here rolled its waters. The valley varied from four to eight miles in breadth, and on each side were high, dark, and barren mountains, bounding it like a wall. On the left were the mountains of Judea, and on the right those of Seir, the portion given to Esau as an inheritance; and among them, buried from the eyes of strangers, the approach to it known only to the wandering Bedouins, was the ancient capital of his kingdom, the excavated city of Petra, the cursed and blighted Edom of the Edomites. The land of Idumea lay before me, in barrenness and desolation; no trees grew in the valley, and no verdure on the mountain tops. All was bare, dreary, and desolate."

Pursuing a route through this dreary tract of wilderness, and on approaching Mount Hor, on the summit of which is a small sepulchral edifice, said to be erected over the tomb of Aaron, the traveller turns aside to the right, and, in the bosom of the mountains, reaches the ancient city of Petra, the Edom of the Edomites, now entirely deserted by human beings, but still presenting to the eye a most wonderful spectacle. It is a city whose houses and temples are cut out of the face of the solid rocks. Petra was the capital of the Edomites, and the centering point of commerce between the Red Sea and the higher part of Syria. Ultimately, it fell under the sway of the Romans, by whose architectural genius it was greatly enriched; its final destruction was only a part of the universal ruin which overtook the Syrian cities by the intrusion of barbarian hordes. Of its present aspect, "conceive (says Mr. Roberts, a late traveller) a town with the most noble mansions excavated in the face of perpendicular rocks, varying from five hundred to a thousand feet in height, and that to an extent of six or eight miles in all directions; the valleys or narrow ravines forming the streets, with lanes winding over from one to the other to the height I mention. The centre of the main valley had originally been occupied by houses built in the usual way, but repeated earthquakes levelled all in one common mass of ruin. There is now a city fortified by nature, such as never city was before or since, surrounded by mountains, the only passage of entrance through which is by a ravine so narrow that two camels can scarcely enter abreast. While the city was inhabited in ancient times, the hills around were cultivated to the very summit; there was a stream of delicious water flowing through it, and the population must have been immense." One of the most beautiful and perfect of the excavated edifices is that called the *Khasne Faraoun*, or Treasury of Pharaoh; an idea of its appearance, cut out in the face of a rocky precipice, may be obtained from the cut introduced at the commencement of the present sheet.

The secluded valley of Petra is now called by the Arabs Wady Moussa, or Valley of Moses, and, with its ruined city, forms one of the greatest wonders of the known world. On all sides are seen traces of a former period of opulence, refinement, and dense population. In a southern direction from Wady Moussa, is the valley of Sabra, which is a smaller Petra. M. Laborde, a late French traveller, thus speaks of it:—"We had scarcely proceeded an hour's distance down the rapid declivity of Wady Sabra, leading our dromedaries after us, when the

supporting walls, ruined buildings, and well-preserved [stone] benches of a theatre, attracted our attention. The ruins of Wady Sabra, as well as those of Wady Pabouchabe, indicate these places to have served as suburbs to the capital—the young swarms sent forth from the parent hive. Had we been enabled to explore the whole of the valleys in the neighbourhood of Wady Mousa, we should, doubtless, have found on all sides similar establishments, which the enormous population of Petra sustained." The prophecies respecting the cities of Mount Seir (Ezekiel, xxxv. 6), are here amply fulfilled. M. Laborde, in his journey along a rocky ridge towards the Red Sea, occasionally met with cultivated spots in this lone wilderness. "The wonderful fertility," he observes, "of these rare patches of earth, in the midst of a sterile country, seemed intended to remind us that one day that region had been happy, before a powerful hand had weighed so heavily upon it. There is to be found at Karek a species of bearded wheat, that justifies the text of the Bible against the charges of exaggeration of which it has been the object; and the vines also of this country, of the fruit of which we saw some specimens, account for the enormous grapes which the spies sent out by Moses brought back from the places they had visited." As the traveller approached the town of Ameimé, about half way between Petra and Akaba, he fell in with another object of art: "We observed with astonishment, as we pursued our way down the mountain, the ancient aqueduct which conveyed the water from the wells of Gana and Gaman to the town of Ameimé, which was built in the plain on the road from Petra or Aila. This aqueduct, extending beyond three leagues [nine miles], follows the level of the surface of the country, above which it never rises. It could only have been by attending most carefully to the undulations of the soil, and by a remarkable proficiency in the scientific operations for taking levels, that the projectors were enabled to succeed in preserving a regular descent for the waters over so great a distance.

The greater part of the remarkable objects of architecture seen at Petra and in this quarter, are obviously of an origin no earlier than the period of the Roman sway over the country, which was at the commencement of the Christian era. These, therefore, are not, in the main, the chief curiosities of the district. The most surprising objects are those remains of art which may have been produced several thousands of years before Christ, when the adjacent land of Egypt on the one side, and Babylonia on the other, were in all their glory. These remains are excavations in the rocks, of a style much more rude than the sculpturings of the Roman and Greek artists, some used for dwellings, and others simply inscriptions. One of the vales proceeding towards Petra in a direction from the Red Sea, is called Wady Mokatteb, or Valley of the Written Mountains, being inscribed with writing in an unknown tongue, in the form of carving, on the face of the precipitous rocks. An account of this remarkable curiosity of art and antiquity, is given by a Franciscan prior, who visited the spot in the course of a journey through the land in 1722. "These mountains," he says, "are called Gebel el Mokatteb, that is to say, the Written Mountains; for as soon as we quitted the mountains of Faran, we passed along others, during a whole hour [a length probably of three miles], which were covered with inscriptions in an unknown character, and carved in these hard rocks of marble, to a height which, in some places, was from ten to twelve feet above the surface of the ground; and although we had amongst us men who understood the Arabian, Greek, Hebrew, Syriac, Coptic, Latin, Armenian, Turkish, English, Illyrian, German, and Bohemian languages, there was not one of us who had the slightest knowledge of the characters engraved in these hard rocks with great labour, in a country where there is nothing to be had either to eat or drink. Hence, it is probable that these characters contain some profound secrets, which, long before the birth of Christ, were sculptured in these rocks by the Chaldeans or some other persons." The publication of this account, upwards of a century ago, excited considerable interest in Europe; and Pococke and Wortley Montague went to Arabia for the purpose of bringing home copies of the inscriptions, and this they accomplished to a certain extent. In 1762, the king of Denmark employed Niebuhr to explore Arabia, but especially to copy the inscriptions on Wady Mokatteb; subsequently other travellers brought copies to Europe, and some were published in the Transactions of the Royal Society in London; but till this day the inscriptions have baffled every attempt to decipher them. The figures composing the inscriptions are partly hieroglyphic, or representations of men and animals with letters, or what appear to be words interspersed. There can be little doubt that they are the oldest writings in the world: their antiquity and signification must be left entirely to the imagination of the reader.

ANCIENT HISTORY OF GREECE AND ROME.

HISTORY OF GREECE.

Ruins of a Grecian Temple.

Greece is a peninsula situated on the northern shore of the Mediterranean, between the Ionian and Ægean seas. It is a beautiful country of hills and valleys, like Wales or the Highlands of Scotland. Some of the hills are so high as to be constantly covered with snow. The vales or low districts enjoy a mild climate, and are of extreme fertility. Some of them, as Tempe and Arcadia, are spoken of with rapture by the poets of ancient times. As the country is much divided by hills and indentations of the sea, it was parted, from an early period, into several states, which were under separate governments, and often made war upon each other. The southern part of the peninsula, anciently styled the Peloponnesus, and now the Morea, was divided into Laconia (containing Sparta), Argolis, Achaia, Arcadia, Elis, and Messenia, each of which was only about the size of a moderate English county. Middle Greece (now Levadia), to the north of the Peloponnesus, and connected with it by the Isthmus of Corinth, on which lay the city of that name, contained Attica (in which was the city of Athens), Megaris, Bœotia (in which was the city of Thebes), Phocis, Locris, Doris, Ætolia, and Acarnania. Northern Greece contained Thessaly (now the district of Jannina), Epirus (now Albania), and Macedonia (now Filiba Vilajeti), the last of which did not, however, belong to Greece till a comparatively late period.

To the east of Greece-proper lay the numerous islands of the Ægean Sea, otherwise denominated the Archipelago; with which may be included certain islands lying in the Mediterranean Sea in the same direction, the principal of which were Rhodes, Cyprus, and the Cyclades. To the south lay Cythera (now Cerigo) and Crete (now Candia). To the west, in the Ionian Sea, lay Corcyra (now Corfu), Cephalonia, Ithaca, and others, now constituting the distinct confederacy of the Ionian Islands, under protection of Great Britain.

Besides having possession of these various districts on the mainland and islands on both sides of the peninsula, the Greeks, in the course of time, acquired colonies on the coast of Asia Minor, adjacent to the islands in the Ægean Sea. The principal of these foreign possessions was Ionia, a beautiful and fertile country, the chief city of which was Ephesus.

In consequence of Greece having been divided into a number of petty states, each of which maintained its own political independence, the history of the country necessarily assumes the character of a number of separate narratives. The Greeks, in the different states, did not consider themselves as constituting a single nation or people, although they were in some measure united by similarity of origin, dialect, religion, and manners. It was not, indeed, till a comparatively late period, that they had any name for the entire country; the name then assumed was Hellas. The term Grecia (Greece) was conferred by the Romans, and has since been generally used.

EARLY HISTORY AND MYTHOLOGY.

The history of the Grecian states commences above 1800 years before Christ, when the Egyptians on the opposite side of the Mediterranean were in a high state of civilization; but the portion of history which precedes 884 B. C. is understood to be fabulous, and entitled to little credit. From their situation in a region whose bays, headlands, and islands, present a great extent of sea-coast, habits of adventure and mutual intercourse were produced among the Greeks in the earliest times these had great influence in cherishing a national activity of character, and making each community eager to rival the prosperity of the others. The people were early accustomed to make voyages, sometimes for traffic, sometimes for war, between the opposite coasts of their gulfs, guiding themselves by the stars from island to island: and a curious proof both of their adventurous spirit, and of the difficulties they encountered in their attempts at navigation, is afforded by the tradition which exists in some old poems concerning one of these isles, called Delos, a huge pile of limestone rock, which was frequently used as a sea-mark in the Ægean: this island is said once to have floated about on the waves, and only to have been fixed in its place at last by Jupiter driving a stake through its centre. In the present age, we can understand by this poetical flight that the Greek canoemen sometimes lost their reckoning, and fell in with the island where they did not expect it.

The accounts given by the poets of this early period of Grecian history, abound in the most ridiculous legends, and these, notwithstanding their absurdity, formed the basis of the mythology or religious belief of the people. A set of imaginary beings, or, perhaps, in some instances, individuals remarkable for warlike genius, or skill in arts, whose names were handed down by tradition, were exalted to the character of gods, and through the medium of beautifully sculptured figures in marble and ivory, were the objects of reverence and worship. Of these various imaginery beings, Jupiter was reckoned the chief; he was believed to possess the sovereignty of heaven and earth. He is always represented as seated upon a throne, with thunderbolts

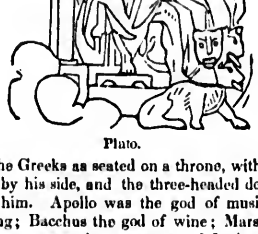
Jupiter.

in his right hand, and an eagle by his side. The wife of Jupiter was Juno, who is described as a beautiful goddess, and is usually depicted as seated in a chariot drawn by two peacocks.

Next in dignity to Jupiter was Neptune, the god of

Neptune.

the ocean, who is painted as a half-naked man, of majestic figure, with a crown on his head, and a trident, or three-pronged fork in his hand. A third principal deity was Pluto, the god of the infernal regions; he was repre-



Pluto.

sented by the Greeks as seated on a throne, with his wife Proserpine by his side, and the three-headed dog Cerberus before him. Apollo was the god of music, poetry and painting; Bacchus the god of wine; Mars the god of war; Mercury was the messenger of Jupiter, and the god of merchandise and thieving; Cupid the god of love; Minerva the goddess of wisdom; Diana the goddess of hunting; Ceres the goddess of grain or of agriculture; Hebe the goddess of youth; Vulcan the fabricator of Jupiter's thunderbolts, and the husband of Venus, the goddess of beauty. There were many other gods and goddesses, held more or less in reverence by the Greeks, and to whom worship was given at altars in the temples. There was also a belief in three vengeful females termed Furies, who were impersonations of Grief, Terror, and Madness; also three females of exceedingly elegant figure, termed the Graces, and whose names were Aglaia, Thalia, and Euphrosyne. The nine Muses, or patronesses of the fine arts, were Thalia, Melpomene, Calliope, Clio, Erato, Euterpe, Polyhymnia, Terpsichore, and Urania. They were supposed to reside upon Parnassus, a lofty mountain in the district of Phocis. Thalia presided over comedy; Melpomene over tragedy; Erato over amatory poetry; Polyhymnia over lyrical poetry; Calliope over heroic or epic poetry and eloquence; Clio over history; Euterpe over music; Terpsichore over dancing, and Urania over the study of astronomy. Besides all these imaginary beings, the mythology comprehended a class of demigods, as Dryads, or wood-nymphs; Satyrs, or rural deities; and Naiads, or water-nymphs.

The gods were supposed to communicate with men, and to reveal the secrets of futurity by means of oracles, several of which existed in various parts of Greece. The most celebrated of the Grecian oracles was that of Apollo at Delphi, a city built on the slope of Mount Parnassus. At a very remote period it had been discovered that from a deep cavern in the side of that mountain an intoxicating vapour issued, the effect of which was so powerful as to throw into convulsions both men and cattle who inhaled it. Of this natural wonder the priesthood readily availed themselves. A temple was reared over the spot, and a priestess, named the Pythoness, was appointed, whose office it was to inhale, at stated intervals, the holy vapour. In performing this dangerous office, the Pythoness was thrown into convulsions, during which she uttered frantic cries, and these being arranged by the attendant priests into sentences, were delivered to the people as the prophecies of the oracle, or god. Lest the oracle should be brought into discredit, care was in general taken by the priest to couch the response to any question put to the Pythoness, in language so obscure and enigmatical, that, whatever course the events should take, the prediction might not be falsified. The Greeks were so superstitious as to put implicit faith in this pretended system of prophecy, and the fame of the oracle of Delphi became so great that no enterprise was undertaken in any part of Greece without a consultation of the Pythoness.

There is probably some shadow of truth in a few of the alleged events of early Grecian history. Theseus, who lived in the thirteenth century before Christ, was said to have laid the foundation of the greatness of the state of Attica, by uniting its twelve cities, and giving them a common constitution. About his time occurred the celebrated *Argonautic Expedition*. This was undertaken by Jason, a prince of Thessaly, in a vessel named *Argo* (hence the name of the expedition); he sailed to Colchis, a place on the east coast of the Euxine or Black Sea, probably with the design of obtaining gold and silver, for which that country was remarkable. Among his companions was a chief named Hercules, a person of uncommon strength, and who afterwards was half deified by the Greeks. The poets say that Phryxus and Helle, the son and daughter of Athamas, king of Thebes, being compelled to quit their native country to avoid the cruelty of their stepmother, mounted on the back of a winged ram with a fleece of gold, and were carried by this wonderful animal through the air towards Colchis, where their uncle, named Æetes, was king. Unfortunately, as they were passing over the strait now called the Dardanelles, which connects the Ægean Sea with the Propontis, or Sea of Marmora, Helle became giddy, and, falling into the water, was drowned. From her, says the fable, the strait was in future named the Hellespont, or sea of Helle. When Phryxus arrived in Colchis, he sacrificed his winged ram to Jupiter, in acknowledgment of divine protection, and deposited its golden fleece in the same deity's temple. He then married the daughter of Æetes, but was afterwards murdered by that king, who wished to obtain possession of the golden fleece. To avenge Phryxus's death, Jason, who was his relation, undertook the expedition to Colchis, where, after performing several marvellous exploits, he not only obtained the golden fleece, but persuaded Medea, another daughter of King Æetes, to become his wife, and to accompany him back to Greece.

Seventy years after the Argonautic expedition, namely, about the year 1194 before Christ, the celebrated Trojan war was commenced. We learn the events connected with this war only through the two heroic poems of the Iliad and Odyssey, which are supposed to have been composed about the year 900 before Christ, by Homer, a blind man who wandered about the country singing his poems for a livelihood. The story is shortly as follows:—Tyndarus, a king of Lacedæmon, had a daughter Helen

of great beauty, whom Theseus, king of Athens, attempted, but without success, to steal from her father. The intelligence of this event rendered Helen famous, and many of the princes of Greece asked her in marriage. Tyndarus, however, allowed his daughter to make choice of a husband, and she pitched upon Menelaus; the successful suitor, on the death of Tyndarus, was raised to the Spartan throne. Shortly after this apparently happy union, Paris, a son of Priam, king of Troy, a small state in Asia Minor, came to reside at the court of Menelaus, and there perfidiously induced Helen to elope with him. Wroth at this baseness, Menelaus summoned various forces to his aid, and set out on a warlike expedition to Troy. Of the chiefs assembled on this occasion, the most celebrated were—Agamemnon, king of Mycenæ; Menelaus, king of Sparta; Ulysses, king of Ithaca, Nestor, king of Pylos; Achilles, son of the king of Thessaly; Ajax, of Salamis; Diomedes, of Ætolia; and Idomeneus, of Crete. The combined forces, on landing in the Trojan territory, commenced a regular siege of the city of Troy. Many skirmishes took place, and there was great slaughter on both sides: the Trojans were led generally in their attacks by the valiant Hector, the eldest son of Priam. At length, after a siege of ten years, Troy was taken, its inhabitants slaughtered, and its edifices burnt to the ground. The Greek princes, however, paid dearly for their triumph by subsequent sufferings, and the disorganization of their kingdoms at home. Ulysses, if we may believe Homer, spent ten years in wandering over seas and lands before arriving in his island of Ithaca; and others of the leaders died, or were shipwrecked, on their way home.

In the course of the eleventh century before Christ, the Greeks began to plant colonies in neighbouring countries. The first colonists, as usually happens in the present day, were dissatisfied citizens, who thought they could form happier communities elsewhere. The Æolians founded twelve cities in Asia Minor, the chief of which was Smyrna. The Dorians sent off colonies to Italy and Sicily, founding, in the former, Tarentum and Locri, and in the latter Agrigetum and Syracuse. In the new settlements, the political system was eminently democratic; and for a long time they enjoyed great prosperity. This prosperity being ascribed at home to their popular institutions, had afterwards the effect of inciting many of the parent states to change their monarchical for a democratic form of government.

SECOND OR AUTHENTIC PERIOD OF HISTORY.

The second and authentic period of Greek history commences in the year 884 B.C., at the institution of the Olympic festival, when the people had begun to emerge from their primitive barbarism. The Olympic festival was instituted by direction of the Delphic oracle, by Iphitus, prince of Elcia or Elis, for the patriotic purpose of assembling together, in a peaceful manner, persons from all parts of Greece. The festival was ordained to take place once every four years, in the month corresponding to our July, and to last five days, during which there was to be complete truce, or cessation from war, throughout the Grecian states. Agreeably to the ancient practice at public solemnities, the festival was celebrated by games and various feats of personal skill, and the whole order of procedure was regulated with extraordinary care. All freemen of Grecian extraction were invited to contend, provided they had been born in lawful wedlock and had lived untainted by any infamous moral stain. No women (the priestesses of Ceres excepted) were permitted to be present. Females who violated this law were thrown from a rock. The competitors prepared themselves during ten months previous at the gymnasium at Elis. During the last thirty days, the exercises were performed with as much regularity as at the games themselves. The festival began in the evening with solemn sacrifices, and the games were commenced the next day at daybreak. These consisted in races on horseback and on foot, in leaping, throwing the discus or quoit, wrestling, and boxing; musical and poetical contests concluded the whole. The honour of having gained a victory in the Olympic games was very great; it extended from the victor to his country, which was proud of owning him. However rude and boisterous were some of the sports of the Olympic festival, it is acknowledged by the best authorities that they were attended with manifold advantages to society. It is sufficient barely to mention the suspension of hostilities, which took place not only during the festival, but a considerable time both before and after it. Considered as a kind of religious ceremony, at which the whole Grecian citizens were invited, and even enjoined, to assist, it was well adapted to facilitate intercourse, to promote knowledge, to soften prejudice, and to hasten the progress of civilization and humanity. The date of the establishment of the Olympic games (884 B. C.) was afterwards assumed by the Greeks as the epoch from which they reckoned the progress of time, the four years intervening between each recurrence of the festival being styled an Olympiad.

At the first institution of the Olympic festival, and for one or two centuries afterwards, the condition of Grecian society was primitive and almost patriarchal, but marked by strong features of heroic dignity, and a certain depth and refinement of thought. The attire of the men was very simple, consisting only of a shirt or close jacket to the body, with a loose robe hanging down over the naked limbs, while performers in the public games were almost naked. The arts, including agriculture, were also little advanced; few persons seemed to have thought of toiling to accumulate wealth; and each community presented, in time of peace, the picture of a large family. That portion of the people constituting the freemen lived much in public, or in the society of their equals, enjoyed common pleasures and amusements, and had daily opportunities of displaying their useful talents in the sight of their fellow-citizens. The frequent disputes between individuals occasioned litigations and trials, which furnished employment for the eloquence and ability of men, in the necessary defence of their friends. The numerous games and public solemnities opened a continual source of entertainment, and habituated every man to active physical exercise and the performance of his duties as a soldier. These were agreeable features in the condition of Grecian society; but there were also some of a contrary kind. The people were of an unsettled disposition, never satisfied long with any kind of government which existed among them, and very much disposed to war against neighbouring states on the most trifling pretences.

The population of the various states was divided into three classes, namely, the citizens, the enfranchised populace, and the slaves. All political power, even in the most democratical of the Grecian communities, was possessed by the first of these classes, while in the oligarchical states only that small portion of the citizens which constituted the nobility or aristocracy, possessed any influence in the management of public affairs. The mechanical and agricultural labours necessary for the support and comfort of the whole, were chiefly performed by the inferior class of free inhabitants, who did not enjoy the privilege of citizenship, and by the slaves, who formed a considerable portion of the population of every state. These slaves were sprung from the same general or parent stock, spoke the same language, and professed the same religion, as their masters. They were, in most cases, the descendants of persons who had been conquered in war, but were in some instances acquired by purchase. Society being thus based on vicious principles, it is not wonderfu

that the Grecian states were the scene of constant civil broils.

Sparta—Lycurgus.

At the beginning of this period of Grecian history, our attention is powerfully attracted by a very remarkable series of proceedings which took place in Lacedæmon, or Laconia, a country in Southern Greece, of which the chief city was Sparta. This city being in a state of intestine disorder, it was agreed by many of the inhabitants to invite Lycurgus, the son of one of their late kings, to undertake the important task of preparing a new constitution for this country. Fortified with the sanction of the Delphic oracle, he commenced this difficult duty, not only settling the form of government but reforming the social institutions and manners of the people. The government he established consisted of two joint kings, with a limited prerogative, and who acted as presidents of a senate of twenty-eight aged men. The functions of the senate were deliberative as well as executive, but no law could be passed without receiving the consent of the assembled citizens. The most remarkable of the arrangements of Lycurgus, was his attempt to abolish difference of rank, and even difference of circumstances, among the people. He resolved on the bold measure of an equal division of lands, and actually parcelled out the Laconian territory into thirty-nine thousand lots, one of which was given to each citizen of Sparta, or free inhabitant of Laconia. Each of these lots was of such a size as barely sufficed to supply the wants of a single family, for Lycurgus was determined that no person should be placed in such circumstances as would permit of luxurious living.

Lycurgus carried into effect a number of other visionary projects: he abolished the use of money, with the hope of preventing undue accumulation of wealth; prohibited foreigners from entering the country, and the natives from going abroad, in order to preserve simplicity of manners among the people; directed that all men, without distinction of rank or age, should eat daily together at public tables, which were furnished with the plainest food; and, finally, ordained that all the children who were born, and seemed likely to be strong, should be reared by public nurses, under a rigid system of privation and personal activity, while the weak infants should be thrown out to the fields to perish. The citizens, when they had attained the age of manhood, were engaged in martial exercises, all labour being left to the slaves, or *helots*, as they were termed; and, in short, the whole nation was but a camp of soldiers, and war was reckoned the only legitimate profession. These laws were in some measure suited to the rude condition of the Spartans, but, as being opposed to some of the best and strongest principles in human nature, they could not possibly endure, and there is reason to believe that some of them were not strictly enforced. It is not unusual to see historians use the term *Spartan virtue* with a certain degree of admiration of its quality, but the Spartans had in reality no moral dignity, certainly no benevolence, in their virtue, either public or private. They were a small confederacy of well-trained soldiers, and, merely as such, deserve no mark of our respect or esteem. The manner in which they used their helots was at once barbarous and cruel. The murder of a serf by a free citizen was not punishable by law; nay it was even allowable for the young Spartans to lie in wait, as a kind of sport, for any good-looking or saucy-looking slave, and stab him to the heart on the highway. It is certain, that at one time, when the helots had stood their masters in good stead in battle, they were desired, by way of reward, to choose out 2000 of their best men, that they might receive their freedom, and be enrolled as Spartans, and that these 2000 men were all silently murdered soon after. At another time, when danger was apprehended from the growing numbers and petty wealth of the boors, the senate enacted the farce of declaring war against them, and coolly murdered many thousands, in order to thin their numbers and break their spirit. Had there been any redeeming trait in the Spartan character to compensate for such barbarity, one would have wondered less at the respect which is sometimes paid them; but their military fame only adds another instance to the many already on record, that the most ignorant and savage tribes make the most dogged soldiers.

Athens.

We now turn to Athens, the capital of Attica, and long the principal seat of Grecian learning and refinement. Athens is said to have been founded by Cecrops, 1550 B. C., and in the most ancient times was called Cecropia. It probably received the name of Athens from the goddess Minerva, who was called also Athena by the Greeks, and to whom an elegant temple had been erected in the city. The old city spread from the mount of the Acropolis over a wide and pleasant vale or low peninsula, formed by the junction of the Cephesus and Ilissus. Its distance from the sea-coast was about five miles. In the course of time, Athens became populous and surpassingly elegant in its architecture, while its citizens contrived to take a lead in the affairs of the communities around. At first they were governed by kings, but, as in the case of the Spartan citizens, they became dissatisfied with their existing constitution, and about the year 600 B. C. invited Solon, one of the wisest men in Greece, to reorganize their political constitution. Solon obeyed the summons, and constituted the government on a broad republican basis, with a council of state forming a judicial court, consisting of 400 members, and called the Areopagus. This court of Areopagus, besides its other duties, exercised a censorship over public morals, and was empowered to punish impiety, profligacy, and even idleness. To this court every citizen was bound to make an annual statement of his income, and the sources from which it was derived. The court was long regarded with very great respect, and the right was accorded to it of not only revising the sentences pronounced by the other criminal tribunals, but even of annulling the judicial decrees of the general assembly of the people. The regulations of Solon were not maintained for any great length of time, although the republican form of government, in one shape or other, continued as long as the country maintained its independence. Clesthenes, the leader of a party, enlarged the democratic principle in the state; he introduced the practice of *ostracism*, by which any person might be banished for ten years without being accused of any crime, if the Athenians apprehended that he had acquired too much influence, or harboured designs against the public liberty. This sentence was called ostracism, because the citizens, in voting for its infliction, wrote the name of the obnoxious individual upon a shell. It is said that Clesthenes was the first victim of his own law, as has chanced in several other remarkable cases.

For a period of about two centuries after the settlement of a republican constitution, there is little of importance to relate in Athenian history. Athens was gradually enlarged, the taste for refinement increased, and various men of sagacious understanding, entitled philosophers, began to devote themselves to inquiries into the nature of the human mind and the character of the Deity. The principal Grecian philosopher who flourished in this era (550 B. C.) was Pythagoras, a man of pure and exalted ideas, and an able expounder of the science of mind.

THIRD PERIOD OF HISTORY.

Persian Invasion.

The year 490 B. C. closes the gradually improving period in Grecian history, or second period, as it has

being armed; and now commenced an era marked by the important event of an invasion from a powerful Asiatic sovereign. Darius, King of Persia, having imagined the possibility of conquering Greece, sent an immense army against it in the year just mentioned. Greatly alarmed at the approach of such an enemy, the Athenians applied to the Spartans for aid; but that people had a superstition which prohibited their taking the field before the moon was at the full, and as, at the time of the application, it still wanted five days of that period, they therefore delayed the march of their troops. Being thus refused all assistance from their neighbours, the Athenians were left to depend entirely on their own courage and resources. A more remarkable instance of a small state endeavouring to oppose the wicked aggression of an overgrown power, has seldom occurred in ancient or modern times; but the constant exercises and training of the Athenian population enabled them to present a bold, and by no means contemptible, front to the invader. War had been their principal employment, and in the field they displayed their noblest qualities. They were unacquainted with those highly disciplined evolutions which give harmony and concert to numerous bodies of men; but what was wanting in skill they supplied by courage. The Athenian, and also other Greek soldiers, marched to the field in a deep phalanx, rushed impetuously to the attack, and bravely closed with their enemies. Each warrior was firmly opposed to his antagonist, and compelled by necessity to the same exertions of valour as if the fortune of the day depended on his single arm. The principal weapon was a spear, which, thrown by the nervous and well-directed vigour of a steady hand, often penetrated the firmest shields and bucklers. When they missed their aim, or when the stroke proved ineffectual through want of force, they drew their swords, and summoning their utmost resolution, darted impetuously on the foe. This mode of war was common to the soldiers and generals, the latter being as much distinguished in battle by their strength and courage as their skill and conduct. The Greeks had bows, slings, and darts, intended for the practice of distant hostility; but their chief dependence was on the spear and sword. Their defensive armour consisted of a bright helmet, adorned with plumes, and covering the

head, a strong corslet defending the breast, greaves of brass descending the leg to the feet, and an ample shield, loosely attached to the left shoulder and arm, which turned in all directions, and opposed its firm resistance to every hostile assault. With men thus organized and accoutred, a battle consisted of so many duels, and the combatants fought with all the keenness of personal resentment; the slaughter in such engagements was correspondingly great, the fight seldom terminating till one party was nearly destroyed, or at least greatly reduced in numbers.

It was a people so animated and prepared that the hosts of Persia were about to encounter. Compelled to meet the invaders unassisted, the Athenians were able to march an army of only 9000 men, exclusive of about as many light-armed slaves, into the field. With Miltiades as their leader and commander-in-chief, they met the Persians in battle on the plain of Marathon, thirty miles from Athens, and by great skill and courage, and the force of their close phalanx of spearmen, completely conquered them. Upwards of 6000 Persians were slain on the field, while the number killed of the Athenians was but 192. This is reckoned by historians one of the most important victories in ancient times, for it saved the independence of the whole of Greece. To the disgrace of the fickle Athenians, they afterwards showed the greatest ingratitude to Miltiades, and put him in prison on a charge of favouring the Persians. He died there, the year after his great victory. Soon after, the citizens of Athens, on a plea equally unfounded, banished Aristides, an able leader of the aristocratic party in the state, and who, from his strict integrity and wisdom, was usually entitled "Aristides the Just." On the banishment of this eminent individual, Themistocles, a person who was more democratic in his sentiments, became the leader of the councils of the Athenians. Meanwhile, the Grecian liberties were again menaced by the Persians. Xerxes, son of Darius, marched an army across the Hellespont by a bridge of boats from the Asiatic shore, and led it towards the southern part of Greece. The utmost force that the confederated Greeks could oppose to the countless host of Persians, did not exceed 60,000 men. Of these, a band of Spartans, numbering 8000 soldiers, under Leonidas their king, was posted at the pass of Thermopylæ, to intercept the enemy, and here they discomfited every successive column of the Persians as it entered the defile. Ultimately, foreseeing certain destruction, Leonidas commanded all to retire but three hundred, with whom he proposed to give the Persians some idea of what the Greeks could submit to for the sake of their country. He and his three hundred were cut off to a man. Xerxes took possession of Attica and Athens, but in the naval battle with the Athenian fleet at Salamis, which occurred soon after (October 20, 480 B.C.), his army was utterly routed, and its scattered remains retreated into Asia.

By this splendid victory, the naval power of Persia was almost annihilated, and the spirit of its monarch so completely humbled, that he durst no longer undertake offensive operations against Greece. Here, therefore, the war ought to have terminated; but so great and valuable had been the spoils obtained by the confederates, that they were unwilling to relinquish the profitable contest. The war, therefore, was continued for twenty years longer, less, apparently, for the chastisement of Persia than for the plunder of her conquered provinces.

But now that all danger was over, many of the smaller states, whose population was scanty, began to grow weary of the contest, and to furnish with reluctance their annual contingent of men to reinforce the allied fleet. It was, in consequence, arranged that those states whose citizens were unwilling to perform personal service, should send merely their proportion of vessels, and pay into the common treasury an annual subsidy, for the maintenance of the sailors with whom the Athenians undertook to man the fleet. The unforeseen but natural consequence of this was the establishment of the complete supremacy of Athens. The annual subsidies gradually assumed the character of a regular tribute, and were compulsorily levied as such; while the recusant communities, deprived of their fleets, which had been given up to the Athenians, were unable to offer effectual resistance to the oppressive exactions of the dominant state. The Athenians were thus raised to an unprecedented pitch of power and opulence, and enabled to adorn their city, to live in dignified idleness, and to enjoy a constant succession of the most costly public amusements, at the expense of the vanquished Persians, and of the scarcely more leniently treated communities of the dependent confederacy.

Pericles.

We have arrived at the most flourishing period of Athenian history, during which Pericles rose to distinction, and greatly contributed to the beautifying of the capital. The talents of Pericles were of the very first order, and they had been carefully cultivated by the ablest tutorage which Greece could afford. After serving for several years in the Athenian army, he ventured to take a part in the business of the popular assembly, and his powerful eloquence soon gained him an ascendency in the national councils; and his power, in fact, became as great as that of an absolute monarch. (445 B. C.) Some of the most interesting events of Grecian history now occurred. After a number of years of general peace, a dispute between the state of Corinth and its dependency, the island of Corcyra (now Corfu), gave rise to a war which again disturbed the repose of all the Grecian states. Corcyra was a colony of Corinth, but having, by its maritime skill and enterprise, raised itself to a higher pitch of opulence than its parent city, it not only refused to acknowledge Corinthian supremacy, but went to war with that state on a question respecting the government of Epidamnus, a colony which the Corcyreans had planted on the coast of Illyria. Corinth applied for and obtained aid from several of the Peloponnesian states to reduce the Corcyræans to subjection; while Corcyra, on the other hand, concluded a defensive alliance with Athens, which sent a fleet to assist the island in vindicating its independence. By way of punishing the Athenians for intermeddling in the quarrel, the Corinthians stirred up a revolt in Potidæa, a town of Chalcidice, near the confines of Macedonia, which had originally been a colony of Corinth, but was at this time a tributary of Athens. The Athenians immediately despatched a fleet and army for the reduction of Potidæa, and the Peloponnesians were equally prompt in sending succours to the city. The Corinthians, meanwhile, were actively engaged in endeavouring to enlist in their cause those states which had not yet taken a decided part in the dispute. To Lacedæmon, in particular, they sent ambassadors to complain of the conduct of the Athenians, which they characterized as a violation of a universally recognised law of Grecian policy, that no state should interfere between another and its dependencies. The efforts of the Corinthians were successful, and almost all the Peloponnesian states, headed by Sparta, together with many of those beyond the isthmus, formed themselves into a confederacy for the purpose of going to war with Athens. Argos and Achaia at first remained neuter. Corcyra, Acarnania, some of the cities of Thessaly, and those of Platæa and Naupactus, were all that took part with the Athenians.

Pericles beheld without dismay the gathering of the storm, but his countrymen were not equally undaunted. They perceived that they were about to be called upon to exchange the idle and luxurious life they were at present leading for one of hardship and danger, and they began to murmur against their political leader for involving them in so alarming a quarrel. They had not at first the courage to impeach Pericles himself, but vented their displeasure against his friends and favourites. Phidias, a very eminent sculptor, whom the great statesman had appointed superintendent of public buildings, was condemned to imprisonment on a frivolous charge; and the philosopher Anaxagoras, the preceptor and friend of Pericles, was charged with disseminating opinions subversive of the national religion, and banished from Athens. Respecting another celebrated individual who at this time fell under persecution, it becomes necessary to say a few words. Aspasia of Miletus was a woman of remarkable beauty and brilliant talents, but she wanted that chastity which is the greatest of feminine graces, and by her dissolute life was rendered a reproach, as she would otherwise have been an ornament, to her sex. This remarkable woman, having come to reside in Athens, attracted the notice of Pericles, who was so much fascinated by her beauty, wit, and eloquence, that, after separating from his wife, with whom he had lived unhappily, he married Aspasia. It was generally believed, that, for the gratification of a private grudge, she had instigated Pericles to quarrel with the Peloponnesian states, and her unpopularity on this score was the true cause of her being now accused, before the assembly of the people, of impiety and grossly immoral practices. Pericles conducted her defence in person, and plead for her with so much earnestness that he was moved even to tears. The people, either finding the accusations to be really unfounded, or unable to resist the eloquence of Pericles, acquitted Aspasia. His enemies next directed their attack against himself. They accused him of embezzling the public money; but he completely rebutted the charge, and proved that he had drawn his income from no other source than his private estate. His frugal and unostentatious style of living must have, of itself, gone far to convince the Athenians of the honesty with which he had administered the public affairs; for while he was filling the city with temples, porticos, and other magnificent works of art, and providing many costly entertainments for the people, his own domestic establishment was regulated with such strict attention to economy, that the members of his family complained of a parsimony which formed a marked contrast to the splendour in which many of the wealthy Athenians then lived.

Confirmed in his authority by this triumphant refutation of the slanders of his enemies, Pericles adopted the wisest measures for the public defence against the invasion which was threatened by the Peloponnesians. Unwilling to risk a battle with the Spartans, who were esteemed not less invincible by land than the Athenians were by sea, he caused the inhabitants of Attica to transport their cattle to Eubœa and the neighbouring islands, and to retire, with as much of their other property as they could take with them, within the walls of Athens. By his provident care the city was stored with provisions sufficient for the support of the multitudes which now crowded it; but greater difficulty was found in furnishing proper accommodation for so vast a population. Many found lodgings in the temples and other public edifices, or in the turrets on the city walls, and great numbers were obliged to construct for themselves temporary abodes in the vacant space within the long walls extending between the city and the port of Piræus.

The memorable contest of twenty-seven years' duration, called "the Peloponnesian war," now commenced (431 B. C.). The Spartan king, Archidamus, entered Attica at the head of a large army of the confederates, and meeting with no opposition, proceeded along its eastern coast, burning the towns and laying waste the country in his course. When the Athenians saw the enemy ravaging the country almost up to their gates, it required all the authority of Pericles to keep them within their fortifications. While the confederates were wasting Attica with fire and sword, the Athenian and Corcyræan fleets were, by the direction of Pericles, avenging the injury, by ravaging the almost defenceless coasts of the Peloponnesus. This, together with a scarcity of provisions, soon induced Archidamus to lead his army homewards. He retired by the western coast of Attica, continuing the work of devastation as he went along.

Early in the summer of the following year, the confederates returned to Attica, which they were again permitted to ravage at their pleasure, as Pericles still adhered to his cautious policy of confining his efforts to the defence of the capital. But an enemy far more terrible than the Peloponnesians attacked the unfortunate Athenians. A pestilence, supposed to have originated in Ethiopia, and which had gradually spread over Egypt and the

western parts of Asia, broke out in the town of Piræus, the inhabitants of which at first supposed their wells to have been poisoned. The disease rapidly advanced into Athens, where it carried off a great number of persons. It is described as having been a species of infectious fever, accompanied with many painful symptoms, and followed, in those who survived the first stages of the disease, by ulcerations of the bowels and limbs. Historians mention, as a proof of the singular virulence of this pestilence, that the birds of prey refused to touch the unburied bodies of its victims, and that all the dogs which fed upon the poisonous relics perished. The mortality was dreadful, and was, of course, greatly increased by the overcrowded state of the city. The prayers of the devout, and the skill of the physicians, were found equally unavailing to stop the progress of the disease, and the miserable Athenians, reduced to despair, believed themselves to be forgotten or hated by their gods. The sick were in many cases left unattended, and the bodies of the dead allowed to lie unburied, while those whom the plague had not yet reached, openly set at defiance all laws, human and divine, and rushed into every excess of criminal indulgence.

Pericles was in the mean time engaged, with a fleet of 150 ships, in wasting with fire and sword the shores of the Peloponnesus. At his return to Athens, finding that the enemy had hastily retired from Attica, through fear of the contagion of the plague, he despatched the fleet to the coast of Chalcidice, to assist the Athenian land forces who were still engaged in the siege of Potidæa—an unfortunate measure, productive of no other result than the communication of the pestilence to the besieging army, by which the majority of the troops were speedily swept away. Maddened by their sufferings, the Athenians now became loud in their murmurs against Pericles, whom they accused of having brought upon them at least a portion of their calamities, by involving them in the Peloponnesian war. An assembly of the people was held, in which Pericles entered upon a justification of his conduct, and exhorted them to courage and perseverance in defence of their independence. The hardships to which they had been exposed by the war, were, he observed, only such as he had in former addresses prepared them to expect; and as for the pestilence, it was a calamity which no human prudence could either have foreseen or averted. He reminded them that they still possessed a fleet which that of no potentate on earth could equal or cope with, and that, after the present evil should have passed away, their navy might yet enable them to acquire universal empire. "What we suffer from the gods," continued he, "we should bear with patience; what from our enemies, with manly firmness; and such were the maxims of our forefathers. From unshaken fortitude in misfortune has arisen the present power of this commonwealth, together with that glory, which, if our empire, according to the lot of all earthly things, decay, shall still survive to all posterity."

The eloquent harangue of Pericles diminished, but did not remove, the alarm and irritation of the Athenians, and they not only dismissed him from all his offices, but imposed upon him a heavy fine. Meanwhile, domestic afflictions were combining with political anxieties and mortifications to oppress the mind of this eminent man, for the members of his family were one by one perishing by the plague. Still, however, he bore himself up, with a fortitude which was witnessed with admiration by all around him; but at the funeral of the last of his children, his firmness at length gave way; and while he was, according to the custom of the country, placing a garland of flowers on the head of the corpse, he burst into loud lamentations, and shed a torrent of tears. It was not long till his mutable countrymen repented of their harshness towards him, and reinvested him with his civil and military authority. He soon after followed his children to the grave, falling, like them, a victim to the prevailing pestilence. (429 B. C.) The concurrent testimony of the ancient writers assigns to Pericles the first place among Grecian statesmen for wisdom and eloquence. Though ambitious of power, he was temperate in its exercise; and it is creditable to his memory, that, in an age and country so little scrupulous in the shedding of blood, his long administration was as merciful and mild as it was vigorous and effective. When constrained to make war, the constant study of this eminent statesman was how to overcome his enemies with the least possible destruction of life, as well on their side as on his own. It is related, that when he was lying at the point of death, and while those who surrounded him were recounting his great actions, he suddenly interrupted them by expressing his surprise that they should bestow so much praise on achievements in which he had been rivalled by many others, while they omitted to mention what was his highest and peculiar honour, namely, *that no act of his had ever caused any Athenian to put on mourning.*

After the death of Pericles, the war was continued without interruption for seven years longer, but with no very decisive advantage to either side. During this period the Athenian councils were chiefly directed by a coarse-minded and unprincipled demagogue, named Cleon, who was at last killed in battle under the walls of Amphipolis, a Macedonian city, of which the possession was disputed by the Athenians and Lacedæmonians. Cleon was succeeded in the direction of public affairs by Nicias, the leader of the aristocratical party, a man of virtuous but unenterprising character, and a military officer of moderate abilities. Under his auspices a peace for fifty years, commonly known by the name of the "peace of Nicias," was concluded in the tenth year of the war (421 B. C.) It was not long, however, till the contest was resumed. Offended that its allies had given up a contest undertaken for the assertion of its alleged rights, Corinth refused to be a party to the treaty of peace, and entered into a new quadruple alliance with Argos, Elis, and Mantinæa, a city of Arcadia; the ostensible object of which confederation was the defence of the Peloponnesian states against the aggressions of Athens and Sparta. This end seemed not difficult of attainment, as fresh distrusts had arisen between the two last-mentioned republics, on account of the reluctance felt and manifested by both to give up certain places which they had bound themselves by treaty mutually to surrender. The jealousies thus excited, were fanned into a violent flame by the artful measures of Alcibiades, a young Athenian, who now began to rise into political power, and whose genius and character subsequently exercised a strong influence upon the affairs of Athens.

Alcibiades.

Alcibiades was the son of Clinias, an Athenian of high rank. Endowed with uncommon beauty of person, and talents of the very highest order, he was, unfortunately, deficient in that unbending integrity, which is an essential element of every character truly great, and his violent passions sometimes impelled him to act in a manner which has brought disgrace on his memory. While still very young, Alcibiades served in the Athenian army, and became the companion and pupil of Socrates, one of the wisest and most virtuous of the Grecian sages. Having rendered some service to his country in a protracted and useless war with Lacedæmon, and being possessed of a talent for addressing the passions of the multitude, Alcibiades, as others had done before him, became the undisputed head of public affairs in Athens. But this pre-eminence was not of long continuance. An opinion arose among the people that he designed to subvert the constitution, and his fall was as quick as his promotion. Many of his friends were put

to death, and he, while absent on an expedition, deprived of his authority. Being thus left without a public director of affairs, Athens, as usual, was torn by internal discords; the aristocratic faction succeeded in overthrowing the democratical government (411 B. C.), and establishing a council of 400 individuals to administer the affairs of the state, with the power of convoking an assembly of 5000 of the principal citizens for advice and assistance in any emergency. These 400 tyrants, as they were popularly called, were no sooner invested with authority, than they annihilated every remaining portion of the free institutions of Athens. They behaved with the greatest insolence and severity towards the people, and endeavoured to confirm and perpetuate their usurped power, by raising a body of mercenary troops in the islands of the Ægean, for the purpose of overawing and enslaving their fellow-citizens. The Athenian army was at this period in the island of Samos, whither it had retired after an expedition against the revolted cities of Asia Minor. When intelligence arrived of the revolution in Athens, and the tyrannical proceedings of the oligarchical faction, the soldiers indignantly refused to obey the new government, and sent an invitation to Alcibiades to return among them, and assist in re-establishing the democratical constitution. He obeyed the call; and as soon as he arrived in Samos, the troops elected him their general. He then sent a message to Athens, commanding the 400 tyrants to divest themselves immediately of their unconstitutional authority, if they wished to avoid deposition and death at his hands.

This message reached Athens at a time of the greatest confusion and alarm. The 400 tyrants had quarrelled among themselves, and were about to appeal to the sword; the island of Eubœa, from which Athens had for some time been principally supplied with provisions, had revolted, and the fleet which had been sent to reduce it had been destroyed by the Lacedæmonians, so that the coasts of Attica, and the port of Athens itself, were now without defence. In these distressing circumstances, the people, roused to desperation, rose upon their oppressors, overturned the government of the 400, after an existence of only a few months, and re-established their ancient institutions. Alcibiades was now recalled; but before revisiting Athens, he was desirous of performing some brilliant military exploit, which might obliterate the recollection of his late connection with the Spartans, and give his return an air of triumph. He accordingly joined the Athenian fleet, then stationed at the entrance of the Hellespont, and soon obtained several important victories over the Lacedæmonians, both by sea and land. He then returned to Athens, where he was received with transports of joy. Chaplets of flowers were showered upon his head, and amidst the most enthusiastic acclamations he proceeded to the place of assembly, where he addressed the people in a speech of such eloquence and power, that, at its conclusion, a crown of gold was placed upon his brows, and he was invested with the supreme command of the Athenian forces, both naval and military. His forfeited property was restored, and the priests were directed to revoke the curses which had formerly been pronounced upon him.

This popularity of Alcibiades was not of long continuance. Many of the dependencies of Athens being in a state of insurrection, he assumed the command of an armament intended for their reduction. But circumstances arose which obliged him to leave the fleet for a short time in charge of one of his officers, named Antiochus, who, in despite of express orders to the contrary, gave battle to the Lacedæmonians during the absence of the commander-in-chief, and was defeated. When intelligence of this action reached Athens, a violent clamour was raised against Alcibiades; he was accused of having neglected his duty, and received a second dismissal from all his offices. On hearing of this, he quitted the fleet, and, retiring to a fortress he had built in the Chersonesus of Thrace, he collected around him a band of military adventurers, with whose assistance he carried on a predatory warfare against the neighbouring Thracian tribes.

Alcibiades did not long survive his second disgrace with his countrymen. Finding his Thracian residence insecure, on account of the increasing power of his Lacedæmonian enemies, he crossed the Hellespont and settled in Bithynia, a country on the Asiatic side of the Propontis. Being there attacked and plundered by the Thracians, he proceeded into Phrygia, and placed himself under the protection of Pharnabasus, the Persian satrap of that province. But even thither the unfortunate chief was followed by the unrelenting hatred of the Lacedæmonians, by whose directions he was privately and foully assassinated. Thus perished, about the fortieth year of his age (403 B. C.), one of the ablest men that Greece ever produced. Distinguished alike as a warrior, an orator, and a statesman, and in his nature noble and generous, Alcibiades would have been truly worthy of our admiration if he had possessed probity; but his want of principle, and his unruly passions, led him to commit many grievous errors, which contributed not a little to produce or aggravate those calamities which latterly overtook him.

DECLINE OF ATHENIAN INDEPENDENCE.

With Alcibiades perished the last of the great men who possessed the power to sway the wild democracy, or, properly speaking, the mob of Athens. From the period of his death till the subjugation of the country, the Athenian people were at the mercy of contending factions, and without a single settled principle of government. During this brief period of their history, in which a kind of popular democracy had attained the command of affairs, happened the trial and condemnation of Socrates, an eminent teacher of morals, and a man guiltless of every offence but that of disgracing, by his illustrious merit, the vices and follies of his contemporaries. On the false charge of corrupting the morals of the people who listened to his admirable expositions, and of denying the religion of his country, he was, to the eternal disgrace of the Athenians, compelled to die by drinking poison, a fate which he submitted to with a magnanimity which has rendered his name for ever celebrated. This odious transaction occurred in the year 400 B. C.

After the death of this great man, the political independence of Athens drew to its termination—a circumstance which cannot excite the least surprise, when we reflect on the turbulence of its citizens, their persecution of virtue and talent, and their unhappy distrust of any settled form of government. Their ruin was finally accomplished by their uncontrollable thirst for war, and can create no emotions of pity or regret in the reader of their distracted history. The Lacedæmonians, under the command of an able officer named Lysander, attacked and totally destroyed the Athenian fleet. By this means having obtained the undisputed command of the sea, Lysander easily reduced those cities on the coasts of Thrace and Asia Minor, and those islands of the Ægean which still acknowledged the supremacy of Athens. Having thus stripped that once lordly state of all its dependencies, he proceeded to blockade the city of Athens itself. The Athenians made a heroic defence; but after a lengthened siege, during which they suffered all the horrors of famine, they were obliged to surrender on such conditions as their enemies thought fit to impose. (404 B. C.) The Spartans demanded that the fortifications of Piræus, and the long walls which connected it with the city, should be demolished; that the Athenians should relinquish all pretensions to authority over their former tributaries, recall the exiled partisans of the 400 tyrants, acknowledge the supremacy of Sparta, and fol-

Thus sank the power of Athens, which had so long been the leading state of Greece, and thus terminated the Peloponnesian war, in which the Grecian communities had been so long engaged, to little other purpose than to waste the strength and exhaust the resources of their common country

Condition of Athens.

During the age preceding its fall, Athens, as already mentioned, had been greatly beautified and enlarged by Pericles. At the same time, the comparative simplicity of manners which formerly prevailed, was exchanged for luxurious habits. This alteration has been described by an able historian.* "In the course of a few years, the success of Aristides, Cimon, and Pericles, had tripled the revenues, and increased in a far greater proportion the dominions of the republic. The Athenian galleys commanded the eastern coasts of the Mediterranean; their merchantmen had engrossed the traffic of the adjacent countries; the magazines of Athens abounded with wood, metal, ebony, ivory, and all the materials of the useful as well as of the agreeable arts; they imported the luxuries of Italy, Sicily, Cyprus, Lydia, Pontus, and Peloponnesus; experience had improved their skill of working the silver mines of mount Laurium; they had lately opened the valuable marble veins in mount Pentelicus; the honey of Hymettus became important in domestic use and foreign traffic; the culture of their olives (oil being long their staple commodity, and the only production of Attica which Solon allowed them to export) must have improved with the general improvement of the country in arts and agriculture, especially under the active administration of Pericles, who liberally let loose the public treasure to encourage every species of industry.

"But if that minister promoted the love of action, he found it necessary at least to comply with, if not to excite, the extreme passion for pleasure, which then began to distinguish his countrymen. The people of Athens, successful in every enterprise against their foreign as well as domestic enemies, seemed entitled to reap the fruits of their dangers and victories. For the space of at least twelve years preceding the war of Peloponnesus, their city afforded a perpetual scene of triumph and festivity. Dramatic entertainments, to which they were passionately addicted, were no longer performed in slight condemned edifices, but in stone or marble theatres, erected at great expense, and embellished with the most precious productions of nature and of art. The treasury was opened, not only to supply the decorations of this favourite amusement, but to enable the poorer citizens to enjoy it, without incurring any private expense; and thus, at the cost of the state, or rather of its tributary allies and colonies, to feast and delight their ears and fancy with the combined charms of music and poetry. The pleasure of the eye was peculiarly consulted and gratified in the architecture of theatres and other ornamental buildings; for as Themistocles had strengthened, Pericles adorned, his native city; and unless the concurring testimony of antiquity was illustrated in the Parthenon, or Temple of Minerva, and other existing remains worthy to be immortal, it would be difficult to believe that in the space of a few years there could have been created those numerous yet inestimable wonders of art, those temples, theatres, statues, altars, baths, gymnasia, and porticoes, which, in the language of ancient panegyric, rendered Athens the eye and light of Greece.

"Pericles was blamed for thus decking one favourite city, like a vain voluptuous harlot, at the expense of hundered provinces; but it would have been fortunate for the Athenians if their extorted wealth had not been employed in more perishing, as well as more criminal, luxury. The pomp of religious solemnities, which were twice as numerous and costly in Athens as in any other city of Greece; the extravagance of entertainments and banquets, which on such occasions always followed the sacrifices; the increase of private luxury, which naturally accompanied this public profusion—exhausted the resources, without augmenting the glory, of the republic. Instead of the bread, herbs, and simple fare recommended by the laws of Solon, the Athenians, soon after the eightieth Olympiad, availed themselves of their extensive commerce to import the delicacies of distant countries, which were prepared with all the refinements of cookery. The wines of Cyprus were cooled with snow in summer; in winter, the most delightful flowers adorned the tables and persons of the wealthy Athenians. Nor was it sufficient to be crowned with roses, unless they were likewise anointed with the most precious perfumes. Parasites, dancers, and buffoons, were a usual appendage of every entertainment. Among the weaker sex, the passion for delicate birds, distinguished by their voice or plumage, was carried to such excess as merited the name of madness. The bodies of such youths as were not peculiarly addicted to hunting and horses, which began to be a prevailing taste, were corrupted by a lewd style of living; while their minds were still more polluted by the licentious philosophy of the sophists. It is unnecessary to crowd the picture, since it may be observed, in one word, that the vices and extravagances which are supposed to characterize the declining ages of Greece and Rome, took root in Athens during the administration of Pericles, the most splendid and most prosperous in the Grecian annals."

During this period flourished Æschylus and Sophocles, Euripides and Aristophanes, dramatists; Pindar, a lyrical poet; Herodotus and Thucydides, historians; Xenophanes, Heraclitus, Empedocles, Anaxagoras, and Socrates, philosophers (reasoners upon the nature of the human mind, and upon man's immortal destiny). In this period, also, under the administration of Pericles (from 458 to 429 B. C.), sculpture and architecture attained their perfection. It was then that Phidias executed those splendid works, statues of the gods and goddesses, which excited the admiration of the world, and which succeeding artists have in vain endeavoured to rival. While Athens had extended its power over a great part of the coasts of the Ægean Sea, and increased its trade and commerce by every available means, it had also become a city of palaces and temples, whose ruins continue to be the admiration of ages for their grandeur and beauty. It is understood that the Greeks had acquired their knowledge of architecture from the Egyptians, but they greatly excelled them in the elegance of their designs, and are in a great measure entitled to the character of inventors in the art. The beauty of the Corinthian pillar, for example, has never been excelled either in ancient or modern times. [See ARCHITECTURE.]

After the surrender of Athens to the Spartans (404 B. C.), the democratical constitution was abolished, and the government was intrusted to thirty persons, whose rapacious, oppressive, and bloody administration, ere long procured them the title of the Thirty Tyrants. The ascendency of these intruders was not, however, of long duration. Conon, assisted privately by the Persians, who were desirous of humiliating the Spartans, expelled the enemy, and re-established the independence of his country. Seventy years later, a new source of agitation throughout Greece was caused by the warlike projects of Alexander, king of Macedon, usually styled

Alexander the Great.

This intrepid and ambitious soldier was the son of Philip, king of Macedon, a small territory adjacent to

*History of Ancient Greece, by J. Gillies.

the Grecian states, from which it had originally received a knowledge of arts and learning. Alexander was born in the year 356 B. C., and by his father was committed to the charge of the philosopher Aristotle to be educated, a duty which was faithfully fulfilled. By the assassination of Philip, Alexander was called to the throne of Macedon while yet only twenty years of age, and immediately had an opportunity of displaying his great warlike abilities in conducting an expedition into Greece, which was attended with signal success, and procured for him the honour of succeeding his father as commander-in-chief of the Grecian states. He now carried out a design which had been formed by Philip, to subdue Persia and other countries in Asia. In the spring of 334 B. C., he crossed over to the Asiatic coast, with an army of 30,000 foot and 5000 horse, thus commencing the most important military enterprise which is narrated in the pages of ancient history. Alexander marched through Asia Minor, and in successive encounters completely conquered the armies of Persia; but the whole history of his progress is but an account of splendid victories. During a space of about seven or eight years, he conquered Persia, Assyria, Egypt, Babylonia, and, in fact, became master of nearly all the half-civilized countries in Asia and Africa. It does not appear that Alexander had any motive for this wide-spread overthrow of ancient and remote sovereignties, excepting that of simple ambition, or desire of conquest, with, perhaps, the indefinite idea of improving the social condition of the countries which he overran. From various circumstances in his career, it is apparent that he never contemplated the acquisition of wealth or of praise, except such as could be shared with his soldiers, for whom he displayed a most paternal affection. His character in this respect shines forth in a remarkable speech which he delivered to his army after these great conquests, and when some mutinous murmurs had broken forth in his camp. Mounting the tribunal, he spoke as follows:—"It is not my wish, Macedonians, to change your resolution. Return home, without hindrance from me. But, before leaving the camp, first learn to know your king and yourselves. My father Philip (for with him it is ever fit to begin) found you, at his arrival in Macedon, miserable and hopeless fugitives; covered with skins of sheep; feeding among the mountains some wretched herds which you had neither strength nor courage to defend against the Thracians, Illyrians, and Triballi. Having repelled the ravagers of your country, he brought you from the mountains to the plain, and taught you to confide, not in your fastnesses, but in your valour. By his wisdom and discipline, he trained you to arts and civility, enriched you with mines of gold, instructed you in navigation and commerce, and rendered you a terror to those nations at whose names you used to tremble. Need I mention his conquests in Upper Thrace, or those, still more valuable, in the maritime provinces of that country? Having opened the gates of Greece, he chastised the Phocians, reduced the Thessalians, and, while I shared the command, defeated and humbled the Athenians and Thebans, eternal foes to Macedon, to whom you had been successively tributaries, subjects, and slaves. But my father rendered you their masters; and having entered the Peloponnesus, and regulated at discretion the affairs of that peninsula, he was appointed, by universal consent, general of combined Greece; an appointment not more honourable to himself than glorious for his country. At my accession to the throne, I found a debt of five hundred talents, and scarcely sixty in the treasury. I contracted a fresh debt of eight hundred; and conducting you from Macedon, whose boundaries seemed unworthy to confine you, safely crossed the Hellespont, though the Persians then commanded the sea. By one victory, we gained Ionia, Æolia, both Phrygias, and Lydia. By our courage and activity, the provinces of Cilicia and Syria, the strength of Palestine, the antiquity of Egypt, and the renown of Persia, were added to your empire. Yours, now, are Bactria and Aria, the productions of India, the fertility of Assyria, the wealth of Susa, and the wonders of Babylon. You are generals, princes, satraps. What have I reserved for myself but this purple and diadem, which mark my pre-eminence in toil and danger? Where are my private treasures? Or why should I collect them? Are *my* pleasures expensive? You know that I fare worse than any of yourselves; and have in nothing spared my person. Let him, who dares, compare with me. Let him bare his breast, and I will bare mine. My body, the fore part of my body, is covered with honourable wounds from every sort of weapon. I often watch, that you may repose safely; and to testify my unremitting attention to your happiness, had determined to send home the aged and infirm among you, loaded with wealth and honour. But since you are all desirous to leave me, go! Report to your countrymen, that, unmindful of the signal bounty of your king, you intrusted him to the vanquished barbarians. The report, doubtless, will bespeak your gratitude and piety."

This impassioned and touching oration deeply affected the discontented soldiers, and all gladly returned to their allegiance. Shortly after this, the extraordinary career of Alexander was suddenly cut short by death. At Babylon, while engaged in extensive plans for the future, he became sick, and died in a few days, 323 B. C. Such was the end of this conqueror, in his thirty-second year, after a reign of twelve years and eight months. He left behind him an immense empire, which, possessing no consolidated power, and only loosely united by conquest, became the scene of continual wars. The generals of the Macedonian army respectively seized upon different portions of the empire, each trusting in his sword for an independent establishment. The greedy struggle for power finally terminated in confirming Ptolemy in the possession of Egypt; Seleucus in Upper Asia; Cassander in Macedon and Greece; while several of the provinces in Lower Asia fell to the share of Lysimachus.

CONCLUDING PERIOD OF GREEK HISTORY.

At the death of Alexander, the Athenians considered it a fit opportunity to emancipate themselves from the ascendency of Macedon, but without success. Demosthenes, one of the most eminent patriots and orators of Athens, on this occasion, to avoid being assassinated by order of Antipater, the Macedonian viceroy, killed himself by swallowing poison; and his compatriot Phocion was shortly afterwards put to death by his own countrymen, the Athenians, in a mad outbreak of popular fury. Greece cannot be said to have produced one great man after Phocion; and this deficiency of wise and able leaders was doubtless one chief cause of the insignificance into which the various states, great and small, sank after this epoch.

The ancient history of Greece, as an independent country, now draws to a close. Achaia, hitherto a small unimportant state, having begun to make some pretensions to political consequence, excited the enmity of Sparta, and was compelled to seek the protection of Philip, the ruling prince of Macedon. Philip took the field against the Spartans, and their allies the Ætolians, and was in a fair way of subjecting all Greece by arms and influence, when he ventured on the fatal step of commencing hostilities against the Romans. This measure consummated the ruin of Greece, as well as that of Macedon. The Romans warred with Philip to the end of his life (175 B. C.), and continued the contest with his son Perseus, whom they utterly defeated, and with whom ended the line of the kings of Macedon. In a few years, the once illustrious and free republics

Greece were converted into a Roman province under the name of Achaia (146 B. C.)

Thus terminates the fourth and last period of Greek history, during which there flourished several eminent writers and philosophers, among whom may be numbered Theocritus, a pastoral poet; Xenophon, Polybius, Diodorus Siculus, Dionysius Halicarnassus, Plutarch, and Herodian, historians; Demosthenes, an orator; and Plato, Aristotle, Zeno, and Epicurus, philosophers; also Zeuxis, Timanthes, Pamphilus, Nicias, Apelles, and Eupompus, painters; and Praxiteles, Polycletus, Camachus, Naucides, and Lysippus, sculptors.

In the condition of an humble dependency of Rome, and therefore following the fate of that empire, Greece remained for upwards of four succeeding centuries; but although of little political importance, it still retained its pre-eminence in learning. Enslaved as the land was, it continued to be the great school of the time. As Greece had formerly sent its knowledge and arts over the east by the arms of one of her own kings, she now diffused them over the western world under the protection of Rome. Athens, which was the emporium of Grecian learning and elegance, became the resort of all who were ambitious of excelling either in knowledge or the arts; statesmen went thither to improve themselves in eloquence; philosophers to learn the tenets of the sages of Greece; and artists to study models of excellence in building, statuary, or painting; natives of Greece were also found in all parts of the world, gaining an honourable subsistence by the superior knowledge of their country. That country, in the mean time, was less disturbed by intestine feuds than formerly, but was not exempt from the usual fate of conquests, being subject to the continual extortions of governors and lieutenants, who made the conquered provinces the means of repairing fortunes which had been broken by flattering the caprices of the populace at home.

The period of the independence of Greece, during which all those great deeds were performed which have attracted the attention of the world, may be reckoned from the era of the first Persian war to the conquest of Macedon, the last independent Greek state, by the Romans. This period, as we have seen, embraced little more than three hundred years. It is not, therefore, from the duration of the independent political power of the Grecian states that their celebrity arises. Even the patriotism of their soldiers, and the devoted heroism of Thermopylæ and Marathon, have been emulated elsewhere, without attracting much regard; and we must therefore conclude that it is chiefly from the superiority of its poets, philosophers, historians, and artists, that the importance of the country, in the eyes of modern men, arises. The political squabbles of the Athenians are forgotten; but the moral and intellectual researches of their philosophers, and the elegant remains of their artists, possess an undying fame.

We now turn to the history of the Romans, by whom the Grecian states were finally overpowered.

HISTORY OF ROME.

MONARCHY AND REPUBLIC.

About the time when Lycurgus was settling the institutions of Sparta, Italy was possessed by a set of tribes, some of which, from the traces of their language and arts which have been preserved, appear to have been of eastern origin, being probably colonies from Greece and Asia Minor. The Etrurians, who occupied modern Tuscany, were the most refined of these races. In the country of the Latins, more to the south, in the middle of the eighth century before Christ, a small settlement was formed on a hill near the Tiber, under the conduct, it is said, of a youthful leader named Romulus. A line drawn by the plough, after the fashion of the Etrurians, became the boundary of the town, which at first was composed of only a few huts, occupied by shepherds, freebooters, and other rude people. From Romulus, the name of Roma was conferred on the new city He became the king of the little state, and as such established certain laws and regulations for the general advantage. The lands, which extended several miles around the city, were divided into three portions, one for the support of government, another for the maintenance of religion, and a third for the people themselves, each person having about two acres. He constituted a senate of a hundred (afterwards two hundred) members, who were named *patres* (fathers), and whose descendants, under the name of patricians, or the equestrian order, formed the nobility of Rome. The senate prepared all measures; but these were ultimately deliberated on by the *plebs*, or bulk of the people, not through the medium of representatives, as in modern states, but by a general assembly held in the open air. At first, to increase the numbers of the people, all kinds of malefactors, who could get no settled footing elsewhere, were invited to the new city: it was then found that the male sex preponderated, and the deficiency was supplied by a stratagem, of a nature which marks a very rude state of society. The Sabines, a neighbouring people, were invited to witness the games at Rome; and while these were proceeding, the young men laid hands each on one of the young Sabine women, whom they carried off, and compelled to become their wives. The Sabines were enraged at this act, but the women themselves, when reconciled to their new situation, interposed to prevent bloodshed, and ultimately the transaction had the effect of uniting the Sabines with the Romans, and thus increasing the powers of the infant state. Such is the history usually given of the origin of Rome. A late German writer has shown reason for regarding it as in a great measure fabulous. He considers Romulus as a being little better than imaginary, and the laws and regulations bearing his name as having sprung up in the course of time, and all of them after the period when Romulus is represented as having lived.

The Roman people, from the earliest period of their history, bore a marked resemblance in religion, manners, and general pursuits, to the Greeks, from whom it is obvious that they drew their origin. They believed in the same imaginary deities, such as Jupiter, Neptune, Pluto, Mars, Venus, &c., besides a great number which, in the course of time, they added to this monstrous system of mythology. Like the Greeks, also, they dressed themselves in a simple manner, with a loose mantle, or toga, over a kind of kilt, which left the legs exposed. At the outset, their dependence was almost entirely on agriculture; but for the cultivation of the peaceful arts generally, they seem to have possessed no taste. War and plunder were their favourite pursuits, in which they far exceeded the Greeks, and almost all other nations of ancient or modern times. Their language, founded on the Greek, was that since known as the Latin, a term derived from Latium, the early name of the country in which Rome was situated.

Roman citizen.

During the early period of its history, the Roman government was monarchical, but restricted by a senate and popular assembly, and therefore favourable to social advancement. From Romulus is reckoned a series of seven kings, the ablest of whom, Servius Tullius, placed Rome at the head of the small states forming what has been

called the Latin confederacy, and considerably improved the municipal institutions of the kingdom. The last of the seven kings of Rome was Tarquinius, surnamed the Proud. His son Sextus having committed an atrocious act of violence on Lucretia, the wife of Collatinus, she, unable to survive the dishonour, killed herself. By this transaction, the disgust of the people with their royal family, and with monarchy in general, was brought to a head; and under a noble Roman named Brutus, they rose and expelled Tarquinius, with all his family. Thus ended the regal power in Rome, in the year before Christ 509.

THE REPUBLIC.

The monarchy was succeeded by a republic, in which the chief legislative authority rested with the senate, and the liberties of the people were very little improved. The executive was committed to two magistrates of equal authority, named *consuls*, who were chosen annually. Brutus, who had distinguished himself in expelling the royal family, was chosen one of the two first consuls. During the time he held office, his two sons joined in a conspiracy to restore Tarquin, and Brutus, with a disregard of his own affections, which was considered a great virtue in Greece and Rome when the public interest was concerned, condemned them both to be beheaded in his presence.

The early years of the republic were marked by great struggles between the patrician, or noble order, and the common people. The vigour and perseverance with which the latter sought to emancipate themselves from the authority of the former, compose a striking picture in ancient history, and convey the impression that there were here elements of character superior to what existed at the time in any other nation besides the Greeks. It would be wearisome, however, to detail the various contentions. From the beginning, the plebeians showed a tendency to acquire the mastery. By "the Valerian law," they acquired the right of giving a final judgment on any person condemned by a magistrate. Their importance in composing armies also helped to give them influence. By seizing an opportunity when the patricians were in difficulties from foreign aggression (492 B. C.), they obtained the right of appointing *tribunes* (at first five in number, afterwards ten), who had the power of suspending the decrees of the senate and the sentences of the consul, and had a general charge over the interests of the common people. The power enjoyed by the plebeians at this time is marked by their causing the celebrated Coriolanus to be sent into banishment, his splendid military services being insufficient to atone for his openly espousing the cause of the patricians, and expressing contempt for the people. By the "law of Volero," which gave the people the right of assembling in comitia, and there discussing public affairs, without the decree of the senate—a measure equivalent to parliament assembling with the king's writ—the government of Rome became essentially democratic. (471 B. C.)

As yet the Romans had had no written law. The kings, and after them the consuls, had administered justice each according to his own sense. In the year 451 B. C., at the suggestion of a tribune named Tertullian, ten men (*decemviri*) were appointed to frame and digest a code of laws for the explanation and security of the rights of all orders of the state. The result was the formation of what have been called the *Twelve Tables of the Roman law*, to learn which by heart was a part of liberal education in ancient Rome.

On the appointment of the decemviri, the consuls were discontinued. Each of the ten men acted as supreme magistrate for a day, the nine other officiating as judges. They did not, however, remain long in authority. One of the number, named Appius Claudius, having formed a base design against a maiden named Virginia, daughter of Virginius, a centurion, and affianced to Icilius, caused her to be claimed as his slave, and, as decemviri, gave judgment in his own favour. When Virginius saw his daughter about to be sacrificed to a profligate monster, he seized a knife from a butcher's stall in the Forum, and stabbed her to the heart. The people rose in fury against Appius, who escaped for the time, but at length only avoided punishment by committing suicide. This event caused the abolition of the decemvirate, after it had lasted only three years. The consuls and tribunes were then restored.

The violent struggles of the patricians and plebeians did not prevent Rome from gradually acquiring an ascendency among the Italian states. The armies of Rome, unlike all others in those early times, were standing armies: the soldiers had regular pay, and made arms a profession. Their compact and well-organized force, meeting in general only ill-disciplined militia, carried every thing before it.* Veii, a state which had long defied and rivalled them, fell before their general Camillus. (396 B.C.) In 385 B. C., they finally reduced the Gauls, a powerful branch of the Celtic race inhabiting the north of Italy. They then fought and subdued the Samnites. Other states fell beneath their powerful arms, and in the year 274 B. C., they had acquired the complete mastery of all Italy.

Wars with Carthage.

A splendid victory which they had gained near the close of the Italian wars over Pyrrhus, king of Epirus, who had come to aid the Samnites, led the Romans to believe that they might extend their conquests to countries beyond Italy. Sicily, originally a Greek colony, was at this time important for the great quantities of grain produced in it. The Carthaginians, an enterprising commercial people, occupying a tract of country in the north of Africa, were anxious to obtain possession of this island; but the Romans were inclined to dispute the prize. They fitted out a fleet, the first they ever had, and sent a large force to aid the Sicilians, who were friendly to them, in expelling the Carthaginians. Agrigentum, a great city in Sicily, was taken, after a long siege, by the joint forces of Rome and Syracuse; and the Roman fleet gained a complete victory over that of Carthage. (260 B. C.) These successes were followed by the reduction of Corsica and Sardinia. The Roman fleet then sailed against Carthage itself; the Carthaginians were at first about to submit, but, inspirited by a timely aid from Greece, they made a strong effort to repel the Roman army, in which they were successful, at the same time taking Regulus, the Roman commander, a prisoner. Some time afterwards, when repeated defeats in Sicily made them desirous of peace, they allowed Regulus to go to Rome to help in negotiating it, under a solemn promise to return if the treaty should fail. It was rejected, at the urgent desire of Regulus himself, as discreditable to Rome, and he then deliberately returned to surrender his life to the enraged Carthaginians. After some further successes on the part of the Romans, the Carthaginians submitted to a humiliating

* The Roman army, in its present state, included infantry and cavalry. The heavy-armed infantry, which was its principal strength, was divided into ten cohorts and fifty-five companies, under the orders of a corresponding number of tribunes and centurions. The first cohort, which always claimed the post of honour and the custody of the eagle, was formed of 1105 soldiers, the most approved for valour and fidelity. The remaining nine cohorts consisted each of 555; and the whole body of the legion amounted to 6100 men. Their arms were uniform, and admirably adapted to the nature of their service; an open iron helmet, with a lofty crest; a breast-plate, or coat of mail; greaves on their legs; and an ample buckler on their left arm. Besides a lighter spear, the legionary soldier grasped in his right hand a formidable javelin which he threw at his foe at the distance of ten or twelve paces. As soon as it was darted, he drew his sword, and rushed forwards to close with the enemy. His sword was a short well-tempered blade, that carried a double edge, and was alike suited to the purpose of striking or pushing. It was by this short sword, which was little more than double the length of our modern table-knives, that the Romans conquered the world. The legion was usually drawn up eight deep, and the regular distance of three feet was left between the files, as well as ranks. The legions entrenched themselves in a camp every regular form every night while out on duty, and the remains of these square earthen ramparts are still observable in Britain and most other countries they visited.

peace (241 B. C.), surrendering Sicily, and agreeing to pay a large sum of money. Sicily, excepting the kingdom of Syracuse, now became a province of Rome, being the first out of Italy which she acquired.

Twenty-three years of peace recruited the power of Carthage, and enabled her to renew hostilities with Rome. Under the celebrated Hannibal, a large army proceeded through Spain and Gaul, crossed the Alps, and descended on the plains of Italy. The Romans lost four battles in succession, the last being that of Cannæ, in which 40,000 of their soldiers, and nearly the whole of their knights (or soldiers of the patrician order), are said to have fallen. If Hannibal had instantly marched to Rome, it is believed that he would have gained possession of it, and probably given a new turn to the world's history. He deliberated, and the Romans had time to concentrate all their remaining strength against him. Under their general, Fabius, they pursued a policy which has since become proverbial, avoiding battle, and exhausting the enemy's strength by delay. The war ended (202 B. C.) by their gaining Syracuse, reducing Spain, and taking from Carthage her prisoners, her fleet, and a vast sum of money.

A third war with Carthage, springing expressly from the ambition of the Roman people, began in the year 149 B. C., and ended, three years after, in the complete destruction of that city and people. Carthage was so thoroughly destroyed, that its very site is now matter of uncertainty. In consequence of this success, a large part of northern Africa became tributary to Rome.

Some years before, the Romans had carried their arms into Greece and Asia Minor. Macedonia, whose kings had not long before conquered Persia, India, and Egypt, became tributary to Rome, and Lesser Asia became one of her provinces. The same year in which the Romans destroyed Carthage, saw Greece subjected to them. Thus, in less than a century, they had conquered the greater number of the countries lying around their own comparatively small state.

Insurrection of the Gracchi.

These triumphs were not an unmixed good. The people were intoxicated with success. Vast wealth, arising from spoil, but accumulated chiefly in the hands of the nobility, led to great luxury, and furnished the means of corrupting the people. The overgrown estates and power of the senators produced great discontent, at the same time that it made the citizens venal. At this time (130 B. C.) arose Tiberius and Caius Gracchus, two noble youths, whose zeal to reform the growing corruptions of the state precipitated them at length into measures destructive of all government and social order. Tiberius, the elder brother, urged the people to assert, by force, the revival of an ancient law, limiting property in land, and thus abridging the estates of the patricians. A tumult was the consequence, in which Tiberius and 300 of his friends were killed in the Forum. Caius Gracchus then took up the cause of the people, and, notwithstanding every opposition, was enabled to abridge the power of the senate, to protect the people from monopolists in corn, and extend the rights of Roman citizenship. Employing, like his brother, the dangerous engine of tumultuary force, he fell a victim to it himself, with 3000 of his partisans, who were slaughtered in the streets of Rome. The tumults attending the sedition of the Gracchi were the prelude to those civil disorders which now followed in quick succession to the end of the commonwealth.

It may here be remarked, that Roman liberty, of which we hear so much, rather refers to the resistance which was offered to monarchical and aristocratic rule in the early days of Rome, than to the actual condition of the people as individuals at any period. With much liberty as to public and national matters, there was a great deal of domestic restraint. Slaves, the prisoners taken in battle, or the descendants of such, formed one half of the population of Rome. This portion of the inhabitants had no political rights whatever: their civil rights were so much curtailed, that they could contract no legitimate marriage, were not admitted to give evidence in law, and could not bequeath their property; they might be flogged, and even put to death, at the pleasure of their masters. It was not mere labourers who were in this condition, but clerks, overseers, and persons acquainted with literature. Even among those nominally free, and who had the right of citizenship, all who were not themselves rich were obliged to attach themselves to some nobleman, or *patrician*, as their protector, and were called *his clients*. Without the powerful influence of such a person to enforce his rights, a Roman citizen would have been excommunicated and defenceless. The tie between a patron and his clients in Rome was as close, and as little flattering to the inferior party, as that between a chieftain and his clansman in more recent times. The rich men kept the poorer citizens in pay, and almost in subsistence, for the sake of their votes in the public assemblies; hence this class lost their habits of industry, and, being content to live in miserable dependence on the largesses of the wealthy and ambitious, became idle and dissipated, less respectable even than the slaves. There was a general caressing of the populace by all who expected to be candidates; shows, entertainments, distributions of corn, were continually proposed or offered by one or other, to keep them in good humour; and a particular system of bribery was practised when the elections came to be decided. Hence Cicero calls the people (*plebs urbana*) "the scum and dirt of the town," "the abandoned mob," "lean miserable leeches;" and all this arose from an humble and inconsiderable class of people having votes to sell, which it became the interest of the rich to buy. The slaves, and freedmen, who formed by far the most numerous part of the working people, had of course no votes; and being maintained and cherished only in proportion to their industry and talents, were many of them a confidential and esteemed class among wealthy people in Rome; while the citizens who had hereditary rights were fed and despised.

Sylla—Pompey—Cæsar.

In the proportion in which Rome became a military state, its commanders acquired a dangerous influence in its affairs. Sylla and Marius, two of these commanders, were rivals in the desire of power. The former, while commanding in a war against Mithridates, king of Pontus, was superseded and recalled from Asia. He refused to obey the mandate, and, finding his army disposed to support him, he led it to Rome, expelled Marius and all his partisans, and for a time reigned triumphant. The desolate condition of the exiled Marius, sitting amongst the ruins of Carthage, is often alluded to. After Sylla had returned to pursue the war with Mithridates, his rival, recovering strength, once more acquired an ascendency in Rome, but was suddenly cut off in a fit of debauch. Sylla, now victorious in Asia, returned to Italy, and, being joined by Verres, Cethegus, and the young Pompey, gave battle to the party of his enemies, and entirely defeated them. His entry into Rome was signalized by a dreadful massacre, and a proscription, which had for its object the extermination of every enemy whom he had in Italy. Elected *dictator*, with the unlimited authority attached to that office (one of occasional creation), he acted with a degree of conscientiousness that could scarcely have been expected from one who had shed so much blood. He restored the senate to its judicial authority, regulated the election to all the important offices of the state, and enacted many excellent laws against oppression and the abuse of power. He then voluntarily resigned his dictatorship, and, retiring to the condition of a private citizen, offered publicly to give an account of his conduct. Not long after, he died of the effects of debauchery. Sylla may be reckoned

remarkable example of that union of great vices with noble points of character, which marks a time of semi-civilization. Before the close of Sylla's career, Julius Cæsar, a young man of high birth and great talents, was rising into notice. The chief power in the state was divided between Pompey and Crassus; when Cæsar, by a master-stroke of policy, caused himself to be associated with them in what was called a Triumvirate, or government of three persons. He now subdued Transalpine Gaul (including the present Belgium and France), and, passing over to Britain (54 B.C.), also reduced the people of that country, which the Romans considered as one of the remotest corners of the earth. By the death of Crassus, Cæsar and Pompey were left sole rivals for power. The high military reputation of Cæsar gave him great popular influence, but Pompey was befriended by the consuls and a majority of the senate. A decree was passed, forbidding Cæsar to pass, with his army, the brook Rubicon, which divided Gaul from Italy: he nevertheless did cross the stream and advance to Rome, of which he immediately gained the mastery, Pompey retiring into Greece. Cæsar, marching into Spain, overthrew Pompey's lieutenants there, and at his return found he had been declared dictator. Then, learning that Pompey had raised a large army in Illyria, he marched thither, and, at the decisive battle of Pharsalia, extinguished the hopes of his rival. (49 B.C.) Pompey, who had divided the empire of the civilized world, fled as a dispirited and powerless fugitive to seek the assistance and hospitality of Ptolemy and Cleopatra, in Egypt, but was barbarously murdered the instant he stepped on shore. From the death of Pompey is to be dated the total overthrow of the Roman republic. The corruptions of the state had become too great to admit of any other cure than that of an absolute government. From this period, therefore, the senate and democratic bodies were dispossessed of all power, and Rome was never without a master.

THE EMPIRE.

Condition of the nation.

At the period when the commonwealth passed into the hands of an absolute monarch, the Romans had attained the height of their power. Directing their main energies to military conquest, they had enjoyed some centuries of glory, with every kind of plunder which the conquered countries could produce. Every district in Europe, Asia, and Africa, lying within reach of the Roman legions, had become tributary to Rome. At this period, the nation reckoned about 7,000,000 of citizens, with twice as many provincials, besides as many slaves. From being an obscure town, Rome had become a wide-spread city, and was adorned with majestic temples, public edifices and palaces. Other towns in Italy also rose into importance, and became the residence of distinguished Roman citizens. The public monuments of this remarkable people were placed, not only in the capital, but all over the provinces; and some of them are till this day reckoned among the greatest wonders of art. But the stupendous character of their undertakings was chiefly seen in their roads. All the cities of the empire were connected with each other, and with the capital, by public highways, which, issuing in various directions from the Forum—or great central place of public assembly—of Rome, traversed Italy, pervaded the provinces, and were terminated only by the frontiers of the empire. On the north-west, the boundary of this extensive empire was the wall of Antoninus, built betwixt the Firths of Clyde and Forth, in Scotland, and on the south-east it was the ancient city of Jerusalem. If the distance between these two points be carefully traced, it will be found that the great chain of communication was drawn out to the length of 4080 Roman miles, or 3740 English measure. "The public roads (says Gibbon) were accurately divided by mile-stones, and ran in a direct line from one city to another, with very little respect for the obstacles either of nature or private property. Mountains were perforated, and bold arches thrown over the broadest and most rapid streams. The middle part of the road was raised into a terrace, which commanded the adjacent country, consisted of several strata of sand, gravel, and cement, and was paved with large stones, or, in some places near the capital, with granite. Such was the solid construction of the Roman highways, whose firmness has not entirely yielded to the effort of fifteen centuries. They united the subjects of the most distant provinces by an easy and familiar intercourse; but their primary object had been to facilitate the marches of the legions: nor was any country considered as completely subdued, till it had been rendered, in all its parts, pervious to the arms of the conqueror. The advantage of receiving the earliest intelligence, and of conveying their orders with celerity, induced the emperors to establish, throughout their extensive dominions, the regular institution of posts. Houses were everywhere erected at the distance of only five or six miles; each of them was constantly provided with forty horses, and, by the help of these relays, it was easy to travel 100 miles in a day along the Roman roads." By these means the Romans maintained their ascendency in every country, and diffused through the whole empire the improvements of social life. There was thus a nobleness and grandeur in various circumstances connected with the Roman sway, which by a moderate, firm, and enlightened system of government, might have ultimately proved of the greatest importance in the social advancement of mankind. It was most unfortunate, however, both for this sacred cause and for the welfare of the Roman people themselves, that the plan of enriching the commonwealth at the seat of power, consisted almost exclusively in robbing foreign territories—a plan which it is impossible ever can permanently exist in any country, whatever be its power. Besides, with all the encouragement given to the fine arts, such as architecture, sculpture, and the production of luxuries, there was no substantial industry or commerce, and no means were taken to enlighten and refine the community, by science, literature, or morals. The whole fabric of Roman greatness, in fact, rested on no sure foundation, and its gradual decline and fall, from the extinction of the republic, cannot excite the smallest degree of surprise.

Julius Cæsar.

The successes of Cæsar placed him at the head of the Roman world. His only remaining opponent was Cato, who has been described as one of the most faultless characters in Roman history. This eminent patriot was, however, unable, by force of arms, to restore the liberties of the people, or to arrest Cæsar in his victorious and ambitious career. Being at last deserted by his friends, and dreading to fall into the hands of his enemy, after pondering a while on the nature of the immortality of the soul, he stabbed himself with his own sword—an act which Roman morality held as perfectly justifiable, and which was committed by many of the first characters of the state, when they happened to be deserted by fortune. After the death of Cato, Cæsar was without a rival. Returning to Rome in triumph, he established his power as dictator, and shortly afterwards received the title of *imperator*, or emperor, with full powers of sovereignty. The assumption of these dignities, as may be supposed, served to unite the friends of the republican form of government, or at least all who had thriven on the diseases of the state, with the view of making away with the usurper. A deep-laid conspiracy was accordingly formed against Cæsar, composed of sixty senators, at the head of whom was Decimus Brutus, whose life Cæsar had spared after the battle of Pharsalia, and Cassius, who was pardoned soon after. Cæsar was privately made acquainted with the existence of plots against his life

but, being of a fearless disposition, he proceeded, on the day intended for the fatal blow, to the senate-house. Here, by a preconcerted signal, he was stabbed behind in the shoulder by Casca. All the conspirators now rushed forward, and he received a second stab in the breast, while Cassius wounded him in the face. In this emergency, he defended himself with great vigour, rushing among them, and throwing down such as opposed him, till he saw Brutus among the conspirators, who, coming up, struck his dagger into his thigh. From that moment, Cæsar thought no more of defending himself, but looking upon the ungrateful assailant, cried out, "And you too, Brutus!" Then, covering his head, and spreading his robe before him, in order to fall with a greater decency, he sank down at the base of Pompey's statue, after receiving twenty-three wounds from hands which he vainly supposed he had disarmed by his benefits. Thus died this remarkable man, the best who ever aspired to sovereignty in Rome, the victor in five hundred battles, and the conqueror of a thousand cities, in the fifty-sixth year of his age, (44 B. C.)

Upon the death of Cæsar, the conspirators were unable to form a government, or to inspire confidence in their designs; and in the distractions which ensued, Mark Antony, an ambitious man and formerly a lieutenant of Cæsar, endeavoured to raise himself to the supreme command. In this effort he was not successful. Octavius grand-nephew and adopted son of Cæsar, also came forward as a candidate for power; and so likewise did a third personage, named Lepidus. As no one of these ambitious men possessed sufficient force to attain supreme command, they entered into a coalition, forming a tripartite power, termed a triumvirate. Being opposed by Brutus, a dreadful civil war ensued, the atrocities of which are scarcely paralleled in history. Brutus was ultimately killed, after which event the triumvirate quarrelled among themselves, and Octavius, by force of arms, becoming conqueror, attained the dignity of emperor of Rome.

Julius Cæsar's successors.

On arriving at this proud eminence, Octavius, now called Augustus Cæsar,* relinquished the ambitious designs of his predecessors; he endeavoured to consolidate the empire, instead of extending it to undue bounds, and introduced a spirit of moderation into the public councils hitherto unknown. Knowing the taste of the Romans, he indulged them in the pride of seeing the appearance of a republic, while he made them really happy in the effects of a most absolute monarchy, guided by the most consummate prudence. Historians delight in recounting the number of good deeds of Augustus, and the glories of his time; and from him the phrase of "the Augustan age," applied by writers to periods in the history of nations remarkable for the prosperity and refinement which prevailed, has been derived. It was in the twenty-fifth year of the reign of this magnanimous prince that Jesus Christ was born, in the Roman province of Judea. In the year 14 of our era, Augustus was succeeded by Tiberius, a person of an entirely different character, and under whom the corruptions of the state became very great. In the nineteenth year of his cruel reign, Christ was crucified, under Pontius Pilate, the Roman governor of Jerusalem. In the year 37, Tiberius was put to death, by smothering him with pillows, or, as some historians allege, by poison; and he was succeeded by Caligula, a person of vicious habits and still more cruel character. This emperor was prodigal and extravagant to a degree almost inconceivable. The luxuries of former emperors were simplicity itself when compared to those which he practised. He contrived new ways of bathing, where the richest oils and most precious perfumes were used with the utmost profusion. He found out dishes of immense value, and had even jewels, we are told, dissolved among his sauces. He sometimes had services of pure gold presented before his guests instead of meat. But his prodigality was the most remarkable in regard to his horse. He built for it a stable of marble, and a manger of ivory. Whenever this animal, which he called Incitatus, was to run, he placed sentinels near its stable the night preceding, to prevent its slumbers from being broken. He appointed it a house, furniture, and a kitchen, in order to treat all its visitors with proper respect. He sometimes invited it to his own table, and presented it with gilt oats, and wine in a golden cup. He often swore by the safety of his horse; and historians mention, that he would have appointed it to a consulship, had not his death prevented. Caligula perished by assassination, after a reign of less than four years; of him it has been said, that nature seemed to have brought him forth, to show what was possible to be produced from the greatest vice, supported by the greatest authority. He was succeeded by Claudius, who was a feeble and contemptible emperor, and who was finally cut off by poison. Nero, the next emperor, was at once noted for his cruelty, his vanity, and his debased passions. The atrocities he committed go beyond the reach of language to describe, and are such as perhaps never entered into the mind of any other human being. A conspiracy having been raised against him, and being at length hunted by assassins, he fell by a stroke of his own dagger. Of the succeeding emperors, we need not here enter into a detail. Under Vespasian, the tenth, and Titus, the eleventh emperor, the state rallied a little, and justice and an appearance of decency were once more resumed.

The reign of Trajan, the fourteenth emperor, almost renewed the glories of Augustus. (A. D. 107.) He advanced the empire to a greater degree of splendour than it had hitherto attained. He pursued his military conquests into new regions, even to Hindostan, and added greatly to the extent of the Roman territories; although this was not ultimately attended with any good effect. Trajan is distinguished as the greatest and the best emperor of Rome. Having given peace and prosperity to the empire, he continued his reign, loved, honoured, and almost adored, by his subjects. A pillar commemorating his great actions, erected in Rome, is still in existence. His successor, Adrian, was also a good sovereign, and was distinguished for his abilities and literary acquirements. After this period, the empire was never again under the authority of any ruler remarkable for his magnanimity. The greater part of the successors of Adrian were dissolute and vicious in their habits, and under them the empire waned to its close. The only one deserving to be noticed was Constantine, the forty-first emperor (A. D. 311.)

Introduction of Christianity.

At the death of Constantius, the fortieth emperor, he bequeathed the sovereignty to his son Constantine, a young prince of promising abilities. In the attempt, however, to take possession of his inheritance, he was opposed by three contending rivals—Maxentius, who governed in Rome, a person of cruel disposition, and a steadfast supporter of paganism; Licinius, who commanded in the east; and Maximin, who also governed some of the eastern provinces. The first step taken by Constantine was an expedition with an army to Rome, to expel Maxentius. One evening, while the army was on its march, Constantine, who was of a meditative disposition, sat in his camp reflecting upon the uncertain fate of sublunary things, and the dangers of the enter-

* A number of the imperial successors of Julius Cæsar assumed the title of *Cæsar*, in addition to their other designations, in the same manner as we find the appellations of Pharaoh and Ptolemy were assumed by many of the Egyptian sovereigns. The name of Cæsar has been curiously enough preserved until modern times, in the title of *Czar*, which is given by the Russians to their monarchs.

prise in which he was engaged. It was then, according to a fabulous legend of the Christian church, that, as the sun was declining, there suddenly appeared a pillar of light in the heavens, in the form of a cross, with the inscription in the Greek language, "In this overcome!" So extraordinary an appearance did not fail to create astonishment and religious awe in the mind of Constantine, and he resolved forthwith to adopt the religious persuasion of the hitherto persecuted Christians. On the day following, he caused a royal standard to be made like that which he had seen in the heavens, and commanded it to be carried before him in his wars, as an ensign of victory and celestial protection. After this, he consulted with several of the principal teachers of Christianity, and made a public avowal of that sacred persuasion. Constantine having thus attached his soldiers to his interest, who were mostly of the Christian faith, lost no time in entering Italy with 90,000 foot, and 800 horse. With this large force, he fought with and overcame Maxentius, and entered Rome in triumph. One of his first acts was to ordain that no criminal should for the future suffer death by crucifixion, which had formerly been the most usual way of punishing slaves convicted of capital offences. Edicts were soon after issued, declaring that the Christians should be eased from all their grievances, and received into places of trust and authority. Thus, the new religion was seen at once to prevail over the Roman empire, and, being associated with the state, the bishops and other clergy were endowed with an authority which had formerly been wielded by the priests of the ancient paganism.

Shortly after the establishment of Christianity (A. D. 321), Constantine executed a resolution of transferring the seat of government from Rome to Byzantium, or Constantinople, as it was afterwards called in honour of his name. As Greece and various provinces in Asia now formed a part of the Roman empire, it was believed that Constantinople would form a more central situation for the capital. Whatever truth there might be in this, the transfer, instead of proving in any respect advantageous, weakened the fabric of the state, and exposed it to a more speedy dissolution. Constantine died when above sixty years old, leaving a mixed character "of piety and credulity, of courage and cruelty, of justice and ambition," and was succeeded by his three sons, Constantine, Constantius, and Constans. These divided the empire among them, but it was subsequently united by Constantius, after a war of twelve years' duration. This union was of no long continuance. Theodosius, in the year 395, permanently divided the empire into the Eastern and Western Roman Empires, the capital of the former being Constantinople, and of the latter Rome. The history of these two divisions of the Roman territory now also separates; and following the usual practice of historians, we leave the Eastern or Byzantine empire to form the subject of a separate narrative, while we conclude with a few words upon the latter days of the old Roman or Western empire.

Destruction of the Roman empire.

For a considerable period, the Roman dominions were pressed upon on nearly all sides by ferocious tribes of barbarians. These were at first unknown to the Romans; but about the era of Constantine they had become formidable, and arose in such numbers, that the earth seemed to produce a new race of mankind, to complete the empire's destruction. Against such an enemy no courage could avail, nor abilities be successful; a victory only cut off numbers without a habitation and a name, soon to be succeeded by others equally desperate and obscure. The emperors who had to contend with this people, were most of them furnished neither with courage nor conduct. Constantius, Julian, Jovian, and Valentinian, successively endeavoured to arrest the tide of barbarism which set in; but they wanted both the personal energy and the stern soldiery of the early commonwealth to accomplish this desirable object. In the vain attempt to stop an immense inundation of Huns, Allanes, and Goths, from the extensive deserts of Tartary and Russia, the Roman armies were greatly weakened; so that the emperors, finding it difficult at last to raise levies in the provinces, were obliged to hire one body of barbarians to oppose another. This expedient had its use in circumstances of immediate danger; but when that was over, the Romans found it was as difficult to rid themselves of their new allies as of their former enemies. Thus, the empire was not ruined by any particular invasion, but sank gradually under the weight of several attacks made upon it on every side. When the barbarians had wasted one province, those who succeeded the first spoilers proceeded on to another. Their devastations were at first limited to Thrace, Mysia, and Pannonia; but when these countries were ruined, they destroyed Macedonia, Thessaly, and Greece, and thence they proceeded to Noricum. The empire was in this manner continually shrinking, and Italy at last became the frontier of its own dominion.

The valour and conduct of Theodosius in some measure retarded the progress of destruction; but, upon his death, the enemy became irresistible. A large body of Goths had been called in to assist the regular forces, under Alaric, their king; but what was brought in to stop the universal decline, proved the last mortal stab to the empire. This Gothic prince, from an ally became a dangerous foe; and finally marching to Rome, made himself master of the city, which he abandoned to be pillaged by his soldiers. (A. D. 410.)

After this disastrous event, Rome was plundered several times, and Italy was overrun by barbarous invaders, under various denominations, from the remotest skirts of Europe. The inhabitants of Rome, who had sunk into the grossest vices by the overpowering influence of wealth and prosperity, were quite unable to make any defence. So debased had they become, or so ill regulated was the balance of wealth, that for many years the whole of the lower classes had been fed daily by the emperors from the public granaries. The power of the state was now entirely broken; the provinces were voluntarily abandoned, or they rebelled, or were seized by the nearest barbarous powers. At length the title of emperor of the west, which, on one occasion, was put up to public auction by the licentious soldiery, expired; and, to finish the melancholy account, one of the princes of the barbarians assumed the title of *king of all Italy*. "Such" (to quote the words of Goldsmith) "was the end of this great empire, that had conquered mankind with its arms, and instructed the world with its wisdom; that had risen by temperance, and that fell by luxury; that had been established by a spirit of patriotism, and that sank into ruin when the empire was become so extensive, that a Roman citizen was but an empty name." Its final dissolution took place in the 480th year of the Christian era, or 1232 years from the date of the foundation of Rome.

ROMAN LITERATURE.

Literature could scarcely be said to exist among the Romans till their conquests in Greece made them acquainted with the admirable productions of that country, and the custom arose of sending youths to be educated in Athens. In the second century before the Christian era, comic dramatic writing was cultivated by *Ennius* and *Plautus*, and after them by *Terentius*, a slave, whose first comedy, the Andria, was acted in the year 165 B.C. Of Roman tragic writing, no remains have come down to our times. The *elder Cato*, who flourished in the same century, is praised as a writer by those who came after him; but we have scarcely any remains of his com

positions. Philosophical writing may be said to have arisen and at once reached its acme in *Cicero*, the celebrated orator (born 106, died 46 B. C.), beyond all question the greatest man in the department of letters to whom the Roman state gave birth. Besides many strictly philosophical treatises, he has left several works on rhetoric, and many orations and epistles.

A philosophical manner of relating events took its rise with *Sallustius* (born 68 B. C.), whose histories of the Jugurthan war and of the conspiracy of Catiline, though perhaps not free from prejudice, are considered as models of composition. The Commentaries of Cæsar, in which, with noble simplicity, he relates the history of his own campaigns, place him among the first Roman writers. *Livius*, who lived in the reign of Augustus, stands unrivalled among the Roman historical writers, being distinguished by consummate judgment in the selection of facts, perspicuity of arrangement, sagacious reflection, sound views of policy, and the most copious, pure, and eloquent expression. Of his history of Rome, written in 142 books, only 35 have reached us. Next to him, in the same department, is *Tacitus* (born A. D. 55), whose Annals of Rome, extending throughout the greater part of the first century, and his life of Agricola, the conqueror of Britain, are remarkable for acuteness of thought and concise style.

Lucretius, a dramatic, and *Catullus*, a lyric poet, were the principal writers of that kind who rose before the reign of Augustus. This reign was not only adorned by Livius, but by a cluster of poets, of unmatched excellence. *Virgilius*, a native of Mantua, wrote Bucolics, or pastoral dialogues, Georgics, or poetical treatises on agricultural subjects, and the Æneid, a heroic or epic poem. His style is remarkable for smoothness, and a fine strain of feeling. *Horatius*, his contemporary and friend, composed odes, satires, and epistles: he has never been excelled in felicity of phrase and epigrammatic point; the general strain of his writings is gay and familiar. *Ovidius* was a most elegant, though licentious poet. *Tibullus*, *Propertius*, and *Martial*, complete the list of the principal Roman poetical writers. *Lucanus*, *Statius*, and *Silius Italicus*, flourished in a later time, when luxuriance of ornament and a tendency to conceit showed that the best days of the national intellect were past.

Plinius (born A. D. 23) was almost the only Roman writer who treated of nature or science; he was an associate of Tacitus, and has left behind him works not less celebrated. He was a diligent student of the operations of nature, both animate and inanimate, and having devoted every spare moment to the noting down of facts and observations, he finally produced a voluminous work on Natural History, in thirty-seven books, which is reckoned the more valuable for its containing extracts from many lost works. Pliny was unfortunately killed in the year 79, by an eruption from Vesuvius which destroyed the city of Herculaneum, where he was at the time residing.

The Romans distinguished themselves in philosophy only by spreading the doctrines of the Greek philosophers in a language more extensively understood. The principal writer on morals was *Seneca*, born in the first year of the Christian era. Gifted by nature with excellent talents, he devoted himself to the cultivation of the Stoic philosophy, and his various learning and practical wisdom procured him the office of tutor to Nero. He afterwards incurred the enmity of that monster of cruelty, and was condemned by him to death. He died with the calmness of a virtuous mind (A. D. 66).

It is perhaps unnecessary to mention, that none of the works of the writers whose names have been quoted, nor of others of less importance, were circulated generally among the Roman people. Being written on rolls of parchment or papyrus, copies were multiplied only by great labour and expense, and sold or exhibited exclusively to persons of taste and opulence. Thus, the great mass of Roman citizens and provincials were left in entire ignorance of books, or of the subjects of which they treated. In the Roman city of Pompeii, lately uncovered from the effects of a dreadful eruption of Vesuvius, many interesting remains of art have been discovered, but no traces of literature whatsoever. Being excluded from the pleasures and advantages of mental culture through the agency of books, the only recreations of the people consisted in boisterous games, witnessing fights of gladiators or swordsmen with each other, or with wild beasts, or attending spectacles probably less barbarous, but not more calculated to cultivate the national intellect, or produce social refinement. In these facts, we find the true cause of the decline of both Greek and Roman civilization. It was a civilization only of castes and classes. There was nothing expansive or vivifying in it. Suddenly it sprang up in the Grecian republics, and was transplanted to Rome; but there, after a short struggle, it was rooted out and destroyed. The modern civilization that arose out of the chaos that followed the demise of the Roman power, is an entirely different thing, because it less or more pervades all classes of society, and by means of the expansive principle of education, aided by the art of printing, promises to extend and increase in vigour throughout every succeeding generation, till it ultimately fulfil the highest conditions of improvement of which the human race is susceptible.

Of the events which ensued on the destruction of the Roman empire, an account is given in the HISTORY OF THE MIDDLE AGES.

HISTORY OF THE MIDDLE AGES.

We comprehend under the title of the Dark or Middle Ages, that period which immediately succeeded the destruction of the Roman western empire, and extended to the end of the fifteenth or the commencement of the sixteenth century. Though named *dark*, those ages comprise a long and very remarkable period in the history of the human race, and exhibit many wonderful phenomena of human nature. It was during this period that all the great foundations on which modern society still rests were first laid, and those great thoughts, discoveries, and inventions, took their rise, which have chiefly distinguished modern from ancient times.

EASTERN EMPIRE TO THE END OF THE ELEVENTH CENTURY.

In another article (ANCIENT HISTORY OF GREECE AND ROME), the decline of the Roman empire has been traced till the period (321) when Constantine transferred the imperial abode to Byzantium (a city situated on the west shore of the Black Sea, and afterwards called Constantinople, in honour of its second founder). In his endeavours to make this city the seat of government, he only partially succeeded; for it generally happened after his day that there was one emperor in the east and another in the west, and not unfrequently two or three different individuals in the provinces, at the head of considerable military forces, claiming partial and even universal empire. Rome itself and the countries of western Europe were soon to lose the characteristics and individuality of empire, but Constantinople continued for a thousand years the abode of men who had still the name of emperors, and reckoned themselves the descendants of the Cæsars, although they had long ceased to wield any thing but the shadow of power. Constantine was himself instrumental in dismembering his empire, having before his death divided it among no fewer than five individuals, namely, his three sons, Constantine, Constans, and Constantius, and two nephews named Dalmatius and Annibalianus, both of whom bore in addition the surname of Cæsar, still popular among a people who wished themselves to be considered Roman.

Constantine II. soon fell a sacrifice to the cruelty and ambition of his brother Constans, who, in his turn, lost his life in attempting to quell a revolt among his subjects; and Constantius, the youngest of the sons, having found means to destroy the two Cæsars, and five other cousins, and two uncles, found himself, at an early period of life, the undisputed master of the empire. He reigned twenty-four years, but left no monuments of goodness or of greatness, having wasted his time in the practice of vice, or in the equally unprofitable, if more innocent, employment of disputing with bishops on the abstrusest points of doctrinal theology, while a host of enemies, apparently from every side of his dominions, were engaged in undermining and laying waste the empire. It was in the west that these attacks were first made, though, perhaps, it was in the east that they were fiercest. Numberless and powerful barbarians now began to pour unceasingly upon Gaul, Spain, and latterly upon Italy itself, from the forests of the north, and in particular from those of Germany—a country whose inhabitants have been remarkable in the history of the world, both as having originated many of the greatest movements in society, and as having laid open more of the sources of human thought than any other people that could be named. The Franks, Saxons, Goths, and Alemanni, devastated the fine countries watered by the Rhine, and so effectually parted them from the empire, that from this period their history becomes wholly separate. At the same time the Sarmatians, Persians, Scythians, and others, made dreadful incursions on the east. All that Constantius did to stem this powerful tide, was to raise his kinsman Julian, whom he surnamed Cæsar, to command in the army.

Julian had been early instructed in the Christian religion, but he is not known to have ever given it any credit, although he has been often called apostate. He had imbibed the philosophy of Plato in the schools of Athens; and with this learning, with the elements of a great character in his mind, and with the models of Cæsar, of Trajan, and of Marcus Antoninus in his eye, he formed the design, and seemed to have the ability, to raise up and consolidate the glories of the falling empire. His victories over the Alemanni in Gaul, although they preserved the empire, excited only the envy of the emperor, and Constantius was about to depose him from his command, when his own death saved him from the ignominy to which the soldiery would certainly have subjected him for any attempt to degrade their favourite commander. Julian was himself declared emperor by the army, and the people had lost both the power and the will to resist. Unfortunately for his fame, Julian perished in battle with the Persians, only three years after his accession. In that short period he had reformed many abuses in the state; and though personally hostile to the Christian religion, and though he used both arguments and ridicule against it, he not only advocated, but practised, universal toleration. It is creditable, also, to Julian, that in establishing the ancient orders of Roman priesthood, he was at pains to enforce a strict morality in all the relations of life. He was succeeded, after the fall of several candidates, by Valentinian, whose father had been a soldier from the Danube. This emperor took for colleague his brother Valens, to whom he assigned Constantinople and the government of the East. The reign of Valens was signalized by the irruption into Europe of an enemy till then unknown to the Romans; these were the *Huns*, a confederation of Tartar tribes, some of whom had attained the ascendency and control over the rest, and led them on to invade the nations of Europe. Their numbers and ferocity led the ancient writers to describe them in terms of consternation, which to moderns, who are no strangers to Calmucs, Cossacks, Tartars, and other savages of similar origin, appear sufficiently ludicrous,

They never lived in houses, slept under trees, ate raw flesh, and were altogether superior in war even to the Goths, who were now in alliance with the Romans, and had begun to relish the comforts of a settled life. They were, therefore, driven away before the Huns, and were forced, in search of a home, to invade the Roman territory. Here they were opposed by the Emperor Valens, but they defeated his army, and made his own life a sacrifice. He was succeeded by his nephew Gratian, who chose for his colleague Theodosius, a general of talents and celebrity. This emperor restored the confidence of his own army, and broke the power of the Goths, by his skill and caution; and was the first of the emperors who practised the mode of dividing the barbarians against one another, by giving money to such of their tribes as he imagined would make useful auxiliaries. This system, which the wealth of the emperors (from their possession of all the maritime and trading cities) enabled them long to use against their poorer enemies, often saved the empire at the expense of its dignity; for though the money was given at first as a gratuity, it was sometimes demanded in times of weakness as a tribute. This Theodosius (commonly called the Great) was the first who made Christianity the established religion of the empire (390). He procured a senatorial edict in favour of the Christians, sanctioned the destruction of the heathen temples, and forbade the performance of sacrifices, either in public or private. The empire under this prince still preserved its original extent; but he divided it between his two sons, Arcadius and Honorius (394), and its parts were never afterwards reunited.

From the death of Theodosius II. (449) to the reign of Justinian (527), the eastern empire continued without any considerable alteration, though there were many changes and intrigues in the court and army. The reign of the latter prince is memorable on several accounts: it was under his auspices that a knowledge of the silk manufacture was first brought to Europe, where it gave employment to much ingenious industry (800). Justinian also caused certain eminent lawyers to prepare a code of laws, and an abridgment of law decisions, &c., called the Pandects, which were used by all his successors, and have been adopted as the basis of their laws by several countries of Europe. With the single exception of the *Code de Napoleon*, these form the only complete and perfect abstract of national law which any government has given to its people. Whatever may have been Justinian's errors, his having projected this work, and procured so many able ministers to execute it, must redound for ever to his honour. The talents and virtues of his general, Belisarius, regained to the empire Africa and great part of Italy, from the Vandals and Ostrogoths; this conquest, however, only prevented the latter region from being united under one government, and has been the cause of its remaining a feeble and divided country ever since. In the reign of Tiberius, shortly after (580), the people of Rome, though they entreated with great earnestness the aid and pity of the emperor, who now claimed to rule over them, were unable to obtain any relief, and remained distracted between their attachment to the ancient head of the empire, and the claims of his enemies who occupied the rest of Italy.

The next emperor who merits attention is Heraclius (610), a native of Africa. The eastern empire had till now preserved its ancient boundaries in their full extent, and was mistress of Carthage, Egypt, Syria, and Asia Minor, besides Greece, and the countries on the Danube. The Roman armies on the eastern frontier had, however, been lately driven in by Chosroes, King of Persia, who now occupied all the north of Africa and Syria. This was the first great violation of their territory sustained by the emperors of Constantinople; and Heraclius avenged it with a celerity and effect which made the Persians tremble. His triumph, however, was short, for the latter part of his reign was disturbed by the rise and victories of Mohammed. The successors of this signal impostor, after breaking the power of Persia (already weakened by the victories of Heraclius), immediately attacked the Roman empire; then defeated its armies in two battles, occupied all Syria, and obliged the emperor (now an old man) to retire to Constantinople. He died in 641.

The continued victories of the followers of Mohammed (called Arabs or Saracens) soon deprived the empire of Egypt, Africa, and Syria; and in 668 they followed up their success by attacking Constantinople itself. The city sustained two sieges, in the first of which the Saracens were encamped in its neighbourhood, and carried on the operations of a siege at intervals, for seven years; and in the second for nearly two. In both, the Saracens wasted immense resources ineffectually.

The empire had now lost all its provinces eastward of Mount Taurus, and the cities of Alexandria, Jerusalem, and Antioch, were in the hands of the Mohammedans. There was little further change in its condition till the year 867, under the Emperor Basil, who gave new vigour both to the internal administration and to the military resources of the government. This prince, and his immediate predecessor Zimisces, made the Roman arms—for they still wished to be called Romans—respected on the Euphrates and Tigris, and asserted the ancient warlike reputation and boundaries of the empire. They were now, however, deprived of the resources they had enjoyed in the secure possession of the great commercial cities of the Mediterranean—Alexandria, Carthage, Cæsarea, &c.; and the trade and revenues of those which remained were crippled and diminished, from the want of that free general intercourse which had existed when they were all under one government. Hence the armies were maintained with greater difficulty, and any victories that were gained could not be followed up with effect. The early enemies of the empire—the Goths, Vandals, and Huns—had now settled into civilized communities, and were no longer formidable. The foes with whom it contended latterly were the Bulgarians and Seljukian Turks; the former of whom were rather troublesome than dangerous, but the latter, who had succeeded the Saracens in the dominion of Asia, aimed at nothing short of the destruction of the Roman name. They succeeded at last, by defeating and taking prisoner the Emperor Romanus Diogenes, in tearing away almost the whole province of Asia Minor (1099); and the emperors were now confined to their dominions in Europe, which, however, still formed a monarchy not much smaller than France or Spain.

The manners of the court of Constantinople, during much of this period, were dissolute and corrupt. We are told of one emperor who ordered a plate of human noses to be brought to his table; another was accustomed to seize the deputies of cities whose tribute was in arrear, and suspend them with their heads downwards over a slow fire; a third got up farces in mockery of the ceremonials of religion: and, in general, the appointment of officers, and even the succession to the empire (where it was not seized by some successful general), was in the hands of the women and eunuchs of the palace. The cities and provinces generally acquiesced, as to the choice of an emperor, in the decision of the capital or army; this circumstance shows that the laws were attended to, and that there was a regular system of government, which was not much disturbed by the personal character of the reigning prince. The countries of Greece, however, which had formerly been the seat of knowledge and the arts, were now sunk in ignorance; and the little learning that was cultivated in Athens was only scholastic divinity, or the pedantry of law and grammar. There is no scholar or philosopher of the empire of Constantinople who is generally known to posterity.

A great change took place in the relations of the empire after the eleventh century. It was still pressed by the Turks on the east, who now occupied Asia Minor, and were only separated from Constantinople by the Hellespont; while, in Europe, its territories were disturbed by the incursions of certain Norman adventurers who had settled in Sicily. Against these enemies the Emperor Claudius Comnenus, an active prince, and full of resources, made all the resistance which his diminished revenues allowed. He applied to the Christian sovereigns of Europe to aid him in expelling the Mohammedans from the territories of the empire, but, above all, to drive out the Turks from the land of Judea, which they occupied and profaned, and where they harassed the Christian pilgrims who desired to visit the scenes of Scripture history. His appeal was received in Europe at a time when many concurring causes had brought the mass of the people to a state of uneasiness which at once foreboded and rendered necessary some extensive change in their condition. Countrymen of their own, pilgrims from the shrine of the tomb of Christ, had returned and filled them with horror by a recital of indignities which Turkish infidels were casting on those scenes and subjects with which their own most sacred feelings were associated; and the result was that extraordinary outpouring of the inhabitants of Europe upon Asia, which has been termed the Crusades, and to which we shall afterwards advert.

ARABIA.—MOHAMMED.—EMPIRE OF THE SARACENS.

It was not before the sixth century that Arabia became peculiarly remarkable in the history of the world. The wild Arabs, as they have been generally called, had already signalized themselves by incursions on the empire of the east, when Mohammed was born, in the year 569 (some say, 571) of the Christian era, at Mecca, the principal city of their country. He is said to have been descended from some great families; but it is certain that his immediate progenitors were poor, and he had little education but what his own means and his own mind could give him. Yet this man became the founder of a great empire, and the fabricator of a religion which has continued to our own day to affect greater numbers of mankind than Christianity itself. At an early period of life, we are told, "he retired to the desert, and pretended to hold conferences with the Angel Gabriel, who delivered to him, from time to time, portions of a sacred book or Koran, containing revelations of the will of the Supreme Being, and of the doctrines which he required his prophet (that is, Mohammed himself) to communicate to the world." The Mohammedan religion, as the so-called revelations of this great impostor have since been designated, was a strange mixture of the superstitions of Arabia, the morality of Christ, and the rites of Judaism. It was to this happy mixture of tenets, usages, and traditions already existing among his countrymen, and to the applicability of the precepts of the Koran to all legal transactions and all the business of life, that Mohammed seems to have owed his extraordinary success. Others, indeed, have attributed this to certain indulgences allowed in the Koran; but in reality these indulgences existed before, and the book breathes upon the whole an austere spirit. This extraordinary work inculcated elevated notions of the divine nature and of moral duties; it taught that God's will and power were constantly exerted towards the happiness of his creatures, and that the duty of man was to love his neighbours, assist the poor, protect the injured, to be humane to inferior animals, and to pray seven times a-day. It taught that, to revive the impression of those laws which God had engraven originally in the hearts of men, He had sent his prophets upon earth—Abraham, Moses, Jesus Christ, and Mohammed—the last, the greatest, to whom all the world should owe its conversion to the true religion. By producing the Koran in detached parcels, Mohammed had it in his power to solve all objections by new revelations. It was only after he was well advanced in years that his doctrines began to be received. At first, indeed, they were so violently opposed by his fellow-citizens of Mecca, that the prophet was obliged to fly from the city to save his life. This event is called by his followers *Hegyra*, or the Flight; it occurred in the 622d year of the Christian era; and they reckon dates from it as we do from the birth of Christ. Mohammed took refuge in the city of Medina, and by the aid of his disciples there, he was soon enabled to return to Mecca at the head of an armed force. This enabled him to subdue those who would not be convinced, and henceforward he proceeded to make proselytes and subjects together, till at length, being master of all Arabia and of Syria, his numerous followers saluted him king. (627.) This extraordinary man died suddenly and in the midst of successes, at the age of sixty-one (632). Abubeker, his father-in-law and successor, united and published the books of the Koran, and continued and extended the empire, spiritual and temporal, which Mohammed had left him.

A more powerful caliph (such was the title given to this series of monarchs) was Omar, the successor of Abubeker (635). Barbarity, ferocity, and superstition seem to have been mingled and to have reached their height in the person of Omar. It was by his order that the most magnificent library of antiquity, that of Alexandria, consisting of 700,000 volumes, was burned to ashes. The reason which he gave for this act is worth preserving: "If these writings," he said, "agree with the Koran, they are useless, and need not be preserved; if they disagree, they are pernicious, and ought to be destroyed." By himself and his generals, this ferocious conqueror added Syria, Phœnicia, Mesopotamia, Chaldea, Egypt, Lybia, and Numidia, to his empire. Next came Otman, and then Ali, the son-in-law of Mohammed himself. The name of Ali is still revered by Mussulmans. His reign was short but glorious. "After some internal troubles, the Saracens won their way along the coast of Africa, as far as the pillars of Hercules, and a third province was irretrievably torn from the Greek empire. These western conquests introduced them to fresh enemies, and ushered in more splendid successes. Encouraged by the disunion of the Visigoths [in Spain], and invited by treachery, Muza, the general of a master who sat beyond the opposite extremity of the Mediterranean Sea, passed over into Spain, and within about two years the name of Mohammed was invoked under the Pyreneans."—(*Hallam*, 710.)

Nineteen caliphs of the race of Omar succeeded Ali, and after these came the dynasty of the Abassyds, descended by the male line from Mohammed. The second caliph of this race, named Almanzor, removed the seat of empire to Bagdat (762), and introduced learning and the culture of the sciences, which his successors continued to promote with zeal and liberality. This was some recompense for those indignities which had been cast upon literature by the brutal Omar. Perhaps the obligations of modern Europe to Arabia at this time have been overstated; but it is not to be denied that learning, almost totally excluded and extinct in Europe during the eighth and ninth centuries, found an asylum here. It has been matter of dispute how the tastes of these fierce Arabians became thus first directed. They probably owed it to the Greeks; but it is certain that what they got they returned with interest. We are said to derive our present arithmetical figures from this strange people; and geometry, astronomy, and alchemy, were their favourite pursuits. The graces of light literature were not neglected, as is shown by the One Thousand and One Nights' Entertainments, a production of this period, which still continues to solace the hours of child-

mood and old age among ourselves, and attests the extent of fancy and the variety of genius among those that gave it birth. Haroun al Raschid, who flourished in the beginning of the ninth century, is celebrated as a second Augustus. He was contemporary with Charlemagne, and communications of a friendly nature are said to have passed between them.

Within fifty years from the death of Mohammed, the Saracens had raised an empire, not only temporal, but also spiritual, more extensive and more powerful than what remained of the empire of Constantinople; and within a hundred, they had subdued not only Persia, Syria, Asia Minor, and Arabia, but also Egypt, North Africa, and Spain. It seemed, indeed, in the course of the eighth century, as if Asia and Europe both should yield to their victorious arms, and become one great Mohammedan dominion. But the mighty fabric, of mushroom growth, crumbled into dust with equal speed. After the first extension of their conquests, they ceased to acknowledge any one head of their empire, and the successful generals of the provinces contented themselves by paying a religious respect to the caliphs of Bagdat, as the successors of the prophet, while they retained the power of conquerors for themselves. In the year 732, they sustained a great defeat in France from Charles Martel, who became the father of an illustrious race of kings. No fewer than 375,000 Saracens are said to have been left dead on the field of this battle, and it is certain that they never after cherished the hope of subduing Europe. About the middle of the ninth century (848), they projected the conquest of Italy, and even laid siege to Rome itself. But they were entirely repulsed by Pope Leo IV.; their ships were dispersed by a storm, and their army cut to pieces. Spain was the only European country in which they were able to obtain a permanent footing, and in it alone have they left traces of their existence.

FROM THE DESTRUCTION OF ROME TO THE AGE OF CHARLEMAGNE.—ORIGIN OF THE FEUDAL SYSTEM.

The empire of the Cæsars fell in the west only by degrees, and the changes introduced by the northern tribes were gradual, though they proved great. Province after province yielded to the invaders; and before the end of the fifth century, every country in Europe had undergone extensive changes, and received fresh accessions to the number of its inhabitants. The Visigoths had seated themselves in Spain, the Franks in Gaul, the Saxons in the Roman provinces of South Britain, the Huns in Pannonia, and the Ostrogoths in Italy and the adjacent provinces. And not only had they been enabled to take up their abode, but in general they became masters, and changed the face of all that they touched: "new governments, laws, languages; new manners, customs, dresses; new names of men and of countries, prevailed; and an almost total change took place in the state of Europe." That change has been called a change from light to darkness, and it assuredly led to the extinction of that taste for literature and that regular administration of government which were the relieving features of the Roman despotism. But if it thus produced an immediate evil, it led to an ultimate good. The population was improved by the admixture of the new races, and from the new elements it had acquired, sprung institutions which might be considered as in many respects an improvement upon those which formerly prevailed.

It was out of these new circumstances that what has been called the Feudal System took its rise. This was a feature in society unknown in former ages. Hitherto men had been the slaves of individual masters, or, as in the more celebrated states of antiquity, they were bound together by the common tie of citizenship, and owed allegiance to none. Patriotism was their highest virtue, and all looked upon the state as a parent, to which, having got support from it, they were bound to give support in their turn. But in these times the rude inhabitants of the north had formed little or no conception of what a state was; and at first they were not prepared to relinquish their much-cherished individual freedom, in exchange for rights which they thought they did not need. Changes at length came over them; and society gradually took new forms. Those who had led them on to battle, began to be looked upon as their guardians in peace. Victorious armies, cantoned out into the countries which they had seized, continued arranged under their officers, each of whom had a separate territory allotted to him, on which he could retain and support his immediate followers, while the principal leader had the largest; and in this way all were bound in allegiance, both to their immediate superiors and to their chief, and all were in readiness to be called out to arms whenever their services were thought to be required. This "military chieftainship," infusing itself as an element in the barbarian societies, was the first advance to any thing like civil or social government, since the extinction of the Roman power. Nations, indeed, were still far from having the advantage of a regular government. The method of conducting judicial proceedings, and of administering justice, was still peculiarly unsettled and uncertain. The authority of the magistrate was so limited, and the independence assumed by individuals so great, that they seldom admitted any umpire but the sword. It was then that trial by ordeal became universal, and men's guilt or innocence was thought to be proved by the capacity of their bodies to withstand the influences of red-hot iron, or boiling water applied to them, or by their overcoming their accuser in single combat.

These observations are applicable, with scarcely any variation, to all the nations which settled in Europe during the fifth and sixth centuries. Speaking of this subject, Dr. Robertson says—"Though the barbarous nations which framed it [the Feudal System], settled in their new territories at different times, came from different countries, spoke various languages, and were under the command of separate leaders, the feuds' policy and laws were established, with little variation, in every kingdom of Europe. This amazing uniformity hath induced some authors to believe that all these nations, notwithstanding so many apparent circumstances of distinction, were originally the same people. But it may be ascribed, with greater probability, to the similar state of society and of manners to which they were accustomed in their native countries, and to the similar situation in which they found themselves on taking possession of their new domains." We shall now say a few words about them individually.

No people at this period exhibited a more energetic character than the Franks, a Teutonic race originally settled on the Lower Rhine and Weser, and who had acquired their name (free-men) while successfully resisting the Roman power in an earlier age. About the year 486, they were under the rule of Clovis, who achieved the conquest of Gaul by the defeat of the Roman governor, and afterwards added Burgundy and Aquitaine to his dominions, the former by marriage, and the latter by the forcible expulsion of the Visigoths. This may be considered as the foundation of the French monarchy. Clovis adopted the Christian faith, and caused his people to follow his example. It is remarkable that, while in war he exercised unlimited power over his subjects, they shared with him the legislative authority, meeting annually in the Champs de Mars to suggest and deliberate upon public measures, in the settlement of which the meanest soldier had equally a voice with his sovereign.

At the death of Clovis in 511, his four sons divided the kingdom, which was afterwards reunited, divided again, and again united, amidst scenes of tumult and

bloodshed. The line of kings proceeding from Clovis (called Merovignian, from his grandsire Meroveus), dwindled in time into utter insignificance, while the chief power was wielded by an important officer, called the Mayor of the Palace. Among the most remarkable of these was Pepin Heristal, Duke of Austrasia, who ruled France for thirty years with great wisdom and good policy. His son, Charles Martel, who succeeded to his power, distinguished himself by that great victory over the Saracens (732), which checked their career in Europe.

An appeal by Pepin le Bref, the son of Charles Martel, to the Pope of Rome, whose authority had by this time become great, ruled that he who had the power should also have the title of king, and this put an end to the reign of the descendants of Clovis (752). Pepin remunerated the pope for this service by turning his arms against the Lombards in Italy, some of whose dominions he conferred upon the Holy See; and these, it is said, were the first of the temporal possessions of the church. Pepin died (768), leaving two sons, Carloman and Charles, who succeeded him in the empire. Carloman died at an early period of life, but Charles survived to achieve for himself a fame greater than that of any other individual during the middle ages, with, perhaps, the single exception of Mohammed. We shall proceed to speak of him and of his times, after making one or two observations on some other European countries.

Spain was among the earliest countries lost to the Roman empire. From about the year 406, this country, in whole or in part, had been successively invaded and subdued by Suevi, Alains, Vandals, and Visigoths. The last-named people were in possession of the greater part of the country before the year 585, and erected a monarchy which existed till 712, when they were subdued by the Saracens or Moors. The Saracens made their descent on Spain from Africa, where Muza, a viceroy of the Caliph of Bagdat, had already made extensive conquests. They easily overran Spain and vanquished Don Rodrigo, or Roderic, the last of the Gothic kings. Abdallah, son of Muza, married the widow of Roderic, and the two nations entered into union. Before the conclusion of the eighth century, Abdalrahman, one of the Moorish generals, had laid aside all temporal subjection to the Caliph of Bagdat, and formed Spain into an independent kingdom. His residence was at Cordova, and this city became renowned as one of the most enlightened in Europe, under several succeeding reigns. Those parts of Spain which were under the Moorish kings embraced also their religion. The north never was.

Towards the conclusion of the sixth century, Italy was in the possession of the Longobeards, or Lombards, who continued masters of the greater part of it for two centuries. Of their rule, history has recorded little besides murders and confusion.

It was during this period that the Saxon Heptarchy was formed in Britain.

CHARLEMAGNE—THE NEW WESTERN EMPIRE.

By far the greatest character who appeared in Europe at this period was Charles, the son of Pepin le Bref, and known in history by the name of Charlemagne, or Charles the Great. "In the course of a reign of forty-five years, Charlemagne extended the limits of his empire beyond the Danube, subdued Dacia, Dalmatia, and Istria, conquered and subjected all the barbarous tribes to the banks of the Vistula, made himself master of a great portion of Italy, and successfully encountered the arms of the Saracens, the Huns, the Bulgarians, and the Saxons. His war with the Saxons was of thirty years' duration; and their final conquest was not achieved without an inhuman waste of blood. At the request of the pope, and to discharge the obligations of his father Pepin to the holy see, Charlemagne, though allied by marriage to Desiderius, King of the Lombards, dispossessed that prince of all his dominions, and put a final period to the Lombard dominion in Italy (774)."—(*Tytler.*)

When Charlemagne made his first entry into Rome, he was crowned King of France and of the Lombards by Pope Adrian I.; and afterwards, on a second visit, he was consecrated Emperor of the West by the hands of Pope Leo III. (800.) He probably attached some importance to these rites; but it is to be remarked that, as yet, the pontiff was not in enjoyment of that high influence by which he afterwards could confer or withdraw sovereignty at his pleasure.

"It is probable" says Mr. Tytler, "that, had Charlemagne chosen Rome for his residence and seat of government, and at his death transmitted to his successor an undivided dominion, that great but fallen empire might have once more been restored to lustre and respect; but Charlemagne had no fixed capital, and he divided even in his lifetime his dominions among his children" (806). Charlemagne died in the year 814, aged 72. His last days were employed in consolidating, rather than extending, his empire, by the making of laws which have rendered his name famous, and his memory even blessed. "Though engaged in so many wars," says Dr. Russell, "Charlemagne was far from neglecting the arts of peace, the happiness of his subjects, or the cultivation of his own mind. Government, manners, religion, and letters, were his constant pursuits. He frequently convened the national assemblies, for regulating the affairs both of church and state. In these assemblies he proposed such laws as he considered to be of public benefit, and allowed the same liberty to others; but of this liberty, indeed, it would have been difficult to deprive the French nobles, who had been accustomed, from the foundation of the monarchy, to share the legislation with their sovereign. His attention extended even to the most distant corners of his empire, and to all ranks of men. He manifested a particular regard for the common people, and studied their ease and advantage. The same love of mankind led him to repair and form public roads; to build bridges, where necessary; to make rivers navigable for the purposes of commerce; and to project that grand canal which would have opened a communication between the German Ocean and the Black Sea, by uniting the Danube and the Rhine." Amidst all his greatness, his personal habits were simple; his dress was of the plainest sort, and such even as to shame his own courtiers: his hours of study were set apart, and seldom omitted even in the busiest times of his life; his daughters were taught spinning and housewifery, and his sons trained by himself: in all the accomplishments of the age. Charlemagne was fond of the company of learned men, and greatly encouraged their residence in his dominions. In this respect he resembled his contemporary Haroun al Raschid, so famous in Arabian history, and Alfred the Great, who appeared in England shortly after this period. Superior to all national prejudice, he elevated an Englishman named Alcuin to the head of his royal academy. He was zealous for the extension of Christianity; and one of the few blots upon his name arises from his having, in the spirit of his age, caused 4000 Saxon prisoners to be beheaded in one day, because they would not submit to be baptized. Charlemagne established schools in the cathedrals and principal abbeys, for teaching writing, arithmetic, grammar, and music.

Of the sons of Charlemagne, Louis, the youngest, surnamed the *Debonnaire*, or gentle, was the only one who survived. He succeeded to all his father's dominions, except Italy, which fell into the hands of Bernard, a grandson of Charlemagne. Louis, deficient in vigour of character, was not able to hold together the great

empire left to him by his father. Having, among the first acts of his reign, given large portions of it to his children, the remainder of his life was spent in disgraceful quarrels with them; and, after his death (840), the empire was formally divided—Lothaire, his eldest son, obtaining Lorraine and Provence; while Charles the Bald, a younger son, continued sovereign of the western parts of France; and Louis became King of Germany. Thus abruptly ends the history of the second western empire.

FRANCE FROM THE TIME OF CHARLES THE BALD TO THE ELEVENTH CENTURY.

During the reign of Charles the Bald, France first suffered from the attacks of the Normans, a race of bold and needy adventurers from the north of Europe. Their plundering invasions were continued for upwards of seventy years; till at length (912) the French king was compelled to purchase their amity, by yielding to Rollo, their leader, the country, afterwards from them called Normandy, of which Rouen was the capital. The first successor of Charles the Bald with whose name history has associated any thing worth remembering, was Charles, surnamed the Fat (885). He was the son of that Louis to whom Germany had been before assigned, and was thus enabled to bring that country and France for a short time once more under a single ruler. In the turbulence of the times, Charles was soon deposed, and during the century which followed, France, so lately the centre of an empire little less than that of Rome in the days of its Cæsars, was split up into a multitude of independencies, by nobles who would own only a very slender subjection to the kings. Out of these nobles at last sprang Hugh Capet (987), who was enabled, on the death of Louis V., to place himself on the throne. He was already possessed of great property, and proved to be also a prince of much ability and penetration. He established the royal residence at Paris, which his predecessors had descended, became the founder of a family which still, in one of its branches, occupies the throne of France. He deserves to be mentioned with honour, as being among the first of European kings who trusted to prudence, counsel, and moderation, rather than force of arms, in effecting his purposes. His success was great, as it deserved to be. On his death (996), in the fifty-seventh year of his age and the tenth of his reign, he was succeeded by his son Robert, who had all his father's equitable disposition without his vigour of character. He was subjected to a degree of tyranny, on the part of the church, of which perhaps the history of the world does not afford such another example. Robert had been guilty of marrying a cousin in the fourth degree, without a *dispensation* from the holy see, that is, without paying a fine for what was only an imaginary offence. Gregory V., who then occupied the pontifical chair, threatened to excommunicate Robert if he should not dismiss his wife, and, on Robert's refusal, actually did so, and laid all his dominions under an interdict. This punishment proved tremendous in its effects; for though the king himself showed sense and courage enough to despise the wrath of the pontiff, yet his subjects deserted him in terror. The priests, in consequence of the interdict, refused sacrament to the sick all over the country, and the dead were everywhere left unburied, when mass was no longer said. In these circumstances, the unfortunate king submitted. A second marriage, contracted with the consent of the church, proved very unhappy. The new queen, Constantia, or Constance, made many efforts to embroil her husband and his family, and in the midst of these Robert died (1031). His son Henry succeeded, and it was during his reign that those pilgrimages to the Holy Land, which were so soon to end in the Crusades, took their rise. Of these we shall speak by themselves. In the mean time we take leave of France by mentioning that Henry's successor was Philip (1060), whose reign is remarkable as having witnessed the beginning of those contests with England which continued at intervals till the early part of the nineteenth century.

At this period (1066), the Normans invaded and conquered England, where their leader, William Duke of Normandy, became the founder of an important dynasty.

THE GERMAN EMPIRE TILL THE ELEVENTH CENTURY.

Germany had no political existence till the time of Charlemagne, when it was formed by him into a part of the western empire. Towards the conclusion of the ninth century, it became an empire of itself. In the year 887, Arnold, a natural son of Carloman, and nephew of Charles the Fat, was declared emperor by an assembly of bishops and nobles. These assemblies in Germany always retained a voice in the election of their emperors; and though they often made their choice from the line of succession, they never acknowledged any hereditary rights whatever. After the death of Arnold's son, called Louis III., their choice fell upon Conrad, Duke of Franconia (912). Conrad's successor was Henry I., surnamed the *Fowler*. He was a prince of great abilities, and introduced order and good government into the empire. "He united the grandees and curbed their usurpations; built, embellished, and fortified cities; and enforced, with great rigour, the execution of the laws in the repression of all enormities. He had been consecrated by his own bishops, and maintained no correspondence with the see of Rome. His son, Otho the Great, who succeeded him (938), united Italy to the empire, and kept the popedom in complete subjection. He made Denmark tributary to the imperial crown, annexed the crown of Bohemia to his own dominions, and seemed to aim at a paramount authority over all the sovereigns of Europe."

In these times the papacy was much disordered. "Formosus, twice excommunicated by Pope John VIII., had himself arrived at the triple crown. On his death, his rival, Pope Stephen VII., caused his body to be dug out of the grave, and after trial for his crimes, condemned it to be flung into the Tiber. The friends of Formosus fished up the corpse, and had interest to procure the deposition of Stephen, who was strangled in prison. A succeeding pope, Sergius III., again dug up the ill-fated carcass, and once more threw it into the river. Two infamous women, Marosia and Theodora, managed the popedom for many years, and filled the chair of St. Peter with their own gallants or their adulterous offspring."—*Tytler*. It was amidst this confusion and these disturbances that Otho was induced to turn his arms on Italy. He shortly became master of it all, and had himself declared emperor by the holy see, with all the pomp that had attended the same ceremony to Charlemagne (962). Pope John XII., whom Otho had been the means of raising to the pontifical chair, rebelled soon after. Otho returned to Rome in fury, had John deposed, hanged one-half of the senate before he left the city, and wrung a solemn acknowledgment from an assembly of reluctant bishops, that the emperor had a right not only to nominate to vacant bishoprics, but also to elect the pope himself. Otho died (972), and was followed in succession by Otho II., Otho III., St. Henry, Conrad II., and Henry III., the history of whose reigns exhibits nothing instructive, or upon which the mind can rest with pleasure. Henry IV. (1056) was a distinguished victim of papal tyranny. The celebrated Hildebrand, known as Gregory VII., was in this age the means of raising the power of the church to a height which it had never reached before. During Henry's contest with this daring and ambitious pontiff, he made him twice his prisoner, and twice did the thunders of the Vatican

excommunicate and depose him in consequence. As a specimen of the power and insolence of this pope, we may mention that Henry, dispirited by the effect which his excommunication had upon his friends and followers, having resolved to go to Rome and ask absolution from Gregory in person, did so; and, presenting himself as an humble penitent at the palace of St. Peter, was there stripped of his robes, and obliged to remain in that condition, in an outer court, in the month of January (1077), barefooted, among snow, and fasting, for three successive days, before he was allowed to implore forgiveness for his offences! On the fourth day he was permitted to kiss the toe of his holiness, and then received absolution! Henry died in the year 1106.

ITALY, FROM THE NINTH TO THE ELEVENTH CENTURY.

The state of Italy during this period has been already partially noticed in the preceding section. From the time of Lothaire, to whom it was nominally assigned as a separate kingdom (843), to that of Otho the Great, (964), the country was ravaged by contending tyrants. Between the invasions of the Normans and the claims of the German emperors, it became much distracted, and was ultimately split up into several independent states. Some of these, particularly Venice, Genoa, Pisa, and Florence, became afterwards independent and powerful republics. It was during the present period that the foundation of the temporal power of the popes was laid.

SPAIN, FROM THE TIME OF ABDALRAHMAN TILL THE ELEVENTH CENTURY.

During the period of which we have been treating, Spain seemed less a part of Europe than any other country in it. The greater part of it still continued under the dominion of the Moors, and apparently with advantage. "This period," says Mr. Tytler, "from the middle of the eighth to the middle of the tenth century, is a most brilliant era of Arabian magnificence. While Haroun al Raschid made Bagdat illustrious by the splendour of the arts and sciences, the Moors of Cordova vied with their brethren of Asia in the same honourable pursuits, and were undoubtedly at this period the most enlightened of the states in Europe. Under a series of able princes, they gained the highest reputation, both in arts and arms, of all the nations of the west." And yet these eastern conquerors seem to have had their troubles as well as others. A race of powerful nobles among them, as in the other countries of Europe, distracted the country and made effective government impossible. The Christian part of the population, still possessed of several provinces in the north, might have taken advantage of such a state of things for repossessing themselves of their lost country. But civil dissension was still greater among themselves, and Christian princes readily formed alliances with the Moors, if they saw a prospect of weakening an immediate enemy by that means, forgetting that the common foe still remained to harass them. But the detail of these numerous and petty contentions need not detain us longer; nor does the history of Spain assume any importance till towards the conclusion of the fifteenth century, when the united arms of Ferdinand and Isabella expelled the Moors for ever from the country.

GENERAL STATE OF EUROPE IN THE ELEVENTH CENTURY.

Before the end of the tenth century, Europe had reached a point of darkness and degradation, beyond which it seemed impossible to go. Though long nominally converted to the Christian religion, the nations of Europe may be said to have scarcely exhibited, up to this period, a single distinctive mark of what men understand by Christian civilization. "The barbarous nations," says Dr. Robertson, "when converted to Christianity, changed the object, not the spirit of their religious worship. They endeavoured to conciliate the favour of the true God, by means not unlike to those which they had employed in order to appease their false deities. Instead of aspiring to sanctity and virtue, which alone can render men acceptable to the great Author of order and of excellence, they imagined that they satisfied every obligation of duty by a scrupulous observance of external ceremonies. Religion, according to their conception of it, comprehended nothing else; and the rites by which they persuaded themselves that they should gain the favour of Heaven, were of such a nature as might have been expected from the rude ideas of the ages which devised and introduced them. They were either so unmeaning as to be altogether unworthy of the Being to whose honour they were consecrated, or so absurd as to be a disgrace to reason and humanity. Charlemagne in France, and Alfred the Great in England, endeavoured to dispel this darkness, and gave their subjects a short glimpse of light and knowledge. But the ignorance of the age was too powerful for their efforts and institutions. The darkness returned, and settled over Europe, more thick and heavy than before." The clergy were the only body of men among whom any knowledge or learning now remained; and this superiority they employed to continue, if not to deepen, the degradation into which society had fallen. The superstitious belief that more crimes could be expiated by presents to the Deity, if not originated by them, at least found them its strenuous defenders, for the reason that a gift to God meant, in plainer language, a *solatium* to the church. The priests would have made men believe that avarice was the first attribute of the Deity, and that the saints made a traffic of their influence with Heaven. Hence Clovis is said to have jocularly remarked, that, "though St. Martin served his friends very well, he also made them pay well for his trouble."

Persons in the highest ranks and most exalted stations, could neither read nor write. Of the clergy themselves, many of them did not understand the Breviary which it was their duty to recite; and some of them, it is said, could scarcely read it. Those among the laity who had to express their assent in writing, did so by a sign of the cross attached to the document (sometimes also by a seal;) and to this day, in consequence, we speak of *signing* a document, when we subscribe our names.

The evils of the feudal system, too, had by this time become excessive and insupportable. Every petty chief was a king in his own dominions, and their vassals were their subjects, if, indeed, they should not be called slaves. These barons made laws of their own, held courts of their own, coined money in their own names, and levied war at their own pleasure against their enemies; and these enemies were not unfrequently their kings. Indeed, the kings of these times can be looked upon in no other light than as superior lords, receiving a nominal and empty homage for lands, which, in the fictitious language of feudal law, were said to be held of the crown. In these circumstances, what might we expect to be the condition of the great body of the people? They were either actual slaves, or exposed to so many miseries, arising from pillage and oppression, that many of them made a voluntary surrender of their liberty in exchange for bread and protection from the feudal lords. There *was* no people, as that term is now understood. "There was nothing morally in common," says Guizot, "between the lord and the serfs; they formed part of his domains, and were his property; under which designation were comprised all the rights that we at present call rights of public sovereignty, as well as the privileges of private property, he having the right of giving laws, of imposing taxes, and of inflicting punishment, as

well as that of disposing and selling. In fact, as between the lord and the labourers on his domain, there were no recognised laws, no guarantees, no society, at least so far as may be predicated of any state in which men are brought into contact." In what away society rose above so many accumulated evils, and light sprang from so much darkness, we shall now endeavour to show. The most remarkable and the most lasting influence, beyond all question, was that exerted by

THE CRUSADES.

"It is natural to the human mind," says Dr. Robertson, "to view those places which have been distinguished by being the residence of any celebrated personage, or the scene of any great transaction, with some degree of delight and veneration. To this principle must be ascribed the superstitious devotion with which Christians, from the earliest ages of the church, were accustomed to visit that country which the Almighty had selected as the inheritance of his favourite people, and in which the Son of God had accomplished the redemption of mankind. As this distant pilgrimage could not be performed without considerable expense, fatigue, and danger, it appeared the more moritorious, and came to be considered as an expiation for almost every crime. An opinion, which spread with rapidity over Europe about the close of the tenth and beginning of the eleventh century, and which gained universal credit, wonderfully augmented the number of credulous pilgrims, and increased the ardour with which they undertook this useless voyage. The thousand years mentioned by St. John [Rev. xx. 2, 3, 4] were supposed to be accomplished, and the end of the world to be at hand. A general consternation seized mankind; many relinquished their possessions, and, abandoning their friends and families, hurried with precipitation to the Holy Land, where they imagined that Christ would quickly appear to judge the world."*

"While Palestine continued subject to the caliphs, they had encouraged the resort of pilgrims to Jerusalem, and considered this as a beneficial species of commerce, which brought into their dominions gold and silver, and carried nothing out of them but relics and consecrated trinkets. But, the Turks having conquered Syria about the middle of the eleventh century, pilgrims were exposed to outrages of every kind from these fierce barbarians. This change happening precisely at the juncture when the panic terror which I have mentioned rendered pilgrimages most frequent, filled Europe with alarm and indignation. Every person who returned from Palestine related the dangers which he had encountered, in visiting the holy city, and described with exaggeration the cruelty and vexations of the Turks."

Among the most notorious of those who had returned with these accounts, was a monk known by the name of Peter the Hermit. By all accounts this individual seems to have been a weak-minded and contemptible being. He is represented as running from city to city, and from kingdom to kingdom, bare-headed, with naked arms and legs, and bearing aloft a ponderous crucifix in his hand, imploring and preaching with an enthusiastic madness on the necessity of wresting the Holy Land from the hands of the infidels. In a more enlightened age, Peter the Hermit would probably have been confined as a troublesome lunatic; in this, however, he was not only allowed to go on, but encouraged and abetted in his career. The ambitious Hildebrande had expressed a strong desire to send armed forces from Europe to exterminate the Mohammedans from Palestine, in order that another country might be brought under his spiritual subjection; and Urban II., who at this time occupied the chair of St. Peter, warmly seconded the efforts of the enthusiastic monk. Nor was Peter's success small. Vast multitudes proclaimed themselves ready to engage in he undertaking. Two great councils of the church, one of them held at Placentia and the other at Clermont, in Auvergne, attended by prelates, princes, and immense multitudes of the common people, declared enthusiastically for the war (1095). The pope himself attended at the last, and Peter and he having both addressed the multitude, they all exclaimed, as if impelled by an immediate inspiration, "It is the will of God! it is the will of God!" These words were thought so remarkable, that they were afterwards employed as the motto on the sacred standard, and came to be looked upon as the signal of battle and of rendezvous in all the future exploits of the champions of the cross. Persons of all ranks now flew to arms with the utmost ardour. The remission of penance, the dispensation from those practices which superstition imposed or suspended at pleasure, the absolution of all sins, and the assurance of eternal felicity, were the rewards held out by the church to all who joined the enterprise; and "to the more vulgar class," says Mr. Hallam, "were held out inducements which, though absorbed in the overruling fanaticism of the first Crusade, might be exceedingly efficacious when it began to flag. During the time that a crusader bore the cross, he was free from suits for his debts, and the interest of them was entirely abolished; he was exempted, in some instances at least, from taxes, and placed under the protection of the church, so that he could not be impleaded in any civil court, except in criminal charges or questions relating to land." It was in the spring of the year 1096, that Peter the Hermit set out for Judea, at the head of a promiscuous assemblage of 80,000 men, with sandals on his feet, a rope about his waist, and every other mark of monkish austerity. Soon after, a more numerous and better disciplined force of 200,000 followed, including some able and experienced leaders. Godfrey of Bouillon, Robert, Duke of Normandy (son of William the Conqueror of England), the Counts of Vermendois, Toulouse, and Blois, are a few of the more illustrious. The progress of this immense mass of human beings on their journey was marked by misery and famine. They had vainly trusted to Heaven for a supernatural supply of their wants, and in their disappointment, they plundered all that came in their way. "So many crimes and so much misery," says Mr. Hallam, "have seldom been accumulated in so short a space, as in the three years of the first expedition;" and another historian says, that a "fresh supply of German and Italian vagabonds," received on the way, were even guilty of pillaging the churches. It is certain that before the hermit reached Constantinople, the number of his forces had dwindled down to 20,000. Alexis Comnenus, then Emperor of Constantinople, who had applied to the states of Europe for assistance, without much hope of obtaining it, in order that he might be enabled to resist a threatened attack by the Turks upon himself, was surprised and terrified at the motley group of adventurers who had now reached the shore of his dominions. He readily afforded them the means of transporting themselves across the Bosphorus, and performed the same friendly office to the larger force which followed under Godfrey and others; glad, apparently, to have the barbarians of the north, as his subjects called them, out of his dominions. The Sultan Solyman met the army of the hermit, if army it could be called, and cut the greater part of it to pieces on the plains of Nicea. The second host proved more successful. In spite of their want of discipline, their ignorance of the country, the scarcity of provisions, and the excess of fatigue, their zeal, their bravery, and their irresistible force, enabled them twice to overthrow old Solyman, to take his capital, Nice, and

* Mr. Hallam mentions, as corroborative of this general belief, that charters at this period usually commenced with these words: "As the world is now drawing to its close;" and that an army, marching under the Emperor Otho I., was so terrified by an eclipse of the sun, which it conceived to announce this consummation, as to disperse hastily on all sides

after an obstinate resistance, the city of Antioch also (1098). At length (1099) they reached Jerusalem, much diminished in numbers and broken in spirit; but, with persevering assiduity, they proceeded to lay siege to the city, and in six weeks they became its masters. Their cruel conduct to the inhabitants attests the barbarous feelings of their hearts. "Neither arms defended the valiant, nor submission the timorous; no age nor sex was spared; infants on the breast were pierced by the same blow with their mothers, who implored for mercy; even a multitude of ten thousand persons, who had surrendered themselves prisoners and were promised quarter, were butchered in cold blood by these ferocious conquerors. The streets of Jerusalem were covered with dead bodies. The triumphant warriors, after every enemy was subdued and slaughtered, turned themselves, with the sentiments of humiliation and contrition, towards the holy sepulchre. They threw aside their arms, still streaming with blood; they advanced with reclined bodies and naked feet and heads, to that sacred monument; they sung anthems to him who had purchased their salvation by his death and agony; and their devotion, enlivened by the presence of the place where he had suffered, so overcame their fury, that they dissolved in tears, and bore the appearance of every soft and tender sentiment. So inconsistent is human nature with itself, and so easily does the most effeminate superstition ally, both with the most heroic courage and with the fiercest barbarity!"

With a becoming foresight, the Crusaders established a Christian kingdom in the heart of Palestine; and at the head of it, by universal consent, was placed Godfrey, whose goodness and justice had signalized him, and gained him respect, in the midst of the general wickedness. The pope, however, was too eager to enjoy the triumph to which he had looked forward, and sending an ignorant and obtruding ecclesiastic to assume this command, Godfrey retired; and thus was lost, undoubtedly, the best chance that Europeans ever had of really possessing the Holy Land. The Turks had now time to recover their strength and renew their attacks: they did so: many of the Crusaders had in the mean time returned home, and those of them who remained, surrounded and menaced by such foes, at last implored aid from Christendom. There the spirit which had been raised by Peter the Hermit was far from being extinguished; and another, more eloquent and more learned than Peter, namely St. Bernard, had arisen to keep alive the flame of devotion. Roused by his preaching, Europe sent forth a second Crusade (1147). It consisted of 200,000 French, Germans, and English, in two divisions, the first led on by Conrad III. of Germany, and the second by Louis VII. of France. Strangely enough, both these leaders permitted themselves to be drawn into a snare by false guides, furnished by the Greek Emperor; and both armies, one after another, were withdrawn amidst the rocks of Laodicea, and, after being nearly starved by famine, they were cut to pieces by the Sultan of Iconium. This Crusade proved the most disastrous of them all. "Thousands of ruined families," says Russell, "exclaimed against St. Bernard for his deluding prophecies: he excused himself by the example of Moses, who, like him, he said, had promised to conduct the Israelites into a happy country, and yet saw the first generation perish in the desert."

It was shortly after this period that the illustrious Saladin appeared (1180). Born among an obscure Turkish tribe, this individual fixed himself by his bravery and conduct on the throne of Egypt, and began to extend his conquests in the east. The still existing, though wretchedly supported kingdom of the Christians in Palestine, proving an obstacle to the progress of his arms, Saladin directed his power against it, and, assisted by the treachery of the Count of Tripoli, he completely overcame the Christians in battle (1187). The holy city itself fell into his hands, after a feeble resistance and, except some cities on the coast, nothing remained to the Christians of all that, a century before, it had cost Europe so much to acquire. The followers of the cross, however, were not yet wholly disheartened; and a third great Crusade was entered into before the end of the twelfth century. The three greatest sovereigns of Europe, Frederick Barbarossa of Germany, Philip Augustus of France, and Richard Cœur de Lion of England, all took part. The forces of Frederick were earliest in the field. He had passed through the unfriendly territories of the Greek empire, crossed the Hellespont, and defeated the infidels in several battles, before Richard or Philip had stirred from home. The Christians of the East were beginning to look with hope and pride on so great assistance; but they seemed fated to be unfortunate. Frederick died (1190), from having thrown his body, heated by exertion, into the cold river of Cydnus; and his army, like the others that had gone before it, dwindled into nothing. The united armies of Richard and Philip followed. In their progress, the feelings of envy and national hatred rose above the object which had brought them together. Philip returned, disgusted or dismayed, shortly after they reached their destination; and Richard was thus left alone to uphold the glory of European arms. He did it nobly. With a mixed army of French, German, and English soldiers, amounting in all to 30,000, Richard performed feats of valour which have not been surpassed in the history of any time or nation. On the plains of Ascalon, a tremendous battle was fought with Saladin, and that brave and great man was defeated, and 40,000 of his soldiers are said to have been left dead upon the field of battle. But this conquest was unavailing, and the followers of Richard began to fear that there would be no end to their struggles. The zeal which had brought so many of them from their homes, and sustained them so long in absence, at last abated. Saladin readily concluded a treaty by which Christians might still be permitted to visit the tomb of Christ unmolested, and Richard left the Holy Land for ever. It is due to the memory of Saladin (who did not long survive this period) to state, that, after he made himself master of Jerusalem, he never molested the Christians in their devotions—a circumstance which, by contrast, reflects infinite disgrace on the cruel barbarities of the first Crusaders. In his last will, he ordered alms to be distributed among the poor, without distinction of Jew, Christian, or Mohammedan; intending by this bequest to intimate, that all men are brethren, and that when we would assist them, we ought not to inquire what they believe, but what they feel—an admirable lesson to Christians, though from a Mohammedan! But the advantages in science, in moderation, and humanity, seem at this period to have been all on the side of the Saracens.

There were no more great Crusades. Considerable bands of private adventurers still continued to move eastward; but disaster and disgrace attended every effort, and Europe at last became disheartened, when the bones of two millions of her sons lay whitened on the plains of Asia, and so little had been accomplished. Nevertheless, in the year 1202, Baldwin, Count of Flanders, was able to raise another considerable army for the rescue of the Holy Sepulchre; but having reached Constantinople at a time when there was a dispute in the succession to the throne, he readily laid aside the project of the Crusade, took part in the quarrel, and in the course of five months he was himself the emperor. The citizens of Venice, in Italy, who had lent their vessels for this enterprise, shared in the triumphs of the piratical Crusaders; they obtained the Isle of Candia, or Crete. Baldwin, however, was soon driven from the throne and

murdered, though the Latins, as his successors from the west were called, kept possession of Constantinople for fifty-seven years.

At this period (1227) a great revolution took place in Asia. Gengis Khan, at the head of a body of Tartars, broke down from the north upon Persia and Syria, and massacred indiscriminately Turks, Jews, and Christians, who opposed them. The European settlements in Palestine must soon have yielded to these invaders, had not their fate been for a while retarded by the last attempt at a Crusade under Louis IX. of France. This prince, summoned as he believed by Heaven, after four years' preparation, set out for the Holy Land, with his queen, his three brothers, and all the knights of France (1248). His army began their enterprise, and we may say ended it also, by an unsuccessful attack on Egypt. The king went home, and reigned prosperously and wisely for thirteen years; but the same frenzy again taking possession of him, he embarked on a Crusade against the Moors in Africa, where his army was destroyed by a pestilence, and he himself became its victim (1270).

Before the end of the thirteenth century (1291) the Christians were driven out of all their Asiatic possessions. "The only common enterprise," says Robertson, "in which the European nations were engaged, and which they all undertook with equal ardour, remains a singular monument of human folly."

INSTITUTION OF CHIVALRY.—STATE OF EUROPE DURING AND AFTER THE CRUSADES.

Among the most remarkable institutions of the middle ages, was that of Chivalry. The institution was certainly not the result of caprice, nor a source of unmixed extravagance, as it has been represented, but an effort of human nature to express its feelings of love, honour, and benevolence, at a time when the spirit of liberty was extinguished, and religion had become debased. The feudal state was a state of perpetual war, rapine, and anarchy, during which the weak and unarmed were often exposed to injuries. Public protective law scarcely had an existence; and in these circumstances assistance came oftenest and most effectually from the arms of private friends. It was the same feeling of courage, united to a strong sense of duty, which both gave rise to chivalry, and led such multitudes to join the Crusades. Chivalry existed before them, and it survived them. Those who devoted themselves to a life of chivalry were called knights, and sometimes knight-errants, in allusion to their habits of wandering from one country to another in search of helpless objects, which their generosity might find a pleasure in relieving and defending. Admission to the order of knighthood was long reckoned an honour of the highest sort; and to fulfil the vows which entrants took upon them, might well be considered so. They were bound, "by God, by St. Michael, and St. George," to be loyal, brave, and hardy; to protect the innocent, to redress the injuries of the wronged; and, above all, to uphold and defend the characters of women. The institution of chivalry is sometimes thought to have thrown an air of ridiculousness upon every thing connected with the softer sex, and some of the vagaries of knight-errantry give sufficient countenance to such a supposition; but on the whole we are bound to rate its beneficial influences in elevating the female character high indeed, when we contrast the gross and grovelling situation held by the sex in former times with the high and virtuous emotions that we have learned to associate in modern times with the name of woman. If the whole of this effect is not to be ascribed to chivalry, not a little of it must certainly be so; nor do its beneficial effects end here. The feelings of honour, courtesy, and humanity, which distinguished it, spread themselves into other parts of conduct. War, in particular, was conducted with less ferocity, and humanity came to be deemed as necessary to an accomplished soldier as courage. The idea of a *gentleman* is wholly the production of chivalry; and during the twelfth, thirteenth, fourteenth, and fifteenth centuries, a sense of honour and a refinement of manners towards enemies sprung up, which have extended to modern times, and form a distinguishing feature of them.

The history of the Crusades has carried us over nearly two centuries of the history of Europe. But Europe might be said, almost without exaggeration, to have been then in Asia. It was certainly not the scene of any transaction of importance during all that period. The numerous quarrels, both public and private, which had before agitated the several countries, and had constituted all their history, gave way, by mutual consent, as well as by the orders of the church, to the one idea which then reigned supreme among them. Society was thus unconsciously the means of permitting some of those powerful and pacific principles to come into play, which were soon to give it a new destiny. The absence of so many great barons, during the time of the Crusades, was a means of enabling the common people, who had hitherto lived as their slaves, to raise themselves in public standing and estimation; while the possessions of many of these barons, by sale, or the death of their owners without heirs, reverted to the sovereigns. In this way the power of the people and of royalty advanced together, and both at the expense of the class of nobility. The people were not unwilling to exchange the mastery of inferiors for that of a superior; and the kings on their part looked on this rising power of the people with pleasure, as it offered a shield to protect them from the insolence of the nobles. In these circumstances boroughs began to flourish. This was a new element in the progress of civilization. Men who had hitherto skulked in castles, and had sacrificed their liberties and their lives for bread and protection from isolated chiefs, now found that, by a union among themselves, they might secure bread by industry, and protection and liberty by mutual aid. Multitudes, therefore, forsook their feudal subservience to enjoy independent citizenship. Villeins, or labourers, joyfully escaped to take their place on a footing of equality with freemen; and sovereigns found means to pass a law that, if a slave should take refuge in any of the new cities, and be allowed to remain there unclaimed for a twelvemonth, he had thereby become free, and was henceforth a member of the community. Another improvement which kings were able to introduce about this time was the gradual abolition of minor courts of justice, which barons had previously held in their several domains, and their getting public and universal law administered by judges of their own appointment. Even single combat, the practice most inveterately adhered to of any among the ancient nobles, became less frequent and less honourable. The more revolting and absurd features of it were wholly abolished, though the great absurdity, and indeed the great crime itself, cannot be said to have become totally extinct, even up to our own day, when we recollect that the barbarous practice of duelling is still permitted to exist.

The effect, however, produced by the Crusades, which proved greatest in its consequences, though perhaps it was the most unlooked for at the time, was the rise of commerce. The first of these expeditions had journeyed to Constantinople by land; but the sufferings were so great, that all the rest were induced to go by sea. The Italian cities of Venice, Genoa, and Pisa, furnished the vessels which conveyed them; and the sums of money obtained for the freight of so many and so great armies were immense. This, however, was but a small part of what the Italian citizens gained by the expeditions to the Holy Land. The Crusaders contracted with them for military stores and provisions; and any of the Asiatic possessions of value, which came temporarily into the

hands of the Christians, became emporiums of commerce for them. The sweet reward of labour was thus first felt for ages in Europe. New arts were brought from the east, and many of those natural productions of the warmer climates were first introduced into the west, which have since afforded the materials of a lucrative and extended commerce. We will allude in a separate section to the brilliant career of several of the Italian Republics.

In these views we represent the fairest side of the picture. There were yet many obstacles in the way of a complete and harmonious evolution of the principles of civilisation. But the elements all seemed now to have acquired existence, and time only was required to consolidate and strengthen them.

CONTINUATION OF THE HISTORY OF EUROPE TO THE MIDDLE OF THE FIFTEENTH CENTURY.—RISE OF SOME NEW POWERS.

The most remarkable general feature of European society about the time of the Crusades was the papal influence. Between the pontiffs and the German emperors there was kept up a perpetual struggle for power; but for a long time the advantage was almost always with the popes. The treatment which some of the emperors received from them was extremely humiliating. Frederick Barbarossa was compelled to kiss the feet of his holiness, Alexander III., and to appease him by a large cession of territory, after having indignantly denied his supremacy, and refused the customary homage. Henry VI., while doing homage on his knees, had his imperial crown kicked off by Pope Celestinus, who, however, made some amends for this indignity by the gift of Naples and Sicily. Henry had expelled the Normans from these territories, which now became appendages of the German empire (1194). In the beginning of the thirteenth century, Pope Innocent III. was imagined to have permanently established the powers of the holy see, and its right to confer the imperial crown; but this proved far from being the case. In the time of Frederick II., who succeeded Otho IV. (1212), the old contentions rose to more than the usual height, and two factions sprung up in Italy, known by the names of Guelphs and Ghibellines, the former maintaining the supremacy of the popes, and the latter that of the emperors. Frederick maintained the contest which now arose between himself and the popes, with much spirit; but, on his death (1250), the splendour of the empire was for a considerable time obscured. At length, Rodolph of Hapsbourg, a Swiss baron, was elected emperor (1274). Rodolph became the founder of the house of Austria, and ruled with both vigour and moderation. His son, Albert I., was the means of causing the inhabitants of Switzerland to assert and obtain their liberty, by his attempting to bind them in subjection to one of his children, and then using force to compel them. In the pass of Morgarten, a small army of four or five hundred of these brave mountaineers defeated an immense host of Austrians (1315). Sixty pitched battles, it is said, were fought between the contending parties; but the spirit of William Tell, who appeared at this time, and of his patriot countrymen, rose above all attempts to enslave them; and the Swiss cantons secured a freedom which their descendants enjoy to this day. The further history of Germany, for nearly a century, is not politically important. Disputes between the emperors and the papacy still continued, though the balance of advantage was now oftener against the church. About the beginning of the fifteenth century the great papal schism, as it was called, took place. It arose from there being no fewer than three different claimants for the chair of St. Peter—Gregory XII., who was owned Pope by the Italian states; Benedict XIII., by France; and Alexander V., a native of Candia, by a number of the cardinals. This schism proved very hurtful to the authority of the church, though in that respect it benefited the interests of society, and contributed to open men's eyes. The appearance of John Huss at this time aided in producing that effect. Huss proclaimed the same opinions as the great English reformer Wickliffe. He was branded, of course, by the clergy as a heretic and propagator of sedition. The general council of the Church, held at Constance (1514), concocted no fewer than thirty-nine articles in which Huss is said to have erred. Some of the points he denied having professed, and others he offered to support by argument; but his voice was drowned by the clamours of bigotry. His hair was cut in the form of a cross; upon his head was put a paper mitre, painted with the representation of three devils; and he was delivered over to the secular judge, who condemned both him and his writings to the flames. A similar fate shortly after befell his disciple, Jerome of Prague, who is said to have exhibited the eloquence of an apostle and the constancy of a martyr at the stake (1416). In revenge for these cruelties, the Hussites of Bohemia kept up a war with the empire for twenty years; and it was only after having their right to express their opinions acknowledged that they desisted. The great schism lasted for many years. A Neapolitan archbishop, named Bari, was elected and deposed by the resident cardinals at Rome within a few months. Boniface IX. and Innocent VI. were each temporarily his successors. The result of the lengthened dispute may be stated to be, that papal authority was greatly weakened; the government of the church was brought down among a class of ecclesiastics that had never before tasted the sweets of power, and future popes were obliged to resort to such questionable practices for the maintenance of their dignity, that men in general began to lose respect for their sanctity, and a foundation was laid for changes which it fell to the lot of Luther and others to effect.

The period which witnessed these transactions was remarkable for the continued wars between France and England. In the beginning of the twelfth century, the famous dispute for supremacy arose between Thomas-à-Becket, Archbishop of Canterbury, and Henry II, which ended in the death of the prelate (1171), but in the triumph of his principles. The beginning of the thirteenth century is memorable in English history, as having witnessed the granting of the Magna Charta by King John; and towards the conclusion of it appeared Edward I., whose name is associated with the first great attempts to subdue the Scots on the part of England. The bravery of Wallace and of others averted that calamity for ever. Wales was not so fortunate; and Ireland had already become a conquered province. The grandson of Edward I., named Edward III., proved himself as ambitious and as sagacious as his predecessor. His attention, however, was greatly diverted from the kingdom of Scotland to that of France, with which country he commenced a war that proved greater in duration and extent than any that had occurred in Europe since the fall of the Roman empire. The proposal of subduing so great a country as France, and seating himself upon the throne of it, seemed at first to be the proposal of a madman; but in less than twenty years Edward had so effectually dismembered the different provinces, alienating some of the nobility and overawing others, that his attaining the object of his desires seemed by that time no improbable nor distant reality. His son, known in history as Edward the Black Prince, named so from the colour of his armour, contributed much, by his presence and his valour, to the success of the English arms. In the battle of Cressy, fought in 1346, with numbers greatly on the side of France, and in that of Poictiers, fought ten years later, under similar circumstances, the English were completely victorious. John, King of France, was taken prisoner, and the conduct of young Edward to his fallen enemy was generous and

delicate in the highest degree, so that the French prisoners are said to have been overcome by the display of such an elevation of mind on the part of their conqueror, and to have burst into tears. This refinement was the result of chivalry, which both the Edwards attached themselves to, and rendered respectable by their virtues.

France was at this time in a deplorable state. A foreign enemy in the heart of the kingdom, the king a prisoner, the capital in sedition, and civil war raging over and above all—these were some of her accumulated misfortunes; and as if nature meant to conspire with man for her destruction, a plague broke out at this time among the people, and consummated the work of famine and the sword. This plague, however, was not confined to France, though, from the dilapidated state of that country, it proved perhaps in it most disastrous. It invaded every kingdom of Europe, and the English historian, Hume, computes that it swept away about one-third of the inhabitants of every country that it attacked. The origin of the disease is not well known; but there can be no doubt that it could only have made the ravages which it did among nations uncivilized and ignorant, heedless of all the cleanliness and comforts which we know, in modern times, to be necessary to the preservation of health. According to the ordinary account, this pestilence took its rise in the Levant about the year 1346, from whence Italian traders brought it to Sicily, Pisa, and Genoa. In 1348, it passed the Alps, and spread over France and Spain. In the next year it reached Britain, where, in London alone, 50,000 persons are said to have become its victims; and in 1350, it laid waste Germany and other northern states, lasting generally in each country about five months. At Florence more than three out of every five of the inhabitants were swept away. It is well known to those acquainted with Italian literature, that the time of Boccaccio's Decameron is laid during this pestilence.

While the plague lasted, a temporary truce had been agreed upon between the French and English. At that time the balance of advantage was greatly in favour of the English. Not to mention less important gains, all Guienne, Gascony, Poitou, Saintonge, the Limousin, and the Angoumois, as well as Calais, and the county of Pointhieu, were ceded in full sovereignty to Edward, and the empty title of King of France was all that he became bound to give up (1360). But it was found impossible to retain possessions in the heart of a foreign country, though won by consummate bravery and ruled with no imprudence. In less than ten years (1368), the war was recommenced, and the English began to lose many of the provinces which they had previously acquired. Charles V., who had acted as regent in France during the captivity of his father John, and was now his successor on the throne, contributed greatly by his wisdom to this result; and his general, Du Guesclin, contributed not less to it by his valour. England had lost both its Edwards, and Richard II. proved destitute of abilities for leading on the enthusiasm of his countrymen to any thing great. Charles died prematurely, however, a circumstance which proved unfortunate for France, as his son, the sixth of the same name, was a very unworthy successor. For forty years, Charles VI. may be said to have borne the name of king, rather than to have reigned in France. The wealth accumulated by Charles the Wise, was, in the first place, stolen by the Duke of Anjou, and afterwards, by reason of want of funds, and misapplication of what they had, Charles VI. and his ministers were fully more engaged in quarrels with the citizens of Paris and other subjects, than in any becoming efforts to expel the English. History records, however, that the king became totally imbecile in mind (1393), so that he was, by universal consent, excluded from all share in the government, and the houses of Burgundy and Orleans long struggled for the regency. At this period, Henry V. of England put in a claim for the government of the kingdom, on the strength of a distant relationship to the reigning family; and, after having gained the memorable battle of Agincourt (1415), he was actually promised the throne on the death of Charles, though his own death prevented this from ever taking place. It may be worth remarking, that *cards* were invented in this age. The desire to amuse the silly king of France was the cause. In the year 1422 Charles VII., surnamed the Victorious, was crowned King of France at Poictiers, while the crown was claimed on the part of Henry VI. of England, yet an infant. The war continued, and the English were like to have proved victorious, when a simple maiden, named Joan of Arc, made her appearance at the head of the armies of France, and turned the tide of fortune in favour of her country. Apparently mistaking the impulses of superstition for divine inspiration, she gave out that she had been commissioned by Heaven to save her country; and having succeeded in inspiring the French soldiery with that belief, she led them on to battle, and they proved victorious. It must be recorded, to the disgrace of our countrymen, that Joan, being shortly after taken prisoner, was condemned to be burnt as a sorceress. The French, however, were but the more exasperated at this; and their victory of Formigny, and the death of Talbot, perhaps the greatest English warrior of the age, now left them in possession of all their country, with the exception of Calais and Greignes (1450).

Of all that was done by England to obtain a footing in France, a barren title to our sovereigns alone is all that was preserved till a recent period. The power and spirit of the French nation rose above all calamities, and in less than half a century, having freed herself of every enemy at home, her arms were in a condition to be directed externally with effect. The invasion of Naples by Charles VIII. was the event that first engaged the principal states of Europe in relations of alliance or hostility, which may be deduced to the present day, and is the point which most appropriately terminates the history of the middle ages.

During this period, several of those countries in the north of Europe, which have made a considerable figure in modern history, for the first time attracted attention. The greatest of these was Russia. In the middle of the thirteenth century, the tribes of Tartary made a complete conquest of this country, and for about a hundred years they maintained their supremacy. At length Ivan ascended the throne of Moscow (1462), and overcoming the Tartars, established a kingdom of his own, and was able to form an alliance with the Emperor Maximilian of Germany, who did not hesitate to style him brother. This was the first entrance of Russia into European politics.

Before the end of the fourteenth century, the Christian religion had penetrated into Denmark, Sweden, Prussia, and Poland; but it failed in producing any immediate beneficial effect. The political events which took place in these countries, however, were very various at this period, but proved too unimportant in their results to admit of being even outlined here.

THE ITALIAN REPUBLICS.—COMMERCE IN GENERAL.

Among the Italian cities, Venice, at the extremity of the Adriatic, Ravenna, at the south of the mouth of the Po, Genoa, at the foot of the Ligurian mountains, Pisa, towards the mouths of the Arno, Rome, Gaëta, Naples, Amalphi, and Bari, were either never conquered by the Lombards, or were in subjection too short a time to have lost many of their ancient habits and customs. In this way, these cities naturally became the refuge of Roman civilization, at a time when other parts of Europe were wading through barbarian darkness. The feudal system never prevailed among them with any force and several

of these and other cities had important privileges conferred upon them by the German emperors at a very early period. Sismondi, the historian of Italy, asserts that Otho I. (936) erected some of them into municipal communities, and permitted them the election of their own magistrates. It is certain that, in 991, the citizens of Milan rose in tumult, expelled an archbishop from their city, and were able to establish a qualified right to interfere in future elections. The after history of Milan is eventful and tragical; but we can only give a short account of it here. In the middle of the twelfth century, Frederic Barbarossa became engaged with the cities of Lombardy, and particularly with it, in extensive and destructive wars. In the year 1162, Milan was finally overcome; the walls and houses were razed from their foundation, and the suffering inhabitants dispersed over other cities, obtaining sympathy in their distress, and communicating their enthusiastic love of freedom in return. The republican form of government was adopted in every considerable town; and before the end of the thirteenth century, there was a power and knowledge among these apparently insignificant republics that all Europe could not match.

The beneficial though unlooked-for effect of the Crusades upon commerce has already been mentioned. During the twelfth and thirteenth centuries, the commerce of Europe was almost entirely in the hands of the Italians, more commonly known in those ages by the name of Lombards. The republic of Pisa was one of the first to make known to the world the riches and power which a small state might acquire by the aid of commerce and liberty. Pisa had astonished the shores of the Mediterranean by the number of vessels and galleys that sailed under her flag, by the succour she had given the Crusaders, by the fear she had inspired at Constantinople, and by the conquest of Sardinia and the Balearic Isles. Immediately preceding this period, those great structures which still delight the eye of the traveller—the dome, the baptistry, the leaning tower, and the Campo Santo of Pisa, had all been raised; and the great architects that spread over Europe in the thirteenth century, had mostly their education here. But, unfortunately, the ruin of this glorious little republic was soon to be accomplished. A growing envy had subsisted between it and Genoa during the last two centuries; and a new war broke out in 1282. It is difficult to comprehend how two simple cities could put to sea such prodigious fleets as those of Pisa and Genoa. Fleets of thirty, sixty-four, twenty-four, and one hundred and three galleys, were successively put to sea by Pisa, under the command of able generals; but on every occasion the Genoese were able to oppose them with superior fleets. On the 6th of August, 1284, the Pisans were defeated in a naval engagement before the Isle of Meloria; thirty-five of their vessels were lost, five thousand persons perished in battle, and eleven thousand became prisoners of the Genoese. After a few further ineffectual struggles, Pisa lost its standing.

The greatest commercial, and altogether the most remarkable city of the Italian republics, was Venice. Secluded from the world, on a cluster of islands in the Adriatic, the inhabitants of this city had taken up their abode in the course of the fifth century, and they boasted themselves to have been independent of all the revolutions which Europe had been undergoing since the fall of the Roman empire. This might be true to a great extent, though for long it was certainly more the result of their obscurity than their power. By the tenth century, however, the descendants of those fishermen that had first taken refuge here, were able to send fleets abroad which could encounter and overawe both Saracens and Normans. The Venetians had all along kept up a correspondence with Constantinople during the darkest periods of the middle ages. This was greatly renewed and extended about the time of the Crusades. When Constantinople was taken by the Latins (1204), the Venetians, under their doge, or chief magistrate, Henry Dandalo, became possessed of three-eighths of that great city and of the provinces, and Dandalo assumed the singularly accurate title of Duke of three-eighths of the Roman Empire. The Venetians greatly increased their share of the spoil by making advantageous purchases from the more needy of the Crusaders. Among the most important of these was the Isle of Candia, which they retained till the middle of the seventeenth century. The idea of a bank took its rise in this city, and an establishment of that nature, simply for the receipt of deposits, is said to have existed in it so soon as the year 1157. But it was not till about a century later that banking, as the term is now understood, began at all to be practised. The merchants of Lombardy and of the south of France began at that time to remit money by bills of exchange, and to make profit upon loans. The Italian clergy who had benefices beyond the Alps, found the new method of transmitting money exceedingly convenient, and the system of exacting usury or interest, after experiencing every obstruction from ignorance and bigotry, became a legal part of commerce. In the thirteenth century the government of Venice was entirely republican; but continued wars with Genoa reduced both cities. These wars were all conducted on the seas, and the display of naval strength on both sides seems prodigious when we reflect on the poor condition of Italy at the present day. Besides these wars for objects of ambition, there were continual jealousies which rose above enlightened views of self-interest, and led to the most disgraceful broils. At the middle of the fourteenth century, a battle took place between the rival citizens, in which the Genoese were defeated. Their loss was immense, and in distress and in revenge they gave themselves up to John Visconti, Lord of Milan, then the richest and among the most ambitious of the petty tyrants of Italy, hoping that he would give them the means to re-establish their fleet and continue the war with the Venetians. He did so, and in another naval engagement, fought in 1354, in the Gulf of Sapienza, the Venetians were entirely defeated. But the Genoese had sacrificed their liberty in their thirst for revenge. Visconti became their master, instead of friend. Venice was able to rise above its temporary discomfiture, and during the fifteenth century its fame and power became greater than they had ever been before. In the beginning of the fifteenth century the Venetians captured the town of Padua, and gradually lost their empire of the sea, while they acquired possessions on the continent.

Among the most famous of the Italian states at this period was Florence; and its fame was founded, not on arms but on literature. Like the other Italian cities, however, it owed its first elevation to the commercial industry of its inhabitants. There was a curious division of the Florentine citizens, subsisting about the beginning of the thirteenth century, into companies or *arts*. These were at first twelve, seven called the greater arts, and five the lesser; but the latter were gradually increased to fourteen. The seven greater arts were those of lawyers and notaries, of dealers in foreign cloth, called sometimes *calimala*, of bankers or money-changers, of woollen-drapers, of physicians and druggists, of dealers in silk, and of furriers. The inferior arts were those of retailers of cloth, butchers, smiths, shoemakers, and builders. It was in the thirteenth century that Florence became a republic, and it maintained its independence for two hundred years. In the beginning of the fifteenth century, it became peculiarly distinguished by the revival of Grecian literature and the cultivation of the fine arts. Cosmo de Medici, who lived a citizen of Florence at this time, and was known by the name of the Grand

Duke of Tuscany, descended from a long line of ancestors whose wealth had been honourably acquired in the prosecution of the *greater arts*, had more riches than any king in Europe, and laid out more money on works of learning, taste, and charity, than all the princes of his age put together. The same liberality and munificence distinguished his family for several generations.

The commercial success of the states of Italy induced the inhabitants of northern Europe to attempt similar enterprises. In the thirteenth century the sea-ports on the Baltic were trading with France and Britain, and with the Mediterranean. The commercial laws of Oleron and Wisbuy (on the Baltic) regulated for many ages the trade of Europe. To protect their trade from piracy, Lubec, Hamburgh, and most of the northern sea-ports, joined in a confederacy, under certain general regulations, termed the *League of the Hanse Towns;* a union so beneficial in its nature, and so formidable in point of strength, as to have its alliance courted by the predominant powers of Europe. "For the trade of the Hanse towns with the southern kingdoms, Bruges on the coast of Flanders was found a convenient enterpôt, and thither the Mediterranean merchants brought the commodities of India and the Levant, to exchange for the produce and manufactures of the north. The Flemings now began to encourage trade and manufactures, which thence spread to the Brabanters; but their growth being checked by the impolitic sovereigns of those provinces, they found a more favourable field in England, which was destined thence to derive the great source of its national opulence."—(*Tytler.*)

THE TURKS.—FALL OF CONSTANTINOPLE.

We have already seen the weakness of the empire of Constantinople at the time of the Crusades; we have seen the city sacked and the government seized by the champions of the cross. The Greeks regained their empire in the year 1261, but in a mangled and impoverished condition. For nearly two centuries it continued in a similar state. Andronicus, son of Michael Palæologus, who had restored the Greek empire, allowed himself to be persuaded that, as God was his protector, all military force was unnecessary; and the superstitious Greeks, regardless of danger, employed themselves in disputing about the transfiguration of Jesus Christ, when their unfortunate situation made it necessary that they should have been studying the art of war, and training themselves to military discipline.

In the mean time, the Turks had become a powerful people. They had embraced the Mohammedan religion long before the time of the Crusades, and proved powerful obstacles to the success of those expeditions. About the beginning of the fourteenth century, they established an empire of their own in Asia Minor, under Othman or Ottoman, and to this day the Ottoman Empire is a name given to the dominions of their descendants. By degrees they encroached on the borders of the empire of Constantinople, and they were only prevented from subverting it at a much earlier period than they did, by being called upon to defend themselves from the arms of an eastern conqueror who arose at this time. Tamerlane, otherwise called Timerbek, was a prince of the Usbek Tartars, and a descendant from Gengis Khan. After having overrun Persia, and a great part of India and Syria, this great conqueror was invited by some of the minor princes of Asia, who were suffering under the Ottoman tyranny, to come and protect them. Tamerlane was flattered by the request, and having brought a great army into Phrygia, he was there met by Bajazet, the Ottoman emperor, who readily gave battle, and was defeated and made prisoner (1402). Tamerlane made Samarcand the capital of his empire, and there received the homage of all the princes of the east. Illiterate himself, he was solicitous for the cultivation of literature and science in his dominions; and Samarcand became for a while the seat of learning, politeness, and the arts, but was destined to relapse, after a short period, into its ancient barbarism. The Turks, after the death of Tamerlane, resumed their purpose of destroying the empire of the East. The honour, or disgrace, as it may be thought, of effecting this, fell to the lot of Mohammed II., commonly surnamed the Great. At the early age of twenty-one, Mohammed projected this conquest. His countrymen had already passed into Europe; they had possessed themselves of the city of Adrianople, and, indeed, had left nothing of all the empire of the East to the Greeks, but the city of Constantinople itself. The preparations made for defence were not such as became the descendants of Romans, and the powers of Europe now looked upon the East with the most supine indifference. The Turks assailed the city both on the land side and on that of the sea; and, battering down its walls with their cannon, entered sword in hand, and massacred all who opposed them (1453). Mohammed, like many other ambitious conquerors, showed himself unwilling to destroy unnecessarily. The imperial edifices were preserved, and the churches were converted into mosques; the exercise of their religion was freely allowed to the Christians, and this privilege they have never been deprived of. Constantine (for that was the name of the last, as well as the first Emperor of the East) was slain in battle. From the time that it was founded by Constantine the Great, the city had subsisted 1123 years. Mohammed liberally patronized the arts and sciences. He was himself not only a politician, but a scholar, and he invited both artists and men of letters to his capital from the kingdoms of Europe. But the taking of Constantinople had an effect contrary to his wishes; it dispersed the learned Greeks, or Greeks who were *called* learned, all over Europe; and this, among other things, may be looked upon as a help to the great revival of letters which the fifteenth century witnessed. The taking of Constantinople was followed by the conquest of Greece and Epirus; and Italy might probably have met with a similar fate, but for the fleet of the Venetians, who opposed the arms of Mohammed with considerable success, and even attacked him in Greece; but the contending powers soon after put an end to hostilities by a treaty. By this time, Europe was trembling at Mohammed's success, and was afraid, not without reason, that he might pursue his conquests westwards. It was relieved from fear by the death of Mohammed (1481). His descendants have continued to our own day to occupy one of the finest countries in Europe; and it was only in the present age that Greece was liberated from their dominion.

RISE OF CIVIL FREEDOM AND SOCIAL IMPROVEMENT.

Civil freedom, as we have seen, dawned first in the great commercial cities of Italy, whence it spread to Germany, Flanders, and Britain. This important change in society may be traced to the institution of free communities of traders, or guilds of merchants; and such confederacies were a necessary consequence of the usurpation and tyranny of the nobles and feudal possessors of the soil. In the eleventh and twelfth centuries, the usurpations of the nobility became intolerable; they had reduced the great body of the people to a state of actual servitude. Nor was such oppression the portion of those alone who dwelt in the country, and were employed in cultivating the estates of their masters. Cities and villages found it necessary to hold of some great lord, on whom they might depend for protection, and became no less subject to his arbitrary jurisdiction. The inhabitants were deprived of those rights which, in social life, are deemed most natural and inalienable. They could not dispose of the effects which their own industry

had acquired, either by a latter will, or by any deed executed during their lives. Neither could they marry, or carry on lawsuits, without consent of their lord. But as soon as the cities of Italy began to turn their attention towards commerce, and to conceive some idea of the advantages which they might derive from it, they became impatient to shake off the yoke of their insolent lords, and to establish among themselves such a free and equal government as would render property and industry secure. The Italian cities were the first to emancipate themselves, and their example was followed in other great seats of population, the king of the country in general countenancing the establishment of free communities, in order to gain support against the encroachments of the overgrown power of the barons. The first community of this description formed in Scotland is understood to have been that of Berwick-upon-Tweed, which received its charter from William the Lion. Towns, upon acquiring the right of community, became so many little republics, governed by known and equal laws. The inhabitants being trained to arms, and being surrounded by walls, they soon began to hold the neighbouring barons in contempt, and to withstand aggressions on their property and privileges. Another great good, of fully more importance, was produced. These free communities were speedily admitted, by their representatives, into the great council of the nation, whether distinguished by the name of a Parliament, a Diet, the Cortes, or the States-General. This is justly esteemed the greatest event in the history of mankind in modern times. Representatives from the English boroughs were first admitted into the great national council by the barons who took up arms against Henry III. in the year 1265; being summoned in order to add to the greater popularity of their party, and to strengthen the barrier against the encroachments of regal power. Readers may draw their own conclusions from an event which ultimately had the effect of revolutionizing the whole framework of society, and of rearing that great respectable body of the people styled "the middle class."

The enfranchising of burgel communities led to the manumission of slaves. Hitherto the tillers of the ground, all the inferior classes of the country, were the bondsmen of the barons. The monarchs of France, in order to reduce the power of the nobles, set the example, by ordering (1315–18) all serfs to be set at liberty on just and reasonable conditions. The edicts were carried into immediate execution within the royal domain. The example of their sovereigns, together with the expectation of considerable sums which they might raise by this expedient, led many of the nobles to set their dependants at liberty; and servitude was thus gradually abolished in almost every province of the kingdom. This beneficial practice similarly spread over the rest of Europe; and in England, as the spirit of liberty gained ground, the very name and idea of personal servitude, without any formal interposition of the legislature to prohibit it, was totally banished *

While society was assuming the semblance of the form it now bears, the progress of improvement was accelerated by various collateral circumstances, the first of which worth noticing was

The Revival of Letters. The first restorers of learning in Europe were the Arabians, who, in the course of their Asiatic conquests, became acquainted with some of the ancient Greek authors, discovered their merits, and had them translated into Arabic, esteeming those principally which treated of mathematics, physics, and metaphysics. They disseminated their knowledge in the course of their conquests, and founded schools and colleges in all the countries which they subdued. The western kingdoms of Europe became first acquainted with the learning of the ancients through the medium of those Arabean translations. Charlemagne caused them to be retranslated into Latin; and, after the example of the Caliphs, founded universities at Bononia, Pavia, Osnaburg, and Paris. Similar efforts were made in England by Alfred; and to him we owe the establishment, or at least the elevation, of the University of Oxford. The first efforts, however, at literary improvement, were marred by the subtleties of scholastic divinity. Perhaps the greatest and wisest literary character of the middle ages was an English friar, named Roger Bacon. This extraordinary individual was not only learned, but, what was more uncommon in those times, he was scientific. Hallam asserts that he was acquainted with the nature of gunpowder, though he deemed it prudent to conceal his knowledge. He saw the insufficiency of school philosophy, and was the first to insist on experiment and the observation of nature as the fittest instruments by which to acquire knowledge. He reformed the calendar, and made discoveries in astronomy, optics, chemistry, medicine, and mechanics.

It is to Italy, however, that we owe the first and greatest exertions in the revival of letters. The spirit of liberty which had arisen among its republics was favourable to the cultivation of literature; and accordingly we find that not only did they produce many individuals who were most active and successful in bringing to light the relics of classical lore, but that there also arose among them men possessed of the highest order of original genius. Florence produced Dante so early as 1265. Dante was associated with the magistracy of his native city in his earlier years, but, having given dissatisfaction in that capacity, he was banished, and in his exile produced his great poem entitled the Divine Comedy. It is a representation of the three supposed kingdoms of futurity—Hell, Purgatory, and Paradise—divided into one hundred cantos, and containing about 14,000 lines. The poem has been much praised. Petrarch, born in the year 1304, was likewise a Florentine by birth. The misfortunes of his father had impoverished the family, and Petrarch was too proud to take the usual method of retrieving his affairs. His genius, however, earned for him the friendship of many Italian princes, and even of more popes than one, although he had exerted his talents to expose the vices of their courts. Petrarch's personal character seems to have exhibited some unamiable traits; but he has sung of love, friendship, glory, patriotism, and religion, in language of such sweetness and power as to have made him the admiration of every succeeding age. Boccaccio, like the two great poets named, was also a Florentine. He was born in 1313, and his name has descended to posterity less associated with his poetry than the light, elegant, and easy prose of his novels. These were the production of his idle hours; and his Latin works, on which he supposed his fame to rest, have long since been forgotten.

The discovery of Justinian's Laws, as detailed in the Pandects (see HISTORY OF LAWS), was another event which powerfully tended to modify the barbarism that prevailed during the middle ages in Europe.

The invention of the Mariner's Compass must be reckoned of still greater importance, and yet it is absolutely unknown to whom we owe it. That honour has been often bestowed on Gioia, a citizen of Amalphi, who lived about the commencement of the fourteenth century. But the polarity of the magnet at least was known to the Saracens two hundred years before that time; though even after the time of Gioia, it was long before the magnet was made use of as a guide in navigation. "It is a singular circumstance," says Mr. Hallam, "and only to be explained by the obstinacy with which men are apt to reject improvement, that the magnetic needle was not generally adopted in navigation till very long after the discovery of its properties, and even after their peculiar

* Robertson's History of Charles V.

importance had been perceived. The writers of the thirteenth century, who mention the polarity of the needle, mention also its use in navigation; yet Capmany has found no distinct proof of its employment till 1403, and does not believe that it was frequently on board Mediterranean ships at the latter part of the preceding age." The Genoese, however, are known in the fourteenth century to have come out of that inland sea, and steered for Flanders and England. But by far the greatest sailors of the age were the Spaniards and Portuguese. This latter nation had little or no existence during the greater part of the middle ages, but in the twelfth, thirteenth, and fourteenth centuries, they were able to expel the Moors from a great part of their country; and in the beginning of the fifteenth, John, surnamed the Bastard, who was then their king, was the first European prince who exhibited a respectable navy. It was in the year 1486 that this adventurous people first doubled the Cape of Good Hope.

The discovery of America (1493) may be mentioned supplementarily to the invention of the mariner's compass, as an event which, without it, could never have taken place. The immortal honour of that discovery rests with Christopher Columbus, a sailor of Genoa. After unsuccessful applications at almost every court in Europe, and braving obloquy and contempt, Columbus at last obtained a miserable force from Ferdinand and Isabella of Spain, and with no landmarks but the heavens, nor any guide but his compass, he launched boldly into the sea, and at last conducted Europeans to the great western hemisphere. The importance of that discovery, and its effect on the destinies of mankind, are subjects on which it is not our present purpose to dilate.

In the course of the fourteenth and beginning of the fifteenth centuries, various discoveries in the arts were made, which powerfully tended to the advancement of society; among these the more important were the invention of gunpowder and fire-arms, clocks and watches, paper-making, and printing. This last, the greatest of all, prepared the way for the Reformation in religion, in the sixteenth century, by which religious was added to civil freedom, and a great spur given to individual activity.

Important as these events were in their ultimate tendencies, it is to be remembered that they did not immediately make any distinct change in the comforts of the people. In the latter centuries of the middle ages, the amusements of the common people were metrical and prose romances, unintelligible prophecies, and fables of giants and enchanters. The state of England and of France, at this period, shows the small advance which had been made towards those comforts and improvements which now exist. Even in the large cities, the houses were roofed with thatch, and had no chimneys. "The two most essential improvements in architecture during this period," says Mr. Hallam, "one of which had been missed by the sagacity of Greece and Rome, were chimneys and glass windows. Nothing apparently can be more simple than the former; yet the wisdom of ancient times had been content to let the smoke escape by an aperture in the centre of the roof; and a discovery, of which Vitruvius had not a glimpse, was made, perhaps in this country [England], by some forgotten semi-barbarian. About the middle of the fourteenth century, the use of chimneys is distinctly mentioned in England and in Italy; but they are found in several of our castles which bear a much older date. This country seems to have lost very early the art of making glass, which was preserved in France, whence artificers were brought into England to furnish the windows of some new churches, in the seventh century. It is said that, in the reign of Henry III., few ecclesiastical buildings had glazed windows. Suger, however, a century before, had adorned his great work, the abbey of St. Denis, with windows not only glazed but painted; and I presume that other churches of the same class, both in France and England, were generally decorated in a similar manner. Yet glass is said not to have been employed in the domestic architecture of France before the fourteenth century, and its introduction into England was probably by no means earlier. Nor, indeed, did it come into general use during the period of the middle ages. Glazed windows were considered as movable furniture, and probably bore a high price. When the Earls of Northumberland, as late as the reign of Elizabeth, left Alnwick Castle, the windows were taken out of their frames and carefully laid by."

By far the finest specimens of architecture which the middle ages produced, were the religious edifices built in the twelfth and three following centuries. The superstition of the times was favourable to the production of works of that sort. To leave one's means for such a purpose was deemed so meritorious as to entitle the donor to eternal happiness in the next scene of existence; and men in this world thought it a duty to render structures designed for purposes so sacred as beautiful and becoming as they could. It was about the middle of the twelfth century that what has been called the Gothic style of architecture took its rise, of which the peculiar feature is thought to be the pointed arch, formed by the segment of two intersecting semi-circles, struck from points equidistant from the centre of a common diameter. This style of architecture has been said by different individuals to have originated in France, in Germany, in Italy, and in England. The truth is, we neither know where it originated nor from what source it was derived. It has afforded antiquaries a curious subject of speculation how so perfect a system, as this has been thought, should not only have originated but reached perfection in times so dark. Any effectual explanation is probably now impossible; the knowledge of the art was never permitted to go beyond a fraternity of freemasons, and it is not to be supposed that the early archives of that mysterious association have survived so many revolutions.

The living even of the highest nobility under the Edwards was such as would not prove very palatable to their luxurious descendants. They drank little wine, had no foreign luxuries, rarely kept male servants except for husbandry, and still more rarely travelled beyond their native country. An income of £10 or £20 was reckoned a competent estate for a gentleman—at least the lord of a single manor would seldom have enjoyed more. A knight who possessed £150 a year passed for extremely rich. Sir John Fortescue speaks of five pounds a year as "a fair living for a yeoman;" and we read that the same sum (£5) served as the annual expense of a scholar attending the university. Modern lawyers must be surprised at the following, which Mr. Hallam extracts from the churchwarden's accounts of St. Margaret, Westminster, for 1476:—"Also paid to Roger Flypott, learned in the law, for his counsel giving 3s. 8d., *with fourpence for his dinner*."

It has been remarked, that the wages of day-labourers, particularly those engaged in agriculture, were better in the times of Edward III. and Henry IV. than they have ever been at any other period of English history; nor can it be denied that this, upon the whole, is true. In the fourteenth century, a harvest man had fourpence a day, which enabled him in a week to buy a comb of wheat; but, says Sir John Cullum, in his History of Hawsted, to buy a comb of wheat, a man must now (1784) work ten or twelve days. "So," says Mr. Hallam, "under Henry VI., if meat was at a farthing and a half the pound, which, I suppose, was about the mark, a labourer earning threepence a day, or eighteenpence in the week, could buy a bushel of wheat, at six shillings the quarter, and twenty-four pounds of meat, for his family. A labourer at present earning twelve shillings a week, can only buy a bushel of wheat at eighty shil

ings the quarter, and twelve pounds of meat at sevenpence." It is thus undeniable that the day-labourers' wages could purchase greater quantities of certain kinds of food than the wages given to the same class of persons could do in the present day, but they wanted a thousand comforts which the meanest of our workmen now enjoy; and few surely would be willing to exchange all these blessings for the wars and miseries which Edward caused, even although they were ensured, along with them, of daily supplies of beef and ale, of which the ancient yeomen boasted.

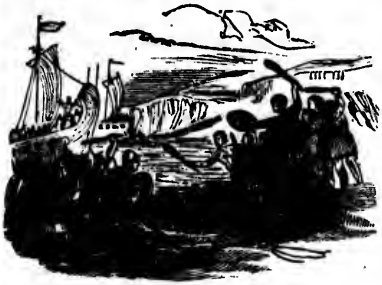
The internal accommodation of houses was even less than their outward splendour. A gentleman's house containing three or four beds was thought to be extraordinarily well provided; few probably had more than two. The walls were commonly bare, without wainscot or even plaster, except that some great houses were furnished with hangings, and that, perhaps, hardly so soon as the reign of Edward VI. Neither books nor pictures could find a place in such dwellings as these. Some inventories of furniture, bearing dates in the fourteenth century, have been preserved to our own day, and they are curious and amusing. In Sir F. Eden's work on the State of the Poor, a carpenter's stock is said to have been valued, in the year 1301, at a shilling! In an inventory of the goods of "John Port, late the king's servant," who died about 1524, we find that this gentleman's house had consisted of a hall, parlour, buttery, and kitchen, with five bedsteads, two chambers, three garrets, and some minor accommodations. From this it may be inferred that Mr. Port was a rather important man in his day, for very few individuals at that time could boast of such accommodation. His plate was valued at £94, his jewels at £23; and his funeral expenses amounted to £73, 6s. 8d.

Of all the arts necessary to existence, perhaps that of agriculture was in the most miserable condition during the middle ages. On a thousand spots of land which we now behold subjected to a fruitful cultivation, there was nothing to be seen at that time but "tracts of forest ground, stagnating with bog or darkened by native woods, where the wild-ox, the roe, the stag, and the wolf, had scarcely learned the supremacy of man." We owe the first efforts at improvement in agriculture over the greater part of Europe to the monks. They chose, for the sake of retirement, secluded regions, which they cultivated with the labour of their hands. "Of the Anglo-Saxon husbandry we may remark," says Mr. Turner, "that Doom's-day Survey gives us some indication that the cultivation of the church lands was much superior to that of any other. They had much less wood upon them, and their meadow was more abundant and in more numerous distributions." The culture of arable land in general was very imperfect; according to Sir John Cullum, a full average crop on an acre sown with wheat amounted only to about nine or ten bushels—a circumstance, the knowledge of which may save us any surprise at a calculation by which it appears that, in the thirteenth century, the average annual rent of an acre of arable land was from sixpence to a shilling. In the time of Edward I., the ordinary price of a quarter of wheat appears to have been about four shillings. A sheep was sold high at a shilling, and an ox might be reckoned at ten or twelve. In considering these statements, however, of positive money values, it must be recollected by persons of this day, that the precious metals were depreciated progressively in their value by every sovereign in Europe, who enabled themselves in this way to pay debts *in appearance*, while in reality they were cheating their creditors to that extent; and sums of small name in those days were every way equal in value to greater sums in our own.

At this time wine was sold only in the shops of the English apothecaries. Yet the progress of luxury, as it was called, had already begun to excite serious alarm. The Parliament of Edward III. passed an act prohibiting the use of gold and silver in apparel to all who had not a hundred pounds a year; and Charles VI. of France ordained that none should presume to entertain their guests with more than two dishes and a mess of soup. It is almost unnecessary to add, that laws of that sort were passed only with a view to persons in the highest ranks; for others they were not needed. Contemporary history has recorded nothing of the poorer classes but their slaughter in war; but we are at little loss to perceive, that domestic comfort must have been few and slender among them, when we know that neither chairs nor looking-glasses could be found in the bedrooms of the nobility. Ages over which this sketch does not extend, were required before the great mass of human beings should become possessed of personal comforts or of political rights.

HISTORY OF GREAT BRITAIN AND IRELAND.

FROM THE CONQUEST BY THE ROMANS TILL THE YEAR 1645.



CONQUEST BY THE ROMANS.

Previously to the year 55 before Christ, the British Islands, in common with the whole of northern and western Europe, were occupied by barbarous tribes, who bore nearly the same relation to the civilized nations of Greece and Italy, which the North American Indians of the present day bear to the inhabitants of Great Britain and the United States. The Romans, who for ages had been extending their power over their rude neighbours, had concluded the conquest of Gaul, now called France, when, in the year just mentioned, their celebrated commander, Julius Cæsar, learning from the merchants of that country that there was another fertile land on the opposite side of the narrow sea now termed the British Channel, resolved to proceed thither, and subject it also to the Roman arms. Disembarking at the place since called Deal, he soon overawed the savage natives, though they were naturally warlike, and averse to a foreign yoke. He did not, however, gain a firm footing in Britain till the succeeding year (54 before Christ), when he employed no fewer than 800 vessels to convey his troops from Gaul. Except on the coasts, where some tillage prevailed, the British tribes lived exactly as the Indians now do, upon animals caught in hunting, and fruits which grew spontaneously. They stained and tattooed their bodies, and had no religion but a bloody idolatry called Druidism. The people of Ireland were in much the same condition.

Little was done on this occasion to establish the Roman power in Britain; but about a century afterwards, namely, in the year of Christ 43, when the Emperor Claudius was reigning at Rome, another large army invaded the island, and reduced a considerable part of it. A British prince called Caradoc, or Caractacus, who had made a noble defence against their arms, was finally taken and sent prisoner to Rome, where he was regarded with the same wonder as we should bestow upon a North American chief who had greatly obstructed the progress of our settlements in that quarter of the world. In the year 61, an officer named Suetonius did much to reduce the Britons, by destroying the numerous Druidical temples in the Isle of Anglesea; religion having, in this case as in many others since, been a great support to the patriotic cause. He soon after overthrew the celebrated British princess Boadicea, who had raised an almost general insurrection against the Roman power.

In the year 79, Agricola, a still greater general, extended the influence of Rome to the Firths of Forth and Clyde, which he formed into a frontier, by connecting them with a chain of forts. It was his policy, after he had subdued part of the country, to render it permanently attached to Rome, by introducing the pleasures and luxuries of the capital. He was the first to sail round the island. In the year 84, having gone beyond the Forth, he was opposed by a great concourse of the rude inhabitants of the north, under a chief named Galgacus, whom he completely overthrew at *Mons Grampius*, or the Grampian Mountain.

It is generally allowed that the Romans experienced an unusual degree of difficulty in subduing the Britons; and it is certain that they were baffled in all their attempts upon the northern part of Scotland, which was then called Caledonia. The utmost they could do with the inhabitants of that country, was to build walls across the island to keep them by themselves. The first wall was built in the year 121, by the Emperor Hadrian, between Newcastle and the Solway Firth. The second was built by the Emperor Antoninus, about the year 140, as a connection of the line of forts which Agricola had formed between the Firths of Forth and Clyde. When the conquest was thus so far completed, the country was governed in the usual manner of a Roman province; and towns began to rise in the course of time, being generally those whose names are now found to end in *chester*, a word derived from *castra*, the Latin word for a camp. The Christian religion was also introduced, and Roman literature made some progress in the country.

CONQUEST BY THE SAXONS.

At length a time came when the Romans could no longer defend their own proper country against the nations in the north of Europe. The soldiers were then withdrawn from Britain (about the year 440), and the people left to govern themselves. The Caledonians, who did not like to be so much straitened in the north, took advantage of the unprotected state of the Britons to pour in upon them from the other side of the wall, and despoil them of their lives and goods. The British had no resource but to call in another set of protectors, the Saxons, a warlike people who lived in the north of Germany and the Jutes and Angles, who inhabited Denmark. The remedy was found hardly any better than the disease. Having once acquired a footing in the island, these hardy strangers proceeded to make it a subject of conquest, as the Romans had done before, with this material difference, that they drove the British to the western parts of the island, particularly into Wales, and settled, with new hordes of their countrymen, over the better part of the land. So completely was the population changed, that, excepting in the names of some of the hills and rivers, the British language was extinguished, and even the name of the country itself was changed from what it originally was, to Angle-land, or England, a term taken from the Angles. The conquest required about a hundred and fifty years to be effected, and, like that of the Romans, it extended no farther north than the Firths of Forth and Clyde. Before the Britons were finally cooped up in Wales, many battles were fought: but few of these are accurately recorded. The most distinguished of the British generals were the Princes Vortimer and Aurelius Ambrosius: it is probably on the achievements of the latter that the well-known fables of Arthur and his knights are founded.

England, exclusive of the western regions, was now

divided into seven kingdoms, called Kent, Northumberland, East Anglia, Mercia, Essex, Sussex, and Wessex, each of which was governed by a race descended from the leader who had first subdued it; and the whole have since been called by historians the *Saxon Heptarchy*, the latter word being composed of two Greek words, signifying *seven kingdoms*. To the north of the Forth dwelt a nation called the Picts, who also had a king, and were, in all probability, the people with whom Agricola had fought under the name of Caledonians. In the Western Highlands there was another nation, known by the name of the Scots, or Dalriads, who had gradually migrated thither from Ireland, between the middle of the third century and the year 503, when they established, under a chief named Fergus, a monarchy destined in time to absorb all the rest. About the year 700, there were no fewer than fifteen kings, or chiefs, within the island, while Ireland was nearly in the same situation. In Britain, at the same time, five languages were in use, the Latin, Saxon, Welsh (or British), the Pictish, and the Irish. The general power of the country has been found to increase as these nations and principalities were gradually amassed together.

Although three of the Saxon kingdoms, Wessex, Mercia, and Northumberland, became predominant, the Heptarchy prevailed from about the year 585 to 800, when Egbert, King of Wessex, acquired a paramount influence over all the other states, though their kings still continued to reign. Alfred, so celebrated for his virtues, was the grandson of Egbert, and began to reign in the year 871. At this time, the Danes, who are now a quiet, inoffensive people, were a nation of pirates, and at the same time heathens. They used to come in large fleets, and commit dreadful ravages on the shores of Britain. For some time, they completely overturned the sovereignty of Alfred, and compelled him to live in obscurity in the centre of a marsh. But he at length fell upon them, when they thought themselves in no danger, and regained the greater part of his kingdom. Alfred spent the rest of his life in literary study, of which he was very fond, and in forming laws and regulations for the good of his people. He was perhaps the most able, most virtuous, and most popular prince that ever reigned in Britain; and all this is the more surprising, when we find that his predecessors and successors, for many ages, were extremely cruel and ignorant. He died in the year 901, in the fifty-third year of his age.

CONQUEST BY THE NORMANS.

The Saxon line of princes continued to reign, with the exception of three Danish reigns, till the year 1066, when the crown was in the possession of a usurper named Harold. The country was then invaded by William, Duke of Normandy, a man of illegitimate birth, attended by a large and powerful army. Harold opposed him at Hastings (October 14), and, after a well-contested battle, his army was defeated, and himself slain. William then caused himself to be crowned king at Westminster; and in the course of a few years he succeeded, by means of his warlike Norman followers, in completely subduing the Saxons. His chiefs were settled upon the lands of those who opposed him, and became the ancestors of the present nobility of England.

Previously to this period, the church of Rome, which was the only surviving part of the power of that empire, had established its supremacy over England. The land was also subjected to what is called the feudal system, by which all proprietors of land were supposed to hold it from the king for military service, while their tenants were understood to owe them military service, in turn, for their use of the land. All orders of men were thus kept in a chain of servile obedience, while some of the lower orders were actually slaves to their superiors.

In the year 853, Kenneth, King of the Scots, had added the Pictish kingdom to his own, and his descendant Malcolm II., in 1020, extended his dominions over not only the south of Scotland, but a part of the north of England. Thus, putting aside Wales, which continued to be an independent country, under its own princes, the island was divided at the time of the Norman Conquest, into two considerable kingdoms, England and Scotland, as they were for some centuries afterwards. Ireland, which had also been invaded by hordes from the north of Europe, was divided into a number of small kingdoms, like England under the Heptarchy.

EARLY NORMAN KINGS.

William, surnamed *The Conqueror*, reigned from 1066 to 1087, being chiefly engaged all that time in completing the subjugation of the Saxons. He is allowed to have been a man of much sagacity, and a firm ruler; but his temper was violent, and his dispositions brutal. At the time of his death, which took place in Normandy, his eldest son Robert happening to be at a greater distance from London than William, who was the second son, the latter individual seized upon the crown, of which he could not afterwards be dispossessed, till he was shot accidentally by an arrow in the New Forest, in the year 1100. Towards the close of this king's reign, the whole of Christian Europe was agitated by the first crusade—an expedition for the recovery of the Holy Land from the Saracens. Robert of Normandy had a high command in this enterprise, and gained much fame as a warrior; but while he was in Italy, on his return, his younger brother Henry usurped the throne left vacant by William, so that he was again disappointed of his birthright.

Henry I.—surnamed *Beauclerk*, from his being a fine scholar—was a prince of some ability; but he disgraced himself by putting out the eyes of his eldest brother, and keeping him nearly thirty years in confinement. Such barbarous conduct shows that, in this age, might was the only right, and that men hesitated at no actions which might promise to advance their own interests.

Contemporary with William the Conqueror in England, was Malcolm III. in Scotland, surnamed *Canmore*, from his having a large head. This prince, after overthrowing the celebrated usurper Macbeth, married Margaret, a fugitive Saxon princess, through whom his posterity became the heirs of that race of English sovereigns. He was a good prince, and, by settling Saxon refugees upon his lowland territory, did much to improve the character of the Scottish nation, who are described as having been, before this time, a nation in which there was no admixture of civilization. At Malcolm's death, in 1093, the crown was contested for a while by a usurper called Donald Bane, and the elder sons of the late monarch, but finally fell to the peaceable possession of his youngest son David I., who was a prince of much superior character, apparently, to the Norman sovereigns who lived in the same age. The Church of Rome having now gained an ascendency in Scotland, David founded a considerable number of monasteries and churches for the reception of the ministers of that religion. All the most celebrated abbacies in Scotland took their rise in his time.

Henry Beauclerk of England, in order to strengthen his claim by a Saxon alliance, married Maud, the daughter of Malcolm Canmore and of the Princess Margaret. By her he had an only daughter of the same name, whom he married first to the Emperor of Germany, and then to Geoffrey Plantagenet, eldest son of the Earl of Anjou, in France. This lady, and her children by Plantagenet, were properly the heirs of the English crown; but on the death of Henry, in 1135, it was seized by a usurper named Stephen, a distant member of the conqueror's family, who reigned for nine

teen years, during which the country was rendered almost desolate by civil wars, in which David of Scotland occasionally joined.

On the death of Stephen, in 1154, the crown fell peacefully to HENRY II., who was the eldest son of Maud, and the first of the Plantagenet race of sovereigns. Henry was an acute and politic prince, though not in any respect more amiable than his predecessors. His reign was principally marked by a series of measures for reducing the power of the Romish clergy, in the course of which, some of his courtiers, in 1171, thought they could not do him a better service than to murder Thomas-à-Becket, Archbishop of Canterbury, who had been the chief obstacle to his views, and was one of the ablest and most ambitious men ever produced in England. For his concern in this foul transaction, Henry had to perform a humiliating penance, receiving eighty lashes on his bare back from the monks of Canterbury. We are the less inclined to wonder at this circumstance, when we consider, that, about this time, the Pope had power to cause two kings to perform the menial service of leading his horse.

Henry was the most powerful king that had yet reigned in Britain. Besides the great hereditary domains which he possessed in France, and for which he did homage to the king of that country, he exacted a temporary homage from William of Scotland, the grandson of David, a monarch of great valour, who took the surname of *the Lion*, and who reigned from 1166 to 1214. Henry also added Ireland to his dominions. This island had previously been divided into five kingdoms—Munster, Leinster, Meath, Ulster, and Connaught. The people, being quite uncivilized, were perpetually quarrelling among themselves; and this, with their heathen religion, furnished a flimsy pretext for invading them from England. Dermot Macmorrough, King of Leinster, having been dethroned by his subjects, introduced an English warrior, Richard Earl of Strigul, generally called *Strongbow*, for the purpose of regaining his possessions. A body composed of fifty knights, ninety esquires, and four hundred and sixty archers, in all six hundred men, was enabled by its superior discipline to overthrow the whole warlike force that could be brought against them; and the conquest was easily completed by Henry in person, who went thither in 1172. The military leaders were left to rule over the country, and they managed their trust so ill, that the Irish never became peaceable subjects of the Norman king, as the English had gradually done.

RICHARD CŒUR DE LION.—JOHN.—MAGNA CHARTA.

Henry II. was much troubled in his latter years by the disobedience of his children. At his death, in 1189, he was succeeded by his son RICHARD, styled *Cœur de Lion*, or the *Lion-hearted*, from his headstrong courage, and who was much liked by his subjects on that account, though it does not appear that he possessed any other good qualities. At the coronation of Richard, the people were permitted to massacre many thousands of unoffending Jews throughout the kingdom. Almost immediately after his accession, he joined the King of France in a second crusade; landed in Palestine (1191), and fought with prodigious valour, but with no good result. On one occasion, being offended at a breach of truce by his opponent Saladin, he beheaded 5000 prisoners; whose deaths were immediately revenged by a similar massacre of Christian prisoners. In 1192, he returned with a small remnant of his gallant army, and, being shipwrecked at Aquileia, wandered in disguise into the dominions of his mortal enemy the Duke of Austria, who, with the Emperor of Germany, detained him till he was redeemed by a ransom, which impoverished nearly the whole of his subjects. This prince spent the rest of his life in unavailing wars with Philip of France, and was killed at the siege of a castle in Limousin, in 1199, after a reign of ten years, of which he had spent only about three months in England.

JOHN, the younger brother of Richard, succeeded, although Arthur, Duke of Bretagne, the son of an intermediate brother, was the proper heir. John, who was at once vain, cruel, and weak alienated the affections of his subjects almost at the very first by the assassination of his nephew, which he is said to have performed with his own hands. The weakness of kings is often the means of giving increased liberties and privileges to the people. The paltry tyranny and wickedness of John caused his barons to rise against him, and the result was, that, on the 19th June, 1215, he was compelled by them to sign what is called the *Magna Charta*, or Great Charter, granting them many privileges and exemptions, and generally securing the personal liberty of his subjects. The principal point concerning the nation at large, was that no tax or supply should be levied from them without their own consent in a Great Council—the first idea of a Parliament. Some excellent provisions were also made regarding courts of law and justice, so as to secure all but the guilty.

The Pope, it appears, regarded the Magna Charta as a shameful violation of the royal prerogative, and excommunicated its authors, as being worse, he said, than infidels. The opinion of a modern historian is very different. He says, "To have produced the Great Charter, to have preserved it, to have matured it, constitute the immortal claim of England on the esteem of mankind."

HENRY III.—ORIGIN OF PARLIAMENT.

John, at his death in 1216, was succeeded by his son, HENRY III., a weak and worthless prince, who ascended the throne in his boyhood, and reigned fifty-six years, without having performed one worthy act of sufficient consequence to be detailed. In his reign was held the first assemblage approaching to the character of a Parliament. It was first called in 1225, in order to give supplies for carrying on a war against France. The money was only granted on condition that the Great Charter should be confirmed; and thus the example was set at the very first, for rendering supplies a check upon the prerogative of the king, and gradually reducing that power to its present comparatively moderate level. Under the earlier Norman kings, and even, it is believed, under the Saxons, an assembly called the Great Council had shared with the sovereign the power of framing laws; but it was only now that the body had any power to balance that of the king, and it was not till 1265 that representatives from the inhabitants of towns were introduced.

EDWARD I. AND II.—ATTEMPTED CONQUEST OF SCOTLAND

Henry III., at his death in 1272, was succeeded by his son EDWARD I., a prince as warlike and sagacious as his father was the reverse. He distinguished himself by his attempts to add Wales to his kingdom, an object which he accomplished in 1282, by the overthrow and murder of Llewellen, the last prince of that country. In the mean time, from the death of William the Lion in 1214, Scotland had been ruled by two princes, ALEXANDER II. and III., under whom it advanced considerably in wealth, civilization, and comfort. On the death of Alexander III., in 1285, the crown fell to his granddaughter MARGARET, a young girl, whose father was Eric, King of Norway. Edward formed a treaty with the Estates of Scotland for a marriage between this princess and his son, whom he styled Prince of Wales. Unfortunately, the young lady died on her voyage to Scotland; and the crown was left to be disputed by a multitude of distant relations, of whom JOHN BALIOL

and ROBERT BRUCE seemed to have the best right. Edward, being resolved to make Scotland his own at all hazards, interfered in this dispute, and being appointed arbitrator among the competitors, persuaded them to own, in the first place, an ill-defined claim put forward by himself of the right of paramountcy or superior sovereignty over Scotland. When this was done, he appointed Baliol to be his vassal king, an honour which the unfortunate man was not long permitted to enjoy. Having driven Baliol to resistance, he invaded the country, overthrew his army, and, stripping him of his sovereignty, assumed to himself the dominion of Scotland, as a right forfeited to him by the rebellion of his vassal. After he had retired, a brave Scottish gentleman, named William Wallace, raised an insurrection against his officers, and, defeating his army at Stirling, in 1298, cleared the whole country of its southern invaders. But in the succeeding year, this noble patriot was defeated by Edward in person at Falkirk, and the English yoke was again imposed. It is to be remarked, that this could have hardly taken place if the common people, who rose with Wallace, and who were wholly of Celtic and Saxon race, had been led and encouraged by the nobility. The grandees of Scotland, and even the competitors for the crown, being recent Norman settlers, were disposed to pay obedience to the English sovereign.

Some time after the death of Wallace, while Edward was engrossed with his French wars, ROBERT BRUCE, Earl of Carrick, grandson of him who had competed with Baliol, conceived the idea of putting himself at the head of the Scots, and endeavouring, by their means, at once to gain the crown, and to recover the independence of the kingdom. After a series of adventures, among which was the unpremeditated murder of a rival named Comyn, Bruce caused himself, in 1306, to be crowned at Scone. For some time after he had to skulk as a fugitive, being unable to maintain his ground against the English officers; but at length he became so formidable, that Edward found it necessary (1307) to lead a large army against him. The English monarch, worn out with fatigue and age, died on the coast of the Solway Firth, when just within sight of Scotland, leaving his sceptre to his son EDWARD II. That weak and foolish prince immediately returned to London, leaving Bruce to contest with his inferior officers.

After several years of constant skirmishing, during which the Scottish king was able to maintain his ground, Edward resolved to make one decisive effort to reduce Scotland to subjection. In the summer 1314, he invaded it with an army of 100,000 men. Bruce drew up his troops, which were only 30,000 in number, at Bannockburn, near Stirling. Partly by steady valour, and partly by the use of stratagems, the Scots were victorious, and Edward fled ignominiously from the field. The Scottish king gained an immense booty, besides securing his crown and the independence of his country. He soon after sent his brother Edward, with a body of troops, to Ireland, to assist the native chiefs in resisting the English. This bold young knight was crowned King of Ireland, and for some time held his ground against the English, but was at length defeated and slain.

The weakness of Edward II. was chiefly shown in a fondness for favourites, into whose hands he committed the whole interests of his people. The first was a low Frenchman, named Piers Gaveston, who soon fell a victim to the indignation of the barons. The second, Hugh Spencer, misgoverned the country for several years, till at length the Queen and Prince of Wales raised an insurrection against the king, and caused him to be deposed, as quite unfit to reign. The Prince was then crowned as EDWARD III. (1327), being as yet only about fourteen years of age; and, in the course of a few months, the degraded monarch was cruelly murdered in Berkeley Castle.

During the minority of the young king, the reins of government were held by his mother and the Earl of March. Under their administration, a peace was concluded with King Robert of Scotland, of which one of the conditions was a full acknowledgment of the independence of the Scottish monarchy, which had been a matter of dispute for some ages.

EDWARD III.—RICHARD II.

Edward III., who soon after assumed full power, was destined to make good the remark prevalent at this time, that the kings of England were alternately able and imbecile. He was a warlike and sagacious monarch, and inspired by all his grandfather's desire of conquest. In 1329, Robert Bruce died, and was succeeded by his infant son DAVID II., to whom a young sister of the English king was married, in terms of the late treaty. Notwithstanding this connection, Edward aided a son of John Baliol in an attempt to gain the Scottish crown. Edward Baliol overthrew the Regent of Scotland at Duplin, September, 1332, and for two months reigned as King of Scots, while David and his wife took refuge in France. Though now expelled, Baliol afterwards returned to renew his claims, and for many years the country was harassed by unceasing wars, in which the English took a leading part.

But for his attention being diverted to France, Edward III. would have made a more formidable effort to subdue Scotland, and might have succeeded. He was led into a long course of warfare with France, in consequence of an absurd pretension which he made to its crown. In the victories which he gained at Cressy (August 26, 1346) and Poitiers (September 17, 1356) the national valour, his own, and that of his celebrated son, the Black Prince, were shown conspicuously; but this lavish expenditure of the resources of his kingdom, in which he was supported by his parliament, was of no permanent benefit, even to himself, for whom alone it was made. In those days, almost all men fought well, but very few had the art to improve their victories. John, King of France, who had been made captive at Poitiers, and David, King of Scotland, who had been taken in 1346, while conducting an invasion of England, were at one time prisoners in England; but no permanent advantage was ever gained over either of the states thus deprived of their sovereigns. In 1361, after about twenty years of active fighting, the English king left France with little more territory than he had previously enjoyed. Edward had invaded Scotland with a powerful army in 1356, but without making any impression. The Scots, under David's nephew, Robert Stewart, effectually protected themselves, not only from his arms, but from a proposal which David himself basely undertook to make, that Lionel, the third son of the English king, should be acknowledged as his successor. Edward died in 1377, a year after the decease of his son the Black Prince; and notwithstanding all their brilliant exploits, the English territories in France were less than at the beginning of the reign.

England was at this time affected more than at any other by the fashions of chivalry. This was a military enthusiasm, which for some centuries pervaded all Christian Europe. It prompted, as one of its first principles, a heedless bravery in encountering all kinds of danger. Its votaries were expected to be particularly bold in behalf of the fair sex, insomuch that a young knight would sometimes challenge to mortal combat any one who denied his mistress to be the loveliest in the world. Tournaments were held, at which knights clad in complete armour would ride against each other at full speed with levelled lances, merely to try which had the greatest strength and skill; and many were killed or

these occasions. It was a system full of extravagance, and tending to bloodshed; but, nevertheless, it maintained a courtesy towards females, and a romantic principle of honour, which we may be glad to admire, considering how rude was almost every other feature of the age.

Edward III. was succeeded by his grandson, RICHARD II., then a boy of eleven years of age, and who proved to be a person of weak and profligate character. The Commons took advantage of the irregularity of his government to strengthen their privileges, which they had with difficulty sustained during the more powerful rule of his predecessor. Early in this reign they assumed the right, not only of taxing the country, but of seeing how the money was spent. Indignant at the severity of a tax imposed upon all grown-up persons, the peasantry of the eastern parts of England rose, in 1381, under a person of their own order, named Wat Tyler, and advanced, to the number of 60,000, to London, where they put to death the chancellor and primate, as evil counsellors of their sovereign. They demanded the abolition of bondage, the liberty of buying and selling in fairs and markets, a general pardon, and the reduction of the rent of land to an equal rate. The king came to confer with them at Smithfield, where, on some slight pretence, Walworth, mayor of London, stabbed Wat Tyler with a dagger—a weapon which has since figured in the armorial bearings of the metropolis. The peasants were dismayed, and submitted, and no fewer than fifteen hundred of them were hanged. Wat Tyler's insurrection certainly proceeded upon a glimmering sense of those equal rights of mankind which have since been generally acknowledged; and it is remarkable, that at the same time the doctrines of the reformer Wickliffe were first heard of. This learned ecclesiastic wrote against the power of the Pope, and some of the most important points of the Romish faith, and also executed a translation of the Bible into English. His writings are acknowledged to have been of material, though not immediate, effect in bringing about the reformation of religion.

The country was misgoverned by Richard II. till 1399, when he was deposed by his subjects under the leading of his cousin, Henry, Duke of Lancaster. This person, though some nearer the throne were alive, was crowned as HENRY IV., and his predecessor, Richard, was soon after murdered. In the mean time, David of Scotland died in 1371, and was succeeded by Robert Stewart, who was the first monarch of that family. Robert I., dying in 1389, was succeeded by his son Robert II., who was a good and gentle prince. He had two sons, David and James: the former was starved to death by his uncle, the Duke of Albany; and the second, when on his way to France for his education, was seized by Henry IV. of England, and kept captive in that country for eighteen years. Robert II. then died of a broken heart (1406), and the kingdom fell into the hands of the Duke of Albany, at whose death, in 1419, it was governed by his son, Duke Murdock, a very imbecile personage.

HOUSE OF LANCASTER.

Henry IV. proved a prudent prince, and comparatively a good ruler. The settlement of the crown upon him by parliament was a good precedent, though, perhaps, only dictated under the influence of his successful arms. He was much troubled by insurrections, particularly a formidable one by Percy, Earl of Northumberland—and one still more difficult to put down, in Wales, where Owen Glendower, a descendant of the British princes, kept his ground for several years.

On the death of Henry IV. in 1413, he was succeeded by his son, who was proclaimed under the title of HENRY V. The young king attained high popularity, on account of his impartial administration of justice, and his zeal to protect the poor from the oppressions of their superiors. His reign is less agreeably marked by the persecutions of the Lollards, a body of religious reformers, many of whom were condemned to the flames. Being determined to use every endeavour to gain the crown of France, which he considered his by right of birth, he landed in Normandy with 30,000 men (August 1415), and gave battle to a much superior force of the French at Agincourt. He gained a complete victory, which was sullied by his afterwards ordering a massacre of his prisoners, under the apprehension that an attempt was to be made to rescue them. The war was carried on for some years longer, and Henry would have probably succeeded in making good his claim to the French crown, if he had not died prematurely of a dysentery (August 31, 1422,) in the thirty-fourth year of his age, leaving the throne to an infant nine months old, who was proclaimed as HENRY VI., King of France and England.

Under Henry VI., whose power was for some time in the hands of his uncle the Duke of Bedford, the English maintained their footing in France for several years, and at the battle of Verneuil, in 1424, rivalled the glory of Cressy and Poitiers. At that conflict, a body of Scotch, 7000 strong, who had proved of material service to the French, were nearly cut off. In 1428, when France seemed completely sunk beneath the English rule, the interests of the native prince were suddenly revived by a simple maiden named Joan of Arc, who pretended to have been commissioned by Heaven to save her country, and entering into the French army, was the cause of several signal reverses to the English. By her enthusiastic exertions, and the trust everywhere reposed in her supernatural character, Charles VII. was crowned at Rheims, in 1430. Being soon after taken prisoner, the heroic maiden was, by the English, condemned for witchcraft, and burnt. Nevertheless, about the year 1453, the French monarch had retrieved the whole of his dominions from the English, except Calais.

Henry VI. was remarkable for the extreme weakness of his character. His cousin, Richard, Duke of York, descended from an elder son of Edward III., and therefore possessed of a superior title to the throne, conceived that Henry's imbecility afforded a good opportunity for asserting what he thought his birthright. Thus commenced the famous *Wars of the Roses*, as they were called, from the badges of the families of York and Lancaster, the former of which was a red, while the latter was a white rose. In 1454, the duke gained a decisive victory over the forces of Henry, which were led by his spirited consort, Margaret of Anjou. In some succeeding engagements, the friends of Henry were victorious; and at length, in the battle of Wakefield (December 24, 1460), the forces of the Duke of York were signally defeated, and himself, with one of his sons, taken and put to death. His pretensions were then taken up by his eldest son, Edward, who, with the assistance of the Earl of Warwick, gained such advantages next year, that he assumed the crown. Before this was accomplished, many thousands had fallen on both sides. Henry, who cared little for the pomp of sovereignty, was confined in the Tower.

Scotland, in the mean time (1424), had redeemed her king from his captivity in England; and that prince, styled JAMES I., had proved a great legislator and reformer, not to speak of his personal accomplishments in music and literature, which surpassed those of every contemporary monarch. James did much to reduce the Highlands to an obedience under the Scottish government, and also to break up the enormous power of the nobles. By these proceedings, however, he excited a deep hatred in the bosoms of some of his subjects; and, in 1437, he fell a victim to assassination at Perth. He was succeeded by his infant son JAMES II., the greater

part of whose reign was spent in a harassing contention with the powerful house of Douglas, and who was finally killed in the flower of his age, by the bursting of a cannon before Roxburgh Castle. His successor, James III., was also a minor, and, on reaching man's estate, proved to be a weak though not ill-meaning prince. He fell a victim, in 1488, to a conspiracy formed by his subjects, and which was led by his eldest son. The morality of princes in this age seems to have been much upon a par with that ascribed to the Turkish sovereigns of a later period. They never scrupled to destroy life, either within the circle of their own family, or out of it, when it suited their interests to do so.

HOUSE OF YORK.

Edward, of the House of York, styled Edward IV., who commenced his reign in the nineteenth year of his age, reigned ten years, perpetually disturbed by renewed attempts of the Lancastrian party, of which he mercilessly sacrificed many thousands who fell into his hands. At length, having offended the Earl of Warwick, who had been chiefly instrumental in placing him upon the throne, that powerful nobleman raised an insurrection against him, and in eleven days was master of the kingdom, while Edward had to take refuge on the Continent. Henry VI. was then restored, and Warwick acquired the title of King-maker. Nine months after (1471), Edward landed with a small body of followers, and, having rallied his partisans around him, overthrew and killed Warwick at St. Alban's. Margaret of Anjou, who had fought battles for her husband in almost every province of England, gathered a new army, and opposed Edward at Tewkesbury Park, where she was completely defeated. Her son and husband, being taken, were murdered in cold blood, and she herself spent the remainder of her singular life in France. Edward reigned, a profligate and a tyrant, till 1483, when he died in the forty-second year of his age. He had previously caused his brother, the equally profligate Duke of Clarence, to be drowned in a butt of malmsey wine.

During the reign of Edward IV., the plague frequently broke out in England, and carried off immense numbers of the people. It was particularly fatal in London, and in all other places where many houses were huddled closely together, with imperfect means of cleaning and ventilation. It was calculated that the disease, on one occasion in this reign, destroyed as many lives as in fifteen years' war. The plague did not cease to occur in England, or in any other European country, until considerable improvements had taken place in the habits of the people, especially in point of cleanliness.

Edward V., the eldest son of Edward IV., was a boy of eleven years when he succeeded to the crown. His uncle, Richard, Duke of Gloucester, a wicked and deformed wretch, soon after contrived to obtain the chief power, and also to cause the murder of the young king and his still younger brother in the Tower. He then mounted the throne under the title of Richard III. For two years, this disgrace to humanity continued to reign, though universally abhorred by his people. At length, in 1485, Henry Tudor, Earl of Richmond, a connection rather than a descendant of the Lancaster family, resolved to make an attempt upon the English crown. Having landed with about 2000 followers at Milford Haven, he advanced into the country, and speedily gained such accessions of force as enabled him to meet and overthrow Richard at Bosworth Field, where the tyrant was slain, and the victorious Richmond was immediately proclaimed king, under the title of Henry VII. The new monarch soon after sought to strengthen his title by marrying Elizabeth, the daughter and heir of Edward IV., by which it was said the families of York and Lancaster were united.

HOUSE OF TUDOR—HENRY VII.

Under Henry VII. the country revived from the evils of a long civil war, in the course of which the chief nobility had been broken down, and the industry and commerce of the land interrupted. It was remarkable, nevertheless, that, during the past period, England was upon the whole an improving country. The evils of war had fallen chiefly on those who made it; the government, however disturbed by various claimants of the throne, was mild and equitable—at least as compared with that of other countries; and the people throve under a system in which their own consent, by the voice of the House of Commons, was necessary to the making of every new law, and the laying on of every tax.

The reign of Henry VII. was much disturbed by insurrections, in consequence of his imperfect title. A baker's boy, named Lambert Simnel, and a Jew's son, named Perkin Warbeck, were successively set up by the York party, the one as a son of the late Duke of Clarence and the other as the younger brother of Edward V., but were both defeated. Warbeck was hanged at Tyburn in 1499, and nearly about the same time, Henry procured, by forms of law, the death of the Earl of Warwick, the real son of the late Duke of Clarence, a poor idiot boy, whom he had kept fifteen years in confinement, and whose title to the throne, being superior to his own, rendered him uneasy.

Henry, though a cruel prince, as were most of the sovereigns of his age, was a sagacious and peaceful ruler. He paid great attention to all his affairs, and, in some of his acts, looked far beyond the present time. For example, by marrying his daughter Margaret to James IV. of Scotland, he provided for the possibility of the future union of the two crowns. By a law allowing men of property to break entails, he insured the reduction of the great lords, and the increase of the number of small proprietors. His constant policy was to depress the chief nobles, and to elevate the clergy, lawyers, and men of new families, as most likely to be dependent on him. The greatest fault of his character was his excessive love of money, of which he amassed an immense sum. During his reign, Ireland was made more dependent on the English crown by a statute prohibiting any parliament from being held in it until the king should give his consent.

HENRY VIII.

Henry VII. died in April, 1509, in the fifty-third year of his age. His oldest surviving son and successor, Henry VIII., was now in his eighteenth year. Young, handsome, and supposed to be amiable, he enjoyed at first a high degree of popularity. Some years before, he had been affianced to Catherine, a Spanish princess, who had previously been the wife of his deceased brother Arthur: he was now married to this lady, the Pope having previously granted a dispensation for that purpose. For many years the reign of Henry was unmarked by any unusual incidents. The chief administration of affairs was committed to a low-born but proud churchman, the celebrated Cardinal Wolsey. The king became much engaged in continental politics; and during a war which he carried on against France, his brother-in-law James IV., who sided with that state, made an unfortunate irruption into the north of England, and was overthrown and slain, with the greater part of his nobility (September 9, 1513), at Flodden.

About this time [illegible] changes of great importance to European society took place. Almost ever since the destruction of the Roman empire, the nations which arose out of it remained in subjection to the papal see, which might be said to have inherited the universal sway of the government, but altered from an authority over the bodies of men to an empire over their minds

In the opinion of many, this authority of the Roman Catholic religion had, in the course of time, become much abused, while the religion itself was corrupted by many superstitious observances. So long as men had continued to be the thoughtless warriors and unlettered peasants which they had been in the middle ages, it is not probable that they would ever have called in question either the authority of the pope or the purity of the Catholic faith. But, with knowledge, and the rise of a commercial and manufacturing class, came a disposition to inquire into the authority of this great religious empire. The art of printing, discovered about the middle of the preceding century, and which was now rendering literature accessible to most classes of the community, tended greatly to bring about this revolution in European intellect. The minds of men, indeed, seem at this time as if awaking from a long sleep; and it might well have been a question with persons who had reflection, but no experience, whether the change was to turn to evil or to good.

When men's minds are in a state of preparation for any great change, a very small matter is required to set them in motion. At Wirtemberg, in Germany, there was an Augustine monk, named Martin Luther, who became incensed at the Roman see, in consequence of some injury which he conceived to have been done to his order, by the Pope having granted the privilege of selling indulgences to the Dominican order of friars. Being a man of a bold and inquiring mind, he did not rest satisfied till he had convinced himself, and many others around him, that the indulgences were sinful, and that the Pope had no right to grant them. This happened about the year 1517. Controversy and persecution gradually extended the views of Luther, till he at length openly disavowed the authority of the Pope, and condemned some of the most important peculiarities of the Catholic system of worship. In these proceedings, Luther was countenanced by some of the states in Germany, and his doctrines were speedily established in the northern countries of Europe.

THE REFORMATION.

Henry VIII., as the second son of his father, had been originally educated for the church, and still retained a taste for theological learning. He now distinguished himself by writing a book against the Lutheran doctrines; and the Pope was so much pleased with it as to grant him the title of *Defender of the Faith*. Henry was not destined, however, to continue long an adherent of the Roman pontiff. In the year 1527, he became enamoured of a young gentlewoman named Anne Boleyn, who was one of his wife's attendants. He immediately conceived the design of annulling his marriage with Catherine, and marrying this younger and more agreeable person. Finding a pretext for such an act in the previous marriage of Catherine to his brother, he attempted to obtain from the Pope a decree, declaring his own marriage unlawful, and that the dispensation upon which it had proceeded was beyond the powers of the former Pope to grant. The Pontiff (Clement VII.) was much perplexed by this request of King Henry, because he could not accede to it without offending Charles V., Emperor of Germany, one of his best supporters, and the brother of Queen Catherine, and at the same time hoping that the professed powers of the Papacy, which were now trembling under the attacks of Luther.

Henry resolved to employ the influence of his minister, Cardinal Wolsey, who had now reached a degree of opulence and pride never before attained by a subject of England. But Wolsey, with all his greatness, could not venture to urge a matter disagreeable to the Pope, who was more his master than King Henry. The process went on for several years, and still his passion for Anne Boleyn continued unabated. Wolsey at length fell under the king's displeasure for refusing to serve him in this object, was stripped of all his places of power and wealth, and, in November, 1530, expired at Leicester Abbey, declaring that if he had served his God as diligently as his king, he would not thus have been given over in his grey hairs. The uncontrollable desire of the king to possess Anne Boleyn, was destined to be the immediate cause of one of the most important changes that ever took place in England—no less than a total reformation of the national religion. In order to annul his marriage with Catherine, and enable him to marry Anne Boleyn, he found it necessary to shake off the authority of the Pope, and procure himself to be acknowledged in Parliament as the supreme head of the English church. His marriage with Anne took place in 1533, and in the same year was born his celebrated daughter Elizabeth.

In 1536, Henry became as anxious to put away Queen Anne as he had ever been to rid himself of Queen Catherine. He had contracted a passion for Jane Seymour, a young lady then of the queen's bed-chamber, as Anne herself had been in that of Catherine. In order to gratify this new passion, he accused Anne of what appears to have been an imaginary frailty, and within a month from the time when she had been an honoured queen, she was beheaded (May 19) in the tower. On the very next day he married Jane Seymour, who soon after died in giving birth to a son (afterwards Edward VI.) His daughters, Mary and Elizabeth, were declared illegitimate by act of Parliament, and therefore excluded from the succession.

Hitherto, though professing independence of Rome, Henry still maintained, and even enforced, by severe and bloody laws, the most of its doctrines. He now took measures for altering this system of worship to something nearer the Lutheran model, and also for suppressing the numerous monasteries throughout the country. Being possessed of more despotic power, and, what is stranger still, of more popularity, than any former sovereign of England, he was able to encounter the dreadful risk of offending, by these means, a vastly powerful corporation, which seems, moreover, to have been regarded with much sincere affection and respect in many parts of England. No fewer than 645 monasteries, 2374 chanteries and chapels, 90 colleges, and 110 hospitals, enjoying altogether a revenue of £161,000, were broken up by this powerful and unscrupulous monarch. He partly seized the revenues for his own use, and partly gave them away to the persons who most actively assisted him, and who seemed most able to protect his government from the effects of such a sweeping reform. By this act, which took place in 1537, the Reformation was completed in England. Yet for many years Henry vacillated so much in his opinions, and enforced these with such severe enactments, that many persons of both religions were burnt as heretics. It was in the southern and eastern parts of England, where the commercial classes at this time chiefly resided, that the doctrines of the Reformation were most prevalent. In the western and northern parts of the country, Catholicism continued to flourish; and in Ireland, which was remotest of all from the Continent, the Protestant faith made little or no impression.

After the death of Jane Seymour, Henry married Anne of Cleves, a German princess, with whose person, however, he was not pleased; and he therefore divorced her by an act of Parliament. He next married Catherine Howard, niece to the Duke of Norfolk; but had not been long united to her when he discovered that she had committed a serious indiscretion before marriage. This was considered a sufficient reason for beheading the unfortunate queen, and attainting all her relations. Though Henry had thus murdered two wives, and divorced other two, and become, moreover, a monster in form as well as in his passions and mind, he succeeded in obtaining for his sixth wife (1543) Catherine Parr, widow of Lord Latimer, who, it is certain, only contrived to escape destruction by

her extraordinary prudence. Almost all who ever served Henry VIII. as ministers, either to his authority or to his pleasures, were destroyed by him. Wolsey was either driven to suicide, or died of a broken heart; Thomas Cromwell, who succeeded that minister, and chiefly aided the king in bringing about the Reformation—Sir Thomas More, lord chancellor, the most virtuous, most able, and most consistent man of his time—the Earl of Surrey, who was one of the most accomplished knights of the age, and the first poet who wrote the English language with perfect taste—all suffered the same fate with Anne Boleyn and Catherine Howard.

When James IV. died at Flodden, in 1513, the Scottish crown fell to his infant son JAMES V., who struggled through a turbulent minority, and was now a gay, and, upon the whole, an amiable prince. His uncle, Henry VIII., endeavoured to bring him into his views respecting religion; but James, who was much in the power of the Catholic clergy, appears to have wished to become the head of the Popish party in England, in the hope of succeeding, by their means, to the throne of that country. A war latterly broke out between the two monarchs, and the Scottish army having refused to fight, from a dislike to the expedition, James died (December 1542) of a broken heart, leaving an only child MARY, who was not above a week old. Henry immediately conceived the idea of marrying his son Edward to this infant queen, by which he calculated that two hostile nations should be united under one sovereignty, and the Protestant Church in England be supported by a similar establishment in Scotland. This project, however, was resisted by the Scots, of whom very few as yet were inclined to the Protestant doctrines. Henry, enraged at their hesitation, sent a fleet and army, in 1544, to inflict vengeance upon them. The Scots endured with great patience the burning of their capital city, and many other devastations, but still refused the match. The government of Scotland was now chiefly in the hands of Cardinal Beaton, a man of bold and decisive intellect, who zealously applied himself to suppress the reforming preachers, and regarded the English match as likely to bring about the destruction of his religion.

EDWARD VI.—QUEEN MARY.

Henry died, January 28, 1547, leaving the throne to his only son, a boy of ten years of age, who was immediately proclaimed king under the title of EDWARD VI. The Duke of Somerset, maternal uncle to the young king, became supreme ruler under the title of Protector, and continued to maintain the Protestant doctrines. Under this reign, the church of England assumed its present form, and the Book of Common Prayer was composed nearly as it now exists. Somerset being resolved to effect, if possible, the match between Edward VI. and Mary of Scotland, invaded that country in autumn 1547, and was met at Musselburgh by a large army under the governor, the Earl of Arran. Though the Scotch were animated by bitter animosity against the English, against their religion, and against the object of their expedition, they did not fight with their usual resolution, but were defeated, and pursued with great slaughter. Finding them still obstinate in refusing to give up their queen, Somerset laid waste a great part of the country, and then retired. Previous to this period, Cardinal Beaton had been assassinated by private enemies; but the Scotch were encouraged to persevere by the court of France, to which they now sent the young queen for protection.

In the reign of Edward VI. the government was conducted mildly, until the Protector Somerset was degraded from his authority by the rising influence of Dudley, Duke of Northumberland, who caused him soon after to be tried and executed. Northumberland, who was secretly a Roman Catholic, was not so mild or popular a ruler. Yet, throughout the whole reign of Edward VI., which was terminated by his death on the 6th of July 1553, at the early age of sixteen, no religious party was persecuted, except those who denied the fundamental doctrines of the Christian religion. It would have been well for the honour of a church which has produced many great men, and to which the modern world is indebted for the very existence of Christianity, if it had not been tempted after this period to commence a very different course of action. The crown now belonged by birthright to Mary, the eldest daughter of Henry VIII., who was a zealous Catholic. Northumberland, however, assuming the illegitimacy of that princess and her sister Elizabeth, set up as queen the Lady Jane Grey, who was descended from a younger sister of king Henry, and who had been married to a son of the Duke of Northumberland. Lady Jane was the most beautiful, most intelligent, and most amiable of all the females who appear in the history of England. Though only seventeen, she was deeply learned, and yet preserved all the unaffected graces of character proper to her interesting age. Unfortunately, her father-in-law Northumberland was so much disliked, that the Catholics were enabled to displace her from the throne in eight days, and to set up in her stead the Princess Mary. Northumberland, Lady Jane, and her husband, Guilford Lord Dudley, were all beheaded by that savage princess, who soon after took steps for restoring the Catholic religion, and married Philip II., King of Spain, in order to strengthen herself against the Protestant interest. Mary experienced some resistance from her Protestant subjects, and being under great suspicion of her sister Elizabeth, who professed the reformed faith, but took no part against her, was almost on the point of ordering her to execution also. As soon as she had replaced the Catholic system, and found herself in possession of sufficient power, she began that career of persecution which has rendered her name so infamous. Five out of fourteen Protestant bishops, including the reverend names of Cranmer, Latimer, and Ridley, were committed to the flames as heretics; and during the ensuing part of her reign, which was closed by her death, November 17, 1553, nearly three hundred persons suffered in the same manner. These scenes did not take place without exciting horror in the minds of Englishmen in general, including even many Catholics; but the royal authority was at all times too great under this line of princes to allow of effectual resistance. Such a persecution, however, naturally fixed in the minds of the British Protestants a hereditary horror for the name of Catholic, which has in its turn been productive of many retaliatory persecutions almost equally to be lamented. In the latter part of her reign, she was drawn by her husband into a war with France, of which the only effect was the loss of Calais, the last of the French possessions of the sovereigns of England. The natural sourness of Mary's temper was increased by this disgraceful event, as well as by her want of children, and she died in a state of great unhappiness.

ELIZABETH.—MARY, QUEEN OF SCOTS.—REFORMATION IN SCOTLAND.

A more auspicious scene opened for England in the accession of ELIZABETH, a princess of great native vigour of mind, and who had been much improved by adversity, having been kept in prison during the whole reign of her sister. From the peculiar circumstances of Elizabeth's birth, her right of succession was denied by all the Catholics at home and abroad. This party considered Mary, Queen of Scots, who was descended from the eldest sister of Henry VIII., and had been brought up in the Catholic faith at the court of France, as their legitimate sovereign. Elizabeth had no support in any quarter, except among the Protestant subjects. The Pope issued a bull, which directly, or indirectly, pronounced her an usurper, and gave permission to her

subjects to remove her from the throne. The court of France professed to consider the Queen of Scots, who had recently been married to the Dauphin, as the Queen of England. Under these circumstances, Elizabeth found no chance of safety except in restoring and maintaining the Protestant religion in her own country, and in seeking to support it in all others where the people were favourable to it. The Scottish nation being now engaged in a struggle with their regent, Mary of Guise, in behalf of Protestantism, Elizabeth gladly acceded to a proposal made by the nobles of that country, and sent a party of troops, by whose assistance the reformed religion was established (1560). In bringing about this change, the chief native leaders were James Stewart, a natural son of King James V., and John Knox, who had once been a friar, but was now a Protestant preacher. As a natural consequence of the obligation which the English queen had conferred upon the Scottish reformers, she acquired an influence over the country which was never altogether lost.

About the time when the Scottish Parliament was establishing the reformed religion, Mary of Guise breathed her last, leaving the country to be managed by the reforming nobles. Her daughter, the Queen of Scots, now eighteen years of age, and the most beautiful woman of her time, had in 1559 become the queen-consort of France; but, in consequence of the death of her husband, she was next year left without any political interest in that country. She accordingly, in August, 1561, returned to Scotland, and assumed the sovereignty of a country which was chiefly under the rule of fierce nobles, and where the people, from the difference of their religious faith, as well as their native barbarism, were little fitted to yield her the obedience of loyal subjects.

REFORMATION IN SCOTLAND.

The change of religion in Scotland was of a more decisive kind than it had been in England. The English Reformation had been effected by sovereigns, who, while they wished to throw off the supremacy of the Pope, and some of the Catholic rites, desired to give as little way as possible to popular principles. They therefore not only seized the supremacy of the church to themselves, but, by bishops and other dignitaries, made it an efficient instrument for supporting monarchical government. In Scotland, where the Reformation was effected by the nobles and the people, at a time when still bolder principles had sprung up, none of this machinery of power was retained; the clergy were placed on a footing of perfect equality; they were all of them engaged in parochial duties, and only a small part of the ancient ecclesiastical revenues was allowed to them. In imitation of the system established at Geneva, their general affairs, instead of being intrusted to the hands of bishops, were confided to courts formed by themselves. These courts, being partly formed by lay elders, kept up a sympathy and attachment among the community, which has never existed in so great a degree in the English church. What was of perhaps still greater importance, while a large part of the ancient revenues was absorbed by the nobles, a very considerable portion was devoted to the maintenance of parish schools, under the express control of the clergy. These at once formed regular nurseries of Protestant Christians, and disseminated the elements of learning more extensively over this small and remote country than it had ever been over any other part of the world.

MARY QUEEN OF SCOTS.

Queen Mary, having no male power in her own country, was obliged to govern by means of her natural brother, James Stewart, whom she created Earl of Moray, and who was the leader of the Protestant interest in Scotland. Personally, however, she was intimately connected with the great Catholic powers of the Continent, and became a party, in 1564, to a coalition formed by them for the suppression of Protestantism all over Europe. She had never yet resigned her pretensions to the English throne, but lived in the hope, that, when the Catholics succeeded in everywhere subduing the Protestants, she would attain that object. Elizabeth, who had only the support of the Protestant part of her own subjects, with a friendly feeling among the Scotch and other unimportant Protestant nations, had great reason to dread the confederacy formed against her. She nevertheless stood firm upon the Protestant faith, and the principles of a comparatively liberal and popular government, as the only safe position.

A series of unfortunate events threw Mary into the hands of Elizabeth. The former queen, in 1565, married her cousin Lord Darnley, and by that means alienated the affections of her brother and chief minister, the Earl of Moray, as well as of other Protestant lords, who raised a rebellion against her, and were obliged to fly into England. Soon after, the jealousy of Darnley, respecting an Italian musician named Rizzio, who acted as French secretary to the queen, united him in a conspiracy with the banished Protestant noblemen for the murder of that humble foreigner, which was effected under very barbarous circumstances, March 9, 1566. Mary, who was delivered, in the succeeding June, of her son James, withdrew her affections entirely from her husband, and began to confide chiefly in the Earl of Bothwell, who some months afterwards caused Darnley to be blown up by gunpowder, while he lay in a state of sickness; in which transaction it has always been suspected, but never proved, that the queen had a considerable share. Bothwell soon after forced her, in appearance, into a marriage, which excited so much indignation among her subjects, that the same Protestant lords who had effected the Reformation, and were the friends of Elizabeth, easily obtained the possession of her person, and, having deposed her, crowned her infant son as king, under the title of JAMES VI., while the regency was vested in the Earl of Moray. In May 1568, Mary escaped from her prison in Lochleven, and put herself at the head of a body of her partisans, but was defeated by the regent at the battle of Langside, and was then compelled to seek refuge in England. By placing her son under strict confinement, and extending an effectual protection to the regents Moray, Lennox, Mar, and Morton, who successively governed Scotland, Elizabeth fortified herself in a great degree against the Catholic confederacy.

GOVERNMENT OF ELIZABETH.

It has already been seen that the liberties of the people were much favoured by the frequent interruptions in the succession to the crown. Whenever one branch of the Plantagenet family displaced another, the new king, feeling himself weak, endeavoured to strengthen his title by procuring a parliamentary enactment in support of it. It thus became established as a regular principle in the English government, that the people who were represented in Parliament had something to say in the appointment of their king. A considerable change, however, had taken place since the accession of Henry VII. The great power acquired by that king, through his worldly wisdom and the destruction of the nobility during the civil wars, had been handed down through four successive princes, who inherited the crown by birthright, and did not require to cringe to the people for a confirmation of their title. The Parliaments, therefore, were now a great deal more under the control of the sovereign than they had formerly been. From an early period of his reign, Henry VIII. never permitted his Parliament to oppose his will in the least. To the various changes of religion under successive sovereigns, the

Parliaments presented no obstacle. An idea was now beginning to arise, very much through the supremacy which the sovereigns had acquired over the church, that the right of the crown was one derived from God, and that the people had nothing to do with it, except to obey what it dictated to them. Of this notion, no one took so much advantage, or was at so much pains to impress it, as Elizabeth. No doubt, her arbitrary measures were generally of a popular nature, yet this does not excuse them in principle; and their ultimate mischief is seen in the attempts of future sovereigns to pursue worse ends upon the same means. Elizabeth's government consisted entirely of herself and her ministers, who were, from the beginning to the end of [illegible] reign, the very choice of the enlightened men of [illegible]. Her prime minister was the celebrated Lord Burleigh, by far the most sagacious man who ever acted as a minister in Britain; and all her emissaries to foreign courts were of one complexion—circumspect and penetrating men, devoted to their country, their mistress, and to the Protestant religion.

On the accession of Elizabeth, the two celebrated acts of supremacy and conformity were passed, for the purpose of crushing the political influence of the Popish religion; an end which they sufficiently accomplished. By the act of supremacy, all beneficial clergymen, and all holding offices under the crown, were compelled to take an oath abjuring the temporal and spiritual jurisdiction of any foreign prince or prelate, on pain of forfeiting their offices, while any one maintaining such supremacy was liable to heavy penalties. The other statute prohibited any one from following any clergyman who was not of the established religion, under pain of forfeiting his goods and chattels for the first offence, of a year's imprisonment for the second, and of imprisonment during life for the third; while it imposed a fine of a shilling on any one absenting himself from the established church on Sundays and holidays. By means of a court of ecclesiastical commission, which the queen erected, these laws, and others of a more trifling and vexatious nature, were enforced with great severity. It may afford some idea of the barbarity of the age, and of the terror in which the Church of Rome was now held, that, during the reign of Elizabeth, one hundred and eighty persons suffered death by the laws affecting Catholic priests and converts.

WAR IN THE NETHERLANDS.

For more than a century after the Reformation, religion was the real or apparent motive of the most remarkable transactions in European history. It is scarcely necessary to point out that this sentiment, though in general the purest by which human beings can be actuated, is, like all the other higher sentiments of our nature, when offended or shocked, capable of rousing the inferior sentiments into great activity. In the sixteenth and seventeenth centuries, European society was comparatively unenlightened and barbarous; we therefore find that variances of opinion respecting religion were then productive of far fiercer feelings than they are in our own more humane age. The Protestant heresy, as it was termed by the Catholics, was also a novelty, the remote effects of which no man could foretell; it was mingled with political questions, and by some princes supposed to forebode a general revolt against [illegible] authority. We are not therefore to wonder that great cruelties were committed, either by the Catholics in seeking to support the Church of Rome, or by the Protestants in endeavouring to ensure themselves against a renewal of severities inflicted by the opposite party. Nor is it necessary, in the present age, that the adherents of either faith should retain any feeling of displeasure against the other, on account of barbarities which took their rise in the ignorance and rudeness of a former period, and of which the enlightened of both parties have long since disapproved.

In the Netherlands, which formed part of the dominions of Philip II. of Spain, the reformed faith had made considerable advances. Philip, like other Catholic princes, entertained the idea that this new creed, besides being condemnable as a heresy and an offence against the Deity, tended to make men independent of their rulers. Finding the people obstinate in their professions, he commenced a war with the Netherlanders, for the purpose of enforcing his authority over their consciences. This war lasted about twenty years; for the Netherlanders, though a nation of no great strength, fought like desperate men, and endured the most dreadful hardships rather than submit. The chief leader in this war of liberty was William, Prince of Orange, one of the purest and most courageous patriots that ever breathed. Elizabeth could not help wishing well to the Netherlanders, though for a long time her dread of Spain, then one of the greatest powers in Europe, prevented her from openly assisting them. At the same time, about two millions of the people of France were Protestants, or, as they were then called Huguenots, who [illegible] for the general Protestant cause with as much energy as the great strength of the French government would permit. Elizabeth at length, in 1578, extended an open protection to the Netherlanders, excusing herself to Philip by stating her fear that they would otherwise throw themselves into the arms of France. The northern provinces were thus enabled to assert their independence, and to form the country which has since been called Holland.

DEATH OF MARY, QUEEN OF SCOTS.

The Catholic powers of the continent formed many schemes for annoying or dethroning Elizabeth; and the imprisoned Scottish Queen, or her adherents, were generally concerned in them. The King of Spain, determined at length to make a decisive effort, commenced the preparation of a vast fleet, which he termed the Invincible Armada, and with which he designed to invade the English shores. Elizabeth, her ministers, and people, beheld the preparations with much concern, and their fears were increased by the plots which were incessantly forming among her Catholic subjects in behalf of the Queen of Scots. An act was passed declaring that any person, by or *for* whom any plot should be made against the Queen of England, should be guilty of treason. When, soon after, a gentleman named Babington, formed a conspiracy for assassinating Elizabeth and placing Mary on the throne, the latter queen became of course liable to the punishment for treason, although herself innocent. She was subjected to a formal trial in her prison of Fotheringay Castle, and found guilty. Elizabeth hesitated for some time to strike an unoffending and unfortunate person, related to her in blood, and her equal in rank. But at length fears for herself got the better of her sense of justice, and, it may be added, of her good sense, and she gave her sanction to an act which leaves an ineffaceable stain upon her memory. On the 7th of February, 1587, Mary Queen of Scots was beheaded in the hall of the castle, after a confinement of more than eighteen years.

James VI. was now, after a turbulent minority, in possession of the reins of government in Scotland, but with little real power, being a dependent and pensioner of Elizabeth, and at the same time much controlled by the clergy, who asserted a total independence of all temporal authority, and considered themselves as the subjects alone of the divine founder of the Christian faith. James made many attempts to assert a control over the church like that enjoyed by the English monarch, and also to introduce an Episcopal hierarchy, but never could attain more than a mere shadow of his object. The

chief influence he possessed arose from his being regarded as heir-presumptive to the English crown.

SPANISH ARMADA.—REBELLIONS IN IRELAND.

In 1588, the Spanish Armada, consisting of a hundred and thirty great vessels, with twenty thousand land forces on board, set sail against England, while thirty-four thousand more land forces prepared to join from the Netherlands. Amidst the consternation which prevailed in England, active measures were taken to defend the country; thirty vessels prepared to meet the Armada, and another fleet endeavoured to block up the Netherlands forces in port. The command was taken by Lord Howard, of Effingham. Troops were also mustered on land to repel the invaders. The English fleet attacked the Armada in the Channel, and was found to have a considerable advantage in the lightness and manageableness of the vessels. As the Armada sailed along, it was infested by the English in the rear, and, by a series of desultory attacks, so damaged as to be obliged to take refuge on the coast of Zealand. The Duke of Parma now declined to embark the Netherlands forces, and it was resolved by the admiral, that they should return to Spain by sailing round the Orkneys, as the winds were contrary to their passage directly back. Accordingly, they proceeded northward, and were followed by the English fleet as far as Flamborough-head, where they were terribly shattered by a storm. Seventeen of the ships, having 5000 men on board, were cast away on the Western Isles and the coast of Ireland. Of the whole Armada, fifty-three ships only returned to Spain, and these in a wretched condition. The seamen, as well as the soldiers who remained, were so overcome with hardships and fatigue, and so dispirited by their discomfiture, that they filled all Spain with accounts of the desperate valour of the English, and of the tempestuous violence of that ocean by which they were surrounded.

Though the Protestant church had meanwhile been established in Ireland, the great bulk of the people continued to be Roman Catholics. The native rudeness of the people and their chiefs, and the discontent occasioned by what was considered as a foreign church establishment, rendered the country turbulent and difficult to govern. Sir John Perrot, the deputy, proposed to improve the country by public works and English laws; but it was thought injurious to England to improve the condition of Ireland. A series of rebellions under chiefs named O'Neill was the consequence, and the English government was maintained with great difficulty, and at an enormous expense. The rebellion of Hugh O'Neill, Earl of Tyrone, was particularly formidable. The English officers were at first unsuccessful, and met with some serious defeats. In 1599, Tyrone gained so great a victory, that the whole province of Munster declared for him. He then invited the Spaniards to make a descent on Ireland, and join him. The queen sent over her favourite, the Earl of Essex, with 20,000 men; but he did not proceed with vigour, and soon after found it necessary to return to England to justify himself. Next year Tyrone broke the truce he had formed with Essex, overran the whole country, and acted as sovereign of Ireland. If Spain had at this time given him the support he asked, Ireland might have been dissevered from the English crown.

Elizabeth now selected, as her deputy for Ireland, Blount, Lord Mountjoy, who was in every respect better fitted than Essex to conduct such a warfare. As a preliminary step, this sagacious officer introduced jealousy and disunion among the Irish chiefs. The very celerity of his movements tended to dispirit the insurgents. In 1601, six thousand Spaniards landed in Kinsale harbour, for the purpose of supporting the Irish. Mountjoy immediately invested the place, and prevented them from acting. Tyrone marched from the south of Ireland to their relief, and was met and overthrown by a much inferior English force, after which Kinsale was surrendered. About the time when Elizabeth died (1603), Tyrone submitted, and Ireland was once more reduced under the authority of the English crown.

CONCLUSION OF THE REIGN OF ELIZABETH.

It is remarkable, that while Elizabeth increased in power and resources, she became more noted for feminine weaknesses. In her early years she had shown a stoicism, and superiority to natural affections, not usually observed in women. But in her old age, she became both volatile and susceptible to an extraordinary degree; so that the hand which she had withheld, in her younger days, from the noblest princes of Europe, seemed likely to be bestowed, in her old age, upon some mere court minion. Her favourite in middle life was Robert, Earl of Leicester, a profligate and a trifler. In her latter days she listened to the addresses of the Earl of Essex, a young man of greater courage and better principle, but also headstrong and weak. Essex, who had acquired popularity by several brilliant military enterprises, began at length to assume an insolent superiority over the queen, who was, on one occasion, so much provoked by his rudeness as to give him a hearty box on the ear. Notwithstanding all his caprices and insults, the queen still dotingly forgave him, until he at length attempted to raise an insurrection against her in the streets of London, when he was seized, condemned, and after much hesitation executed (February 25, 1601).

Elizabeth, in at last ordering the execution of Essex, had acted upon her usual principle of sacrificing her feelings to what was necessary for the public cause; but in this effort, made in the sixty-eighth year of her age, she had miscalculated the real strength of her nature. She was seen from that time to decline gradually in health and spirits.

About the close of 1601, she fell into a deep hypochondria or melancholy. She could scarcely be induced to have herself dressed, and at length became so much absorbed by her sorrow as to refuse sustenance, and sat for days and nights on the floor, supported by a few cushions brought to her by her attendants. On the 24th of March, 1603, she expired, after a reign of nearly forty-five years, during which England advanced from the condition of a second-rate to that of a first-rate power, and the Protestant religion was established on a basis from which it could never afterwards be shaken.

The reign of Elizabeth saw the commencement of the naval glory of England. Down to the reign of Henry VII., there was no such thing as a navy belonging to the public, and the military genius of the people was devoted exclusively to enterprises by land. The rise, however, of a commercial spirit in Europe, which in 1492 had caused the discovery of America, and was again acted upon by the scope for adventure which that discovery opened up, had latterly caused great attention to be paid to nautical affairs in England. Englishmen of all ranks supported and entered into enterprises for discovering unknown territories; and under Drake, Cavendish, Raleigh, and Frobisher, various expeditions of less or more magnitude were sent out. The colonies of North America were now commenced. Amongst the exertions of private merchants, our attention is chiefly attracted by the commencement of the northern whale-fishery, the cod-fishery of Newfoundland, and the less laudable slave-trade in Africa. When hostilities with Spain became more open, the English commanders made many successful attacks upon her colonies in the West Indies, and also upon the fleets of merchant vessels which were employed to carry home the gold, and other almost equally valuable products of the New World, to the Spanish harbours. These attacks were now made in a

more systematic manner, and with more effect, as a revenge for the affair of the Armada. It may almost be said that the dominion of Britain over the seas was perfected in one reign; a power which has been of such advantage to the country, both in protecting its commerce and keeping it secure from foreign invasion, that its origin would have conferred everlasting lustre on this period of our history, even although it had not been characterized by any other glorious event.

The chief articles exported from England to the Continent were wool, cloth, lead, and tin: formerly these had been sent in vessels belonging to the Hanse Towns—certain ports of the north of Europe, possessing great privileges—but now English vessels were substituted for this trade. Birmingham and Sheffield were already thriving seats of the hardware manufacture, and Manchester was becoming distinguished for making cottons, rugs, and friezes. Stocking-weaving and the making of sailcloth, serge, and baize, took their rise in this reign. The progress of other arts was much favoured by the bloody persecutions in the Netherlands, which drove into England great numbers of weavers, dyers, cloth-dressers, and silk-throwers. Amongst the wealthier classes, the wearing of handsome apparel and of gold ornaments and jewelry, made a great advance. Coaches were introduced, but for a time thought only fit for the use of ladies. Great improvements were made in the building of houses. Theatrical amusements were begun, and attained great vogue, though only in London. The smoking of tobacco was introduced by Sir Walter Raleigh, who became acquainted with the plant in Virginia. At the end of Elizabeth's reign, the population of London was about 160,000, or a tenth of what it now is; and the whole kingdom probably contained about 6,000,000 of inhabitants.

THE STUARTS—JAMES I.

The successor of Elizabeth, by birthright, was JAMES VI. OF SCOTLAND (styled JAMES I. OF ENGLAND), who was now arrived at the prime of life, and had been married for some years to the Princess Anne of Denmark, by whom he had two sons, Henry and Charles, and one daughter named Elizabeth. James immediately removed to London, and assumed the government of England, while his native kingdom, though thus united under the same sovereignty, still retained its own peculiar institutions. At the suggestion of the king, who wished to obliterate the distinction of the two countries, the common name of *Great Britain* was now conferred upon them. King James was an oddity in human character. His person was naturally feeble, particularly in the limbs, which were scarcely sufficient to support his weight. He had great capacity for learning, some acuteness, and a considerable share of wit; but was pedantic, vain, and weak. He believed kings to be the deputies of God, and accountable to God alone for their actions. He was equally disposed with Elizabeth to govern despotically, or according to his own will; but he wanted the vigour and the turn for popularity which enabled his predecessor to become so much the mistress of her subjects.

Notwithstanding the energy of Elizabeth, the popular spirit had gradually been acquiring force in her reign. It was chiefly seen in the acts of the Puritans, a religious party who wished to make great reforms in the church, both in its government and its worship, and who, from the fervour of their devotions and the strictness of their manners, might be likened to the Presbyterians of Scotland. King James found considerable difficulty at the very first in controlling this party and evading their demands. He was no less troubled, on the other hand, by the Catholics, who, recollecting his mother Mary, conceived that he would be inclined to make matters more easy to them in England. Upon the whole, there were such difficulties in the way, as, to have steered clearly through them, would have required a wiser instead of a weaker ruler than Elizabeth.

GUNPOWDER PLOT.

The disappointment of the Catholics, on finding that the severe laws against them were not to be relaxed, led to a conspiracy on the part of a few gentlemen of that persuasion, of whom the chief was William Catesby, a person of dissolute habits. It was arranged that, on the day of the meeting of Parliament, November 5, 1605, the House of Lords should be blown up by gunpowder, at the moment when the King, Lords, and Commons, were all assembled in it, thus destroying, as they thought, all their chief enemies at one blow, and making way for a new government which should be more favourable to them. Accordingly, thirty-four barrels of powder were deposited in the cellars beneath the house, and a person named Guy Fawkes was prepared to kindle it at the proper time. The plot was discovered, in consequence of the receipt of a letter by Lord Monteagle, warning him not to attend the meeting of Parliament. An investigation took place during the night between the 4th and 5th of November, when the gunpowder was discovered, and Fawkes taken into custody. He confessed his intentions; and the rest of the conspirators fled to the country, where most of them were cut to pieces in endeavouring to defend themselves. Notwithstanding the atrocious character of this plot, the king could never be induced to take advantage of it, as most of his subjects desired, for the purpose of increasing the persecution of the Catholic party: he probably feared that new severities might only give rise to other attempts against his life.

PLANTATIONS IN IRELAND.

The state in which the king found Ireland at his accession, afforded an opportunity for commencing a more generous policy in reference to that country, and introducing regulations favourable to internal improvement. Previously to this reign, the legislative authority of the English government was confined to the small district called the "Pale," while the rest was governed by native sovereigns or chiefs, whose connection with the King of England was merely that of feudal homage, which did not prevent them from making wars or alliances with each other. Subject to depredations from these powerful barons, the native Irish, from a very early period, petitioned for the benefit of the English laws; but the Irish Parliament, which was composed of the English barons, was never at a loss for the means of preventing this desirable measure from being effected. James was, in reality, the first king who extended the English law over the whole of Ireland, by making judicial appointments suited to the extent of the country. This he was enabled to do, by the recent wars having put the country more completely in his power than it had been in that of any former monarch. He began by extending favour to the Irish chiefs, not excepting Tyrone. He passed an act of oblivion and indemnity, by which all persons who had committed offences, coming to the judges of assize within a certain day, might claim a full pardon. At the same time, toleration was virtually refused to the Catholic persuasion, and much discontent therefore still existed. Some of the chieftains, having conspired against the crown, were attainted, and their lands were given to English settlers, with a view to improving the population of the country by an infusion of civilized persons. But this experiment, though well-meant, was managed in a partial spirit, and gave rise to much injustice. In 1613, the first Irish Parliament was held in which there were any representatives of places beyond the Pale.

THE KING'S CHILDREN.—THE SPANISH MATCH.

In 1612, the king had the misfortune to lose his eldest son, Henry, a youth of nineteen, who was considered

as one of the most promising and accomplished men of the age. The second son, Charles, then became the heir-apparent, and James was busied for several years in seeking him out a suitable consort. The Princess Mary of Spain was selected, a match which could ot be popular, considering that the young lady was a Catholic, and of a family who had long been the enemies of England. The prince, attended by the Duke of Buckingham, made a romantic journey in disguise to Madrid, to push the match; but a quarrel between the British and Spanish ministers led to its being broken off, and to a bloody war between the two nations.

Elizabeth, the only remaining child of the king, was married, in 1613, to Frederick, Prince Palatine of the Rhine, who was afterwards so unfortunate as to lose his dominions, in consequence of his placing himself at the head of the Bohemians, in what was considered as a rebellion against his superior, the Emperor of Germany. This discrowned pair, by their youngest daughter Sophia, who married the Duke of Brunswick, were the ancestors of the family which now reigns in Britain.

FEATURES OF JAMES I.'S GOVERNMENT.

The reign of James I. was not marked by what are called great events. This was greatly owing to his timid character, which induced him to maintain peace, at whatever sacrifice, throughout the greater part of his reign. The prime leaders of his government were youthful favourites, who possessed ... merit but personal elegance. Experienced statesmen, brave soldiers, and learned divines had to bow to these dissolute youths, if they wished to remain, and still more if they hoped to advance, in the royal favour. Even Bacon, the noblest intellect of the age, and who, by the result of his studies, has done more than almost any other man to promote the progress of knowledge, is found to have attached himself to the minion Duke of Buckingham, for the purpose of improving his interest at court.

In despotic countries, the vices of the court often corrupt all classes; but it was otherwise at that period in Britain. The country gentlemen, and the merchants in the incorporated towns, had privileges which the court dared not to violate, and a feeling of rectitude and independence was encouraged among these classes, which the statesmen of the age too much overlooked. The House of Commons gave frequent resistance to the court, and often compelled James to yield, at the very moment when he was preaching his doctrines of divine right. In his first Parliament, they took into consideration several grievances, such as *purveyance*, a supposed right in the officers of the court to seize what provisions they pleased, at any price, or at no price; another was the right of granting *monopolies*, which had become a source of revenue to the court by cheating the country, certain persons having the monopoly of certain manufactures and articles of domestic consumption, which they were allowed to furnish at their own prices. The Commons likewise remonstrated against pluralities in the church, and against a new set of canons which the king and the church tried to force on the nation without their consent. In 1614, they threatened to postpone any supply till their grievances were redressed. The king, in his turn, threatened to dissolve them if they did not immediately grant a supply; and they allowed him to take his course, which did not fill his coffers. These, and many other instances of bold resistance, should have been warning to the court. They were the shadows of coming events, and attention to them might have saved the bloodshed and confusion of the next reign.

The English literature, which first made a decisive advance in the reign of Elizabeth, continued to be cultivated with great success in the reign of King James. The excellence of the language at this time as a medium for literature, is strikingly shown in the translation of the Bible now executed. It is also shown in the admirable dramatic writings of Shakspeare, and in the valuable philosophic works of Bacon. The inductive philosophy made known by the last writer—namely, that mode of reasoning which consists in first ascertaining facts, and then inferring conclusions from them—reflects peculiar lustre on this period of our history. Very great praise is also due to Napier of Merchiston, in Scotland, for the invention of *logarithms*, a mode of calculating great numbers, essential to the progress of mathematical science.

CHARLES I.—HIS CONTENTIONS WITH THE HOUSE OF COMMONS.

King James died in March, 1625, in the fifty-ninth year of his age, and was succeeded by his son CHARLES, now twenty-five years of age. One of the first acts of the young king was to marry the Princess Henrietta Maria, daughter of Henry IV. of France, and a Catholic. This was an unfortunate step for the house of Stuart, for the two eldest sons of the king and queen, though educated as Protestants, were influenced in some measure by the religious creed of their mother, so that they ultimately became Catholics; and this, in the case of the second son, James II., led to the family being expelled from the throne.

After breaking off the proposed match with the Princess Mary of Spain, Britain eagerly threw itself into a war with that country, which was still continued. To supply the expenses of that contest, and of a still more unnecessary one into which he was driven with France, the king applied to Parliament, but was met there with so many complaints as to his government, and such a keen spirit of popular liberty, that he deemed it necessary to revive a practice followed by other sovereigns, and particularly Elizabeth, of compelling his subjects to grant him gifts, or, as they were called, *benevolences*, and also to furnish ships at their own charge, for carrying on the war. Such expedients, barely tolerated under the happy reign of Elizabeth, could not be endured in this age, when the people and the Parliament were so much more alive to their rights. A general discontent spread over the nation. The Commons, seeing that if the king could support the state by self-raised taxes, he would soon become independent of all control from his Parliaments, resolved to take every measure in their power to check his proceedings. They also assailed him respecting a right which he assumed to imprison his subjects upon his own warrant, and to detain them as long as he pleased. Having made an inquiry into the ancient powers of the crown, before these powers had been vitiated by the tyrannical Tudors, they imbodied the result in what we called a PETITION OF RIGHT, which they presented to him as an ordinary bill, or rather as a second Magna Charta, for replacing the privileges of the people, and particularly their exemption from arbitrary taxes and imprisonment, upon a fixed basis. With great difficulty Charles was prevailed upon to give his sanction to this bill (1628); but his disputes with Parliament soon after ran to such a height, that he dissolved it in a fit of indignation, resolving never more to call it together. About the same time, his favourite minister, the Duke of Buckingham, was assassinated at Portsmouth, and Charles resolved thenceforward to be in a great measure his own minister, and to trust chiefly for the support of his government to the English hierarchy, to whose faith he was a devoted adherent, and who were, in turn, the most loyal of his subjects. His chief counsellor was Laud, Archbishop of Canterbury, a man of narrow and bigoted spirit, and who made it his duty rather to increase than to diminish the ceremonies of the English church, although the tendency of the age was decidedly favourable to their diminution. For some years Charles governed the country entirely as an irresponsible despot, levying taxes by his own orders, and imprisoning such persons as

were obnoxious to him, in utter defiance of the Petition of Right. The Puritans, or church reformers, suffered most severely under this system of things. They were dragged in great numbers before an arbitrary court called the Star-Chamber, which professed to take cognisance of offences against the king's prerogative, and against religion; and sometimes men venerable for piety, learning, and worth, were scourged through the streets of London, and had their ears cut off, and their noses slit, for merely differing in opinion, on the most speculative of all subjects, with the king and his clergy. The great body of the people beheld these proceedings with horror, and only some opportunity was wanted for giving expression to the public feeling.

It is to be observed, that none of the taxes imposed by Charles were in themselves burdensome; the country was then in a most prosperous condition, and the taxes far less in proportion to every man's means than they have ever since been. It was only to the principle of their being raised without Parliamentary sanction, which had formerly been so necessary a control on the royal power, that the people were disposed to resist them. It may easily be supposed, that, though there might be a general disposition to resistance, the most of individuals would not like to be the first to come forward for that purpose, as, in such an event, they would have been sure to experience the severest persecution from the court. At length, John Hampden, a gentleman of Buckinghamshire, resolved to undergo any personal inconvenience rather than pay his twenty shillings of ship-money. The case was tried in the Exchequer (1637); and as the judges were then dismissible at the royal pleasure, and of course the humble servants of the king in every thing, Hampden lost his cause. He roused, however, more effectually than ever, the attention of the people to this question, and means were not long wanting to check the king in his unfortunate career.

TROUBLES IN SCOTLAND.—THE NATIONAL COVENANT.

An attempt had been made by King James to introduce the Episcopal Church into Scotland, because it was thought dangerous to the English church that a form of worship, resembling that of the Puritans, should be permitted to exist in any part of the king's dominions. The same object was prosecuted with greater zeal by King Charles; and although the people were generally adverse to it, he had succeeded, after a visit which he paid to the country in 1633, in settling thirteen bishops over the church, by whom he hoped to govern the clergy as he did those of England. But when he attempted, in 1637, to introduce a new Book of Common Prayer into the Scotch churches, the spirit of the people could no longer be kept within bounds. On the Liturgy being opened in the principal church at Edinburgh, the congregation rose in a violent tumult, and threw their clasped Bibles, and the very stools they sat on, at the minister's head; and it was not till the whole were expelled by force, that the worship was permitted to proceed. It was found necessary, by the Scottish state-officers, to withdraw the obnoxious Liturgy, till they should consult the king, who, not dreading any mischief, gave orders that it should be used as he had formerly directed, and that the civil force should be employed in protecting the clergymen. It was found quite impossible to obey such an order in the face of a united people, who, by committees assembled at Edinburgh, representing the nobles, ministers, gentry, and burghers, endeavoured to awe the king into an abandonment of the late innovations. Charles endeavoured, by every means in his power, to avoid such a humiliation, which he believed would give immense force to the innovators in England. But the Scotch, when they found him hesitating, bound themselves (March, 1638), under a bond called the *National Covenant*, which was signed by nineteen-twentieths of the adult population, to resist their sovereign in every attempt he might make to bring in upon them the errors of Popery—for such they held to be the forms of worship and ecclesiastical government which Charles had lately imposed upon their church. The king sent his favourite Scotch counsellor, the Marquis of Hamilton, to treat with his northern subjects, but nothing would satisfy them but the calling of a General Assembly of the church, for the purpose of settling all disputes. Charles, though he saw that this was only an appeal to the heads of the party by which he had been opposed, consented to the proposal, for the purpose of gaining time, in order that he might make warlike preparations against his refractory people.

The Assembly met at Glasgow in November, and, as might have been expected, formally purified the church from all the late innovations, excommunicating the bishops, and declaring the government of the clergy to rest, as formerly, in the General Assembly, which consisted of a selection of two clergymen from each presbytery, with a mixture of lay elders, and nothing to control its proceedings but their interpretation of the will of the divine founder of the Christian religion. Early in the succeeding year, the king, with great difficulty, collected an army of 20,000 men, whom he led to the border of Scotland, for the purpose of reducing these despisers of his authority. The Scotch, however, strengthened by devotional feeling, and a certainty that the English, in general, were favourable to their cause, formed an army equal in number, which was placed under the command of General Alexander Leslie, an officer who had served with distinction in the long Protestant war carried on against the Emperor of Germany. The Scottish army was encamped on the top of Dunse Law, a hill overlooking the border, where the duties of military parade were mingled with prayers and preachings, such as were never before witnessed in a camp. The king, seeing the wavering of his own men, and the steadfastness of the Scotch, was obliged to open a negotiation, in which it was agreed to disband both armies, and to refer the disputes once more to a General Assembly and a Scottish Parliament.

The king now adopted a new policy with the turbulent people of Scotland. Having formerly gained over some of the English patriots, he thought he might be equally successful with the lords of the Covenant, whom he therefore invited to attend him at Berwick, where the late negotiations had been conducted. A few obeyed the summons; but he failed with all except the Earl (afterwards Marquis) of Montrose, a noble of vigorous genius, whose ambition had been wounded by not having so high a place in the counsels of his countrymen as he thought he deserved. In the new General Assembly and Parliament (1640), the votes were equally decisive against Episcopacy; and though Charles prorogued the latter body before it had completed its proceedings, it nevertheless continued sitting, and voted every measure which it thought necessary. The king collected a second army, and, in order to raise money for a second expedition against the Scots, was reduced to the necessity of calling an English Parliament, the first that had met for eleven years. It met (April 13), but, without listening for a moment to a request for subsidies, began to discuss the national grievances. Finding it quite intractable, the king dissolved it (May 5), and endeavoured to obtain supplies in other quarters. A convocation of the clergy granted him £20,000 per annum for the next three years. The nobility and gentry advanced £[illegible], but when the city of London was asked for a loan of £200,000, it absolutely refused.

The Scots did not, on this occasion, wait to be attacked by the king, but, in August, 1640, marched into the north of England, in the expectation of being sup-

ic their claims by the English people in general. A victory gained by them at Newburnford, and their taking possession of Newcastle, together with the manifest disaffection of his own troops, made it necessary that Charles should once more resort to negotiation. It was agreed at a council of peers that all the present dissensions should be referred to the Parliaments of the two countries, the Scottish army being in the mean time kept up on English pay, till such time as they were satisfied with the state of their affairs.

THE LONG PARLIAMENT.—THE IRISH REBELLION.

The English Parliament met in November, and immediately commenced a series of measures for effectually and permanently abridging the royal authority. There was even a party who, provoked by the late arbitrary measures, contemplated the total abolition of the monarchy, and the establishment of a republic. The first acts of the Parliament had little or no immediate reference to Scotland. The Earl of Strafford was impeached of treason against the liberties of the people, and executed (May 12, 1641), notwithstanding a solemn promise made to him by the king that he should never suffer in person or estate. Archbishop Laud was impeached and imprisoned, but reserved for future vengeance. The remaining ministers of the king only saved themselves by flight. Some of the judges were imprisoned and fined. The abolition of Episcopacy was taken into consideration. The Catholics fell under a severe persecution; and even the person of the queen, who belonged to this faith, was not considered safe.

It was not till August, 1641, when the English Parliament had gained many of its objects, that they permitted the treaty of peace with Scotland to be fully ratified. They then gratified the troops, not only with their full pay at the rate of £850 a day, but with a vote of no less a sum than £300,000 besides, of which £80,000 was paid down, as an indirect way of furnishing their party with the means of future resistance. The king, on his part, also took measures for gaining the attachment of this formidable body of soldiery, and of the Scottish nation in general. In Edinburgh, which he visited in August, he squared his conduct carefully with the rigour of Presbyterian manners. In the Parliament he was exceedingly complaisant; he readily ratified all the acts of the preceding irregular session; he yielded up the right of appointing the state officers of Scotland, and he ordained that the Scottish Parliament should meet once every three years without regard to his will—all of which were points of the greatest importance. The men who had acted most conspicuously against him in the late insurrections, now became his chief counsellors, and he seemed to bestow favours upon them exactly in proportion to their enmity. He created General Leslie Earl of Leven, putting on his coronet with his own hand. The Earl of Argyle, who had been the chief political leader of the Covenanters, was made a marquis. Many others received promotions in the peerage. The offices of state were distributed among them. Thus, it will be observed, the affections of the Scots were in a manner set up to auction between the king and his English Parliament, and from both did they receive considerable advantages.

But, while thus intriguing with the Covenanting leaders, Charles also kept up a correspondence with a royalist party which had been imbodied by the Earl of Montrose. This nobleman was now suffering confinement in Edinburgh Castle, for his exertions in favour of the king. An obscure conspiracy which he formed against three of the chief popular nobles, Argyle, Hamilton, and Lanark, as a preliminary step to the re-establishment of the royal power, became known at this time, and did some injury to the king's cause in both countries. After spending about three months in Edinburgh, Charles was suddenly called away in consequence of intelligence which reached him from Ireland.

The cruel policy already mentioned, by which large portions of Ireland were depopulated, and then planted with colonies of English and Scotch settlers, had been continued during the reign of Charles. In addition to this and other local causes of complaint, the state of religion was one which pervaded nearly the whole country, and was always becoming more and more important. Though the reformed faith had been established for nearly a century, it had made little progress except among the English settlers. The greater part of the nobility, and also of the lower orders, were still attached to the ancient creed; and a Catholic hierarchy, appointed by the Pope, and supported by the people, enjoyed as much respect and obedience as when that religion was countenanced by the state. The refusal of the Catholics to take the oath of supremacy, which acknowledged the king to possess a right which their faith taught them to belong to the Pope, necessarily excluded them from all branches of the public service. There were also penal laws against the profession of Catholicism, and a severe court of Star-Chamber to carry these into execution. Thus situated, the Irish Catholics had two strong motives to mutiny—a confidence in their numbers, and a constant sense of suffering under the government.

In 1633, the Earl of Strafford was appointed viceroy of Ireland. His government was vigorous, and those institutions which he thought proper to patronize, flourished under it; but his great aim was to make the king absolute, and he rather subdued than conciliated the popular spirit. When summoned in 1640 to attend the king in England, he left the Irish government in the hands of Sir William Parsons and Sir John Borlase, as lords justices. Immediately after his departure, the spirit which he thought he had quelled began to re-appear, being encouraged both by his absence, and by the success which the Scottish Covenanters had experienced in a war against religious restraint. A conspiracy, involving most of the country without the Pale, and including many persons within it, was formed chiefly under the direction of a gentleman named Roger Moore, who possessed many qualities calculated to endear him to the people. Some circumstances excited the suspicion of the Protestants; and, among others, the return of several officers who had been in the service of the King of Spain, under pretence of recruiting for the Spanish army. But the apparent tranquillity of the country baffled all scrutiny.

The 23d of October, 1641, being a market-day, was fixed on for the capture of Dublin Castle. During the previous day, nothing had occurred to alarm the authorities. In the evening of the 22d, the conspiracy was accidentally discovered, and measures were taken to save Dublin; but a civil war raged next morning in Ulster and speedily spread over the country. The design of Sir Phelim O'Neill, and the other leaders of the insurrection, was simply political. They conceived the time a good one for striking a blow against the government, as the Scots had done; and their conduct was in the outset characterized by lenity. They could not, however, allay the hatred with which the Catholics looked upon their adversaries; and a spirit of revenge broke out among their followers, which was aggravated to cruel outrage, when they heard that the conspiracy was discovered in Dublin. The spirit of retaliation was let loose, and political wrongs, unfeelingly inflicted, were, as is often the case, ferociously avenged. The massacre of an immense number of Protestants held forth an awful lesson of the effects which oppressive laws produce on the human passions. The government rather aggravated than alleviated the evil, by offering the estates of all in rebellion to those who should aid in reducing them to obedience. This drove the insurgents to desperation,

and postponed the complete extinction of the war for several years. It is to be remarked, that, though the Irish were struggling for both national and religious freedom, they gained no sympathy from the patriots of Britain, who, on the contrary, urged the king to suppress the rebellion, being afraid that a religious toleration in Ireland would be inconsistent with the same privilege in their own country. The Scottish Covenanters, themselves so recently emancipated from a restraint upon their consciences, contributed ten thousand troops to assist in restoring that restraint upon the Irish.

THE CIVIL WAR.

It was generally allowed by moderate people, that in the autumn of 1641, at which time the labours of the Parliament had continued one year, the king had granted redress of all the abuses for which the earlier part of his reign, and the British constitution in general, were blamable. Unfortunately, the character of the king for fidelity to his engagements was not sufficiently high to induce the leaders of the House of Commons to depend upon him: they feared that, if they once permitted him to resume his authority, there would be no longer any safety for them; and they deemed it necessary that things should be prevented from falling into their usual current. They therefore prepared a paper called *The Remonstrance*, containing an elaborate view of all the grievances that had ever existed, or could now be supposed to exist; and this they not only presented to the king, but disseminated widely among the people, with whom it served to increase the prevailing disaffection.

From this time it was seen that the sword could alone decide the quarrel between the king and the Parliament. Charles made an unsuccessful attempt (January 4, 1642) to seize six of the most refractory members, for the purpose of striking terror into the rest. This served to widen the breach. In the early part of 1642, the two parties severally employed themselves in preparing for war. Yet, even now, the king granted some additional concessions to his opponents. It was at last, upon a demand of the Parliament for the command of the army—a privilege always before and since resting with the crown—that he finally broke off all amicable intercourse. He retired with his family to York.

The Parliament found its chief support in the mercantile classes of London and of the eastern coast of England, which was then more devoted to trade than the west, and in the Puritan party generally, who were allied intimately with the Presbyterians of Scotland, if not rapidly becoming assimilated with them. Charles, on the other hand, looked for aid to the nobility and gentry, who were able to bring a considerable number of dependants into the field. The Parliamentary party was by the other styled *Roundheads*, in consequence of their wearing short hair; while the friends of the Parliament bestowed upon their opponents the epithet of *Malignants*. The Royalists were also, in the field, termed Cavaliers, from so many of them being horsemen.

On the 25th of August, the king erected his standard at Nottingham, and soon found himself at the head of an army of ten thousand men. The Parliament had superior forces, and a better supply of arms; but both parties were very ignorant of the art of war. The king commanded his own army in person, and the Parliamentary forces were put under the charge of the Earl of Essex.

The first battle took place, October 23, at Edgehill, in Warwickshire, where the king had rather the advantage, though at the expense of a great number of men. He gained some further triumphs before the end of the campaign, but still could not muster so large an army as the Parliament. During the winter, the parties opened a negotiation at Oxford; but the demands of the Parliament being still deemed too great by the king, it came to no successful issue.

Early in the ensuing season, the king gained some considerable advantages; he defeated a Parliamentary army under Sir William Waller at Stratton, and soon after took the city of Bristol. It only remained for him to take Gloucester, in order to confine the insurrection entirely to the eastern provinces. It was even thought at this time that he might have easily obtained possession of London, and thereby put an end to the war. Instead of making such an attempt, he caused siege to be laid to Gloucester, which the army of Essex relieved, when it was just on the point of capitulating. As the Parliamentary army was returning to London, it was attacked by the royal forces at Newbury, and all but defeated. Another royal army in the north, under the Marquis of Newcastle, gained some advantages; and, upon the whole, at the close of the campaign of 1643, the Parliamentary cause was not in a flourishing condition.

In this war, there was hardly any respectable military quality exhibited, besides courage. The Royalists used to rush upon the enemy opposed to them, without any other design than to cut down as many as possible, and, when any part of the army was successful, it never returned to the field while a single enemy remained to be pursued; the consequence of which was, that one wing was sometimes victorious, while the remainder was completely beaten. The Parliamentary troops, though animated by an enthusiastic feeling of religion, were somewhat steadier, but nevertheless had no extensive or combined plan of military operations. The first appearance of a superior kind of discipline was exhibited in a regiment of horse commanded by Oliver Cromwell, a gentleman of small fortune, who had been a brewer, but was destined, by great talent, hypocrisy, and address, joined to an unrelenting disposition, to rise to supreme authority. Cromwell, though himself inexperienced in military affairs, showed, from the very first, a power of drilling and managing troops, which no other man in either army seemed to possess. Hence his regiment soon became famous for its exploits.

The royal successes of 1643 distressed alike the English Parliament and the Scottish nation, who now began to fear the loss of all the political meliorations they had wrested from the king. The two parliaments therefore entered, in July, into a *Solemn League and Covenant*, for prosecuting the war in concert, with the view of ultimately settling both church and state in a manner consistent with the liberties of the people. In terms of this bond, the Scots raised an army of 21,000 men, who entered England in January, 1644, and, on the 1st of July, in company with a large body of English forces, overthrew the king's northern army on Long Marston Moor. The conduct of the Scottish nation in this transaction was not unexceptionable. They had been gratified in 1641 with a redress of every grievance they could name; since which time the king had not given them the least cause of complaint. In now raising war against him, they had no excuse but the very equivocal one, that it was necessary to guard against the possibility of his afterwards being able to injure them. They were also acting on English pay, a proceeding not very consistent with their pretensions to independence. The mainspring of their policy was a hope of being able to establish the Presbyterian religion in England. The Episcopal church being now abolished, divines were nominated by both nations to meet at Westminster, in order to settle a new form of worship and church government; and after a long course of deliberation it was agreed that the Presbyterian system should be adopted, though in England it was provided that the new church should have no connection with or influence over the state.

ne defeat at Long Marston was severely felt by the king. He gained victory over Waller at Copredy bridge, and caused Essex's army to capitulate in Cornwall (September 1), but in consequence of a second fight at Newbury (October 27), in which he suffered a defeat, he was left at the end of the campaign with greatly diminished resources. A new negotiation was commenced at Uxbridge; but the terms asked by the Parliament were so exorbitant as to show no sincere desire of ending the war. In truth, though the Presbyterian party were perhaps anxious for peace, there was another party, now fast rising into importance, who had no such wishes. These were the Independents, a body of men who wished to see a republic established in the state, and all formalities whatever removed from the national religion. Among the leaders of the party was Cromwell, whose mind seems to have already become inspired with lofty views of personal aggrandizement. This extraordinary man had sufficient address to carry a famous act called the *Self-Denying Ordinance*, which ostensibly aimed at depriving all members of the legislature of commands in the army, but had the effect only of displacing a few noblemen who were obnoxious to his designs. He also carried an act for modelling the army anew, in which process he took care that all who might be expected to oppose his views should be excluded. It was this party, more particularly, that prevented any accommodation taking place between the king and his subjects.

While the negotiation was pending, the Marquis (formerly Earl) of Montrose produced a diversion in Scotland in favour of the king. Having got fifteen hundred foot from Ireland, to which he added a few Perthshire Highlanders, he descended upon the Lowlands, and on the 1st of September (1644) gained a complete victory over a larger and better-armed force at Tippermuir. At Aberdeen, whither he went for the purpose of increasing his army, he gained another victory over a superior body of Covenanters. He was then pursued by a third army, under the Marquis of Argyle, and, after some rapid movements, seemed to dissolve his forces in the Highlands. Ere his enemies were aware, he burst in the middle of winter into the country of his great rival Argyle, which he did not leave till he had made it a desert. Finding himself timidly followed by the marquis, at the head of a large body of the clan Campbell, he turned suddenly, and falling upon them at Inverlochy (February 2, 1645), gained a complete victory. He then moved along the eastern frontier of the Highlands, where he found himself opposed by a fourth army under General Baillie. After sacking Dundee, and eluding Baillie's troops, he encountered at Aldearn, in Nairnshire (May 4), a greatly superior force, which he also overthrew. Then turning upon Baillie, whom he met at Alford, in Aberdeenshire (July 2), he gained a fifth victory, almost as complete as any of the rest.

In all these battles Montrose carried every thing before him by the spirit of his first onset, and the slaughter was in general very great. He now descended to the Lowlands, and at Kilsyth, near Glasgow, was opposed by an army of 6000 men, whom the insurgent government at Edinburgh had hastily assembled from Fife and Perthshire. These, with a much smaller force, he also defeated (August 15), killing great numbers in the pursuit. The committees of church and state then broke up and left the kingdom, leaving him in appearance its sole master. His successes had in the mean time given the king hopes of carrying on the war with success; but Montrose had in reality gained no sure advantages. Besides his small army of mingled Irish and Highlanders, there was hardly any portion of the nation who did not regard him as only a great public enemy. While lying with a diminished force at Philiphaugh, near Selkirk, he was surprised (September 11), by a detachment of the regular Scottish army, under General David Leslie, who completely defeated his troops, and obliged him to leave the kingdom. His having gained six victories in succession, over larger bodies of men, has procured for him a distinguished name; but his cruelty, and the ambition to which his motives were confined, detract greatly from his character.

FROM THE YEAR 1645 TILL THE PEACE OF 1763.

CONCLUSION OF THE CIVIL WAR.

The English campaign of 1645 ended in the complete overthrow of the king. Throughout the war, his enemies had been continually improving in discipline, in conduct, and in that enthusiasm which animated them so largely, while the royalists had become, out of a mere principle of opposition, so extremely licentious as to be rather a terror to their friends than to their enemies. The new-modelling of the parliamentary army, which took place early in 1645, had also added much to the effectiveness of the troops, who were now nominally commanded by Sir Thomas Fairfax, but in reality by Oliver Cromwell, who bore the rank of lieutenant-general. The consequence was, that, in a pitched battle at Naseby (June 14), the king was so completely beaten, that he and his party could no longer keep the field. He had no resource but to retire into Oxford, a town zealously affected to his cause, and well fortified.

He endeavoured, from this forlorn position, to renew the negotiations for a peace; but every attempt of that kind was frustrated by the Independents, who, though a minority in the House of Commons, possessed great power through the army, and, as already mentioned, were desirous of effecting greater changes in church and state than those for which the war was originally undertaken. Dreading the influence of this body, Charles retired privately from Oxford (May 1646) on the approach of the parliamentary forces, and put himself under the protection of the Scottish army at Newark.

As the views of the Scots throughout the war had been steadily confined to the security of the Presbyterian religion, along with the safety of the king's person and the establishment of a limited monarchy, they received him with great respect at their camp, and entered into negotiations for effecting their grand object. If Charles would have acceded to their views, he might have immediately resumed a great part of his former power; and the agitations of many subsequent years, as well as his own life, might have been spared. But this was forbidden, not only by his strong prepossession in favour of the Episcopal forms of worship, but also by his conviction, that the Episcopal form of church government was alone compatible with the existence of monarchy. He therefore disagreed with the Presbyterians on the very point which they considered the most important.

From the time when Charles first threw himself into the Scottish camp, the English Parliament had made repeated and strenuous demands for the surrender of his person into their hands. The Scots, however, though acting partly as a mercenary army, asserted their right, as an independent nation under the authority of the king, to retain and protect him. At length, despairing of inducing him to sanction the Presbyterian forms, and tempted by the sum of £400,000, which was given to them as a compensation for their arrears of pay, they consented to deliver up their monarch, but certainly without any apprehension of his life being in danger, and, indeed, to a party quite different from that by which he afterwards suffered. The Scottish army then retired (January 1647) to their native country, and were dismissed.

The king was now placed in Holdenby Castle, and negotiations were opened for restoring him to power, under

certain restrictions. While these were pending, the Parliament deemed it unnecessary to keep up the army, more especially as its spirit was plainly observed to be of a dangerous character. On attempting, however, to dismiss this powerful force, the English Commons found that their late servants were become their masters. The troops began to hold something like a Parliament in their own camp; a party of them, under Cornet Joyce, seized the king's person, and brought him to Hampton Court. Cromwell, who was at the bottom of their machinations, received from them the chief command; and, at his instigation, they retorted upon the Parliament with a demand for the dismissal of the leaders of the Presbyterian party, and a general right of new-modelling the government and settling the nation. The House of Commons, supported by the city of London, made a bold opposition to these demands, but was obliged to yield to a force which it had no means of resisting. From that time military violence exercised an almost uncontrolled mastery over England.

TRIAL AND EXECUTION OF THE KING.

The leaders of the army, being anxious to fortify themselves by all possible means against the Presbyterians, opened a negotiation with the king, whose influence, such as it now was, they proposed to purchase, by allowing Episcopacy to be the state religion, and leaving him in command of the militia. Charles, however, with characteristic insincerity, carried on at the same time a negotiation with the Presbyterians, which, being discovered by the military chiefs, caused them to break off all terms with him. Under dread of their resentment, he made his escape from Hampton Court (November 11, 1647), and, after an unsuccessful attempt to leave the kingdom, was obliged to put himself under the charge of the governor of Carisbrooke Castle, in the Isle of Wight. Here he entered upon a new negotiation with the House of Commons, to whom he made proposals, and from whom he received proposals in return; all of which were, however, rendered vain by a secret treaty which he at the same time carried on with a moderate party of the Scottish Presbyterians.

He finally agreed with the latter party, but under strict secrecy, to give their form of church government a trial of three years, and yield to them in several other points; they, in return, binding themselves to unite their strength with the English Royalists, for the purpose of putting down the Independent party, now predominant in the English Parliament. With some difficulty the Duke of Hamilton and others, who conducted this negotiation, succeeded, by a vote of the Scottish Parliament, in raising an army of 12,000 men, with which they invaded England in the summer of 1648. The more zealous of the clergy and people of Scotland protested against an enterprise, which, from its co-operating with Royalists and Episcopalians, and not perfectly ensuring the ascendency of the Presbyterian Church, appeared to them as neither deserving of success nor likely to command it. As the Scottish army penetrated the western counties, parties of Presbyterians and Royalists rose in different parts of England, and for some time the ascendency of the Independents seemed to be in considerable peril. But before the forces of the enemy could be brought together, Cromwell, with 8000 veteran troops, attacked and overthrew Hamilton at Preston, while Fairfax put down the insurgents in Kent and Essex. Hamilton was himself taken prisoner, and very few of his troops ever returned to their own country.

While Cromwell was employed in suppressing this insurrection, and in restoring a friendly government in Scotland, the Presbyterians of the House of Commons, relieved from military intimidation, entered upon a new negotiation with Charles, which was drawing towards what appeared a successful conclusion—though the king secretly designed to deceive them, and to pursue such means for an effectual restoration—when the army returned to London, breathing vengeance against him for this last war, of which they considered him as the author. Finding the Parliament in the act of voting his concessions to be satisfactory, Cromwell sent two regiments under Colonel Pride, who forcibly excluded from it about two hundred members of the Presbyterian party; a transaction remembered by the epithet of *Pride's Purge*. The remainder, being chiefly Independents, were ready to give a colour of law to whatever further measure might be dictated by the military leaders. Convinced of the utter faithlessness of the king, and that, if he continued to live, he would take the earliest opportunity of revenging himself for what had already been done, Cromwell and his associates resolved to put him to death. A High Court of Justice, as it was called, was appointed by ordinance, consisting of a hundred and thirty-three persons, named indifferently from the Parliament, the army, and such of the citizens as were known to be well affected to the Independent party. This body sat down in Westminster Hall (January 20, 1649), under the presidency of a barrister named Bradshaw, while another named Coke acted as solicitor for the people of England. Charles, who had been removed to St. James's Palace, was brought before this court, and accused of having waged and renewed war upon his people, and of having attempted to establish tyranny in place of the limited regal power with which he had been intrusted. He denied the authority of the court, and protested against the whole of the proceedings, but was nevertheless found guilty and condemned to die. On the 30th of January, he was accordingly beheaded in front of his palace of Whitehall. The people were in general horror-struck at this event; but they were too effectually kept in check by the army to have any influence in preventing it.
