Technical and Bibliographic Notes/Notes techniques et bibliographiques

The Institute has attempted to obtain the best original copy available for filming. Features of this copy which may be bibliographically unique, which may alter any of the images in the reproduction, or which may significantly change the usual method of filming, are checked below.

L'Institut a microfilmé le meilleur exemplaire qu'il lui a été possible de se procurer. Les détails de cet exemplaire qui sont peut-être uniques du point de vue bibliographique, qui peuvent modifier une image reproduite, ou qui peuvent exiger une modification dans la méthode normale de filmage sont indiqués ci-dessous.

- ☐ Coloured covers/ Couverture de couleur
- ☐ Covers damaged/ Couverture endommagée
- ☐ Covers restored and/or laminated/ Couverture restaurée et/ou pelliculée
- ☐ Cover title missing/ Le titre de couverture manque
- ☐ Coloured maps/ Cartes géographiques en couleur
- ☐ Coloured ink (i.e. other than blue or black)/ Encre de couleur (i.e. autre que bleue ou noire)
- ☐ Coloured plates and/or illustrations/ Planches et/ou illustrations en couleur
- ☐ Bound with other material/ Relié avec d'autres documents
- ☑ Tight binding may cause shadows or distortion along interior margin/ La reliure serrée peut causer de l'ombre ou de la distortion le long de la marge intérieure
- ☐ Blank leaves added during restoration may appear within the text. Whenever possible, these have been omitted from filming/ Il se peut que certaines pages blanches ajoutées lors d'une restauration apparaissent dans le texte, mais, lorsque cela était possible, ces pages n'ont pas été filmées.

- ☐ Coloured pages/ Pages de couleur
- ☐ Pages damaged/ Pages endommagées
- ☐ Pages restored and/or laminated/ Pages restaurées et/ou pelliculées
- ☑ Pages discoloured, stained or foxed/ Pages décolorées, tachetées ou piquées
- ☐ Pages detached/ Pages détachées
- ☑ Showthrough/ Transparence
- ☐ Quality of print varies/ Qualité inégale de l'impression
- ☐ Includes supplementary material/ Comprend du matériel supplémentaire
- ☐ Only edition available/ Seule édition disponible
- ☐ Pages wholly or partially obscured by errata slips, tissues, etc., have been refilmed to ensure the best possible image/ Les pages totalement ou partiellement obscurcies par un feuillet d'errata, une pelure, etc., ont été filmées à nouveau de façon à obtenir la meilleure image possible.

☑ Additional comments:/ Commentaires supplémentaires: Pagination as follows : [2], [7] - 847 p.

This item is filmed at the reduction ratio checked below/

CHAMBERS'S

INFORMATION FOR THE PEOPLE.

HEATING, VENTILATION, LIGHTING.

Upon judicious means of heating, ventilating, and lighting apartments, manufactories, and several classes of public buildings, very important consequences depend, including not only the ordinary comfort, but the health of human beings. We propose here to treat the three subjects (with the addition of the kindred use of smoke-consumption) in one paper, but to confine our attention chiefly to plans involving scientific principle, as well as ingenious mechanical contrivance.

HEATING

It is scarcely necessary to remark, that the mode of heating apartments most prevalent is by a fire of coal placed in a grate, having a chimney above, through which the vaporized products of the fuel are carried off. Of one class of results from this mode there can be no doubt. The fire, sparkling or glowing in its appropriate receptacle, has an air of cheerfulness and comfort which strikes every beholder, causing the domestic group to cluster around it with that feeling of satisfaction which makes an Englishman regard his fireside as among the most precious things connected with his existence. But while the common open fire is almost an object of worship among us on account of its pleasant look and power of concentrating the whole family in one social circle, it is not unattended with certain drawbacks, difficulties, and disadvantages; nor can it be applied well in any place besides an ordinary apartment. The greatest drawback is the uneconomical use which it makes of fuel. About one-half of the heat produced by a common fire ascends with the smoke. The smoke itself is an unconsumed part of the fuel. Finally, about a fourth of the heat which is radiated into the apartment is, in ordinary circumstances, carried into the chimney between the fire and the mantel-piece, and thus lost. It is calculated by Dr. Arnott that only about one-eighth part of the heat-producing power of the fuel used in common fires is realized, all the rest being dissipated into the surrounding atmosphere. Count Rumford gave even a more unfavourable calculation, making the dissipated or lost part to be no less than fourteen-fifteenths. He probably over-estimated the loss considerably; but that a very large portion of the power of fuel is forfeited in the use of common chimneys, is just as certain as it is that an open fire is an object which every eye delights to rest upon. Dr. Arnott's estimate is probably not much, if at all, above the truth. It is also unquestionable that often a common fire is found to give a partial kind of warmth, heating the side of our persons next to it, but leaving the rest cold; that it also produces draughts into our rooms which are any thing but safe or agreeable; that often one active fire deranges the action of the chimneys of other fires, and fills the house with smoke; that smoke and dust are annoyances more or less inseparable from it in all its shapes; and that it is by no means a mode of heating free from danger to both property and person. These are disadvantages of which every one is aware; and although they are not sufficient to extinguish the pleasure which we take in our sea-coal fires, they may certainly be allowed to furnish reason for inquiring if, by any modification of present plans, fuel could be applied more economically, and at the same time agreeably. There is also, we must recollect, the necessity for modes of heating applicable to public buildings, where the common fire is of little service.

WARMING BY HIGHLY HEATED SURFACES.

One of the first attempts to arrive at a mode of warming more economical than the common fire, and applicable to large buildings, suggested the raising of plates of iron to a high temperature, and causing air to pass over them on its way to supply the rooms or halls where it was required. In some part of the building a furnace was employed to heat the plates, which were of cast iron, and the air, after passing over them, was sent forward through a tunnel, and ushered into the hall or other place required to be heated, either through a grated aperture in the floor, or by pipes distributed round the walls or galleries. This mode was introduced into many churches in the early part of the present century, and it was fully tried in the London Custom-house. In the latter building there are several large rooms, in which a great number of clerks and other officers are assembled for business. Into one, called the Examiners' Room, the air rushed at a temperature of 170 degrees, to be reduced to a more moderate heat by its mixing with the air already in the apartment. In another called the Long Room, the air entered at a temperature varying from 90 to 170 degrees, being liable to be reduced by a regulated admission of cold air into the apartment from without. It is not easy to excuse the ignorance which dictated this mode of heating. When air passes over plates raised to red heat, as these were, it is desiccated, or deprived of its natural mu-

midity; animal and other matters floating in it are decomposed, it is charged with sulphurous fumes from the iron; and lastly, by the drying or desiccation, it is thrown into a state highly electric. The condition of the air is then nearly the same with that which African travellers recognised with terror under the name of the simoom. The consequence in the Custom-house was a general falling off in the health of the officers, which became at length so alarming, that that mode of warming the apartments had to be given up.

The mode of warming by highly-heated surfaces is now generally condemned on account of its deleterious effects on the air; but it is still in practice to some extent, and we have therefore thought ourselves called upon to introduce a brief description of it, in order to have an opportunity of explaining its unsuitableness, and warning against its use. It may be safely set down as a first principle in the science of heating, that no mode which materially alters the chemical character of the air can be compatible with health. Common stoves are liable to this objection in greater or less measure, and are therefore rarely used excepting in lobbies.

WARMING BY MODERATELY HEATED SURFACES.

The objections to the above mode of heating would obviously be in a great measure overcome, if, instead of a small surface highly heated, a large one moderately heated were used. This may be done in various ways, as—1. By a furnace operating upon the heat-giving surface; 2. By steam in tubes; or 3. By hot water also in tubes.

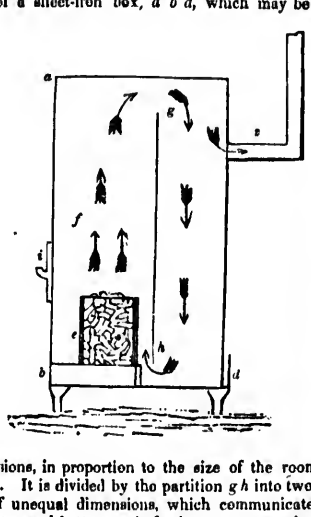
Surfaces Heated by Internal Furnaces—Strutt's and Arnott's Stoves.

The first attempt of which we are aware to give warmth by hot air from large moderately heated surfaces, was made by Mr. William Strutt, of Derby, in 1792. The cotton-mill of the copartnery to which he belonged was in that year fitted up with a stove constructed upon this principle; and the same plan, after being tried in his own house and those of his friends, was introduced, with all the improvements of which it was deemed capable, into the Derby Infirmary in 1807. It has since been copied in various public and private buildings.

Shortly, and dismissing unimportant details, the Strutt-stove consists of a *cockle*, or plate-iron box, of about two feet in height by one in breadth of sides, inverted with the open mouth downwards over a small close furnace, which heats it about 280 degrees. Another somewhat larger box surmounts this, leaving the space of an inch or so between. This outer box is perforated with numerous holes, into which short open tubes are fitted, projecting outwards. This apparatus being constructed in a small close room, a channel or culvert of considerable width is made to communicate between that room and the open air on the outside of the house. On the fire being kindled in the furnace, the cockle is heated to the desired height, and no more, a control being exercised over the fire by a valve for communicating air to the furnace. The air immediately without the cockle is warmed, and, by virtue of its increased temperature, begins to ascend. To replace it, fresh air is drawn in through the culvert, and through the numerous tubular apertures of the outer case, and made to rush against the heated vessel within. This air is accordingly heated too, and pursues the same line of ascent. Thus there is a constant flow of moderately heated air upwards. This may either be allowed to pass into an open hall, staircase, or any other single space which it is desired to warm, or it may be carried along in flues and distributed into different rooms. It will be observed that the instrument or medium for warmth in this case is a stream of heated air: the temperature desired for it is about 64 degrees, and it is kept at this low point by the spaciousness of the culvert. In the house of Sir John Robinson, Randolph Crescent, Edinburgh, fitted up on this plan, there are two culverts giving a total area of fourteen square feet. The constant rushing of so large a volume of air into the house implies a necessity for some flues or apertures to carry it off after it has served its purposes. The collective areas of these flues or apertures ought to be the same as those of the cold air passages or culverts. In the stove used in the Derby Infirmary, it was found that one pound of coal raised 20,000 pounds of air through one degree of temperature.*

The Arnott stove is upon the same principle of an extensive and moderately warm heating surface, but it has as yet been only constructed in a portable form. Dr. Arnott was gradually led to the adoption of this mode of warming. He had got a large box of hot water fitted up in his study, which gave the requisite temperature; but the hot water being supplied by a pipe from the kitchen fire below, some inconveniences were experienced, which suggested to him the fitting up of what has been called a water-clad stove, namely, an ordinary room stove, surrounded by a close outer case containing water, which the fire within maintained at boiling heat. From this it was but a step to the adoption of a similar large case, to be maintained at about the temperature of boiling water by a small and regulated fire within. Such is the Arnott stove.

The learned inventor has described several modifications of his stove,† and it has been copied in many various ways, generally with little regard to the original principle. We shall select for description one simple form, which seems to have been the first exemplified by Dr Arnott, and in which the fundamental principle seems to be as well brought out as in any other. This stove consists of a sheet-iron box, *a b d*, which may be of any



dimensions, in proportion to the size of the room to be heated. It is divided by the partition *g h* into two chambers of unequal dimensions, which communicate freely at the top and bottom. A fire-box, *e*, composed of iron lined with fire-brick, rests at the bottom of the larger chamber. Access is obtained to it, for the purpose of supplying fuel, by the door *i*, which must fit closely. The refuse of the fire falls into an ash-pit, the door of which is at *b*. Here, also, is a valve for the supply of air to the fire-box. The fumes and heat of the fire pass in the direction indicated by the arrows, giving warmth to the outer case. The smoke finally passes off, by the

* Sylvester's Philosophy of Domestic Economy, &c., 1819.

† Dr. Arnott on Warming and Ventilating, 1838.

flue *c*, into an adjoining chimney. The aim of the inventor was to heat an extensive surface to about 200 degrees Fahrenheit, so as to diffuse a moderate warmth into a room. He attains the power of keeping the heat at this height by the valve for admitting air. When this is opened widely, a large stream of air enters, and combustion becomes active. When, on the contrary, the aperture is reduced, a comparatively small stream is admitted, and combustion languishes. The temperature of the outer case is raised or depressed accordingly. By the revolution of the heat and smoke round the division of chambers, their power of giving forth warmth is expended as far as possible on the plates of the outer case, so as to be serviceable for the end in view; and it might be possible to exhaust the whole for that end by lengthening the flue, or causing a great extent of it to pass through the air of the room before entering the chimney. The Arnott stove certainly makes the most economical use of fuel of any species of contrivance for producing artificial heat as yet known. Six pounds of Welsh coal or coke, of the value of one penny, will serve an ordinary one for a whole day.

The Arnott stove is capable of something nearly approaching to self-regulation. When it was invented, about 1834, there was in existence a well-known means of adjusting the temperature of bakers' ovens by a self-acting thermometer. Though an old expedient, some person had recently secured a patent upon it, and Dr. Arnott was therefore unable to take advantage of it for his stove. There are, however, many modes of producing the same curious mechanical results, and a few of these he specifies. That which he has employed in the stoves made under his own care, consists of a glass tube inserted horizontally into the upper part of the heated chamber of his stove, with a downward bend on the out side. Mercury is put into the bend of this tube, leaving the part which is within the stove empty of all but common air. This air, of course, expands in proportion to the heat of the stove, and in doing so presses upon the mercury in that part of the outer bend next to it. The mercury in the other part of the bent tube accordingly rises. A float on its surface is thus raised. Connected with the float is a wire, which acts upon a valve at the door of the fire-box, causing it to open and shut according as the float falls or rises. By such simple means, the least increase of heat within immediately and unavoidably brings about a diminution of the supply of air to the fire, which therefore instantly begins to burn less intensely. So, also, any decrease of heat instantly produces a larger supply of air, by which the fire is, as it were, *poked*, and begins to burn more brightly. The cooling from a fresh supply of coke must of course cause that increased supply of oxygen which is necessary to make the new materials glow; and the new and great heat thus brought about must immediately check itself by the closing of the valve. It is also obvious, that when the materials are nearly burnt down, and the supply of air thus increased, the only consequence is, that the air rushes in as long as there is any thing to burn, and no longer.

The express advantages of the thermometer stove are enumerated by the learned inventor under fourteen heads, which we shall abridge. 1. Economy of fuel. While in the case of a common open fire, seven-eighths of the heat goes up the chimney, nearly the whole heat is secured by the stove. A gentleman known to us saw Dr. Arnott put a few leaves of a pamphlet into his fire-box, the ignition of which immediately heated the whole stove, and diffused an agreeable warmth throughout the room. An ordinary room can be kept warm by the stove for twenty-four hours, at the expense of one penny in coke or anthracite. 2. The temperature diffused by the stove is uniform throughout the room. 3. The stove is always alight, to the saving of much of that inconvenience and loss of time occasioned by the going out and kindling of ordinary fires. 4. No smoke, of the character of the smoke of a common fire, arises from the stove, but only a slight stream of volatile gases. 5. No dust is diffused throughout the room. 6. The dangers to which children, old people, and others, are exposed from a common fire, are obviated. 7. The danger to property is as little as the danger to persons. 8. The stove is obedient to command, and could be managed by a child. 9. It can be established at little expense. 10. It saves all expense for attendance. 11. It is easily moved. 12. It may be fashioned into any graceful or convenient form, so as to ornament a room. Dr. Arnott mentions that it may be in the form of a statue. 13. A drawer inserted into the heated chamber of the stove would serve for cooking meat, and a pot for boiling might be placed upon the fire-box; it is therefore, as Dr. Arnott remarks, peculiarly the *poor man's* stove. 14. No sweeping-boys are required.

Under a sense of professional honour, Dr. Arnott did not take out a patent for his stove. Regarding it as an invention for the improvement of health, he presented it to the world, as he had previously done his hydrostatic bed. It was therefore made by many furnishing ironmongers in the metropolis and elsewhere, some of whom took out patents for what they considered as improvements upon it. Though the intention of the inventor was good, his liberality has had a bad result. The principle, simple as it appears, was not well understood. The stoves made by all, except a very few ironmongers, were constructed erroneously, the prevalent fault being a diminution of the heating surface in proportion to the strength of the furnace. It is a curious fact in science, well worthy of being noticed, that twelve patents were taken out in one year for modifications of the Arnott stove, *all of which Dr. Arnott considered to be upon false principles.* The consequence has been, that many Arnott stoves, which had been introduced into houses with a good hope of their acting beneficially, have been given up on account of the inconvenience felt from the species of heat which they generated. It is also, however, to be observed that the stove, made even upon the most approved principles, would require certain adjuncts and conditions in order to operate agreeably.

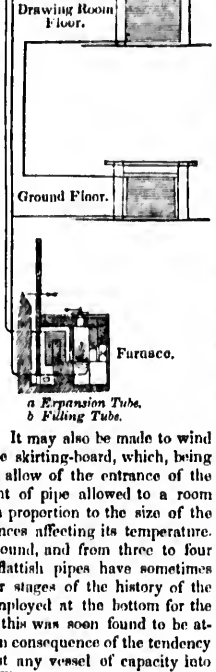
All metal surfaces, however well the principle of a large superficies moderately warmed may be observed, raise the temperature by two means, namely, by radiation and by conduction. Radiated heat, which is that given by a common fire, is perfectly safe; but the heat produced by the air coming in contact with a warmed surface is more or less deteriorated. The air, which forms the instrument or medium for heating the rest, has been altered in its character, particularly in being desiccated, or deprived of its humidity. It is necessary to counteract this result by an artificial infusion of humidity into the atmosphere. This may be done in various ways. The most common plan is to place a large open dish of water upon the stove; but in this case the evaporation does not proceed rapidly enough. It is better to keep a large wet cloth hanging near the stove. Perhaps the best possible arrangement is that consisting in a trough of water, with a roller moving in it, and a similar roller forming a windlass about two feet above. Between the windlass and the roller an endless piece of towelling revolves. The bottom of the piece of towelling passing, of course, through the water, it is only necessary to turn the windlass a few times in order to make the whole wet; and this process may be repeated as often as necessary. The vapour constantly arising from the cloth will, if sufficient in quantity, make good the want of humidity in the stove-heated air. Such an arrangement is necessary, not only in connection with the Arnott stove, but with Mr. Strutt's contrivances, and with all the modes of heating by warmed metal surfaces. We shall consider some further arrangements which such modes of

heating render necessary, under the head VENTILATION.

Hot-Water and Steam Apparatus.

In the hot-water and steam apparatus, the immediate agent for heating is the same as in the Strutt and Arnott stoves, namely, an extensive metallic surface moderately heated. But the heating is in these cases effected by hot water and by steam respectively, and the arrangement and character of the warm surfaces are different.

The idea of warming rooms by pipes filled with hot water occurred to the Marquis de Chabannes, who first exemplified it in his own house in England. The plan has latterly been patented, and extensively acted upon by the ingenious copartnery of Perkins and Heath, London. It proceeds upon a simple law of heat, that particles of any fluid warmed above the temperature of those surrounding them, ascend. Thus, in a kettle of water upon a fire, the particles at the bottom are heated first, and immediately ascend to the surface, their place being instantly taken by cool particles from above, which again in like manner ascend as soon as heated; so that there is a constant flow of cool particles downward and warmed particles upward, until the whole are heated. The hot-water heating apparatus consists of a stout metal pipe, pervading the house in all the parts which are desired to be heated, having a valve at the top, and a coil at the bottom exposed to a furnace. This tube being filled with water from the top, and the fire being kindled in the furnace, warm particles begin to ascend, and are quickly felt at the very highest part of the pipe. The water heats gradually from the top downward, until the whole is warm. The pipe then gives off heat to the surrounding atmosphere. Such is the principle. The arrangement of the pipe may be various: the plan generally followed is to place a considerable coil of it within a pedestal or bunker, with open trellis work in front, in a convenient part of the room. It may also be made to wind round the room, behind the skirting-board, which, being perforated with holes, will allow of the entrance of the warmed air. The amount of pipe allowed to a room ought of course to bear a proportion to the size of the room, and other circumstances affecting its temperature. The pipes are generally round, and from three to four inches in diameter; but flattish pipes have sometimes been used. In the earlier stages of the history of the apparatus, a boiler was employed at the bottom for the heating of the water; but this was soon found to be attended with great danger, in consequence of the tendency of water in a tube to burst any vessel of capacity into which it may descend. The substitution of a coil of pipe was an improvement suggested by Mr. A. M. Perkins. At the top of the apparatus, the pipe expands into what is called the expansion tube, which is left empty, to save the risk of bursting by the expansion of the water. Fifteen per cent. of space is found by experience to be an ample allowance for the expansibility of the water. A compendious and readily understood specimen of the apparatus, calculated for a house of three stories, is presented in the accompanying engraving. It is important to observe that the pipe, while operating, is closed in every part, the air having been previously pumped out of it. The heat usually maintained is 180 degrees; but it can be increased to 400 degrees, where such is necessary, as it is, for example, in certain drying houses.



a Expansion Tube.
b Filling Tube.

The hot-water apparatus has been fitted up by Messrs. Perkins and Heath in various public buildings, warehouses, and gentlemen's houses;* and, while sufficiently effective for the desired end, it has been proved to be attended with as few drawbacks as any regulated mode of heating whatever. But there is a great obstacle to its general adoption in its expensiveness. If this difficulty were not insuperable, the plan, from the natural principles on which it is founded, could be applied very easily to several buildings at once, or even to a considerable part of a town—if not, indeed, to an entire city. From some central establishment, on a low level, where the heat was applied, there might proceed pipes to the various houses, in the same manner as the pipes from a gas-work. There would of course be a waste of heat in all those parts of the pipe which passed through streets and between one house and another; but this might be amply compensated by other economical features in the arrangement.†

There is a variation of the hot-water apparatus, in which it is made to take much of the form of Mr. Strutt's plan, a large coil of pipe in one hot-air chamber being the means of supplying warmed air to be distributed over the building. It has been exemplified at Coleshill, the mansion of the Earl of Radnor in Berkshire. The plan, in its ordinary form, has been applied also to vineries, conservatories, and forcing-houses, to which it must be considered as undeniably appropriate, if there be no objection on the score of expense.

Heating by steam-pipes is the only mode which remains to be considered. It was suggested nearly a century ago in the "Philosophical Transactions," but was not for many years after reduced to practice. At length it began to be introduced into factories, where a great facility existed for its operation in the boilers connected with the steam-engines. As respects its power of heating, and effect upon the surrounding air, it is identical with the plan last described, excepting only that the surface of the pipes in this case can never be at a higher temperature than 212 degrees. The size of the pipes and other arrangements are considerably different. The following is an account of the apparatus fitted up on this plan in the printing-office from which the present work is issued:—"An iron tube, on which there is a crane, carries the steam from the boiler to a connected series of long tin pipes within the building. The diameter of these tin pipes is about ten inches, and they hang from the ceiling by means of small chains a few inches in length, so as to be quite clear of every article of furniture, and every head passing beneath. There is just one pipe going along each of the two lower stories in this manner; and from each a small waste pipe goes outside to let off the waste steam and condensed water. The pipes are varnished black, to cause the heat to radiate freely from them. The whole apparatus is exceedingly simple, and is managed with perfect ease. The

* The British Museum in London, and the Register House and Justiciary Court Room in Edinburgh, are warmed upon this plan.

† A minute account of the hot-water plan is given in C. J. Richardson's "Popular Treatise on the Warming and Ventilation of Buildings." 1839.

smallest turn of the crane permits the steam to rush through, and to fill the pipes, when an immediate radiation of heat commences. So effectual is the process, that if the steam be admitted only twice a day, for an hour at a time, the premises are kept in a state of the most agreeable warmth for the whole day. There can be no proper comparison betwixt this plan of heating and that of common fireplaces. Coal fires cannot warm the air in large workshops; they only heat the air in their own immediate neighbourhood; and hence the workmen are often obliged to draw near the grate to warm themselves. According to the plan we have adopted, every part of the house is equally heated, and the whole of the workmen are as comfortable during the hardest frosts as if they were working in a pleasant summer day. In consequence of this abundant warmth, all the fires have been withdrawn. It is difficult for us to say what is the probable expense of supplying the heat, seeing that we happen to draw our steam from a boiler which is always in operation for other purposes. We believe, however, that the expense of keeping up a necessary supply of steam for such an apparatus must be very small, perhaps not more than that for a single coal fire. Our apparatus cost about £80, and this sum will doubtless be saved in the course of a few winters. A similar plan of steam-heating by means of cast-iron pipes is pursued in many places, but we approve most of tubes of sheet tin soldered together. Tin is light and cheap, and allows the heat at once to operate, and, in case of explosion from improper management, will rupture or give way without causing any mischief; whereas iron is heavy and dear, takes long to heat, and in exploding would perhaps cause some injury. Excellent, however, as is the process which we have mentioned, we do not believe that it is calculated for private dwelling-houses. In the first place, few domestic servants can be trusted with the management of any apparatus of this description, and this forms an almost insurmountable obstacle to the general introduction of the process. Secondly, the pipes are clumsy, and therefore unsuitable for passing through elegant apartments; and, thirdly, there is at times a noise of the rushing of the steam in the pipes, which would be quite insufferable in a private residence."*

"To determine," says Dr. Arnott, "the extent of surface of steam-pipe or vessel necessary to warm particular apartments, it is to be considered that the loss of heat from them occurs in three ways—1st, rapidly through the thin glass of the windows; 2dly, more slowly through the thick substance of the walls, floor, and ceiling; and, 3dly, in combination with the air which escapes at the joinings of the windows and doors, or at other openings purposely made for ventilation. Different writers and manufacturers have made very different estimates of the quantities of heat lost in these various ways, and as yet no exposition of the matters has been made with the accuracy which the subject deserves; but an intermediate estimate, as applied to common cases, may be shortly stated thus:—that in a winter day, with the external temperature at 10 degrees below freezing, to maintain, in an ordinary apartment, the agreeable and healthful temperature of 60 degrees, there must be of surface of steam-pipe, or other steam vessel, heated to 200 degrees (which is the average surface temperature of vessels filled with steam of 212 degrees), about one foot square for every six feet of single glass window, of usual thickness; as much for every 120 feet of wall, roof, and ceiling, of ordinary material and thickness; and as much for every six cubic feet of hot air escaping per minute as ventilation, and replaced by cold air. A window with the usual accuracy of fitting, is held to allow about eight feet of air to pass by it in a minute, and there should be for ventilation at least three feet of air a minute for each person in the room. According to this view, the quantity of steam-pipe or vessel needed, under the temperatures supposed, for a room sixteen feet square by twelve feet high, with two windows, each seven feet by three, and with ventilation by them, or otherwise, at the rate of sixteen cubic feet per minute, would be—

For 42 square feet of glass (requiring one foot for 6),	7
" 1248 feet of wall, floor, and ceiling (requiring 1 foot for 120)	10½
" 16 feet per minute, ventilation (requiring 1 foot for 6)	2½
Total of heating surface required,	20

which is, twenty feet of pipe four inches in diameter, or any other vessel having the same extent of surface—as a box two feet high, with square top and bottom of about eighteen inches. It may be noticed that nearly the same quantity of heated surface would suffice for a larger room, provided the quantity of window-glass, and of the ventilation, were not greater; for the extent of wall, owing to its low conducting quality, produces comparatively little effect."

* Chambers's Edinburgh Journal, p. 319

VENTILATION.

In our article on the PRESERVATION OF HEALTH, the necessity of a constant supply of fresh air for that object is so fully explained, and so earnestly insisted on, that on this occasion little more than an allusion to the subject is required. Each human being consumes the oxygen of the sixth of a cubic foot per minute, replacing it from his lungs by carbonic acid gas, a substance which cannot be inhaled again without injury. Hence the necessity for a constant change of the atmospheric contents of any room in which human beings are placed—and the same law holds with regard to all the warm-blooded animals. In an ordinary apartment, heated by a common open fire, there is an imperfect kind of ventilation always going on by means of the fire, which draws in through the door, windows, and other apertures, fresh air to supply that consumed by itself, or which the chimney-draught otherwise carries off. This is imperfect, in as far as the draught may only clear a certain space near the bottom of the room between the door or windows and the fireplace, and because it may over rarely the air of the room in instances where the apertures are unusually well closed up—also, in as far as it only operates when there is a fire, and therefore not in the summer time. It therefore becomes desirable that a regulated mode of ventilation, calculated to be thoroughly and at all times effectual, should be applied to ordinary apartments. It is not less necessary that churches, court-rooms, theatres, and all large rooms in which great numbers of persons assemble, should be subjected to a mode of ventilation, regular, certain, and complete. Nor is it unworthy of notice, that a regular means of ventilation is also required in stables, cow-houses, and other places where valuable animals are kept.

VENTILATION BY APERTURES IN CEILINGS AND FLUES IN WALLS.

The simplest and perhaps the earliest expedient for ventilation, was one formerly much employed in churches and other places of assembly. It consisted merely in a round hole of considerable size opened in the ceiling, and communicating with the outer air by a tube or trunk, having a cap over the top to keep out rain. The expired air of the assemblage, by virtue of its greater rarity, of course ascends to the ceiling, and tends to find its way out by this aperture; but it does not pass forth either rapidly or with certainty, and the plan is therefore to be considered as defective.

The plan adopted for carrying off used air in the Derby Infirmary, and other buildings warmed by Mr

Strutt's plan, appears strikingly inferior in efficiency to the expedients for heating. The whole arrangement consisted in a flue from each room, terminating in the space under the roof, through which was a passage to the outer air, protected by a turn-cap. There cannot be, we apprehend, any certainty that such flues will act for the removal of used air.

Sir John Robinson of Edinburgh has exemplified Mr. Strutt's plans in his house in Randolph Crescent, with an ingenious improvement upon the ventilation flues. Having small fires in each room—for the purpose, mainly, of drawing the warmed air from its reservoir, the well of the staircase, into each apartment—he passes the ventilation flues close beside the ordinary smoke chimneys. The consequence is, that the heat of the smoke chimney is imparted to the ventilation flue, an upward current is established, and ventilation proceeds with certainty. This is a mode of ventilation which may be advantageously adopted in new houses, but could not easily be applied to those already built. In Sir John Robinson's house, the air of each apartment reaches the ventilation flue through a slit masked by the stucco-work upon the ceiling.

In many cases, it may be found expedient to adopt a simple mode of ventilation which was suggested by Dr. Arnott, and applied in Buckingham Palace. An aperture of from four to six inches is cut in the wall over the chimney, as near to the ceiling of the apartment as may be convenient. Into this is fitted a short metal tube, having a valve suspended at the extremity next to the apartment, and capable of opening inward to the chimney, but not in the other direction, by which means a return of smoke is prevented. This simple apparatus may be painted, or otherwise made ornamental. It operates by virtue of the draught in the chimney. Whenever that is active from the presence of a fire, the valve is seen to open inwards, and a stream of air from the top of the apartment passes through into the chimney, and is carried off. The operation is precisely equivalent to the stream of air always passing into a chimney between the fire and the mantel-piece, but has the great superiority of draining off the most impure air in the room.

THE VENTILATING FAN AND PUMP.

This is a piece of mechanism which has for many years been used in factories, to which it is particularly applicable from the readiness with which a mechanic power to keep it in motion can be obtained from the steam-engine. It is placed at the top of a flue, into which branches from all parts of the establishment proceed. Consisting simply of what its name imports, it only requires to be set in motion in order to draw off the air from every apartment communicating with it. Dr. Ure calculates that a steam-engine of one horse power will drive a fan which has equal effect with a draught produced by fuel equal to twenty horse power; in other terms, the economy of ventilation is to that by chimney-draught as 38 to 1.* Of its efficacy there seems no room for doubt; but as yet there has been scarcely any attempt to show how it can be conveniently applied elsewhere than in factories. Dr. Arnott has shown pretty clearly that it has heretofore been used in a very uneconomical way, in consequence of ignorance. A far greater power has been in most cases applied than was strictly necessary, its constructors not being aware that air, like other fluids, cannot be forced more quickly through one part of a passage than it enters by another, without a super-expenditure of force. Under judicious arrangements, Dr. Arnott thinks that fans which have required steam-engines to drive them, might be made to operate by a weight no greater than that required for a large clock. He seems, however, to prefer to the fan a valved piston moving like a pump in a square or round trunk. "Such a pump," says he, "answers not only for extracting foul air, but also for forcing in pure air where wanted. It may," he adds, "be fixed in position, or may be a movable piece of furniture; to be used, for instance, to draw out air from the top of a window opened on a ball night, or from an opening in the wall concealed from view by a picture frame. By such a pump, air of perfect purity, and in any quantity, may easily be sent from any neighbouring situation, as from the top of a lofty tower, to supply a dwelling placed where unwholesome exhalations might enter by the doors and windows.

* Architectural Magazine.

FIRE-DRAUGHT.

One of the most certain and effectual of all means of ventilation is that by fire-draught. It proceeds upon the simple principle that combustion demands a constant supply of air: a fire being placed in a certain convenient situation, and closed up from all supply of air excepting through flues communicating with the rooms to be ventilated, a flow of air out of those rooms is necessarily established, and this will proceed as long as the fire is kept burning. The plan has been exemplified with success in mines, where, a fire being lighted at the bottom of a shaft, air is drawn off in all directions around and sent up the shaft; to replace which, fresh air is constantly pouring down other shafts. There is one objection to fire-draught ventilation, that, in most circumstances, it requires both attention and considerable expense; but this might perhaps be overcome by a little ingenuity. There can at least be no doubt that, where established, it most completely answers the end in view, while it is equally true that in some situations there are means of arranging it in such a way as to require neither attention nor expense.

The plan has been exemplified during the last few years by Dr. D. B. Reid, first in his class-rooms in Edinburgh, afterwards in the temporary House of Commons, and since then in various other structures, public and private. We shall endeavour to give an account of Dr. Reid's arrangements in the House of Commons, but deem it necessary first to advert to the plans of Mr. Joseph Fleming of Glasgow. Mr. Fleming originally contemplated ventilation in immediate connection with the objects of his profession (medicine), and in 1833 published a pamphlet on what he called a Disinfecting Apparatus, which he proposed to apply in hospitals and in beds for the sick generally. It consisted simply in tubes communicating between the top or back of the beds and a fire solely supported by air through those channels, so that any infectious virus arising from the patient's body was in every case carried off without coming in contact with those who stood near.

The plan was first tried in a large and densely peopled house which had long been remarkable as a focus of fever infection, in consequence of the wretchedness and filth of the inhabitants, and the narrow space allotted to them. This building, usually called from its size and appearance *the Barracks*, was connected with the factory of Messrs. Houldsworth and Son in Anderston, a suburb of Glasgow. It was divided into a multitude of small apartments, each consisting of a single room and closet, and each devoted to the accommodation of a single family. The total amount of inhabitants is rarely under 500. We have inspected this building, and can testify that the habits of the occupants, with a few exceptions, are of that uncleanly and ill-ordered character which naturally results from a mode of life in which housewifely economy is not a part of female education. Many of the inhabitants, it may be added, are Irish. The huddling of so many human beings into such small space, joined to filth, poverty, and intemperate habits, rendered the building, up to 1832, the permanent abode of pestilential disease. Five have been seen ill with

fever in one room. In the two last months of 1831, the total cases of typhus were 57. It was then that Mr. Fleming was allowed by the proprietor to apply his ventilating process. From an upper corner of each of the apartments, he led a metal tube of about an inch and a half in diameter, which, passing into the adjacent gallery, there met and joined a general pipe, nine inches in diameter, suspended immediately under the ceiling. One of these general pipes passed along each gallery in the four stories, and the whole joined in one vertical tube at the end of the house, communicating at the bottom with the base of an adjacent chimney-stalk serving the work. It follows that, when this flue is active—and practically it is so day and night—a draught is established upon the air contents of every room in the house. To regulate this draught according to necessity, a valve or damper is placed in the short horizontal channel of communication between the vertical tube and the basis of the flue. In ordinary circumstances, when the door of one of the rooms is shut, the rush of air into the aperture of the tube is sufficient to extinguish a candle held near. It becomes quite clear to any one inspecting the process, that, while the chimney is active and the aperture kept open, there must be a complete exchange of air in each room in no long space of time. It may be remarked, that no expedient has been adopted to obviate the chance of an over-rarefaction of the air-contents of the rooms. The melancholy truth is, that the doors and windows are by no means deficient in the means of admitting a full supply of fresh air. At the same time, it is to be observed that few of the tenants complain of cold as a result of the ventilation. Some have attempted to stuff up the apertures of the tubes, under an impression that too much cold air was brought in upon them; but these cases are rare, and the attempt has always been checked.

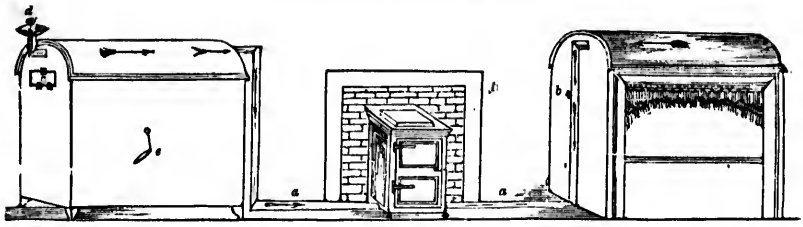
Since 1832, when this apparatus was fitted up, Glasgow has suffered more from fever than any other city in the empire in proportion. During the five years ending with 1839 there were 55,949 cases. It may well be presumed from the ordinary conditions of the Anderston house, and its previous history, that it should have had its full proportion of fever cases during that period, which would have been about 112 (taking the population of the city at 240,000). But so far from this being the case, there were only four instances of fever in the house from the beginning of 1832 till December, 1840, laying aside one year during which it was not under Mr. Fleming's charge, when there were a few more. Early in 1841, there were eight cases; but most of these, as of the previous cases, were ascertained to have been brought in from without. Since then, the house has remained free of fever. It is impossible to doubt that the change from extreme unhealthiness to the reverse is mainly owing to the ventilating apparatus—for no other condition has been changed. On this subject we have been favoured with the opinion of the proprietors, Messrs. Houldsworth and Sons. They say (March, 1841)—"Previous to the introduction of this improvement, fever was almost continually in the Barracks, and the annual number of cases ranged about fifty; during the last eight years, only a few cases have occurred, and all these, we believe, can be traced to individuals coming into the Barracks having the fever upon them at the time. We cannot expect, however, that our houses will always be free from fever, so long as a similar mode of ventilation is not generally adopted in the neighbourhood." It is not unimportant to remark, that the expense of fitting up the apparatus in the Barracks was *under fifty pounds*.

Mr. Fleming has since applied his ventilating apparatus in a steam-vessel. There are no places adapted for the reception of human beings which require ventilation more than ships, for there the space allotted to each individual is necessarily smaller than anywhere else. The sleeping berths, in particular, would be much improved in comfort by a draft being established upon the close, stifling, and often positively fœtid atmosphere which is generally experienced in them. Dr. Reid, a few years ago, showed how easily a ship might be ventilated in all its habitable parts; and in 1840–1, he was employed to exemplify his theory in the vessels destined for the Niger expedition. Since then, Mr. Fleming has been called upon to adapt his ventilating plan to the Princess Royal steamer, a passage vessel between Glasgow and Liverpool. In this case he has led a small tube from the top of each bed into a general pipe passing along under the deck, the extremity of which enters the ash-pit of a common stove. There is thus a draught out of every berth in the ship; and the consequence is a degree of comfort for which every passenger feels thankful. It may be presumed that the ventilation of a ship or steamer would be made still more effectual if fresh air were supplied in some regular manner, instead of being merely drawn in by chinks in the cabin doors. It would be easy to have flues communicating directly between the outer air and a perforated board in front of each bed. It is also obvious that, in steamers, a valved passage into the funnel of the engine would answer the purposes of draught, without the least danger.

In rooms where large numbers of workmen are assembled, a mode of ventilation is obviously of great importance. Not long since, conversing with a man who had once wrought as a journeyman tailor in London, we were informed by him that workmen of his order in that city are obliged to pursue their calling in warm close rooms, in consequence of it being thought by the masters that heat is necessary to the goods making a fair appearance in the eyes of customers. The consequence, said he, is, that working tailors generally break down at forty-five, and the latter part of their lives is often very miserable. Now, it may be true that a high temperature is necessary for the work; but a high temperature is not necessarily connected with defective ventilation. The rooms in which the tailors work might all be supplied with constant streams of fresh air, although Fahrenheit's thermometer should never stand in their apartments below 66 degrees. A liberal-minded copartnery of clothiers in Glasgow, Messrs. Lockhart, have lately had their workroom fitted with a ventilating apparatus by Mr. Fleming, the apertures in this case being distributed over the ceiling, while the means of draught is supplied by the furnace in which the irons are heated. The result in comfort is described by Messrs. Lockhart as very great; we cannot doubt that in health also, the best consequences may be anticipated.

The application of the plan to sources of morbid infection is equally simple. Mr. Fleming has fitted up several specimens of ventilated beds for hospitals or private sick-rooms, and placed them for public inspection in the warehouse of Andrew Liddell and Company, ironmongers, Glasgow. In addition to these, he has prepared a ventilating washing apparatus for the clothes of patients affected by infectious disease. The simplicity of the arrangement, united to its manifest efficiency, must be generally admired. In the accompanying wood-engraving, a stove is represented as placed in front of a common fireplace, having a bed for a patient on one side and a washing machine on the other. Air tubes, *a a*, branch off from the stove, and terminate one in the semicircular roof of the bed, the other in the semicircular top of the washing apparatus. In the washing apparatus there is a plash-wheel, of which *c* is the handle; while *d* is a filler for the admission of air and water, and *e* a door.

Infected clothes being put in by the door *e*, a sufficient quantity of boiling water is poured into the washing box by the filler. The door being now kept shut, the plash-wheel is set in motion, and driven as long as may be thought necessary for disinfecting the clothes. During



this process, the air to support combustion in the stove being supplied through the filler, passes on through the washing box, and carries with it to the fire, as soon as disengaged, all the infectious matter arising from the clothes. In place of boiling water, the clothes might be purified by steam or heated air, and the infectious virus would be carried off and destroyed in the same way. At the end of this disinfecting process, the clothes may be taken out and washed in the usual way, the foul water being previously run off through a tube placed for that purpose in the bottom of the apparatus.

The infectious matter generated by a patient placed within the bed is in like manner carried off and destroyed in the fire. To insure its complete removal, the tube passing along the roof of the bed is perforated by a series of small holes. To regulate the ventilation there is a stop-cock at *b*, which the patient or his attendant may turn at pleasure. To prevent the escape of any infectious matter from the bed, the front only is left open. The opening may be increased or diminished at pleasure by the raising or depressing of the curtain at the top. It is clear that there must be a stream of pure air constantly passing into the bed, and that any one standing immediately in front is as completely exempt from all noxious influences, as far as that patient is concerned, as if he were at many miles' distance.

An experiment on this principle is at length in the course of being made in the Glasgow Fever Hospital, in ward 8th of that establishment, which consists of two patients' apartments, each twenty-four feet square, by twelve in height, and a separate smaller room for the nurse; a stove in the fireplace of the latter is supplied with air solely by a pipe communicating in branches with apertures in the ceilings of the patients' rooms. There is accordingly a draught of air from the top of each of the patients' rooms, and this is so powerful, that on the two rooms being filled with dense smoke from wet straw, they were completely cleared in thirty-five minutes, the aggregate contents of the two being 14,000 cubic feet. It is obvious that the arrangement, although a great improvement upon no-ventilation, will only be complete when there is a particular draught from the top or back of each bed; in which case alone will the medical attendants and others be exempt from the contact of infectious matter. While we are writing the present sheet, the authorities connected with the hospital, satisfied so far with the experiment, are about to extend Mr. Fleming's mode of ventilation to the whole establishment; it is to be hoped that they will not rest content with a tube opening in the ceiling, but extend one to each bed.

A description of the arrangement made by Dr. Reid in the House of Parliament involves the principle of heating, or rather of temperature-regulation, as much as those of ventilation. The present House of Lords is a portion of the old palace of Westminster, which was formerly called the Painted Chamber. The House of Commons is the building which, down to the conflagration in November, 1834, was used as the House of Lords. They are contiguous; and beneath both there is a series of vaults, part of which (beneath the old House of Lords and present House of Commons) were those in which the gunpowder conspirators had deposited the means of blowing up the Parliament in 1605. It is in these vaults that science now conducts a signal example of one of her most striking though most simple triumphs. One vault is devoted to the purpose of introducing and purifying the air, which is done by means of a wide space towards the public street, covered with a piece of coarse gauze, to stop as much as possible of the soot and dust with which the air is necessarily loaded in the centre of a large city. Having passed into the vaulted apartment, it is completely washed with water as it rushes across to the passage beyond. The washing apparatus consists of a number of pipes laid longitudinally and transversely on the floor; each pipe is perforated with a great number of holes, and from these spout jets d'eau in all directions, so as to fill the apartment with an intense spray, and effectually wash the air as it proceeds through it. On the inner side of the vault the air is as fresh and pleasant as at the brink of a waterfall. Being thus purified, the air, if necessary, is made to pass through a vaulted chamber, containing a congeries of pipes of hot water; and being there warmed is sent on by a channel or passage to the House. The temperature of the air which is admitted can be at all times regulated with perfect nicety, by allowing it to go, more or less, through the warming room; and for the purpose of discovering at any time what is the degree of heat the persons above are enjoying, a thermometer is pulled down by a string from a concealed part of the house.

The air, thus regulated in temperature, is admitted into the house through canvas which covers the walls, and also behind the bar, seats, and tables. The canvas, which is stretched upon the walls, or rather at a little distance from them, is of a thin yellowish description, and is streaked or marked to resemble oak panels. As high up as the heads of the members, the canvas is papered in a neat style. When the air admitted in this manner all round the house, through the texture of the canvas walls, has been breathed and vitiated, it passes off through ventilators in the roof into a kind of garret, whence it proceeds along a passage, and descends a shaft to the ground. On going round by a stair to the bottom of this very strange air-channel, we find ourselves in a vestibule opening upon an immense ash-pit, into which we perceive red-hot cinders occasionally falling. We step forward and enter the ash-pit. We now find ourselves standing at the bottom of a round chimney, measuring a hundred feet high, and eleven feet broad at the base, and in which, at the height of some ten or twelve feet overhead, we observe a large blazing fire suspended on a capacious grating. There is no opening into the chimney except from the vestibule, into which all the vitiated atmosphere of the House is poured—the fire being trimmed only by means of a small door on the outside, but which is usually kept shut—and therefore this forms the great organ or draught in this extensive ventilating apparatus.

For the House of Commons, the air is admitted through gauze into a lower vault, in the same manner as for the Lords; passes, if required, through a heating room, and is thence conducted in a purified state to a

space beneath the floor. For its admission the floor and rising steps are penetrated with millions of small holes, and rising in these, it passes through a coarse carpeting into the house. Having there performed its office, the air passes off by openings round the edges of the panels in the ceiling into a garret above, where it is led away by a passage to the descending channel to the ash-pit and fire which has already been described, and which answer for both Houses. In the garret there is a passage containing a sash-window, which assists in regulating the supply of air and draught. In ordinary circumstances, the opening through which fresh air is supplied to the House of Commons allows 60 cubic feet to pass in at the rate of 10 feet per second; 60 multiplied by 10 makes 600 feet per second, and this again multiplied by 60 seconds, gives, 36,000—that is, thirty-six thousand cubic feet of fresh air supplied every minute for the consumption of the House. The air, likewise, can be admitted in either a cold or warm, moist or dry state, at a moment's notice. On one occasion, seventy gallons of water were sent in in the shape of moist air in the course of a few hours. The feelings of the members being very various, the regulation of these details, as may be supposed, is a matter of extreme delicacy. The great object desired by the learned superintendent is to afford at all times a profuse supply of the best air for breathing, without any sensible feeling of draught to the members; and this he seems to have admirably accomplished by his ingenious arrangements for both Houses. It has been alleged, that the method of admitting the air through the carpet on the floor has the effect of raising a dust in the apartment; but this is not the case. Every precaution is taken to avoid this, not only by the universal porosity, but by the plans adopted for brushing the feet of the members as they pass along the passages and lobbies. It is further necessary to observe, that the plans, at the best, are only preparatory to others of a more perfect kind in connection with the new Houses of Parliament now in course of erection, and for the superintendence of which Dr. Reid is now necessarily resident on the spot.

It is abundantly evident that the choice of a mode of ventilation, and also its minor arrangements, must often be determined by considerations of local convenience and of economy. A factory and a steam-vessel present an ever active furnace or chimney, into which a flue for ventilation can be conducted. In these situations, accordingly, there may be ventilation absolutely without cost. In the same situations, the mechanic power for a fan or pump can be readily obtained, but in that case the power is both a matter of cost, and it requires attention to regulate it. Generally, therefore, though not perhaps in all instances, the plan by fire or chimney draught will be preferable in such situations. Where there is an apparatus for warming as well as for ventilating, and where economy is an object, the draught might without much difficulty be effected by the fire which is used for the former purpose. It would only be necessary to conduct flues from the various rooms down to the ash-pit of the furnace. In this case, however, there would be a certain loss of control over both processes. In buildings already completed there might be a tolerably efficient ventilation obtained by flues conducted into the kitchen chimney, which, being always active, would keep up a nearly unvarying draught. Dr. Arnott has suggested that the fresh air in entering might be heated to nearly the desired temperature, especially in churches and other crowded places of assembly, if the flues for its admission were made to pass longitudinally through the centre of those by which the used air was passing out. Another and simple mode of draught has been practised in connection with the hot water warming apparatus, consisting merely of a flue into which a small coil of the hot water-pipe is introduced. This small coil, situated in the flue, and near its bottom, acts precisely like the fire in the chimney for ventilating the Houses of Parliament.

For obvious reasons, the admission of warm air is generally at the bottoms of rooms, while the used air is drawn off by apertures in or near the ceiling. Mr. Perkins, it appears, pursues exactly the reverse plan, conceiving that it "introduces the warm temperature insensibly, and removes the impurities of the room more effectually." Mr. Alfred Aimer, an architect, also adopts this plan; he remarks that, "with upward ventilation, a great part of the vitiated atmosphere [of crowded rooms] being specifically heavier than common air, is liable, by the slightest check or condensation, to be thrown down and mixed with the air which is already partly unfitted for the purposes of life. But let the ventilating current descend, we have a bright atmosphere consisting of an immense reservoir of pure air, arriving immediately at the lungs, and which, as it becomes contaminated, is drawn downwards by a force with which most accidents will co-operate."*

GAS-LIGHTING.

The existence of an inflammable air, as a natural production, has been known from a period of great antiquity. It was observed to issue spontaneously from fissures in the earth; and we are told that it has been employed in such situations, as a source of light and heat, both in ancient and modern times.

This natural gas is also found in abundance in some coal-mines, where, being liable to mix largely with the air when ventilation is defective, it constitutes the "fire-damp" so destructive to the miner. From an old wrought-out seam at Wallsend colliery, "a discharge of this gas takes place, through a four-inch metallic pipe, of two cubic feet per second. The pipe is carried up as high as the head-gear above the shaft; and from its orifice issues, with a roaring sound, the stream of gas, which, having been ignited, forms a flag of flame seven or eight feet in length, conspicuous by day, and at night illuminating the entire neighbourhood."

The artificial production of an inflammable air from coal is first mentioned in a letter by the reverend Dr. John Clayton of Kildare to the Honourable Robert Boyle, who died in the year 1691. In this letter, published in the "Philosophical Transactions" for 1739, he states, that he distilled coal in a close vessel, and obtained abundance of gas, which he collected in bladders, and afterwards burnt for the amusement of his friends. Other experimenters, among whom Bishop Watson is conspicuous, followed Dr. Clayton, and the properties of coal-gas, and the method of preparing it, thus became well known to chemists.

It was only, however, esteemed as a philosophical curiosity until the year 1792, when it attracted the attention of Mr. Murdoch, an engineer, then residing at Redruth in Cornwall. In that year he commenced a series of experiments on the gases obtained by the action of heat upon coal, wood, peat, and other inflammable substances, and actually prepared coal-gas on a scale sufficiently large to light up his own house and office. Five years after, while living at Cumnock in Ayrshire, he again erected a coal-gas apparatus. In 1798, he was engaged to put up his apparatus at the manufactory of Messrs. Boulton and Watt, Soho, near Birmingham, where he continued to experiment, with occasional interruptions, until the year 1802. It does not appear, however, that much attention was excited by these first efforts at gas lighting, except among a very few scientific individuals, until the general illumination at the peace of Amiens afforded opportunity for a more public display. On this occasion, the front of the manufactory was brilliantly lighted up by the new method, and it at once at

* Richardson on Warming and Ventilation, p. 78

tracted the wonder and admiration of every one who saw it. "All Birmingham poured forth to view the spectacle; and strangers carried to every part of the country an account of what they had seen. It was spread about everywhere by the newspapers; easy modes of making gas were described; and coal was distilled in tobacco-pipes at the fireside all over the kingdom."

By the exertions of a Mr. Winsor, a company was formed for supplying London with gas; but it struggled for many years with the difficulties at once of inexperience and public prejudice, and was a source of loss to many individuals. At length most of these difficulties were overcome, and gas-lighting began to spread over the kingdom. Its progress in dwelling-houses has been retarded by several considerations, most of which are now in a great measure overcome. It was injurious to delicate furniture, and to many of the wares exposed in shops; it often caused headaches when used in close apartments; and, above all, it was dirty, and had a most disagreeable smell.

Science, however, has not been deaf to these complaints urged against the obnoxious qualities of her gift; by means of the joint labours of the chemist and practical engineer, all reasonable grounds of objection have been long ago removed; and the art is now so perfected in our best gas-works, that it is doubted whether much remains to be discovered either for simplifying the process or improving the quality of the product.

It is true that unburnt gas has still a disagreeable smell, but this, instead of being an evil, is in reality a most valuable property; it thus gives warning of its own escape, at once directing the attention of the consumer to his stop-cocks or fittings, without some imperfection of which, the smell of gas cannot be perceived.

The success which has attended gas-lighting wherever it has been introduced, has now effected its adoption in almost every town in Great Britain. The continental nations are slowly following our example, where coal can be obtained. In America, it is used extensively in the large towns; and it has even reached the remote colony of New South Wales, the town of Sydney being now lighted in this manner.

The employment of gas at a distance from towns is limited by the expense of the apparatus compared with the quantity of light required; but where the annual expenditure for light is not less than £40, it is probable that gas might be made with advantage.

The employment of gas made by the decomposition of oil was at one time common. It had two great advantages over coal-gas, namely, a greater brilliancy of light, and a much simpler mode of preparation. These qualities, however, have not enabled it to compete with the superior economy of its rival; and it is so fast going out of use, that it does not appear to require further notice in this short paper.

NATURE AND PROPERTIES OF COAL-GAS.

In their physical properties, gases are similar to common air, which is itself included among them. Like it, they are elastic, for the most part invisible, and possessed of little weight when compared with liquids and solids. They are either simple—by which is meant that they consist of only one ingredient—or compound. We find among them some that are capable of burning when supplied with common air; others that do not burn, but, like common air, assist the combustion of inflammable substances; while a third class have neither of these properties.

The gas prepared from coal is neither a simple nor a single gas; it is a very variable mixture, chiefly composed of two inflammable gases, commonly known by the terms, olefiant gas, and light carbureted hydrogen. Both these gases are compounded of hydrogen and charcoal, in definite proportions. The first, namely, olefiant gas, is composed of 2 atoms of hydrogen with 2 atoms of charcoal; or by weight, 2 hydrogen to 12 charcoal Its specific gravity—that is, its relative weight when compared with common air—is 9722, common air being considered as unity, or 1·000. The weight of 100 cubic inches is 29·652 grains. When passed through red-hot tubes, it is easily decomposed, depositing charcoal, and evolving light carbureted hydrogen and hydrogen. When pure, it has no taste, and scarcely any smell; it burns with a dense white light, combining with three times its bulk of oxygen; or by weight, 14 olefiant gas with 48 oxygen.

The second, namely, light carbureted hydrogen, is composed of 2 atoms of hydrogen combined with 1 atom of charcoal: or by weight, 2 hydrogen to 6 charcoal. Its specific gravity is ·5555; the weight of 100 cubic inches is 16·944. It does not part with its carbon when passed through red-hot tubes, unless the heat is very intense. It is this gas which is met with in coal-mines. According to the experiments of Sir Humphry Davy, it forms explosive mixtures with air when the latter is mixed with it in any proportion between 5 and 14 times its bulk; it burns with a yellowish flame, combining with twice its bulk of oxygen; or by weight, 8 light carbureted hydrogen to 32 oxygen.

Other gases enter into the composition of coal-gas, though in smaller proportions; thus hydrogen, carbonic oxide, and nitrogen, are uniformly present; and it is inferred from the result of experiments by Dr. Faraday on oil-gas, that coal-gas also contains certain other compounds of hydrogen and charcoal in a state of vapour. To these last, in which the proportion of charcoal is very high, both the smell and a considerable increase in the luminous property are attributed.

An analysis of 100 measures of coal-gas, of specific gravity ·650, by Dr. Henry, is as follows:—

Olefiant gas	16
Carbureted hydrogen	62·2
Carbonic oxide	3·5
Nitrogen	1·3

Mr. Clegg has given an analysis of 100 parts of gas, specific gravity ·471, as follows:—

Olefiant gas	8
Carbureted hydrogen	72
Carbonic oxide and hydrogen	13
Carbonic acid	4
Sulphureted hydrogen	3

The relative proportions of the different ingredients in coal-gas are ever-varying, being dependent upon the quality of the coal from which it is made, and to a considerable extent upon the methods employed in its preparation; and, as may be supposed, it must vary also in its specific gravity and luminous quality. When it is made in the best manner from good coal, the specific gravity is sometimes as high as ·675, or even ·700; in other circumstances, it is as low as ·400, or even lower. The former specific gravity indicates with tolerable certainty a large proportion of olefiant gas; the latter a superabundance of light carbureted hydrogen and hydrogen. And as the amount of light evolved by combustion depends greatly upon the quantity of olefiant gas, which has a high specific gravity, the specific gravity of any specimen of coal-gas may be taken as a pretty correct indication of its actual value —the heaviest gas giving the most light, and *vice versa*.

It is a curious fact, that the dilution of the heavier gases by hydrogen does not only detoriorate their quality by the actual amount of dilution—as in the familiar example of spirits and water—but to a much greater extent. This fact, important to the makers of gas, has been experimentally proved by the author of the article *Gas-Light*, in the "Encyclopædia Britannica." In this article it is thus stated:—"In the first experiment, we took a portion of coal-gas, of the specific gravity ·67, which we found consumed at the rate of 4400 cubic inches per hour, and yielded the light of 11 candles, being 400 cubic inches per hour for the light of one candle. This gas being diluted with a fourth part of its bulk of pure

hydrogen, acquires the specific gravity ·55, and wasted away at the rate of 6545 cubic inches per hour, yielding the light of 10 candles. As a fifth part of the compound gas was hydrogen, the remaining four-fifths, amounting to 5236 cubic inches, was the quantity of the coal-gas which, in its diluted state, gave the light of 10 candles for an hour; so that 524 cubic inches of the original coal-gas were requisite to give the light of one candle for the same time. But in its unmixed state, 400 cubic inches were sufficient to give the light of one candle for an hour, and consequently the deterioration caused by the dilution was in the ratio of 524 to 400, or of 100 to 76, being 24 per cent."

A similar or even greater proportionate deterioration is caused by the carbonic oxide and nitrogen commonly present in coal-gas. Their amount, however, is small when compared with the hydrogen occasionally found, and it is much less under the control of the gas-maker.

Two other gases, namely, carbonic acid and sulphureted hydrogen, are sometimes mixed with coal-gas; but they are to be regarded as impurities, which ought always to be separated by the manufacturer, and not as constituents of the gas. They may be detected by the following processes:—

1. Shake a portion of the gas, with lime-water, in a phial. If carbonic acid be present, the water will become turbid by the formation of carbonate of lime.

2. Write on, or wet a slip of paper with a solution of sugar of lead; and while still wet, expose to a stream of the suspected gas. If sulphureted hydrogen be present, even to the extent of one part in twenty thousand, it will be at once detected by the browning or blackening of the solution of lead.

MANUFACTURE OF GAS.

The best coal for gas-making is that which is called *cannel* or parrot. It is characterized by its great hardness and close texture; its colour is dark-brown, approaching to black; it does not soil the fingers when handled; and it has a splintery conchoidal fracture, the broken surface exhibiting a peculiar velvety lustre.

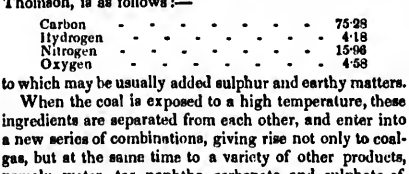
The best parrot we have seen is procured at the Marquis of Lothian's colliery, near Newbattle, Mid-Lothian; its specific gravity is 1·2115. The produce of gas from this coal, on the large scale, is usually about 1000 cubic feet from 200 lbs., and its specific gravity is sometimes as high as ·700. We have seen a small balloon filled with 800 cubic feet of this gas, which would not ascend, to the great disappointment of the experimenter, who had found no difficulty on former occasions with an inferior quality of gas.

The analysis of Newcastle coal, according to Dr. Thomson, is as follows:—

Carbon	75·28
Hydrogen	4·18
Nitrogen	15·96
Oxygen	4·58

to which may be usually added sulphur and earthy matters.

When the coal is exposed to a high temperature, these ingredients are separated from each other, and enter into a new series of combinations, giving rise not only to coal-gas, but at the same time to a variety of other products, namely, water, tar, naphtha, carbonate and sulphate of ammonia, carbonic acid, and sulphureted hydrogen. These substances are separated from the gas in the apparatus which we have attempted to exhibit by the following wood-cut:—



Where dimensions are stated, they are taken from a small gas-work belonging to a town of 5000 inhabitants. A represents the retort, of which several are commonly in use at once. It is a cylindrical or D shaped vessel of clay or cast-iron, about 8 feet in length and 20 inches in ternal diameter. It is built horizontally into a furnace, either singly or otherwise, in such a way that the fire can act completely around it, so as to keep it at a full red heat. Iron retorts have, until of late, been almost exclusively used, but they are inferior in almost every respect to the clay retort which has been lately introduced.

For instance, the latter is only one-third of the cost of iron, and we state with confidence that it is more durable, that it can be heated with less fuel, that it is easier kept at a uniform heat, and that it consequently produces a larger quantity of gas.

The retort, whether of clay or iron, has two openings both external to the building; one of them is the end of the cylinder, which is furnished with a closely-fitting lid of iron; the other is an aperture in its upper surface for the exit-pipe, which passes from the retort to B, a vertical section of the hydraulic main—this is a round or square vessel of iron about 10 inches by 14 in size. It passes above and in front of the whole line of retorts; it is half filled with liquid, into which the exit-pipe dips; it serves to collect the gas and other matters from any number of retorts, and to cut off its escape by any retort which may be open. It is connected by means of a wide pipe with C, the tar-cistern, in which the tar and every thing deposited from the gas by cooling is collected. From the tar vessel a tube rises in a sloping direction to D, the condenser—a series of tubes through which the gas is made to pass, that it may be thoroughly cooled. To the condenser there is sometimes attached E, an upright cylindrical vessel filled with brushwood, through which the gas passes before it is sent to F, the chemical purifier There are usually several vessels of this kind, and of various forms; they contain quick-lime, either dry or mixed with water to the consistence of cream. From the purifier a tube passes to the bottom of the tank in which G, the gasometer, is suspended—this is a large vessel of sheet-iron for holding the gas.

The retort being heated to red heat, the charge of coal, about 200 pounds or upwards, is quickly shoveled in, and immediately gives off dense smoke and flames. The mouth of the retort is now closed by its lid, which extinguishes the flame by shutting off the air, and leaves no outlet for the dense vapours arising from the coal, except by the exit-pipe; they rush through this tube, and are heard bubbling up into the hydraulic main until the charge is exhausted.

It is of importance in this part of the process to attend to the temperature of the retort; for if it is too hot, some of the heavy gas will be decomposed, depositing part of its carbon, and forming light carbureted hydrogen; if, on the contrary, it is not of a certain temperature, there will be formed a large proportion of tar, and the gas will be light and of bad quality. It is also essential to draw the charge before it is quite exhausted, as the last portions of gas consist chiefly of hydrogen and carbonic oxide, both of which, as already stated, have a most injurious effect upon the quality of the whole product.

The time required for a charge of cannel coal is from three to four hours. As soon as one is withdrawn in the form of coke, a second is thrown in, the process being thus continued uninterruptedly night and day.

The dense vapours which pass from the retort into the hydraulic main, consist of coal-gas, mixed with tar, water, naphtha, salts of ammonia, carbonic acid, sulphureted hydrogen, &c. Being subjected to a process of cooling in all parts of the apparatus as far as the brushwood-box, the impurities are condensed, with the exception of the carbonic acid and sulphureted hydrogen; and from the sloping or descending direction of the apparatus to the

tar-cistern, they collect in it, and are pumped off as occasion requires. A considerable quantity of carbonate and sulphate of ammonia is also deposited in the tubes of the condenser in a crystalline form, and requires to be cleared out periodically. This is easily accomplished by passing a current of steam down each pair of tubes, by which these salts are at once dissolved. The gaseous matter still retains particles of tar mechanically mixed with it, from which it is freed by being forced through the brushwood vessel. It is now made to enter the chemical purifiers, where it is either washed by agitation with a mixture of quick-lime and water, or is passed through a succession of trays covered with thin layers of this substance in a slightly moistened state. In this process the lime combines with the sulphureted hydrogen and carbonic acid, forming hydrosulphuret and carbonate of lime, which, being both solid, are retained, and the gas now purified is at once passed into the gasometer, where it is stored for nightly use.

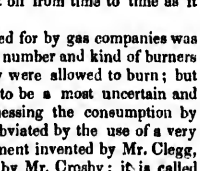
DISTRIBUTION OF GAS.

The distribution of the gas from the gasometer to its places of consumption is effected in cast-iron pipes called mains. They are cast in pieces of from 4 feet 6 inches to 9 feet in length, according to their diameter, and are joined together to any required length. The diameter of the mains varies from 1½ inches to 16 or 18 inches, and depends in every case upon the quantity of gas required to flow through them, taking into account at the same time the distance it has to flow, and some other data of less importance—such as the elevation above or below the horizontal line, the curvatures in the pipe, the specific gravity of the gas, &c., all of which are matters of exact calculation to the practical engineer.

The pipes branching from the mains to supply gas to dwelling-houses or manufactories are called service-pipes. They are commonly made of wrought iron or pewter, and vary in diameter according to circumstances.

Throughout all the ramifications of the fittings, the pipes have, or should have, an inclination to the main, and the main itself should incline towards the gas-work. The necessity for this arrangement arises from the presence of watery vapour in small quantity in the gas; being condensed into water in the pipes, it naturally collects in the lowest part, and at last interrupts the continuous flow of gas, so as to cause a flickering of the flame in the burners. Where the proper inclination of the pipes cannot be attained, this is obviated by placing a stop-cock and pipe at the part where liquid is apt to collect, so that it can be let off from time to time as it accumulates.

The quantity of gas charged for by gas companies was at one time regulated by the number and kind of burners employed, and the time they were allowed to burn; but this was everywhere found to be a most uncertain and unsatisfactory method of guessing the consumption by any individual. It is now obviated by the use of a very simple and ingenious instrument invented by Mr. Clegg, and subsequently improved by Mr. Crosby; it is called the gas-meter, and consists of a hollow case of iron, containing an inner cylinder or drum, so constructed that the gas passing through it, by the pressure it receives at the gas-work, causes it to revolve on an axis; each revolution allows a known quantity of gas to pass through the water, with which the outer vessel is partially filled, to the exit-pipe, and as the revolutions are registered by wheel-work and an index, the quantity of gas consumed is indicated with considerable accuracy. It is usually examined quarterly by a person employed by the gas company, who charges the consumer according to the quantity indicated.



The rate at which gas escapes from an open burner is determined, and to a certain extent regulated, by the pressure applied to it at the gas-work. This is increased or diminished by the application of weights to the counterpoise of the gasometer, and is measured by the elevation of a column of water in a bent glass tube. The usual pressure is about one inch of water above the atmospheric pressure. By the experiments of Messrs. J. Milne and Son, Edinburgh, it appears that every addition of one-eighth of an inch to the pressure causes an extra expenditure equal to about fourteen per cent., and variations to a much greater amount than this are not unfrequent. It is of usual occurrence, for instance, in the vicinity of large manufactories, when their lights are extinguished; and though attention is usually paid to this at the gas work, it is impossible so accurately to regulate the pressure according to the quantity of gas required by any particular main, as to obviate all loss or inconvenience from this cause.

An increase of expenditure is also experienced in the lights that remain burning. When other lights in the same premises have been put out, the gas that supplied these burners increases the pressure in the pipes, and is diffused over the other lights in the premises; and if not checked, there will be comparatively little reduction in the expenditure, although one-fifth of the lights are extinguished. To obviate these inconveniences, instruments called *governors* or *regulators* have been constructed by different individuals. The following wood-cut represents a regulator invented by Messrs. J. Milne and Son, which has been found to answer well in the premises where this sheet is printed. It can be readily placed upon any service-pipe, and being adjusted to the pressure required, it gives a regular flame and expenditure of gas, notwithstanding any variation of pressure in the main. "It is a very general complaint in cotton-mills, that the light in the under floors is deficient, while at the upper floors there is a greater supply of gas than is necessary. This inconvenience arises from the upper floors being subject to less atmospheric pressure than the under one, every additional rise of ten feet making a difference on the pressure of about $\frac{1}{10}$th of an inch. Suppose a mill of six floors is supplied from the gas main at a pressure of $\frac{6}{10}$ths, and that the difference of altitude between the highest and lowest lights is equal to fifty feet, the gas in the highest or sixth floor will issue from the burners at a pressure of $\frac{1}{10}$ths, the fifth floor at $\frac{2}{10}$ths, the fourth at $\frac{3}{10}$ths, and so on. To gain full advantage, in this case, from the regulator, one should be placed in each floor; and in this manner a regulator placed in the top or sixth floor, and adjusted to $\frac{6}{10}$ths of an inch pressure, will send the surplus pressure of $\frac{5}{10}$ths to the floor below; another regulator placed in the fifth floor, also set to $\frac{6}{10}$ths, will send the surplus pressure of $\frac{4}{10}$ths down to the fourth floor; a regulator on the fourth floor will send the surplus $\frac{3}{10}$ths to the third floor; and the regulator in it will send its surplus $\frac{2}{10}$ths to the second floor. Between that floor and the ground, the fall being ten feet, the remaining surplus of $\frac{1}{10}$th is lost; and thus a uniform pressure of $\frac{6}{10}$ths will be established over the whole building; and to prevent any inequality from outward pressure, a regulator ought to be placed in the ground floor also."

BURNING OF GAS.

When coal-gas is burning, it combines with the oxygen of from 10 to 12 times its bulk of common air, or

even more, the quantity varying according to the quality of the gas. By this combination, which in fact constitutes combustion, watery vapour and carbonic acid are formed, the former being composed of all the hydrogen of the gas, with 8 times its weight of oxygen, the latter consisting of all the charcoal, united with oxygen, in the proportion of 6 to 16 by weight. These products, which are similar to those from a candle or lamp, mingle with the air of the apartment, and are removed with it in the course of ordinary ventilation. In some circumstances, the watery vapour is condensed on the windows; and in street lamps it may be seen, when the weather is cold, bedewing the inside of the globes, and even collecting in considerable quantity at the bottom.

The carbonic acid is not removed in the same manner by condensation, and it may accumulate to a hurtful extent; this can only happen, however, where ventilation is peculiarly defective, and the remedy is sufficiently apparent. When the carbon is not all consumed, it flies off in smoke—an occurrence which should be guarded against, not only on account of its offensive qualities, but also from the great loss of light in proportion to the gas expended, which it invariably indicates.

The emission of light, though usually an effect of combustion, is yet a different phenomenon. Many substances are incapable of burning, and yet emit the most brilliant light when they are intensely heated. Gases possess this quality in a very feeble degree. Air, indeed, may be so hot that a solid body becomes luminous in it, while it gives off no light of itself. The temperature at which solids begin to emit light is about 800 degrees of Fahrenheit; they are then incandescent, or red hot; and if the temperature be increased, they become more and more luminous, until at 4000 or 5000 they are so brilliant that the eye cannot look on them without pain.

The lime-ball light is an example of this fact; it gives an intense light without being itself burnt. Pure hydrogen burns with a pale bluish flame; and coal-gas, when made to burn without depositing its charcoal, by reducing its flame to a speck, or by previously mixing it with common air, gives also a feeble blue light. The light from coal-gas, then, actually comes not from the gas itself as gas, but from the particles of charcoal which are separated from their gaseous combination by the incipient combustion; they exist as solid charcoal in the flame, and being heated by it to intensity, they are highly incandescent.

The presence of charcoal in a free state can be detected in a gas or candle flame by the very simple experiment of introducing the edge of a white plate into it; at the lowest part of the flame where it is still blue, the plate is not affected—the charcoal is not yet deposited; the same happens at the top of the flame, the charcoal being now burnt; but in the middle, at that part from whence the light is seen to be chiefly emitted, the plate is instantly coated with pure charcoal.

It will now be understood that the manner in which gas is burnt may actually have an effect upon the amount of light derivable from a given quantity, the condition for obtaining the largest amount being, that the charcoal deposited in the flame shall be heated to the greatest possible intensity. This condition is very differently attained by the different burners in common use. It is found by experiment, that when an argand burner is constructed with holes of a proper size, and of a proper distance from each other, with an internal tube so proportioned as to admit the exact quantity of air necessary for the perfect consumption of the gas, it gives more light than can be obtained from the same quantity of gas by any other method of burning.

In the argand, the flame is steadied and the current of air increased by the use of a glass chimney, which sensibly diminishes the size of the flame, at the same time increasing its brilliancy It has been proposed to improve this burner by heating the air with which it is supplied by means of a double chimney, the outer glass being so constructed that the air must descend between it and the inner glass before it arrives at the burner; and it has been stated that a saving of gas to the extent of 20 per cent. may be effected in this manner. This assertion has, however, been contradicted by other experimenters; and certainly the plan has not been adopted into common use.

The proper size of the holes for an argand burner, and the length of the flame which gives the greatest proportion of light, have been experimentally determined by various individuals. Drs. Christison and Turner state that the diameter which appeared to answer best for coal-gas of the specific gravity ·6, when the holes are ten in a circle of three-tenths of an inch radius, was a thirty-second of an inch; the distance between the holes should be about one-seventh of an inch. A series of experiments by the same individuals on the relative amount of light from flames of different lengths in an argand burner, show that the light is increased about six times for the same expenditure by raising the flame from half an inch to three or four inches; but beyond this height, the gain was comparatively little in the burners experimented on.

Other burners in common use are known by the names—single jet, fish-tail (so called from its resemblance in shape to a fish's tail), and bat-wing. The relative quantity of light which they yield from the combustion of similar quantities of gas is thus given by Dr. Fyfe; namely, single jet, 100; fish-tail, 140; bat-wing, 160; argand, 180.

These burners are commonly used in street-lamps, and they are convenient in some circumstances; for instance, in small apartments where less light is required than is given by an argand, burning at its full height, namely, three or four inches; and it should be distinctly known, that the greatest amount of light is only obtained from any given quantity of gas by burning it in this manner.

The single jet burners, with an aperture from a twenty-eighth to a thirty-sixth of an inch, gives most light in proportion to the gas burnt, when the flame is five inches in height. In the experiments of Drs. Christison and Turner, they found that in the case of coal-gas of specific gravity ·602, while the lights emitted from a two-inch and five-inch flame were as 556 to 1978, the corresponding expenditures were to each other as 605 to 1437. Hence the ratio of the lights, in reference to the expenditure, was as 100 to 150.

If the flame smokes in an argand, it is evident that some adjustment is necessary, and the gas should either be lowered or the chimney contracted until it gives a clear cylindrical flame of three or four inches in height. In the fish-tail burner, if the flame flares or makes a noise in burning, the gas should also be lowered; but to diminish either much below these points does not effect a saving of gas in proportion to the diminution of light. Hence the important conclusion, that it is more economical when the light is too strong to procure a smaller kind of burner, or where several lights are used, to put out some of them altogether, than to lower the flame in the whole.

Various calculations of the relative expense of gas-light, compared with other lights, have been made Thus, when tallow-candles are 9d. per lb., wax-candles three times the price of tallow; train-oil 2s. per gallon, and coal-gas 9s. per 1000 cubic feet, it is computed that the relative expense will be as under, namely,

Wax	100	Oil	5
Tallow	25	Coal-gas	3

In a recent paper by Dr. Fyfe, the relative expense is computed as follows:—Gas giving 12 per cent. condensation with chlorine—that is containing 12 per cent. olefiant gas, at 8s. 6d. per 1000 cubic feet—being 1, the

expense of wax-light of equal quantity will be about 14; sperm-oil, 8; tallow-candles, 7½; rectified whale-oil, 5; common train-oil, in an improved description of burner, 2.

Many individuals, who complain that the adoption of gas-light has proved no saving to them, will be surprised at the above statements. They will find, however, on examination, that they now light up their houses far more brilliantly than they were accustomed to do when candles or oil-lamps were in use, and that their equal expenditure is thus accounted for.

In addition to its greater economy, gas-light may also be pronounced safer than any other ordinary light. It produces no sparks, it cannot be carelessly placed in contact with bed-curtains or substances easily ignited, and it requires scarcely any attention. It may be turned down in an instant to the most minute speck of flame, ready to be restored when necessary by the simple turning of the stop-cock; and even when it escapes by the carelessness of an attendant or a defect in the fittings, it at once indicates the accident to the whole household by the disagreeable smell which it occasions. From the large quantity which must be mixed with air before it becomes explosive, it is scarcely possible that this accident could occur in any ordinary apartment, even if the gas were allowed to escape on purpose. And as its smell so well indicates its presence in cellars or other confined situations, where it may have escaped in quantity from the accidental breaking or leakage of a pipe, it is only by the grossest carelessness or ignorance that a light will be approached to it before it has been allowed to escape by the free admission of air. There is no such thing as the bursting of a pipe or the blowing up of a gasometer. A gas pipe may be broken, as any other pipe, by accident; and if a leaky gasometer is covered over by a building, an explosion may then take place; but these are accidents which can very rarely occur, and they do not concern in any way the ordinary consumer of gas.

BUDE LIGHT.

We have now to notice a new method of using coal-gas, lately introduced into the House of Commons, an account of which is thus given in "Chambers's Edinburgh Journal,' No. 445:—"The light employed is the invention of Mr. Goldsworthy Gurney, and is called the 'Bude Light,' from the name of his residence in Cornwall, where it first became known to him. In 1823, Mr. Gurney published a work on the elements of chemical science, in which he described the powerful light produced from lime by the action of the mixed gases. This light, about seven years afterwards, was employed by Lieutenant Drummond on the Trigonometrical Survey of Ireland, in consequence of which it took the name of the 'Drummond Light.' A Committee of the House of Commons on light-houses, in 1834, recommended the lime-light to be experimented on, with a view to remove the practical difficulties connected with the subject, and adapting it for light-house illumination. In consequence of Mr. Gurney having first announced the discovery of the light, he was recommended by the committee to the Trinity House to carry out the experiment. In the course of his engagement in this office, he discovered the present light, which he considered better for light-house purposes, and, as already mentioned, called the Bude Light. This light is produced by introducing oxygen gas in the interior of the flame of a lamp. An ordinary flame is hollow, the exterior part being only ignited by the atmosphere; the interior part is unburnt, containing the vapour of oil and carbureted hydrogen; and the burning of this unused interior vapour, as quickly as it is distilled, by the admission of oxygen, forms the principle of the Bude Light. As soon as a small tube, conveying a stream of oxygen, is introduced into the heart of the flame, the light is immediately increased in its intensity. Since this valuable discovery was made, Mr. Gurney has effected various alterations and improvements on the light. Formerly he used oil, but now he employs common street gas. This gas, however, is made to pass through a box containing naphtha, which naphthalizes it, and renders it equal to the best oil without the trouble of wicks. The London street gas, it is necessary to explain, is of bad quality, and is improved by the vapour of naphtha. The Edinburgh gas, being much superior to it, would not require any such assistance. The apparatus for supplying the oxygen is placed in a vault adjacent to Dr. Reid's ventilating process. It consists of two iron retorts built over a furnace, and in these is put a certain quantity of oxide of manganese (a metallic substance which resembles brayed coal in appearance), from which oxygen is evolved, and led away in pipes to a gasometer; from the gasometer small pipes proceed to the burners in the House, each conducting a stream of oxygen into the heart of the flame. The light so produced is most intense in brilliancy, but is softened by the intervention of ground glass, and illuminates, with a powerful effect, the whole interior of the apartment. A more perfect substituto, in every respect, for day-light, could not, I believe, be found. The flame being supplied freely with oxygen, a comparatively small quantity of atmospheric air is abstracted or consumed, and all offensive heated air from the combustion is carried away in a small tube into Dr. Reid's ventilating gallery above. Before the introduction of this beautiful light, the House of Commons was illumined with 240 wax candles dispersed about in different parts—a method of lighting which Sir David Brewster has described 'as most absurd, and such as no person at all acquainted with the physiological action of light on the retina, and the principles of its distribution, could have adopted.'* Dr. Ure, on being examined by the committee of members respecting the power of the Bude Light, previous to the substitution of gas for oil, observed—'I made experiments upon it very carefully in my own house last night, and compared its relative illuminative powers with argand lamps and candles with great pains, both by the method of shadows and also by Mr. Wheatstone's photometer. Mr. Gurney's larger Bude lamp, furnished with a wick of five-eighths of an inch, but emitting a white flame of only three-eighths in diameter, was found to afford thirty times more light than a wax candle, and nearly three times more light than the standard flame of the mechanical lamp, which was equal to from ten to eleven candles. Secondly, Mr. Gurney's smaller Bude burner, with a flame one quarter of an inch, was found, by the same methods, to afford a light eighteen to twenty times greater than a wax candle.'

"The adoption of the Bude Light in the House of Commons, as now improved and simplified by the substitution of gas for oil, has completely set at rest all theoretic speculations on the subject. The light is not only by far the most brilliant, without distress to the eye, but is cheaper by two-thirds than the old wax candle plan of illumination. If I recollect properly, Mr. Gurney told me that the expense of using the Bude Light, in which naphtha is required, is about twelve times greater than that of common London gas, sizes of flame being equal; but that as the Bude flame gave twelve times more light, the expense was in reality the same, without the inconvenience of many burners, and a great consumption of air. The property of giving little heat, in comparison to what is produced by common gas, is in itself of great importance. Another useful property is, that the light may be varied in tone, from the most perfect white down to the red ray, by increasing or diminishing the quantity of oxygen."

INCONVENIENCES FROM ARTIFICIAL LIGHT.

We have now briefly to notice certain inconveniences

*Report of Committee on Lighting the House.

occasionally attending the employment of gas, as well as every other kind of artificial light in common use. There are, in the first place, headache, giddiness, and other unpleasant symptoms, which are sometimes complained of in small or ill-ventilated apartments where gas is burned. They may be justly attributed to the heat and carbonic acid produced during the combustion of the gas, although they also depend to some extent upon similar changes effected on the air of the room by respiration, and would occur even to a greater degree were common oil or candles employed, so as to give an equal amount of light. The remedy for the evil is simply *ventilation*. The other inconvenience is of a more insidious nature, and may be ultimately attended with even more serious consequences; we allude to the injurious effect of artificial light upon the organ of vision itself. It is well known that the eyes become fatigued and painful, and they are actually weakened for a time, by exposure to any object strongly illuminated. This may be proved by reading even for a few minutes with one eye tied up, and then comparing the power of vision of this eye with the other. It is also remarkable, that although illumination by artificial means be much less brilliant than daylight, its weakening effect upon the eye is perceived in a greater degree. For example, let the same experiment be repeated by candle or gas-light. The exposed eye will be found now to be more weak than in the former case. The sensibility of its nervous structure in these circumstances is actually impaired for a time, and requires a short period of rest to restore its power. If the eyes be habitually exposed to this stimulus for long periods without rest, as is often the case with literary men, and others, who work to late hours with artificial light, there is no doubt that a permanent weakness of the eyesight may be occasioned, which may even terminate in the destruction of the sensibility of the eye—a disease known by the term *amaurosis*, or nervous blindness.

The first intimations of these injurious effects are usually a sensation of heat and soreness of the eyelids, and pain of the eye-ball, particularly at night, when artificial light is used; in some cases there is an unusual degree of irritability of the eyes, followed by flashes of light when they are touched, or specks floating before them, and ultimately dimness of vision, so that a stronger and stronger light is required. These symptoms may arise from other causes; but it is certain that they are often produced or augmented by the injudicious use of strong artificial light, when minute objects are contemplated. Happily, they may be obviated to a great degree without difficulty. To effect this, the eyes should in the first place be protected from the direct rays of the light itself, not only by raising it above the object out of the line of the eye, but also by the use of a shade placed upon it, so as to prevent its rays from falling upon the face; a minute object is now seen more distinctly than before, even with a less amount of illumination. There is another method which may be adopted, and it has the advantage of being equally simple, though more philosophical. It is derived from the examination of the nature of light, and of the difference between daylight and that which is obtained from combustion. Sir Isaac Newton made the discovery, that light was not simple, but a compound of seven different coloured rays, such as are seen in the rainbow. More recent discoveries have reduced the number of simple rays to three—red, yellow, and blue—which exist in daylight in the following proportions, namely, red 5, yellow 3, blue 8. In artificial light the proportions are different, yellow and red preponderating to a great degree. Experiment proves that each of these rays can act separately upon the eye. For example, if the red ray only be admitted into it, as by looking at the sun through red glass, the nervous structure of the eye is for a time weakened to the stimulus of red; and when the uncovered eye is now turned to a white object, the other rays only are seen, namely, the yellow and blue, giving it a greenish tinge. If, again, the sun be looked at through a green glass, a white object seen immediately after will appear to be red, the eye being insensible to the complementary colours, yellow and blue. For a similar reason, when the eye, passing suddenly from daylight, views objects by means of a candle or gas, they appear of a yellowish hue; and, on the contrary, passing from artificial light into day, the whole prospect has a blue or purplish aspect.

It is also proved by experiment, that the red and yellow rays have a more weakening effect upon the eye than blue; hence, to a certain extent, the more injurious effect of artificial light, which, as already stated, contains those rays in excess. This fact at once suggests a method of obviating the bad effects of gas or candle light, which is either to make it pass through a blue glass shade, so as to obstruct a portion of the red and yellow rays, or to reflect down blue rays by placing a blue reflector above the light; in this manner the quality of artificial light is made more nearly to approach to that of the sun, and objects are seen by it of a purer white, and agreeably cool and refreshing to the eye.

For further information on this subject, we would strongly recommend a small volume by Dr. James Hunter, entitled, "On the Influence of Artificial Light in causing Impaired Vision."

PREVENTION OF SMOKE.

The smoke arising from the furnaces employed at factories has, within the last twenty or thirty years, been felt as a great nuisance in most manufacturing towns, polluting, as it does, the pure air of heaven, and begriming every exposed object within the range of its influence. Those employing furnaces have also become generally aware that smoke is only a volatile form of fuel, and that if either less of it were generated, or if, when generated, it could be consumed, there would be a great saving in the expense of raising steam. These circumstances have led to various devices for the combustion and prevention of smoke, the chief of which it is our duty to describe in this place.

IVISON'S PLAN FOR CONSUMING SMOKE.

This plan, the invention of Mr. Ivison of the silk factory, Fountainbridge, Edinburgh, and which is covered by a patent, consists in the projection of a stream of steam into the space between the fire and the boiler. It proceeds upon the theory, that, the steam so introduced being decomposed by the heat of the furnace, its oxygen unites with the carbon of the smoke, and causes the combustion of that material, while the hydrogen also burns through its own inflammable quality. The arrangement for the introduction of the steam is simple: a small iron pipe, proceeding from the top of the boiler, bends over and enters the furnace immediately above the door, the termination being fitted with a fan-shaped expansion full of small holes, by which the steam is dispersed throughout the fiery space. By a steam-cock on the pipe at the furnace door, the discharge can be regulated or altogether stopped. The due working of the apparatus depends on admitting into the furnace a certain quantity of hot air, and this is done through two pipes which, opening from the open air, pass into the furnace and out again, the inner terminations being inserted in the door.

With regard to the prevention of smoke, Mr. Ivison's plan seems to have established for itself a certain measure of success; but we have understood that the theory is extensively doubted, and that the plan is not likely to be universally adopted. At the silk factory, Edinburgh, at which it is professedly applied, large volumes of black smoke are still frequently seen, and this affords reason

to doubt its utility in general circumstances. The plan was tried on the furnace of the steam-boiler used in the office where this work is printed, and was found to be defeated, in consequence of the extremity of the steam-pipe being constantly liable to be destroyed by the fire. This difficulty may be obviated, and the whole benefit of the plan may, we believe, be secured, if the steam-pipe be introduced below the bars of the furnace, or the bottom ash-pit be kept constantly covered with water.

JUCKES'S PLAN.

Mr. Juckes's plan is designed for consuming smoke and economizing fuel. The following description of it was given by himself at the meeting of the British Association at Manchester, June, 1842. "His grate-bars are endless chains passing over rollers, and moved forward about an inch per minute. The coals employed are common siftings or screenings, which are heaped on the bars outside the furnace door, which slides upwards. The door is left a little open, and by passing under it, the small coal is spread uniformly over the bars. The air is constantly supplied through the bars directly to the fuel while burning, and in this way perfect combustion is obtained. The bars, being slowly moved on, carry the ashes to the ash-pit, which lies at the back of the grate. Clinkers are prevented from incrusting the bars, by their passing under a gauge, which effectually removes them; and the burning away of the bars is prevented by their constantly moving away from the hottest place. The bars or chains, with their rollers and driving-wheels, are fixed in a frame which can be completely drawn out from under the boiler, for the purpose of removing injured bars, or any other purpose. A boiler has been at work for two months at Mr. Baird's saw-mill, Wapping, and given great satisfaction. No smoke is ever seen, and the consumption of coal is only 12 cwt. per day, whereas, with the old boiler, they had used a ton of coal, besides a ton of wood and saw-dust."

SMITH'S NEW BOILER.

The principle of this boiler was suggested to Mr. Smith by a consideration of the upper and under currents in the ocean and in the air, often flowing in opposite directions. He has tried to avail himself of this principle in his furnace, considering that, from the great rapidity with which the gases leave the fire, it is impossible to effect their perfect incorporation with atmospheric air and consequent combustion; and believing that, when these gases are allowed to pass off directly through the flues in nearly straight lines, the gases and air pass along in separate threads or films, sufficient time for their proper mixture not being given under the ordinary systems of combustion. Mr. Smith, therefore, constructs a boiler and furnace in the following manner:—Beyond the bridge of the furnace, he places a chamber within the boiler entirely surrounded by the water; this chamber only leaves room for small water space along the sides and bottom of the boiler; it is arched elliptically, and of course, like all internal flues or fire-boxes, leaves sufficient space above for water and steam. The funnel or chimney is placed on the same side as the fire, and as low as possible. The hot gases and air rush over the bridge gradually, from the size of the chamber, losing their initial velocity. When they impinge against the opposite side of the chamber, the current is directed downwards; and the return current, with diminished velocity, flows back to the chimney under the stratum of gas and air issuing from the fire-bridge. In this way time is given for combustion, and the gases are inflamed or exploded before going up the chimney. From the chamber being quite within the boiler, nearly all the heat is made available. Mr. Smith considers his plan particularly applicable to marine boilers and reverberatory furnaces. He lately had one established at Messrs. Page and Grantham's, Liverpool, working an engine of ten horse power, the pressure in the boiler being 50 lbs. This did as much work with 8 cwt. of coal as the best tube boiler which these gentlemen ever tried had performed with 12 cwt.

WADDINGTON'S PATENT BOILER.

The chief novelty in this plan is a contrivance for introducing coal in a gradual manner. Put in at the sides of the boiler, it is made to descend inclined planes to the bars, before reaching which it is coked by the fuel burning on the bars, and smoke is prevented.

GREENWAY'S METHOD.

This is a plan of considerable ingenuity, as well as simplicity, for *consuming* smoke. He employs, in each case, two boilers and two furnaces. The furnaces are supplied with dampers, so that their communication with their respective flues can be cut off, and a communication opened between the two fires by an intermediate flue. When fresh coals are put on one fire, the damper of that fire is shut, and the intermediate flue opened, so that the smoke is obliged to descend through the bars, and ascend through the burning fuel of the other fireplace. By alternating this, as fresh coals are put on the fires, smoke is said to be prevented.

VARIOUS MINOR PLANS.

We here briefly notice a few plans of inferior note and likelihood, which have been recently brought before the world. Mr. *Kurtz's* is by hollow bars admitting fresh and heated air to a hollow bridge. Mr. *Samuel Hall's* is a plan of much the same nature, by air heated in a quantity of pipes in the flue between the boiler and the chimney, passing thence to perforations in or near the bridge. Mr. *John Chanter's* is by an "auxiliary boiler," the bars under which are inclined, and have below an iron plate termed a "deflector." At the lower end of this furnace a common furnace is constructed, which receives the coke or charred coal in an incandescent state from the upper bars. Mr. *R. Rodda's* is by a furnace divided into two parts, one for coking the coal, the other for receiving the coke—the gas from the coal passing through lateral openings into the second division, where they are to be destroyed by the bright fire. A stream of fresh air is admitted, joining the smoke in the passage, thus effecting its combustion.

It may here be remarked, that coal may be economized and the escape of its fumes much diminished, without any peculiar contrivances, simply by careful and skilful feeding of the furnace by the firemen. In Cornwall, where no contrivances exist, fuel is managed in such a way by the firemen that the consumption in general is only about 2¼ pounds per horse power per hour, and smoke is said to be "never seen." The coal is regularly weighed to the firemen, and the "duty" of the engines is reported every week. This excites emulation among the men, and when a falling off in their attention takes place, it is instantly detected. The great object held in view is to keep thin bright fires, coking the coal in front.

MR. C. W. WILLIAMS'S PLAN.

This is the plan most in esteem at present, and which seems most likely to prove generally serviceable. Mr. Williams is one of the oldest managing directors of the City of Dublin Steam Packet Company, and the author of a treatise entitled, "The Combustion of Coal, and the Prevention of Smoke, Chemically and Practically Considered." Though not by education and circumstances a man of science, his attention having been powerfully called to the subject, he has prosecuted his inquiries into it to at least scientific results, all of which have been vouched for by eminent practical chemists.

Mr. Williams aims not at burning the smoke, which he holds to be a chemical absurdity, but at preventing its

formation. "One of my objects," he says in his treatise, "is to show how the combustion of the volatile portions of coal may be effected as completely when issuing from the throat of a furnace as from the beak of a gas-burner." To pursue the explanations afforded in the Polytechnic Journal—"It is ascertained that 20 cwt. of bituminous coal affords about 10,000 cubic feet of coal-gas—some qualities more, some less; now, chemistry teaches that every measure of this gas requires for its perfect combustion ten measures of atmospheric air, thus making from a ton of coal a gaseous mixture of about 100,000 cubic feet. With more or with less air, we still have imperfect combustion. This is the whole theory of the process; it is what every chemist has long known, and no obstacle is offered to its solution or comprehension. How can so large a body of air as ten cubic feet to every single cubic foot of gas by any possibility be admitted, without cooling down the furnace? Opening the door would let in air enough, with the disadvantage of cooling the furnace and lowering the steam. The doctrine of the diffusion of gases, due to the elaborate and interesting experiments of Dr. Dalton, comes to our aid. For perfect diffusion, we require time; the process of the furnace will not afford time. We must, then, resort to some mechanical arrangement to overcome this difficulty in the simplest possible manner. Now, we may have enough of air; but from having it applied in the wrong mode, as is done in opening the door, though we lose the smoke, we lose the steam also; in this case it is somewhat like the two conditions of gas burnt from a common pipe with and without an argand burner. Why does it in the one situation smoke and give little heat, while in the other it is smokeless and intensely hot, seeing it is surrounded in both instances with an abundant supply of air? Merely because the numerous minute jets of gas, supplied by the argand burner, afford that more perfect diffusion refused by the wide bore of a single orifice. So, in the furnace, if we can admit the ten measures of air in the same way by means of small jets, we do all we want by obtaining rapid diffusion, complete mixture, and therefore perfect combustion."

In the "Practical Mechanic and Engineer's Magazine" for 1841, there is a paper on Mr. Williams's plan, illustrated by sections of the furnace and boiler. From this we learn that a long boiler is supposed, and that the grate is placed under one end, having its ash-pit below as usual. The fumes of the coal pass onward under the boiler, towards a chimney at the opposite extremity. Under the centre of the boiler, and quite separate from the ash-pit, there is a square chamber, having a flue by which air can be admitted from without. From the iron plate forming the roof of this chamber, three short vertical tubes, unclosed at the lower ends, project upwards into the space beneath the boiler along which the fumes pass. These tubes are perforated all round the sides and tops with holes of a quarter-inch, set one inch apart. The air, accordingly, passing first into the square chamber, then proceeds upwards, and rushes into the space above in the form of small jets. At every charge of fresh coal on the fire, the first product is, not smoke, but a very large body of crude impure coal-gas, the unconsumed portion of which, as it passes the bridge, meeting the air, mingles with it and instantly inflames, being encompassed with a hot gaseous atmosphere. The effect then is, that each jet of air seems to be a common gas flame, and these vertical tubes have not inaptly been compared to trees of fire. To those who are not familiar with the fact of flame from a jet of air in gas, it may be interesting to quote the observations of Professor Blande on this subject:—"I fill a bladder with coal-gas," says he, "and attach to it a jet, by which I burn a flame of that gas in an atmosphere of, or a bell-glass filled with, oxygen; of course the gas burns brilliantly, and we call the gas the combustible, and the oxygen the supporter of combustion. If I now invert this common order of things, and fill the bladder with oxygen, and the bell-glass with coal-gas, I find that the jet of oxygen may be inflamed in the atmosphere of coal-gas, with exactly the same general phenomena as when the jet of coal-gas is inflamed in the atmosphere of oxygen." Such are the means by which Mr. Williams *prevents* smoke. The saving of fuel is said to be about 25 per cent.

ARCHITECTURE.

Architecture, or the art of planning and raising edifices, appears to have been among the earliest inventions. The first habitations of men were such as nature afforded, with but little labour on the part of the occupant, and sufficient to supply his simple wants—grottos, huts, and tents. In early times, the country of Judea, which is mountainous and rocky, offered cavernous retreats to the inhabitants, who accordingly used them instead of artificial places of shelter. From various passages in Scripture, it appears that these caves were often of great extent, for, in the sides of the mountain of Engedi, David and 600 men concealed themselves. In the course of time, art was employed to fashion the rude cavernous retreats, and to excavate blocks by which rude buildings were composed in more convenient situations. The progress of architecture, however, from its first dawn, differed in almost every different locality. Whatever rude structure the climate and materials of any country obliged its early inhabitants to adopt for their temporary shelter, the same structure, with all its prominent features, was afterwards kept up by their refined and opulent posterity.

From the cause now mentioned, the Egyptian style of building had its origin in the cavern and mound; the Chinese architecture, with its pavilion roofs and pointed minaret, is moulded from the Tartar tent; the Grecian is derived from the wooden cabin; and the Gothic from the bower of trees. It is evident that necessity as much as choice or chance led to the adoption of the different kinds of edifices. Among a roving and pastoral people, the tent, which could be easily struck and removed, was obviously more suitable than an immovable and difficultly erected structure; it is equally clear that lofty and substantial edifices would be out of place in a country subject to earthquakes, or low buildings in situations liable to periodic inundation. Thus local circumstances everywhere produced local styles of architecture, and these distinctions are now almost as observable as they were thousands of years ago.

After mankind had learned to build houses, they commenced the erection of temples to their gods, and these they made still more splendid than private dwellings. Thus architecture became a fine art, which was first displayed on the temples, afterwards on the habitations of princes and public buildings, and at last became a universal want in society.

Traces of these eras of advancement in the art of erecting buildings are found in various quarters of the

globe, especially in eastern countries, where the remains of edifices are discovered of which fable and poetry can alone give any account. The most remarkable of these vestiges of a primitive architecture are certain pieces of masonry in the island of Sicily, as well as in some other places, called the works of the Cyclops, an ancient and fabulous race of giants, mentioned by Homer in his Odyssey. By whom these walls were actually erected is unknown.

Of the progressive steps from comparative rudeness to elegance of design, history affords no certain account, and we are often left to gather facts from merely casual notices. The most ancient nations known to us, among whom architecture had made some progress, were the Babylonians, whose most celebrated buildings were the temple of Belus, the palace and the hanging gardens of Semiramis; the Assyrians, whose capital, Nineveh, was rich in splendid buildings; the Phœnicians, whose cities, Sidon, Tyre, Aradus, and Sarepta, were adorned with equal magnificence; the Israelites, whose temple was considered as a wonder of architecture; the Syrians, and the Philistines. No architectural monument of these nations has, however, been transmitted to us; but we find subterraneous temples of the Hindoos, hewn out of the solid rock, upon the islands Elephanta and Salsette, and in the mountains of Elora. These temples may be reckoned among the most stupendous ever executed by man. The circuit of the excavations is about six miles. The temples are 100 feet high, 145 feet long, and 62 feet wide. They contain thousands of figures, appearing, from the style of their sculpture, to be of ancient Hindoo origin. Every thing about them, in fact, indicates the most persevering industry in executing one of the boldest plans. In the chief temple, the vault is supported by several rows of columns, which form three galleries, one above the other. Twenty-four colossal monolenthes, representing Indian gods, are placed in separate divisions, the sculpture of which, though on the whole rude, shows in some parts an advanced period of art, and a certain development of taste. Latterly, several travellers have made known the remains of an architecture and sculpture not very dissimilar to that of the ancient Hindoos, in certain districts of Central America, believed to be the execution of a people anterior to those Mexicans who existed at the period of the invasion of Cortes.

EGYPTIAN STYLE OF ARCHITECTURE.

All the architectural remains of ancient times sink into insignificance when compared with those of Egypt. The obelisks, pyramids, temples, palaces, and other structures of this country, are on the grandest scale, and such as could only have been perfected by a people considerably advanced in refinement. The elementary features of Egyptian architecture were chiefly as follows:—1. Their walls were of great thickness, and sloping on the outside. This feature is supposed to have been derived from the mud walls, mounds, and caverns of their ancestors. 2. The roofs and covered ways were flat, or without pediments, and composed of blocks of stone, reaching from one wall or column to another. The principle of the arch, although known to the Egyptians, was seldom if ever employed. 3. Their columns were numerous, close, short, and very large, being sometimes ten or twelve feet in diameter. They were generally without bases, and had a great variety of capitals, from a simple square block, ornamented with hierogiyphics or faces, to an elaborate composition of palm-leaves, not unlike the Corinthian capital. 4. They used a sort of concave entablature, or cornice, composed of vertical flutings, or leaves, and a winged globe in the centre. 5. Pyramids, well known for their prodigious size, and obelisks, composed of a single stone, often exceeding seventy feet in height, are structures peculiarly Egyptian. 6. Statues of enormous size, sphinxes carved in stone, and sculp- in outline of fabulous deities and animals, with innumerable hieroglyphics, are the decorative objects which belong to this style of architecture.

The main character of Egyptian architecture is that of great strength with irregularity of taste. This is observable in the pillars of the temples, the parts on which the greatest share of skill has been lavished. The following are examples:

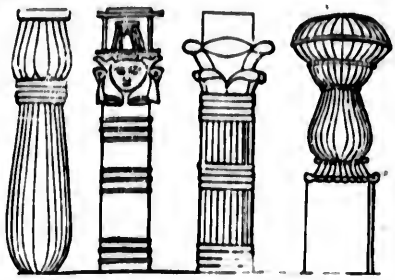


Fig. 1. Fig. 2. Fig. 3. Fig. 4.

In these columns, we may notice that sturdiness is the prevailing characteristic. The desire has been the support of a great weight, and that without any particular regard to proportion or elegance either as a whole or in parts. When assembled in rows or groups, the columns had an imposing effect, because, from their height and thickness, they filled the eye and induced the idea of placid and easy endurance. In fig. 5, which represents the exterior of a temple, this simple and imposing character is conspicuous.

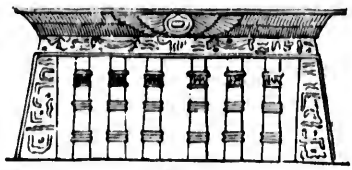

Fig. 5.

GRECIAN STYLE OF ARCHITECTURE.

From Egypt, the architectural art spread to Greece, where it passed from the gigantic to the chaste and elegant. The period during which it flourished in the greatest perfection was that of Pericles, about 440 years before Christ, when some of the finest temples at Athens were erected. After this, it declined with other arts, and was carried to Rome, where, however, it never attained the same high character. The Grecian temples were built chiefly of marble, and surrounded or decorated with columns, and had a pleasing effect when situated amidst groves of trees or other kinds of natural scenery; and as they were lighted from the roof, the beauty of the structures was not deformed by formal rows of windows, such as are now common in modern edifices. Before describing the various orders of Grecian and Roman architecture, it will be advantageous to explain the terms ordinarily employed in reference to the component parts of buildings.

Explanation of Terms.

The *front* or façade of a building, made after the ancient models, or any portion of it, may present three parts, occupying different heights:—The pedestal is the lower part, usually supporting a column; the single pedestal is wanting in most antique structures, and its place supplied by a *stylobate*: the stylobate is either a platform with steps, or a continuous pedestal, supporting a row

of columns. The lower part of a finished pedestal is called the *plinth*; the middle part is the *die*, and the upper part the *cornice* of the pedestal, or *surbase*. The *column* is the middle part, situated upon the pedestal or stylobate. It is commonly detached from the wall, but is sometimes buried in it for half its diameter, and is then said to be engaged. *Pilasters* are square or flat columns attached to walls. The lower part of a column, when distinct, is called the base; the middle, or longest part, is the shaft; and the upper or ornamented part, is the capital. The swell of the column is called the *entasis*. The height of columns is measured in diameters of the column itself, taken always at the base. The *entablature* is the horizontal continuous portion which rests upon the top of a row of columns. The lower part of the entablature is called the *architrave* or *epistylium*. The middle part is the *frieze*, which, from its usually containing sculpture, was called *zophorus* by the ancients. The upper or projecting part is the cornice. A *pediment* is the triangular face produced by the extremity of a roof. The middle or flat portion enclosed by the cornice of the pediment is called the *tympanum*. Pedestals for statues, erected on the summit and extremities of a pediment, are called *acroteria*. An *attic* is an upper part of a building, terminated at top by a horizontal line instead of a pediment. The different mouldings in architecture are described from their sections, or from the profile which they present when cut across. Of these, the *torus* is a convex moulding, the section of which is a semicircle, or nearly so; the *astragal* is like the torus, but smaller; the *ovolo* is convex, but its outline is only the quarter of a circle; the *echinus* resembles the ovalo, but its outline is spiral, not circular; the *scotia* is a deep concave moulding; the *cavetto* is also a concave, and occupying but a quarter of a circle; the *cymatium* is an undulated moulding, of which the upper part is concave and the lower convex; the *ogee* or *talon* is an inverted cymatium; the *fillet* is a small square or flat moulding. In architectural measurement, a diameter means the width of a column at the base. A module is half a diameter. A minute is a sixtieth part of a diameter.

In representing edifices by drawings, architects make use of the plan, elevation, section, and perspective. The plan is a map or design of a horizontal surface, showing the ichnographic projection, or groundwork, with the relative position of walls, columns, doors, &c. The elevation is the orthographic projection of a front, or vertical surface; this being represented, not as it is actually seen in perspective, but as it would appear if seen from an infinite distance. The section shows the interior of a building, supposing the part in front of an intersecting plane to be removed. The perspective shows the building as it actually appears to the eye, subject to the laws of scenographic perspective. The three former are used by architects for purposes of admeasurement; the latter is used also by painters, and is capable of bringing more than one side into the same view, as the eye actually perceives them. As the most approved features in modern architecture are derived from buildings which are more or less ancient, and as many of these buildings are now in too dilapidated a state to be easily copied, recourse is had to such initiative restorations, in drawings and models, as can be made out from the fragments and ruins which remain. In consequence of the known simplicity and regularity of most antique edifices, the task of restoration is less difficult than might be supposed. The groundwork, which is commonly extant, shows the length and breadth of the building, with the position of its walls, doors, and columns. A single column, whether standing or fallen, and a fragment of the entablature, furnish data from which the remainder of the colonnade, and the height of the main body, can be made out.

Grecian temples are well known to have been constructed in the form of an oblong square, or parallelogram, having a *colonnade* or row of columns without, and a walled *cell* within. The part of the colonnade which formed the front portico was called the *pronaos*, and that which formed the back part the *posticus*. There were, however, various kinds of temples, the styles of which differed; thus, the *prostyle* had a row of columns at one end only; the *amphiprostyle* had a row at each end; the *peripteral* had a row all round, with two inner ones at each end; and the *dipteral* had a double row all round, with two inner ones at each end, making the front three columns deep.

The theatre of the Greeks which was afterwards copied by the Romans, was built in the form of a horse-shoe, being semicircular on one side and square on the other. The semicircular part, which contained the audience, was filled with concentric seats, ascending from the centre to the outside. In the middle or bottom was a semicircular floor, called the *orchestra*. The opposite, or square part, contained the scene. Within this was erected, in front of the audience, a wall, ornamented with columns and sculpture, called the *scena*. The stage or floor between this part and the orchestra was called the *proscenium*. Upon this floor was often erected a movable wooden stage, called by the Romans *pulpitum*. The ancient theatre was open to the sky, but a temporary awning was erected to shelter the audience from the sun and rain.

Orders.

Aided, doubtless, by the examples of Egyptian art, the Greeks gradually improved the style of architecture, and originated those distinctions which are now called the "Orders of Architecture." By this phrase is understood certain modes of proportioning and decorating the column and its entablature. These were in use during the best days of Greece and Rome, for a period of six or seven centuries. They were lost sight of in the dark ages, and again revived by the Italians at the time of the restoration of letters. The Greeks had three orders, called the Doric, Ionic, and Corinthian. These were adopted and modified by the Romans, who also added two others called the Tuscan and Composite.

The Doric order.—This is the earliest of the Greek orders, and we see in it a noble simplicity on which subsequent orders were founded. Compared with the best of the Egyptian models, it exhibits a great advance in purity of taste. From the remains of ancient art, it is found that the Doric varies in its proportions. The column, in its examples at Athens, is about six diameters in height; but in those of older date, as those at Pæstum, it is only four or five. One of the most correct examples is that given in fig. 6. The shaft of the Doric column had no base, ornamental or otherwise, but rose directly from the smooth pavement or stylobate. It had twenty flutings, which were superficial, and separated by angular edges. The perpendicular outline was nearly straight. The Doric capital was plain, being formed of a few annulets or rings, a large echinus, and a flat stone at top called the *abacus*. The architrave was plain; the frieze was intersected by oblong projections called triglyphs, divided into three parts by vertical furrows, and ornamented beneath by *guttæ*, or drops. The spaces between the triglyphs were called *metopes*, and commonly contained sculptures. The sculptures, representing Centaurs and Lapithæ, carried by Lord Elgin to London, were metopes of the

Fig. 6.

Parthenon, or temple of Minerva, at Athens. The cornice of the Doric order consisted of a few large mouldings, having on their under side a series of square sloping projections, resembling the ends or rafters, and called *mutules*. These were placed over both triglyphs and metopes, and were ornamented on their under side with circular guttæ. The Romans, in adopting the Doric, greatly spoiled its simplicity and grandeur by unduly lengthening the shaft, and making other tasteless alterations. To have a just idea of the Doric, therefore, we must go back to the pure Grecian era. The finest

Fig. 7.—Façade of the Parthenon.

examples are those of the temple of Theseus, and the Parthenon (fig. 7) at Athens. The Parthenon, which is now a complete ruin, has formed a model in modern architecture. It was built by the architect Ictinus, during the administration of Pericles, and its decorative sculptures are supposed to have been executed under the direction of Phidias. The platform or stylobate consists of three steps, the uppermost of which is 227 feet in length and 101 in breadth. The number of columns is eight in the portico of each front, and seventeen in each flank, besides which there is an inner row of six columns, at each end of the cell. The proportional height of the columns is five diameters and 33 minutes, and they diminish thirteen minutes in diameter from bottom to top. The sculpture of the frieze represented the combats of the Centaurs and Lapithæ; those of the eastern pediment represented the fabulous birth of Minerva; and those on the western the contests between the goddess and Neptune for the right of presiding over the city. The building was destroyed by the explosion of a bomb-shell, during the siege by the Venetians in 1687.

Speaking of these splendid objects of art, a respectable writer observes:—"Of their effect it is impossible to form a competent idea without seeing one. And whence, it may be asked, does this interest arise? From their simplicity and harmony; simplicity, in the long unbroken lines which bound their forms, and the breadth and boldness of every part; such as the lines of the entablature and stylobate, the breadth of the corona, of the architrave, of the abaci, of the capitals, and of their ovalos also; in the defined form of the columns, and the breadth of the members of the stylobate; harmony, in the evident fitness of every part to all the rest. The entablature, though massive, is fully upborne by the columns, whose spreading abaci receive it, and transmit the weight downwards by the shafts, which rest on a horizontal and spreading basement; the magnitude of every part being determined by the capacity of the sustaining power. Besides graceful and elegant outline, and simple and harmonious forms, these structures possess a bewitching variety of light and shade, arising from the judicious contour and arrangement of mouldings, every one of which is rendered effective by the fluting of the columns, and the peculiar form of the columnar capital, whose broad square abacus projects a deep shadow on the bold ovalo, which mingles it with reflections, and produces on itself almost every variety. The play of light and shade, again, about the insulated columns, is strongly relieved and corrected by the deep shadows on the walls behind them; and in the fronts, where the inner columns appear, the effect is enchanting. For all the highest effects which architecture is capable of producing, a Greek peripteral temple of the Doric order is perhaps unrivalled."*

The Ionic order.—In this order the shaft begins to lengthen, and to possess a degree of ornament, but still preserving a great degree of simplicity of outline. In the best examples as represented in fig. 8, the column was eight or nine diameters in height. It had a base often composed of a torus, a scotia, and a second torus, with intervening fillets. This is called the Attic base. Others were used in different parts of Greece. The capital of this order consisted of two parallel double scrolls, called volutes, occupying opposite sides, and supporting an abacus, which was nearly square, but moulded at its edges. These volutes have been considered as copied from ringlets of hair, or perhaps from the horns of Jupiter Ammon. When a column made the angle of an edifice, its volutes were placed not upon opposite, but on contiguous sides, each fronting outwards. In this case the volutes interfered with each other at the corner, and were obliged to assume a diagonal direction. The Ionic entablature consisted of an architrave and

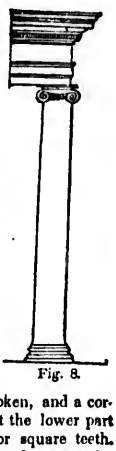

Fig. 8.

freize, which were continuous or unbroken, and a cornice of various successive mouldings, at the lower part of which was often a row of dentels, or square teeth. The examples at Athens of the Ionic order were the temple of Erectheus, and the temple on the Ilissus, both now destroyed. Modern imitations are common in public edifices.

The Corinthian order.—This was the lightest and most highly decorated of the Grecian orders. (Fig. 9.) The base of the column resembled that of the Ionic, but was more complicated. The shaft was often ten diameters in height, and was fluted like the Ionic. The capital was shaped like an inverted bell, and covered on the outside with two rows of leaves of the plant acanthus, above which were eight pairs of small volutes. Its abacus was moulded and concave on its sides, and truncated at the corners, with a flower on the centre of each side. The entablature of the Corinthian order resembled that of the Ionic, but was more complicated and ornamented, and had, under the cornice, a row of large oblong projections, bearing a leaf or scroll on their under side, and called *modillions*. No vestiges of this order are now found in the remains of Corinth, and the most legitimate example at Athens is in the choragic monument of Lysicrates. The Corinthian order was much employed in the subsequent structures of Rome and its colonies. The finest Roman example of this order is that of three columns in the Campo Vaccino at Rome, which are commonly considered as the remains of the temple of Jupiter Stator. This example has received the commendation of all modern artists, yet has seldom been executed in its original form. This is probably owing to the excessive richness and delicacy of it, which renders its adoption very expensive; and perhaps the modification of it by Vignola is preferable to the original, possessing a sufficient enrichment without the excessive refinement of the other. In this order the

Fig. 9.

* Encyclopædia Britannica, article *Architecture*.

base is one module in height; the shaft sixty modules twenty minutes; and the capital two modules ten minutes; thus giving ten diameters to the whole column. The architrave and frieze are each one module fifteen minutes in height, and the cornice two modules. The cornice is distinguished by modillions interposing between the bead mouldings and corona; the latter is formed by a square member surmounted by a cymatium, supported by a small ogee; the former is composed of dentels, supported by a cyma reversa, and covered by the ovalo. When the order is enriched, which is usually the case, these mouldings, excepting the cymatium and square of the corona, are all sculptured; the column is also fluted, and the channels are sometimes filled to about a third of their height with cablings, which are cylindrical pieces let into the channels. When the column is large, and near the eye, these are recommended as strengthening them, and rendering the fillets less liable to fracture; but when they are not approached, it is better to leave the flutes plain. They are sometimes sculptured, but this should only be in highly enriched orders.

The flutes are twenty-four in number, and commonly semicircular in their plan. The Corinthian base is similar to that of the Composite order, excepting that two astragals are employed between the scotiæ instead of one; but the Attic is usually employed for the reason before assigned.

"The Corinthian order," says Sir William Chambers, "is proper for all buildings where elegance, gayety, and magnificence are required. The ancients employed it in temples dedicated to Venus, to Flora, Prosperine, and the nymphs of fountains, because the flowers, foliage, and volutes with which it is adorned, seemed well adapted to the delicacy and elegance of such deities. Being the most splendid of all the orders, it is extremely proper for the decoration of palaces, public squares, or galleries and arcades surrounding them; and on account of its rich, gay, and graceful appearance, it may with propriety be used in theatres, in ball or banqueting rooms, and in all places consecrated to festive mirth or convivial recreation."

Caryatides.—The Greeks sometimes departed so far from the strict use of the orders as to introduce statues, in the place of columns, to support the entablature. Statues of slaves, heroes and gods, appear to have been employed occasionally for this purpose. The principal specimen of this kind of architecture which remains, is in a portico called Pandrosium, attached to the temple of Erectheus at Athens, in which statues of Carian females, called Caryatides, are substituted for columns. One of these statues has been carried to London.

ROMAN STYLE OF ARCHITECTURE.

Roman architecture possessed no originality of any value; it was founded on copies of the Greek models, and these were modified to suit circumstances and tastes. The number of orders was augmented by the addition of the Tuscan and Composite.

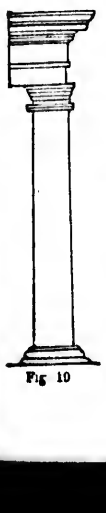

Fig. 10

Tuscan order.—This order is not unlike the Doric, and is chaste and elegant. As represented in fig. 10, the shaft had a simple base, ornamented with one torus, and an astragal below the capital. The proportions were seven diameters in height. Its entablature, somewhat like the Ionic, consisted of plain running surfaces. There is no vestige of this order among ancient ruins, and the modern examples of it are taken from the descriptions of Vitruvius. The general effect is strength with simplicity, and the order is considered to be well adapted for such buildings as prisons, public halls, and inferior parts of edifices.*

The Composite order.—Of this there were various kinds differing less or more either in the ornaments of the column or in the entablature. The simplest of this hybrid order was that which we represent in fig. 11, which may be observed to combine parts and proportions of the Doric, the Ionic, and the Tuscan. From this handsome modification of previous orders, the Romans advanced to the ornamental composite, represented in fig. 12, which, in point of fact, is a barbarously modified Corinthian. It would appear from these efforts, as well as from all subsequent attempts, that the Greeks attained the highest state of improvement of which their style was susceptible, and that, consequently, all schemes to execute something better must prove abortive. The higher class of Roman architects were convinced of this fact, and very judiciously held to the Corinthian order in all their finest buildings, both in Rome and in the provinces. Thus the Corinthian prevails among the ruins of Palmyra and Balbec, and other great cities founded by Roman provincials.

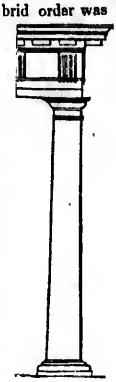

Fig. 11.

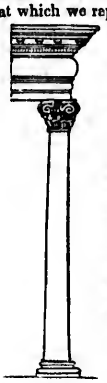

Fig. 12.

The temples of the Romans sometimes resembled those of the Greeks, but often differed from them. The Pantheon, which is the most perfectly preserved temple of the Augustan age, is a circular building, lighted only from an aperture in the dome, and having a Corinthian portico in front. The amphitheatre differed from the theatre, in being a completely circular or rather elliptical building, filled on all sides with ascending seats for spectators, and leaving only the central space, called the *arena*, for the combatants and public shows. The Coliseum is a stupendous structure of this kind. The aqueducts were stone canals, supported on massive arcades, and conveying large streams of water for the supply of cities. The triumphal arches were commonly solid oblong structures, ornamented with sculptures, and open with lofty arches for passengers below. The edifice of this kind most entire in the present day is the triumphal arch of Constantine, at Rome, represented in fig. 13. This structure is ornamental, and far from inelegant, but it contains much that is tasteless, inasmuch as being without meaning; and there is also an undue overloading of embellishment, or at least frittering away in details. Carrying the eye up the columns, and dissecting their individual bearings, we perceive that each may be resolved into the shafting represented on a larger scale in fig. 14, which is evi-

Fig. 13.

* Vitruvius was a celebrated writer on architecture, who is supposed to have flourished in the time of Julius Cæsar and Augustus. His treatise on architecture was first printed at Venice in 1497. An English translation appeared in 1771. A new translation by Wilkins was published in 1812.

dently anomalous in design, and inconsistent with the dignified simplicity of the pure Grecian models. The arch of Constantine has been copied at Paris, in the structure erected by Napoleon in front of the Tuileries.

The *basilica* of the Romans was a hall of justice, used also as an exchange or place of meeting for merchants. It was lined on the inside with colonnades of two stories, or with two tiers of columns, one over the other. The earliest Christian churches at Rome were sometimes called *basilicæ*, from their possessing an internal colonnade. The monumental pillars were towers in the shape of a column on a pedestal, bearing a statue on the summit, which was approached by a spiral staircase within. Sometimes, however, the column was solid. The *thermæ*, or baths, were vast structures, in which multitudes of people could bathe at once. They were supplied with warm and cold water, and fitted up with numerous rooms for purposes of exercise and recreation.

Fig. 14.

ITALIAN STYLE OF ARCHITECTURE.

After the dismemberment of the Roman empire, the arts degenerated so far that a custom became prevalent of erecting new buildings with the fragments of old ones, which were dilapidated and torn down for the purpose. This gave rise to an irregular style of building, which continued to be imitated, especially in Italy, during the dark ages. It consisted of Grecian and Roman details, combined under new forms, and piled up into structures wholly unlike the antique originals. Hence the names Græco-Gothic and Romanesque architecture have been given to it. After this came the *Italian style*, which was professedly a revival of the classic styles of Greece and Rome, but adapted to new manners and wants—a kind of transition from ancient to modern times. Its great master was Andrea Palladio, a Venetian (born 1518—died 1580). This highly accomplished man expelled much of the Græco-Gothic taste, and established in the sixteenth century what may be called a new era in architecture. The majestic simplicity of the ancient orders was always present to the mind of Palladio, and he has left behind him many beautiful buildings which attest the purity of his taste. The writer in the "Encyclopædia Britannica," already referred to, alludes to some peculiarities of the Italian style:—

"Prostyles being almost unknown in Italian architecture, antæ are not often required. Pilasters, however, are very common—so common, indeed, that they may be called pro-columns, as they are often used as an apology for applying an entablature. They are described as differing from columns in their plan only, the latter being round, and the former square; for they are composed with bases and capitals; they are made to support entablatures according to the order to which they belong, and are fluted and diminished with or without entasis, just as columns of the same style would be. When they are fluted, the flutes are limited to seven in number on the face, which, it is said, makes them nearly correspond with the flutes of columns; and their projection must be one-eighth of their diameter or width when the returns are not fluted; but if they are, a fillet must come against the wall. Pedestals are not considered by the Italo-Vitruvian school as belonging to the orders, but they may be employed with them all, and have bases and surbases or cornices to correspond with the order with which they may be associated. Following Vitruvius, the Italian school makes the central intercolumniation of a portico wider than any of the others. Arched openings, in arcades or otherwise, are generally about twice their width in height; if, however, they are arranged with a columnar ordinance, having columns against the piers, they are made to partake of the order to which the columns belong, being lower in proportion to their width with the Tuscan than with the Doric, and so on; and the piers are allowed to vary in the same manner, from two-fifths to one-half of the opening. With columnar arrangements, moulded imposts and archivolts are used; the former being made rather more than a semi-diameter of the engaged columns in height, and the latter exactly that proportion. (Fig. 15.)

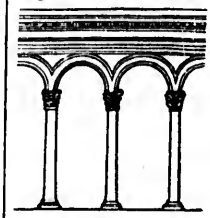

Fig. 15.

Variously moulded key-stones are also used, projecting so that they give an appearance of support to the superimposed entablature. Smaller columns with their entablature are sometimes made to do the duty of imposts, and sometimes single columns are similarly applied; at others, columns in couples are allowed to stand for piers to carry arches. In plain arcades, the masonry is generally rusticated, without any other projection than a plain blocking course for an impost, and a blocking course or cornice crowning the ordinance. Niches and other recesses are at times introduced in the plain piers, which are in that case considerably wider than usual, or in the spandrels over wide piers. Very considerable variety is allowed in these combinations, which will be best understood by reference to the examples. Doors and windows, whether arched or square, follow nearly the same proportions, being made, in rustic stories, generally rather less than twice their width in height, and in others either exactly of that proportion, or an eighth or a tenth more. If they have columned or pilastered frontispieces, these are sometimes pedimented; and, except in rustic stories, whether with or without columns, a plain or moulded lining, called an architrave, is applied to the head and sides of a door or window. This architrave is made from one-sixth to one-eighth the width of the opening it bounds, and it rests on a blocking course or other sill, as the case may be.

The rule for the form, composition, and application of pediments in Italian architecture, if it may be gathered from the practice of the school, appears to be to set good taste at defiance in them all. We find pediments of every shape, composed of cornices, busts, scrolls, festoons, and what not, and applied in every situation, and even one within another, to the number of three or four, and each of these of different form and various composition. The proportion laid down for the height of a pediment is from one-fourth to one-fifth the length of its base, or the cornice on which it is to rest. Balustrades are used in various situations, but their most common application is in attics or as parapets, on the summits of buildings, before windows, in otherwise close continued stereobates, to flank flights of steps, to front terraces, or flank bridges. Their shapes and proportions are even more diversified than their application; that of most frequent use is shaped like an Italian Doric column, compressed to a dwarfish stature, and consequently swollen in the shaft to an inordinate bulk in the lower part, and having its capital, to the hypotrachelium, reversed to form a base to receive its grotesque form. The base and coping cornice of a balustrade are those of an ordinary attic, or of a pedestal whose dado may be pierced into balusters. The general external proportions of an edifice, when they are not determined by single columnar ordinances, appear to be unsettled.

There is considerable variety and beauty in the foliate and other enrichments of an architectural character in many structures in Italy, but very little ornament enters into the columnar composition of Italian architecture. Friezes, instead of being sculptured, are swollen; the

shafts of columns are very seldom fluted, and their capitals are generally poor in the extreme; mouldings are indeed sometimes carved, but not often; rustic masonry, ill-formed festoons, and gouty balustrades, for the most part supply the place of chaste and classic ornaments.

THE CHINESE STYLE.

The ancient Tartars and wandering shepherds of Asia appear to have lived from time immemorial in tents, a kind of habitation adapted to their erratic life. The Chinese have made the tent the elementary feature of their architecture; and of their style any one may form an idea, by inspecting the figures which are depicted upon common China ware. Chinese roofs are concave on the upper side, as if made of canvas instead of wood. A Chinese portico is not unlike the awnings spread over shop windows in summer time. The verandah, sometimes copied in dwelling-houses, is a structure of this sort. The Chinese towers and pagodas have concave roofs, like awnings, projecting over their several stories. A representation of this barbaric style of erection is given in fig. 16. Such structures are built with wood or brick; stone is seldom employed.

Fig. 16.

THE SARACENIC, MOORISH, AND BYZANTINE STYLES.

The Arabs, or Saracens, as they are more usually called, and the Moors, introduced into Spain certain forms of architecture which differed considerably from the Grecian in appearance, though founded on its remains in Asia and Africa. The chief peculiarity of this architecture was the form of the arch; the Saracens are understood to have made it of greater depth than width, thus constituting more than half a circle or ellipse, and therefore unphilosophical and comparatively insecure (fig. 17); while the Moorish style was principally distinguished by arches in the form of a horse-shoe, or a crescent. The Saracens and Moors, however, were so much one people that the works of each are not easily pointed out in the present day; both styles were highly ornamented with flowery tracery, called *arabesque*, and the pillars supporting the arches were generally slender and elegant. The crescent-like or bulging dome of the oriental mosque was likewise introduced by the Moorish architects into Europe. This bulging, or onion-shaped form of dome, is common in the church-spires of the Netherlands, having been brought thither by the Spaniards when in possession of the country.

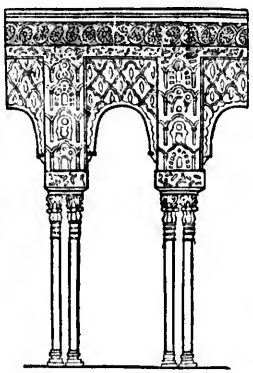

Fig. 17.

We associate with these styles another, which arose at Constantinople, called the Byzantine, likewise formed on the remains of Grecian art, and partaking of a slightly eastern character. It became known in western Europe along with the Lombard, another degenerate Grecian style, about the ninth and tenth centuries. The two united received the name of the Lombard-Byzantine, and were employed upon the cathedrals of Worms and Mayence, and several other ecclesiastical structures in Germany. This style is distinguished by small arches resting on connecting central pillars, like the Saracenic, and sometimes there are rows of such arches one above another. Either pure or mixed, the Byzantine style remained in vogue till it was superseded by the modern Gothic or German style, about the middle of the thirteenth century.

SAXON STYLE.

Many centuries before the Gothic or German style became known, a peculiar modification of the Grecian, since entitled the *Saxon style*, was invented and used in ecclesiastical edifices, and, as generally believed, led to the discovery of the Gothic. The Saxon style is distinguished by rounded arches over doors and windows, or in the entablature of turrets and walls. Sometimes the arch was composed of semicircles of different widths, swelling from a small to a larger compass, and thus affording a convenient entrance to porches in churches. An example is presented in fig. 18.

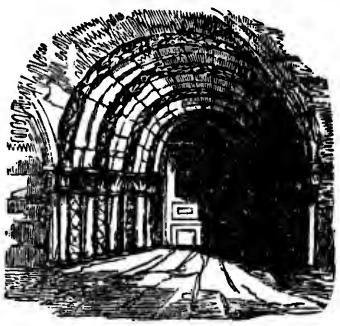

Fig. 18.

This style commenced at the establishment of Christianity among the Saxons in the sixth century, and is called Saxon, from its having prevailed during the reigns of the Saxon and Norman kings in England. Some of the finest specimens extant are the entrance to the Temple Church, London; the Abbey Gate, Bristol; and the church of Ramsey in Hampshire. The style continued in England till about the year 1135, in the reign of king Stephen.

GOTHIC OR POINTED STYLE.

The term Gothic is a modern error, which, being now impossible to correct, is suffered to remain as the generally distinguishing appellation of the kind of architecture possessing pointed arches. This style originated in Germany about the middle of the thirteenth century, and was zealously pursued as the leading fashion for ecclesiastical structures all over Europe. Executed by a class of skilled artisans, who wandered from country to country,* the finest specimens of the pointed style are the

* We here allude to the order or craft of Free-Masons, the origin of whose associations may be dated from the ninth or tenth centuries, and who attained their greatest numerical strength and importance at the introduction of the Gothic or pointed style of architecture. Afterwards, the order became a speculative society, unconnected with the practice of architecture, and finally has sunk before the spread of universal intelligence and a common philanthropy which recognises all men as brothers.

cathedrals of Strasburg, Cologne, and Antwerp, and the splendid abbeys of Melrose and Westminster. (Fig. 19.)

In this fanciful and picturesque style of architecture, the slender columns, always united in groups, rise to a lofty height, resembling the giants of the grove, in whose dark shade the ancient Teuton used to build his altar. In the obscure depth of the dome, the mind is awakened to solemn devotional feelings. The decoration of the ancient Christian churches is by no means an accidental ornament. They speak a figurative religious language; and at the tabernacle or cherubim, over the altar, where the pyx is kept, the whole temple is presented in miniature to the view of the beholder. In these edifices,

Fig. 19.

every one must admire the accurate proportions, the bold yet regular construction, the unwearied industry, the grandeur of the bold masses on the exterior, and the severe dignity in the interior. We must therefore ascribe to the German architecture more symbolical than hieroglyphic eloquence and dignity.

In England, the transition from the Saxon to the pointed style of arch is observed on various old buildings. The accidental intersection of rounded Saxon arches with each other, produces sharp points at the intersections, and this is believed by some to have been the origin of the pointed forms. The crossings of the boughs of trees in an avenue also afford a familiar illustration of the same fact. In the Temple Church the two arches may be found united, and other specimens may be seen in the Church of St. Cross near Winchester; and Fountains Abbey, Rivaulx Abbey, and Roche Abbey, in Yorkshire.

Fig. 20.

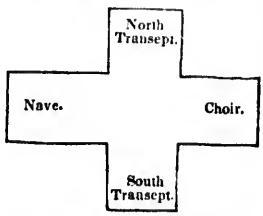
When the circular arch totally disappeared in 1220, the early English style commenced. The windows of this style were at first very narrow in comparison with their height; they were called lancet-shaped, and were considered very elegant: two or three were frequently seen together, connected by dripstones. In a short time, however, the windows became wider, and divisions and ornaments were introduced. Sometimes the same window was divided into several lights, and frequently finished at the top by a light in the form of a lozenge, circle, trefoil, or other ornament. A specimen of this kind may be seen in the beautiful church of St. Saviour's, Southwark, which has lately been thrown open to view by the improvements connected with the erection of the New London Bridge: and another and a very beautiful example in the "Lady Chapel," near London Bridge, on the Surrey side of the Thames. A specimen of the pointed or Gothic doorway is offered in fig. 20.

About the year 1300, the architecture became more ornamental, and from this circumstance received the name of the decorated English style, which is considered the most beautiful for ecclesiastical buildings. The windows of this style are very easily distinguished; they are large and wide, and are divided into several lights by mullions, which are upright or perpendicular narrow columns, branching out at the top into tracery of various forms, such as trefoils, circles, and other figures. York Cathedral affords a fine specimen of this sort of architecture, and there is a beautiful window of the same style in the south transept of Chichester Cathedral. The west front of that of Exeter is another specimen, and the doorway of Lincoln Cathedral is in the same style.

The transition from the decorated to the florid or perpendicular style was very gradual. Ornament after ornament was added, till simplicity disappeared beneath the extravagant additions; and about the year 1380, the architecture become so overloaded and profuse, that it obtained the title of florid, which by some persons is called the perpendicular, because the lines of division run in upright or perpendicular lines from top to bottom, which is not the case in any other style. King's College Chapel, Cambridge, begun in the reign of Henry VI., though not finished till some time after; Gloucester Cathedral; Henry VII.'s Chapel at Westminster; St. George's Chapel at Windsor; Wrexham Church, Denbighshire; and the Chapel on the bridge at Wakefield, Yorkshire—are all of this character. Many small country churches are built in this style; and their size not admitting of much ornament, they are distinguished from structures of a later date by mouldings running round their arches, and generally by a square head over the obtuse-pointed arch of the door. A peculiar ornament of this style is a flower of four leaves, called, from the family reigning at that period, the Tudor flower.

Definitions of Parts.

Gothic architecture being for the most part displayed in ecclesiastical edifices, it may be of service to explain the usual plan of construction of these buildings. A church or cathedral is commonly built in the form of a cross, having a tower, lantern, or spire, erected over the place of intersection. The part of the cross situated towards the west is called the *nave*. The opposite or eastern part is called the *choir*, and within this is the *chancel*. The transverse portion, forming the arms of the cross, is called the *transept*, one limb being called the northern, and the other the southern transept.



Generally, the nave is larger than the choir. If the nave, choir, and transepts be all of the same dimensions

the form is that of a Greek cross. When the nave is longer than the other parts, forming a cross of an ordinary shape, the edifice is said to be in the form of a Latin cross. The different open parts usually receive the name of *ailes* or *aisles*, from a word signifying a wing: the nave or largest open space is called the main aisle. Originally, the floors of all such edifices were open and unencumbered with fixed pews or seats, and as the floors were ordinarily of mosaic or tesselated pavement,* the effect was exceedingly grand.

The roofing of Gothic churches is of stone, in the form of *groins*, in which the arches are poised with intersecting points, and the whole skilfully adjusted so as to bear on the side rows of pillars (fig. 21). Any high building erected above the roof is called a *steeple;* if square topped, it is a *tower;* if long and acute, a *spire;* and if short and light, a *lantern*. Towers of great height in proportion to their diameter are called *turrets*.

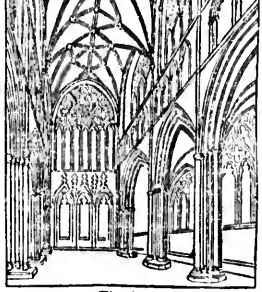


Fig. 21.

The walls of Gothic churches, on which the outer strain of the roof arches ultimately rests, require to be of great strength; and the imparting this necessary degree of resistance without clumsiness is the glory of this style of architecture. The plan adopted is to erect exterior *buttresses* (fig. 22). These rise by gradations from a broad basis to narrow pointed *pinnacles*, and, placed opposite the points of pressure, secure, without the slightest appearance of clumsiness, the general stability of the building. Slanting braces, which spring from the buttresses to the upper part of the roof, are called *flying* buttresses; such, however, are not always required in those modern edifices in which the roof is of wood and lead.

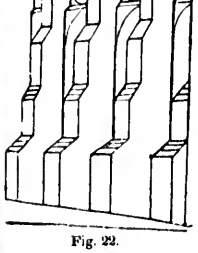

Fig. 22.

The summit or upper edge of a wall, if straight, is called a *parapet;* if indented, a *battlement*. Gothic windows were commonly crowned with an acute arch; they were long and narrow, or, if wide, were divided into perpendicular lights by *mullions*. The lateral spaces on the upper and outer side of the arch are called *spandrelles;* and the ornaments in the top, collectively taken, are the *tracery*. An *oriel*, or *bay window*, is a window which projects from the general surface of the wall. A *wheel*, or *rose window*, is large and circular. A *corbel*, is a bracket or short projection from a wall, serving to sustain a statue or the springing of an arch. The Gothic term *gable* indicates the erect end of a roof, and answers to the Grecian pediment, but is more acute.

Fig. 23.

The polished taste of the architects employed in constructing Gothic edifices, led to numerous devices in the form of the pillars Sometimes the column was single, round, and massive; at other times it was composed of seemingly a cluster of smaller pillars, and this had always the lightest effect; but occasionally the column was given the appearance of two shafts twisted, as represented in fig. 23, or of a single shaft with a festoon of flowers twined spirally around it. In the collegiate church at Roslin, there are some highly ornamented pillars of this kind.

The Gothic style of building is more imposing, and more difficult to execute than the Grecian. This is because the weight of its vaults and roofs is upheld at a great height by supporters acting at single points, and apparently but barely sufficient to effect their object. Great mechanical skill is necessary in balancing and sustaining the pressures; and architects at the present day, hampered by principles of economy, find it difficult to accomplish what was achieved by the builders of the middle ages.

NORMAN, TUDOR, AND MODERN GOTHIC.

Throughout England may be seen many aged castles, some still in a state of good preservation, but the greater number in ruins, and occupying, with their picturesque remains, the summit of a rising ground or rocky precipice. These castles are of a style which prevailed during the feudal ages in Europe, and was brought to this country by the Normans, who erected them as fastnesses into which they might retire and oppress the country at pleasure. The same kind of buildings are seen in Scotland, where the barons ruled with the same feudal power as in the southern parts of the island.

The feudal castles in England, like those on the Rhine, consisted for the most part of a single strong tower or keep, the walls of which were from six to ten feet thick, and the windows only holes of one or two feet square, placed at irregular intervals. The several floors were built on arches, and the roof was flat or battlemented, with notches in the parapet, from which the inhabitants or retainers of the chieftain might defend themselves with instruments of war. The accommodations for living were generally mean, and what would now be called uncomfortable. Around or in front of the main tower there was usually a court-yard, protected by a high wall, and the arched entrance was carefully secured by a falling gate or portcullis. Outside, there was in many cases a regular wet ditch or fosse. Castles of greater magnitude consisted of two or more towers and inner buildings, including a chapel and offices for domestics, and horses and other animals. Some of them were on a great scale, and possessed considerable grandeur of design.

As society advanced, and civil tranquillity was established, these military strengths gradually assumed a character of greater elegance and less the appearance of defence. The wet ditch disappeared, and was superseded by a lawn or shrubbery. Instead of the drawbridge and portcullis, there was a regular approach and gate of ordinary construction. The windows became larger, and were fitted with glass frames, and stone was abandoned for the greater comfort of wooden floors. Instead, also, of a bare region around, in which no foe might lurk, gardens were established, and a long avenue of trees led to the front of the modernized mansion. In some instances, the popper-box turrets at the upper cor-

* Mosaic, or more properly *Musaic* (from the Latin *opus Musivum*), was of Roman origin. It consisted of pavement formed of pieces of marble of different colours, arranged in a tasteful manner, and was very costly.

ners of the building remained. Of the class of structures that sprung up in this period of transition, which we may refer in England to the fifteenth and sixteenth, and in Scotland to the seventeenth centuries, there are several highly interesting remains. These edifices of the nobility and gentry were no longer called castles: they took the name of *halls*, and such had attained so great a pitch of magnificence in the reigns of Henry VIII. and Elizabeth, as to have subsequently given a name to a new style—the *Tudor* or *Elizabethan*. Latterly, and with no very distinct reference to any particular period, this remarkable fashion of building has been pretty generally called the *old English* style of architecture. One of the best existing specimens of the Tudor era of architecture is Hadden Hall in Derbyshire, the property of the Duke of Rutland.

A writer in the "Quarterly Review," speaking of this species of architecture, takes occasion to notice that "in a few of the houses built during the reign of Henry VIII., we may observe some slight traces of the Italian architecture, which in the next reign was more liberally introduced, and mixed up with the original Tudor, or early English, into an irregular, certainly, but in most instances an exceedingly rich and effective composition." This was traceable to the influence of the Italian architects in England, whose "fame was a subject of deep interest in this country, where the rage for building was no less strong and general than in Italy. In the brilliant reign of Elizabeth, the English nobles and princely proprietors vied more than ever with each other in the magnificence of their mansions. It might have been supposed that the noble Tudor houses, with their panelled walls, buttresses, and battlements, traceried windows, sculptured drip-stones, florid pinnacles, and embossed chimney-shafts, were sufficiently rich and gorgeous to satisfy the prevailing taste for splendour; but in their anxiety to strike and surprise the admiration of their countrymen, many deserted the native styles, and sought for designs, and even artists, from abroad. Italian architecture became, by degrees, the mode; and even where the indigenous style was adhered to in the general design, many of the enrichments and ornamental features were borrowed from the Italian. First of all, the porch or gateway, as the most conspicuous points on which to exhibit these exotic novelties, were decorated on each side of the entrance, and, perhaps, a second or third story above, with pilasters belonging to the different Greek orders; the doorway itself exchanged the low-pointed or Tudor for the circular arch; the deep, elegant, and sweeping Gothic mouldings for the Vitruvian architecture, cut across by the awkward projecting imposts. Next was introduced the cupola, whose invention in Italy had made so much noise, that it appears our country squires were anxious to have miniature specimens of it at home. It was applied as a covering to the high turrets, round, square, or polygonal, which flanked the entrance or terminated the angles of the building, and, surmounted with gilded vanes, certainly produced a rich and imposing effect. Then followed the removal of the panelled battlements, and the substitution of a parapet, carved into fantastic notches or scrolls, or perforated with oval openings, and ornamented with obelisks, balls, busts, statues, and other singular decorations. These ran up the gables, which were often twisted into strange shapes, and sometimes wholly replaced by the level balustrade; and thus the most characteristic features of the old style —its numerous steep gables and spiry pinnacles—were succeeded by the uniform horizontal straight lines of the new. At length the whole building was surrounded by columns or pilasters, rising tier above tier, to the exhaustion sometimes of the five orders; open arcades took the place of the entrance porch; and nothing remained of the Tudor style but the mullioned window, which, however was of itself sufficient to give a peculiarly picturesque and old-fashioned aspect to the whole building."

"It has always appeared to us," continues our authority, "that this architecture of the Elizabethan age constitutes a style of its own—a compound of two extremely different modes, the Italian and the Tudor Gothic. It is evident that the Italian design was always greatly altered to suit the climate and the taste of England. Indeed, were we not afraid that the comparison might be considered profane, we should say there is something in the rich irregularity of the Elizabethan architecture, its imposing dignity, gorgeous magnificence, and quaint and occasionally fantastic decoration, reminding us of the glorious visions that flitted across the imagination of Shakspeare, the immortal bard of the same age. He, like the architects of his day, borrowed largely from the foreigner, but made his importations appear exclusively his own. The architectural garden, which always accompanied this style of mansion, is not the least pleasing part of it. We delight in its wide and level terraces, decorated with rich stone balustrades, and these again with vases and statues, and connected by broad flights of stone steps—its clipped evergreen hedges—its embowered alleys—its formal yet intricate parterres, full of curious knots of flowers—its lively and musical fountains —its steep slopes of velvet turf—its trim bowling-green —and the labyrinth and wildness which form its appropriate termination, and connect it with the ruder scenery without. This kind of ornamental garden came from Italy, with the change we have been discussing in domestic architecture.

"The quadrangular embattled mansion of the last Henries affords scope for the display of much grandeur and magnificence, and adapts itself more conveniently to the plan of a modern house. The carved oriel, and deep many-lighted bay window, often projecting in a multitude of capricious angles and curves, besides the regular octagon, the panelled angled-turrets, with richly embossed finials, and the wreathed chimney-shafts, are characteristic beauties of this class of building. The gabled manor-house, together with these ornamental features, admits at the same time of a much greater irregularity of form and outline, so as to accommodate itself to every variety of disposition, and to buildings of every size, from the baronial residence to the parsonage and grange. All the forms which particularly mark the Elizabethan style, may be wrought in the cheapest materials with comparatively little labour; and a small portion of ornamental work, tastefully disposed, is capable of producing very considerable effect. Lastly, the Elizabethan house is distinguished by the number and size of its rectangular and many-mullioned windows, which gave a peculiar lightness and elegance to its several parts. The roof-line may be either horizontal or broken with gables, turrets, and cupolas. In either case, it is enriched with perforated parapets, balustrades, or other architectural devices, while similar embellishments ornament the entrance, and the terraces which connect the building with the garden."

Fortunately, this light and elegant style of domestic architecture is gradually superseding the bald Græco-Italian style of the eighteenth century. A better taste is evidently extending itself, particularly as regards the erection of villas, cottages, hunting-seats, gate-lodges and other rural residences. To these the old English style is peculiarly well adapted. The leading feature of this style applied to cottages is the dispensing with unbroken lines. The house is composed of different parts projecting at right angles from each other, with also a projecting porch, and the outshot octagonal window commanding views in three different directions. It also sometimes exhibits an open rustic arcade along a portion of the front or back, which will be found useful as agreeable both in sultry and cold broken weather. It

not uncommon for a cottage of this kind to have on the ground-floor two parlours, communicating by folding-doors, fourteen feet by twelve each, and ten feet in height; a kitchen and scullery, with a porch seven feet by five feet six inches, opening to a staircase seventeen feet six inches by eight feet, with three rooms above. The gables are enriched with pendants and ornamental dressings to the doorways and windows, and handsome octagonal chimney-stalks. We offer a representation of a cottage in this elegant style in fig. 24.

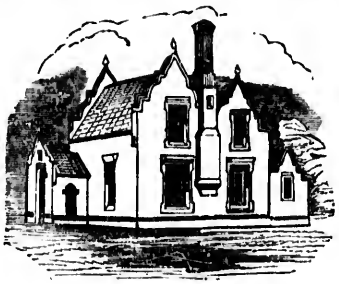

Fig. 24.

In erecting ornamental cottages of this kind, there ought to be a lightness in the pointing of the upper projecting windows, with a sharp angularity in the roof; and the chimney-stacks ought to stand well out, in order to create effect in different points of view. When the little gardens adjacent are well trimmed and blooming, and the woodbine and ivy trained round the porch or mullioned window, the prospect exhibited is such as it would be impossible to surpass in rural elegance. We have not here room to enlarge on this interesting topic, and must conclude by recommending that, in applying cottage architecture to a residence, much care ought to be taken to preserve the simplicity of the component parts, or the idea of the cottage will be lost in the magnitude of the dwelling. Loudon's Encyclopædia of Cottage and Villa Architecture should certainly be consulted by gentlemen and others in the country, before fixing on the style or mode of construction of their residences—that is to say, when skilful architects are not employed.

Fig. 25.

Improvement is also shown in the style of church-building, particularly in the northern part of the United Kingdom, where there was most room for it. Since the Reformation, churches have been built in Scotland with very little regard to elegance; and in the last century, particularly, there flourished a style, the products of which are scarcely to be distinguished from barns and granaries. Within the last twenty years, very few such structures have been erected without an effort being made to unite some degree of taste with a regard for convenience. A modest Gothic style has become very prevalent, which, though not always free of faults, is a surprising advance upon the homely edifices of the last century.

In fig. 25, a representation is given of one of these improved ecclesiastical structures, suitable for a rural scene, or any other situation in which economy of means requires to be consulted. In general, these handsome Gothic churches are calculated to accommodate from a thousand to twelve or fourteen hundred sitters, are neatly fitted up with pews and galleries, and cost from three to four thousand pounds.

MODERN BRITISH ARCHITECTURE.

During the sixteenth century, as has been mentioned, an extraordinary effort was made in Italy to restore the purity of Grecian architecture; and in this attempt Palladio was followed by the not less eminent Michael Angelo Buonarotti, who, at an advanced age, in 1546, undertook the continuation of the building of St. Peter's at Rome, a work on which the greatest splendours of the Italian style are lavished. Into England, this revived taste for the Grecian was introduced at the beginning of the seventeenth century by Inigo Jones, to whose contemptuous observations on the German or pointed style the term *Gothic* has been traced; and after his decease, the Grecian, or more properly the Italianized Grecian, was perpetuated on a scale still more extensive by Sir Christopher Wren. The edifices erected by this great master are characterized by the finest taste, and his spires in particular are models of elegance. The greatest work of Wren was St. Paul's cathedral in London, in which the Italian is seen in all its glory.

The eighteenth century was an era of decline in architectural taste. Every other style merged in that of a spiritless and often mean Græco-Italian, out of which the architects of the nineteenth century have apparently had a difficulty to emerge. Latterly, there has been a revival in England of a purer kind of Grecian, and also, as we have already said, of old English, and the Gothic or pointed style, and in most instances with good effect. It is only to be lamented that, by the manner in which state patronage is distributed in this branch of the fine arts, some of the largest and most expensive structures—Buckingham Palace and the National Gallery, for example—have been erected on the poorest conceptions of the Grecian style, and with a general effect far from pleasing. In Paris, there now exist some modern structures after correct Grecian models, which cannot be too highly praised; we would, in particular, instance the building called the Madeleine, the Bourse, and the interior of the church of St. Genevieve, which are exceedingly worthy of being visited by young and aspiring architects from Britain.

House and Street Architecture.

Till about the year 1820, the street architecture of Britain was on a poor scale; the houses ranging evenly with each other, being plain stone or brick edifices, of generally three stories in height, overtopped by a slanting and tasteless roof of slate or tile; in London and some other places, the ugly tile roof was hid by a portion of the front wall carried upwards as a parapet. At the above period, a new era may be said to have begun in town architecture, whereby the houses were built more in a bold continental style, in which the Græco-Italian was aimed at with more or less success; and latterly, this improved taste has altogether superseded the barren architecture prevalent during the reign of George III. According to this revived taste, the houses are now constructed of po

lished sandstone or covered with a plaster to resemble that material; the doors and windows are enlarged and ornamented, the floors more spacious and lofty, and the roof is invariably secluded from the eye by a balustrade or elevated coping. Some of the edifices erected at the west end of London, to accommodate clubs of gentlemen, are reckoned among the finest examples of the revived Italian style, and worthy of the best days of Palladio. The following cut, fig. 26, represents the front of the

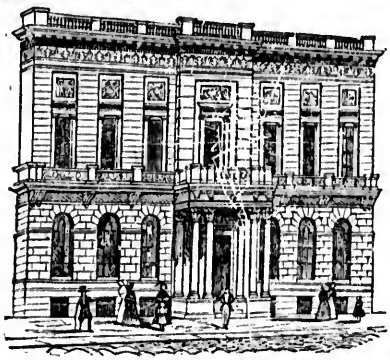

Fig. 26.

Oxford and Cambridge University Club-House, in Pall Mall, erected from a design of Mr. Sydney Smirke and his brother Sir Robert, and which is distinguished for the richness of its cornice and entablature, as well as its generally imposing effect.

The various changes effected in recent times in general street architecture are not more remarkable than those on the construction of shop-fronts, some of which now vie with the greatest efforts of the old Italian masters. A century ago, shop-fronts were little else than open booths, with an overhanging canopy, as exemplified in the antique shop of a fishmonger still remaining in the Strand, near Temple Bar. They afterwards were closed, and, as is well known, attempts were finally made to Grecianize them with pillars and pediments. The increasing rivalry and taste of shop-keepers, however, did not stop here; and in the present day very extraordinary efforts are making to place shop-fronts among the works of classic architecture. The design, generally, is to supersede plain Grecian or Roman models by highly ornamental designs after the Italian style. The most favour-

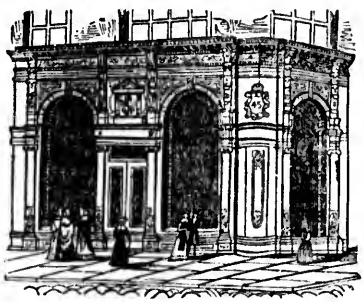

Fig. 27

able specimen we can present of this elaborate and splendid style of shop-frontage is that observable at the corner of the Quadrant, Regent Street, London (fig. 27). As an architectural composition, it possesses considerable merit, presenting, with the lightness of the plate-glass windows, the appearance of sufficient solidity and strength, and not looking as if likely to be crushed by the upper part of the edifice.

MONUMENTAL COLUMNS.

The erection of triumphal or monumental columns was a favourite idea of the Romans. Augustus erected a column of white marble near the Temple of Saturn, in the Forum at Rome, as a centre whence the account of the miles began in the calculation of distances from the city. This celebrated column, which is still in existence, is, however, not of great altitude. Among the principal triumphal columns of antiquity now remaining, is what is called the column of Pompey, constructed of red granite, and situated on a rock, about a mile without the walls of Alexandria in Egypt. The total height of this column is variously mentioned as being ninety-two feet and one hundred and fourteen feet. The spectator can never be tired with admiring the beauty of its Corinthian capital, the length of the shaft, or the extraordinary simplicity of the pedestal. To whom this famous pillar was erected is now unknown. It acquired the name of Pompey's Pillar so late as the fifteenth century. The preceding cut will convey a correct idea of its outlines.

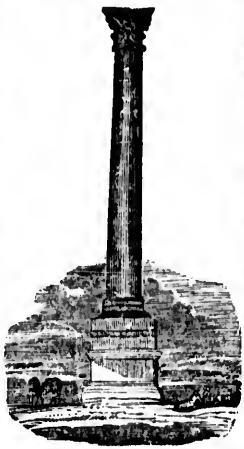

Fig. 28.—Pompey's Pillar.

The Trajan Column, which falls next to be mentioned, is one of the most celebrated monuments of antiquity. Its height including the pedestal and statue, is 132 feet. This monumental column was erected in the centre of the Forum Trajani, and dedicated to the Emperor Trajan for his decisive victory over the Dacians, as is testified by the inscription on the pedestal. It is of the Doric order, and its shaft is constructed of thirty-four pieces of Greek marble, joined with cramps of bronze. For elegance of proportion, beauty of style, and for simplicity and dexterity of sculpture, it is the finest in the world. The figures on the pedestal are masterpieces of Roman art. It was formerly surmounted by a statue of Trajan, which has been succeeded by one of St. Peter. There are other columnar erections in Rome; one of which is the column of the Emperor Phocas, near the Temple of Concord; it is of Greek marble, fluted and of the Corinthian order, four feet diameter, and fifty-four feet high, including the pedestal.

The column which ornaments the British metropolis, better known as the Monument, was designed by Sir Christopher Wren, and erected by order of parliament, in memory of the burning of the city of London, anno 1666, in the very place where the fire began. This pillar was begun in 1671, and finished in 1677. It is of the Doric order, fluted, 202 feet high from the ground and fifteen feet in diameter, of solid Portland stone, with a staircase in the middle, of black marble, containing 385 steps. The lowest part of the pedestal is twenty-eight feet square, and its altitude forty feet; the front being enriched with curious bas-reliefs. It has a balcony within thirty-two feet of the top, on which is placed a blazing urn of gilt brass.

The column in Phœnix Park, Dublin, differs from any

other work of this descriptio.. It was erected in 1745. It stands in the centre of an area where four great avenues meet, and from which there are entrances to the viceregal lodge, and that of the chief secretary. The trees which shade the avenues form vistas, through which the perspective view of the column forms a picturesque object. The pillar is formed of Portland stone, and is of the Corinthian order, fluted, and highly ornamented—the base and pedestal five feet in height, the shaft and capital twenty, and the phœnix which surmounts the column five feet, so that the whole presents an object thirty feet high.

The Napoleon Column has justly been considered as the greatest ornament of the French capital. It stands in the Place Vendôme, and was erected to commemorate the successful result of Bonaparte's arms in the German campaign of 1805. Its total elevation is one hundred and thirty-five feet, and the diameter of its shaft is twelve feet. It is in imitation of the pillar of Trajan at Rome, and is built of stone, covered with bas-reliefs (representing the various victories of the French army), composed of twelve hundred pieces of cannon taken from the Russian and Austrian armies. The bronze employed in this monument was about three hundred and sixty thousand pounds' weight. The column is of the Doric order. The bas-reliefs of the pedestal represent the uniforms and weapons of the conquered legions. Above the pedestal are festoons of oak, supported at the four angles by eagles, in bronze, each weighing five hundred pounds. The bas-reliefs of the shaft pursue a spiral direction from the base to the capital, and display in chronological order the principal actions of the campaign, from the departure of the troops from Boulogne to the battle of Austerlitz. The figures are three feet high; their number is said to be two thousand, and the length of the spiral band eight hundred and forty feet. Above the capital is a gallery, which is approached by a winding staircase within, of one hundred and seventy-six steps. The capital of the column is surmounted by an acroterium, upon which stands the statue of Napoleon, measuring eleven feet in height, and weighing five thousand and twelve pounds. The total expense of this sumptuous monument was 1,500,000 livres.

There are also several smaller columns, but of beautiful proportions, in various parts of England, in imitation of the above, but mostly of the Grecian or pure Doric order, as the Anglesea Column, erected in commemoration of the battle of Waterloo, and the noble earl of that name, in the island of Anglesea; the column at Shrewsbury, erected in commemoration of the same event, and of another noble general, Lord Hill; the Nelson Columns at Yarmouth and in Dublin; the Wellington Column at Trim, in the county of Meath, Ireland; the monument commemorative of Lord Melville at Edinburgh; and a similar one at St. James's Park of the Duke of York, &c. A very common error is committed in the erection of monumental columns, by loading their summit with a clumsy mass of masonry, on which the statue is placed, and technically called an *acroterium*. The Melville monument at Edinburgh presents the most notable instance of this kind of defect. If there must be an acroterium, it cannot be too modest in its proportions, or too little seen by the spectator.

BRIDGES.

The art of bridge-building is traced to the Romans. In the brightest days of the Grecians, when their fine style of architecture was complete, when their porticos were crowded with paintings and their streets with statues, the people of Athens waded or ferried over the Cephisus for want of a bridge. The Greeks do not seem to have valued the construction of the arch sufficiently, to excel in bridge-building. No people of the ancient world carried the power of rearing the stupendous arch and the magnificent dome to such an extent as the Romans. After the construction of their great sewers, the aqueducts, and the cupola over the Pantheon M Agrippa, a bridge over the Tiber was of easy execution and the invention of the architecture of stone bridges, a practised in its best and most effectual manner, must be conceded to this great and indefatigable people. The most celebrated bridges of ancient Rome were not distinguished by the extraordinary size of their arches nor the peculiar lightness of their piers, but, like the rest of the magnificent works of this city, as far as constructior is concerned, they are worthy of study from their excellence and durability. The span or chord of their arches seldom exceeded seventy or eighty feet, and the versed sine or height was nearly half of the chord, so that they were mostly semicircular, or constituted a segment nearly of that form.

Among the most celebrated bridges in modern times, or those built subsequently to the destruction of the Roman empire, are those of the Moors in Spain, who imitated and rivalled the best constructions of the Romans. In Great Britain, the art of building bridges appears to have been diligently studied from early times. The most ancient bridge in England is the Gothic triangular bridge at Croyland, in Lincolnshire, said to have been built in 860. The ascent is so steep that none but foot passengers can go over it—a common peculiarity of old bridges.

The greatest improvement effected in modern times upon bridge-building consists in constructing them with so level a surface or roadway above, that they are easy of access. The most splendid work of art of this kind is Waterloo Bridge, across the Thames. Its length is 1250 feet. It consists of nine elliptical arches, each of 120 feet span and 32 feet in height. Westminster Bridge was commenced in 1740, and completed in 1750. It is 1220 feet long, and 44 feet between the parapets; has thirteen large and two small arches, all semicircular. The middle arch is 76 feet in span. The newly-erected London Bridge is also an elegant structure, and excepting Waterloo Bridge, is perhaps the finest bridge in the world. At Paris there are some remarkably good stone-bridges across the Seine, also an excellent suspension bridge. One of the most curious provincial bridges in Great Britain, is that at Taff, in Glamorganshire. It is of one arch, and its span is rather more than 140 feet. The architect of this bridge was a poor uneducated man; and the persevering courage with which he pursued his object till the completion of the edifice, is worthy of record. His first attempts failed, in consequence of the enormous pressure of the haunches or sides of the bridge, which forced up the key-stone; and to obviate this, he pierced the stonework with cylindrical apertures, which remedied the defect. Prior to the erection of this bridge, that of the Rialto at Venice had the largest span of any in existence.

Metal bridges are the invention of British artists. The true elements of their construction are as yet but imperfectly understood. The Southwark bridge over the Thames is at present the finest iron bridge in the world. It consists of three arches. The chord of the middle arch is 240 feet long, and its height 24 feet. There are several other fine bridges of this kind in England, in particular one at Sunderland, in the county of Durham.

The art of making suspension bridges is not new, but it is only in recent times that it has been brought to perfection. In this kind of erection the flooring or main body of the bridge is supported on strong iron chains or rods, hanging in the form of an inverted arch, from one point of support to another. The points of support are the tops of strong pillars or small towers, erected for the purpose. Over these pillars the chain passes, and is attached at each extremity of the bridge to rocks, or massive frames of iron firmly secured under ground.

The largest suspension bridge in Great Britain is that erected by Mr. Telford over the Menai Strait, between the Isle of Anglesea, and the mainland of Caernarvonshire, in North Wales. The roadway is 100 feet above the surface of the water at high tide, the opening between the points of suspension is 560 feet, and the platform 30 feet in breadth. This elegant and stupendous work has been outmatched by the suspension bridge across the river Saane, at Friburg, in Switzerland, erected by M. Chaley, a French engineer. The bridge is entirely of one span, and perfectly level. The roadway, which is of wood, is supported not by solid iron rods, as is usual with such fabrics, but by four cables of small iron wires, each cable being composed of 1056 wires, bound in close union by bands of wires at regular distances; the thickness of each cable may be about ten inches. The total length of the roadway is 905 feet, its elevation above the bed of the Saane 174 feet, and its breadth 28 feet. The striking grandeur of this stupendous work of art cannot be described. The bridge must be visited in order fully to appreciate its wonderful architectural excellences.

THE PRACTICE OF ARCHITECTURE.

Architecture is practically conducted by two distinct classes of men—*architects*, whose profession consists in planning designs of buildings according to the wish of an employer; and *builders*, who, assisted by operative masons and other artisans, work out the plans in all their various parts. Some architects derive celebrity for designs for churches and public edifices, others for domestic structures, and a third class, who are sometimes styled *civil engineers*, are eminent for their plans of piers, quays, bridges, docks, aqueducts, and other great public works.

In representing proposed edifices by drawings, architects make use of the plan, elevation, section and perspective. The *plan* is a map or design, of a horizontal surface, showing the ground-work, with the relative position of walls, columns, doors, and other details. The *elevation* is a drawing of the front, without any perspective effect. The *section* shows the interior of the building as if the outer wall were removed. The *perspective* shows the building as it appears to the eye at a little distance, and is generally executed so as to give the effect of a picture. Along with the different designs, *specifications* of the work to be executed are put into the hands of the builder; these specifications are minute definitions of what must be done in the departments of the stone-mason, bricklayer, joiner, slater, plumber, glazier and plasterer, as well as of the nature of the materials to be employed.

The rules of building require, that in a whole fabric judiciously and elegantly erected, there should be solidity, convenience and beauty, along with simplicity and harmony of design. The structure, whatever it is, must be in character, or look like that for which it is intended. If a church, it should have the appearance of a church; if a house, a house; and if a castle a castle. Some tastes would construct a cottage in the shape of a Norman fortress, with battlements and loop-holes; but all such oddities are essentially vulgar. It is an important principle in architecture to preserve character, and to make a building expressive yet simple in its outlines, and all of a piece. If there is ornament, it must be duly distributed, not overloaded at one part and meagre at another. The design, to be striking, must also be of a height and breadth sufficient to fill the eye of the spectator. To aid in this desirable object, the buildings should be well placed, and, if possible, at the summit of slightly rising grounds, where they will stand clear of ungraceful objects. Unfortunately this principle has not always guided our architects. Magnificent temples which crowned the summits of rising grounds in Greece, we find imitated in hollows; and the eye of the spectator, instead of taking in a bold and lofty outline of pillars relieved against the clear blue sky, is offended by looking down upon clusters of chimney-pots. Thus innumerable public buildings in England and Scotland, possessing, intrinsically, good architecture, are greatly spoiled by the want of taste in those who have placed them in unseemly awkward situations. It appears to us, likewise, that far too little attention is usually paid by architects to the nature of our climate. We cannot recall to remembrance one public edifice in the Grecian style in this country which does not exhibit a dingy damp look. At every projecting point, and particularly over the pediments, pillars, and flat cornices of doorways, there is generally an ugly spot covered with moisture, and exhibiting the early rudiments of vegetation on the walls. All this offends the eye of the spectator, and excites universal notice, except among those who can see nothing but beauty in Grecian architecture, however clumsy it may be, and however much out of place. Architects likewise require to guard against introducing forms which will revive recollections of unpleasing or mean objects. Fine buildings have been rendered ridiculous by inattention to this point. One structure is defaced by a dome the exact model of an inverted punch-bowl; the pinnacles of another resemble the upturned legs of a foot-stool; the front of a third is like a grenadier's cap; and the corners of a fourth are defaced by turrets the shape of pepper castors. The most distant resemblance to all familiar objects ought to be carefully shunned.

Another point requires consideration. In cases where ornament is not introduced on a large scale, masses of wall will be greatly improved by being thrown into different projections; and this leads us to notice that the effect of interiors, when ornamented with pillars, is vastly enhanced by causing some to project and others to recede, thus gratifying the eye with what is seen, and raising hopes of beauties in those parts which are partially hid from observation. This breaking into seen and unseen parts is well exemplified in the church of St. Genevieve at Paris.

Certain practical matters equally require attention in the erection of buildings. The foundation must be laid on a solid basis of rock, gravel or till; and if the situation be soft or of doubtful stability, the ground should be fixed by piles of timber driven to a considerable depth. It is likewise a point of first importance to have the stool or lower part of the house free of damp; and this is only attainable by excavating the loose earth, and paving the surface with a material impervious to moisture. In general, in the construction of cottages or villas, far too little attention is paid to this particular, and they are therefore much colder and more damp than they ought to be.

In designing windows, the approved rule is to make each twice its width in height; those in the upper-floor story are generally made nearly square, but it is preferable to make them a third higher than broad. The stairs should be of easy access; the rise of each step to be six, or not more than seven inches, and the breadth at least ten inches.

MATERIALS USED IN ARCHITECTURE AND KINDRED ARTS.

Stones.

Marble.—The class of rocks denominated *calcareous* are exceedingly numerous and abundant in nature; and of these, marble in its different varieties is one of the most beautiful. It is a granular carbonate of lime, varying in colour, texture, and hardness, and being susceptible of a fine polish, it is extensively used for building, statuary, decorations, and inscriptions. In dry and temperate countries, it is one of the most durable of substances, as is proved by the edifices of Athens, which have retained their polish for more than two thousand

years. Severe frost, preceded by moisture, causes it to crack and scale; and great heat reduces it to quicklime. Marble is wrought by chiselling, and by sawing with smooth plates of iron, along with sand and water. It is polished by rubbing with sand and water, and afterwards with putty and other soft substances.

Numerous stones of the calcareous class, more or less approaching to marble in their character, have been converted to use in different countries. The pyramids of Egypt are built of a grayish-white calcareous stone, enclosing shells. The Parthenon and other structures of Athens are of Pentelican marble, distinguished by slight green veins. The mosques of Constantinople are of a fine-grained limestone from Pappenheim, the same which is now used in lithography. At Rome, a porus whitish limestone, called *tophus* by the ancients, and *travertino* by the moderns, is the material of the Coliseum, of St. Peter's Church, and other structures. The ruins of Pæstum are of a stone nearly similar. Paris is built with a calcareous stone very prevalent in France, nearly the whole range of the Jura being of that material. The Portland stone, of which St. Paul's and other edifices in London are constructed, is a calcareous rock called *oolite* by geologists. (See article GEOLOGY.) Of those finer calcareous rocks, constituting the marbles, many are found in Great Britain, particularly in Wales and the Highlands of Scotland; but they are not wrought extensively, as they are not employed except for interior ornaments, such as chimney-pieces, and for this purpose they are excelled by foreign marbles of the pure white variety. The Parian marble, of which the Venus de Medicis is formed, is reckoned the finest of its kind.

Granite.—This is apparently the oldest and most deeply situated of all rocks, and is often found shot up to great heights among rocky materials of more recent formation. It is very hard and durable, and is obtained for the purpose of the architect or sculptor in larger pieces than any other rock. Granite is a compound stone, varying in colour and coarseness, having generally a whitish-gray or mixed appearance. It consists of three constituent parts, namely, *quartz*, the material of rock crystal; *feldspar*, which gives its colours, and which is the material of porcelain earth; and *mica*, a transparent, thin, or foliated substance, which affords a flexible substitute for glass, when obtained in large pieces. Granite is chiefly used for building. It is split from the quarries by rows of iron wedges driven simultaneously in the direction of the intended fissure. The blocks are afterwards hewn to a plain surface by strokes of a sharp-edged hammer. Granite is also chiselled into balustrades, capitals, and other ornamental objects; but this operation is difficult, owing to its hardness and brittleness; it is polished by long-continued friction with sand and emery. There are large quarries of granite in the British islands, particularly near Dublin and Aberdeen; the stone from the latter is highly celebrated, and has been used in building Waterloo Bridge in London.

Porphyry.—This, like granite, is a compound rock, commonly consisting of felspar and quartz; the former in more or less distinct crystals; there are, however, several varieties. The colour of porphyry is often red or green, and, when polished, is valuable for ornamental work, being superior to marble on account of its greater hardness. This rock abounds in Egypt, in Mexico, and in South America; it also exists in the vicinity of Boston, in North America.

Lapis Lazuli.—This is a stone of splendid azure-blue colour, often mingled with small crystallizations, and thready lines of gold-like metal. The finest specimens are brought from China, Persia, and Great Bucharia. It is much esteemed for ornamental purposes, especially for pillars and inlaid work. The most superb exhibition of this rare substance is made in the celebrated marble palace built by Catherine, at St. Petersburg, for her favourite Orlof, in which the[illegible] are costly apartments inlaid with lapis lazuli. The great expense prevents it from being used to any extent in Great Britain, where, however, it is occasionally well imitated on wood by decorative painters. It is employed in forming the valuable pigment called *ultramarine*.

Freestone, or, more properly, *sandstone*, consists of particles of sand, or silica, united by a natural cement and great pressure. It varies in colour from dusky red to yellow and grayish-white. The most esteemed for building is the yellow or white kind, and particularly that which possesses no tinge of iron. The best varieties are hard, but easily wrought by hammers and chisels, and are so close in texture as not to scale off or moulder through the influence of the weather. Those kinds which are inclined to softness, should, after building, be smeared with a light varnish of oil, to fill the pores and prevent the encroachments of damp. The thinnest possible pellicle of white oil paint will be found to render sandstone indestructible by weather. Freestone is largely employed in Great Britain for fronts to public edifices and churches, but is not much employed in domestic architecture. The chief towns built of it are Bath, Edinburgh, and Glasgow. Near Edinburgh, and also in Fife, there are large quarries of this useful stone, suitable either for architecture or sculpture.

Trap.—The variety of this class of rocks, usually called *greenstone*, and in Scotland *whinstone*, is largely used in some places for house-building. It is a hard bluish substance, which breaks easily into square lumps, but is too brittle for polishing like sandstone. Quartz, felspar, and hornblende, form a variety of trap called *sienite*. All varieties of trap make excellent materials for macadamizing roads.

Bricks.

Bricks are artificial stones formed of clay, one of the most abundant and useful of earths, composed principally of alumine and silex. When wetted, clay assumes the character of a tenacious paste, which is changed by heat to a stony hardness. Common clay, of which bricks are most generally made, and also coarse potter's ware, contains oxide of iron, which causes it to turn red in burning. The purer sorts burn to a yellow appearance, and pipe-clay becomes white. *Refractory* clays are those which endure the greatest heat without melting. The best fire-brick, or that which is capable of resisting the action of the fire in ordinary furnaces, is made from a slaty kind of clay, and contains a good deal of sand.

"The general process of brick-making consists in digging up the clay in autumn; exposing it, during the whole winter, to the frost and the action of the air; turning it repeatedly, and working it with the spade; breaking down the clay lumps in spring, throwing them into shallow pits, to be watered and soaked for several days. The next step is to temper the clay, which is generally done by the treading of men or oxen. In the neighbourhood of London, however, this process is performed in a horse-mill. The kneading of the clay is, in fact, the most laborious but indispensable part of the whole business; and that on which, in a great measure, the quality of the bricks depends. All the stones, particularly the ferruginous, calcareous, and pyritous kinds, should be removed, and the clay worked into a homogeneous paste, with as little water as possible. The earth being sufficiently kneaded, it is brought to the bench of the moulder, who works the clay into a mould made of wood or iron, and strikes off the superfluous matter. The bricks are next delivered from the mould, and ranged on the ground, and when they have acquired sufficient firmness to bear handling, they are dressed with a knife, and staked or built up in long dwarf walls, thatched over, and left to dry. An able workman will make, by hand, 5000 bricks in a day."

Bricks are baked either in large square masses, called *clamps*, in which there is a layer of brick and small coal alternately, or in kilns. Baking in kilns, continues our authority, is preferable, "as less waste arises, less fuel is consumed, and the bricks are sooner burnt. The kiln is usually 13 feet long by 10½ wide, and about 12 feet in height. The walls are one foot two inches thick, carried up a little out of the perpendicular, inclining towards each other at the top. The bricks are placed on flat arches having holes left in them resembling lattice-work; the kiln is then covered with pieces of tiles and bricks, and some wood put in to dry them with a gentle fire. This continues two or three days before they are ready for burning, which is known by the smoke turning from a darkish colour to transparent. The mouth or mouths of the kiln are now dammed up with pieces of bricks piled one upon another, and closed with wet brick earth, leaving above it just room sufficient to receive a fagot. The fagots are made of furze, heath, brake, fern, &c., and the kiln is supplied with these until its arches look white and the fire appears at the top; upon which the fire is slackened for an hour, and the kiln allowed gradually to cool. This heating and cooling are repeated until the bricks are thoroughly burnt, which is generally done in forty-eight hours. One of these kilns will hold about 20,000 bricks."—*Ure's Dictionary of Arts.*

Mortar, Plaster, Cement.

Mortar.—The mortar or cement employed to unite stones or bricks into a compact mass in building, is formed of quicklime, sand, and water. Quicklime is procured by burning limestone in kilns. It is brought from the kilns in the form of *shells* or brittle masses, which are reduced to powder by pouring water upon them. This process is called the slaking of the lime. When intended for mortar, it should immediately be incorporated with sand, and used without delay, before it imbibes carbonic acid from the atmosphere. Lime, thus mixed with sand, becomes harder and more cohesive and durable than if it were used alone. It is found that the sand used in common mortar undergoes little or no change; while the lime, seemingly by crystallization, adheres to its particles and unites them together. The mortar or cement formed in this manner continues to increase in strength and solidity for an indefinite period, the hydrate of lime being gradually converted into a carbonate. Such is the strength which mortar thus acquires by time, that in some old buildings the lines of cement remain entire, while the stones have decayed.

In making mortar, fresh sand from a pit is to be preferred to that taken from the sea-shore, the salt of which is liable to keep the building moist, and to weaken the strength of the cementing property. The sand most proper for mortar should consist of angular particles not rounded by attrition. The proportions of the lime and sand to each other are varied in different places; the amount of sand, however, always exceeds that of the lime. The more sand that can be incorporated with the lime the better, provided the necessary degree of plasticity be preserved; for the cement becomes stronger, and it also sets or consolidates more quickly, when the lime and water are less in quantity and more subdivided. The more pure the lime, and the more thoroughly it is beaten or worked over, the more sand it will take up, and the more firm and durable does it become. In many cases, modern builders pay little or no attention to the slaking and preparing of their mortar, which, from whatever cause, is very inferior to the ancient cements.

Plaster, or the material which is used to spread smoothly over walls, is of various kinds. That which is applied to inner walls or partitions is formed of certain proportions of slaked lime, fine sand, and water, with an infusion of neat's hair to assist in giving cohesion. The lime requires to be sifted finely, and the more free it is of small lumps the better it is; as such lumps are apt to swell in the walls and cause blisters, it is usual to allow plaster to remain some time made before using.

Stucco.—This is the name ordinarily given to plaster of Paris, which is gypsum reduced to powder by heat and grinding. Gypsum, which is found in roundish hard masses, is properly a sulphate of lime, and like all other varieties of lime, it has a strong power of absorbing water. The practice is to put the masses into a heated oven, and when duly baked, to take them out and grind them to powder in a mill. This powder, when sifted, is a beautiful white substance, resembling flour. A quantity of powder being put in a vessel, water is poured upon it, and immediately the stuff thickens in a surprising manner, and becomes a hardened mass. While still thickening or setting, it is poured into a mould for any required shape; or it may be applied along with a little lime as a fine plaster, which it is desirable should dry speedily. It is used largely for all kinds of casts from pieces of sculpture, mouldings for cornices, and is indispensable in stereotyping.

Mastic.—This is a resinous substance obtained from incisions made in the branches of the *pistachia lentiscus*, a small tree or shrub growing in the Levant and other countries bordering on the Mediterranean. It abounds in Scio, where it has long been cultivated. The gum being chewed or used as a *masticatory* by women in Turkey, for the purpose of cleansing the teeth and imparting an agreeable odour to the breath, hence its European name of *mastic*. The mastic used by builders for closing seams in outer walls is generally composed of Roman cement, oil, and sand, the whole mixed as a paste; it takes a considerable time to dry, but ultimately becomes hard and durable.

Puzzolano.—Water cements, also called Roman cements, are those which have the property of hardening under water, and of consolidating almost immediately on being mixed. Common mortar, although it stands the effect of water very well when perfectly dry, yet occupies a considerable time in becoming so, and dissolves or crumbles away if laid under water, before it has had time to harden. It is found that certain rocks which possess an argillaceous as well as a siliceous character, if mixed with lime or mortar, communicate to them the property of hardening in a very few minutes after the mixture has taken place, as well under water as out of it. Substances of this sort have therefore been made the basis of water cements. The ancient Romans, who practised building in the water, and particularly in the sea, to a great extent, first availed themselves of a material of this kind. They erected their villas, not only on the sea-shore, but in artificial quays and islands constructed in the water. To enable them to erect these marine structures, they fortunately discovered, at the town of Puteoli, a peculiar earth, to which they gave the name of *pulvis puteolanus*, and which is the same as that called by the modern Italians *Puzzolano*. This earth is a light porous friable mineral, various in colour, and evidently of volcanic origin. When reduced to powder by beating and sifting, and thoroughly mixed with lime, either with or without sand, it forms a mass of great tenacity, which in a short time cements to a stony hardness, not only in the air, but likewise when wholly immersed in water.

Cements of various kinds are employed for covering the outer walls of buildings, so as to resemble stone. One of the best, we believe, is Martin's Patent Cement, which is extensively used in England, in imitation of Bath, Portland, and other descriptions of stone. A very excellent plan of cementing for this purpose is to employ good plaster of lime and sand; only two coats to be

laid on and finished without stucco, and afterwards well painted. If stucco be dressed on as a third coat, it will scale off.

Pavements—Roofing.

Pavements are formed of marble, stone, slate, or some kind of artificial compound. Marble, on account of its costliness, is little employed for this purpose in Great Britain; and the floors of lobbies, halls, and also pathways, are more generally formed of slabs of sand-stone, bedded on mortar, and neatly joined together. The stone employed for pavements exposed to the atmosphere should be hard, and not liable to scale off by the effects of the weather. Stone inclining to slate forms the most durable pavement, and possesses the great advantage of being impervious to damp. The floors of churches in the Netherlands, and also the common pavements of that country, are of a material of this kind, and we should recommend the use of slate for ground-flooring in all similarly damp countries and situations.

Wooden pavement.—The idea of paving with pieces of wood, the points of the grain upwards, was propounded in the year 1825, but was not carried into execution till nearly fifteen years later. Two plans have been pressed on public attention; the first is that of Mr. Stead. It consists of pieces of wood, each from four to eight inches deep, as cut lengthwise from the timber, and about six inches across, but fashioned round the sides into a hexagonal shape; these are set in rows on a flat basis, and are held together by mutual pressure throughout the mass. This plan, by which individual pieces are apt to sink and form ruts or hollows, is, in our opinion, inferior to that of an ingenious foreigner, Count de Lisle, which is conducted by the Metropolitan Wood-pavement Company, in London. By this plan, a squared piece of timber is cut diagonally into pieces, rhomboidal in shape, or each the stereotony of a cube. The size is six inches deep by nearly the same in width. The pieces are set on a flat basis, one overlapping the other, and are held together and in their places by pins in the sides.

When one row has been laid down, all the pieces lean in one direction across the street, the next row being made to lean the contrary way, and so on with all succeeding rows. By means of the pins in the side, each row is fastened close and firmly up to the other, so as to prevent all shifting. If we now examine the principle on which the pressure is sustained by the united blocks, it will be observed that, by means of the overlapping, no single block supports any given pressure that falls upon it, except at a point in the middle; at other points, the pressure is distributed over at least two blocks—the upper part of one, and the lower part of another. The resistance which is therefore given by the mass to all the ordinary kinds of pressure from horses and vehicles, must be much greater than that offered by blocks standing isolated, either with respect to overlapping or pinning. Another very great advantage is the mode of laying down blocks pinned together in masses. It seems that lumps of a yard square, or thirty-six blocks, may be put down at once, and that a mile of street could be laid down in three days. In the event of after-repairs, or when the streets are to be opened for laying gas or water pipes, these lumps can again with ease be taken up and laid aside. Across the upper surface, grooves are cut at short intervals, to afford indentations for the horses' feet. The whole, when laid in a proper manner, has the appearance of neat oblong pavement.

The advantages of wood over stone pavement are far greater cleanliness, as respects either dust or mud, much less noise, and in some places considerably less expense. The only disadvantage, as far as we have ever heard, is the over-smoothness of surface, in consequence of which horses have a tendency to slip and come down. In London and various towns in England, the Count de Lisle's plan has latterly spread considerably, and is now generally esteemed. It does not appear likely to come into use, however, in places where stone is abundant. The cost of about 11s. or 12s. per square yard for wooden blocks may be cheap in London, but would be excessively high in Edinburgh and other places where stone abounds.

Slates.—The thin and trimmed laminæ of slate from the quarries form the handsomest and most durable roofing for all kinds of houses in which a slope is allowable or required. The best kinds of this material are found in Wales, and are now thence imported to most seaports. Tiles, formed of burnt clay, are a more unsightly and less durable kind of roofing, but their comparative cheapness causes them to be largely employed for at least all common edifices. The neatest tiles are flat and angular, and are held to the rafters by pegs, the interstices of each row being plastered before lapping over the next above it. Those tiles are the strongest which contain a proportion of iron.

Asphalte has lately been adopted to a large extent in France and some other countries, both as pavement and as waterproof roofing for buildings. Asphalte, or asphaltum, is a bituminous mineral, allied in its nature to pitch, and is found in the form of rocky masses in different parts of the world. The chief quarries for it in continental Europe are in the Val de Travers, province of Neuchatel, the excavations being in the Jura range of mountains, which are calcareous in their nature. An inferior kind is a species of bituminous molasse, which exists in various parts in what must be called lakes, or vast semi-fluid masses. The true asphalte, or asphaltic cement of Neuchatel, is procured by boring and blasting the bituminous rocks, and the pieces being brayed and then melted in large boilers, the hot fluid is poured out so as to form conveniently-sized cakes. When needed for smearing on roofs, it requires to be only melted and spread, and when dry, it remains impervious to the weather, neither cracking in winter nor melting in summer. If designed for pavement, it is customary to mix fine river sand with it, which gives it more stability, and a degree of roughness that is not unnecessary. It is spread while hot on a properly prepared bed, and being rendered smooth on the surface, it offers an exceedingly agreeable resistance to the foot, being not so hard as stone, nor so soft as a mud pathway. Wherever stone is expensive, this asphaltic pavement may be advantageously employed, not for streets, but floors of dairies and other outhouses, garden-walks, and terraces.

Zinc (see article CHEMISTRY), a metal of a light-bluish tinge, has lately come into use for covering buildings, and also for forming gutters to carry off the rain from roofs. It is much thinner than lead, and being made in large rolls, it can be laid to any length; its lightness and comparative cheapness render it suitable for temporary edifices, and also for buildings which could not support a heavy roof. It does not oxidize or rust by exposure, and will last a long period of time if not damaged.

Note.—In the compilation of the present sheet, besides the authorities mentioned, we have been indebted to some learned articles in the "Encyclopedia Americana" (Conversations Lexicon), and also to "Elements of Technology," by Dr. Jacob Bigelow.

DICTIONARY OF CLASSICAL TERMS.

[The extensive use of classical terms and allusions in modern literature, places a serious stumbling-block in the way of all readers who have not received a regular scholastic education. Hence, such an explanatory dictionary as that contained in the present sheet, will prove, it is hoped, alike acceptable and useful to a large section of the public.]

Academia, a pleasant and finely wooded spot in the vicinity of Athens, which derived its name from the proprietor Academus, and became renowned as the spot where Plato taught philosophy to his pupils. These were thence termed Academics; and a familiar appellation, originating in the same source, is bestowed on seats of learning and education at the present day.

Achaia, a district of the Peloponnesus or Morea, the people of which held so considerable a station among the ancient Greeks, that their name was frequently used to denote the entire population of the country.

Achates, a follower of Æneas, so faithful and devoted that his name has become proverbially significant of constancy in friendship, being applied to Sir John the Graeme, among others, on account of his adherence to Wallace.

Acheron, a gloomy river in the fabulous infernal regions of the classical mythology, imagined by some writers to lie near the south-west extremity of the Euxine or Black Sea.

Achilles, son of Peleus, king of Thessaly, by the sea-goddess Thetis. Educated by Chiron, a learned centaur (half man, and half horse), Achilles is represented as having become perfect in all the accomplishments of his heroic age, and had just attained the prime of youthful manhood, when the princes of Greece went to war with Troy. Thetis, foreknowing that her son would fall in that contest, disguised him as a female to prevent his entering into it, but he was detected, and, not against his will, went with the other chiefs to Troy, where he distinguished himself above all the Greeks by consummate daring and prowess. A quarrel with the leader, Agamemnon, caused him at length to withdraw in disgust from the field; and, in spite of the entreaties of his countrymen, he remained obstinately inactive in his ships, until the death of Patroclus by the hand of Hector caused him to don the splendid panoply formed for him by the armourer of the gods, and rush to the scene of battle. Many Trojans fell before the infuriated chieftain, and, finally, Hector himself was cast lifeless on the field. In his youthful days, Thetis had rendered her son invulnerable by dipping him in the river Styx; but the tendon of the heel by which she held him (hence called the *tendo Achillis*) was left unsecured, and Paris, the brother of Hector, slew the chief by a wound in that spot, thus fulfilling the decree of fate. Strength, swiftness, and beauty of person, are the leading characteristics assigned to Achilles by the poet Homer; and it is worthy of remark, that speed of foot is one of the most valued qualities of a Greek chief at this day, Marco Bozzaris, a man worthy of the old times, being renowned for this property.

Acis, a son of Faunus, slain by the one-eyed giant Polyphemus, on account of a rivalry between them for the love of the nymph Galatea. The latter changed Acis into a river, yet called the Jaci. Handel produced a fine opera on the subject of Acis and Galatea.

Acrocorinthus, the citadel rock of Corinth, an eminence of great height and strength.

Actæon, a Boeotian huntsman, who, having accidentally beheld Diana bathing, was changed by the chaste goddess into a stag, and torn to pieces by his own dogs. The "Fate of Actæon" is a phrase expressive of the ruin of a man by his own friends, or from unwittingly becoming cognisant of dangerous secrets.

Adonis, a youth of great beauty beloved by Venus, who, on his being gored to death by a wild boar, converted him into the flower Anemone. Some say, however, that life was granted to him during six months of every year, at the entreaties of Venus.

Æneas, a Trojan prince, son of Anchises and Venus, who, on the fall of Troy, is said to have wandered with a small band to Italy, and there to have laid the foundation of the Roman empire. The Romans were proud of this traditional descent; and Virgil made it the subject of his great national epic.

Æolus, the god of the winds, according to the classical mythology. The "Æolian harp" derives from him its designation.

Æschylus, a tragic writer of Athens, whose style is peculiarly vehement and sublime.

Æsculapius, a personage honoured as the god of medicine, and reputed to be the son of Apollo by a mortal nymph. Exposed in infancy to save his mother's reputation, he fell under the care of Chiron the centaur, and acquired such skill in the healing art as even to recover dead persons from the grave. For this feat, Pluto, the king of the nether realms, persuaded Jupiter to kill him with a thunderbolt. Many temples were erected to Æsculapius; and he was generally represented in the form of an old man, with one hand on a staff and the other on a serpent's head. The latter animal is to this day the emblem of medical science; and the name of the supposed divinity is familiarly applied to the art and its professors.

Æsop, a native of Phrygia, renowned as a writer of fables. His actual productions are lost; but the Latin fabulists profess to have translated from his original Greek. He is stated to have been deformed in person, and a slave by station.

Ætna, the most famous volcanic mountain in the world, situated in Sicily, and rising to a height of more than 11,000 feet above the sea-level. The noise and flame emitted from it led the imaginative ancients to make its interior the workshop of the smith-god Vulcan.

Agamennon, king of Mycenæ, in the Peloponnesus, and leader of the Greeks in the expedition against Troy. The character given to him by Homer is one of massive grandeur. He was murdered, on his return home, by his wife Clytemnestra and her paramour Ægisthus.

Aglaia, one of the three Graces.

Agrarian Law.—During the times of the republic, some ambitious men endeavoured to win the favour of the Romans by passing a law for the equal division among them of portions of individual property. Great disturbances followed. The phrase is yet often used to signify arbitrary divisions of individual property among a community.

Agricola (Cn. Julius), a Roman general, who, under various emperors, served with great distinction in Britain, defeating Galgacus, among others, near the Grampian hills.

Ajax, son of Telamon, and famous in the war of Troy for his bravery, and vast though unwieldy strength. He became mad, and slew himself, because the arms of the deceased Achilles were not assigned to him. Another Ajax also figured in the same contest.

Alcestis, wife of Admetus, king of Pheræ, who vo

untarily died for her husband's sake, and was brought again from the regions of the dead by Hercules.

ALCIBIADES, an Athenian noble, remarkable for beauty of person and intellectual capacity, and not less notorious for his vices and luxurious effeminacy. He was a pupil of the philosopher Socrates, and owed much to his instructions. After a youth spent for the most in folly, yet folly redeemed in part by generous actions, he entered into the service of the state, and showed eminent talents as a military and naval commander. However, his fickle countrymen, influenced by demagogues, soon found cause of quarrel with him. In his absence, some of his wild frolics were represented as a profanation of the rites of religion, and he was recalled for trial. He did not obey, and his property was confiscated. Boiling with indignation, the high-spirited Alcibiades united himself with Sparta and Persia, the rival and the enemy of Athens. The latter state began then to decline before its adversaries, until Alcibiades relented, and restored its fallen fortunes. But after raising him once more to command, the Athenians anew pulled him down, and Alcibiades took refuge first in Thrace, and afterwards in the Persian possessions in Asia Minor. The viceroy there grew jealous of him, however, and sent assassins to his lodging, who, not daring to meet him hand to hand, basely slew him by projectile weapons as he attempted to escape. Alcibiades was a being of great and varied endowments, but his life proves he was deficient in that settled rectitude of principle which can alone constitute the perfect statesman and hero.

ALECTO, one of the three Furies, daughters of Nox or Night.

ALEXANDER, a name borne by several Macedonian princes and others, but rendered chiefly illustrious as the designation of the son of Philip of Macedon by his wife Olympias. Born about 356 B.C., Alexander enjoyed in youth the advantage of the instructions of Aristotle, and showed, at the age of fifteen, the well-developed qualities of a commander and prince. When he succeeded to the throne, he first brought to submission the states around him, and then looked abroad for a wider field wherein to gratify his boundless ambition. Persia was the quarter to which his eyes naturally turned; and after arousing the Greek republics to join him, he marched into Asia. On the banks of the Granicus he defeated the Persian monarch, Darius, and in a second engagement the latter lost his life. Asia Minor, Tyre, Egypt, Media, Syria, and Persia, succumbed in turns to the conquering Macedonian, and he even pushed his victories beyond the Indus. Returning to western Asia, he perished suddenly at Babylon, either through poison or excesses in drinking. The extent of Alexander's conquests has amazed posterity; and the marvel has not been lessened by the fact, that his possession of the territories overrun by him was not temporary, but laid the foundation of many new kingdoms for his successors. Great virtues and great vices were mingled in Alexander's character. One striking proof of his transcendant talents is, that during his life he ruled with ease the numerous and able chiefs who, at his death, disdained to stoop to any other man, and showed each the capabilities of a great ruler. They originated so many separate kingdoms as to change the face of the world.

ALEXANDRIA, a city of Egypt, founded by Alexander the Great, famous for its lighthouse, its learned men, and its two splendid libraries, successively destroyed by Augustus Cæsar and the Caliph Omar.

AMALTHEA, the reputed nurse of the god Jupiter, whom she fed with goat's milk. Some mythologists say that she herself was a goat, and her horn is often termed the Horn of Plenty.

AMAZON.—The Amazons are said to have been a tribe of Thian women, who did not allow men to live with them, killed the majority of their male children, and trained their female offspring to war, burning off their right breasts for the better use of the bow. Whether an imaginary race or not, the word Amazon has become a proverbial designation for a woman of masculine habits and temperament.

AMMON, a name under which Jupiter was worshipped in Egypt. An oasis in the deserts bordering on the Nile contained a famous temple and oracle of Jupiter Ammon, the ruins of which are still discernible.

AMPHICTYON, a person who founded a general council for the twelve leading states of Greece, and from whom such assemblages were permanently called Amphictyonic councils.

AMPHION, an individual of semi-divine origin, who founded Thebes, in whole or part, and is stated to have excelled so much in music as to have moved the stones voluntarily to take their places in the structures of the new city.

AMPHITRYON, husband of Alcmena, the mother of Hercules by Jupiter. An expression of Moliere in a play on this subject, "l'Amphitryon où l'on dine," has caused a hospitable dinner-giver to get the familiar name of an Amphitryon.

ANACREON, a bard of Ionia, whose graceful verse is devoted to love and wine.

ANDROMACHE, wife of Hector and mother of Astyanax, celebrated by Homer for her conjugal affection and domestic virtues.

ANDROMEDA, daughter of an Ethiopian king, who, being chained to a rock, and exposed to a sea-monster, was rescued from that peril by Perseus, son of Danäe, and, by promise, became his wife.

ANTÆUS, son of the Earth and Sea, a Libyan giant, slain by Hercules. When a man seems to derive fresh vigour from an overthrow, he is compared to Antæus, because, at every fall, his mother earth gave that giant fresh strength; and Hercules only foiled him by holding him up, and squeezing him to death.

ANTINÖUS, a friend of Adrian, whose form, as represented by ancient sculptors, has become significant of a peculiar description of physical beauty.

ANTONIUS (MARCUS), a Roman, who shared for a time the empire of the world with Augustus Cæsar. Antony was a follower of Julius Cæsar, and when that great leader was slain by Brutus and Cassius, he joined Augustus Cæsar in pursuing the conspirators to the death, when the two victors acquired almost uncontrolled dominion. Antony fatally revenged himself, at the same time, on Cicero, who had always been obnoxious to him. Being called to the east, he became enamoured of the beautiful but licentious Cleopatra, queen of Egypt, and passed years with her in luxurious inactivity. Roused by some proceedings of his colleague in power, Augustus Cæsar, Antony would have gone to war, but peace was restored by his marriage with the sister of Cæsar. He soon left this lady, however, to return to the east, where Cleopatra again threw her fetters around him. The consequence was an open and decisive war between the two lords of the world. Antony was vanquished at Actium, and fled to Egypt, where he committed suicide, and was followed in the same course by Cleopatra. Mark Antony was, in a measure, a Roman Alcibiades. Elegant in person, and engaging in manners, an admirable speaker, and distinguished equally for skill and endurance in war, he was at the same time a man of unbounded profligacy, and stained with every species of vice and crime.

ANUBIS, an Egyptian idol, represented with the head of a dog.

APELLES, a native of the isle of Cos, usually regarded as the greatest of the ancient painters. He followed for a time the fortunes of Alexander.

APICIUS, a noted Roman epicure, who expended

£800,000 on his appetite, and finally killed himself in fear of want, the £80,000 which still remained to him at the time being insufficient to sustain the proper rate of gourmandizing extravagance.

Apis, a god of the Egyptians, venerated under the form of a white bull.

Apollo, the son of Jupiter and Latona, god of the sun, music, medicine, and the fine arts. Born in the isle of Delos, he soon after slew the serpent Python, sent by Jupiter's wife to plague Latona, and thus gained for himself the name of the Pythian Archer. A noble ancient statue, existing in Rome, and splendidly described by Lord Byron, gives an image of him in this character. He is usually pictured as a beardless youth, holding a bow or lyre. Like others of the mythological deities, he is said to have had many amours with the daughters of earth, and even to have dwelt there for nine years as a shepherd, when expelled from heaven by his sire. The chief supplementary names given to him in poetry are, the Delian, Cynthian, Delphic, and Lycian god; and, as sun-god, he is commonly named Phœbus. His principal temples and oracles were at Delphi, Delos, and Claros, the Delphic one being the most renowned oracle of the earth. A youth of fine form is often styled an Apollo, and the poets allude endlessly to the god as their patron and guardian.

Aquarius, or the Waterman, the eleventh sign of the zodiac.

Arachne, a woman of Colophon, so well skilled in needle-work that she challenged competition with Minerva, and being defeated, hanged herself, on which the goddess changed her to a spider.

Arcadia, a pastoral region in the centre of the Peloponnesus, so much distinguished for natural beauty, and for the happy and simple life of its population, that the word has long been used to signify a scene of rural and inartificial enjoyment.

Archimedes, a geometrician of Syracuse, of great abilities. Among his other inventions, he is said to have discovered a mode of setting fire to ships from a distance by means of burning glass, a feat which Buffon proved to be not impracticable. When his sovereign suspected a tradesman of having used some alloy in making a golden crown, Archimedes was applied to in order to discover the truth. At a loss at first, the philosopher finally ran out of his house towards the palace, crying, *Eureka* (I have found it), the idea having occurred to him of immersing the crown in a vessel of water, and measuring what quantity of liquid ran over. He was killed at the siege of Syracuse, and, though interred with honour, the spot where he lay remained long unknown, till discovered by Cicero. Archimedes also invented the pumping-screw. A small part only of his writings is now in existence.

Archipelagus (Archipelago), a name given to any sea studded with islands, as the Grecian or Indian Archipelago.

Archons, the ancient title of the chief magistrates of Athens.

Arcturus, a star near the tail of the Great Bear.

Areopagitæ, the judges of the Areopagus, a seat of justice on a mount near Athens.

Arethusa, a nymph of Diana's train, changed by her mistress into a Sicilian fount, to preserve her from the pursuit of the Grecian river-god, Alpheus. The waters of the latter, however, were fabled to pass under the seas to join the fount.

Argo, a famous ship of antiquity, which is said to have carried Jason and a renowned body of Greeks (called the Argonauts to Colchis, a district on the eastern shore of the Black Sea, in quest of a Golden Fleece, surreptitiously taken from the Greeks. Numerous writers have treated of this subject. By many, the Argo is styled the first ship ever built.

Argus, a being with a hundred eyes, set by Juno to watch an earthly mistress of Jupiter, and slain by Mercury. A jealous custodian often receives the title of an Argus.

Ariadne, daughter of Minos, king of Crete, who, when the Athenian prince, Theseus, was shut up in the celebrated Cretan labyrinth to be devoured by a monster, gave him a clue of thread by which he extricated himself. The Clue of Ariadne has become a byword. Being cruelly abandoned by Theseus, Ariadne, according to the poets, gained the love of the god Bacchus, and by him was elevated to a place among the constellations.

Aries, the sign of the Ram.

Arion, a famous musician, who, when in peril of his life at sea, played so sweetly that some grateful dolphins bore him safely ashore.

Aristides, a statesman and warrior of Athens, whose conduct earned for him the title of the *Just*. He died virtuously poor.

Aristophanes, a famous comic satirist of Athens.

Aristotle, a Greek philosopher of the first rank, born at Stagyra, in Macedon, and hence called the Stagyrite. After studying under Plato, who valued him so much as to style him the *mind* of the school, Aristotle opened a seminary of his own, and long taught with great success. From his lecturing to his pupils while walking, they received the name of the Peripatetics. Aristotle also spent ten years as the tutor of Alexander the Great, who said that "Philip had given him life, but Aristotle had taught him to live well." By the aid of this prince, the philosopher was enabled to produce his "History of Animated Nature," describing from collected specimens. He also wrote on Physics, Metaphysics, Ethics, Logic, Rhetoric, and Criticism. His canons on the latter subject are yet held in high respect. Compelled to leave Athens, Aristotle died at Chalcis, at the age of sixty-five. His works prove his intellect to have been one of extraordinary acuteness.

Arria, wife of the Roman Poetus, famous for stabbing herself and saying, "Oh, Poetus, it is not painful!" when her husband hesitated to free himself in the same manner from his woes.

Ascanius, son of the Trojan Æneas, and successor to his power in Italy. The young inheritor and hope of a house or party is sometimes designated by this title.

Aspasia, a celebrated courtesan of Athens, mistress and ultimately wife of Pericles, and so eminent for her intellectual accomplishments that even modest women resorted to her to enjoy her instructive converse.

Astræa, the goddess of Justice in the classical mythology.

Atalanta, a princess of the isle of Scyro, of great beauty, and determinedly averse to matrimony. As she excelled in running, she consented to wed him who foiled her in a trial of speed, and defeated all her lovers, until one came forward who was favoured by the goddess of love. From that deity he received three golden apples, and was directed to throw them down at intervals in the race. The stratagem succeeded. Atalanta could not refrain from stopping to pick up the apples, and the lover obtained her hand. But, for subsequent disrespect to Jupiter, the pair were changed into a lion and lioness. The race of Atalanta is often alluded to.

Ate, the goddess of Evil.

Athos, a mountain of Macedonia, which a sculptor proposed to cut into a vast statue of Alexander the Great.

Atlas, a Titan or giant who warred with Jupiter, and was ultimately changed into the mountain, or chain of mountains, of the same name in Africa, which, from their height, were supposed to support the heavens. Hence the frequent allusions to the load of Atlas.

Atreus, king of Argos, who, having cause of offence against his brother Thyestes, caused the latter unwittingly to eat the flesh of his own children. The son of

Thyestes revenged this deed by slaying Agamemnon, the son of Atreus. The whole history of this family was a subject of horror and frequent allusion among the Greeks.

Atropos, one of the Fates or Parcæ, whose task it was to cut the thread of life.

Attica, a district of Greece, lying south of Bœotia, and west of the Ægean Sea. It was supposed to be so peculiarly favourable to genius, and its dialect to be so pure, that the phrase of "Attic wit" or "salt" became indicative of the highest literary merit, as garrets got the name of "Attics" from writers being too often the inhabitants of such poor places in times not far distant.

Atticus, an intimate friend of the orator Cicero, and a man pre-eminently distinguished by the superior qualities of his head and heart.

Aventinus, one of the seven hills on which Rome was built.

Avernus, a lake of Campania, so unwholesome and putrid that the ancients made it the entrance to the infernal regions.

Augeas, king of Elis, whose vast stables for oxen and goats were so overrun with filth that it was deemed impossible to cleanse them, until Hercules effected the task by turning a river into them. Difficult cases of purification or reformation are proverbially compared to this feat of cleaning the Augean stables.

Augurs.—The Augurs of Rome were officials who foretold events by sacrifices and divination.

Aurora, the goddess of the Morning, usually represented as drawn by two horses in a rose-coloured chariot. She was called sister to the sun and moon, and mother of the winds and stars.

Autolycus, a famous thief of antiquity, whose name is sometimes bestowed on the members of the same craft.

Babylon, the capital of Assyria, a city of vast size in early times, with walls 60,000 paces in circumference, 200 feet high, 50 feet in thickness, and in their circuit 100 brazen gates. Hanging gardens of great extent, the temple of Belus, and an artificial lake 160 miles in circumference, with large canals, were among the other wonders of the place.

Bacchantes, priestesses of Bacchus, who did honour to the god of wine by the most frantic and licentious orgies.

Bacchus, god of wine, son of Jupiter by Semele, who, being a mortal, fell a victim to her vain wish of seeing her lover in all the blaze of his divinity. Jupiter rescued her unborn child from the same fate, and placed him in his own thigh, until grown to infant maturity. Bacchus, in his adult state, underwent many adventures, according to the poets. He made an expedition to India with his bacchanalian followers, and made an easy conquest of the intermediate nations, teaching them the use of the vine. As Bacchus the conqueror, he is painted as drawn in a chariot by a lion and a tiger; and in other circumstances he is represented as a plump, smooth-skinned young man, with a crown of vine and ivy leaves, and a thyrsus or rod in his hand. His common names, besides that mentioned, are Iacchus, Liber, Bromius, Lyæus, and Evan. The rites in his honour were called Bacchanalia.

Baucis, a poor old woman of Phrygia, with her spouse Philemon, received Jupiter so kindly that he made their house a splendid temple, and created them his priest and priestess. Allowed to die together at their request, they were converted into trees. Dryden and Swift tell this story in verse.

Bavius and Mævius, two inferior and malevolent poets in the time of Augustus Cæsar, whose names have become a by-word for all envy of superior merit.

Belisarius, an able general of the Constantinopolitan emperor, Justinian, reduced to beggary in his old age, and afflicted with blindness. "*Date obolum Belisario*" (Give the smallest coin to Belisarius), the usual petition of the fallen soldier, has become proverbial.

Bellerophon, a son of the king of Ephyre, who, having committed an act of violence, fled to the court of Prœtus, king of Argos, where the queen fell in love with him, and, finding herself slighted, accused him to her husband. The latter sent Bellerophon to Lycia with sealed letters, desiring that the bearer should be put to death. The Lycian king sent his guest, with this view, against a monster called the Chimæra, but receiving from Minerva a winged horse called Pegasus, Bellerophon overcame the monster; and after other trials, ultimately wedded the daughter of the Lycian monarch. From this story, all letters unfavourable to the bearer have been called Letters of Bellerophon.

Bellona, sister and charioteer to Mars, the god of war.

Berenice, a name borne by several Egyptian princesses, one of whom was noted for her beautiful hair, which was placed by her in the temple of Venus. Being lost, the locks were said by the court-astronomers to have been turned into a constellation.

Bias, one of the seven wise men of Greece.

Boadicea (or Bendicea), queen of the Iceni ans, a tribe of South-Britons, who took up arms to avenge the outrages of the Romans, but, in spite of her undaunted conduct in the field, was vanquished by them, and poisoned herself.

Bœotia, a district of Greece, now forming part of Livadia, and lying between Phocis and Attica. Partly from an idea that the atmosphere of the region was peculiarly thick, the inhabitants gained a reputation for stupidity which has yet adhered to their name. Yet Pindar, Plutarch, and others of the brightest spirits of Greece, were Bœotians.

Boötes, a northern constellation near Ursa Major.

Boreas, a title of the north-wind.

Bosphorus, the early name of the strait of Constantinople.

Briareus, a famous gisnt with fifty heads and a hundred hands, son of the Heaven and Earth.

Brutus (Lucius Junius), a noble Roman, who, in the days of the last king of Rome, feigned himself an idiot to ensure his safety, but threw off the mask, and overturned the royal authority, when Lucretia fell a victim to the brutality of the son of Tarquin. When the sons of Brutus afterwards conspired to restore the Tarquins, he himself, as consul, was called upon to act as judge, and his high-minded victory over parental feeling has made his name immortal. Brutus (Marcus Junius), descendant of the preceding, who emulated his virtues and his fame. When the power of Julius Cæsar became dangerous to the liberties of Rome, Marcus Brutus, though one of his warmest personal friends, rose against him, and united with Cassius and others in stabbing him in the Capitol. Cæsar, as he received the last blow, uttered to him who dealt it the memorable words, "Et tu Brute!" (Thou, too, Brutus!). The friends of Cæsar were avenged at Philippi, where the chief conspirators fell; and Plutarch tells that Brutus was forewarned of the event by the spirit of Cæsar, which appeared in his tent, and said, "I will meet thee again at Philippi"—words often used to convey an indication of coming evil.

Bucephalus, a horse tamed by Alexander the Great in youth, and which became so renowned for bearing him in the field of battle as to give a common name to all spirited animals of its species.

Busiris, an Egyptian king, who followed the shocking custom of sacrificing strangers.

Cacus, a renowned robber of Italy, who, being descended from Vulcan, could defend himself by emitting fire and smoke; but being detected in stealing cows, though he dragged them backwards to prevent discovery Hercules, the owner, strangled him by main force

Cadmus, a prince of Phœnicia, who generally receives the credit of inventing letters, or at least of introducing them into Greece. Though some writers ascribe the erection of Thebes to Amphion's music, others term Cadmus its founder. Ere he could do so, he killed a dragon which had devoured his companions; and from the teeth of this monster, when sown in the earth, a band of armed men sprung up. These fought among themselves, till only five were left to assist Cadmus in building the city. The sowing of the teeth and its consequences are often alluded to, and form an apt comparison when the germs of strife are planted in any instance.

Caduceus, a rod entwined at one end by serpents, and which served as the rod of power and office of the herald-god Mercury.

Cæsar, an illustrious name in history, first given as a surname to the Julian family of Rome. Caius Julius Cæsar, who gained for the family supreme power, was born in the year 100 B.C., and early distinguished himself by his eloquence, his captivating manners, and generous habits of life. His military commands lay in succession in Spain and Gaul, whence he passed over into Britain, then an unknown land. The successes of Cæsar created jealousies betwixt him and Pompey, another renowned soldier of Rome, and to seek satisfaction from whom the governor of Gaul resolved to march homewards, despite the commands of the senate. The stream of the Rubicon was the boundary of his province; he crossed it, and in so doing, threw off his allegiance to the authorities of the republic. Italy and Rome quickly succumbed to him, and he finally overthrew Pompey on the plain of Pharsalia. The patriot Cato then resisted him on his way to uncontrolled power, but fell likewise before his triumphant fortunes. Cæsar was named perpetual dictator; but was slain by Brutus and others in the height of his glory when he had reached the age of fifty-six. The passing of the Rubicon has been long a by-word for the taking of any decisive and irretraceable step; and Pharsalia is a term applied to any scene where a great cause has been lost, for in that battle fell the Roman liberties. Cæsar wrote in an able and modest manner the annals of his own campaigns. Cæsar (Octavius, afterwards named Augustus), nephew of Julius Cæsar, and his successor in power. After avenging the death of his uncle, Augustus became a member of a triumvirate who ruled the world, and subsequently divided authority with one man, Mark Antony, after whose death he stood "sole monarch of the universal earth." Of a less noble character than Julius Cæsar, the first Roman emperor, as Augustus was entitled, was possessed of sufficient talent, caution, and prudence, to hold his sovereignty undisturbed in a most precarious time. Nor was he without virtues. From his patronage of literature, its palmy periods have ever since been compared to the Augustan age. The title of Cæsar, specially given to the first twelve emperors (commencing with the dictator, Julius Cæsar) who sat on the Roman throne. The name of Cæsar was also assumed by later Roman emperors, and both the kaisars of Germany and the czars of Russia owe their designation to the same source.

Caligula, the fourth of the twelve Cæsars, who derived his name from his habitually wearing the *caliga* or military boot of the age, and made himself noted as a cruel and senseless tyrant. From mere wantonness he made his horse high-priest and consul of Rome; and he spilt blood without cause and without remorse. He died a violent death.

Calliope, one of the Muses, who presided especially over eloquence and heroic poetry.

Calypso, a beautiful goddess who, according to Homer, dwelt on an island of the earth, and who received Ulysses hospitably as he wandered home from Troy. Her story forms an exquisite episode in the Odyssey.

Camilla, queen of the Volsci, who fought against Æneas, and is described as having been so swift of foot that she could fly over a field of corn without bending the blades. Pope, and the later poets generally, have adopted her as the type of female speed in running.

Campus Martius, a plain near Rome, used for the military exercises of the youth of the city.

Capitolium, the citadel of ancient Rome, founded on the Tarpeian rock, and containing also a temple, from which Jupiter was named Capitolinus. The capitol was a noble structure, occupying four acres of ground, and accessible by a hundred steps. The Romans held it in peculiar veneration, and it was the scene of all their triumphal processions. By the cackling of geese the Romans were once roused to the protection of their capitol, and this is often alluded to when slight means serve great ends.

Capricornus, a sign of the Zodiac, so termed from some resemblance in the arrangement of its twenty-eight stars to a goat.

Carthage, a great maritime and republican city of Africa, founded about 900 years B.C., by the Phœnician princess Dido, and long the rival of Rome. Carthage existed for upwards of 700 years, and possessed during its palmy days a great part of Africa on the Mediterranean, as well as Spain, Sicily, and Sardinia. Its generals, and particularly Hannibal, pressed Rome so severely, that Cato, one of the wisest of the Romans, pronounced its destruction indispensable. His words, *Delenda est Carthago* (Carthage must be destroyed), have become proverbial. The power of the African republic was at last overthrown by Scipio Africanus, and the city ruined by fire. The Romans, in their hate, used to call the Carthagenians all that was treacherous; and, from one of the names of the latter people, *Punica fides* (Punic faith), was made by their foes a lasting synonym for "faithlessness."

Cassandra, a Trojan princess, who is said to have received the gift of prophecy from Apollo, but having afterwards slighted the god, was doomed by him to have all her predictions disbelieved. When she foretold the fall of Troy, accordingly, she was deemed insane. An unheeded prognosticator of evil is hence termed a Cassandra.

Castalia, a Parnassian fount, sacred to the Muses, and a fertile theme of poetical allusions.

Castor, son of Leda, whom the enamoured god Jupiter is said to have wooed in the form of a swan. Leda bore at once two sons and two daughters, Castor, Pollux, Clytemnestra, and Helena, of whom the second and fourth were deemed children of Jupiter, and the other two of the husband of Leda. Pollux, on being elevated to a star, exhibited his love for Castor by seeking for the latter a share of his immortality, and it was granted to them to live six months alternately. They were famed for horsemanship.

Catilina (Sergius), a noble Roman of great talents, but infamous character and habits. To gratify his ambition, avarice, and revenge, he rebelled against his country, but was overcome and slain in battle. The name of Catiline is used to express all that is evil in the character of a conspirator and liberticide.

Cato, a name borne by several illustrious Romans. Cato surnamed the Censor, was famous for his valour, temperance, wisdom, and eloquence. He studied and acquired the Greek tongue at the age of eighty. Fragments of his compositions yet exist. Cato, surnamed Uticensis, was the great-grandson of the Censor, and made himself celebrated by his patriotic resistance to the usurpations of Julius Cæsar, to avoid falling into whose hands he ultimately stabbed himself, after reading Plato on the Soul's Immortality.

Catullus, a Roman poet, whose pieces have much sweetness and feeling, though occasionally marked by immorality.

Censors, two important Roman magistrates, who had the care of the manners and morals of the people.

CENTAURI, a monstrous people of Thessaly, described as having the head, chest, and arms of men placed on the trunks of horses. A band of them being invited to a wedding-feast of the Lapithæ, a quarrel ensued, and a fearful battle took place, in which Hercules and Theseus peculiarly distinguished themselves in combating and defeating the Centaurs. Many sculptors, from the Greeks to the moderns, have used the chisel on this subject, which is, indeed, rich in the picturesque. The first use of horses for riding seems to have originated the fable of the Centaurs, but Pliny actually states that he saw one embalmed!

CEPHALUS and PROCRIS, a wedded pair, who, having each tried the other's fidelity by disguises, found that human nature is frail, and became content and happy. But Procris, uncured of jealousy, followed her husband one day to the chase, and was accidentally slain by him. The story of these lovers is often told and alluded to by the classical poets.

CERBERUS, a dog with three heads, guardian of the Infernal gate. Watch-dogs, nay, guardian bipeds, frequently receive this name.

CERES, the goddess of corn and harvests, daughter of Saturn and Vesta. She was worshipped everywhere for her bounties, having taught Triptolemus of Eleusis all the arts of agriculture, and sent him to disseminate them over the earth. At Eleusis, she also established the famous rites called the Eleusinian Mysteries. Her daughter Proserpine having been carried off from Sicily, while gathering flowers, by Pluto, king of the shades, Ceres sought her long in vain; and when she was discovered, could only obtain permission to have her half the year in heaven. This is understood to allude to the changes of the moon. Ceres is represented with a garland of corn on her head, and is placed either on the back of an ox or in a chariot drawn by dragons. Her festivals were called Cerealia, and a sow with young was usually sacrificed to her, as being an enemy to fields of grain.

CHAOS, the rude shapeless mass of matter composing, according to the ancients, the yet unformed universe.

CHARON, the ferryman who wafted the dead over the river Styx into the regions below. As the boatman demanded a "consideration" for his services, it was customary for the ancients to place a small coin below the tongues of the dead.

CHARYBDIS, a deep whirlpool in the Sicilian seas, opposite to the rock Scylla. The combined dangers of both led to the well-known saying—"*Incidis in Scyllam, cupiens vitare Charybdim*" (Shunning Charybdis, you on Scylla strike), which is familiarly applied in the same sense as the Scottish proverb, "Out of the frying-pan into the fire."

CHIMÆRA, a fabled monster killed by Bellerophon, which had a triple head, composed of those of a goat, a lion, and a dragon, and which breathed flame. Any monstrous thing of fancy is now termed a Chimera.

CHIRON, a centaur skilled in music, medicine, and other arts, which he taught to Achilles, Æsculapius, Hercules, and others.

CICERO (MARCUS TULLIUS), an orator of Rome, whose speeches against Catiline, Antony, and others, remain imperishable monuments of his powers. His eloquent denunciations saved Rome from the tender mercies of Catiline, and he was termed by the people *the father of his country*. After serving the state in the highest situations at home and abroad, and suffering exile for his attacks on the bad, he took the side of Pompey against Cæsar; but the latter, on becoming victor, treated Cicero with much respect. However, when Cæsar was slain, Antony, the bitter foe of the orator, acquired a fatal degree of power. At length, Antony despatched assassins on the track of Cicero, and soon after his bleeding head was brought to Rome, where the wife of the master-murderer tore out the once persuasive tongue in remorseless spite. Besides his orations, various other productions of Cicero still remain to testify to the splendour of his talents.

CIMMERIAN, a local epithet for the natives of the district now called the Crimea, and some parts of which were thought to be so dark that "Cimmerian gloom" has become a proverbial phrase.

CINCINNATUS, an illustrious Roman, who was taken from the plough, which he left with regret, to serve and save his endangered country. His task fulfilled, he again contentedly retired to his farm.

CIRCE, a witch of semi-divine origin, whose irresistible enchantments drew many into her power, only to be changed, after a short career of voluptuousness, into filthy swine. Circe is evidently an emblem of debasing pleasure.

CIRCUS, the place where shows were exhibited at Rome.

CLEOBULUS, one of the seven wise men of Greece.

CLEOPATRA, a name borne by several princesses of Egypt, and rendered particularly famous by one whose surpassing beauty enslaved Mark Antony, and led to his ruinous contention with Cæsar Augustus. When Antony fell, Cleopatra applied an aspic to her breast, and died from its venomous bite. As voluptuous as beautiful, this queen is generally held as the type of these combined characteristics.

CLIO, the muse who presided over history.

CLOACINA, a goddess to whom the Romans assigned the care of all the refuse of their city.

CLOTHO, one of the Fates, who held the distaff from which was spun the thread of life.

CLYTEMNESTRA, wife and murderess of Agamemnon, and the victim of her own son's revenge.

CODRUS, an Athenian king, who, prompted by an oracle, gave up his life to save his country.

COLOSSUS, a brazen image placed with its feet on the two moles of the harbour of Rhodes, and of such magnitude that ships passed easily between its legs. It was 105 feet high, and was deemed one of the seven wonders of the world. The term has become firmly established in modern languages.

CONSUL, the highest Roman magistrate. This office was held annually and conjunctly by two individuals, who conducted the wars of the state, presided over the senate, and held, in short, nearly absolute power.

CORINTH, a famous city of Greece, situated on the isthmus between the Gulfs of Ægina and Lepanto, and remarkable in classical times for its power and opulence. *Corinthian brass* is frequently alluded to, and is said to have been an alloy accidentally formed when the city was burned by the Romans in the second century, A. D. The common adage, "*Non cuivis homini contingit adire Corinthum*"—(It is not every man's luck to visit Corinth), is supposed by Suidas to refer to its difficulty of access by sea.

CORNELIA, a noble Roman lady, who, though her sons were put to death for their turbulence, was so proud of them that it was her boast to be simply named "The mother of the Gracchi." The phrase has long been a familiar allusion.

CORYDON, a name in Virgil's pastorals, often applied to shepherds.

CORYPHÆUS (or CHORYPHÆUS), a title formerly given to the leaders of choral bands, and now frequently assigned to leading men of any description.

CRETE.—The island of Crete was chiefly renowned of old for its labyrinth, laws, luxury, and lies. The name of a Cretan, indeed, became a by-word for falsehood.

CRŒSUS, a king of Lydia, supposed to be the richest of mankind, and desirous of being thought the happiest. Solon, the Athenian philosopher, told him that wealth did not insure happiness, and that no man could be safely called happy before death. Crœsus disliked this

plain speaking, but, when overcome by Cyrus, and led out to execution, he acknowledged aloud its truth. Struck himself by the circumstance, Cyrus pardoned. Crœsus is a common synonym for a very opulent man.

Cupid, god of love, and son of Venus, queen of beauty. He is represented as a winged infant, naked, and armed with a bow and arrows.

Curtius (Marcus), a young Roman of high military fame, who, when a wide gap opened in the forum, armed himself, mounted his horse, and leaped into the gulf, which instantly closed behind him. To this renowned act of patriotic devotion he was incited by the oracle, which indicated that the sacrifice of a life of price could alone remedy the calamity.

Cybele, a goddess worshipped with many mystic rites, and usually painted with a turreted crown, keys in her hand, and a lion-drawn chariot.

Cyclops, are a race of one-eyed giants, who acted as assistants to the smith-god Vulcan, and devoured human being One of the cyclops, named Polyphemus, appears prominently in the Odyssey.

Cyprus.—The island of Cyprus, from its luxurious fertility, was supposed to be the residence of the goddess of beauty and pleasure, and from this cause the epithet "Cyprian" has acquired a licentious meaning.

Cythera, an island off the Morea, sacred to Venus, and from which she is often called Cytherea, or the Cytherean goddess.

Dædalus, an Athenian of great skill in the mechanical and fine arts, to whom some ascribe the invention of the wedge, the axe, the wimble, and the level. He is said also to have formed the many-pathed labyrinth of Crete, in which he himself was ultimately confined with his son Icarus. Not being able to get out of his own trap, he made wings for himself and Icarus, with which they flew away; but the too-daring youth rose so near the sun that the waxen fastenings of the wings melted, and he fell into the sea. Dædalus is the nominal prototype of all ingenious mechanics.

Damocles, a courtier, who, having loudly flattered Dionysius of Sicily on the score of his wealth and fortunate greatness, was placed, for a time, by way of trial, upon the tyrant's throne. Damocles gazed a while with delight on the splendour around him, but, looking up, he saw a sword suspended above his head by a single hair, and his fancied happiness vanished. This incident is often referred to in illustration of the perils and turmoils of greatness.

Damon and Pythias, two friends of such constancy, that when the former of them was doomed to die, and sought for a respite, that he might go home and settle his affairs, the latter offered his life as a security for the return of the other. Damon returned, even to his friend's regret. The scene betwixt them was so moving that it led to a pardon.—Damon is a common name for a swain, being much used in the old pastorals.

Danae, the daughter of a king of Argos, was shut up in a tower because it was foretold that a son of hers should kill his grandfather. The god Jupiter, however, introduced himself in the form of a golden shower, and Danaë bore to him Perseus, with whom she was exposed at sea in a slight bark, and who afterwards accidentally killed his grandfather with a quoit.

Danaides, the fifty daughters of King Danaüs, who, to prevent the fulfilment of an oracle of fatal import, caused them to murder their husbands. All obeyed but one, and, for the crime, they were condemned perpetually to the fruitless task of filling a sieve with water in the infernal regions.

Daphne, a nymph, who, when flying from the enamoured pursuit of Apollo, was converted into the laurel-tree.

Delphi (now Castri), a town of Phocis, situated on the side of Mount Parnassus. The place was especially sacred to Apollo, both as the god of Poetry and Divination, and here stood the most famous of the Greek temples and oracles. The decrees of fate were expounded by a priestess, called the Pythia or Pythoness, who stood on a tripod while under the inspiration of a god. The convulsions which she then seemed to labour under have been held real by some, and ascribed to an asphyxiating vapour issuing from the earth at the spot.

Delta, a Greek letter of triangular shape (Δ), the name of which was given formerly to the alluvial land lying between the outlets of the Nile, and is now applied to the mouths of other streams.

Democritus, a personage called the laughing philosopher, from his deeming it better to smile than to weep at the follies of mankind.

Demosthenes the greatest of the ancient orators. An Athenian by birth, he was early seized with an ardent desire to excel in speaking; and though he had many natural disadvantages to contend with, he overcame them all. He cured a habit of stammering by placing pebbles in his mouth; he inured himself to the turbulence of a popular auditory by speaking on the seashore during storms; and he removed the distortions of his visage by delivery before a mirror. He shut himself up, moreover, to indulge in study; and over the midnight lamp were composed those sublime orations which yet remain without parallel, and by which he wielded at will the fierce democracy of Athens. His greatest efforts, when he had raised himself to power, were directed against Philip of Macedon; and from the title given to his harangues on this subject, similar attacks are yet commonly termed Philippics. The Macedonians ultimately triumphed, however, and Demosthenes escaped from his enemies by taking poison in the sixtieth year of his age.

Deucalion, a prince of Thessaly, who, with his wife Pyrrha, alone escaped, by means of a ship, from a great deluge said to have occurred in their time. The vessel rested on Parnassus, and Deucalion, directed by an oracle how to repeople the earth, threw stones over his shoulder, which instantly became men. Pyrrha did the same, and women were formed.

Diana, sister of Apollo, goddess of hunting, and in heaven called Luna, or the Moon. She was represented in the garb of a quivered huntress followed by dogs, and was a renowned patroness of maiden chastity, though she is said to have fallen in love with Endymion, a young man of Latmos, as he lay asleep, and even to have wedded him. She had eighty nymphs who attended her in the chase. The most famous temple of Diana was that at Ephesus, called one of the seven earthly wonders, and set fire to by one who sought thereby to gain an immortal name. Diana is often called Cynthia, or Delia, from the place of her birth; and, in the character of the moon, is usually termed Phœbe.

Dido, a Phœnician princess, who founded Carthage, and, while it existed, was worshipped in that city. Æneas, after wooing Dido, deserted her, and her memory has become associated with the idea of a forlorn woman.

Diogenes, the type of all sour, snarling philosophers. He was of the Cynic sect, and so despised luxury as to live in a tub. Many of his sayings are frequently quoted; as, for example, his answer to Alexander the Great, when that prince asked him what he could do to oblige him. "Stand away from betwixt me and the sun," said Diogenes.

Dionysius (the elder), tyrant of Sicily, who, amongst other characteristic deeds, constructed a cave commonly called The Ear of Dionysius, which was of such a form that every word uttered by his prisoners in an adjoining prison could be heard by him.—Dionysius, son and successor of the preceding, and so apt an imitator of his cruel practices that he was finally driven from his throne

and, to earn his bread, was compelled to teach a school at Corinth, whence fallen despots are often compared to him.

DIS, a name used by the poets for Pluto.

DODONA, a town of Epiro, and the site of an oracle of Jupiter whose responses were frequently delivered by or among the sacred oaks of the neighbourhood.

DOMITIAN, a Roman emperor, proverbial for his cruelty.

DRACO, a lawgiver of Athens, whose statutes were so severe that it was said they were written in blood. Harsh edicts are often compared to them.

DRYADES, nymphs fabled to preside over the woods.

ECHO, a nymph, whose powers of speech, as a punishment for prating, were limited to the answering of questions. Falling afterwards in love with Narcissus, that youth's cruelty caused her to pine away, and she was changed to a stone, which still retains the power of speech.

EGERIA, a nymph or deity from whom Numa, king of Rome, pretended to receive counsel in secret on affairs of state.

ELEUSIS, a city of Attica, the chief scene of the celebration of the Eleusinian Mysteries. Initiation into these was one of the most solemn of all the mythological rites of Greece, and was supposed to confer high privileges. The nature of the ceremonial is now a mere matter or conjecture.

ELYSIUM, the happy seat of the departed spirits of the good, according to the Greek and Romans. The pleasures said to be enjoyed there were in some respects pure and refined; but in others, the tastes of the living humanity of the age were too grossly intermingled with the views taken of Elysian enjoyments. As among the Indians, for example, warriors sought in hunting animals a substitute for the pleasures of fighting.

EMPEDOCLES, a man of superior talents, who, wishing to be deemed a god, leapt into the crater of Ætna, thinking that he might so conceal his having been subject to death like common mortals. But his sandal was thrown up, and frustrated his insane ambition.

ENDYMION, a youth of Latmos, beloved of the moon.

EPAMINONDAS, a Theban chief, one of the most noble characters in Grecian history. A great and victorious soldier, he was even more conspicuous for virtue, wisdom, temperance, and patriotism.

EPICURUS, a celebrated philosopher of Attican descent, whose name has most unfairly become a synonym for a sensualist of a gross kind. His philosophy was certainly based on the maxim that "Pleasure is the highest good;" but Epicurus well knew, and ever taught, that moderation in the gratification of the senses is the sole means of attaining to true and lasting pleasure, and that a "happy life" rests fundamentally on health of body and tranquillity of mind, possessions never to be won or preserved by excessive sensual indulgence. What propriety is there in a word of such etymology as the word "epicure," when the daily diet of the man whose name is so abused consisted of "barley cake and water from the spring?"

ERATO, the Muse who presided over lyric and amorous verse.

EREBUS, an infernal deity, whose name is often used to signify the supposed place of his abode.

EURIPIDES, a Greek poet, whose tragedies are marked by great tenderness and elegance.

EUROPA, a beautiful woman, to whom the enamoured Jupiter appeared in the form of a bull, and when she thoughtlessly mounted on the back of the supposed animal, carried her off. She gave name, it is further fabled, to the European continent.

EURYDICE, wife of the poet and musician, Orpheus. When she died from the bite of a serpent, Orpheus was so deeply grieved that he ventured to seek her among the shades; and having, by his music, drawn "iron tears down Pluto's cheek," was permitted by the infernal chief to take his wife back to earth, on condition that he did not turn to look on her till his arrival there. He violated the condition, and lost her for ever.

FABIUS, the name of a noble Roman house, the most illustrious member of which was QUINTUS FABIUS MAXIMUS. The alarming successes of the Carthaginian, Hannibal, who defeated in succession all who came against him, received a notable check when Fabius took the command of the Roman army. His policy was not to fight, but to wear out Hannibal, then in a hostile country; and from this circumstance Fabius received at the time the name of "The Delayer." Ever since that age, every cautious commander has been called a follower of the Fabian policy.

FAUNS.—The fauns were minor rural deities, painted as having the form of goats from the middle downwards, with the horns and ears of the same animals. They favoured agriculture, and peasants sacrificed to them.

FLORA, a goddess of the Roman Pantheon, who presided over flowers, gardens, orchards, and vineyards, and was usually painted as crowned with flowers, and holding the horn of plenty. She married Zephyrus, the god of the west wind, and received from him the privilege of immortal youth.

FORUM, the market place and also the seat of a prætorian court of justice in the Roman cities. The word is now applied to courts of justice, whence the phrase of "forensic" or legal oratory.

FURIÆ, the three Furies, named *Alecto*, *Megæra*, and *Tisiphone*. These sisters were supposed to be the ministers of divine vengeance, punishing mortals on earth both with external evils and the stings of conscience, and inflicting continued torments on the bad in the infernal regions. They were represented as holding in one hand a torch and in the other a whip of scorpions. The ancients sacrificed to them with fear and trembling.

GALATEA, a sea-nymph in love with Acis, whom Polyphemus the Cyclop killed through jealousy.

GALEN, a celebrated physician of the second century, A. D., who was greatly esteemed at Rome, and who wrote five hundred volumes, some fragments of which only are now extant. He had made many valuable discoveries in medicine, and has left a by-name to its professors.

GANYMEDES, a beautiful Phrygian youth, carried away by Jupiter to be the cup-bearer of the gods in place of Hebe. An eagle conveyed him, and he is usually pictured on the back of that bird.

GERYON, a monstrous being with three heads, slain by Hercules.

GLADIATORII LUDI.—Gladiatorial Sports, so called from *gladius* (a sword), were exhibitions at which slaves, captives, and trained fighters, butchered one another for the amusement of the people, male and female, of the city of Rome.

GORDIUS, a Phrygian peasant, who, when his countrymen were told by the oracle to enthrone the first man whom they met going to the temple of Jupiter in a car, had the good fortune to be found in that situation. Immediately afterwards he consecrated his car in the temple, tying the yoke to the draught with such art that it could not be unloosed. Then the report spread that the oracle had decreed the empire of Asia to him who should untie the Gordian knot. Coming to the place, Alexander the Great made short work of the difficulty by cutting the cord with his sword, and thereupon he claimed to be the foretold ruler of Asia.

GORGON, a name specially applied to Medusa, one of three sisters who had wings of gold, and but one eye for use among the three. The "Gorgon's head," or "Medusa's head," is frequently alluded to as significant

of an object of terror, because it was encircled with snakes, and turned the beholder to stone.

GRACCHUS, the name of a noble family of republican Rome, two members of which made themselves noted for turbulence, and gave origin to the well-known line of the poet, "*Quis tulerit Gracchos de seditione querentes?*"—(Who could bear that the Gracchi should complain of sedition?)

HALCYONE, a princess who grieved so deeply for the loss of her spouse at sea, that she was sent to that element out of pity, changed into a king-fisher. Being favoured with seven calm days for brooding, the phrase of "Halcyon days" came to denote a time of peaceful happiness.

HAMADRYADS, rural nymphs, who were said to preside over trees.

HANNIBAL, a famous Carthaginian, who, when a boy, was made by his father to vow eternal enmity to Rome. He fulfilled in due time the oath, proving the most dangerous foe ever known to the Romans. So great was the promise of his early days, that before the age of twenty-five he received the command-in-chief of all the armies of his country. In this situation he determined upon the bold step of crossing the Alps, and carrying war into the heart of Italy. His passage has ever been viewed as a wonderful military feat, and was partly accomplished, historians say, by his kindling large fires, and pouring vinegar on the heated rocks, which caused them to rend or crumble in pieces. Once in Italy, he defeated, one after another, all the commanders sent against him from Rome, and for sixteen years held that city in continuous alarm. At length the Romans sent a force to menace Carthage, and Hannibal was hastily recalled, only to be wholly vanquished near his native city by Scipio Africanus. A brief peace was granted afterwards to Carthage, but, mistrustful of his enemies, Hannibal fled to Syria, and subsequently to Bithynia, where, his person being demanded by the Romans, he ended his life by taking poison, 182 a. c. The youthful vow and acts of Hannibal meet with frequent notice in literature.

HEBE, daughter of Jupiter and Juno, and the goddess of youth, for which, in its beautiful forms, her name is a synonym. She was the first cup-bearer of the gods.

HECATE, the goddess supposed to preside over enchantments.

HECTOR, the most valiant of the sons of King Priam, of Troy, ultimately killed by Achilles. His name is applied to brave men, and not unfrequently to boastful ones, though Homer assigns none but truly great qualities to the Trojan prince.

HELENA, the most beautiful woman of her age, and whose abduction from her husband, Menelaus, king of Sparta, by the Trojan prince Paris, caused the siege and fall of Troy, all the Greek princes having united to effect her recovery. Helen was one of the children of Leda by Jupiter. She was restored ultimately to Menelaus. Allusions to her on account of her beauty, and the evils which she caused, are endless in song and story.

HELICON, a mountain of Bœotia, sacred to the Muses, who had a temple there.

HELIOGABALUS, a Roman emperor, so extravagantly devoted to the pleasures of the table that his name has become a synonym for a glutton.

HELOTS, a menial caste at Sparta, whose name has become significant of the most abject slavery.

HERCULES, the most famous personage of the heroic age of Greece. He was styled the son of Jupiter by Alcmena, and began his feats of valour in his cradle, by strangling two snakes sent by the jealous queen of heaven to devour him. Hercules performed, compulsorily, it is said, twelve celebrated labours, of which the following are examples:—He killed the terrible Nemean lion; he destroyed the Lernean hydra, a monster with many heads, each of which, when struck off, instantly grew again, till the hero thought of searing them with a red-hot iron; he cleansed the vast Augean stables by turning a river into them; and he brought the dog Cerberus from the infernal regions. Fate also compelled him to become three years a slave to Omphale, queen of Lydia, who made him handle a distaff instead of his victorious club. Finally, when his wife Dejanira was forcibly seized by the Centaur Nessus, Hercules shot him across a river with an arrow. The revengeful centaur, before he died, gave Dejanira a tunic, which he said had the power of curing conjugal infidelity, but which, when donned at her wish by Hercules, caused him to die a painful death. He was afterwards raised to a place among the gods. The many-headed hydra, the Augean stable, and Hercules subdued to the distaff, are specimens of the frequent allusions made to the story of this demigod. He is the type of physical power in painting and sculpture, and is always drawn with a mighty club in his hand.

HERO, a fair priestess of Venus, who, when her lover Leander perished in swimming across the Hellespont, threw herself into the sea. She is often painted with a torch in her hand, as a guide to the bold but unfortunate swimmer.

HERODOTUS, a famed historian of Greece.

HESIOD, a very early Bœotian poet of superior powers.

HESPERIDES, three celebrated nymphs, who, with a dragon for a watch-dog, were intrusted with the care of Juno's golden apples, placed in a garden, it was said, in the neighbourhood of Mount Atlas. Hercules, in one of his labours, carried off some of this much-prized fruit. This story of the apples of the Hesperides is often used, by way of comparison, to signify things of difficult access and great rarity and price.

HESPERUS, a name given to the planet Venus as the evening star.

HIPPOCRATES, a physician of the isle of Cos, whose existing writings prove him to have made wonderful advances, for his time, in the art of medicine, and whose name is yet often alluded to.

HIPPOCRENE, a fountain on Mount Helicon, the waters of which are said to have given inspiration to poets, because the hill was sacred to the Muses.

HOMER, the greatest of the poets of Greece, born, according to the most probable accounts, in the isle of Chios. His name signifies "The Blind," and he is said not only to have suffered under this calamity, but to have been a mendicant, or at least a wanderer dependent on his minstrelsy for daily bread. The combination of all the highest poetical qualities in the writings of Homer, from terrible sublimity to the tenderest pathos, has been a fruitful source of astonishment to succeeding times, the rudeness of the age in which he lived being considered. He certainly stands second, as a poet, but to one man who ever lived—William Shakspeare. The Iliad and the Odyssey are Homer's great works.

HORACE, a Roman poet, whose lyrics and satires abound in moral maxims that are often and deservedly quoted.

HYBLA, a mount of Sicily, famous for its fragrant thyme and its honey.

HYDRA, a many-headed monster killed by Hercules, to which an unruly rabble is often compared.

HYGEIA, the goddess of health, daughter of Æsculapius.

HYMEN (or *Hymenæus*), the god of marriage, whose favour was solemnly invoked with song and sacrifice by all entering on the wedded state.

HYMETTUS, a mountain of Attica, celebrated for its bees.

DAEDALUS, son of Eupalus, who, in flying from Crete with his son, soared so near the sun as to melt the joints of the wings made by his father, and fell into the sea.

IDA, a mountain near Troy, where Paris assigned to Venus the prize of beauty over Juno and Minerva.

ILISSUS, a river, and river-god of Attica, remarkable as the subject of a noble extant piece of Greek statuary.

ILIUM, a name for Troy, whence the term *Iliad*.

IO, a beautiful woman whom Jupiter fell in love with, and whom he changed into a heifer, to preserve her from the jealousy of Juno. The suspicious Juno begged the heifer and set Argus of the hundred eyes to watch it; but Mercury, to oblige the superior deity, killed the keeper and set free the metamorphosed lady.

IPHIGENIA, daughter of Agamemnon. That chief, while at Aulis, on his way to Troy, was detained by contrary winds, and was told that only by the sacrifice of his daughter to Diana could the Greek fleet proceed in their course. He reluctantly consented; but when Iphigenia was brought to the altar, she suddenly disappeared, and a goat was seen in her place. Diana carried her off, says the story, to be a priestess at Taurica.

IRIS, the messenger of the queen of heaven, and the goddess of the rainbow, the appearance of which was held to indicate a mission of Iris to earth.

ISIS, a celebrated female deity of the Egyptians, wedded to her brother Osiris.

ISTHMIA, solemn triennial games of the Greeks, which derived their name from being celebrated on the Isthmus of Corinth. Combats, races, and athletic sports of every kind were among the exhibitions, and the poets also contended there for the prize of the baya.

ITHACA, a small islet, now called Thiaki, in the Ionian sea, famous as the kingdom of Ulysses.

IXION, a king of Thessaly, who rendered himself so odious on earth by the murder of his father-in-law, that Jupiter, in misplaced compassion, took him up to heaven. There, however, Ixion behaved so insolently, that Jupiter struck him down to the infernal regions, and ordered him to be tied with serpents to a wheel, which, revolving for ever, rendered his punishment eternal. This story is a frequent theme of allusion.

JANUS, one of the primitive kings of Italy, placed after his decease, on account of his equity, among the gods. He was the guardian of gates, and was represented with two heads, probably to indicate the watchfulness required in such custodians. Any one remarkable for duplicity or two-facedness is familiarly called a Janus. January was named from this deified personage.

JASON, the leader of the Argonauts, with whom he went to Colchis on the Euxine Sea to regain the golden fleece. The king of Colchis promised its restoration if Jason could tame certain flame-breathing bulls, slay a dragon, and perform other difficult feats. Aided by Medea, the king's daughter, an adept in all the arts of enchantment, the chief of the Argonauts accomplished these tasks, and won the fleece; after which he departed secretly, carrying Medea with him as his wife, according to his solemn engagement. Returning home, he found his father Æson too infirm to partake of his triumph, but the art of Medea restored the old man to youth. Jason subsequently became unfaithful to Medea, and, roused to madness, she slew her own children before their father's face. The renewal of Æson's youth, and the filicidal fury of Medea, are often referred to by the poets.

JUGURTHA, an illegitimate nephew of Micipsa, king of Numidia, who slew his cousins, and seized their throne. The historian Sallust has made his name proverbial for cunning, daring, and cruelty.

JULIAN, an emperor of Rome in the fourth century A. D., usually named *The Apostate*, from his having deserted Christianity for Paganism, after being trained up to the former faith. He was, notwithstanding, a man of many virtues, and also of superior talents, as his acts, as well as some of his extant writings, sufficiently indicate. His last moments, when mortally wounded in Persia, were spent in calm converse on the immortality of the soul.

JUNO, sister and wife of Jupiter, and queen of the mythological heaven of Greece and Rome. Her beauty was of a grand and stately kind, and not feminine enough to fix the affections of her husband, whom she annoyed with her jealousies. Her most famous acts consist of persecutions of his mortal mistresses. She was almost universally worshipped, and had splendid temples at Argos, Olympia, Samos, Carthage, and Rome. Her favour was peculiarly implored by women, on account of her being the patroness of marriage and childbirth; and she was also the assigner of power and riches. Juno was usually represented sitting in a chariot drawn by peacocks, and wearing a long veil. She had many names.

JUPITER, son of Saturn and Ops, king of heaven, and ruler of all the gods. Saturn habitually devoured his own children, but Ops deceived him at the birth of Jupiter with a stone, and the child was saved. On reaching the age of one year, he warred with the giant-gods called Titans, and after conquering them, and besides dethroning his father, became the supreme deity and sole wielder of the dreadful thunder. It would be fruitless to go over the actions ascribed to Jupiter, which consist chiefly of low and often ridiculous amours. He was usually represented as a being of majestic countenance, seated on a throne, with a messenger-eagle at his feet, and a thunderbolt and sceptre in his hands. His chief temples were at Dodona in Greece, and Ammon in Libya, and he had numerous names, corresponding to the site of these or to some of his actions; as *Jupiter Capitolinus* (the Capitoline Jove), and *Jupiter Tonans* (Jupiter the Thunderer).

JUVENAL, an able and unsparing satirist of Rome in the early times of the empire.

KALENDS, the name given by the Romans to the first day of every month. As the Greeks had no kalends, it became common in Rome for people to say that any thing would take place "at the Greek kalends," when they meant that it would not take place at all.

LABYRINTH, any place with so many windings as to render escape from it difficult. The most famous of the several labyrinths mentioned by old writers was the Cretan one, built to confine a monster called the *Minotaur*.

LACHESIS, one of the Fates, who spun the thread of life.

LACONIA, a Peloponnesian district, of which Lacedæmon was the capital. The people of the region spoke little, and hence the application of the epithet *Laconic* to concise talking or writing.

LAIS, a Corinthian courtesan of such beauty and notoriety that her name has become a synonym for others in her position.

LAOCOON, a Trojan prince, priest of Apollo, who having offended Neptune, was strangled with several of his sons, by two enormous serpents which issued from the sea. This fable has been rendered immortal by an ancient sculptor, whose work on the subject is yet preserved.

LAPITHÆ, a family or tribe descended from Apollo, famous for having gained, with the aid of Hercules, a dreadful battle against the Centaurs.

LARES, minor deities, supposed by the Romans to

preside over households, and represented by small images, which the possessor always took with him on a change of residence.

Latinus, king of the Italian aborigines, who gave his name to the Roman language.

Latona, mother of Apollo and Diana by Jupiter, and worshipped in many temples.

Leander, a youth of Abydos, who, being in love with Hero, of Sestos, was wont nightly to swim across the Hellespont to meet her, but was at last drowned in a storm.

Leda, wife of Tyndarus of Sparta, visited by the enamoured Jupiter in the form of a swan, and mother of Helen, Clytemnestra, Castor and Pollux.

Leonidas, a renowned Spartan, who, when the Persians invaded Greece with several millions of men, took post at the Pass of Thermopylæ with no more than 300 men, and, self-devoted to death, defended it for three days, until he and all his companions perished, after making fearful havoc among the enemy.

Lethe, an infernal river, whose waters made those who drank it forgetful of all the past. Lethe is a poetical synonym for oblivion.

Livy, one of the most illustrious of the Roman historians.

Lucretia, a young and noble Roman matron, who fell a victim to the licentious passion of the son of Tarquin, king of Rome. After her dishonour, she summoned to her presence her husband and relatives, and disclosing her injuries to them, took away with her own hands the life which she could no longer endure. Junius Brutus took up the bleeding knife which she had used, and swore upon it to avenge her death, an oath amply fulfilled. The name of Lucretia is a by-word for female chastity.

Lucretius, a Roman poet, whose work on the Nature of Things (*Natura Rerum*) forms one of the best expositions of the heathen philosophy.

Lucullus, a Roman noble, not less famous for his talents and virtues than for his extravagant and luxurious mode of living.

Lyceum, a name originally given to the place where Aristotle taught, and since applied to establishments in some respects similar.

Lycurgus, a celebrated lawgiver of Sparta, whose maxims all tended to make men live simply and plainly.

Meander, a river of Asia Minor, so notable for its windings as to have originated the word *meander*, bearing that meaning.

Maeonides, a name applied to Homer, and from him, in the plural, to the Muses.

Maia, mother of mercury by Jupiter.

Manes, a term applied by the ancients to the souls of the dead.

Marathon, a plain of Attica, where Miltiades the Athenian, with comparatively a mere handful of men, routed the vast army of the Persians.

Marius, a Roman of celebrity, who, from ... rank of a peasant, raised himself by his talents to the highest offices of the state. Reduced at one time to the greatest danger and distress, he fled to Africa, and, himself then a ruin, he sat down on the ruins of Carthage. The striking nature of this position has caused frequent allusions to be made to it. Again obtaining power, Marius glutted his vengeance by the most inhuman massacres, and died amid the blood he had spilt.

Mars, the god of war, son of Jupiter and Juno. He was represented as an armed figure in a chariot, driven by Bellona, and drawn by two horses, which the poets named Terror and Flight.

Mausolus, king of Caria, so dearly beloved by his wife, that at his death she drank up his ashes, and erected to him a monument so splendid as to be deemed one of the seven wonders of the world. Hence the word *mausoleum*.

Maecenas, prime minister to Augustus Cæsar, and so highly famed for his countenance of Virgil, Horace, and other men of letters, that a literary patron has since been commonly named a Mæcenas.

Medea, princess of Colchis, and wife of Jason, celebrated for her magical arts, her restoration of the youth of Æson, and her murder, when infuriated by jealousy, of the children born by her to her husband. Few names occur so often in ancient and even modern poetry.

Medusa, one of the Gorgons, whose frightful snake-encircled head turned the beholders to stone. She was slain by Perseus, who placed her head on Minerva's shield, thence rendered unendurable by mortal eyes. The head of Medusa is synonymous with any terrible object which causes stupefaction in him who sees it.

Meleager, an ancient hero, celebrated for slaying the monstrous Calydonian boar.

Melpomene, the Muse who presided over tragedy.

Memnon, an aboriginal Ethiopean or Egyptian king, to whose memory the people of Thebes raised a colossal statue of black marble, which had the wonderful power of emitting musical sounds when struck by the rays of the rising and setting sun. Most writers ascribe this phenomenon, which is often adverted to, to the jugglery of the priests; but some modern travellers, who have visited the yet extant ruins of the statue, have fancied that it emits sounds even at this day.

Menelaus, king of Sparta, the abduction of whose wife Helen by Paris caused the Trojan war.

Mentor, a name which Minerva assumed when she became the guide of Telemachus in his wanderings. Hence arises a familiar title for a counsellor.

Mercury, otherwise called Hermes, son of Jupiter and Maia, and herald of the gods. He presided over oratory, commerce, and thieving, and conducted the spirits of men to the infernal regions. He was represented as a youth with winged cap and sandals, and a magical rod of office, called his caduceus, in his hand. Like his brother deities, he had numerous amours with mortals; and in mere infancy he displayed the strongest qualifications for becoming the patron of robbers, by filching from the other gods all that each deemed most valuable.

Messalina, wife of the emperor Claudius, a woman whose name has become a by-word for incontinence and cruelty.

Midas, a Phrygian king, who, having done a favour to Bacchus, was requested by the god to ask what reward he chose, and, out of foolish avarice, requested that all he touched might become gold. As his very food was converted into that metal, he soon besought the withdrawal of the gift, and was freed from it by bathing in the river Pactolus, the sands of which were turned to gold. For subsequently preferring the music of Pan to that of Apollo, the latter gave Midas the ears of an ass. The story of Midas, and the golden sands of Pactolus, are frequent themes of poetical reference.

Milo, an athlete of old, famous for his great strength. He could carry a large ox, kill it with a blow of his fist, and finally eat it up in one day.

Miltiades, the illustrious Athenian who commanded at Marathon, and afterwards died in prison, a sad monument of human ingratitude.

Minerva, goddess of wisdom, war, and the arts and sciences, who sprung completely armed from Jupiter's brain, according to the fable, without a mother. She is described as one of the most chaste and respectable of all the deities; and though swayed at times by passions far from divine, was a great benefactress of mankind, who owed to her most of the liberal arts. She was usually pictured as a helmeted female of majestic aspect

with a shield in her hand, or ægis, furnished with the head of Medusa. The owl was sacred to her, and she had many magnificent temples erected for her worship. The name of Pallas was as often given to her as Minerva; and, from being the patron deity of Athens, she was also called Athena.

Minos, a famous king and lawgiver of Crete, who, for his equity, was appointed one of the judges of the spirits of men after his decease. A monster called the Minotaur was shut up in the labyrinth of Dædalus; and Minos, severe though just, gave it the captive youth of Athens to devour, till Theseus slew it.

Mithridates, a name borne by several kings of Pontus, one of whom, a man of super-eminent talents, had such a knowledge of pharmaceutical herbs that he could counteract the effect of the most deadly poisons, and hence the use of the word *mithridate* as a synonym for an antidote to such drugs.

Mnemosyne, the goddess of Memory, and mother of the nine Muses by Jupiter.

Momus, the god of fun and pleasantry, jester-general and satirist of the mythological heaven. His name is yet frequently alluded to in connection with these qualities.

Morpheus, son and minister of Somnus, the god of Sleep. He visited mortals in dreams.

Muses, the nine Muses, daughters of Jupiter and Mnemosyne. Their names were Clio, Euterpe, Thalia, Melpomene, Terpsichore, Erato, Polyhymnia, Calliope, and Urania, each of whom (as indicated under their names) presided over a department of poetry or the arts. Apollo was their patron, and the conductor of their orchestra. From certain spots consecrated to them, the poets call them the Pierian, Castalian, and Aonian maids.

Myrmidons, an attached band of Thessalians who accompanied Achilles to the war of Troy. Eager followers of any description are familiarly called by this title, as "the *myrmidons* of the law."

Naiads, certain minor goddesses who presided over springs, fountains, and rivers.

Narcissus, a beautiful youth, who pined away and finally killed himself through love for his own image, as reflected in a fountain. He was said to have been changed into the flower which bears his name. Self-admiring fops often receive this appellation.

Nemesis, the goddess of vengeance, implacable to the bad, but kind to the virtuous.

Neptune, god of the sea, which element was assigned to him when Jupiter and Pluto, the two other chief deities, assumed the sway of the other portions of the universe. Neptune was represented in a chariot of sea-shell, drawn by horses with wings, and in his hand he held a trident, the emblem of his authority. He was almost universally worshipped in the classical times. Of his numerous descendants it is unnecessary to speak.

Nereus, a minor deity of the sea, represented as an old man with a long beard, attended by fifty sportive maids, his daughters, who were called Nereids, and were worshipped by the ancients.

Nero, a Roman emperor, proverbially infamous for his crimes and vices. Originally a youth of promise, Nero was quickly changed in character by the unbounded rule, too much for a mortal to possess, which was then attached to the imperial throne. He assassinated his own mother, and, for the mere luxury of the sight, set fire to the city of Rome. His employment during the fatal conflagration is shown by the sentence "Nero fiddled while Rome was burning." He died by his own hands, to escape the fury of his outraged countrymen.

Nestor, king of Pylos, who at a very advanced age went to the Trojan war; and is so highly lauded by Homer for his eloquence, that posterity have adopted his name as a synonym for a wise and venerable old man.

Numa, a sovereign of Rome, proverbial for legislative skill, which he affected to owe to the counsels of a supernatural and secret visitant named Egeria.

Nymphs, a general term applied to all the minor goddesses of the land and sea, such as the Dryads, Naiads, and Nereids. The nymphs were held not to be immortal, but to live for several thousand years.

Oceanides, sea-nymphs, daughters of Oceanus, and numbering several thousands. Their father Oceanus, like Cœlus the Heaven and Terra the Earth, was one of the primitive divinities, and was totally different from Neptune, being the creation of a much older mythology.

Œdipus, king of Thebes, son of Laius and Jocasta. Being exposed in youth, he had the misfortune to kill his father and marry his mother ere he discovered his parentage. These events made his story a sorrowful theme for the poets; but his name is now chiefly familiar in the sense of an expounder of riddles, because he solved the enigma proposed by a talking monster called the Sphinx, and put an end to its ravages.

Olympia, a town of Elis in the Peloponnesus, where the famous Olympic games were celebrated. These were of great antiquity, and comprised not only athletic exercises of every kind, chariot-racing, and the like, but also contentions in poetry, eloquence, and the fine arts. The celebration took place at the end of every four complete years, and hence it became the fixed practice to measure time by these intervals, called Olympiads. People attended them from all parts of Greece; and the most powerful monarchs, from Alexander the Great to Nero, were proud to win prizes at Olympia, while men of letters valued the honour not less highly.

Olympus, a mountain of Thessaly, which, from its altitude, the ancients conceived to reach the heavens, and which they made the home of the gods.

Orcus, a name of Pluto, frequently used to signify the nether regions.

Oreads, the goddess-nymphs of the mountains.

Orestes, the son of Agamemnon and Clytemnestra, and the avenger on the latter of his sire's murder. Pursued in consequence by the Furies, Orestes could find peace nowhere, though tenderly consoled and supported by Pylades, whose name and his own have become proverbial for bosom friendship. Orestes was at length purified from stain by bringing the Taurican statue of Diana to Greece.

Orion, a gigantic personage, who, after various adventures on earth, had the honour of being elevated to a place among the constellations.

Orpheus, the most famous of the early poets and musicians of Greece, who, by his art, could not only "charm the savage breast," but cause mountains to dance and streams to pause in their course. On the death of his wife Eurydice, he went to seek her, and so enchanted Pluto with his strains, that the god gave back his spouse to him, only stipulating that he should not look upon her till the earth was reached. But Orpheus turned to gaze, and Eurydice was lost. A poem on the Argonauts and some other extant pieces, are assigned to Orpheus, but on imperfect grounds.

Osiris, a great Egyptian deity.

Ossa, a lofty mount of Thessaly, said to have been moved by the giant Titans, when they sought to scale the heavens. Hence the well-known allusion to the piling of Pelion, another hill, on Ossa.

Ovid, a poet of Rome, noted for the ease and elegance of his verse, but stained by immoralities of thought and diction.

Pactolus, a river of Lydia, the sands of which were said to be converted into gold when Midas dipt his hands in them. A Pactolus is a term for a mine of wealth.

Pæan, a hymn sung in honour of the Pythian Apollo.

Palinurus, a pilot who has given a name to his craft, from his skill in guiding the bark of Æneas.

Palladium, a famous colossal statue of Pallas-Minerva, on which the city of Troy, in which it stood, depended for preservation. It was stolen by the Greeks. The importance of the statue to Troy has originated such phrases as the "Palladium of our liberties," applied to important privileges, statutes, and the like.

Pallas, a name of Minerva.

Pan, the god of shepherds, huntsmen, and rustics generally, and son of Mercury. He was painted like the satyrs, having horns and the limbs of a goat. He invented the flute with seven reeds. Pan was worshipped very extensively, but particularly in Arcadia, where he had an oracular temple on mount Lycæus. The poets abound in allusions to this deity.

Panacea, the skilful daughter of the medicine-god Æsculapius, from whose name originated a word signifying a universal cure.

Pandora, the first woman, according to some ancient writers. Jupiter, wishing to punish the Titan Prometheus, caused Pandora to be made of clay, and each of the deities bestowed some personal gift on her. She was then sent with a closed box to Prometheus, but he suspected some artifice, and sent her away. His brother was less cautious, and wedded Pandora, from whose box, when opened, there issued all the ills that have since afflicted mankind. As a cure for these ills, Hope only remained upon earth. This fable is often quoted and applied.

Pantheon, a temple of Rome, dedicated, as its name implies, to all the gods.

Paphos (now Hafo), a city of Cyprus, from which Venus, to whom that isle was sacred, frequently receives the name of the Paphian goddess.

Parcæ, the powerful goddesses called the Fates, who were named Clotho, Lachesis, and Atropos. One held a distaff, another spun from it the thread of human life, and the third divided it with shears, when the decreed term had arrived. The decrees of the Fates were unchangeable even by the greatest of the gods, and they were worshipped with more true devoutness, perhaps, than any other supposed divinities.

Paris, son of Priam of Troy, exposed in infancy, because his mother Hecuba dreamt that she had brought forth a fatal torch. Educated as a shepherd on Mount Ida, Paris was chosen to decide on the comparative beauty of Juno, Minerva, and Venus, when these deities were rivals for a golden apple, inscribed by the goddess Discord with the words, "To be given to the fairest." Paris decided for Venus, who so favoured him in consequence, that he persuaded Helen, the most beautiful woman of the age, to fly with him to Troy. But all the Greek princes joined in resenting the injury, and Paris proved, indeed, the firebrand by which Troy was ruined. The judgment of Paris and the apple of Discord are the subjects of many classical allusions.

Parnassus, a very lofty mountain of Greece, to which, as the supposed favourite seat of Apollo, and the Muses, poets have looked in all times for inspiration.

Parthenon, a splendid temple of Minerva at Athens, adorned by the works of the sculptor Phidias.

Patroclus, the bosom friend of Achilles, slain by Hector before the walls of Troy.

Pegasus, a winged horse given by Minerva to Bellerophon when he went to combat the monster termed the Chimæra. Requiring a lofty flight, the poets frequently choose to imagine their motions aided by Pegasus.

Pelion, a Thessalian mount, on which Ossa was piled when the Titans sought to scale heaven.

Peloponnesus, the ancient name for the Morea.

Penates, a class of inferior gods who presided over the inmost recesses of households.

Penelope, wife of Ulysses, king of Ithaca, famous for her fidelity to her husband during his long absence despite the assaults of numerous importunate suitors. To deceive these, she said that she would wed when a certain piece of tapestry was finished by her, but the work done by day the chaste matron undid by night. Hence the phrase Penelope's Web, applied to cases where progress is similarly retarded.

Penthesilea, a queen of the Amazons, proverbial for her boldness in war, and slain by Achilles before Troy.

Pericles, a renowned warrior, statesman, and orator of Athens.

Peripatetic Sect.—The pupils of Aristotle, so named (from the Greek) because instructed by him while walking.

Perseus, son of Danaë by Jupiter; exposed in infancy with his mother in a small bark, but preserved to fulfil the decrees of Fate by accidentally killing his grandsire. Perseus became a renowned hero, slaying the Gorgon Medusa, among other feats, by the aid of Pluto's invisible helmet and Minerva's shield. He also relieved Andromeda, an Ethiopian princess, from a sea-monster to which she was exposed in chains. After his death, Perseus received the honours of a demigod, and poets and painters have dwelt much on the supposed incidents of his career.

Petronius (Arbiter), a favourite of Nero, often named in connection with gayeties and revels, from his being the caterer for amusement (*arbiter elegantiarum*) to that prince.

Phaeton, son of the sun-god Phœbus-Apollo, by the nymph Clymene. Taunted as of unknown birth by his youthful companions, Phaëton is said to have visited the palace of the sun, and to have received from his sire a solemn promise that whatever he asked should be granted. The vain youth asked to drive the chariot of the sun for one day, and, bound by oath, Phœbus was reluctantly forced to comply. The issue was, that the fiery steeds became unmanageable; and to prevent a universal conflagration, Jupiter struck Phaëton to earth with a thunderbolt. His death was so deeply mourned by his sisters, that in pity they were changed to poplars. Phaëton is a by-word for rash ambition.

Phalaris, a cruel Sicilian tyrant, who caused a brazen bull to be made for the purposes of torture, and consigned to it the inventor Perillus as the first victim. Letters ascribed to Phalaris, but shown by the critic Bentley to be spurious, are in existence.

Pharos, an islet in the bay of Alexandria, containing a splendid light-house, deemed one of the seven wonders of the world.

Pharsalia, a place in Greece, where the republican liberties of Rome received the final blow from the hands of Julius Cæsar, his great opponent Pompey being there conquered by him.

Phidias, the most illustrious of Greek sculptors.

Philippi, a town of Macedon, where Brutus and Cassius were routed by Augustus Cæsar and Mark Antony.

Philip, a famous Macedonian monarch, father of Alexander the Great. By his great valour and consummate address, Philip enlarged his dominions, and gained a fatal ascendency over the free republics of Greece. Trained in youth in the schools of Thebes, he polished and disciplined his rude subjects, and raised them from a secondary to a primary position among their neighbours. Philip was an ambitious and unprincipled man, though capable of generous and even noble actions. His barbarian-like indulgences in drinking has been made memorable by the words of a claimant for justice at his hands "I appeal from Philip drunk to Philip sober" was the

reproof, and he bore it calmly. From the denunciations of him by Demosthenes, such oratorical invectives have been called Philippics.

Philomela, sister of Progne, who was wife to Tereus, king of Thrace. While bringing Philomela to see her sister, Tereus offered violence to her, and after cutting out her tongue to prevent discovery, confined her in a lonely castle. He then told Progne that her sister had died by the way, but the former detected the falsehood by means of a piece of tapestry wrought by Philomela. The infuriated wife of Tereus slew and served up to him his own son in a dish, on discovering which he would have slain her, but was on the spot changed into a hoopoe, while the son's remains became a pheasant, Progne a swallow, and Philomela a nightingale. The nightingale yet bears his name, and is supposed by the poets to wail her sad fate in the sounds "Teru ! Teru !"

Phœbe, a name given to Diana in the character of the moon.

Pieria, a spot in Thessaly, which gave the epithet Pierian to the Muses.

Pindar, a poet of Thebes in Bœotia, justly regarded as the prince of lyric poetry. His odes are without parallel for sublimity and fire. The poets say that the settlement of a swarm of bees on his lips foretold his future greatness.

Pirithous, an ancient hero, between whom and Theseus so strong a friendship existed, that the pair are quoted as models of that sentiment.

Pittacus, one of the seven wise men of Greece.

Plato, a philosopher of Athenian descent, whose name stands at the head of his class among the Greeks. He was a disciple of Socrates and founded the school of Academics. Plato laboured to construct a great system of metaphysics, morals, and policy, and displayed his own genius in eliciting many profound isolated truths; but, as a whole, his system is but a maze of ingenious conjecture. The phrase Platonic Love, indicating an affection seated merely in the mind, is derived from some principles evolved in his account of an imaginary and perfect republic.

Pleiades, the seven daughters of Atlas, placed at their death among the constellations.

Pliny.—Two members of the Pliny family, uncle and nephew, have left brilliant names in Roman literature. The elder Pliny wrote many works, but his "Natural History," a production alike full of truths and absurdities, has alone been preserved; and of the younger Pliny the Letters are still extant. The uncle perished in an eruption of Vesuvius, A. D. 79.

Plutarch, a Greek historical biographer, whose valuable works have given a name to many compositions of the same class.

Pluto, one of the sons of Saturn, and king of the infernal regions. He married Proserpine, the daughter of Ceres, having borne her off from Sicily while gathering flowers, "herself a fairer flower." Black bulls were most frequently sacrificed to Pluto, who is represented as a grim figure, with a two-pronged trident in his hand, and keys to indicate his close wardship of the dead. He sat on a throne of sulphur, and around him were his gloomy courtiers, the Fates, the Furies, and other infernal powers. Dis, Ades, Orcus are names sometimes given to Pluto.

Plutus, the god of riches among the ancients, painted as blind.

Pollux, son of Leda, and brother to Castor, raised to a place among the stars.

Polyhymnia, the muse of singing and rhetoric.

Polyphemus, a gigantic Cyclop, whose one eye Ulysses burnt out with a firebrand, on being captured by the monster. The story is told in the Odyssey.

Pomona, a Roman deity, who had charge of gardens and fruit-trees. She had vowed to live single, and changing herself into an old woman, as the pretty fable runs, Vertumnus, the god of spring, induced her to change her purpose.

Pompey.—The family of Pompey was a famous one at Rome, but chiefly rendered eminent by one member, called Pompey the Great. The conquests of this Roman were of vast extent, and his triumphs numerous, while his character is described as noble in the extreme. But though Pompey married the daughter of Julius Cæsar to cement their friendship, two men of such aspiring minds could not co-exist in peace in Rome. They turned their arms against one another, and at Pharsalia Cæsar proved the conqueror. Pompey fled to Egypt, and was there basely and ungratefully murdered.

Praxiteles, a native of Cnidus, famous for his skill in statuary.

Priam, king of Troy, an aged man when the Greek princes besieged and took his city.

Priapus, a son of Bacchus and Venus, whose statues, set up in gardens, were of a very offensive nature.

Priscianus, a grammarian of the Greek empire, whose name is often quoted in reference to correctness of language.

Procne (or Progne), wife of Tereus, changed to a swallow.

Procrustes, a robber chief of Attica, who was wont to bind travellers down to a bed, and to cut off a portion of their bodies, or to rack these out, if they chanced in either way not to fit the couch. He was killed by Theseus. The bed of Procrustes is a familiar allusion.

Prometheus, one of the Titanic race, famed for his knowledge and address, and capable of deceiving Jupiter himself. To punish a fraud exercised upon him, that god took away fire from mankind, but Prometheus climb the heavens and regained the element by theft. Jupiter, still more provoked, sent down Pandora with a box of ills, but Prometheus was too cautious to accept the gift. The supreme deity, however, chastised him by chaining him to Mount Caucasus, and sent a vulture to feed perpetually on his liver, which still remained undiminished. Hercules at length set the sufferer free. The stealing of the fire is supposed to refer to the discovery of its use; and Prometheus, whose story is often referred to, is called the inventor of many useful arts.

Propertius, one of the secondary Roman poets, author of many beautiful though not perfectly moral compositions.

Proserpine, the daughter of Ceres and wife of Pluto, permitted to spend half the year in heaven at her mother's entreaties. The changes of the moon are supposed to be indicated here. Proserpine was universally worshipped, sometimes under the name of Libitina, Hecate, and Libera.

Proteus, a sea deity, who possessed the gift of prophecy, but was difficult of access, and, unless properly chained, had the power of assuming different shapes to elude his interrogators. Proteus affords a favourite similitude to express a change of form or purpose.

Psyche, a beauteous nymph, whom Cupid married and long lived with in a state of bliss. Venus put her to death, but Jupiter in pity made her afterwards immortal. As Psyche means the soul, this story is thought to present a personification of it: and to indicate the light ethereality of the soul, Psyche is painted with the wings of a butterfly.

Ptolemy.—The Ptolemies were a race of sovereigns, descended from a general of Alexander the Great who obtained the throne of Egypt.

Punica Fides.—The Romans in their enmity called the Carthaginian or Punic people extremely treacherous, and hence sprung the phrase *Punica fides* (Punic faith), to express utter faithlessness.

Pygmalion, a sculptor of Cyprus, who having made

a beautiful ivory statue of a female, fell in love with his own work, and by his prayers moved Venus to animate it. This fable is the theme of frequent allusion.

PYLADES, a prince of Phocis, bound so closely in the bands of friendship with Orestes, that they are cited as exemplars of that feeling in its strongest form.

PYRAMUS, a youth of Babylon attached to Thisbe, whom, from the hostility of their parents, he could only converse with through a chink in the wall between their habitations. The lovers, however, appointed to meet at the tomb of Ninus. Thisbe arriving first, was frightened away by a lioness, which, with bloody jaws, tore a scarf dropped in her flight. Pyramus saw this article, and believing Thisbe dead, slew himself. The distracted maiden, on her return, followed him to the tomb.

PYRRHA, wife of Deucalion, and saved with him from the great Thessalian deluge. By throwing stones behind her she is said to have repeopled the earth with women, as Deucalion supplied it with men.

PYTHAGORAS, a celebrated philosopher of Samos, who, amid many useful doctrines, taught the curious one of the transmigration of souls, and even said that he remembered what bodies he had occupied before. He made his pupils keep silence for many years. The greatness of his real talents is shown by his assertion that the planets moved round the sun as a centre, an idea laughed at in his own time, but since established as a certainty.

PYTHIA (Pythoness), the priestess of Apollo at Delphi, who, inspired by vapours from the earth, delivered, amid convulsive writhings, the oracles of the deity.

PYTHON, a serpent killed by Apollo, from which his priestess received her name, as he himself was called the Pythian god.

REGULUS, a Roman consul, who, in warring with Carthage, was taken prisoner, and afterwards sent home to negotiate a peace. Aware of the reduced state of their enemy, Regulus advised the Romans not to agree to a cessation of hostilities. The noble prisoner thus sealed his own doom, as he was bound, if peace was not obtained, to return to Carthage. He did so, and underwent, after cruel tortures, the horrible death of being shut up in a barrel pierced on all sides with sharp spikes. His devotion to his country and his promise have gained him an undying name.

RHADAMANTHUS, brother of Minos, and so famous for his equity on earth, as to have been appointed one of the judges of the dead.

ROMULUS.—Romulus and Remus, the two brothers who founded Rome, were fabled by their proud descendants to be the sons of Mars by a princess of Italy. They were exposed in infancy, but were saved and suckled by a she-wolf. The twins, on reaching manhood, resolved to found a city; but, for a trifling offence, Remus was slain by his brother. Romulus, however, with a band of fugitives and criminals, founded Rome; and as the neighbouring tribes despised his followers, he carried off mates for them from among the women of the Sabine nation. This abduction was often adverted to by the descendants of its authors. Romulus reigned thirty-nine years, and was then carried up to heaven, according to a story invented, most probably, to conceal his assassination. He received divine honours after his death.

ROSCIUS, a Roman actor of such celebrity, that every distinguished follower of that profession has received his name.

RUBICON, now Rugone, a small stream of Italy, which, after long hesitation, Julius Cæsar crossed, thus throwing off allegiance to the Roman senate, and affording a lasting simile for the taking of any decisive and hazardous step.

SABINI.—The Sabines were a primitive Italian people, from among whom Romulus carried off wives for his followers on founding Rome.

SALLUST, a Roman historian, whose works, though not lengthened, are justly valued for their style and accuracy.

SAPPHO, a famous poetess of Lesbos, whose scanty fragments indicate extraordinary powers, and who was so tortured by love as to throw herself into the sea.

SARDANAPALUS, the last of the Assyrian monarchs, noted for his luxury and effeminacy. His officers having conspired against him, and besieged him in Nineveh, he set fire to his palace, and was consumed in the flames, with all his slaves, concubines, and treasures.

SATURNALIA, festivals held in honour of Saturn, and intended to commemorate the freedom and equality which prevailed in the golden age, when Saturn was king. From the privileges enjoyed during these holidays by the poor man and the slave, any revels where a free and levelling spirit is displayed have been called Saturnalia.

SATURN, son of the heaven and earth, and supreme ruler of the earth till he was dethroned by his son Jupiter. Saturn afterwards fled to Italy, and so cultivated there the arts of peace and simple industry, that his reign was called the golden age. Saturn is represented as an aged man with a scythe in his hand and a serpent wound into a circle, to indicate the ceaseless round of time. *Chronos*, or Time, is also one of the names of Saturn.

SATYR.—The Satyrs were minor deities of the country, shaped like goats inferiorly, and having horns on their head and long hair over the body. The idea of them most probably came from the baboon tribe.

SCIPIO, the patronymic of an illustrious family of Rome, one member of whom, surnamed Africanus from the feat, was the conqueror of Hannibal at Zama. He was equally famous for his private virtues as for his military successes; and "the continence of a Scipio," a common phrase, had its origin in the refusal of Africanus to see a beautiful princess who had fallen into his hands, lest the frailty of human nature should tempt him to take any advantage of his power over her fate.

SCYLLA, a rock off Sicily, famous as dangerous to mariners, in combination with the whirlpool Charybdis. The ancients called the rock a monster, into which the nymph Scylla had been changed by Circe.

SEMELE, daughter of Cadmus, and mother of Bacchus by Jupiter, destroyed by her vain wish to behold her lover in all the insupportable blaze of his divinity.

SEMIRAMIS, a queen of Assyria, celebrated for her masculine strength of character, her warlike successes, and the magnificent buildings which she constructed in Babylon.

SERAPIS, a deity of the ancient Egyptians.

SESOSTHIS, an early king, renowned for the extent of his conquests and the mildness of his sway.

SIBYL.—The Sibyls were women inspired by the gods with the spirit of prophecy. The most famous of them was the Cumæan Sibyl, who is said to have resided at Cumæ, in Italy, and to have obtained from Apollo the privilege of living as many years as there were grains in a handful of sand. But she forgot to ask for youth also, and grew old and decrepit. It is stated that the Sibyl sold three of nine volumes of prophesies to the monarch Tarquin, and that these were preserved and consulted by the Romans with great reverence, until they were destroyed by fire. A book of Sibylline verses is extant, but scholars universally deem it spurious and modern. Every gipsy fortune-teller is familarly named a Sibyl.

SILENUS, a son of Pan, and attendant of Bacchus, usually painted as a jolly intoxicated old man riding on an ass, and crowned with flowers.

SINON, a Greek, whose frauds before Troy have made his name a by-word.

SIRENS.—Three sea-nymphs who lived on a small

is.and near Sicily, and so charmed the passing voyager with their melodious voices that he forgot all else, and died of starvation while listening. Ulysses, in order to hear them safely, had the ears of his crew stuffed, and himself tied to the mast of his ship. He was enchanted with the music, but the crew would not obey his commands to stop, and thus he listened and yet lived. The disappointed Sirens threw themselves into the sea. Fine female singers are now Sirens in common speech.

Sisyphus, a crafty prince of the heroic times of Greece, who, for some uncertain offence to the gods, was doomed, in the infernal regions, to roll a huge stone up a hill, whence it redescended immediately, rendering his punishment perpetual. The fruitless toil of Sisyphus is often the theme of allusion and comparison.

Socrates, the wisest and best character, perhaps, of antiquity. He was born and lived in Athens, where, in an unpretending way, he taught men to love virtue and cultivate knowledge. His opinions and actions, as recorded by his pupils Plato and Xenophon, have filled posterity with admiration for him from whom they came. Socrates was at length accused by the ungrateful Athenians of offences against religion, and died, according to his sentence, by drinking a cup of hemlock presented to him. His last moments, spent among his weeping friends, brought out his character in even a nobler light than it had before appeared in.

Solon, one of the seven wise men of Greece, celebrated for the equity of the laws dictated by him to the Athenians. His fame for wisdom has caused men of similar repute to be called Solons.

Somnus, the god of Sleep, and son of Night.

Sophocles, a tragic poet of Greece, who composed in a grave and lofty style.

Sphinx, a monster with the head and chest of a woman, a dog's body, a serpent's tail, and the wings of a bird, sent by Juno to devastate Bœotia. An oracle told that the Sphinx would destroy herself on one of her enigmas being explained, and Œdipus, on being asked by her what animal walked on four legs at morn, two at noon, and three in the evening, correctly answered "man," referring to infancy, manhood, and old age. The Sphinx then killed herself against a rock.

Stagyra, the birth-place of Aristotle, whence he was called the Stagyrite.

Stentor, a Greek whose voice, according to Homer, equalled those of fifty men combined. "Stentorian" is a settled synonym for excessively loud enunciation.

Stoic.—The Stoics were a sect of philosophers founded by Zeno, who professed so grave and stern a morality that their designation has been applied to men who exhibit great powers of self-restraint and endurance.

Styx, a cold and venomous river of the infernal regions, famous on account of the estimation in which it was held by the gods, who swore by it, and held such oaths inviolable.

Sybaris, a town on the bay of Tarentum in Italy, the inhabitants of which were so effeminate, that "a Sybarite" has become a phrase applied to any person of such a character.

Tacitus, a Roman annalist of the empire, whose writings have been deemed models of excellence in historical literature.

Tantalus, who, for murdering his own son, and serving him up to Jupiter to try his divine insight, was condemned to remain up to the neck in water, which ever fled from his lips as he sought to slake his perpetual thirst. Hence the word "tantalize," now firmly fixed in various modern languages.

Tarpeia, a woman who is said to have given name to the Tarpeian rock on which stood the Capitol, and from which great malefactors were hurled by the Romans.

Tarquin.—From the son of the last Tarquin of Rome,

forcible despoilers of female honour have gained a name appropriate to their actions.

Tartarus, the most familiar name of the infernal regions. Though taken often for the whole, Tartarus properly expressed the last abode of the wicked, as Elysium indicated that of the good.

Telemachus, son of Ulysses, who showed his filial piety by travelling in quest of his father, when the latter wandered from place to place on his way from Troy. Minerva accompanied the young prince under the form of an old man named Mentor, whence a common term for a counsellor and guide.

Tempe, a vale of Thessaly, described by the poets as the most delightful spot on the earth, and used as a by-name for all similar scenes of natural beauty.

Terpsichore, the Muse of dancing.

Thales, one of the seven wise men of Greece, peculiarly famous for his skill in astronomy.

Thalia, the Muse who presided over comic poetry, pastorals, and festival celebrations.

Themis, a goddess whom Homer calls the presiding guardian of justice and civil law, and whom modern lawyers nominally acknowledge as their patroness. She is painted holding a sword and scales.

Themistocles, a famous Athenian commander, who conquered the Persians at the great naval fight of Salamis Several anecdotes of him are often quoted. "Strike, but hear me!" were words used by him to an angry adversary. Napoleon Bonaparte, at his surrender to England, compared himself to Themistocles, who in a similar way had planted himself on "the hearth" of a foreign king and sought refuge.

Theocritus, a native of Syracuse, styled the father of pastoral poetry.

Theseus, an Athenian prince of the heroic ages, renowned for his great deeds. In youth he went to Crete as one of the tributary band to be sacrificed in the Labyrinth to the Minotaur, but he slew the monster, and escaped by the help of the clue of Ariadne. He afterwards deserted Ariadne. The share of Theseus in the battle of the Lapithæ, his friendship for Pirithous, proverbial for its closeness, and a visit to Tartarus, are among the principal other features in his story.

Thespis, an ancient Greek poet, from whom, as the supposed inventor of tragedy, springs the phrase of the Thespian art, applied to the drama.

Thetis, a sea-deity, who, by marriage with the mortal Peleus, became the mother of Achilles.

Thisbe, a maiden of Babylon, beloved by Pyramus.

Thucydides, a historian of Athens, highly esteemed for his fidelity and the merits of his style.

Thule, an island in the northern parts of the German Ocean, termed by the Romans *Ultima Thule*, as the ultimate point of the earth in that direction. Some have thought it Greenland and some Iceland, but the probability is that the name was really applied to the Shetland Isles.

Tiberius (Cæsar), successor of Augustus, and only less proverbial for cruelty than his successors Nero and Domitian.

Tibullus, a poet of Rome, whose graceful and chaste compositions have gained for him a first place among elegiac bards.

Timotheus, a poet and musician who followed the fortunes of Alexander, and is celebrated by Dryden as "raising a mortal to the skies"—that is, flattering his master as a divinity.

Tiresias, a famous Theban, struck blind, as the story runs, by Juno, but gifted with prophecy by Jupiter, and consulted during his life by all Greece.

Tisiphone, one of the three Furies.

Titan.—The gigantic family of the Titans, descended from the Heaven and Earth, warred against Jupiter, and tossed mountains at him in their fury, but were subdued

and condemned to heavy punishments. This is the common fable, though other giants are said by some to have been Jupiter's enemies.

Trajan, a Roman emperor, whose many virtues are chiefly sullied by his cruelty to the primitive Christians of Rome. Trajan's pillar at Rome is a work of great celebrity.

Triptolemus, a native of Eleusis, whom Ceres sought to make immortal by laying him upon flames to purge away the grossness of humanity; but his mother, through curiosity, peeped upon the proceedings, and, terrified at the sight, frustrated the design. In compensation, Ceres taught Triptolemus the art of agriculture, and gave him the honour of its dissemination over the earth.

Triton, a leading sea-god, represented as half man half dolphin, and always seen blowing a horn.

Tusculum, the country-seat of Cicero, from which similar retreats of great men are sometimes called Tusculan villas.

Tyrtæus, a Greek poet, usually held the type of martial verse writers.

Ulysses, king of Ithaca, usually deemed the wisest of the Greeks who went to Troy. After the close of the siege of that city, during which he carried off its Palladium, and performed many feats of address and valour, he underwent many years of adventure, described in the Odyssey, ere he reached his home. There he found his means wasted by suitors to his wife Penelope, but the tried warrior soon slew or dispersed them all, and resumed his throne in peace.

Urania, the Muse who presided over astronomy.

Venus, the goddess of love and beauty, and mother of Cupid. Her parentage is not settled, but she sprung directly, it is said, from the froth of the sea, and was immediately received among the deities. The character given to Venus is one befitting only the goddess of licentious pleasure. Her power to charm is stated to have depended on her *cestus* or zone, and she was usually represented sitting in a chariot drawn by doves. From various favourite spots she is called by the names of the Cytherean, Cyprian, and Paphian goddess, as well as by other names.

Vertumnus, the god of spring among the Romans.

Vesta, usually termed the mother of the deities, and patroness of the virgins called Vestal, who, like modern sisterhoods of nuns, retired from the world to live in sacred establishments. Any departure from chastity was fearfully punished in them, and to seduce a vestal virgin was deemed a horrible crime in men. A fire was kept burning continually in the vestal establishments, its extinction being dreaded as an omen of heavy calamity. The phrases of "vestal virgins" and "vestal flames" are familiarly used in the sense here indicated.

Virginia, daughter of the tribune Virginius. Having arrested the licentious eye of Appius Claudius, then in power, he endeavoured to get possession of her by proving her to be his slave; but her father defeated his nearly successful design by stabbing her with his own hands, to preserve her honour. Many a poet has dwelt on this story.

Vulcan, son of Juno, and god of Fire, supposed to work, with his assistants the Cyclops, in the interior of Mount Ætna. Though lame and deformed, he was the husband of the goddess of beauty, and father of Cupid. He acted as armourer to the gods, and sometimes wrought for men, as in the case of Achilles. The worship of Vulcan was well established.

Xantippe, wife of Socrates, and so great a shrew as to have given a name to all ladies similarly gifted.

Xenophon, an illustrious writer and soldier of Athens, who went to Persia to assist Cyrus to obtain the throne of that country. When Cyrus was defeated, the auxiliary Greeks made that retreat homewards so often adverted to as the Retreat of the Ten Thousand. Xenophon latterly was their leader.

Zoilus, a critic, who made himself so [illegible], his animadversions on Homer and other writers, that a carper of the same craft is yet called by his name.

Zoroaster, a famous Persian sage, who is said to have founded or reformed the religion of the Magi

DICTIONARY OF TERMS IN SCIENCE, LITERATURE, AND ART.

[A COMPREHENSIVE and minute Terminological Dictionary, or vocabulary of all the terms now in use in literature, science, and art, would require a much larger amount of space than can be here afforded. Fortunately, so extensive a view of terminology is not required, as the terms appertaining to many branches of knowledge have already been explained in the present series. For example, in those numbers of the "Information for the People" which treat of Astronomy, Geology, Zoology, the Anatomy of the Human Body, Chemistry, and Mechanics, the principal terms connected with these subjects will be found, with ample accompanying explanations; and the case is the same as regards other matters discussed in the course of these sheets. It is not in general difficult to discover the department, at least, of science to which any word of doubtful meaning belongs, and reference may be satisfactorily had. It is imagined, to the quarters alluded to, for interpretations not given in the present dictionary. As the insertion of radical or primitive words would have occupied much space, without answering any good purpose, it may be here generally observed that men of science have almost universally selected the Greek language as the one best suited by its idiomatic peculiarities for the formation of compound terms. It may be of some little advantage to name here a few of the most common roots so used. Many of the names of sciences are framed from the word *grapho*. Thus, Geography, derived from *grapho*, which signifies to *write*, and *ge*, the *earth*, has the sense of "a writing on or description of the earth." Other scientific terms are formed from *logos*, a *discourse*. Thus, Ornithology means "a discourse on birds," *ornis* being the Greek term for a bird. *Nomos*, a *law*, composes other words; as, for example, Astronomy, which signifies the "law of the stars," *astron* being the word for a star. The word *scopé*, an *observation*, compounds a few terms, as Craniosceopy, which, with *cranion*, means "observation of the skull." Various terms are also formed from *metron*, a *measure;* thus, Geometry signifies a "measuring of the earth," and Thermometer "a measure of heat," *thermé* being the term for heat or warmth. In the science of Geometry, many words are compounded of *gonia*, an *angle*, as in the case of Pentagon, a word signifying "a figure of five (*pentè*) angles;" and some are formed from *hedra*, a *base* or *side*, as Octahedron, "a figure of eight sides." Again, in the science of Botany, a great many words are framed from *andros*, *men*, and *gunè*, a *woman*. For instance, when the former word is compounded with *monos*, *alone* or *single*, it forms Monandria, a word applied to plants with one stamen to each of its flowers. Monogynia, framed similarly with *monos* and *gunè*, signifies a plant with one pistil. The whole of the Greek numerals are joined with these words in the like manner, and indicate in each case the existing number of what are called the sexual parts of plants. The following is the mode of the use of these numerals with *andros*, and they are similarly compounded with other words:—Monandria, 1; Diandria, 2; Triandria, 3; Tetrandria, 4; Pentandria, 5; Hexandria, 6; Heptandria, 7; Octandria, 8; Enneandria, 9; Decandria, 10; Dodecandria, 11 to 17. Where numbers not reckoned in detail are to be indicated, *polus*, signifying *many*, is the compounding term, as in Polyandria, a plant with many stamens.

The same words *monos* and *polus* form many general terms, as Monotonous, in the sense of *single-toned*, and Polytechnic, having the meaning of *many-sciened*. The word *polis*, a *city*, compounds many words, as Metropolis, signifying the *mother-city*. *Hudor*, *water*, and *pur*, *fire*, also form a number of scientific terms: as Hydrophobia, a *dread of water*, and Pyrotechny, the *art of making fireworks*.

These general hints on the compounding of technical terms are all that can be given here. As in the preceding instances, the majority of the epithets used in science are simple in construction; and in the present sheet, the language which renders the original roots most directly into English has been chosen in giving the sense of the words compounded from them. Some are disposed, it may be observed, to find fault with men of science for not making use of modern and vernacular language, but the complaint is made without due consideration. The idiom of the English and most living tongues is opposed altogether to such a system of compounding; and as each country might fairly demand to employ her own language, what a maze of confusion scientific nomenclature would inevitably become, were there not some common form of speech intelligible to all.]

ABEYANCE.—Lands are said, in law, to be in abeyance when they are not actually in the possession, but only in the expectance, of the next inheritor.

ABORIGINES, a name given first to the ancient inhabitants of Latium, and now applied to the original natives of any country.

ACCIDENCE, a display of the variations of words according to their government or sense. The term is often applied to any work that teaches the rudiments of grammar.

ACCOLADE, the ancient ceremony of conferring knighthood, consisting, formerly, in an embrace given to the young knight by the sovereign. The neck is now gently touched with a sword instead.

ACCORDION, a new and small musical instrument, the sounds from which are produced by air acting on vibrating tongues. It is held during use in the hands.

ACIDS, compound chemical bodies which are tart to the taste, change the vegetable blues to red, and form salts with alkalies and earths.

ACOLYTE, a name applied to the young official attendants of the Catholic bishops.

ACOUSTICS, that branch of science which treats of the nature and modification of sound. (See article ACOUSTICS, in the present series.)

ACROSTIC, a poem, the first letters of which compose, collectively, some name, title, or word chosen for the purpose.

ADIPOCERE, a fatty or waxen substance, into which, under certain circumstances, decomposed animal bodies resolve themselves.

ADVOWSON, the right of presentation to a church or benefice.

AEROLITES, meteoric stones which fall from the atmosphere, and have been found at different times in considerable numbers, some of them weighing but a few grains, and others upwards of a hundred pounds.

AERONAUTICS.—The art of aëronautics or aërostation consists in the navigation of the air by means of balloons filled with a gas of greater rarety than the atmosphere. Heated or rarefied air was first used for the purpose, but now hydrogen gas is universally employed.

AGRICULTURE, the art of cultivating the earth. (See article AGRICULTURE.)

ALBINOS, a class of human beings remarkable for the red colour of their eyes, their white hair, and pale skin, peculiarities caused by a defective physical constitution.

ALCHEMY, a name now applied to the vain art which had in view the discovery of the elixir of perpetual life, and of the power of transmuting baser metals to gold.

ALCORAN, or The Koran (meaning The Book), a work containing the precepts and disquisitions of Mohammed.

ALGEBRA, the science of computing abstract quantities by symbols or signs. (See article ALGEBRA.)

ALIAS and ALIBI.—Alias, used in the sense of *otherwise* or *at another time*, is applied to a case where a man bears two names, as Brown *alias* Smith. When a party proves himself to have been at a different place when a crime was committed at any given spot, he is said to have proved an *alibi*, or that he was *elsewhere* at the time.

ALKALI, a metallic oxide which changes vegetable blues to green, and forms neutral salts with acids.

ALLUVIUM, a term applied to flat patches of soil, formed by the wearing-down action of moving waters on mountains and other elevated portions of ground.

ALPHA, the first letter of the Greek alphabet.

ALTO-RELIEVO, an expression used by sculptors to designate figures brought out strongly from any surface, or in *high relief*.

ALUMINA, an earth containing alum, and forming the basis of clayey soils.

AMALGAM.—A mixture of mercury with any metal was formerly called an amalgam; but any thorough union of one article with another is now termed amalgamation.

AMAUROSIS, a disease of the eye, consisting in a general dimness of vision, and caused by defects in the power of the retina.

AMBROSIA, the imaginary food of the heathen gods.

AMMONITE, or ammite-stone, a fossil-shell rolled up into a serpentine shape.

AMPHIBIA, a class of animals which exist both in land and water.

ANACHRONISM, an error with respect to the computation of dates or time.

ANAGRAM, the change of any word or set of words into another by the transposition of the component letters. For example, *James Stuart* has been anagrammatized into *A just master*.

ANALOGY, the relation which two different things bear, or seem to bear, to one another from resemblance or respective proportions.

ANALYSIS, the discovery of truth by the resolution of any thing into its fundamental constituents.

ANATHEMA, a term used by ecclesiastical writers, and expressing the separation or cutting off of any person from religious privileges.

ANATOMY, the art of examining into the structure of bodies by dissection. (See the article termed ACCOUNT OF THE HUMAN BODY.)

ANDANTE, an Italian term indicating such a degree of slowness in musical execution that each note is distinct; *andantino* signifies a more gentle rate of execution.

ANEMOMETER, an instrument used for measuring the degrees of force and speed of the wind.

ANEURISM, a diseased swelling on an artery, filled with blood, and resulting from a rupture of one of the arterial coats.

ANIMALCULE, an animal of very minute size.

ANNULAR, a term signifying *ringed* or like a ring. The annular eclipse of the sun is so named from the ring-like shape of that part of the sun's surface left visible by the moon, the relation of the luminaries being then such that the latter and smaller body is placed fairly in front of the former.

ANODYNE, any medicine of sedative or soothing powers.

ANTEDILUVIAN, an epithet for any thing supposed to have existed before the flood.

ANTENNÆ, the horns or feelers of insects.

ANTEPENULTIMATE, the last but two of any number of letters, words, or things.

ANTHOLOGY, a word signifying a collection of flowers, but usually applied to assemblages of short poems.

ANTHRACITE, a valuable species of coal, composed almost wholly of carbon or fossilized wood.

ANTHROPOPHAGI, a word signifying men-eaters.

ANTICLIMAX, a descent or fall, in oratory, or writing, from the great to the little.

ANTIPODES, the people of the earth who live opposite one another, or "foot to foot."

ANTISPASMODICS, medicines alleviative of spasms.

ANTITHESIS, a rhetorical figure, by which contraries are rendered effective through contrast.

APHELION, the point at which any planet is farthest removed from the sun.

APOGEE, the point of the orbit at which the sun, moon, or any planet is most distant from the earth.

APOLOGUE, a fable conveying covertly some important truths.

APOPHTHEGM, a brief, pointed, and forcible saying.

APOPLEXY, a disease resulting from the pressure of blood generally effused upon the brain, and of which the result is paralysis, partial or complete.

APOSTROPHE, a figure in rhetoric, consisting in an address or appeal made to some absent person, as if he were present.

APOTHEOSIS, a classical term expressive of the deification of some person after death.

AQUATINT, a style of etching producing effects similar to those of drawings with Indian ink. (See art. DRAWING.)

ARABESQUE (or Moresque), a style of ornament in sculpture or painting practised by the Arabs, and abounding in foliage, while animal figures are excluded.

ARBORICULTURE, the science of cultivating trees.

ARCANUM, a secret.

ARCHETYPE, the first model of any work.

ARCHITRAVE, that part of a column lying immediately on the capital.

ARGILLACEOUS.—The species of earth called clay, and containing alumine, is styled argillaceous.

ARIOSO, the Italian term for common musical time.

ARITHMETIC, the science of numbers. (See the separate article on that subject.)

AROMA, a name for the odorous principle in spicy shrubs and other plants and flowers.

ARPEGGIO, a word used to signify distinctness of tone in musical language.

ARTERY, the name of the class of vessels which distribute the red or oxygenated blood over the body.

ARTESIAN WELLS.—On boring deeply into the earth in many situations, water is reached, which, being collected from higher grounds, rises spontaneously to the surface, through its tendency to find its level. From being early formed in the province of Artois, such wells have received the name of Artesian Wells. One of the largest is that recently formed at Grenelle, near Paris.

ASAFŒTIDA, a fœtid resinous gum, used in medicine to allay spasmodic irritation.

ASBESTOS, a mineral substance, remarkable for its power of resisting combustion.

ASCARIDES, worms that infest the intestines of animals.

ASCENDANT, in astrology, is the term used to express that degree of the ecliptic which chances to rise above the horizon at the hour of any one's birth.

ASPHALTUM, a bituminous or pitchy substance, found both in lakes and among rocky strata, and recently used for forming pavements.

ASPHIXIA, a term used by physicians to express the fainting or swooning state.

ASSAYING, the process of testing the purity of the precious metals, or the quantity of them contained in any ore.

ASTEROIDS, the name given to the four small planets Vesta, Juno, Ceres, and Pallas.

ASTRINGENTS, medicines which, by their corrugating or constringing powers, strengthen the parts of the animal frame to which they are applied.

ASTROLABE, an instrument for taking the altitude of the heavenly bodies.

ASTROLOGY, an exploded science, which professed to foretell and divine by means of the celestial bodies.

ASTRONOMY, the science which treats of the nature, position, and movements of the heavenly bodies. (See that article.)

ATHENÆUM, a name given in ancient times to a kind of public school and lecture-room, of which several existed in Athens.

ATHLETE, the title bestowed on those who contested at the public games of Greece for the prizes given in reward of superior personal strength and agility.

ATROPHY, a malady marked by the wasting away and emaciation of the body.

AULIC (from *aula*, a hall), the epithet assumed by a high court or council of the German empire.

AURICULAR, the epithet applied to the mode of confessing practised by the members of the Roman Catholic Church, and so named from the Latin word *auris* (the ear), the revelations being whispered, as it were, into the ears of the priests.

AURORA BOREALIS, or the Northern Lights. These meteoric flashes of flame, seen commonly in the north, are ascribed by some to electricity, and by others to reflections from the sheets of polar ice.

AUSCULTATION, the discovery of disease from the internal sounds.

AUTOGRAPH, a word expressing whatever is written by a person's own hand.

AUTOMATON, a name given to any self-acting machine which imitates the movements of living bodies. Machines that imitate the form and motions of man are also called Androides.

AVATAR, a word used by the Hindoos to express an incarnate descent of the god Vishnu upon earth, nine of which descents are held to have been already made, while the tenth is yet to come.

AVIARY, a place devoted to the keeping of birds.

AXILLA, the arm-pit in anatomical language.

AZOTE, the old term for nitrogen gas, the chief component of the atmospheric air.

BALÆNA, the scientific name for the whale tribe.

BALLET, a pantomimic piece, consisting only of action and dancing.

BALUSTRADE, a series of small columns of wood, stone, or metal, united by a cross top or rail.

BANDANA, a species of calico-printing, first practised in India, and originally consisting of light spots impressed on a red or dark ground.

BANIAN-TREE, a vegetable production of the east, which sends down branches that take root in the ground, and themselves become trunks, thus forming, in some cases, a pillared arcade of such enormous extent as to be capable of covering and sheltering a numerous army.

BARBICAN, an outer defence to a city or fort.

BARILLA, a species of crude soda, procured by burning kelp or marine plants, and used in bleaching, as well as in the manufacture of glass and soap.

BAROMETER, an instrument used for marking the variations of weight in the atmosphere, being so constructed that the presence or absence of vapour raises or depresses a column of quicksilver placed upon a graduated scale.

BARYTA, an earth of a ponderous sort, formed of oxygen gas and a metal called barium.

BASILICON, a word applied to a resinous ointment in common use, and signifying an ointment of "sovereign" value.

BASSO-RELIEVO (or BAS-RELIEF), a style of sculpture in which figures are brought out slightly from the surface, or in low relief.

BELLES-LETTRES (Elegant Letters), a French term, now generally applied to polite literature of every description. The branches of knowledge ranged under this comprehensive head by the learned men who established the Lyceum of Arts at Paris in 1792, and gave a definite sense to the term for the first time, were the sciences of grammar, languages, rhetoric, geography, history, antiquities, and numismatics; and to these poetry would certainly have been added, had lectures on that subject been then founded. From the list of the belles-lettres were excluded the mathematical and natural sciences—jurisprudence, ethics, metaphysics, theology, the fine arts, and the mechanical arts. It may be reasonably doubted, however, whether antiquarian literature should be ranked among the belles-lettres, while writings relative to the fine arts are excluded. But the term in question must ever of necessity have a somewhat vague meaning, and it is of little consequence that differences should exist respecting its interpretation. Generally speaking, it may be said that within the range of the belles-lettres are to be included all branches of knowledge or which the imagination and taste are exercised, while a graver name befits the exact and observant sciences, and those generally which call into play the more profound powers.

BELVIDERE, a name given by the Italians to the open tops of houses, which are ascended for the enjoyment of fine prospects and pure air. From being placed in a part of the Vatican bearing this character, the famous antique statue of Apollo is usually called the *Apollo Belvidere*.

BIBLIOGRAPHY, a term signifying a knowledge of books, of the number of their editions, the dates of their issue, and other particulars relative to their publication.

BIBLIOMANIA, a rage or passion for books, particularly old and scarce ones.

BIBLIOTHECA, a word anciently signifying a library, and more lately applied to general accounts of the works that treat of particular subjects.

BIOGRAPHY, the history of the life of any individual, or the art of writing such histories.

BISMUTH, a yellowish metal, very brittle and fusible, and used, on account of the latter quality, for making solder, pewter, and other alloys.

BITUMEN, a soft viscid substance, found both in the vegetable and mineral world, and called, according to its various states of consistence and purity, naphtha, petroleum, tar, pitch, and asphaltum. Bituminous substances are very combustible, and emit a strong odour when ignited.

BIVALVES, a class of shell-fish, comprising those which have shells of two pieces united by a hinge.

BLANC-MANGER, a light article of diet, compounded of milk, sugar, and other ingredients, purified by isinglass, and garnished with blanched almonds.

BLAZONRY, the art of scientifically describing all that belongs to coats of arms or heraldic bearings.

BLOWPIPE, a tabular instrument through which air is blown from the mouth, and which forms a most useful species of bellows to chemists and glass-blowers.

BOLUS, a medicinal mass, resembling a large pill.

BORAX, a salt found in a fluid or dissolved form in nature, and of great value in soldering metals, as well as for other purposes of art and medicine.

BOTANY, that branch of natural history which treats of vegetables, their characters, classes, and varieties. (See article on BOTANY.)

BOUTS-RIMES (rhymed endings), a term for verses formed from a succession of given rhymes or terminatio

BRAVURA, a difficult passage in music, or musical composition, requiring a brilliant and dashing style of singing.

BRECCIA, or pudding-stone, an aggregate substance formed of several varieties of small stones.

BREVIARY, the book containing the Roman Catholic church service.

BRONCHIAL TUBES, the branches or ramifications of the air-vessels in the lungs.

BRONCHOCELE, a tumour in the fore part of the neck over the windpipe.

BRONCHOTOMY, an incision made into the windpipe, to permit of breathing there, when the parts above are closed by accident or disease.

BUCOLIC, a synonym for the epithet *pastoral*, as applied to poetry.

BULBOUS, a term applied to roots of rounded shape, with fibres for the most part at the base.

BURLETTA, a light description of comic drama, named from the Italian word *burlare* (to jest).

BURSÆ MUCOSÆ, a set of small organs which secrete a fatty fluid for the lubrication of joints and tendons.

BURSAR, a pupil in schools, hospitals, or colleges, supported upon a bursary or endowment from the purse (or burse) of the institution, or from funds specially left by some donor for the purpose.

CAABA, a word signifying a *square building* in Arabic, and particularly applied by the Mohammedans to the great temple of Mecca, in which stands a sacred black stone worn down by the lips of the devout worshippers.

CABALA, a mystic science which the old Jewish rabbins pretended to have received by divine revelation, and which was connected with the magical art.

CACHALOT, in zoology, the physeter or spermaceti whale.

CACOPHONY, a bad tone of the voice, or discordant mode of enunciation.

CALCAREOUS, an epithet applied to a species of spar

and to other earthy matters containing lime, or formed wholly of it.

Calcination, the process of reducing bodies to a brittle pulverizable condition by the action of fire.

Calculus, a name given by medical men to stones or concretions found in the body, and commonly deposited either from the bile or the urinary secretion.

Calenture, an old name for a fever incident to sailors in hot climes, and characterized by a desire to rush into the sea on the part of those affected.

Caliber, the diameter of a cannon bore. A word usually spelled *calibre* has sprung from the preceding, indicating *quality* or *degree*. The association betwixt the two words rests in the sense or meaning of *capacity* attached to both. The term *callipers* is from the same source, and signifies a pair of curved compasses for measuring the diameter of cannon, shot, and other rounded bodies.

Calligraphy, properly fine handwriting, but now applied generally to the art of penmanship.

Callus, a term applied to newly-effused bone, or to any hard knob or secretion of an unnatural kind in the body.

Calomel, a compound of oxidized mercury with muriatic acid, named submuriate of mercury, and much used in medicine.

Caloric, the scientific synonym for *heat*.

Calumet, a long reed with a stone bowl used for smoking by the American Indians, and of which there are two kinds, one the calumet of war, and the other that of peace. The Indians smoke with these respectively in a solemn manner, when making hostile or pacific declarations.

Calyx, the cup or chalice which encloses and supports the parts of fructification in flowers.

Cameo, a kind of onyx stone. The term is commonly applied in art, however, to all stones or gems having figures raised in relief upon the surface, and many exquisite specimens of the artistical skill of the ancient Greeks and Etruscans exist in this shape.

Camera Lucida, a contrivance for throwing the image of any body on the wall of a room during sunshine, by means of an aperture in the window-shutter, through which the image of the strongly illuminated object without is received, and, after passing through a convex lens properly placed, is cast on the wall beyond with greater or lesser distinctness, according to distances.

Camera Obscura, a machine resembling an artificial eye, by which images received through a *double* convex glass are exhibited in their native colours on a white space in the focus of the glass. The whole is arranged in a darkened box or chamber, whence the name arises.

Canzone, a song or air in two or three parts, or a lyric of similar length to which music may be composed. *Canzonet* is a shorter piece of the same kind.

Caoutchouc, an elastic gum familiarly termed India rubber, which exudes from the bark of an oriental and South American shrub, and being impermeable to water, is now employed to give that property to articles of dress, as well as for other important ends.

Capillary, a word derived from *capilla* (a hair), and applied to fine delicate tubes in botanical and anatomical language.

Capitation, a term derived from *caput* (the head), and originally used in connection with the word *tax*, to signify an impost laid on per head, or on all persons indiscriminately.

Capsule, in botany, the seed-vessel of plants.

Caracole, a half-wheel made by a person on horseback either to the right or left.

Carat, a weight equivalent to four grains, made use of in weighing diamonds. Gold is also said to be fine or otherwise in proportion to the number of carats which it retains or loses in purifying.

Carbon, the pure part of charcoal, an elementary or simple body which exists to a vast extent in vegetable substances, as well as in the atmosphere, and in earthy stratifications. One of its chief compounds is *carbonic acid gas* (a compound with oxygen gas); and further compounds, called *carbonates*, are formed by that acid with lime and other bodies. Other compounds of pure or simple carbon with various substances are called *carburets*.

Carbuncle, a name for a fine red gem; and also for a deep purplish tumour frequently occurring on the surface of the human body.

Carminatives, medicines which relieve flatulency and spasm.

Carnivorous, an epithet applied to animals which feed on flesh.

Carotid Arteries, the two arteries which carry the blood from the heart to the head, and which are liable to be severed in the case of any deep wound in the neck.

Carte-blanche, a term applied to a piece of blank paper, signed by any party who wishes to give another full powers to act in the name of the subscriber.

Cartilage (or gristle), a substance of hard consistence, yet softer than bone, which is chiefly of use in the animal frame as a means of joining two or more portions of the latter material. Cartilaginous is an epithet applied to that class of fishes which have skeletons of cartilage instead of bone.

Cartoon, a design drawn upon paper for the purpose of being traced afterwards upon any other substance, as the famous cartoons of Raphael were designed for tapestry.

Caryatides in sculpture, columns imitating the bodies of women clothed in the Caryan dress.

Catacomb, subterranean grottoes or vaults for the reception of the bodies of the dead.

Catalepsy, a kind of paralytic seizure, during which the person affected is speechless, senseless, and to all appearance dead; with this difference, that on raising any of the limbs, it rigidly retains the position given to it, however awkward.

Cataplasm, a synonym for a poultice.

Cataract, a fall of water; in medicine, an affection of the eye, consisting in a thickening of the crystalline lens or its enclosing membrane.

Catarrh, a defluction from the nose, throat, or windpipe, constituting one common shape of the complaint termed a cold.

Catastrophe, a term originally signifying the winding up of a play, and now applied to the close of any event or course of events, particularly of a calamitous description.

Category, a class or order of ideas or attributes; or, in common speech, a list or series.

Catholic, an epithet properly signifying *universal*, and bestowed with that sense on the Church of Rome in early times.

Catholicon, a supposed *universal* remedy for diseases.

Catoptrics, that branch of the science of optics which treats of the properties of reflected light.

Caustics, a class of drugs of so acrid a nature—as, for example, nitrate of silver (lunar caustic)—that they corrode the animal texture, and create breaches of the surface.

Caviare, sturgeon-roes, salted and preserved as a condiment in some parts of Europe.

Cellular Membrane, a thin layer of celled network, filled with a fatty fluid, and forming the intermediate texture between the layers of skin, the muscles, and, in short, all the organs of the body.

Cenotaph, a monument to the dead, differing from a sepulchre in containing no body.

Centipede, an insect with a hundred feet.

Centrifugal, an epithet expressing the tendency of bodies moving in a circle to fly off from the centre.

Centripetal, a term signifying the bent of bodies kept in circular motion, to gravitate towards the centre.

CEREBELLUM, the two posterior lobes of the brain, divided by a strong partition from the

CEREBRUM, or larger portion of the brain, occupying the upper and fore part of the skull.

CHALYBEATE, a term applied to those mineral springs which hold iron in solution, such as the springs of Moffat and Tunbridge.

CHARADE, a species of puzzle, which calls upon the solver to find out some particular word from a hint given of its syllabic constituents severally.

CHARLATAN, a quack, empiric, or boastful pretender to gifts not possessed.

CHEMISTRY, the science which investigates into the nature and properties of material bodies. (See article on CHEMISTRY.)

CHIARO-SCURO, two Italian words signifying *clear-obscure*, and indicating the distribution of clearness and obscurity, or light and shade, in paintings.

CHIROMANCY, the art of divination by examining the lines of the palm or hand.

CHLORINE, one of the simple or uncompounded gases, of strong corrosive powers, and used in bleaching, chiefly in the shape of those compounds of it called *chlorides* and *chlorates*.

CHROMATICS, that branch of optics relating to the colours of rays of light.

CHRONIC (from *Chronos*, time), an epithet applied to any thing that has been of long duration.

CHRONOLOGY, the science which examines into the divisions of time. (See article on CHRONOLOGY.)

CHRYSALIS, the state (otherwise named that of *nympha*, *pupa*, or *aurelia*) into which an insect passes while spinning its cocoon, and changing from a worm to a perfect insect.

CHRYSOLITE, a mineral of green tint, often transparent, and found both in the shape of grains and crystals.

CHYLE, a fine white fluid, into which the food is converted by digestion previously to its assimilation with the blood.

CHYME, a fluid into which the food is changed preparatorily to its conversion into chyle.

CIRRHUS, the term indicating clouds of a feathery or hairy aspect and shape.

CLAVICLE, the scientific name for the shoulder-blade.

CLERICAL, a term which, besides its modern and ordinary sense of "belonging to the clergy," is also used as an epithet for errors of the press, from the circumstance of *clerks*, or transcribers of manuscript, being answerable for such errors in early times. All writers and scholars, moreover, were anciently called clerks.

CLIMACTERIC, a term commonly used to signify a critical and advanced period of life. The ages of sixty-three and eighty-one have been deemed the climacterics of man, and the latter term has been specially called the *grand climacteric*.

CLIMAX, a figure in rhetoric expressive of the gradual and connected rising of a sentence or passage till it closes in a point which clinches forcibly all that precedes it.

CLINICAL, a word applied to medical lectures, the materials of which have been gathered at the actual bedsides of patients.

COBALT, a brittle metal of a grayish-white hue, used in an oxidized state for giving a lasting blue colour to enamels, porcelain, and the like articles.

COCOON, the silken or thready case which insects spin around themselves in assuming the chrysalis state, and which forms so valuable an article in the instance of the silk-worm.

COLEOPTEROUS INSECTS, a class of beetles, so named scientifically from their being sheath-winged.

COLLECTANEA, a word signifying any notes, extracts, or comments, referring to a collection of works.

COLLYRIUM, a lotion for the eyes.

COMATOSE, an epithet derived from the term *coma*, indicating a state of lethargic drowsiness or stupor.

COMMENDAM.—When an ecclesiastical benefice is temporarily intrusted to a layman for any secular purpose, or to one clergyman to hold till the regular incumbent is appointed, it is said to be given *in commendam* to such parties.

COMMISSARIAT, the department of the commissaries of an army, or those officers who have the charge of furnishing the troops with the necessaries of life.

COMPOSITE, the term for the fifth order of columnar architecture, so named from its capital being composed out of those of the other orders.

CONCENTRIC, an epithet given to figures or circles having a common centre, like those formed by dropping a stone in water.

CONCHOLOGY, the science which treats of shells and shelled animals.

CONCORDANCE, an index comprising every word in a book, and giving reference to every place where it is to be found.

CONDUCTOR, in the language of electrical science, a substance which transmits the electrical fluid readily. Non-conductors are bodies which have the opposite quality. The majority of metals are good conductors, and glass is a good specimen of a non-conducting substance.

CONGLOMERATE, a term in mineralogy for a stone compounded of quartz, siliceous slate, flint, and other stones.

CONVEYANCING, the profession of drawing up deeds conveying property.

CONVOLUTED, a term signifying "rolled one upon another."

CORDON, a line drawn around a military force or infected spot, and called in the latter case a sanatory cordon.

CORNEA, the transparent membrane on the fore part of the ball of the eye.

CORNUCOPIA, the horn of plenty, in the language of classical mythology.

COROLLA, the coloured part of a flower, composed of the petals.

COROLLARY, an inference from certain given premises.

CORTICAL, any thing belonging to the bark, rind, or outer covering of bodies.

COSMOGONY, the science that treats of the origin of the world.

COSMOPOLITE, a citizen of the world.

COUCHING, the operation for curing cataract by turning the opaque lens out of the axis of vision.

CRANIOLOGY, the science which investigates into the structure and divisions of the skull.

CRANIOSCOPY, the art of discovering the internal organs of the brain by observing and measuring the outward protuberances.

CRANIUM, the bony case enclosing the brain.

CRATER, the mouth or opening of a volcano.

CRETACEOUS, a synonym for the term *chalky*.

CRUCIBLE, a pot usually made of clay, and employed in melting substances, or exposing them to a strong heat.

CRUSTACEOUS, an epithet applied to those fishes which are covered by jointed scaly shells.

CULMINATION, a term expressing the attainment of the highest point of daily altitude by any heavenly body.

CUNEIFORM, a word signifying formed like a wedge.

CUPOLA, the dome or vaulted roof of a building.

CUSPIDATED, spear-pointed.

CUTANEOUS, of or belonging to the skin.

CUTICLE, the outer or scarf-skin, which is very thin and insensible.

CYCLE, a continual revolution of numbers, applied to a series of years which go on for a certain period, and then return to the same starting point, thus circulating perpetually.

CYCLOPÆDIA, a word expressing the cycle or entire compass of the arts and sciences.

CYLINDER, a long circular body of uniform diameter such as a gun-barrel.

CYNANCHE, an inflammation of the larynx, familiarly called a quinsy or sore throat.

DA-CAPO, a term implying that a musical piece is to be repeated.

DACTYL, a poetic foot or division of a line, consisting of a long syllable and two short ones.

DAGUERREOTYPE, a recent invention of M. Daguerre of Paris, by which external objects are made to impress their image on a surface of silver or paper prepared for receiving it by certain coatings extremely sensible to light, and of which iodine is the basis. The process is conducted by means of a camera obscura.

DECADE, any thing numbering ten, as ten years or ten days.

DECAHEDRON, a figure having ten sides.

DECALOGUE, the ten commandments of the Jewish Scriptures.

DECAMERON, a work of which the supposed action occupies ten days, such as Boccaccio's Decameron, the hundred tales of which are described as employing ten days in the narration.

DECIMATION, the execution of every tenth man in a body of men, a mode of punishment inflicted by the Romans on mutinous and cowardly soldiers.

DELIQUESCENCE, spontaneous liquefaction on exposure to the atmosphere.

DEMOCRACY, properly a form of government in which the people hold power collectively. *Democratic* is an epithet having virtually the sense of ultra-republican.

DEMONOLOGY, a discourse on demons.

DEMULCENTS, drugs which soothe irritation and diminish acridity.

DENTAL, of or belonging to the teeth.

DENTATED, tooth-like.

DENTIFRICE, a preparation for cleansing the teeth.

DEODAND, a word meaning "given to God," and applied to fines allotted to pious ends.

DESIDERATUM, any thing not possessed, but desired.

DETONATION, a report made by the explosion of combustibles.

DIACHYLON, an adhesive and softening plaster.

DIAGNOSTICS, a term given to the signs by which diseases are recognised by physicians.

DIAGONAL, a line drawn from one angle of a figure to another.

DIAGRAM, a scheme or series of figures, drawn for the purpose of illustrating any proposition.

DIALECTICS, the art of logic.

DIAMETER, a right line passing through the centre of any curvilinear figure.

DIAPASON, in music, the interval of an octave.

DIAPHRAGM, the strong muscular partition dividing the chest from the intestinal region.

DIAPHORETICS, medicines which cause perspiration.

DIARRHŒA, a billious flux from the intestinal canal.

DIETETICS, the science which has reference to the arrangement of the diet.

DILETTANTE, an amateur of letters and the arts.

DILUVIUM, a term applied to strata or soils bearing marks of the action of a deluge.

DIOCESAN, a bishop, or one who has charge of a diocese.

DIOPTRICS, the science which considers the subject of refracted light.

DIORAMA, a word from the Greek signifying "to see through." Exhibitions of large paintings have received this name, when arranged with an open stage-like front and a shifting light from above, so as to give the effect of distance and change of time to the paintings displayed.

DIPLOMA, a document conferring some honour or privilege.

DISPENSATORY, an authorized collection of receipts, by which medicine may be compounded; also a place where they are dispensed.

DIURETICS, medicines which promote the urinary secretion.

DIVINATION, the exploded art of foretelling things to come, by ceremonies of various kinds.

DOMINICAL DAYS, a term for Sun days, signifying, etymologically, "days of the Lord." The letter denoting the Sabbath in calendars is named the *Dominical letter*.

DOMICILIARY, an epithet often applied to visits made by *authority* to private domiciles.

DOMINO, a game played with ivory pieces; and also a long mantle used at masquerades.

DORIC, a term bestowed on language of a simple and rustic order, such as that used by the ancient Dorians. The *Doric* is one of the architectural orders, and is noted for simplicity and strength.

DOXOLOGY, a hymn in praise of the Almighty.

DRAGOMAN, an oriental interpreter.

DRASTIC, an epithet given to aperient medicines which act powerfully.

DUET, an air in two parts.

DUODECIMO, a name applied to books having twelve leaves to a sheet; duodecimals are numbers counted by twelves.

DUPLICATE, a second copy of any thing.

DURA MATER, a strong membrane enclosing the brain, and dividing some parts of it into separate sections.

DYNAMETER, an instrument for determining the magnifying power of telescopes.

DYNAMOMETER, a machine which measures the strength of the human or animal frame.

DYSENTERY, an intestinal disease, accompanied with severe fluxes, partly of blood.

DYNAMICS, the science which considers of moving powers and the motions of bodies, with their relations and mutual reactions.

DYSPEPSIA (or Dyspepsy), a medical term for the malady of disordered digestion, which lies at the bottom of so many other diseases.

EASTER, a Christian festival commemorative of the resurrection of Jesus Christ, and celebrated on the Sunday following the first full moon after the 21st of March. No better etymon can be found for the word Easter than the name (Ostera) of a Pagan goddess.

ECCHYMOSIS, a blue mark caused by blood effused under the skin.

ECLECTICS, philosophers who are of no sect, but choose the best portions from the collective doctrines of others.

ECLIPTIC, the apparent orbit of the earth, or that circle in the heavens through which the earth would seem to move if seen from the sun.

ECLOGUE, a simple pastoral poem, where shepherds are introduced in discourse.

EFFLORESCENCE, the flowering of plants; in chemical language, the formation of small white grains on the surface of bodies.

EFFLUVIUM or EFFLUVIA, the minute particles "flowing out of" or exhaled from bodies, as in the case of putrefying matter. It is common, also, to attach the meaning of a strong odour to the term.

ELECTRICITY, a word taken from *electron* (amber), because that substance was early observed to attract other bodies, when excited by friction. This action was found to depend on a remarkable principle, commonly called the electric fluid, and existing more or less in all material bodies in a latent state, when it is impalpable to the senses. When drawn from bodies, it assumes the appearance of a spark or streak of light. The electric fluid travels with vast rapidity, is the source of thunder, and bears striking relations to the galvanic and magnetic principles, as well as to light, heat, and the vital power itself. (See article ELECTRICITY.)

ELECTRO-MAGNETISM, the science which treats of elec

tricity and magnetism, and the relations existing between them.

ELECTUARY, a name given to medicinal preparations, consisting of powders, or such like dry substances, mixed up with some syrup or conserve.

ELEEMOSYNARY, an epithet for whatever pertains to or is sustained by charity.

ELEGY, a short poem, essentially of a pensive cast.

ELIXIR, a liquid essence or extract of any substance.

ELLIPSIS, an oval figure; in grammar, an omission of words easily supplied by the reader.

EMBARGO, a prohibition to sail laid on shipping.

EMBOSSING, the graving of words in relief, or the working of embroidery.

EMBROCATION, a name for medicinal liquids used for rubbing sprains and other external ailments.

EMBRYO, the rudiment or germ of animal or vegetable bodies.

EMETIC, a vomitory drug.

EMOLLIENTS, medicines which soften and supple the parts brought into contact with them.

EMPIRIC, a name applied to quacks of every species, and chiefly to pretenders in medicine.

EMPORIUM, a word usually bestowed on any great centre of commerce, or of a branch of commerce.

EMPYREAN, the heaven of heavens; whence the adjective empyreal, signifying aërial or celestial.

EMULSION, a milky medicinal mixture, formed of oil and water, or mucilaginous.

EMUNCTORY, any part of the body which carries off excretions, as, for example, the nostrils.

ENCYCLOPÆDIA, a term now generally given to dictionaries embracing a view of all the arts and sciences.

ENTOMOLOGY, that department of zoological science which relates to the natural history of the insect world. (See articles on ZOOLOGY.)

EPHEMERA, the day-fly, so called from its existing but for one day. Hence the use of the epithet *ephemeral* in the general sense of short-lived or transitory.

EPHEMERIS or EPHEMERIDES, a tabular almanac, showing the state of the heavens and heavenly bodies for every day at noon.

EPIC POEM.—The *epos*, or epic poem, is a composition which relates to the life of some hero or eminent person, and treats of great events in a grave and lofty style. It is considered as the grandest species of poetry. The subject or plot is termed the *Epopeia*.

EPIDEMIC, a disease which affects a large number of persons in the same locality at one time, lasts for irregular periods, and is in most cases contagious.

EPIGASTRIC, of or belonging to the upper abdominal region.

EPIGLOTTIS, the cartilaginous lid which covers the top of the windpipe in swallowing.

EPIGRAM, a short poem, terminating in a witty point, and commonly satirical.

EPILEPSY (or falling sickness), a nervous disease, marked by convulsions and loss of sensation.

EPILOGUE, an address affixed to the end of a play.

EPISCOPACY, that form of church government in which authority is in the hands of *episcopi* or bishops.

EPISODE, an interjectional story or passage in any composition, connected more or less with the main narrative.

EPITHALAMIUM, a nuptial song.

EPITOME, a summary or compendium of any thing.

EQUATOR, a great circle, equally distant from the poles of the earth, and dividing it into two equal sections.

EQUILATERAL, equal-sided.

EQUILIBRIUM, in mechanics the condition of equality of weight.

EQUINOX, the period when the sun enters the point of the heavens above the equator, making equal night and day over the globe, whence that point is called the *equinoctial* (equal-nighted) line.

ERYSIPELAS, an eruptive and highly inflammatory disease, vulgarly styled St. Anthony's Fire.

ESCHAROTIC, a caustic application, which forms an *eschar* or scar on the skin.

ESCULENT, a term applied to roots and plants which may be eaten.

ESOTERIC, an epithet given to private instructions like those, so called, of Pythagoras.

ETHICS, moral philosophy, or the science which treats of morals and manners.

ETHNICAL, of or belonging to heathenism.

ETIOLATION, the process of blanching.

ETYMOLOGY, a branch of learning which has reference to the derivation and radical meaning of words.

EUCHARIST, the sacrament of the Lord's Supper.

EUDIOMETER, an instrument for ascertaining the composition and purity of air.

EUPHONY, a sweet sound or enunciation, whence the adjective *euphonious*.

EXEGESIS, an illustrative discourse.

EXFOLIATION, a surgical term expressing the casting off of a portion of diseased bone from the sound parts.

EXOTIC, an epithet for any thing of foreign origin.

EXPECTORANTS, medicines which promote the discharge of fluid matters from the chest.

EXPERIMENTUM CRUCIS, a decisive experiment.

EXTRAVASATION, the discharge of blood from a vessel below the surface of the body.

EXUVIÆ, the cast skins or coverings of animals, or refuse of any similar kind; also the organic remains found in the strata of the earth.

FALSETTO, in music, the species of vocal sounds produced by straining the voice above its natural compass.

FANTASIA, a term for an unpremeditated piece of irregular music.

FARINA, meal or flour; also the fine dust found on flowers.

FASCICULUS, a medical synonym for a handful or small bundle; also a term given to a part of a book or a short treatise.

FATALISM, the belief in an irresistible destiny.

FEBRIFUGE, a drug which dispels fever.

FELSPAR, crystallized mineral, compounded of silica, alumina, and potash, and gray or reddish in appearance.

FELUCCA, a light open boat with six oars.

FEMME COUVERTE, a title for a married woman, used in law to indicate the protection from personal liabilities resulting from that condition.

FERRUGINOUS, rusty, or of the colour of iron rust.

FERULE, a rod of correction.

FESCENNINE VERSES, a species of poems first composed at Fescennia, in Tuscany, and which, from their licentious character, have caused the term to be given to subsequent productions of the same description.

FIBRINE, a whitish body, insoluble in water, which forms the chief or fibrous part of muscles.

FIBULA, the smallest of the two bones of the leg below the knee.

FIMBRIATED, fringed, or fringe-like.

FIRMAN, a passport for travel and trade in the east.

FISCAL, of or belonging to the revenue of prince or people.

FISTULA, a deep ulcerated hole or canal.

FLUORINE, the basis of a very corrosive acid called the *fluoric*, which with lime forms the fluor spar so abundant in Derbyshire.

FLUXIONS, that branch of algebra which treats of the velocity with which the fluents or flowing quantities increase or decrease.

FOCUS, the point to which the rays of light or heat converge after being reflected or refracted, often also called the focal point.

FŒTUS, the embryo of young animals, advanced so far as to possess form and shape.

FOLIATED consisting of thin plates or leaves.

FOLLICLE, a seed-vessel open at one side, and having the seeds loose in it.

FORMULA, a prescribed rule or creed.

FORENSIC, a word applied to legal oratory, from judicial courts being held in the Forum of Rome.

FOSSIL, any substance of which the pores have been so penetrated by earthy or stony matter that the consistence seems altogether changed.

FRESCO, a durable method of painting in distemper or size colours on walls.

FRUCTIFICATION.—The parts of fructification, in botany, are those devoted to the propagation of vegetables, and consisting of the flower and the fruit.

FUCUS, the name formerly given to sea-weeds of the class from which kelp is procured.

FULCRUM, in mechanics, the prop or support on which the lever rests.

FULMINATION, a word expressing a very loud explosion and applied to the report given on ignition by mercurial and other preparations, called fulminating powders.

FUMIGATION, the dissemination of smoke or fumes for the purification of apartments, clothes, or other articles supposed to be infected by noxious effluvia.

FUNGUS, a class of vegetables of extremely rapid growth, which spring up in the form of excrescences from decaying matter.

FUSES, a small tube filled with combustibles, used for the discharge of bombs and fireworks.

GALAXY, the astronomical name for the accumulation of stars forming the Milky Way, familiarly used to signify any assemblage of bright objects.

GALLINÆ (GALLINACEÆ), the scientific epithet for the pheasant tribe, which includes the common domestic fowls of Britain.

GALVANISM.—This term is derived from an Italian philosopher named Galvani, who discovered that certain metals develop a peculiar power, which resembles the electric fluid in its effects. His discovery subsequently led to the formation of the Galvanic Battery, in which machine plates of zinc and silver are arranged in pairs, with a saline solution between each pair; and from which the galvanic fluid may be drawn off by conductors, giving a smart shock to the animal frame similar to that caused by electricity. The electro-galvanic fluid, as it is called, has been found of great use to chemists in decomposing compound bodies, as well as for other purposes.

GAMUT, table or scale of notes in music, marked by the monosyllables, *ut, re, mi, fa, sol, la,* and *si.*

GANGLION, a hard swelling, found on the course of tendons, and most frequently appearing upon the hand or wrist; also a knob upon the course of nerves.

GANGRENE, the name applied to the first stage of mortification, before the vitality is completely gone.

GASTRIC, the epithet given to the juice from which the digestive powers of the stomach are derived.

GASTRONOMY, the "science of the stomach," or of eating.

GELATINE, a jelly or soft substance, obtained by boiling either the soft parts or bones of animal bodies. Glue and isinglass are almost wholly composed of gelatine.

GENEALOGY, a history of the descent of any person or family.

GEOGNOSY.—This word signifies a "knowledge of the earth," and has been used by writers to express that branch of science which takes cognisance of the natural history of the substances composing the earth's crust.

GEOGRAPHY, a description of the surface of the earth, its natural divisions and general characteristics.

GEOLOGY a word signifying a "discourse on the earth," and applied to the science which treats of the structure of the crust of the globe, and the changes undergone by its constituent parts.

GEOMETRY, a term which properly means the art of "measuring land," but is applied to that branch of mathematics which considers of magnitudes generally, or the properties of dimension and figure.

GEORGICS, books treating of the art of tilling the earth, as those of Virgil.

GERMINATION, the act or process of sprouting forth, applied to plants.

GIBBOUS, an epithet bestowed on the moon when the dark part is horned in shape, during the change from full to new.

GLACIERS, vast fields of ice or concrete snow, which are formed in the hollows between lofty mountains, and abound in the Swiss and Tyrolese Alps.

GLAND, a name given to all those organs of the body, large or small, which separate a secretion from the blood, and have ducts to secrete it.

GLOTTIS, the opening at the top of the windpipe.

GLUTEN, an elastic and tenacious substance, found largely in flour and other vegetable bodies, and resembling glue.

GLUTINOUS, an adjective signifying something soft and adhesive.

GNEISS, in mineralogy a species of rock having a slaty texture, rich in metals, and found in many countries lying immediately over the great mountain masses of granite.

GNOMON, the erect style or pin of a dial, which indicates the hour by its shadow.

GOITRE, a large tumor on the fore-part of the neck, characterizing an unhappy class of weak-minded beings who reside in Alpine districts, and are generally named Cretins.

GOTHIC, a title applied to a species of architecture, chiefly marked by pointed arches and sharp angles, and admitting of much sculptural decoration.

GRADIENT, a word now used to denote the deviation of railways from a level to an inclined plane.

GRALLÆ (GRALLATORES), the scientific name for birds of the same class with the crane, or wading-birds.

GRANITE, a hard rock, usually grayish, but varying considerably in colour, and considered as of volcanic origin and great antiquity. It is the fundamental rock of the earth, on which the others lie, though it shoots up to the surface both in lofty mountain-ranges and low-lying grounds. Its compact and uniform texture renders it easily discoverable.

GRANULATION, the process of forming into grains; a word which is applied to the small specks of red flesh which spring up in healing sores.

GRAVITATION, the law of attraction by which bodies fall to the earth in the direction of its centre, and by which, moreover, the planets themselves are kept moving in their fixed relations to the sun.

GREYWACKE, a composite rock of a grayish colour, resembling a sandstone mixed with various minerals.

GREGORIAN, a name applied to the arrangement of the calendar year made by Pope Gregory, and familiarly called the change from the old to the new style.

GUTTA SERENA, a disease or defect of the optic nerve, causing blindness.

GYMNASIUM, the place appointed among the Greeks for the athletic exercises of their youth, and named from *gymnos* (naked), because some of these exercises were performed in that condition. Gymnastics is a term derived from the preceding, and is synonymous with "athletic exercises."

GYMNOTUS, the electrical eel.

GYPSUM, a substance composed of sulphate of lime, and found largely in the stratifications of the globe.

HÆMORRHAGE, a bleeding or flux of blood.

HALO, a white or luminous ring appearing round any of the constellations.

HARMONICA, a musical instrument formed of cup-like glasses, from the brims of which the music is elicited by rubbing with the fingers.

HEBDOMADAL, or HEBDOMADARY, weekly, or recurring every seven days.

HECATOMB, among the Greeks, a sacrifice of a hundred oxen.

HECTIC FEVER, a slow fever, marked by emaciation of the body, a quick weak pulse, and a frequent flush on the cheeks.

HEGIRA, the epoch of Mahomet's flight from Mecca, which took place on the 10th July, 622. From this term is dated the series of eastern years of 354 days.

HEMISPHERE, half a sphere.

HEMISTICH, in poetry, a line left half completed.

HEPATIC, an epithet for any thing pertaining to the liver. Hepatic air is a term for inflammable air in chemistry.

HERBARIUM, a collection of dried plants.

HERBAL, a work giving a summary view of plants.

HERMAPHRODITE, a term applied to plants which have the material parts of fructification within the same receptacle.

HERMETICAL, an epithet for any mode of sealing bottles or similar articles, which effectually excludes all foreign bodies, gaseous or fluid.

HERNIA, an intestinal rupture.

HEXAMETER, a Latin line of six feet.

HIERARCHY, a term signifying "holy" or ecclesiastical government.

HIEROGLYPHICS, symbols substituted for words by the Egyptians to prevent the vulgarization of their sacred learning, and for other purposes of concealment.

HIEROPHANT, a name for the Greek priests who had care of the sacrifices and sacred rites.

HISTRIONIC, of or belonging to the stage or dramatic performers.

HOLOCAUST, a burnt-offering, or sacrifice consumed by fire.

HOLOGRAPH, a deed or testament wholly written by the hand of the testator.

HOMŒOPATHY, a system of medicine which upholds natural diseases to be curable by similar artificial ones, or by such medicines as would produce them; and which prescribes remedies also in infinitely small doses.

HOMOGENEOUS, of the same or a uniform nature.

HOMOLOGOUS, of the same manner or proportion.

HORIZON, the line that terminates the view of the heavens from any spot, and divides them into an upper and lower hemisphere; whence the adjective horizontal, applied to any straight line which would form a right angle with one descending perpendicularly from above.

HORNBLENDE, a slaty stone usually of blackish-green tint, abundant in Britain.

HOROLOGY, the art of measuring time.

HOROSCOPE, the configuration of the heavenly bodies at the time of any one's birth, whence his fate was supposed to be discoverable.

HORTICULTURE, the art of cultivating gardens.

HORTUS SICCUS (literally, a dried garden), a collection of specimens of preserved plants.

HOURIS, exquisitely beautiful females, said by Mohammed to dwell in Paradise.

HYBRID, a mule, or creature sprung from parents of different races.

HYDATIDS, small bag-like bodies, filled with fluid matter, which are sometimes found in animals, and are themselves thought to be animalcules.

HYDRAULICS, the science which treats of the motion of fluids, and the art of conveying water.

HYDROCEPHALUS, the disease commonly called water in the head.

HYDROCYANIC ACID, a deadly poison, otherwise termed Prussic acid.

HYDROGEN, an elementary gas, the lightest of known bodies, which forms water with oxygen gas. It is inflammable and is used to elevate balloons.

HYDROGRAPHY, the science which describes gulfs, lakes, rivers, and other accumulations of water.

HYDRODYNAMICS, the science which treats of the states and forces of liquids in motion or at rest. It comprehends both hydraulics and hydrostatics.

HYDROPHOBIA, the disease of canine madness, marked by a dread of water, as the name radically implies.

HYDROSTATICS, the science which takes cognisance of the weight and equilibrium of fluids.

HYGEIST, a professor of the art of healing.

HYPERBOLA, a section of a cone in geometry.

HYPERBOLE, a figure of speech consisting in an exaggeration of any sentiment to give it greater force. It is a figure much in use. A man cannot complain of cold but he is "cold as ice," or of heat but he is "broiling."

HYPERBOREANS, the people living in the regions of the extreme north.

HYPERCRITIC, a personage finically fastidious, or critical to a superfluous excess.

HYPOCHONDRIAC, a person affected with indigestion and labouring at the same time under low spirits and unnecessary fears.

HYPOTHENUSE, the longest side of a right-angled triangle, or that subtending the right angle.

HYPOTHESIS, a theory; or a principle assumed whence from to draw certain inferences.

HYSTERICS, a nervous and convulsive disease, chiefly attacking females, and liable to be brought on by strong mental emotions.

IAMBIC, a metrical foot or division of a line of poetry, consisting of a long and short syllable. Iambic verses are lines composed of a succession of such syllabic divisions.

ICHOR, a thin watery humour, such as exudes from a particular species of sores.

ICHTHYOLOGY, that branch of zoological science which treats of fishes, their structure and varieties.

IDES, eight days in each month of the Roman calendar, beginning in some with the fifteenth and in others with the thirteenth day.

IDIOSYNCRASY, a peculiarity of constitution or temperament confined to an individual.

IDYL, the name assigned to short pastorals by several writers of them among the Greeks.

IGNIS FATUUS, a title for the Will-o'-the-Wisp, or phosphorescent light springing from marshy grounds by night.

IGUANODON, an extinct animal of the *Iguana* or lizard species, the fossil remains of which indicate its length to have been extraordinary, not less perhaps than fifty or sixty feet.

ILIAC PASSION, an obstruction of that portion of intestine called the *ilium*, attended with great pain and danger.

IMPOSTHUME, an abscess, or collection of purulent matter in the interior of the body.

IMPROVISATORI, persons who compose and recite poetry extemporaneously, according to a long prevalent Italian custom.

INCANDESCENCE, the state commonly called a *white heat*.

INCUBATION, the process of hatching.

INCUBUS, a synonym for the nightmare.

INFLUENZA, a species of epidemical catarrh, so styled either because it was ascribed to the influence of the stars, or on account of the wide extent of its influence.

INFUSORIA, in entomology, a term applied to the class of animalcules discovered by the microscope in stagnant water and other fluids.

INGUINAL, of or belonging to the groin.

INORGANIC, any thing without natural vitality, or possessing no organs. Under this head are included all material substances not pertaining to the animal or vegetable kingdom.

INSECTIVOROUS, an epithet for creatures which feed on insects.

INTAGLIOS, gems on which heads or inscriptions are engraved, as on the stones of ancient rings.

INTEGER, a whole, as opposed to a fraction.

INTERCALARY, the epithet given to the 29th of February, a day introduced every fourth year into the calendar.

INTERCOSTAL, a term applied to such parts as lie between the ribs.

INTERLUDE, a light piece introduced on the stage between the principal performances.

IODINE, a simple or uncompounded body, having the form of black lustrous scales, and used extensively in medicine for the reduction of swellings in the glands of the body.

IONIC, an epithet for one of the architectural orders regarded as forming a mean between the lighter and stronger ones.

IPECACUANHA, a medicinal root, used in a dry and powdered state as an emetic.

IRIS, in anatomy, the contractile circle which surrounds the pupil of the eye, so called because, like the rainbow (styled by the Greeks *Iris*), it varies in colour.

JUGULAR, the epithet distinguishing two large veins, called external and internal, which lie on each side of the neck.

JURISCONSULT, a person learned in the laws.

JURISPRUDENCE (medical), that branch of medical science which takes cognisance of the bodily injuries resulting from assaults, poisoning, and the like causes, with a view to the attainment of the ends of justice.

KALEIDOSCOPE, an optical instrument invented by Sir David Brewster, and consisting of a tube, with slips of glass so arranged in the interior that small heads, pieces of coloured glass, and similar substances, are thrown into an endless variety of shapes, and are very useful in suggesting patterns to cotton-printers and other tradesmen who manufacture figured articles.

KORAN (Alcoran), the book containing the doctrines of Mohammed.

KRAKEN, a supposed sea-animal of vast bulk, the descriptions of which give to it long arms or tentacula like those of the cuttle-fish.

KREOSOTE, an anti-putrescent principle extractible from vinegar, used for relieving toothache.

LABIALS, the letters formed in pronunciation by the lips.

LACHRYMATORY, a small vessel anciently used for collecting the tears shed on the death of friends, in order to their being placed in the funeral urn. The word is from *lachryma*, a tear; whence also the adjective *lachrymal*, applied to the ducts and glands of the eye.

LACTEALS, vessels which convey the chyle to a duct leading into the blood-vessels.

LAMINA, a plate, whence the epithet *laminated*, of which *lamellated* is the diminutive.

LARVA, the grub or caterpillar state of insects.

LARYNX, an assemblage of cartilages in the windpipe, by which the voice is formed.

LATITUDE, the distance of any place from the equator, marked by degrees of 360 miles.

LATITUDINARIAN, a free-thinker, or one who indulges in great latitude of thinking on any subject.

LAUREATE, the name given to the court-poet of Great Britain, a pensioned functionary.

LAZARETTO, an Italian term, applied to hospitals for persons affected with contagious diseases.

LEGATION, the body of persons composing an ambassador's suite.

LEGUMINOUS, an epithet assigned to certain vegetables, such as the pea, of which the seed-vessels are in the form of pods.

LENS, in optics, a piece of glass or other transparent substance, so formed as to make the rays of light either diverge or converge, in order, respectively, to magnify or diminish objects viewed through the lens. It is by means of the crystalline lens that external objects are pictured on the retina or sentient part of the eye, and vision is effected.

LEONINE, an epithet given to Latin lines, of which the middle rhymes with the end.

LEVIGATION, the process of grinding substances with water, so as to make a paste.

LEXICON, a dictionary.

LIAS, a name given to a species of stratified clay abounding in organic remains.

LICHEN, a species of moss.

LIGAMENT, a strong flexible substance, which serves to bind together the bones of the body.

LINIMENT, any medicinal liquid of a thickish consistence, used as an external application.

LITERATI, men of letters.

LITHOGRAPHY, the art of writing or engraving on stone, for the purpose of taking copies or impressions.

LITHOTOMY, the operation for extracting stones from the bladder.

LIXIVIATION, the process of separating soluble from insoluble matters by repeated washings with water.

LIXIVIUM, the water holding substances obtained by lixiviation.

LOGARITHMS, the exponents of a series of powers and roots. (See article on ARITHMETIC and ALGEBRA.)

LONGITUDE, in geographical science, the distance of any place from a first meridian, as that of Greenwich, taken east and west.

LUMBAGO, rheumatism in the lumbar region or loins.

LUNAR CAUSTIC, nitrate of silver, a preparation that burns or corrodes the animal substance.

LUSTRE (or LUSTRUM), a term of five years.

LYCANTHROPY, an old term for a species of madness, in which human beings howled like wolves, and were even fabled to be changed into these animals.

LYDIAN, a soft and effeminate kind of music, so termed because such music was popular among the inhabitants of Lydia.

LYMPHATICS, vessels which absorb the watery fluids or lymph of the animal system, and convey it to the sanguineous circulation.

LYRICS, short verses, composed originally to be sung to the lyre.

MACARONIC, an epithet denoting verses of a burlesque kind, framed out of a jumble of different languages, or of Latin words Anglicized or modernized.

MACERATION, the process of softening or digesting bodies in fluids.

MACHIAVELISM, a word expressive of cunning and artifice. It is derived from the name of Machiaveli, a Florentine writer, whose real principles, nevertheless, were not such as to warrant the attachment of a disreputable meaning to a term founded on his name.

MAGNETISM, that branch of science which treats of the property of attracting or repelling iron, displayed by the magnet or loadstone.

MAGNETISM (ANIMAL), a phrase invented in consequence of a supposed action of the magnet on animal bodies. It is now applied to an imaginary influence of one animal body upon another, resembling that of the magnet in some degree.

MALARIA, an Italian term signifying "bad air," and applied to the fever resulting from it in certain marshy situations.

MALLEABLE, an epithet distinguishing such metals as are capable of extension by hammering.

MAMMALIA, a term derived from the Latin *mamma* (the breasts), and applied in zoology to that numerous class of animals which *suckle* their young. The adjectives *mammalian* and *mammiferous* (breast-bearing) are sometimes used to denote the members of this class.

MAMMOTH, a large extinct species of elephant found in a fossil state.

MANDIBLE, the term applied to the upper and under jaws of birds and insects.

MARANATHA, a word expressive of a curse, and generally coupled with *anathema*, bearing the same sense.

MARASMUS, a species of wasting illness, unmarked by any strong recognisable symptoms.

MASTODON, a large extinct animal resembling the elephant, and found in a fossil state.

MATHEMATICS, the science which takes cognisance of magnitude and number, or whatever may be measured or computed. (See articles GEOMETRY and ALGEBRA.)

MATRIX, a mould of any kind that forms or imbeds bodies.

MAXILLARY, of or belonging to the jaws.

MECHANICS, that branch of science which treats of moving forces, and their practical application to the making of tools, engines and machines.

MEDULLARY, an adjective derived from *medulla* (marrow), and used to indicate any substance such as that of the brain, resembling marrow in appearance and consistence.

MEGATHERIUM, a gigantic animal of the sloth tribe, now existing only in a fossil state.

MENSTRUUM, any medium in which bodies are dissolved.

MEPHITIC, a word designating foul or poisonous gases.

MERIDIAN, in geography a great circle passing through the poles and any given place on the earth, and exactly dividing it into two hemispheres, eastern and western. Meridians being entirely suppositious lines, it is necessary to fix arbitrarily on certain spots wherefrom to reckon longitudes, or the distances of places to the east or west. Greenwich is chosen for this purpose in Britain, Paris in France, and so on. In astronomy, meridian signifies a circle in the heavens directly above the terrestrial meridian.

MESENTERY, a thick membrane full of glands, lying among the intestines and connected with them.

METACARPUS, the skeleton of the palm, or that part of the hand between the wrist and fingers.

METALLURGY, the art of separating metals from their ores, and of assaying, refining, and working them.

METAMORPHOSIS, a transformation or changing of any thing into a new and different shape.

METAPHOR, the application of words in a figurative sense, or in one to which, in their ordinary signification, they cannot be put.

METAPHYSICS, that science which treats of the nature and properties of mind or spiritual existence.

METATARSUS, that part of the foot between the heel and toes.

METEMPSYCHOSIS, the doctrine of transmigration, which supposes that souls pass from body to body in succession, entering the lower animals as well as human beings.

METEOROLITES (ÆROLITES), solid mineral bodies varying in bulk, which fall from the atmosphere, and are by some deemed of lunar origin.

METEOROLOGY, the science which takes cognisance of meteors or luminous appearances in the atmosphere, of changes of weather, and of aërial phenomenon generally.

METONYMY, a rhetorical figure by which one thing is put for another, as the cause for the effect, a part for the whole, and the like.

MEZZOTINTO, a particular kind of engraving, resembling drawings in Indian ink, and effected by first roughening the plate of metal, and afterwards smoothing parts of it, less or more, till the figure is wrought in as desired.

MIASMA, a name applied to all noxious effluvia, whether arising from putrefying matter or from the presence of contagious disease.

MICROSCOPE, an optical instrument which magnifies objects, and seems to bring them nearer to the eye, by means of lenses properly placed.

MINERALOGY, that branch of science which treats of the structure, properties, and varieties of minerals.

MIRAGE, an optical illusion, consisting in the production of double images of objects by refraction, or the assumption of the appearance of sheets of water by tracts of desert sands.

MNEMONICS, the art of assisting the memory by artificial rules.

MOLAR, a word applied to and signifying the *grinder*-teeth.

MOLLUSCA, a great class of animals whose bodies are soft, and neither furnished with skeletons nor with articulated coverings; though some of them, as the snail, have shells attached to their system.

MOMENTUM, the impulse or quantity of motion in a moving body.

MONOLOGUE, a scenic speech uttered by one person.

MONOMANIA, madness upon one point or ruling idea.

MONOTHEISM, the doctrine of the belief in one God.

MOSAIC, a species of inlaid work, in which pieces of glass or marble, gems, and other articles, cut into squares, are arranged in cement, so as to imitate the effect of painting.

MUCILAGE, a solution of gum, or tenacious fluid extract of vegetable matters.

MUCUS, a viscous animal fluid, secreted in the body to moisten the *mucous* membrane, which is a continuation of the skin, carried into all passages of the body that communicate by openings with the external air.

MURIATIC ACID (commonly called *spirit of salt*), a strong acid composed of chlorine and hydrogen, which forms many salts, called *muriates*, with the alkalies and earths, of which muriate of soda (common sea-salt) is an example.

MUSCLE, the red fibrous portion (called *flesh*) of the animal frame, the contractility of which, exercised at the impulse of the will, is the direct source of all bodily motion, thence called *muscular*.

MYTHOLOGY, the term applied to the history of the fabulous gods and demigods of Greece and Rome.

NARCOTICS, a class of medicines which allay pain by producing a stupifying effect on the nervous system.

NAUSCOPY, the art of discovering the approach of vessels not in sight, or detecting land from sea in the same way.

NEBULÆ, in astronomy, certain spots in the heavens, now understood to be clusters of stars, and some of them seeming to be systems in course of formation.

NECROLOGY, a biographical register of deaths.

NECROPOLIS, literally, "the city of the dead," a name bestowed on cemeteries.

NECTARY, that part of the corolla of flowers in which the honey-dew is accumulated.

NEOPHYTE, a new convert or proselyte to any doctrine.

NERVOUS, of or pertaining to the nerves, the organs of sensation and volition. A nervous temperament, properly speaking, is one in which the nerves are peculiarly sensitive, though the term nervous is often misapplied in the sense of strong or muscular.

NEUTRAL, a term bestowed on salts compounded of acids and metallic oxides, in which the properties of the constituents are neutralized or changed.

NICOTIAN, the scientific epithet for the tobacco-weed.

NITRATES, those salts which are formed of nitric acid (*aqua fortis*) and various oxides.

NITROGEN, an elementary gas, the principal ingredient in atmospheric air, and which, in a pure state, destroys life and extinguishes flame. Besides the air, it forms with oxygen various other compounds, of which one, the nitrous-oxide gas, is well known, and is named the *laughing gas*, from its exhilarating qualities.

NODE, in surgery, a hard tumour on the bones.

NOMADE or NOMADIC, an epithet denoting and applied to pastoral tribes that lead a wandering life.

NONES, the seventh days of the months of March, May, July, and October, and the fifth of the others.

NUCLEUS, the kernel of a nut; a term given to any originating centre around which other things accumulate.

NUMISMATICS, the science which has for its object the study of coins and medals.

NUNCUPATIVE, a term applied particularly to testamentary acts expressed verbally, and not, primarily at least, put into writing.

NUTATION, a tremulous motion of the earth's axis, inclining it to the ecliptic, twice a year.

OBLATE, a term of geometry applied to such flattened figures as that of the earth, in which the diameter at the poles is lesser than that at the equator.

OBSERVATORY, a building suitably placed and fitted up for astronomical observations.

OCCIPITAL, of or pertaining to the *occiput*, or back part of the skull.

OCCULTATION, the obscuration of any celestial body by the intervention of another.

OCTAGON, a figure of eight sides and angles.

OCTAVO, a name given to a sheet of eight leaves or sixteen pages, or to books so divided into sheets.

ODE, a lyrical poem, generally divided into parts, regular or irregular, and conveying an outburst of vivid feeling. Odes have been written, however, in numberless forms.

ODONTALGIA, the toothache.

ŒDEMATEUS, an epithet for a watery swelling of a soft kind, which dimples or *pits* on pressure.

ŒSOPHAGUS, the passage of the gullet.

OFFICINAL, a term given to such medicines as are directed by authority to be kept by druggists.

OLFACTORY (smell-giving), the epithet designating the nerves of the nose.

OLIGARCHY, a form of government where power is in the hands of a few.

OMEGA, the last letter of the Greek alphabet.

ONTOLOGY, the science or doctrine of Being.

OPHTHALMIA, inflammation of the outer covering of the eyeball and eyelids.

OPODELDOC, a solution of soap and camphor in spirit of wine, used as a liniment.

OPTICS, the science which takes cognisance of the phenomena of light and vision.

OPTIMISM, the doctrine which holds all to be for the best in the system of things.

ORATORIO, an elevated species of musical composition, expressive of tender and sublime feeling.

ORGANIC, an epithet used to contradistinguish the animal and vegetable kingdoms from the mineral, being applied to every thing which possesses or has possessed organs.

ORGANOLOGY, the science which treats of organs, a term sometimes applied to that branch of phrenology which has reference to the divisions of the mental faculties.

ORNITHOLOGY, that branch of natural history having reference to birds.

ORRERY, a machine for representing on a small scale the motions of the heavenly bodies.

ORTHOEPY, the art of correctly pronouncing words.

ORTHOGRAPHY, that branch of grammar which teaches the art of accurate spelling.

OSCILLATION, the motion of a body suspended at right angles, as in the case of a pendulum.

OSSIFICATION, the making of bone, or conversion of other animal matters into bone.

OSTEOLOGY, that branch of anatomy which treats of the skeleton.

OSTRACISM, banishment by the popular voice, done in Greece by writing names on shells, as the word implies.

OTTOMAN, an epithet synonymous with Turkish, derived from an early chief named Othman

OVATION, a triumph or triumphal procession.

OVERTURE, in musical language, the prelude to an opera, composed in such a style as to prepare the auditors for what is to follow.

OVIDUCT, a duct for the passage of eggs.

OXALIC, the name of a vegetable acid of a strongly poisonous character.

OXYGEN, an uncompounded gas, the most extensively prevalent and most important element in nature. It is one of the two gases which form water, and one of the two which compose the atmospheric air. It is essential to animal vitality, being absorbed into the blood by respiration; and it is the great supporter of combustion. It forms compounds (called *oxides* or *oxydes*) of all kinds —gaseous, fluid, and solid—and is found in the material world, in short, in unnumbered shapes.

PACHYDERMATOUS, a term signifying thick-skinned, and applied to a large class of animals, of which the horse, pig, and elephant are specimens.

PALÆSTRA, one of the titles for the gymnastic schools of antiquity.

PALATINE, a term applied, in one sense, to certain English counties which have or had *separate jurisdictions*.

PALINODE, a recantation in verse, or amend made for any injurious charge.

PALMATED, resembling the palm of the hand in shape.

PALMISTRY, fortune-telling by the lines of the hand.

PANORAMA, a name given to the exhibition of a large painting, arranged circularly, so that, from a central point, the spectator commands an equal and complete view of the whole at once.

PANTHEISM, a word commonly applied to that religious theory which holds that deity is universally present, forming and existing in all living things.

PANTHEON, a heathen temple dedicated to all the gods.

PANTOMIME, a scenic representation wholly composed of mimicry.

PARABOLA, a curve formed by cutting a cone by a plane parallel to one of its sides.

PARACHUTE, a large umbrella-shaped machine, by means of which persons have descended from balloons.

PARADOX, a truth adverse to facts in seeming.

PARALLAX, a change in the apparent place of any heavenly body, when viewed from different places.

PARALLELOGRAM, the proper term for the four-sided figure vulgarly called an oblong square.

PARASITICAL, a term derived from *parasite*, a fawning hanger on, and given, in natural history, to certain animals and plants always found attached to others, or dependent more or less upon them.

PARIAS, a degraded Hindoo caste or tribe.

PARK, a piece of enclosed ground, for the legal constitution of which three things were formerly necessary —a royal license, enclosure by some species of fence, and the presence of beasts of chase. Such regulations, of course, are not now enforced.

PARODY, a kind of imitative composition, in which sublime or serious writing is, by slight changes, burlesqued.

PASQUIN, the name of a witty cobbler of Rome, applied after his death to a statue on which it became common to paste satirical verses, whence the use of the word *pasquinade*, to signify a lampoon.

PASTORAL, a poem relating to shepherd-life.

PATELLA, the knee-pan, or small bone in front of the knee-joint.

PATHOLOGY, that branch of medical science which treats of the signs and tokens of disease, external and internal.

PELLICLE, any very thin membrane, such as that found inside an egg-shell.

PENITENTIARY, a title given to prisons formed upon a new plan, where convicts are employed in regular labours.

PENTAMETER, a form of line in Greek and Latin poetry, consisting of four feet (of two and three syllables each) and two cæsuras or monosyllables. Elegiac verse, in the classical writings, is composed of a hexameter alternating with a pentameter.

PERICARDIUM, the membrane enclosing the heart.

PERIURANIUM, the membrane enclosing the skull

PERIHELION, in astronomy, that point of the orbit of any planet at which it is nearest to the sun.

PERIOSTEUM, the membrane covering the bones.

PERIPHERY, the circumference of any curvilinear figure.

PERIPHRASIS, a circumlocutory form of expression.

PERISTALTIC, the epithet assigned to the regular serpentine movement which takes place in the intestines.

PERITONÆUM, the membrane encircling the intestines.

PERORATION, the winding up of an oration.

PETAL, in botany, a flower-leaf.

PETRIFACTION, signifying conversion into stone, and applied to animal and vegetable bodies so changed by long exposure to impregnation from earthy substances.

PHANTASMAGORIA, an optical exhibition resembling that of the magic lantern.

PHARMACEUTICS, a title for the science of *pharmacy*, which takes cognisance of the preparation of drugs for medical purposes.

PHARMACOPŒIA, a dispensatory, or work which directs the preparation of drugs.

PHARYNX, the muscular cavity at the back of the mouth, leading into the gullet.

PHENOMENON, a word signifying "an appearance," and familiarly used in an extended sense, being applied to any remarkable thing discoverable by observation or experiment, whether common or uncommon in occurrence.

PHILANTHROPY, literally, "love of mankind."

PHILOLOGY, that department of literature which involves the consideration of words and languages, their origin, structure, and significations.

PHILOSOPHY, the "love of wisdom or knowledge."

PHLEBOTOMY, bleeding or opening a vein.

PHONICS, a title for the science of sounds.

PHOSPHORESCENCE, a luminousness emitted by certain bodies, animal and vegetable, and unaccompanied by heat. The light of the glow-worm exemplifies the meaning of the term, which is derived from

PHOSPHORUS, a simple body, yellowish and solid like wax, and which emits light at common temperatures without much heat. It enters into bones, and forms a variety of compounds in nature.

PHOTOGENIC, a term invented for the new mode of "drawing by means of light," where, upon a surface rendered peculiarly sensitive by certain preparations, the rays of light impress perfect images of external objects.

PHRENOLOGY, a science which holds the intellectual and moral character of men to be determined and recognisable by the magnitude and figure of the skull.

PHYLACTERY, a spell or charm of any kind.

PHYSICS, a science of vast extent, which explains the doctrine of natural bodies, and all the phenomena connected with them.

PHYSIOGNOMY, the study of men's characters, as indicated by the external features of the face.

PHYSIOLOGY, a term confined to that branch of physics which treats of the functions and properties of living bodies, animal and vegetable.

PIA-MATER, the inner tunic which dips into and lines all the folds of the brain.

PLAGIARY, a literary person who pilfers from the works of others.

PLANISPHERE, a sphere laid down on a plain surface, as in the case of maps of the world and the heavens.

PLASTIC, a word applied to substances, such as clay, capable of being moulded into any desired shape, as well as to the art of so moulding them.

PLEONASM, the use of a redundancy of words to express an idea, as "I heard it with my own ears."

PLETHORA, a condition of the body in which the vessels are surcharged with blood.

PLEURISY, inflammation of the pleura or membranous covering of the lungs.

PNEUMATICS, the science which treats of the mechanical properties of air and other compressible aëriform fluids.

PNEUMONIA, inflammation of the lungs.

POLARITY, the property of pointing to the poles, a word used in reference to mineral bodies when they attract one pole of the magnet and repel another.

POLARIZATION OF LIGHT, a changed state of light, in which it exhibits the property of polarity, when acted on by certain mediums.

POLE, in magnetic science, the two points of a magnet which correspond and point the poles of the world, north and south.

POLEMICS, controversial writings on theology.

POLLEN, the fructifying powder or farina of plants.

POLYGAMY, a plurality of wives or husbands.

POLYGLOT, a book written in various languages.

POLYPE, living creatures, remarkable for their soft texture, and tendency to reproduce parts cut from their bodies.

POLYTECHNIC, a word applied to institutions where many sciences are taught, or to scientific exhibitions of a varied description.

POLYTHEISM, the belief in many gods.

PORPHYRY, a compound rock, granular and crystalline, and susceptible of a fine polish.

PORTE (the *Sublime* or *Ottoman*), a title for the Turkish sovereignty, derived from the fameus gate (*porta*) of the sultan's palace at Constantinople.

POSITIVE, a term used in connection with electricity, to indicate its presence in bodies in a quantity greater than natural. Negative electricity is a phrase expressive of the opposite condition.

POSTULATE, a point "demanded" as fundamental in any demonstration.

PRÆNOMEN, a name prefixed to the family name.

PRATIQUE, a license to crews to trade after performing quarantine or proving health.

PRAIRIE, the grassy plains in North America

PRECIPITATE, the chemical term for matters precipitated from solutions by change of affinity.

PRIMÆ VIÆ, the alimentary canal in animals.

PRISM, in optics, a triangular glass body used for separating rays of light into their primitive colours.

PROGNOSIS, the art of foretelling the issue of maladies from their symptoms.

PROLOGUE, an address prefixed to dramatic compositions.

PROPAGANDISM, a term commonly given to the system of propagating political doctrines, and originally derived from the court of the propaganda at Rome for disseminating the papal faith. The secret revolutionary societies of France also took the name of propaganda.

PROPOLIS, a resin gathered from trees, and used in the architecture of the bee tribe.

PROSCENIUM, the front of the stage in the theatres of Greece and Rome.

PROSODY, the part of grammar which treats of the quantities and accents of words, and of the rules of versification.

PROTOCOL, the first draught of a diplomatic agreement or treaty.

PSYCHOLOGY, the doctrine of the nature and properties of the soul.

PULMONARY, of or pertaining to the lungs.

PUNDIT, a learned Brahmin, or one versed in Hindoo learning.

PUPA, the chrysalis state of the insect, or that intermediate between the worm and the insect.

PYLORUS, the orifice by which the stomach communicates with the intestines.

PYROLIGNEOUS, an epithet for acetic acid, or vinegar produced from wood.

PYROTECHNY, the art of arranging fire-works.

QUADRATURE (of the CIRCLE), a problem in geometry long undetermined, of which the object is to find a right-lined figure equal to the area of any given circle.

QUARANTINE, denoting the period of restraint, formerly forty (*quaranta*) days, to which ships' crews are subjected when infection is presumed to be among them.

QUARTAN, a fever or ague, of which the paroxysm recurs every fourth day.

QUARTO, a term for that size of books formed by dividing a sheet into four leaves.

QUARTZ, a species of stone, often found in pure white crystalline masses, and sometimes endowed with various tints by other minerals, as in the case of amethyst, which is a purple quartz.

QUININE, a bitter alkaline body, extracted from Peruvian bark, and much used as a tonic in the form of sulphate.

QUOTIDIAN, an intermittent fever, of which the fit occurs once every day.

RADIAL and RADIATED, adjectives applied to bodies of a figure resembling in whole or in part a cart-wheel, of which each spoke is a *radius* or ray, such being the name given to lines passing from the centre to the circumference of every circle.

RADIX, a root.

RAMADAN, a solemn fast kept by the Mohammedans during the ninth month of the Arabic year, and lasting, each day, from dawn till sunset.

RATIO, the proportion of one thing in regard to any other thing.

REBUS, properly a species of riddle, in which some name or word is represented by figures or pictures.

RECIPE, a receipt or prescription.

RECITATIVE, a kind of musical composition, in which the accentuations of common speech are imitated.

RECTANGLE, a right angle or angle formed by two sides which are perpendicular to one another.

RECTUM, the terminating section of the intestines.

REGATTA, a word adapted from the Italian, and applied to boat or yacht races.

REGIMEN, a regulated course of diet in medical language.

RELIEVO (or RELIEF), a word applied to that mode of sculpture or carving in which figures are raised more or less from the surface.

RETINA, an expansion of the optic nerve, on which external images are cast, and through which ocular perception is effected, the other parts of the eye being strictly mechanical.

RHETORIC, the art of speaking with propriety, elegance, and force.

RHOMBOID, a four-sided figure of which the opposite sides and angles are equal, but which is neither equal-sided nor right-angled.

RHOMBUS or(RHOMB), a four-sided figure with equal sides, but not right-angled ; for example, a card-diamond.

RHYTHM, the measured division of time in music, or in verses of poetry.

RIPACCIMENTO, a word from the Italian, signifying something dressed up anew.

RONDEAU, a short species of poem with few rhymes, in which the sense of the opening lines is repeated, or nearly so, at the close.

ROSICRUSIANS, a sect of mysticists of the middle ages, who called themselves Brethren of the Rosy Cross, and prosecuted in secret the search for the philosopher's stone and the elixir of life.

ROUND-ROBIN, a mode of addressing or petitioning, in which, to prevent any subscriber from seeming more forward than another, the names are arranged in a circle.

RUNIC, the title of the characters forming the language of the ancient Scandinavians or northern Goths.

SABBATICAL, an epithet given to every seventh year in the Jewish economy, because they then allowed their fields to rest without tillage, and gave external nature a long Sabbath

SACCHARINE, of or pertaining to sugar.

SACRUM, the small terminating bone of the back-bone

SALIQUE, the title of the old law of France, which excluded females from the throne.

SALIVATION, an increased flow of saliva from the glands of the mouth, caused by medicines.

SANHEDRIM, a word signifying the great public council, civil and religious, of the Jews.

SANSCRIT, the old or dead tongue of Hindostan, in which much valuable learning is contained.

SAPPHIC, a species of verse among the Greeks and Romans, consisting of four lines, and named from Sappho.

SARCOPHAGUS, a word applied to tombs, and derived from the body-consuming effects of a species of limestone which was anciently used for making coffins.

SCAPULA, the shoulder-blade.

SCARABÆUS, the beetle.

SCROFULA, a disease consisting in hard tumours of the glands, chiefly of the neck.

SENSORIUM, the brain or centre of nervous energy, including sensation and volition.

SEPTIC, any thing that promotes putrefaction. *Antiseptic* signifies any thing that checks it.

SEPTUAGINT, a Greek version of the Old Testament, named from its being executed by seventy (*septuaginta*) Jews, or perhaps seventy-two.

SERRATE(or SERRATED),something notched like a saw.

SERUM, a very thin and transparent fluid, which lubricates those surfaces in the interior of the body which do not communicate with the external air.

SETON, an issue on the body formed by the insertion of a cord.

SIDEREAL, of or pertaining to the stars.

SIENITE, a compound, granular, grayish-tinted rock, named from Siene in Upper Egypt.

SIERRA, a Spanish name for an eminence or chain of hills.

SILICA (or SILEX), a primitive earth, the main constituent in all stones and rocks whatsoever.

SINAPISM, a mustard poultice.

SIPHON, in hydraulics, a tube from which the air is extracted for the purpose of raising fluids, by the atmospherical pressure behind, above the level of the reservoir.

SMELTING, the art of fusing ores for the extraction of the metallic parts from the refuse.

SOLECISM, in grammar, a violation in one way or another of the rules of the art.

SOLSTICE, the term given to the two periods at which the sun enters the tropics of Cancer and Capricorn, which is respectively on June 21st, and December 21st.

SOMNAMBULISM, a word denoting the act or phenomenon of sleep-walking.

SOPHISM, a false species of reasoning, not supported by the premises. *Sophistry* is the art or practice of using sophisms.

SOPORIFIC, an epithet for any thing inducing sleep.

SOPRANO, in music, a term applied to a species of treble, suited to the female voice.

SPECIFIC, in medical language, a remedy which cures any special disorder with more or less common certainty.

SPECTRUM, a bright spot formed by admitted light on any surface, or the image of an object seen after the eye is withdrawn from it.

SPECULUM, in optics, a polished body impervious to light, or which reflects it.

SPHEROID, a body nearly approaching a sphere in shape.

SPONDEE, a poetic foot, or division of a line, consisting of two long syllables.

SPORADIC, an epithet opposed in sense to epidemic, and meaning diseases which are neither general nor contagious

STALACTITE, a name for the concretions formed of carbonate of lime, which accumulate in consequence of the drippings from the roofs of caverns.

STAMEN, the male organ of fructification in plants

STANZA, a word now used to designate every portion of a poem united by rhymes.

STATICS, that department of mathematics which has reference to bodies at rest.

STATISTICS, a science of a comprehensive order, embracing every thing connected with the population of a country, their condition and employments.

STEARINE, the solid constituent of oils and tallow.

STENOGRAPHY, the art of writing in short-hand.

STEREOTYPE, a solid plate of metal, cast from a preparation of stucco, and receiving from it an impression of drawings or letter-press, previously communicated by common gravings or types. The art of stereotyping is now of great use in giving to publishers permanent impressions of their works.

STERTOR, a noisy kind of breathing, following affections of the brain.

STETHOSCOPE, a tubular instrument, by applying the ear to which internal diseases of the chest or abdomen are discovered.

STIGMA, in botany, the top of the pistil into which the pollen is received.

STRABISMUS, in technical language, a squint.

STRATIFICATION, the process by which any portions of the earth have been arranged in layers or beds, called *strata*. Generally speaking, all stratified rocks have been subjected to the influence of water, while unstratified rocks are more or less volcanic in their origin.

STRIATED, streaked or marked with lines.

STROPHE, the first division of a Greek ode, succeeded by the *antistrophe*.

STRUMOUS, an epithet applied to glandular tumours.

STYLITES, fanatics who lived on pillars.

STYPTICS, medicines which check bleeding.

SUBLIMATION, the process of volatilizing or distilling a dry substance by heat.

SUBSTRATUM, any substance that underlies another substance.

SUCCEDANEUM, any thing which serves as a substitute.

SUDORIFICS, medicines which promote perspiration.

SULPHURIC, the title of a well-known acid (oil of vitriol), which is composed of sulphur and oxygen, and forms many salts called *sulphates*, of great importance in nature.

SUPPURATION, the generation of *pus*, a thick diseased secretion, of yellowish hue.

SYLLOGISM, an argument consisting of three parts, called the major, minor, and the conclusion, and which bear a relative sense, such as is exemplified in the following case:—"Every madman should be confined: A. B. is a madman, therefore A. B. should be confined." All accurate reasoning is syllogistic.

SYMPOSION, a social entertainment among the ancients.

SYNCHRONISM, a word expressing the simultaneous occurrence of two events.

SYNCOPE, a faint or swoon.

SYNONYM, a word having the same meaning with another.

TABLEAUX (VIVANTS), a term applied to groups of persons, arranged scenically, and so dressed as to represent the actors in some famous historical incident, or the scene of some noted painting.

TALC, an earthy stone, usually of greenish tint, and found in lustrous layers or plates of a soft or unctuous feel.

TALMUD, the book of the oral law of the Jews, of great antiquity, and containing many of their traditions.

TANGENT, in geometry, a line which touches a curve, but does not cut it.

TANNIN, the principle in galls, oak-bark, and other substances, upon which their astringent qualities depends.

TARANTULA, a name given to a large spider, the bite of which, long held to be venemous, was deemed curable by music alone.

TARIFF, a table of the customs or duties chargeable upon goods.

TARSUS, the bones of the foot immediately adjoining the heel.

TAUTOLOGY, the needless repetition of the same words or ideas in speech or writing.

TECHNOLOGY, a treatise on the arts; a word derived from *techne* (art), and *logos* (a discourse). The epithet *technical*, denoting something belonging to art, is from the same source.

TELEGRAPH, a word signifying "writing to or for a distant point, and applied to the various inventions by which news is communicated between distant spots by flags or other means."

TELESCOPE, a term signifying and applied to an instrument through which distant objects are viewed.

TENTACLES (TENTACULA), the organs of feeling, prehension, and motion, in various insects and other animals, and sometimes viewed also as organs of hearing.

TERMINOLOGY, that branch of philological science which explains the sense of terms of art.

TERRA-COTTA, an Italian word signifying baked clay, and applied to a class of relics of art, such as vases and the like, formed from that substance, and found in considerable quantities in Tuscany.

TERTIAN, an ague of which there are two paroxysms every three days.

TERTIARY, a term used to denote the later formations in the earth's crust, comprehending the superficial alluvial deposits, and such as are composed chiefly of sand and clay.

TESTACEOUS, a word given to animals which have a strong thick shell, such as oysters, and are included in an order called by the general name of *testacea*.

TESTUDO, the tortoise tribe of animals.

TETANUS, a word usually applied to *locked-jaw* by medical men.

THEISM, the doctrine of the existence of a God, opposed directly in sense to *atheism*.

THEOLOGY, literally, a discourse on divinity, and commonly denoting the study or science of religion.

THEOREM, a speculative proposition deduced from several definitions compared together.

THERAPEUTICS, a term applied to the study of the symptoms of disease and its remedies, and denoting, in short, the healing art generally.

THERMAL, an epithet equivalent to *warm* or *tepid*, and usually assigned to mineral waters so characterized.

THERMOMETER, an instrument for *measuring heat* by means of a graduated scale of degrees.

THESIS, a theme or proposition advanced and maintained by illustration and argument.

THORACIC, of or pertaining to the *thorax* or chest.

TONICS, medicines which increase or restore the healthy tone of the coats of the stomach and muscles generally.

TOPOGRAPHY, a description of places, or minute branch of geographical science.

TORNADO, a whirlwind.

TORSO, the trunk of a statue deprived of head and limbs.

TOURNIQUET, a surgical instrument for repressing the flow of blood.

TOXICOLOGY, a treatise on poisons, or the science which takes cognisance of them.

TRANSCENDENTAL, the philosophy of pure or speculative reason, which occupies itself not so much with objects as with the way of knowing them.

TRANSITION, the term applied to those parts of the earth's crust supposed to have been arranged when the earth was passing from the uninhabitable to the habitable state.

TRANSUBSTANTIATION, the conversion of the sacramental bread and wine into the body and blood of the Saviour, held by Roman Catholics to take place in reality.

TRAP, a dark semi-volcanic rock, usually found in a columnar form, or arranged in successive layers like stepping-stones.

TRAPEZIUM, a geometrical figure having four unequal sides.

TRAVESTIE, a burlesque imitation of grave writing.

TREPANNING, in surgery, an operation by which the skull is perforated in order to raise a depressed portion.

TRIGONOMETRY, the art of measuring the sides and angles of triangles.

TROCHEE, a poetical foot of two syllables, one long and the other short.

TUBERCLES, in anatomy, small round suppurative tumours, such as those affecting the lungs in consumptive disease; the adjectives *tubercular*, *tuberose*, and *tuberous*, are applied, in medical and botanical language, to denote the presence of knobs or growths so shaped.

TUBULAR, having the form of a tube.

TUMULUS, a barrow or mound of earth or stones formerly erected over the dead.

TUNICATED, covered with one or more tunics or coverings.

TURBINATED, in conchology, a term applied to any shell wreathed serpentinely from a broad base to a narrowed apex.

TURBINITE, a fossil turbinated shell.

TUSCAN (ORDER), an ancient, massive, and simple style of architecture.

TYMPANY, flatulent distension of the abdominal region.

TYMPANUM, the drum of the ear, or partition dividing the outer from the inner parts of the organ of hearing.

TYPHUS, a dangerous species of continued fever of a contagious nature, and marked by a tendency in the system to putrefaction.

TYPOGRAPHY, literally, "writing with types," or the art of printing.

ULTRAMONTANE, signifying "beyond the mountains."

UMBILICAL, of or pertaining to the navel.

UNCIAL, an epithet for writing in which large characters are used.

UNGUICULATE, provided with claws or nails.

UNIVALVE, a shell of one piece.

URANOLOGY, a discourse on the heavens.

URANUS, the planet Herschel or Georgium Sidus.

UTILITARIAN, an epithet first applied to the followers of Jeremy Bentham, or those who estimate all things by their degree of usefulness in promoting "the greatest happiness of the greatest number."

UVULA, a small dependent body at the back of the mouth, familiarly called the pap of the throat, and useful as a sort of defence to the tops of the windpipe and gullet.

VACCINATION, the operation of introducing cow-pox matter into the human body, in order, by producing a greatly mitigated disease, to preserve the system against natural small-pox, which rarely occurs twice in one person. From noticing that cow-milkers were strangely free from liability to small-pox, Dr. Jenner discovered the invaluable secret that certain pustules on the udders of cows possessed the property described.

VACUUM, a space named as being void or vacant, but always containing, in reality, some amount of highly rarefied air even under the most powerful air-pump.

VARICOSE, an epithet for veins distended in an uneven or knotted manner.

VASCULAR, provided with or pertaining to vessels.

VATICAN, the title of a palace built on a hill of the same name at Rome, and containing the magnificent library collected by successive popes.

VELOCIPEDE, a wheeled machine so constructed that a man, while seated on a sort of saddle, can propel the wheels by pressing on the ground, or acting on the wheels themselves. Velocipedes have as yet been objects of curiosity merely, not of utility.

VENTILATION, free introduction of air into any place.

VENTRICLES, a name given to cavities in the heart and brain.

VENTRILOQUISM, a word signifying "speech from the stomach," and erroneously used to denote the art by which the voice is made to appear as if it *came from different places*—an art dependent on skilful management of the voice in the windpipe, and other necessary means of illusion. Ventriloquism, in short, seems to consist simply in a vocal mimicry of a very perfect kind.

VERMICULAR, of or belonging to worms, called the *vermes* in the Linnæan classification.

VERMIFORM, shaped like worms.

VERTEBRÆ, the twenty-four strong and united bones which form the spine or vertebral column, and sustain the trunk and head.

VERTEX, the top or summit of any thing; whence the adjective vertical, applied commonly to any thing placed or rising directly upwards in the air or heavens.

VIADUCT, a carriage-way, raised or arched over any hollow or low-lying spot.

VILLOUS, covered with down or soft hairs.

VIRUS, poisonous or corrosive matter.

VISCUS, an organ in medical science.

VITREOUS, a term signifying *glassy*, and applied to the soft pellucid humour filling the fore-parts of the eye.

VITRIFACTION, conversion into glass.

VIVIPAROUS, a term applied to animals which bring forth living young, as opposed to egg-bearing creatures.

VOLCANO, in geology, a burning mountain or eminence from which ignited and melted matters are cast forth. Volcanoes have evidently been instrumental in moulding a great proportion of the existing crust of the globe. Traces of them, in an extinct state, are noticed almost everywhere.

VOLTAIC PILE, the upright series of alternate zinc and silver plates, which the chemist Volta formed, as a mode of developing the galvanic power, after its discovery by Galvani. The pile is now disused, the galvanic trough being substituted for it, as more useful and convenient.

VORTEX, the centre of a whirlwind or whirlpool, or of any body or bodies in rapid circular commotion.

VULCANIC, the title sometimes given to the theory of Dr. Hutton, which ascribes almost all geological phenomena to subterranean fire.

WERNERIAN, a name for the aqueous theory of the earth, or that which regards water as the chief geological agent, derived from the German philosopher Werner.

WRANGLER, a term applied to the successful competitors for degrees in the English universities, particularly in mathematical contests.

ZENITH, that point in the heavens which is directly above or vertical to the spectator, or to any given spot of the earth.

ZERO, the point of the thermometer from which it is graduated, or the numbers are begun. Fahrenheit's zero is thirty degrees below the freezing point of water.

ZODIAC, an imaginary belt or broad circular space in the heavens, within which the whole of the planets make their revolutions. It is divided into twelve parts of 30 degrees each, called the Signs of the Zodiac, and named respectively from the constellations which were observed to pass them.

ZOOLOGY, the science which treats of the structure, character, and varieties of animals or living creatures.

ZOOPHYTES, a class of remarkable animals, of which sponges and corallines are specimens, and which resemble plants, having stems more or less calcareous and in which many of the animals are congregated together.

THE STEAM-ENGINE.

The apparatus which, after numerous improvements by Watt and others,* has assumed its complete form of a *Steam-Engine*, and has been universally adopted as a convenient and economical means of impelling machinery, is dependent on the properties of water and heat for its source of power, and an account of these seems an indispensable preliminary to any description of its character. We shall, therefore, in the present sheet of popular information, begin by giving, first, a history of the properties of water, with the general nature of aërial bodies; embracing an account of the different kinds of fuel which are employed to convert the water into steam: and then proceed to a detailed account of the various parts which enter into the formation or construction of the engine, taken in the widest sense of the word, and the mode in which these are arranged so as to obtain the maximum of power, including the different kinds of engines adapted to navigation, railroads, &c. The whole to conclude with an historical sketch of the invention, from the earliest period, until its almost final perfection in the hands of Watt.

Watt.

WATER.

The matter of which the external world is composed presents itself to our notice in three palpable forms or conditions, namely, the *solid*, the *liquid*, the *aëriform*. Stones or pieces of metal belong to the first kind; water and quicksilver are instances of the second; in the air, and in gases, such as carbonic acid gas, we find examples of the third. But all the different kinds of matter, whether simple or compound, are not specially found *only* under one or other of these forms; for it may be truly said, that the solid, the fluid, or the aëriform condition, is merely contingent, that is, depending on certain circumstances besides the inherent nature of the particles of matter of which each body individually is composed. Hence it is that the same kind of matter may, on changing those conditions referred to, assume first the solid form, then the fluid, and finally the aërial state; or, conversely, being in the aërial state, it may be rendered fluid, and lastly become solid.

The law applies to bodies whether they are simple or compound, and is beautifully seen in the different forms which water assume when exposed to a varied range of temperature. For, below 32 degrees of Fahrenheit, it is solid (*ice*); between 33 and 212 degrees, it is fluid (*water*); and above 212 degrees, it is in the form of vapour (*steam*); changes in its physical form, immediately related to and connected with changes in the amount of heat with which it has been supplied.

Water, which forms the grand agent in the steam-engine, is not a simple or elementary body, but consists of two distinct kinds of matter, the natural condition of which, when free under the ordinary circumstances of our globe, is that of an aërial substance. These two distinct matters, or substances, are oxygen and hydrogen; combined together in the proportion of one by bulk of the former, with two by bulk of the latter, they constitute the compound *water*, which had been, until nearly the close of the last century, considered as an elementary body. But water, as it is found in nature, though it is essentially composed of the matters now mentioned, does not consist solely of these, inasmuch as whether it be taken from springs, from lakes, from the sea, from rivers, from melted snow or ice, or from rain, or from any other source, it contains many other substances held in solution, and which affect its character very much—rendering it, indeed, often totally unfit for those purposes to which it is usually applied. When devoid of these substances, the water is considered by chemists as *pure*.

The substances which are dissolved by the water, and which render it impure, are of two distinct kinds—solid matters, such as lime, magnesia, and iron; gaseous matters, such as the elements of the air, oxygen and nitrogen, and carbonic acid. The proportion of solid matter varies considerably. In the waters of the sea which surround our shores, the amount of solid matter is estimated at nearly about 3½ per cent. Again, in river water, the proportion of solid matter is considerably less than that found in the sea.

The quantity of gaseous matter varies, but not so much as that of the solid matter. In rain water, there is usually noticed 2½ per cent. of atmospheric air, but in which the usual proportion between the oxygen and nitrogen is not preserved, as there is 32 of oxygen out of the 100, the remainder being nitrogen, whereas 21 is the proportion of oxygen in atmospheric air. Carbonic acid gas also is found in water.

On boiling the water, these gaseous bodies are set at liberty, and pass off as gases. Also the solid substances, such as the compounds of lime, are deposited, and form thick incrustations on the boiler, which requires to be removed, otherwise it would be rendered totally useless.

It is only the pure matter of oxygen and hydrogen—the actual water, as it may be termed—which is required in the working of the steam-engine; the other substances, whether aëriform matter or the solid particles held in solution, being not only useless, but even injurious. It will be seen that there are particular contrivances devised in the structure of the steam-engine to remove these.

Water is a fluid at ordinary temperatures, but may become *solid* on the one hand, or *aëriform* on the other by changes in the amount of caloric (heat) with which it is supplied. These two remarkable changes in the condition of water occur at specific temperatures; it becomes solid when the degree of temperature indicated by the thermometer of Fahrenheit is 32 degrees, and passes off in the state of vapour or steam when the same thermometer indicates the temperature to be 212 degrees. On the fluid being cooled down to 32 degrees, it becomes ice, the temperature 32 degrees being named the freezing point of water.

When the temperature is increased, so that the thermometer indicates 212 degrees, the water becomes steam

*James Watt, whose discoveries entitle him to be called the inventor of the steam-engine, was born at Greenock, in Scotland, January 19, 1736. At fourteen years of age he removed to Glasgow, and there, while afterwards acting as mathematical instrument-maker, he began those great improvements on the steam-engine which were completed in future years. Watt died on the 25th of August, 1819.

or vapour, assuming that condition in which its elastic force is applied to act as a moving power.

On the water passing off in this new form or condition, two very remarkable phenomena take place, namely, the fluid expands to a very great extent, the vapour occupying nearly 1700 times the space which the fluid occupied from which it was generated; and at the same moment, an immense quantity of caloric or heat enters into the water while becoming steam, and disappears; which heat, from the circumstance that it cannot be discovered by the thermometer, is usually called *latent* heat, in contradistinction to that which affects the thermometer, and which is accordingly named *sensible* heat, that is, heat whose effects are apparent in producing the movement of the fluid in the thermometer tube.

When the water has assumed the state of vapour, it is invisible, being as perfectly transparent as the atmospheric air; and in this form it becomes obedient to those laws which affect gaseous or aëriform bodies, supposing always that the usual increased temperature is maintained (212 degrees Fahrenheit) to preserve it in this new state; for, on withdrawing the caloric, it then returns to its liquid inelastic condition, which is termed condensation. This elastic state of the vapour may be suddenly destroyed by bringing it in contact with a large quantity of cold water—a process essentially a part of the greater number of steam-engines.

In this state of vapour the temperature is 212 degrees, or the same as that of the water from which it is generated. This may be easily determined by placing a thermometer in the boiling water, and then in the steam which arises from it.

Under the usual conditions in which water is made to boil, as in an open vessel on the fire, the temperature indicated by the thermometer is commonly about 212 degrees, the water acquiring at that temperature sufficient elastic force to overcome the weight of the atmosphere. But it is to be observed, that the pressure of the air must tend to retard the water swelling out into vapour; it will follow, therefore, that if we reduce the pressure on the surface of the water, the escape into the state of vapour will take place at a lower temperature, as was first observed by Dr. Cullen, and subsequently more minutely detailed by the late Professor Robinson. The latter has, indeed, established the general proposition, that vapours are produced from fluids *in vacuo* (where all atmospheric pressure is removed) at 140 degrees of Fahrenheit below the temperature at which these fluids naturally pass into vapour, under the usual pressure of the air. Water, for instance, which usually boils at 212 degrees, in this case would boil at 72 degrees, a temperature of the atmosphere frequently observed in the summer months of this country; and ether, which boils at 96 degrees, a temperature nearly corresponding with that of the human body (being lower only by 2 degrees), *in vacuo* would boil at 44 degrees below zero, or at a temperature lower than that which would suffice to render mercury solid.

The thin aërial fluid called the *atmosphere*, or commonly the air, is a distinct material substance surrounding the globe, and possessing considerable weight. That the air is actually a material substance, may be easily shown by connecting a thin glass flask, provided with a good stop-cock, with the exhausting tube of an air-pump. The air can in this manner be withdrawn, and the flask will be found to weigh less than before. One hundred cubic inches of air, when perfectly dry, weigh, according to very careful investigations of Dr. Prout, 31·0117 grains, the temperature of the air being 60 degrees Fahrenheit, and the pressure of the air, as indicated by the barometer, being equal to 30 inches of mercury.

If, instead of air (the oxygen and nitrogen which constitute the atmosphere), an atmosphere of mercury were to envelop the globe, which would have the same weight as the air, it would be about 30 inches above the level of the sea; and if, in like manner, instead of the air, the fluid water were substituted, it would be nearly 34 feet above the level of the sea. Hence, we say that the pressure of the air is equal to a column of mercury 30 inches in height, or to a column of water 34 feet high; or, in other words, whatever extent of surface we have, the pressure of the atmosphere is equal to the pressure or weight of 30 inches of mercury, or 34 feet of water, over a similar surface.

The amount of this pressure, estimated by the extent of surface, is as 14·7 pounds on the square inch, or nearly 15 pounds. In other terms, the weight of air pressing on a square inch is 15 pounds, and the weight of the column of water is also 15 pounds. That is, the column of air whose basis is exactly a square inch, extending from the surface of the globe to the highest or extreme range of the atmosphere (nearly 45 miles), is equivalent to the column of mercury which is only 30 inches in height, or to a weight of 14·7 pounds.

It is this weight, then, which the water has to overcome before it pass into vapour. The greatest pressure of the atmosphere will be at the surface of the earth; and as we ascend in elevation above the sea level, this pressure will gradually decrease, less air being above us, and in a corresponding ratio the volume will be augmented.

By attending to these circumstances, we perceive that when the pressure is lessened, water boils at a lower temperature than 212 degrees; and therefore, that we have not merely to consider the temperature to which the water is exposed, but also the amount of the weight of the atmosphere at the time, or the height of the mercury in the barometer tube. For example, at Quito, which is 10,000 feet above the level of the sea, water boils at 194 degrees Fahrenheit, while at Geneva, ebullition begins at 209 degrees, that city being 12 feet above the sea level.

The law, then, as regards the pressure of the atmosphere, simply is, that the boiling temperature is uniformly the same when the barometer is at the same height. If we employ the thermometer of Fahrenheit, it will be found that the boiling point is exactly 212 degrees if the barometer indicate 30 inches; but if the boiling point rise to 213 degrees, then the barometer also will ascend to about 30½; and conversely, if it be nearly 211 degrees, the barometer conversely also will fall to about 29½. It is obvious, then, from these facts, that the boiling point is an index of the height of the barometer, and, on the other hand, that the height of the barometer will give the point of ebullition according to the thermometer of Fahrenheit, or any other which may be used.

Experimentally, the effect of a diminution of pressure on the temperature at which water boils may be shown by the common air-pump. If a jar of water, at the temperature of 178 degrees, be placed under the large bell receiver, and the air be withdrawn so as to reduce the pressure very speedily, the water will be found to boil at the reduced temperature. The pressure at which this takes place, as measured by the barometer, is equal to half the ordinary weight of the air, or 7½ pounds on the square inch. If the barometer be retained in the jar, it will be found to indicate 15 inches when the ebullition takes place. Should the barometer fall lower before the boiling commences, then it will also be noticed that the thermometer points to a lower temperature, corresponding always in an exact ratio.

Steam, or the vapour of water, when produced at the usual pressure of the atmosphere, is commonly denominated *low-pressure*, in opposition to that which is formed at a higher pressure than that of the air, and accordingly named *high-pressure* steam. In common language, however, the term low-pressure steam is applied to the steam which has even a force of several pounds on the square inch, and therefore formed at a temperature

higher than 212 degrees. The steam is in this case condensed in working the engine, and receives this general name because the pressure does not range higher than a few pounds.

In order to produce steam of greater pressure or force than that obtained by boiling water in the open air, means must be adopted to confine the vapour as it is generated from the water. If we have a stout copper vessel, containing a considerable quantity of water, and provided with stop-cocks which can be properly closed, and then expose it to heat, a quantity of vapour will be disengaged; but as it cannot fly off, all the stop-cocks being closed, it must necessarily, in proportion to its density, compress the fluid below, and proportionately prevent any further escape of vapour. But the heat being continued and increased, vapour will then rise, which in like manner will increase the degree of compression on the water, for the density of the first disengaged vapour will now be increased by this new accession of vapour, and the further formation of vapour will be checked until the heat is again so far increased as to be able to overcome resistance offered by the pressure of the vapours. In this manner vapour or steam, of any degree of elasticity, may be generated from water merely by having a firm and stout vessel capable of bearing great pressure, in which the vapour is to be formed.

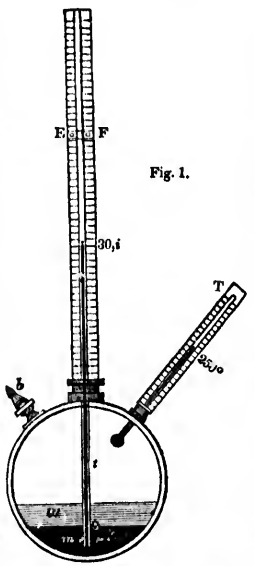

Fig. 1.

The generation of steam in this manner, and the relation between the temperature at which the steam is produced and the pressure upon it, and consequent force or elasticity of the steam, may be illustrated by the apparatus represented in the adjoining cut, fig. 1. A firm copper vessel is procured, sufficient to bear a considerable heat and a great degree of pressure. It is provided with three apertures, as in the figure. The aperture at the summit has a barometer tube, E F, fixed in it, open at both ends, but at the same time perfectly air-tight, so as to prevent all communication between the interior of the vessel and the external atmosphere. The upper extremity of the tube is immediately in contact with the atmosphere, while the lower is very near the bottom of the vessel. In the lower part of the vessel there is a quantity of mercury (*m*), into which the under extremity of the barometer tube dips. At one side of the vessel an aperture receives a thermometer (T), which is securely fixed, so as to be perfectly air-tight, and introduced obliquely, so that the bulb rests a little above the middle height of the vessel. The other or third aperture (*b*) is provided with a stop-cock, which admits of being opened or closed at pleasure. The vessel is now to be supplied with water (*w*), filling it to the middle, and heat is to be applied by a furnace below. It is apparent that if the heat be applied and continued while the stop-cock (*b*) is open, the air will fill the upper portion of the boiler, and the ordinary pressure of that body will be exerted on the surface of the water. The water will therefore, as already noticed, boil when the temperature 212 degrees of Fahrenheit is indicated by the thermometer. But if we now shut the stop-cock, so that there is no longer escape for the steam, the temperature of the water gradually rises, because the heat is continued, and the steam accumulating in the upper part of the boiler, exerts, first on the water, and immediately on the mercury beneath, a force or pressure equal to its increased elasticity. The mercury, is, however, in an open tube, or rather is placed between the extremity of an open tube and the water and its vapour. Accordingly, if the force of this vapour is greater than what is requisite to overcome the pressure of the atmosphere, the mercury will be forced into the tube, and in proportion to the increasing force which it possesses, will the mercurial liquid ascend. In proportion, then, as the heat continues to be applied, the mercury will be seen to ascend in the barometer tube, indicating the force which the steam exerts on the surface of the water in the boiler, while the actual amount of the heat at which the water is passing off into vapour will be shown by the thermometer.

But, as already stated, if the height at which the mercury stands corresponds in a distinct ratio with the temperature, it will be sufficient to ascertain either the one or the other, so as to know both. Suppose the column of mercury has risen nearly 15 inches, or even 60, then we know that the pressure which the steam has is equal to half an atmosphere, as indicated by the mercurial tube, over and above the actual pressure of the atmosphere, so that the whole pressure exactly amounts to an atmosphere and a half. But the thermometer will also have risen, and now will point out a temperature of 230 degrees Fahrenheit—water at that temperature, when converted into vapour, having a force equal to an atmosphere and a half, according to the usual mode of expression. If the heat be still continued, the further ascent both of the mercury in the barometer tube and the mercury in the thermometer will be observed; and when the former stands at 30 inches, the latter will indicate exactly 250 degrees, as may be seen in the diagram. But as 30 inches is equal to one atmosphere, and as the tube was open admitting the pressure of the air, the vapour of water was able to overcome the resistance of two atmospheres; or water under a pressure of two atmospheres boils at a temperature of 250 degrees Fahrenheit, and the vapour possesses that strength in elastic force.

Suppose the thermometer (T) now stands at 250 degrees (*l*), and the stop-cock (*b*) be suddenly turned, an immense volume of steam, formed under the high pressure, suddenly escapes; the mercury in the tube (*t*) falls rapidly, and the thermometer also equally descends, until it attains the temperature of 212 degrees. The mercury will fall down to the level it had immediately under the water, and steam will now be produced as under ordinary circumstances. The moment, however, the stop-cock is shut (the heat still being kept steadily applied), the thermometer will begin to rise, and the column of mercury begin to ascend.

The application of the heat may be continued, in a good stout vessel, up to a greater elevation than what is now described, causing the production of steam of a still higher pressure, and, of consequence, greater elastic force, the barometer and thermometer mutually reflecting each other. It is in this manner that the high-pressure steam, as it is ordinarily called, is generated; but in proportion as the higher the temperature is at which it is produced, the greater is the danger to be apprehended from the bursting of the boiler, unless proper precautions are adopted.

The accompanying table gives the correspondence observed between the temperature at which the water boils, the density of the steam generated, and the force it possesses in inches of mercury and atmospheres.—

Temperature Fahrenheit.	Sp. gr. air at 60 being 1.	Pressure in inches of a column of mercury.	Pressure in pounds on the square inch.
212°	0·484	30	14·7
222°	0·551	35·00	17·15
232°·80	0·637	45·00	22·05
242°·50	0·81	52·50	25·725
250°·20	0·915	60·00	29·4
274°·70	1·33	90·00	44·1
320°·60	2·5	180·00	88·2
350°·00	3·61	270·00	132·3
450°·00	10·75	900·00	441·

By this table we observe that the elastic force of the vapour produced from water rises in a rapid ratio above the ordinary temperature of boiling. If, for example, we take the temperature of water at 350 degrees, the specific gravity of the vapour produced, air at 60 degrees being 1, will be 3·6; and it would have a force equal to maintain a column of mercury 270 inches high, or 22 feet 6 inches, if no atmosphere pressed on the mercury; and 240 inches of mercury, if the atmosphere pressed on the fluid in the tube; the total sum of pressure on the square inch being then equal to 132·3 pounds, or corresponding exactly with the weight of nine atmospheres.

Tables have also been drawn up from experiments, illustrating the force of vapour from water at temperatures below the ordinary point of boiling, as in the subjoined:—

Temperature.	Force of vapour in inches of mercury.
32°	·200
50°	·375
68°	1·00
100°	1·86
150°	7·42
180°	15·15
200°	23·64
212°	30·

From all these tables, it is apparent that there is an invariable correspondence always observed between the force of the vapour of steam and the temperature at which it is generated. Hence the one may be given as the rule of the other. For instance, if it is required to know the force with which the steam is working in any machine, the thermometer, which is preserved in a case air-tight, and introduced into the boiler where the steam is generated, will indicate the temperature of the water, or of the steam (for they are always the same; that is, at whatever temperature water boils to afford steam, the steam so produced is of the same temperature). On ascertaining, then, the temperature by a reference to the table, we find the corresponding force of the elastic vapour (the steam). An example will be sufficient to show this most clearly. When the thermometer stands at 212 degrees, and steam escapes from the water, we know it is then able to support a column of mercury 30 inches high; and a column of mercury 30 inches high is equivalent to the pressure of 1 atmosphere. The steam, then, is of the kind called low pressure. If, however, the temperature indicated be 250 degrees, then opposite in the table we find 29·4 pounds pressure on the square inch, and 60 inches of mercury; but as 29·4 pounds is double the weight of the atmosphere on the square inch, and also as 60 inches of mercury is double the height of the column which the air will support, the steam must then be acting with a force equal to 2 atmospheres.

The force with which steam acts increases proportionally much greater than the temperature at which it is generated. If, for example, the pressure be equivalent to 1 atmosphere at 212 degrees, at 250 degrees it will be equal to 2 atmospheres; that is, in the addition of heat equal to 38 degrees of Fahrenheit above 212 degrees; and at 293·7, which is little more than the difference between 212 and 250 degrees, which gives only an increase of 1 atmosphere, the pressure is equal in all to 4 atmospheres, or double that above 250 degrees; and so on, as will be seen in the preceding table.

Mr. Tredgold gives the following rule to ascertain the elastic force of the vapour of water, in inches of mercury, at any given temperature of Fahrenheit's thermometer. To the given temperature 100 is to be added, and the sum divided by 177. The quotient is to be raised to the sixth power, which is the force required. If, for example, the temperature be 307 degrees; to this 100 added gives 407. This, divided by 177, gives 2·3, of which the sixth power is nearly 148, the elasticity of the vapour, in inches of mercury, almost equivalent to 5 atmospheres. This rule, it is to be observed, only refers to the vapour produced from pure water; when it is mixed with a considerable proportion of saline matter, as in the case of sea-water, a different divisor must be adopted, which is to be regulated by the temperature at which the water boils, for the point of boiling varies with the amount of salt in the water. Water saturated with common salt contains about $\frac{1}{3}\frac{2}{3}$ portions of that matter, and its boiling point is about 226 degrees. The divisor to be used in this case is 185 instead of 177, and the elastic force of the steam will then be found not to exceed 113 inches.

The existence of any body in the aëriform state is only a contingent condition of matter; some, called *gases*, have naturally no tendency to pass into the fluid or solid form; others, however, called *vapours*, are maintained in the gaseous state by the influence of heat—and on withdrawing it, speedily resume their ordinary condition. Steam belongs to this class of bodies, and on being cooled, immediately condenses or returns to the fluid state. The white cloud produced on steam escaping from the safety-valves of boilers, or from high-pressure engines, is not steam, in the strict acceptation of the word, for steam is invisible, but the water formed by the condensation of the steam in consequence of the cold air with which it now mixes. The extent to which the water expands is variously estimated; but it seems to be very nearly that 1 cubic inch of water becomes 1 cubic foot of steam, or the space occupied by 1 cubic inch of water, when converted into steam, is nearly 1700 times greater—correctly as 1 to 1696.

In the state of vapours, the vapour may be in two distinct and very different conditions; it may be immediately in contact with the water whence it is formed, or it may be in a vessel distinct and separate from all connection with the water. In either condition it is a distinct aëriform body, and possesses all these properties peculiar to that class of bodies, it being always understood that the heat is maintained sufficiently high to preserve it in this particular condition, to wit, of vapour. Aëriform bodies, and consequently water, when in the aëriform condition, have a property quite peculiar, denominated their elasticity. This essentially consists in a disposition of all the particles, whereby they have a tendency to recede outwards or fly from the centre, so that they spread themselves out into a more extended area. If, for instance, we have a bladder partially filled with air under the receiver of an air-pump, and then exhaust the air, it will be found, that proportionally as the air is removed from the interior of the receiver, the bladder expands, and finally it will swell, and even be burst, by the expansive force of the air within. Aëriform bodies have a tendency, accordingly, to expand indefinitely, were there not causes which counteract this disposition.

The first of these is the pressure to which they are subject, and the second is the attraction of gravitation, by which all particles of matter are drawn down towards a centre, and which is incessant action. A similar power is also exercised by the application of cold, which diminishes the repulsive tendency. As there is a constant force counteracting this disposition to expand, the elasticity of a gas or vapour is in the exact ratio of the counteracting force. Gases, as they are capable of expansion, so they may be condensed or diminished in bulk. But in this condensed state, as they then occupy less space, there necessarily must be an increase

of the density or specific gravity. Thus, if the space occupied by any gaseous body be equal to 100 cubic inches, and the 100 cubic inches weigh 31 grains; on compressing these to one-half, so that they only occupy 50 cubic inches, each cubic inch will obviously contain double the amount of matter it previously had, and therefore, whatever was previously the weight of the cubic inch, it will now be double. But with this increase of density there is an increase of elasticity; for as the elasticity of a gas is directly proportionate to the force which compresses it, and as this force has diminished the bulk by one-half, hence, as the density is doubled, the elasticity is increased in the same ratio. The elastic force of a gas, therefore, is directly in proportion to its density, and in the inverse proportion of its bulk.

On removing the pressure, then, it seems that gaseous matter extends through space, so as to fill up what otherwise might seem a vacuum.

Incidental to the formation of steam, it may be observed that there is a great quantity of heat which disappears on the vapour being formed, and which cannot be discovered by the thermometer, but is again given out when the vapour returns to the state of water. This invariably takes place, and always in a definite proportion.

The most singular and most important practical fact connected with this property is, that whatever be the temperature at which the water is boiled to form steam, the sum of that temperature and the number of degrees of latent caloric (as the heat which disappears is technically named, from the Latin word *lateo*, to lie hid), is always the same. Suppose the water boils at 212 degrees, and the quantity of latent caloric absorbed be equal to 1000 degrees, the sum of these will be exactly 1212. But if the water boil at 112 degrees (under diminished pressure), the latent caloric will then be 1100, to make up the aggregate sum 1212 degrees; and in like manner, if, under increased pressure, the water be made to boil at 312 degrees, the quantity of latent caloric will only be 900 degrees. Hence steam formed at a low pressure, or at the ordinary temperature of the air, does not require a different amount of fuel that it may undergo this change, than the same vapour generated at 100 degrees higher, or any other temperature; for the sum of the latent and sensible heat is always the same—1212 degrees, as measured by the thermometer of Fahrenheit. To convert, accordingly, a given weight of water into steam, the same amount of fuel is required at all temperatures.

The condensation of steam by water may be easily shown by taking a flask with a small quantity of water in it, and, exposing it to a temperature sufficient to produce ebullition, steam will rapidly be formed, and all the atmospheric air expelled. A cork (previously ascertained to fit accurately) is then introduced into the neck of the flask, which is at the same time withdrawn from the fire. The flask, now full of the vapour of water, is introduced into a vessel of cold water with the neck inverted; on the cork being withdrawn, the cold water immediately absorbs the elastic vapour, and is forced in by the pressure of the atmosphere, so as completely to fill the vessel, if it contained nothing but the vapour of steam. The same phenomenon may be observed by acting in a similar manner with the vapour of ammonia, or of muriatic acid (spirits of salt). The application of this additional property of steam, and the mode of bringing it into play, will be specially detailed under the description of the steam-engine. It is here merely cursorily noticed, lest we might seem to overlook one of the most important properties of this fluid.

It is owing to this important property, namely, the great degree to which it can be condensed by cold water, that the production of a vacuum is accomplished, and the steam-engine rendered complete in almost all its parts.

The chief properties of water, then, as converted into steam or vapour, may be briefly enumerated:—Expansion—the matter in this new condition of vapour occupying about 1700 times the space it occupied as water, the disappearance of a great amount of caloric, which bears always a definite proportion to the temperature at which the water passes into steam; the exertion or display of a definite elastic power, bearing a fixed ratio to the temperature at which it is generated; the natural return of the gaseous fluid to the state of water, either on gradually withdrawing the heat, or on suddenly bringing it in contact with cold water.

Accessory to the consideration of water and its various properties, physical as well as chemical, is the history of the different matters which are employed to give out heat, and to convert it into steam. The consumpt of coal or fuel, of whatever kind it may be, constitutes one of the most serious obstacles in the extension of the steam-engine, and especially in its application to long voyages. The great object is to produce the greatest amount of heat at the least possible expense of fuel. Charcoal, or the substance carbon, is, properly speaking, the principal ingredient in the combustible matters which are usually taken to produce heat. It constitutes the main bulk of coal, of anthracite, a species of coal chiefly found in America. It is found also in great quantities in the matter of saw-dust, tar, &c.

During the process of combustion, the quantity of heat which is disengaged can be precisely determined, as, for instance, by ascertaining how much of a given amount of combustible matter is required to raise the temperature of water from 32 degrees to the boiling point (212 degrees). In a series of experiments made on this subject, Despretz obtained the following results, which are here arranged in a tabular form:—

	Pounds of Water.
1 Pound of charcoal heats from 32° to 212°	78
" charcoal from baked wood	75
" baked wood	36
" wood containing 20 per cent. water	27
" bituminous coal	60
" turf	25 to 30
" alcohol	67.5
" olive oil, wax	90 to 95
" ether	80
" hydrogen	236.4

In this process of combustion, the chemical action consists in the union of the oxygen supplied from the air with the inflammable matter, whether carbon alone, hydrogen alone, or both together. The amount of heat depends exclusively on the quantity of the oxygen consumed, as the important fact has been determined, that the heat evolved was always in a direct ratio with the oxygen lost. Thus, in a series of experiments, it was discovered that

	Pounds of Water.
1 Pound of oxygen with hydrogen raises from 32° to 212°	294
" " charcoal	29
" " alcohol	28
" " ether	28½

The importance of this subject is sufficiently obvious when we consider the immense number of steam-engine incessantly at work, and the enormous annual consumpt of coals. In long voyages in steam-vessels, the greater part of the cargo is necessarily composed of coal instead of merchandise, and thereby one of the chief objects of steaming is virtually defeated.

It is here to be carefully noted, that to raise water to the boiling point, and to convert water into steam, do not imply the same thing, though they both imply the application of heat steadily to the fluid matter. This arises from the great quantity of latent caloric which the steam requires, and which amounts by calculation, as well as by careful experiment, nearly to 1000 degrees of Fahrenheit; that is to say, if it takes a given time, with an equal and

uniform quantity of heat, to raise water from 32 to 212 degrees (180 degrees), it will require that time multiplied by 5½ to convert the water into steam. But in one period (namely, the time required to raise the water to the boiling point) as much heat as raised the water 180 degrees was added, and 180 degrees multiplied by 5½ gives exactly 1000 degrees. It is to supply this great quantity of latent caloric that so immense an amount of coal is consumed by the steam-engine. For if 1 pound of the best coal raises 33·3 pounds of water from 32 to 212 degrees, then one pound will only suffice to convert 5·5 pounds of water into steam. Or while 1 pound of coal raises 33·3 pounds of water to the boiling point, it will require [illegible] pounds more of coal to convert all that water into steam.

To convert the coal into those chemical compounds, during which the formation of heat takes place, a very great proportion of air is required. For the atmospheric air contains four-fifths of its bulk of matter, which does not in any manner assist combustion. Two pounds and a half of oxygen, or nearly 30 cubic feet, are requisite for the combustion of 1 pound of coal: 150 cubic feet, therefore, of atmospheric air will supply this. It has, however, been found that one-third of the [illegible] which enters the furnace passes through it without directly contributing to the process of combustion, but withdraws heat. The actual amount, therefore of air required is about 220 cubic feet in round numbers.

In these observations made regarding the boiling point of water, whether in the open air or under varying degrees of pressure, the water is to be held as pure, or nearly so. For when it is mixed with much saline matter, the temperature at which it boils is raised. Water, it may be noticed, saturated with common salt, boils at a temperature of 226 degrees Fahrenheit. The temperature at which water containing various proportions of salt boils is given in the annexed table:—

Proportions of Salts.					
Common water,	.	.	.	0	212
Sea water,	.	.	.	1/33	213·2
Boiler water,	.	.	.	2/33	214·4
.. ..	.	.	.	3/33	216·7
.. ..	.	.	.	4/33	219·0
.. ..	.	.	.	5/33	221·4
.. ..	.	.	.	6/33	223·7
Saturated water,	.	.	.	12/33	226·

In steam-boilers, where the water used contains a great quantity of saline matter, a particular process is resorted to called *blowing out*, by which the heavy water impregnated with saline matter is removed, and the salts prevented from accumulating. From such a mechanism not being known at the time, the City of Edinburgh steamship, on her first voyage to Leith, had her boilers so obstructed and rendered useless by the immense accumulation of salts, that it was found necessary to clear the boiler out on the voyage, while she proceeded under canvas during the time. Some further remarks are to be found under the description of the marine steam-boiler

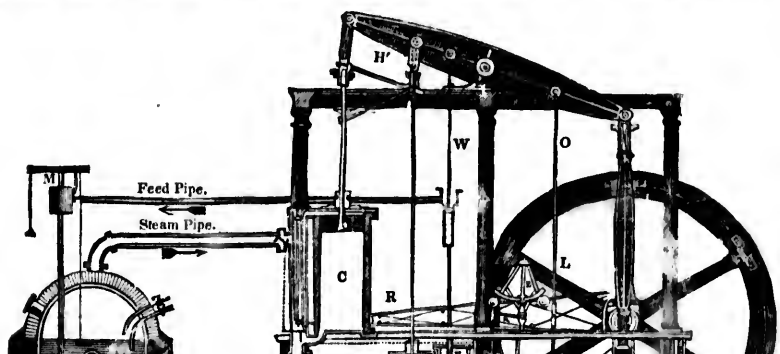

Fig. 2.

DESCRIPTION OF THE ENGINE, &c.

The entire apparatus of a steam-engine is comprehended in two distinct parts—the Boiler, which generates the steam, and the Engine, by which the duty of the steam is performed. It is necessary, however, to remark, that there are various kinds of engines, differing as to mechanism. Two general divisions may be formed of them—1st, Those in which condensation takes place, or low-pressure engines; and 2d, Those in which there is no condensation, or high-pressure engines. In the first class we have the common atmospheric engine, as it is called, invented by Newcomen, and long in use; then the double-acting engine of Watt, working by pressure and condensation, or working by pressure, expansion, and condensation; so, also, in the second class, we have engines working only by pressure, and engines working by pressure and expansion. In the subjoined cut, fig. 2, we present an outline of what may be esteemed the most complete engine of the condensing class, with the boiler adjacent, and connecting pipes.

We shall now proceed to describe the various parts of this most ingenious apparatus. And, first, of

The Boiler.

The boiler, as its name implies, is the large iron vessel in which the water is exposed to the action of heat, so as to be converted into steam. In its structure and connection with the cylinder (that part of the engine in which the steam acts), it constitutes a very beautiful illustration of different pieces and forms of machinery all happily arranged, so as to contribute to one important end. In examining the boiler, we have to attend to the following leading parts or portions of mechanism:—The form of the boiler, the feed-pipe, the steam-pipe, the

damper, the steam-gauge, the gauge-cocks, the safety-valve, the internal safety-valve, the man-hole, and the furnace. Fig. 3 is a representation of the various parts on a minute scale.

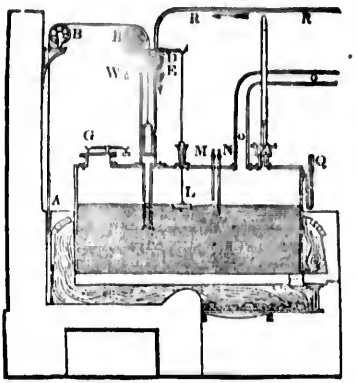

Fig. 3.

Various forms have been proposed for the low-pressure boiler. That which is chiefly used as here represented, is called the wagon-shaped; it is fashioned in a semi-cylindrical manner above, the sides being nearly perpendicular, while the face is gently concave or hollow. When the pressure is not great, that is, does not exceed six or eight pounds on the inch, this form of boiler is sufficient for the generality of purposes. The chief object in selecting the form of the boiler is, that it may permit the water to pass speedily into vapour with the smallest amount of caloric, as little as possible being given off to the surrounding matters and atmosphere. For it is to be here observed, that when two bodies at different temperatures are placed contiguous to each other, the warmer of the two soon becomes cooler, and the colder becomes warmer, so that after a given lapse of time, they both have the same or a common temperature. It becomes, therefore, an object of the utmost moment to place the boiler in such a position that as little heat as may be can escape from it. This is effected by building it in brickwork, or matters which are bad conductors of caloric.

Whatever form may be selected for it, it has two main pipes, one which conveys the steam from it (O); and the other, which, as it supplies it with water to generate the steam, is called the feed-pipe (R).

It is further provided with several other highly important and essential parts; these are the *steam-gauge*, which indicates the elasticity or force of the steam which is formed; the *gauge-cocks*, by which it is known whether the boiler is supplied with the proper amount of water or otherwise; the *safety-valve*, so denominated by way of distinction, which allows a free egress to the steam, when pressing beyond a certain force, and thereby preventing any danger from explosion; the *internal safety-valve*, which obviates any risk of the sides of the boiler collapsing by the pressure of the atmosphere—should, from any circumstance, the force of the steam become inferior to that of the external air. To these there is to be added the *man-hole*, which is for the object of cleaning the boiler out when requisite.

The feed-pipe is a very ingenious arrangement by which water is brought to the boiler. It proceeds from a cistern (E) situated immediately above the boiler and extends into the boiler a little lower than its middle height.

The water which is conveyed to this cistern is drawn from the hot well (H) (a part of the engine connected directly with the condenser, and afterwards to be noticed) by means of a pump worked by the engine (W), fig. 3. As this water is of considerable warmth, a proportionate saving accrues in using it. The water, however, does not enter this tube to pass to the boiler always in a continuous stream, independent of the condition of the boiler as to its being scantily or liberally supplied with water, but, by an ingenious arrangement, it is made to descend in such a continuous current, so as exactly to be equivalent to the amount of water expended in the formation of steam. This is accomplished in the following mode:—A valve is situated at the bottom of the cistern, which is made to open upwards, on the rod being raised which connects it with a lever (D). This lever is so placed as to move on a fixed point at the upper part of the cistern. At one extremity of it a small wire (K) is attached, running through a steam-tight aperture in the boiler, having a float (L) at its termination resting on the water. To counterpoise this, there is a weight (W) suspended at the other extremity of the lever connected with the cistern. As this float is balanced in the water, when it is rapidly evaporated it will follow the water level, and as it descends, necessarily will bring down the arm of the lever to which it was connected; the other arm will be elevated in a corresponding manner. But the valve in the feed-pipe being attached to a rod which is fixed to the lever, will be carried upwards as it is raised, and the water will pass down, until the float, being raised in a corresponding degree, will enable the other arm of the lever to which the counterpoise was attached to fall, and thereby bring down the other end of the lever, and close the valve. By this arrangement, as long as there is a sufficient supply of water, from which the cistern can be filled, there will always be a sufficiency running down in a stream continuously to feed the boiler for the production of steam.

The steam-gauge (Q) is adapted to the boiler, in order that the engineer may always be able to know the elastic force of the steam. Its form and principle are illustrated by the subjoined figure. A tube, curved in the form of the letter U, is connected with the boiler from which the steam is disengaged. This tube is open at both extremities (perfectly analogous to the tube rising from the centre of the stout copper vessel in which the principle of the formation of high-pressure steam was explained; (see p. 76), one of which is immediately exposed to the air or vapour in the vessel, while the other is directly under the influence of the pressure of the atmosphere, whatever that may be. Into this tube mercury is introduced, which, supposing the boiler to be full of air, or of steam having the same tension as the atmospheric air, will have the same level in both legs of the tube; should, however, the fluid ascend in A, that in B falling in a corresponding degree, the steam pressing on B must have a greater force than the external atmosphere and the difference in the levels of the mercury in the two limbs will indicate the excess of the force of the steam above one atmosphere. Every two inches' difference in the levels indicates a pressure of one pound on the square inch. Conversely, the fluid mercury falling in A, and rising in B, indicates that the steam is *not* of pressure equal to that of the air, the proportion of which is to be determined in the same manner. This tube may be constructed either of glass or of iron. If a metal tube is employed, a thin wood rod is introduced, with a float

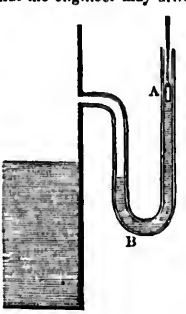

Fig. 4.

in the open end A, so that the distance of the mercury from the level of the summit of the tube is easily ascertained.

The gauge-cocks (MN) are two pipes or tubes, armed with stop-cocks, passing vertically downwards into the boiler. These tubes are of unequal length. One descends somewhat more than the third of the depth of the boiler from the summit, the other somewhat less; so that the former dips in the water, while the other opens into the air or vapour a little above the water level. When the boiler is filled with its proper amount of water, and steam duly formed, on opening the stop-cock of the longer tube, water will be discharged; and on opening the shorter, steam will escape. If, however, there be an excess of water, so that the less also dips into it, water will be projected from both; and again, if from inadvertency the water be deficient, so that the longer tube dips into air or vapour, the water-level being below it, steam, on both the stop-cocks being opened, will escape freely.

The safety-valve (G) is designed to permit the free escape of the steam when it is generated of greater elasticity than is required, or the sides of the boiler are well able to resist. If we suppose the boiler can bear a pressure of twenty pounds on the square inch at every part of its surface, and there were no valves, should the force of the steam be increased so as to exert a pressure of twenty-*one* pounds, the walls would necessarily yield, and an explosion be the result. If, on the other hand, we suppose that the engine will work well with an elasticity of four or five pounds on the square inch, it is apparent, that so long as the elasticity does not increase, the steam will pass by the steam-pipe freely to the cylinder, and the steam-gauge in the boiler will indicate the pressure to be that now stated. But, while things are in this state, if we were to render *one point* of the boiler so weak that a force of ten pounds would be too great for it, and the steam were to acquire an elasticity sufficient to overcome that, a rupture necessarily would take place at that point, or the boiler would burst. The valve is then to be considered as a part of the boiler, which yields to a pressure much less than that which would be capable of bursting the boiler, but which permits a pressure to be made sufficiently strong to allow the free working of the cylinder with steam of or under a definite pressure. The mode in which the valve is frequently made to work is by the steel-yard. This is a lever having a support fixed close by a tube communicating with the boiler. The aperture of this tube is closed by a plug or plate, which is fixed to the lever, and weights are arranged in the usual manner to the extremity of the lever. If the atmosphere and the weight fixed to the end of the lever are unable to resist the elasticity of the steam which is generated in the boiler, its greater pressure forces the plug upwards, and the tube being opened, the steam escapes.

It is apparent that, if the tube were open, steam could not be generated of higher pressure than one atmosphere; again, if the boiler were made of sufficient strength to bear the pressure of 16 atmospheres, it could be heated sufficiently so as to give steam of that force without danger. But as the safety-valve may be loaded upwards with a pressure ranging from one pound on the square inch to 100 or more, it is evident, that so long as we are secure of the positive strength of the boiler, we may cause steam to be generated of any given strength, within the range determined, merely by adding or subtracting from the pressure on the safety-valve. From different causes, as, for instance, the valve adhering to the tube, or corrosion taking place, or the aperture being too small, it is occasionally inefficient, and from this explosions may arise, should the force of the steam be greatly augmented.

In some boilers, two safety-valves are employed, the one being at a much lower pressure than the other; so that when it yields, the engineer has a clear intimation of the increasing elasticity of the steam, and then can easily adopt precautionary measures. It has been strongly recommended that in every instance there should be two valves. Hastily, indeed, has the observation been made, that the more valves the better, as it is altogether improbable that they can all be obstructed at the same moment.

A plug of fusible metal is occasionally used in boilers which are raised to a very high temperature. The fusible metal is an alloy (mixture) of different metals, which are so apportioned to each other that the mass will melt at any given temperature. For instance, there is the popular toy, the fusible spoon, which will melt and totally liquefy in a cup of tea a little below the boiling point of water. Now, it has been already stated that steam of higher elastic force than that of the air can only be formed at a higher temperature than 212 degrees, at which it is formed under the ordinary pressure of the air; when, therefore, the steam is generated of a greater elastic force, it must be at a proportionally higher temperature; and if, then, there is a fusible plug which liquefies or melts at that particular degree of heat, it will be melted, and an outlet at once given to the vapour and water; it will be, in other words, the same as a valve. However ingenious in theory this invention may seem (and it certainly has considerable credit), it does not so happily correspond in practice, as it is found that the metals melt unequally; or, in other words, that the most fusible melts at the low temperature, and is retained in the small cells of the less fusible, so that the whole may not be fused until a temperature is obtained 100 or 200 degrees higher than what was arranged or anticipated; and accordingly, by trusting to this alone, every danger that might occur from an explosion is to be apprehended.

The furnace under the boiler is so arranged that the fuel is thoroughly consumed; and further, so that a draught of air may have free access to the fuel, which may be increased or diminished by means of a damper (A), worked on the wheels BB, when the steam is coming off too rapidly or too slowly for the demands of the engine. This object is effected by a contrivance somewhat analogous to the mode in which the supply of water is regulated for the feed-pipe, through the medium of the float and valve connected with the cistern.

The Engine

Is that part of the steam-engine where the force or power is developed by the action of the steam, and thence by appropriate machinery adapted to whatever object it is desirous to give the impulse of a first moving power. There are a number of parts essentially belonging to the engine, each of which requires to be considered separately, in order that the mechanism of the whole may be rightly understood. These parts are—the cylinder, the condenser, the air-pump, the hot well, the cold water-pump, the beam, the crank, the fly-wheel, the governor, the eccentric and valves, and the indicator. For the convenience of description, these parts and the minor subordinate pieces of mechanism, may all be arranged under two heads—1st, Those relating to the steam; and 2d, Those connected with the motion, the regulation of the valves, &c. The engine now to be described is that called the *double-acting engine*, so named in opposition to the *single-acting engine*, in which the piston is forced downwards by the steam, but is elevated by a weight attached to the remote extremity of the beam. It is so called because the motion *downwards* and the motion *upwards* are both effected solely by the agency of the steam.

The cylinder (C, fig. 2) is the stout iron vessel into which the steam is introduced, and by its elastic force

according as it is alternately admitted and withdrawn below and above, causes the piston-rod to ascend and descend by an alternate and almost uniform movement. This iron vessel is steam-tight at the aperture where the piston-rod moves, and is equally so at the different apertures by which the steam either enters or escapes, these apertures all being securely protected by valves. When the piston has arrived at the top of the cylinder, the lower part is full of steam. To produce a vacuum, so that the piston may be readily depressed by the introduction of steam above, this vapour below must be removed. For this purpose the cylinder has a valve at its lower surface connected with the *condenser* (an apparatus immediately to be described), and on this being opened, the steam rushes into it and is condensed. But while this has taken place, the passage to admit the steam above the piston is opened, and as it enters immediately, by its elasticity it depresses the piston to the bottom part of the cylinder, constituting the downward movement.

But the piston has now arrived at the lower part of the cylinder, and it is required to raise it to the summit again. This is effected by the very same arrangement as that employed to bring it down. The steam which is in the cylinder above the piston is now, by the shifting of the valve, allowed to communicate freely with the condenser, escaping from the upper aperture in the cylinder. In this manner a vacuum is produced above, and the steam simultaneously being admitted from below, the ascent of the piston takes place to the upper part of the cylinder. By a continued succession of this alternate ascent and descent, motion is communicated to the beam, and thence transferred to whatever object it is desired to affect.

The condenser (A, fig. 2), is the next part to be described. The position of it is under and at a little distance from the cylinder, with which it communicates directly by a pipe or tube. The condensation of the steam by the aid of cold water, it will be remarked, is effected at a distance from the cylinder. This, indeed, constituted the chief improvement of Watt. The condenser may be considered as a vessel with three apertures in it—one leading from the cylinder, protected by a valve; another leading from it to the air-pump, also protected by a valve, permitting the free passage of matter, whether water or gases, to the air-pump, but not allowing any backwards into the condenser; and the third or last tube, which allows fluids also to escape, but has no communication with the air-pump, the fluids being discharged into the cold water which surrounds all this part of the machinery: this is usually named the *snifting* valve. But there is also another aperture, through which the cold water is admitted to the condenser; this is regulated by the injection-cock. This cold water, when it is thrown in, immediately condenses or absorbs the vapour of steam, so that a vacuum, comparatively speaking, is formed; for, as has been already observed, one cubic inch of water expands into 1700 cubic inches of steam, and therefore the converse takes place during the condensation; that is to say, the 1700 cubic inches now occupy a space not exceeding one cubic inch.

The condenser-gauge is intended to determine the force of the vapour which may be in the condenser, for it must be observed, that a complete vacuum is scarcely ever produced. The extent of the vacuum it is essential to know, in order that the engineer may precisely ascertain how far it is working correctly. It may here be observed, that water can exist in the form of vapour even at very low temperatures. The force or elasticity it possesses is to be determined in the ordinary mode by a bent tube containing mercury, open at one extremity to the condenser, and at the other to the atmospheric air—the same principle, in short, as was applied to the estimation of the force of steam in the boiler.

Immediately contiguous to the air-pump is the hot well (H), into which the hot water from the condenser is brought, and any aëriform bodies remaining in the condenser. The piston of this air-pump being drawn up by means of the connection it has with the great cross-beam, a vacuum is produced; but at the lower part of the air-pump there is the valve communicating between it and the condenser. This valve, however, opening towards the air-pump, not in the other direction, the fluids pass immediately towards the air-pump; and the descent of the pump, the fluids are necessarily driven back, but their return to the condenser is altogether prevented by the structure of the valve; accordingly, from the compression they are exposed to, they open the valves of the air-pump piston, and are carried to the upper part, where they are gathered together. On the ascent of the piston taking place, they are carried by it and brought into the hot well.

As the piston which works the air-pump is attached to the great arm of the beam, it is apparent that its operation is carried on steadily while the engine is acting, and accordingly, that the fluid formed by the condensed steam, as well as the fluid which produced the condensation, is incessantly being removed from the condenser, and successively brought to the hot well.

To supply this part of the engine, there is a pump which brings cold water into the cistern in which the condenser is placed. From the character of the water which it conveys, it is technically named the *cold-water pump* (O, fig. 2). At the point, then, where the heated water is drawn from the condenser, and brought into the hot well, the course of the water, proceeding from its fluid state in the boiler, then as steam, and finally condensed, may be said to be concluded. The water, however, it was observed, in the state of steam, acquires a great amount of heat, somewhat more than five times the heat required to raise it from the freezing to the boiling point. It is then returned by means of a tube to the cistern which is placed above the boiler, and supplies the feed-pipe leading to the boiler. The mechanism employed here has already been detailed. It will therefore be apparent, that a quantity of the water which was at the beginning in the boiler, is returned again to it, having previously passed through the state of steam, and having been condensed, performing a complete circle of changes.

The air-pump is not merely observient to removing the water found in the condenser, but it effectually removes the gases which are found associated with the steam, and which exist also always in certain amount, more or less, in water. These gases, were they to accumulate in the condenser, would effectually interfere with the production of a vacuum, and the consequent efficiency of the engine, by the accumulation of heated water, which would oppose the dissolving the steam or condensing it, as the term is. The air-pump is usually made to equal one-fourth of the cubic contents of the cylinder.

There is not, perhaps, any piece of mechanism so complete in all its various parts as the steam-boiler, or all those parts which are immediately subservient to the purpose of forming the steam—conveying the steam to the cylinder, condensing it, and again returning it in the form of water, from which it was originally produced, to be again converted into the same powerfully elastic body by the agency of heat. If, indeed, the condensation could be effected by other means than the agency of water, all the steam might be returned to the boiler, and thus, in an unceasing circle, the amount of water at first started with would suffice.

At first sight, it might appear that these were all-sufficient to determine the movements of the steam-engine, but there are other parts which are no less essential to the perfection and uniformity of its movements. These are, the eccentric rod, the governor, and indicator.

The eccentric rod (R, fig. 2) is designed to work the valves, which were formerly managed in a very different manner, by means of catches or lappets fixed to the air-pump, and so placed as to elevate levers, which opened and closed the valves at the proper intervals. These valves require to be worked in a vertical manner, so that the steam may alternately enter and be shut off from the aperture into the cylinder, at the top and the bottom; and the regularity of the movement of these valves is indispensable to the permanent uniformity of action in the engine.

The eccentric consists of a circle of metal connected with a revolving axle, while the centre of the circle differs from the centre round which the revolutions of the axle are performed. It receives the name *eccentric* because it is out of the centre (*ex*, the Latin for *out of*, or *away from*). If we suppose a circular metallic plate made with a shaft fixed in it, on which it revolves, but which is not in the mathematical centre, that is, the real centre of the circular plate, and if we suppose the diameter of the circle to be four inches, the exact centre will be two inches, or the radius of the circle will have that length. If, then, the shaft is fixed into the metallic plate firmly in the middle of the radius, that is, at one inch from the circumference, and therefore at the same distance from the centre, it is obvious that, as the metal plate revolves so as to complete half a circle, three-fourths of the whole diameter will be placed exactly to the outer side of the axis on which it revolves; and on the revolutions being completed, the three-fourths will then be on the interior side, as the axis on which the plate revolves is permanently a fixed point. Round this eccentric a ring is adjusted with screws, to which metallic rods are fixed. As the eccentric revolves, the ring does not associate in the rotatory movement; it will, however, be carried to the right and left by the movement of the centre of the eccentric, as it comes round the axle. And as, in the case we have proposed for illustration, the distance between the real centre of the ring, and the centre of revolution is one inch, the attached rod will be moved twice that space to either side during the revolution which the horizontal axle performs.

In this manner a rectilineal movement is procured from one that is circular; and by means of levers arranged at the extremity of the rod around the eccentric, the valves are alternately elevated and depressed, so as to permit the free entrance of the steam to the cylinder above the piston, while free exit is given to the steam below to the condenser, and then to permit the equally free ingress of the steam below the piston, while the escape of it from above is equally free to the condenser. Whatever variation may be given to the levers employed, the principle is the same, in so far as a horizontal lateral movement is obtained through the medium of the eccentric.

In the escape of the steam, either of increased elasticity or increased quantity, it is obvious that the movements of the engine will become more rapid, and so much accelerated as not to be adapted to the work it is intended that it should perform. It became, therefore, an object of the highest importance to regulate the quantity of steam as it was transmitted from the boiler by the steam-pipe to the cylinder. To accomplish this, Watt very ingeniously applied the mechanism so long employed in mills, and which is almost universally known by the name of the *governor* (Z, fig. 2). The nature of this piece of mechanism will be understood by the foregoing figure. A spindle or upright rod, with a pulley on its lower part by which it is moved, receiving motion through a strap attached to the shaft or axle, has two balls, which revolve along with it. These balls, by the means of joints, may be separated considerably from, or brought nearer to, the spindle. Two levers are connected with the rods to which the balls are attached, having a free movement on other levers similar in length and thickness, but which meet in a metallic ring movable upwards and downwards on the spindle. Immediately above the ring, a lever is placed transversely across the ring, fixed at one point, but connected to another which is bent, to the end of which the throttle-valve of the steam-pipe is attached. This valve, it may be here noticed, is intended to regulate the supply of steam, allowing it to escape when horizontal in full stream, and obstructing it proportionately as it assumes a vertical direction. When, therefore, the engine acts with increased speed or velocity, and the main shaft to which this spindle is attached is revolved with a proportionate degree of rapidity, the balls will recede to a greater distance from each other, and accordingly the levers acting on the throttle-valve will raise it so as to diminish the flow of steam. But if the shaft revolves slowly, the spindle also having its velocity regulated by it, the balls will naturally approximate each other, and the lever will now so act on the valve as to throw it completely open, and thereby permit the steam to enter in a full current to the cylinder, and accelerate the motion.

Whatever is the velocity of the axle, such also will be in a proportionate ratio the velocity of the spindle, and in a corresponding manner will the position of the throttle-valve, either to close or enlarge the opening, be modified. In the engines built for Ibrahim Pacha, there is no governor, the valve of the steam-pipe being immediately under the control of the engineer by means of appropriate levers, as in all marine engines.

The indicator is a piece of mechanism devised by Watt, by means of which the force of the steam, and the state of exhaustion in the cylinder, are known at the different periods of the stroke of the piston. It is a small cylinder 8 inches long and 1¾ inches in diameter, communicating directly with the cylinder, and supplied with a piston. If the force of the steam in the cylinder exceeds the pressure of the atmosphere, the piston of the indicator then rises, and if it be less, is depressed. A tracer is connected with the indicator, by which a curve is drawn on paper, indicating the variations occurring in the pressure of the steam.

Hitherto, those parts only have been detailed which are immediately related to the course of the steam. There remain now to be described those parts more directly, or rather essentially, connected with the regulation of the motion: these are the beam, the crank, and the fly-wheel.

The beam is the large and strong mass of iron moving on a centre, and resting on a large pillar or pillars firmly secured to the base of the machinery and floor. It is so fixed on the summit of the pillar, that it may move freely on its centre, so that the extremities can alternately rise and fall with the alternate elevation and descent of the piston: the pump-rods attached to the beam are also worked in the same manner, and so were the valves formerly, but the latter are now acted on by the eccentric, which has been explained above.

In the single-acting engine, where the steam is employed to depress the piston, and a weight at the end of

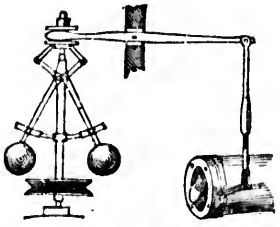

Fig. 5.

the bearr to elevate, the connection between the piston and the beam is by means of a chain, as the force acted on the beam only during the descent of the piston. When the double-acting engine is in play, the beam is pulled down by the piston-rod, and a chain would be sufficient for this end; but when the piston ascends, any force communicated from it to the beam, through the medium of the chain, would be totally lost; for as the piston was carried upwards, the chain would relax, and the beam remain in the condition it was at the beginning of the movement upwards.

A different mode of connection, therefore, is required. of such a mechanism, that the inflexible connection between the arch-head of the beam and the piston-rod may push the beam upwards. Different plans were proposed to effect this end, one of which was the suggestion of Watt, namely, to attach to the end of the piston-rod a straight rack, which could play in a similar rack formed on the arch-head of the beam. But this did not suit well, for the movement in the stuffing-box of the cylinder, if not of the most equable and smooth character, rendered the working of the cylinder inefficient, by allowing the steam to escape, or the air to enter. This plan, then, was ineffectual; and it, as well as others, have all yielded to that most elegant disposition of mechanical forces to which the term *parallel* motion is given (H, fig. 2).

The Crank.

The movement produced by the ascent of the piston and its descent, acting on the beam alternately, causing its elevation and descent, is to be converted into a perpetual circular movement, in order to adapt the engine for the great number of purposes for which it is usually employed. This is effected by the Crank. This piece of mechanical apparatus is to be held merely as the handle of a wheel, which turns it round on any power being applied, as the hand of a man. The line stretching out like one of the radii of a wheel from the axis, is called the crank; the rod, again, at right angles to it, is called the *crank-pin*, while the rod at the other extremity is the *crank-axle*. In the steam-engine, then, a rod is attached to this crank, which (through the beam) is connected with the piston-rod in the steam cylinder; as it ascends and descends, an impulse is necessarily given to the crank, which causes one-half of a circle in the one movement and one-half in the other. When we reflect on the nature of the movements produced, it is apparent that there are two distinct movements, one upwards and the other downwards, and consequently that there is a cessation of impulse at the alternate change of the direction of the force. For when the steam enters above the piston, it depresses naturally the piston to the bottom of the cylinder. It is then, however, intercepted previous to its being introduced below the piston, during which time there can be no moving power exerted. Again, when the steam is introduced below, the same succession of actions arise; and when the piston is at the summit of the cylinder, there is, for the same reason as in the movement downwards, no force exerted. These two points, then, at which there is no power acting on the crank so as to turn it round, are usually denominated *dead points*.

How, then, is the movement continuously carried on? what is it that prevents the action of the crank ceasing at these two points? The crank and axle have received from the engine a certain amount of motion, and as the motion which it has received continues after it has come to one or other of the dead points, it continues still to move in consequence of the momentum it has received, and with force sufficient to carry it beyond the range of the immovable point. But now that it is liberated from these points, it becomes immediately acted on by the piston-rod's connection through the connecting rod. In this manner it is carried through the other half of the circle, until it comes to the other dead point, where, from a similar cause, it does not stand, but is urged round, and in this manner a continuous circular movement is effected The fly-wheel, also, in a similar manner assists in clearing the dead points. The velocity with which the movement is carried on is not equal, for, in the first place, there are the two dead points through which the crank is worked solely by the impulse or momentum it had already received; and, in the second place, from the mode in which the connecting rod plays on the crank, it must be greatest where the angle of these two is a right angle; and diminish proportionably as it recedes from that position to the dead point, where it is least. The reality of these dead points, and also of the unequal velocity, any one may easily see if he attend to the commencement of the motion of the engine, when the steam has not got sufficient force, when he will find that it cannot carry the crank beyond the point until it is urged with increased force; and the same will conversely be seen as the engine is stopping. The continuous movement being effected in this manner, it is apparent that it is not always at every point produced with the same force; and therefore that the action, though, in as far as the amount of force exerted be the same, yet it is unequally divided over a given time, as, for instance, a revolution of the crank. But this would not suffice in the very nice and equable movements and applications of force to which the steam-engine is now so universally applied in the various manufactures of this country. To render the machine as perfect as possible, the fly-wheel was constructed for this object. This is merely a large iron wheel attached to the axis turned by the crank, and consequently carried along with it in its revolutions. This wheel is made very heavy, with the object that it may produce uniformity in the motion by the momentum which it receives, (L, fig. 2).

This arrangement has been found sufficiently perfect in the more ordinary cases, where an extreme degree of equality and nicety of movement is not required. Where such is an essential point, then the plan devised by Mr. Ruckle of Soho is that which is to be put in execution. By means of a wheel working in the rack of another and smaller wheel, the action of the engine is made subservient to drsw a piston from the bottom of a cylinder, so as to leave a vacuum. When this piston was at the summit, and the vacuum below, the action of the steam being withdrawn, it necessarily was carried down by the pressure of the atmosphere, acting with a force of 14·7 pounds on the square inch. A considerable amount of power was thus employed in producing a vacuum, which was regained by the atmospheric pressure. This arrangement was next adopted in flour-mills with the most complete success, and subsequently has been carried into effect in other mills with equal success. From the uniformity of the movement produced, the quality of the matters produced has been greatly enhanced.

Having described all the parts connected with the engine, we have now to consider the mode in which it is worked. The first point, after the steam has begun to be freely produced in the boiler, is to expel all the air which may be in the different parts of the apparatus by opening the valves, and allowing the steam a free transit, finally permitting it to escape by the shifting-valve. When nothing but steam fills the different cylinders, then the noise at the shifting-valve ceases, and the injecting-cock for the cold water is to be trimmed for the purpose of throwing in the cold water to produce the condensation of the steam.

The steam is now ready to act on the piston, and when it has moved it (whether admitted in a full stream, or expansively, it matters not) to the extremity of the cylinder, by the mode in which the valves are disposed, it passes immediately to the condenser, where the cold water play

ing on it, converts it to its original condition of water. The alternate elevation and depression of the piston being continued, and the steam passing eventually to the condenser, this latter part would soon be completely filled by the condensed water, so as to be totally unfit for its duty. This is obviated by the action of the air-pump, the valves of which are arranged so as to open only upwards. By means of the piston of this air-pump, the fluids are carried to the hot well. To this hot well a pump is attached, by which the water, which is of considerable warmth, is conveyed to the cistern (M, fig. 2) situated over the boiler immediately at the summit of the feed-pipe (R, fig. 3). The beam of the engine carries a rod by which this pump is worked, as well as another through which cold water is continually supplied. The valves by which the steam escapes from above and from below the piston, during its alternate ascent and descent, are opened and closed by the eccentric (R, fig. 2), and the force and power with which the engine should work is determined by the governor (Z), in the mode already explained, the continuity and the uniformity of the movement being mainly controlled by the fly-wheel and crank, or by the crank and pneumatic pump of Mr. Ruckle.

In this manner the engine continues its action as long as it is supplied with a due proportion of steam; and if there is a definite force with which it should act, on the supposition that there is always abundance of fuel and water, the amount of steam is definitely maintained by the governor and throttle-valve, and by the float in the piston the exact quantity of water is duly preserved; and also by the damper, a greater or less current of air enters the flues, either to increase the production of steam when it is tardy, or diminish it when generated in excess. By the proper arrangement of the valves, likewise, no danger can result from the boiler, and thus, in the strict sense of the word, it is a self-acting and self-adjusting machine; it does, in short, as has been truly said, every thing but speak.

Expansive action of Steam.

Steam, it is already observed, being a vapour, possesses consequently the expansive property peculiar to such bodies, and as the piston either descends or ascends by the impulse of the steam, it follows that the velocity of the stroke is not equal all throughout. Suppose the piston is at the summit of the cylinder, and the steam enters above, the piston will then begin to descend, opposed only by its inertia and friction against the sides of the cylinder. But as the motion downwards continues, this becomes accelerated from its own inertia, and therefore the resistance being less than at first, the steam forces it downwards with increased velocity. The velocity will be at the *maximum*, or nearly so, when it has completed the descent. Watt, ever alive to all the modes of bringing the greatest effect from the steam, considered that a moving power, in addition to that obtained by the stroke of the piston, might be obtained and rendered practically available. We refer to a method of still doubling the effect of the steam, and that tolerably easy, by using the power of steam rushing into a vacuum—at present lost. This would do little more than double the effect, but it would too much enlarge the vessels to use it all: it is particularly applicable to wheel engines, and may supply the want of a condenser, where the force of steam only is used. Open one of the steam valves, and admit steam until one-fourth of the distance between it and the next valve is filled with steam; then shut the valve, and the steam will continue to expand and to press round the wheel with a diminishing power, ending in one-fourth of its first exertion. The sum of the series will be found greater than one-half, though only one-fourth of steam was used.

This mode of using the steam expansively may be illustrated in the following manner:—If the piston is pressed by a weight of one ton, and can be raised four feet, when the cylinder is supplied with steam of the ordinary pressure of one atmosphere, the same piston loaded with four tons will be raised one foot, if the cylinder be one-fourth full of steam of four atmospheres. When the steam of four atmospheres is admitted, it is cut off when the piston is raised one foot. But the piston has now received an impulse, and the steam, beginning to expand under it with a gradually diminishing force, is raised to the second foot, the volume now being doubled, and its elasticity only equal to two atmospheres. On the piston being elevated to the third foot, the volume of the steam will be trebled, and its pressure or elasticity now reduced to one atmosphere and a third. But when the piston is raised the fourth foot, the steam will now have become quadrupled in volume, and the force equal to that of one atmosphere.

This principle is now much employed, and particularly in the Cornish mines, where it has been used with great success, the pressure of the steam in these engines being four atmospheres. The benefit of working a steam-engine in this mode increases the earlier the steam is cut off, but not much after steam is rarefied four times.

Single-acting Engine.

The machine already described is the common double-acting engine, as it is named, or simply the steam-engine in a complete form for application to useful machinery. A few remarks will be sufficient to explain the nature and principle of the single-acting engine, and the purposes for which it is specially employed. In this form of the engine, the principle is in part that of the old engines, where the atmospheric pressure was brought to act, and also of the new or engine of Watt, in which the steam is condensed in a separate vessel.

The single-acting engine was that which Watt first invented. In the form of the engine, the steam was admitted only above the piston, at first the vacuum being below it. When the piston had gained the lower part of the cylinder, the communications between the steam-pipe and cylinder, and also between the condenser and cylinder, were closed; and through the medium of a tube communicating laterally, the steam which was above diffused itself below the piston, so that on either side it was subject to an equal force. But on the other extremity of the beam there was a weight, which raised the piston up, and the steam all necessarily flowed below the piston. On the communication between the condenser and cylinder being made free, a vacuum was induced, and the steam-pipe being then opened, a stream of steam proceeded to the upper part of the piston, and the movements were repeated as before.

This form of engine was not by any means well suited for the purposes of communicating motion to machinery, in consequence of the inequality of its action, but it served admirably for the purpose to which it had been first applied, namely, that of raising water from mines. It is, however, in a great measure, even for that latter purpose, superseded by the double-acting engine.

Marine Engine.

In the steam-engines employed in the navigation of vessels, there are certain modifications which it is requisite here to detail, and then briefly to point out the lead

ing circumstances connected with the important application of steam.

The most striking peculiarity is the position of the beam in British steamers, which, instead of being placed above, is situated below, chiefly with the view of saving room, and is not single, but two, one at either side of the cylinder. To the upper portion of the piston-rod there is a cross bar, which is placed transversely across the cylinder, at right angles to the long axis of the ship, or from starboard to larboard, in nautical language. From the extremities of this transverse bar, rods stretch down, connected interiorly to the termination of the beams, moving on pivots at both their connections with the cross head and beams. The other extremities of the beams are attached to a cross piece, on the centre of which the rod is fixed by which the crank is worked. The shaft of the paddles is firmly connected to this crank, so that it is worked along with the rod. In small vessels, only one engine is usually employed, but in vessels of considerable tonnage there are two, and their action is so adjusted, that while the one is at its fullest strain the other is in the reverse condition. In this manner the motion of the wheels is preserved uniform and equal. These forms of engine are usually called condensing, the steam being worked at high pressure, and then condensed, an object which is very readily accomplished in consequence of the abundance of water.

From the peculiar structure of these engines, they emerge considerably above the level of the deck, and consequently they have been designated by the apt name of the *steeple engines*. They are worked with air-pumps and condensers, and, as in the other marine engines, there is no fly-wheel. The chief advantage they possess is the small space they occupy, and thereby not only afford room for more merchandise, but further save the great weight necessarily incurred where the beam is employed.

Another modification adapted to the steamboat, by which it is rendered unnecessary to have the beams and its appendages, is that proposed by Mr. Witty, and called the *vibrating engine*. The object is to obtain a circular movement from the vertical motion of the piston-rod. This is effected by the cylinder being suspended on an axis at its middle, so that it has an alternate movement forwards and backwards, vibrating in a manner analogous to a beam on its axis. In this manner there are two distinct movements of the piston-rod—the common one upwards and downwards, and this lateral movement, in which it is immediately connected with the crank.

In this form of the engine, the axes on which the cylinder moves are hollow tubes, one being the steam-pipe by which the steam passes to the cylinder, and the other being the eduction pipe, by which it is transmitted to the condenser.

There is a peculiarity in the arrangement of the marine boilers, which it is necessary here to point out. This consists in the process of *blowing out*, as it is technically named. In sea-water there is a considerable quantity of saline matter, about three per cent., which, accumulating in the boiler, not only retards the process of boiling, but is apt to give rise to explosions. To obviate these imperfections, hot water is permitted to escape freely from the boiler at stated intervals, and as the discharge takes place from the interior surface, the greater portion of the saline matter is carried off. In this mode, a very serious obstacle was effectually removed, but this was not done but at a considerable expense, the loss being estimated at nearly 1-54th part by Mr. Tredgold. For it is apparent that an immense quantity of heat must have been lost in the warm water employed for this purpose, and not subsequently converted into steam.

A very ingenious method has been invented by Messeurs Maudsley and Field, which preserves a uniform standard of the quantity of salt in the water of marine steam-boilers. This is effected by means of pumps, called *brine-pumps*, which are worked by the engine, and remove from the boiler the strong solution of salt and water. These pumps discharge so much salt, combined with the small quantity of water, as the feed pumps supply to the boiler, so that the quantity of salt remains almost always the same. Further, before this hot brine is discharged into the sea, it passes through a tube included in another, which is the feed-pipe, supplying the boiler from the sea, so that the greater amount of its caloric is imparted to the water, and it is reduced to nearly 100 degrees before it is thrown out.

The paddle-wheel by which the steam vessel is propelled has undergone many modifications, for, in the common mode in which the flat boards or float-boards are disposed, they both enter the water obliquely and leave it obliquely, occasioning a considerable loss of power; for it is apparent that their greatest effect must be when they are nearly in a vertical position. The complex nature of several of these wheels, proposed as substitutes, prevents their employment. Latterly, the Archimedean screw has been adopted in several vessels with great prospect of success.

In Great Britain the engines adopted are those called condensing, and they usually work with a pressure of about forty pounds on the square inch. In America, the high-pressure engine is generally used; and Stevenson states he was in a vessel on the Ohio, where the common pressure used was 138 pounds on the square inch.

High-Pressure Engines.

The steam which is produced at ordinary temperatures and pressure, cannot produce any motion if opposed to the atmosphere, as it merely possesses a force equal to it. Hence to give it any power, the piston by which it acts must be pushed towards a vacuum. To accomplish this, additional apparatus is requisite—all, in short, that is used in condensing the steam. If we desire, therefore, to have an engine of as simple and light a construction as possible, the bulky condensing apparatus must be dispensed with. The steam must be generated at a higher temperature. Steam of greater elastic force must be employed. Before this can act, it must first overcome the resistance of the air; and it is only the pressure it has in excess over one atmosphere that will exert any efficient power. These engines, from the kind of steam which they use, and the absence of the condensing apparatus, are usually denominated *high-pressure*, or non-condensing engines. High-pressure engines are now made in various small sizes, and of exceedingly neat workmanship, to impart motion to machinery of limited extent. Those made for turning coffee-mills, of which we give a sketch in fig. 6, are of a handsome compact form, costing from £20 to £50, without the boiler.

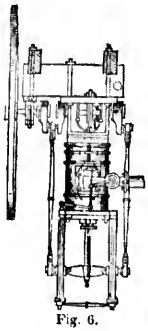

Fig. 6.

The mode of generating the steam in high-pressure engines, with its action upon the piston, is the same as in the other; there is one difference, however, that the pipe from the cylinder leads at once out into the open air, where the coolness of the atmosphere soon condenses the steam into a white cloud or mist. These high-pressure engines are more dangerous, on account of the great force of the steam in the boiler, which is consequently very apt to be burst; but with a reasonable degree of care, and an attention to the valves, no explosion need be anticipated. The pressure with which those in ordinary circumstances work, varies from 30 to 45 pounds on the square inch

The employment of high-pressure engines affords an opportunity of heating premises with the waste steam.

Rotary Engines.

This engine specially consists in the application of the steam disengaged from a boiler, so as to produce directly a continuous circular movement. In it there are no cylinder and piston, no beam and crank; in short, there is merely the boiler to disengage the steam, and the object to which it is to be applied. The most simple form of this is the engine formed analogous to the æolipile. A pipe rising vertically from a steam boiler ends in a horizontal arm moving freely round the pipe. This arm or horizontal tube has apertures, in the same manner as in the æolipile, at the opposite sides from which the steam escapes, urging the horizontal pipe forwards in a course the reverse of that in which the steam is disengaged. Mr. John Ruthven of Edinburgh has several years been engaged in making engines of this simple nature; one of these which has come under our notice works with great power, the pressure being from 30 to 70 pounds on the inch. The length of the arms is five feet, the breadth five inches and a half, and the apertures from which the steam issues are one-fourth inch in diameter. Mr. Ruthven has, as he informs us, sent a great many to England and abroad. One of 20 horse-power has been working at a coal-pit at Stovely, in Yorkshire, where it raises above a ton of coal 55 fathom in less than a minute, the engine never requiring to be stopped or reversed. Sixty horse-power is also applied at a short distance from it, working a rotary fan-blast for smelting iron ore; they work night and day, and have done so for upwards of six months. The Rotary fan employed for such a powerful blast is the invention of Mr. Ruthven's son. Several of the rotary engines are in London, one near Bristol, in Newcastle, Thirsk, Oatley, Kilmarnock, &c., &c.

Locomotive Engines on Railroads.

The form of engine adapted to the railway differs from those already described, these being stationary or fixed in large vessels, while here the smallest bulk possible is essentially required, at the same time as little weight as convenient. Accordingly we find, that in the arrangement of these engines, all that apparatus is rejected which is intended for condensation, and therefore high-pressure steam is used.

In the arrangement or disposition of the parts of the boiler and engine, there are certain peculiarities which require to be described It is necessary to premise, that the great object is to effect as speedily as possible the conversion of a large quantity of water into vapour. This is accomplished by arranging the boiler in a peculiar manner. It is not one large mass, as in the marine boiler, or land boiler, with a great quantity of water in the centre, but an oblong cylinder, through which are disposed a vast number of brass tubes of a cylindrical shape, amounting to about ninety in number, arranged horizontally. These tubes communicate with the furnace, and the heated air passes through them as it proceeds to the chimney, in which manner an immense quantity of the caloric is applied to assist in the evaporation of the water; so that the boiler might, nevertheless, be considered merely the same as the common one, but with the chimney subdivided into an immense number of small tubes passing through it to the large vent hole or grand chimney. These tubes were suggested by Mr. R. Stephenson in 1829, and constituted a great advance in the efficiency of the locomotive steam-engine.

In the sketch, fig. 8, is given a general exterior view of a locomotive, and in fig. 9 a longitudinal section of the apparatus. The boiler is seen forming the great bulk of the engine; its form is cylindrical, being about three feet in diameter, and eight in length. The numerous tubes, as they proceed through this part of the apparatus, are seen in transverse section in fig. 7, and longitudinal section, fig. 9. At the front of the engine is the smoke-box, terminating in the chimney above, and below, there is the steam tube, and the cylinder and piston, which lie horizontally (A). At the back of the engine is the fire-box, almost completely surrounded by water, and immediately behind this is the railed space (P) on which the engineer stands. On the upper surface of the engine, proceeding from the hind part forwards, there is the steam whistle (X), by which notice is given of the approach of the engine. A little

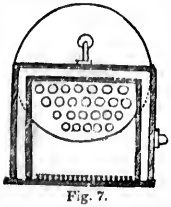

Fig. 7.

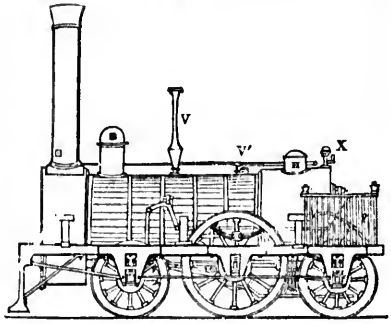

Fig. 8.

anterior to it is the man-hole, by which the boiler can be cleaned, and such repairs made as are requisite. Still farther forwards, we arrive successively at the two valves (V' V), by which the safety of the boiler is secured. The first (V') is always under the control of the engineer; but the second, nearer the chimney (V), is loaded higher, but completely shut up. A round spherical eminence (B) is then perceived immediately behind the chimney, called the *separator*, in which the steam gathers before it is conveyed by the tubes to the cylinder. The cylinders (two in number) are placed below the chimney, and lie immediately before the front wheels (A, fig. 9), and the steam passes to them by the steam pipe (S) into the two cylinders, whence it escapes afterwards into the chimney. The reason why this tube rises so high in the large chamber is, that no water may descend down to the cylinder, which might likely arise from the agitation the water suffers from the motion. At the point where the steam tube in the hot-air chamber meets the connecting pipe with the boiler, a regulator is placed, which can be worked so as to increase or diminish the flow of steam.

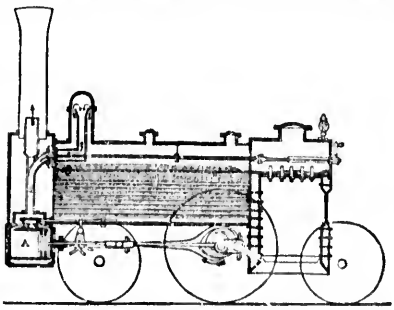

Fig 9.

The steam, as it escapes from the cylinder by two pipes, meets in the common tube, and rushing upwards into the chimney, is in part condensed, and mainly contributes to the draught of the chimney, which otherwise would be totally inefficient to work the fire.

From the great number of the tubes which fill up the boiler, the locomotive engine is not attended with much danger in bursting; for these tubes being weak, compared with the external casing of the boiler, yield readily on any unusual increase of the elastic force of the vapour; the consequence is, that the fire is put out gradually. When one yields, a plug of wood is introduced, which is generally sufficient till the end of the *run*.

The eccentrics for working the valves, and allowing the steam to gain either side of the piston, are fixed to the main crank axle. Sometimes there are two pair of eccentrics, the additional one being for the movement backwards, when the engine makes a retrograde movement. The size of the steam cylinder is about twelve inches' diameter, and eighteen inches' stroke. The driving wheels are usually six feet diameter; and some of ten feet diameter have been tried on the Great Western railway.

The engine is always attended by a tender, in which the coke and water are conveyed. The mode in which the different coaches are arranged may be seen in the article CONVEYANCE, where a train is figured with the engine and tender.

The power of a locomotive is estimated by the quantity of water which the boiler can convert into steam within a given time. Between 70 and 80 cubic feet is the average amount; but in the Bristol railway so much as 200 cubic feet are evaporated within the same time. The quantity of fuel consumed in Stephenson's engine is about a quarter of a pound for every ton per mile.

Horse Power.

In forming the estimate of the power of a steam-engine, it is usual to refer to horse power as a standard. Different values have been given of the power of a horse;* but that generally adopted is, that it can raise a weight of 33,000 pounds one foot per minute, and therefore a steam-engine, capable of executing that work, is rated at one horse power. On a railway, this power is considered equal to transport 400 tons 1 mile per day; or a horse draws 200 pounds at the rate of 2½ miles in an hour, continuously, over a pulley. The evaporation of a cubic inch of water, when converted into steam, affords a mechanical force capable of raising a ton one foot high. Fifteen cubic inches of water, therefore, when converted into steam, are equal to the power of one horse per minute, or 900 cubic inches per hour for each horse power.

To evaporate this, from 7 to 12 pounds of fuel are required in the same time (one hour); but in marine engines, the quantity consumed is about 8 pounds; the proportion of fuel they consume being as 2 to 3, compared with other engines.

Engineers possess rules for calculating the elastic force of steam and power of engines. The following may give an idea of the method of calculation:—

To find the power of an engine, multiply double the length of the stroke† by the number of strokes per minute, and we get the velocity of the piston per minute. If the engine works expansively, the mean effective pressure must be found. Multiply the square of the cylinder's diameter in inches by the mean effective pressure on the piston in pounds on the square inch, and by the velocity of the piston, point off these figures, and divide the product by 42, and the quotient will express the number of horses' power. Let the diameter of the cylinder be 36 inches, the length of stroke 4 feet, the number of strokes per minute 24, and the mean effective pressure on the piston 4 pounds per second inch, then

8 Feet + 24 = 192 per minute.

*The *medium* power of the horse is rated at 22,000 pounds raised one foot per minute: but 33,000 is the standard applied to the steam-engine.

†The length of the stroke of an engine implies the space moved through by the piston in its ascent and descent, and consequently is equal to one complete revolution of the crank shaft; hence the reason why the length of the stroke must be doubled.

History of the Discovery.

It appears, by careful examination of the records of history, that the action of steam for producing motion (though not then proposed to be applied to practical purposes) was known as early as 130 years B.C. This was produced by an instrument denominated an *æolipile*, described by Hero of Alexandria, of which a figure is annexed, and which may be considered the original of the steam-engine. The æolipile is formed by a globular metallic vessel, which rests on pivots, at and where it can revolve with perfect facility. Two tubes proceed from this ball at right angles to the pivots, shut at the extremities, but with a small aperture at the side, whence steam may escape. The pivots are the extremities of the tubes connected with a boiler below, as marked in the sketch. On the boiler being heated, steam passes by the pivot tubes (C B) into the cylinder, from which it issues by the little aperture (F) at the side of the cylinder tube (E). As the steam escapes, it rushes out with great force, and as it acts on the side opposite to the aperture, it forces it and the cylinder to move round in the contrary direction. One tube will suffice. The same action may be shown even in a more simple manner, as is often done by glass-blowers. A small glass globe is formed, and two arms are attached to it, which are cylindrical tubes. In the globe a quantity of water is introduced, and on applying heat below, the same action takes place. It is of course necessary that the globe should be properly supported.

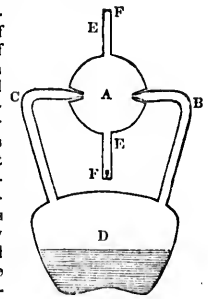

Fig. 10.

The next notice of steam power worthy of our attention is in the seventeenth century. In the year 1663, a work was published by the Marquis of Worcester, named, in the language of that period, "A Century of the Names and Scantlings of such Inventions as at present I can call to mind to have tried and perfected." The following extract, describing what he terms a "fire water-work," seems distinctly to convey the idea of a steam-engine:—"An admirable and most forcible way is to drive up water by fire, not by drawing or sucking it upwards, for that must be as the philosopher calleth it, *intra sphæram activitatis*, which is best at such a distance. But this way *hath no bounder* if the vessel be strong enough; for I have taken a piece of a whole cannon, whereof the end was burst, and filled it three-quarters full of water, stopping and screwing up the broken end, as also the touch-hole, and making a constant fire under it; within twenty-four hours it burst, and made a great crack; so that, having a way to make my vessels so that they are strengthened by the force within them, and the

one to fill after the other, I have seen the water run like a constant fountain stream forty feet high; one vessel of water, rarefied by fire, driveth up forty of cold water. And a man that tends the work is but to turn two cocks, that one vessel of water being consumed, another begins to force and re-fill with cold water, and so successively; the fire being tended and kept constant, which the self-same person may likewise abundantly perform in the interim between the necessity of turning the said cocks."

In 1698, Mr. Savery, or Captain Savery, obtained a patent for a steam-engine, which was the first introduced to raise water. The principle of his plan consisted in injecting steam into a vessel connected with a vertical pipe, dipping into the water to be raised, and then condensing it by cold water, so as to form a vacuum, or at all events a space in which there is vapour of very feeble elastic force. By the pressure of the atmosphere, the water was then driven up until it attained a height proportionate to the pressure of the atmosphere, diminished by the force of the uncondensed vapour. By a peculiar but a simple disposition of the valves, the return of the water was prevented; but as the water could not in this manner be elevated higher than 26 feet (64 feet by force of steam), the plan was not adopted to any extent.

The next decided and most important improvement which took place in the progressive advance of the steam-engine, was that of having a piston introduced into a cylinder, and when it is at the bottom, directing a current of steam so as to raise it, which is to be condensed by being cooled. A vacuum is thereby produced, and the pressure of the atmosphere forces the piston down to the bottom of the cylinder. A rude and imperfect idea of this plan was suggested by Papin (a celebrated Frenchman, who discovered the Digester, and invented the safety-valve) about 1690, but laid aside. Engines were invented and constructed on this principle in the year 1713, by Newcomen and Cawley.

The engine so constituted is commonly called the *Atmospheric Engine*, because the power is derived from the pressure of the air, the steam being used merely to form a vacuum against which the atmosphere is to act. As this engine constituted a very important era in the history of steam, a short account, with a diagram of it, is subjoined, more especially as it shows in very bold

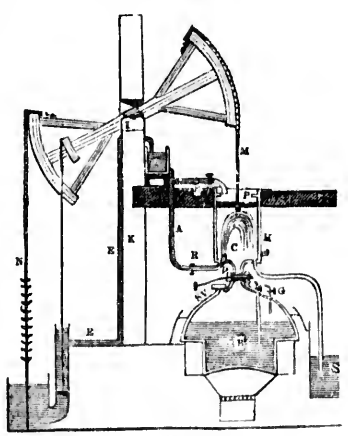

Fig. 11.

contrast the many and great advantages that resulted from the application of the genius of Watt to the steam-engine. There are three essential parts in the engine—the boiler, in which the steam is produced; the cylinder, in which it is condensed; and the beam, where its movements alternate with the ascent and descent. The boiler (B) is placed over a proper furnace, and built in with bricks. The summit of the boiler has a pipe or tube which communicates with the cylinder (C), situated immediately above. The communication between the cylinder and the boiler is protected by a valve (V), called the *regulator*, or regulating-valve, so that the admission of steam may be regulated at will. The boiler is provided with gauge-cocks (G G) as already noticed under the head of *boiler*, and also with a safety-valve (S V), which is not loaded to any great extent, as the engine works at a low pressure. The cylinder, which is placed above, is made of cast-iron, and nicely bored, so as to permit the free working of the metallic piston, but at the same time to prevent the access of air or steam. The piston (P), in short, works like the piston of a common syringe. There are four apertures in the cylinder, while it is also open at the summit. There are, first, that marked V, the valve of communication between the boiler and cylinder; second, that at the left inferior angle in the opening of the pipe (A), which transmits the water for condensation, armed with the stop-cock (R), named the *injection-cock*. This pipe leads from the cistern (C), which is kept constantly supplied with cold water by the action of the small pump attached to the beam, raising the water and carrying it along the tube or water-pipe (E).

At the opposite angle below H, an aperture is observed, being the commencement of the eduction pipe, by which the water injected for condensation is removed to a cistern beneath. This pipe is conveyed a considerable way down into the cistern, and is protected with a valve at its extremity, opening outwards, so as to permit free passage of the water from the cylinder, but none to regurgitate from the cistern. The fourth aperture opposite the opening of the injection pipe (H) is also supplied with a valve opening outwards. It is commonly known by the name of the *blowing-valve* or *snifting-valve*. It is through this valve that any air in the cylinder is expelled before the engine starts.

On a large support (K) a beam (I) is placed transversely across, which moves on an axis at I. This beam has one arched head at either extremity, to both of which chains are attached. On the one immediately above the cylinder the chain is continued down to the piston-rod (M), into which its fixed, so that, as the piston ascends and descends, there will be a similar movement of the arched head of the beam. To the other end the chain is connected with the pump-rod, by which the water is to be brought up. But the pump-rod is made heavy, so that it naturally draws down this extremity, and elevates the piston-rod.

The mode in which this engine is worked is the following:—The fire being properly raised and steam freely formed, the valve (V) is opened, to allow the entrance of the steam. The snifting-valve (H) is now forced open, and the air escapes along with the steam, until the cylinder is full of steam. The regulator-valve (V) is now shut, and the stop-cock (R) on the pipe A being opened, the cold water is injected, and condenses on the steam. But as a vacuum is effected by the condensation of the vapour of the water, the pressure of the air, now acting with a force equal to fifteen pounds on the square inch on the surface of the piston, carries it down to the bottom of the cylinder, and consequently raises the other end of the beam to which the pump-rod (N) is attached. In this manner the water is raised from the mine; and by a repetition of the movements already noticed, a constant discharge of water results. There were not a few difficulties or impediments in the free working of this engine, one of the most laborious of which was the incessant attendance of a person to open

and shut the stop-cocks alternately as it was required. This was accomplished by catches (scoggans) worked by the beam, or strings connected with the lever of the valves and the beam—an invention of a boy, Humphrey Potter, to avoid the trouble that constant attendance on the levers demanded. By means of a plug frame fixed to the beam, invented by Beighton, the engine was made to work the valves with great regularity—a most important practical advance in making the steam-engine work itself, and adjust its own valves. The analogous part of this machinery in the modern double-acting engine is to be observed in the eccentric.

This, the atmospheric or Newcomen's engine, had many and very striking advantages over all others previously proposed. It may, indeed, be considered the basis of the engine subsequently modelled by Watt. But there were very serious defects in it, which the reader will in some measure be acquainted with from the history of Watt's engine. It is here sufficient briefly to enumerate them. Much steam must, then, be lost during the process of the heating of the cylinder after each condensation; for it must always at least be raised to the temperature of the steam that can, as such, continue in it, and be in any degree efficient; and on the other hand, the cold air which follows the descent of the piston must necessarily withdraw a considerable portion of heat. By the calculations of Watt, it was estimated that *three* times as much steam was expended in this manner as would have been equal to work the engine—a loss, therefore, equal to 75 per cent. Nevertheless, this, as has been correctly observed, "was the first really efficient steam-engine; that is, the first engine which could be applied *profitably* and *safely* to the most important purposes for which such machines were required at the time of its invention."

In the further history of steam-engines, we fall on the era of Watt, the atmospheric engine having been very extensively used for a period of nearly one hundred years. The modifications it afterwards underwent have been sufficiently explained in the history of Watt's engine, and it is therefore unnecessary to extend these observations further.

MINING—METALS—COAL—SALT.

The objects upon which mining industry is exerted are, as is well known, metals, coal, salt, and various kinds of earths and other substances employed as drugs, or in different departments of the useful arts. Confining our paper to the mining industry of the British islands, which are rich in mineral products, we shall, in the first place, treat of the metallic class of minerals, such as tin, copper, iron, lead, &c., and afterwards of coal and salt.

METALLIFEROUS DEPOSITS.

Metals are not distributed accidentally and promiscuously in the earth, nor do they exist, with rare exceptions, in a pure and unalloyed state. They are found in connection with various earthy impurities, and in different states of chemical combination with other mineral substances. Such deposits are called *metalliferous*, or containing metal. The chief forms in which they occur are veins, beds, and fragmentary deposits.

Fragmentary deposits are associated with many of the superficial beds of sand and gravel which occur in the valleys of mineral districts, consisting of the detritus of the neighbouring metalliferous mountains, which has been washed down from them at remote geological epochs. These mineral accumulations are not equally and indiscriminately mixed up with the sands and alluvial matter, but the excess of their specific gravity has occasioned their separation into distinct layers, commonly found towards the bottom of the alluvium. It is well known that minute grains of gold, or gold dust, are interspersed in this manner with the sands of the Brazils; and it is estimated that the gold derived from the washings in the chief province of the Brazilian gold district produces about 2800 pounds of fine metal—worth nearly one million of pounds sterling. It is less generally known that there exist three small gold washing stations in the county of Wicklow in Ireland. Little streams running from the mountains are slightly diverted into reservoirs, where the particles they deposit undergo divers washings in wooden bowls, and among the purified remains are discovered rare grains of gold. On the occasion at which we visited these washing places, the produce of the morning's labours at one of them was about six shillings worth of gold.

Tin ore is also found in Cornwall, in deposits generally considered alluvial, mixed with the debris of different rocks, and often covered with an alluvial bed. Repeated washings, by means of running water, being the chief process by which such ore is separated, the name of *stream work* is commonly applied to this method of obtaining it. The water being excluded from one of the branches of Falmouth harbour, a bed of rounded masses of tin ore, from two to ten feet thick, was found fifty feet below a bed of alluvium—£50,000 was made by this discovery.

Beds.—By mineral beds are meant the metalliferous strata which sometimes alternate with earthy strata. Mineral beds are for the most part horizontal, or slightly inclined, and occur in what are geologically termed primitive and secondary countries, of various elevations. The ores of copper, iron, and lead, occasionally occur together in beds in primitive mountains, and sometimes small quantities of gold and silver are mixed with them. Cobalt and certain ores of mercury also occur in beds. Almost all the ores of metals in the great mining district of Sweden are found in beds in primitive mountains. Lead, zinc, and iron ores, occur abundantly in beds in secondary mountains.

In England, the principal metal whose deposits assume the form of beds is iron, in the state called ironstone. This alternates in thin beds with beds of coal, and frequently with beds of limestone. Thus the metal, and the means of heating and fluxing it, are most fortunately combined in one and the same locality. One of the most important mineral productions of Scotland is the thin bed of ironstone called *black-band*, which is not known to exist beyond a space of from eight to ten square miles in the mineral district around Airdrie, near Glasgow. The true black-band is found from fifteen to sixteen fathoms below the splint coal, and is only from fourteen to eighteen inches in thickness. The "output" from Rochsolloch is 4500 tons per month; and the an

nual it come to the proprietor amounts to about £12,600 per annum, on a property which, if let for tillage, would yield only a few hundreds a year. Some of the ironstone beds, as in south Staffordshire, consist of pulverized matter, with rounded boulders of ironstone distributed through it; and some few contain flattened spheroids, or roundish masses. The beds of ironstone being commonly situated at a much less depth, and being more readily arrived at than veins of metals in general, the pits are both shallow and simple, and therefore require no particular notice. In this country they are worked principally in south Staffordshire, Shropshire, south Wales, and the eastern and western mineral fields of Scotland.

Veins are the principal forms in which metallic ores are distributed throughout the globe. A description of the veins of Cornwall will almost suffice for those of every other country, as the differences are of a comparatively unimportant character to the general observer. A vein may be said to resemble a deep cleft or crack in a clayey field, which has been subjected to the exhaling influences of the hot sun for some time. This cleft, whatever may be its depth, must of course have a direction under ground, either slanting or straight; and if we suppose it filled with metallic ore, we form the idea of a vein, or, as it is provincially termed in Cornwall, a *lode*; if we suppose the cleft filled with any other stony substance, we can imagine what is called a non-metalliferous vein, of which there are many, sometimes pursuing their own exclusive courses, and at others intersecting the metalliferous veins.

The direction of the lodes is by no means accidental, but nearly determinate. They usually run east and west, and dip or underlie either towards the north or south; while the non-metalliferous veins, which run north and south, dip either towards the east or west. The cases in which metalliferous veins assume a north and south direction are few, and chiefly foreign. It frequently happens that the metalliferous lodes, as we have said, cross each other; and, as a leading fact, the intersection of two lodes at a small angle is productive of good ore. Should, however, a copper lode pass through a tin lode, the copper lode invariably divides the tin lode, and generally heaves it out of its course, to the frequent perplexity and loss of the miner. All mining experience of a general character is, however, sometimes set at defiance; for, in the small space of one little hill, instances may be found in which veins of almost every description dip or underlie in almost every possible direction, traversing each other in such a manner as completely to baffle the miners; but it is an ascertained fact, that there are seldom or never, *in the same district*, two *series* of metalliferous veins running at right angles to each other. As a tolerable average, we may assume the direction of the Cornish lodes to be about four degrees south of true west, and their dip or inclination to average sixty or seventy degrees from the horizon. Taken on the whole, the lodes appear tolerably straight both in direction and inclination, but when examined in detail, they exhibit almost continual curvatures and irregularities in both respects, although these flexures would seem to be projected on certain lines which manifest considerable constancy.

The length of no one lode has yet been satisfactorily traced. Some of them, indeed, have been followed for two or three, or even four or five miles; but no instance has occurred in which a vein has been known to stop nor has the miner ever yet seen the bottom of one, although there are several mines in Cornwall upwards of 1000 feet in depth from the surface, and two or three about 1300 feet deep. The lodes differ exceedingly in respect of width, in which, indeed, they vary from a mere line to forty or fifty feet. On the average, they may be assumed to be three feet and a half wide. Lodes of from one to three feet in width are usually less intermixed with foreign and troublesome substances than those which are wider. A vein of tin in a mine called Whealan Coates was only three inches wide, and yet proved so rich as to be worth working. Some of the veins containing copper in Herland mine did not exceed six inches in width; and after continuing this thickness for a few fathoms, eventually passed away east and west in mere strings; but they yielded copper of a very rich character. In the next hill there was also a very productive copper vein of from twelve to twenty-four feet in width.

The compositions of the lodes or veins are as variable as the nature of the rocks through which they pass. By far the greatest portion of them, however, is earthy matter, of the nature of the contiguous rock, but also containing large intermixtures of quartz. These ingredients occasionally occur in separate veins, but for the most part they are mingled without regularity or order, and throughout them are dispersed the metallic ores. Sometimes they are aggregated very thickly, and very generally occur in large irregular lumps or patches called *bunches*, connected with each other by small veins of ore. At other times the ore is very sparingly sprinkled through the whole of the earthy matter of the vein, and in some rare instances it forms the larger part of its contents. The sides of metalliferous veins are generally very determinate, being covered by a hard, dark-coloured crust, called by the miner the *walls* of the vein.

We have noticed that there is a second series of veins, called non-metalliferous veins, which run north and south; that is, nearly at right angles to the metalliferous lodes. When these veins are chiefly composed of quartz, they are locally denominated *cross-courses*, and when consisting mostly of clay, they are named "flucans." Their general direction, when accurately traced, is about south-east and north-west. Their dimensions are variable, being perhaps on an average about two feet; their dip, too, fluctuates, but, as a general rule, it is greater from the horizon than that of the lodes. The clay with which the flucans are filled invariably partakes of the same character as the contiguous rock. Tin and copper ores are occasionally found in small quantities in the cross-veins, and in two or three instances silver and its ores have occurred in them to some amount. The chief metallic produce, however, of this class of veins, is lead ore; but this they seldom yield in the neighbourhood of lodes which have been productive of other metals. Indeed it is, as we have said above, a general law in Cornwall, that two series of productive metalliferous veins, at right angles to each other, are very seldom or never found in the same district. Both the lodes and the cross-veins ramify and divide; and whilst the part which in one place is large will sometimes, within a short distance, dwindle and die away, the portion which is small, where the other is rich, will often, within a small space, enlarge and become productive.

As these two series of veins, the lodes and the cross-veins, run at right angles to each other, they of course frequently meet and intersect. In a few instances the lodes traverse the cross-veins, but in far the greater number of cases the cross-veins cut through the lodes. Occasionally, the cross-vein simply intersects the lode, but more generally displacements, provincially termed *heaves*, attend their contact. These heaves, although usually only amounting to displacements of a few feet or fathoms (a fathom being equal to six feet), yet in some cases turn off 20, 30, or 40 fathoms, and in one instance to the extent of 72 fathoms. If, for example, a cross-vein, in its north or south course, meets with a lode containing copper or tin, the last seems to have been split, as it were, into numerous little branches by the first, which generally pursues its uninterrupted course straight forwards. Another effect, too, of a much more extraordinary kind, is produced by this intrusive cross-vein. In

searching for the tin or copper lode on the other side of this north and south vein, a lengthened period frequently elapses before the fugitive can be discovered. Notwithstanding the experience of the miners, forty years have sometimes passed over, before the search, though carried on with vigour and great expense and labour, has proved successful. It is by no means a simple task for the mining engineer to lay down a law for the recovery of the lode. Instances have been known in which it has been again found 120 or even 450 feet north or south of its original course. The cross-vein will not perhaps generally intersect the lode exactly at right angles, but its inclination to the course of the lode will usually be such as to produce at the intersection an obtuse angle at one side of the lode and an acute at the other side; and it is thought, by the most experienced observers, as well in Saxony as in Cornwall, that the second portion of the lode will more frequently be discovered on the side of the obtuse angle, formed by it with the cross course, than on the side of the acute angle. In other words, on whichever portion of the lode we approach the cross-vein, the other portion will be found towards the same hand, namely, the right hand. There are other kinds of interruption to which metalliferous veins are subject, though far less extensive in their agency than are cross-veins. These are denominated *slides*, and generally consist of clay or argillaceous matter. Their direction is nearly parallel to that of the contiguous lodes, but their dip or *underlie* being either greater than, or opposed to, that of the latter, they intersect them either in a horizontal or more or less inclined direction. Slides are common in Cornwall, and occur also in Mexico and other mining countries.

It is a well known but remarkable fact, that some of the metallic ores lie much nearer to the surface than others. Gold, in the small veins of it which are sparingly distributed through some of the rocks in Brazil and elsewhere, is worked by open cuttings from the surface. Silver is found in some foreign mines at a depth of from two to three hundred feet, while the silver mines of Mexico are of a much more considerable depth. Tin is also found at shallow depth, of which the great lode of the Charleston mines in Cornwall furnish a good example. Lead is usually met with at a very trifling depth, and slightly spotted veins of it are sometimes to be observed in the sides of brooks, and in the rocky channels of rivers. Copper, on the contrary, generally lies deep, and the enormous deposits of this metal found in Cornwall are generally situated two or three hundred feet below the surface. Where tin and copper are found together in the same vein, the tin commonly occupies the upper part, and disappears at the depth at which the copper is discovered. Sometimes, however, the ores of both metals occupy the vein together to a great depth, as at the Poldice mine near Redruth. On referring to the *known* depths to which different metals extend, it will be found that those which commonly lie near the surface, as lead, zinc, gold, and occasionally tin, do not generally penetrate to any great depth; while those which lie deeper, as copper and silver, are worked in the bottoms of our deepest mines. This coincidence may be the result of a natural law, or it may be apparent, and consequent only upon the limit of our experience and knowledge.

Cavities or open spaces frequently occur in metalliferous veins, which may reasonably be conjectured to be such portions of the original fissures as have not, owing to local causes, been filled up in the same manner as the remainder. These cavities are very irregular both in size and form, but yet, in their size, appear to bear some relation to that of the vein in which they are situated. They are probably the secret laboratories in which nature has perfected some of the most beautiful productions of the mineral kingdom. The whole of their interior is generally lined with various substances, often crystallized in beautiful groups of dazzling brilliance. It has been elegantly though fancifully observed, that minerals are the flowers of rocks; and might we not, in pursuance of the same idea, call these cavities the gardens of the mineral kingdom? It is from these open spaces that most of the mineral specimens are collected for the cabinets of the curious and the wealthy.

Situation of Metalliferous Deposits.

Metalliferous veins, and, indeed, metalliferous deposits generally, are found traversing a great variety of rocks stratified and unstratified, and appear to belong equally to formations of igneous and sedimentary origin. Although not confined to that class, they may be said to exist most abundantly in the older and more crystalline rocks, and usually in those bordering upon mountain chains. They are mostly found in those situations where a junction occurs between two contiguous rocks; where different rocks are interstratified, or where they are broken or dislocated by faults and cross-courses. Thus, in Great Britain, the tin and copper mines of Cornwall and Devon are situated in granite and different varieties of slate belonging chiefly to the primary class, and are most productive near the junction of these strata.* Many of the metalliferous deposits of Wales and the north of England, producing both lead and copper, are also contained in slaty rocks, which are generally referred to the grauwacke series. Our great deposits of lead, however, are contained in the lower rocks of the carboniferous series, which is the case in the lead mines of North Wales, of Derbyshire, Yorkshire, and the great lead mine district of the north of England. Above the carboniferous series no metalliferous deposits of any value occur in this country. The metalliferous deposits of Scotland occur in primary and transition rocks; and those of Ireland occur mostly in granite, mica slate, and clay slate, although extending also into the carboniferous series.

The mining district of the west of England may be considered to commence at Dartmoor, and terminate at the Land's End. The surface is gently undulating, the loftiest hills rarely exceeding 1000 feet above the level of the sea, whilst the greater number of them range from 500 to 700, and the plains at their bases are usually from 100 to 200 feet above high water. The highest peaks are for the most part granite, whilst the lower hills and most of the plains consist of various descriptions of slate. The granite may be considered to present six patches of large dimensions, as Dartmoor, &c.; and three eminences of Minor dimensions, in which we include St. Michael's Mount. All the other parts of Cornwall (except the Lizard district, which is composed of serpentine) may be said to consist of slate of various kinds. The granite is commonly coarse-grained, and of porphyretic structure; the slates, in general, partake of the character of felspar, and are of a compact structure when near the granite, and otherwise when at greater distances. Both the granitic tracts and the slates in their vicinity are intersected by veins or dykes of a porphyretic felspar rock, provincially termed *elvan*. These dykes or veins have, in a few cases, been traced for miles, and they pass uninterruptedly through both granite and slate; their usual direction is about 20 degrees south of west, and they are generally several fathoms in width.

The sulphuret of zinc (blende, or the *black jack* of the Cornish miners) occurs very abundantly in the mineral veins of Cornwall, being, however, more frequently associated with the ores of copper than those of tin. The conditions favourable to the production of tin and copper lodes have been favourable also to the appearance of the sulphuret of zinc or blende, which, however, frequently occurs in the continuation of tin or copper lodes, far beyond those localities where the tin or copper can be profitably raised. Viewed on a large scale, blende is one of the most widely distributed ores in Cornwall

while the carbonate of zinc, or calamine, is a very rare one in this district. The sulphuret of zinc is not, however, an ore much worth raising at present for profit.

Cobalt is a rare ore in this district, and does not seem to be accompanied by any marked geological conditions, as far as regards its occurrence in any particular class or kind of rock. The same may be said of bismuth; and nickel is a very uncommon metal too, and has only been found in any workable quantity near St. Austell.

The Silver of Devon and Cornwall has for the most part been obtained from those ores of lead (argentiferous galena) in which its presence has been detected. Silver ores-proper have, however, been obtained in several mines, in lodes or cross-courses in the grauwacke. Such ores have consisted of native or pure silver, and silver in various states of chemical combination with sulphur, arsenic, &c.

MINING OPERATIONS.

Preliminary Proceedings.

When the mineral contents of a spot are entirely unknown, the operations instituted for the discovery of lodes must be founded upon the general presumptions furnished by geological science in connection with mining experience, as mineral deposits usually present no precise traces of their existence at the surface. The first objects of pursuit, in such circumstances, to the Cornish miner, are what he denominates *shode* or *shoad-stones*. These stones are partially rounded and apparently water-worn, and are found on the surface or at very small depths below it. Their mineralogical characters nearly resemble those of the contents of the lodes in the vicinity, of which they are presumed to be portions removed by diluvial action. As, however, the shoad-stones contain tin ore, a careful search for them has been constantly kept up, and their increasing scarcity will probably render this mode of discovery impracticable. When they were uncollected, the examiner might commence marking their presence at any given spot, and then trace them to where they appeared in the greatest abundance, which situation was probably the nearest position of the lode itself. Upon arriving at this place, he would cut trenches, or dig little shafts, to ascertain how far his suspicions were well founded.

Should the precise situation of the vein, whose existence has been ascertained by tracing the shoad-stones, or by any other mode be unobservable, it may be ascertained by opening trenches in the alluvial soil, deep enough to expose the solid rock; their direction being at right angles to that in which analogy, or the position of other veins in the neighbourhood, would render it probable that those in question should lie. Supposing the direction of the vein, and its dip or *underlie*, to be ascertained either by the shoding, and by sinking a few shallow pits upon it, or by previous experience in some adjoining mine, the further exploration may be continued either by sinking upon its course from the surface, or by forming a horizontal passage to intersect it, which is commenced from a valley, or the lowest point in the neighbourhood, and is called an *adit*. This last plan, however, being both slow and costly, is seldom adopted, unless there is a tolerable certainty of its results being highly favourable. The mode of proceeding is in a great degree dependent upon the means and prospects of the undertakers, and upon the commercial arrangements and pecuniary resources of the mining company.

The lode and its directions being discovered by the means above detailed, the next point is to determine the site of the shaft upon some convenient spot of ground. If the shaft is to be sunk in an inclined direction upon the course of the vein, which is frequently desirable, the site is not so circumscribed as when it is to be sunk perpendicularly upon it. In the latter case, the shaft is necessarily commenced upon that side towards which the vein inclines or underlies, and at such a distance from its appearance at the surface (or outcrop) as to cut the vein at a premeditated depth, which may be from ten to thirty fathoms, in accordance with the means of the adventurers, and with their knowledge of the quality and conditions of the lode, the upper portions of which are seldom productive.

The vein being cut, the shaft may be continued either perpendicularly, and through the vein, or obliquely, and in the course of the vein. Should the lode be expected to turn out excellent and profitable, the former plan will be adopted, as it will be ultimately the most advantageous, and will enable a large mine to be carried out. But if the lode is questionable, and the means of the miner the same, the latter course will be proceeded upon, as it is far the cheaper one as well as the speedier.

In driving the second and the succeeding levels, it is clear that the further we proceed from the shaft in each direction, the greater will be the closeness of the air, and the more essential will ventilation become. It is then that small shafts, called *winzes*, are sunk. Thus a communication is opened between all the levels, each one of them possessing winzes opening upwards from itself to the next superior level, and also others opening downwards from itself to the next inferior level, by which means a double communication with the atmosphere and every level is effected, and an ascending and descending current of air produced.

But in addition to their utility for the purposes of ventilation, winzes are equally necessary to the working out of the ore from the lode, and, indeed, are advantageous in trying its value. Unless little or no ore has been discovered upon the opening of the first level, winzes will be commenced at a very early stage of the mining operations; and when the ore is found to be tolerably good, they will be opened at intervals of twenty or thirty fathoms in each level. Their position will be especially determined, so as to prove the richest and most promising parts of the vein, and to avoid those hard and unproductive portions which may be supposed to be unworthy of exploration. As far, too, as it can be effected in accordance with these views, the position of the winzes will be such as that each of them may come about mid-way between the nearest two above it. The system of works, therefore, by which the lode is explored and the mine established, is not unlike a system of masonry, if the horizontal joints of the stone work be supposed to represent the levels, and the vertical joints the winzes. When, by these arrangements, the lode has become divided into a number of solid rectangular masses, as just described, the mine will have been brought into an effective state of working, and parties of men will be set to raise ores from all the most productive points. Where the vein is not very hard and stubborn, the ore may be broken down with the pick only, but it is generally necessary to blast the rock with gunpowder, by which mode large quantities of ore are detached at every "shot." In working the ores either by the pick or the blast, the men usually work upwards, from the upper part of one level towards the bottom of the one above it; and the excavations are so arranged that the ore may readily fall down to the level below them, whence it is carried in train wagons to the nearest point of the shaft, and is thence raised to the surface.

Tools—Excavating Processes.

The principal tools used by the miners are *picks* for working the rocks, and *borers* and *mallets* for making the holes for blasting. These are often sent up and down in the bucket in which the ore or rubbish is drawn to the surface, but the miner very commonly carries with him from ten to twenty pounds' weight of tools. A constant necessity exists for hardening and sharpening these tools

which is done at a smith's shop above ground, though it would seem more advantageous to establish a forge under ground, as has been done in one Cornish mine only, but with considerable economy; such subterranean forges are more common in Ireland, two having been in use for several years in a mine in the county of Cork.

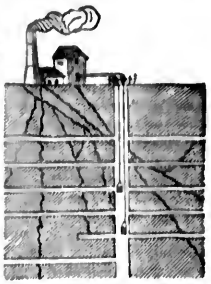
The great body of the miners under ground are employed in excavating the rock, whether for the sinking of shafts, the driving of levels, or the removal of the pieces of ore from the lode. These operations require, in most of the mines, the almost constant occupation of the explosive force of gunpowder. A great part of the work, therefore, consists in "beating the borer;" that is, driving an iron cylinder, which terminates in a wedge-aped point, by blows with a heavy hammer (mallet), hilst it is turned by another hand. The necessity or advantage of making the hole in a particular direction, often constrains the miner to assume every variety of posture in carrying on his work. When the rock has been bored to a sufficient depth, the charge is introduced, and rammed down with a *tamping-iron*, a particular clay being used as wadding, and a certain length of safety-fuse keeping up the communication with the powder; fire is applied to this, and the miner retires till the explosion has taken place. It is [illegible] that the safety-fuse misses fire, but such accidents [illegible] then arise from the impatience of the miner [illegible] to an imprudent examination of the fuse when [illegible] slowly than usual, which may occur from [illegible] burning down. Safety-fuse is a kind of cord, into the texture of which gunpowder is introduced, and which is afterwards covered with a coating of a bituminous nature—the process being secured by patent. Previously to its employment, frequent accidents occurred to the eyes of the blasters, but such calamities are now rare in comparison. The form of the tamping-wedge, and the metal of which it is made, are of great importance, more especially the latter, as it is obvious that any metal, the friction of which shall produce sparks, is excessively dangerous. In the great lead mines of Northumberland, we lately found that the use of copper prickers and beaters has been adopted to some extent in blasting, but certainly not to so great an extent as necessary. Wherever copper tools have been employed, no accidents have occurred by sparks flying from the *needle*.

The pick is a very useful tool, and one very much employed by the miner both in working in the rock and in breaking down ore, where the ground is not so hard as to require blasting. It resembles a common pick-axe, but is smaller and more convenient, the iron head being sharp and pointed at one end, and very short and hammer-shaped at the other, a form which peculiarly adapts it for under-ground employments. The wedge, or *gad*, made of wrought iron, and often with curved sides, is sometimes used, together with the pick. The borer, or *jumper*, is an iron rod or circular bar, commonly about two feet long, and steeled and formed into a flat sharp edge at the end, which is driven into the rock, as before said, while a person turns it round, so as to expose the cutting edge to fresh surfaces of rock; the pulverized matter is drawn out from time to time by a *scraper*, and the charge is introduced when the hole is fully perforated.

Working.

A mine in a complete working condition exhibits a most extensive series of operations, in connection with the shaft, the lifting and descending by ropes and pulleys, the drainage, the excavation, the ventilation, &c. At the bottom of the shaft, and in the various stages in which the excavations are going on by the miners, in their attempts to follow the lodes, the operations are on a scale which seldom fails to surprise the stranger.

It is judged most expedient in mines, more especially in those worked upon a large scale, and for a continuance, not to take out all the ore which could be immediately got at, but to leave it here and there, to be worked as the general prospects of the mine may require. It is, in fact, in such establishments, desirable to regulate the quantity of ore raised to a uniform rate, and therefore the processes of excavation or *opening ground* will generally either keep pace with or even exceed the amount of exhaustion. Thus a portion of the ore laid open may always be held as a reserve fund to regulate the returns of the mine during periods of temporary depression, or when only poor and unproductive ground may be bared by the works of discovery. The ores thus left in [illegible]s places are often termed the *eyes* of the mine; [illegible] it is judged necessary, from the depressions [illegible] from the abandonment of that portion of [illegible] to remove them, the process is termed *picking at the eyes of the mine*. Where there are workings upon different lodes in the same mine, these are often connected with each other by means of cross-cuts, so that the ore may be brought to the shafts not only in the course of the lodes, but at right angles to their courses. Thus, in the Fowey Consols mine, one shaft cuts perpendicularly through five lodes, and by means of a cross-cut at the sixty-fathom level, it communicates with all the lodes, namely, thirteen, found at that level, in this mine.



By these processes, the workings of the mines have become so extended as gradually to lose their original simplicity. When the levels have been extended to a considerable distance from the shaft, the ventilation will again be found defective, notwithstanding the frequent communications by winzes; for the greater the distance the current of air is carried, the more feeble it plainly becomes. This deficiency is still further augmented by the increasing number of the men now employed in the works, the presence of a great number of candles, and the smoke resulting from the larger employment of gunpowder in the process of blasting. The expense, too, of the transport of ore and masses of rubbish to the shaft, is, on account of its greater distance, much more considerable. To add to these, we have the greater expenditure necessary for the drainage of the water from the mine, and for the support of its passages and roofs by timber. In order to obtain a clearer idea of these several matters, we shall consider them separately, and speak first of the shafts.

In addition to the circumstances just named, the irregular distribution of the metalliferous portions of the lode will cause inequality in the workings, and will, with the other matters, render the sinking of one or more shafts indispensable. Again, when the depth becomes very considerable, many of the first shafts are rendered in a great measure useless, either from their being inclined, and thus inconveniently circumstanced for machinery, or from having cut the lode at a shallow depth, and thus requiring cross-cuts progressively, longer in proportion to the increase of the depth and inclination or distance of the lode from the shaft. Hence, in very deep mines, a double line of shafts will often be found to range along the course of the principal veins; and sometimes even three shafts will be found placed opposite each other, and intersecting the same lode successively at increased depths. In such cases as this, while the most recent shafts are used for drainage and the extraction of the ore and masses of rock, the older and more shallow shafts are

often fitted up as foot-ways, and serve for the partial ascent and descent of the miners. In some of the large Cornish mines, it is customary to sink two new shafts within a few fathoms of each other, one being of large dimensions, and intended as a drainage or *engine-shaft*, and the other being smaller and adapted to the drawing only of ore and *stuff*. Both shafts are united at convenient distances by cross-cuts.

When circumstances permit, mines are entered by an adit in a hill-side, instead of by shafts. Of this character are the openings into the lead mines of the north of England, of Derbyshire, and of North Wales, all of which are situated in the carboniferous limestone, and the grits and shales resting upon it. In some valley, where the edges of the strata are exposed to view, a spot is selected from which it may be practicable to drive a level upon the vein itself, and in one of the beds known to be favourable to its productiveness. The progress of such a level explores the vein most efficiently, and opens a convenient passage for the extraction of the ore.

Drainage.

The influx of water from the rocky sides and bottom of mines, is a general and constant cause of annoyance, and the drainage is effected frequently at an enormous expense. So great is the cost of drainage in some instances, that, if the mines be of only a moderate value, they are altogether abandoned, and become choked with water. The process of drainage is usually effected by pumping, the apparatus being moved by either water or steam-power.

Pumps.—In the early periods of mining industry, wooden pumps alone were employed; but they have been for many years entirely superseded by iron pumps, which admit of the *lifts*, or columns, being carried to a great height without the danger of leaking or bursting. While the water-wheel, or steam-engine, is in course of erection, pumps are fixed in the shafts, of ten or twelve inches in diameter, for a moderate influx, and of proportionably larger size for a considerable body of water. None of the pumps used in mines act at all by atmospheric pressure, as in the case of the common household pumps; for they are invariably arranged in lifts of considerable height, such as from twenty to thirty fathoms, and the water itself is discharged into cisterns placed at the foot of each lift, whence it is raised again by mechanical means. The whole column of pumps in a shaft is usually worked by a single pump-rod, which traverses the middle of it, and communicates with each column by a rod attached to its side. To impart a reciprocating motion to the main pump-rod, a crank fixed on the axle of the water-wheel is attached to one end of a horizontal rod, the other end of which is connected with an apparatus termed a *bob*, consisting of an upright post movable on a centre, and firmly braced to a horizontal piece framed into it at bottom, the further end of which piece is connected with the pump-rod. Thus the rotatory motion of the water-wheel is converted into a uniform reciprocating motion, when communicated to the pump-rod.

Steam-Engines.—In our coal mines, where the fuel is of scarcely more than nominal value, the steam-engine is the only power ever employed for drainage, and in all deep and extensive works for extraction also. Hence, at the mouth of a coal-pit, almost any sort of a steam-engine or fire-engine has always been considered better than horse-power, because the former consumes the produce, and often the refuse, of the pit, and is very valuable for volatilizing the mass of small coals, which would otherwise lumber the mouth of the pit, and which, until very lately, were wantonly consumed in large burning heaps. The worst sort of engine would almost raise more coal in twelve minutes than it would consume in twelve hours.

Of course the steam-engines employed for drainage are erected close to the shaft in which the pumps are fixed, and which is called the *engine-shaft*. Over the centre of this opening one end of the beam hangs, and is connected with the pump-rod, which is elevated at each stroke of the engine, afterwards sinking by its own weight. This rod being counterbalanced by a *balance-bob*, as above described, the whole power of the engine is exerted in raising the column of water in the pumps. It has generally a cylinder of not less than forty inches in diameter, and of various diameters between that and eighty or ninety inches, according to the work to be done; ninety inches is, however, the largest cylinder ever constructed, and belongs to an engine estimated to be of 300 horse-power. The engine is enclosed in a large substantial *engine-house*, two or three stories high, so constructed as to afford convenient access to every part of the machine. The centre of the beam is supposed to be the front wall of the house, and a low building attached contains the boilers.

The present perfection to which the art of mining has attained, and the vast produce now afforded by our mines, are so intimately connected with the application of the steam-engine to mining purposes, that a brief notice of the improvements connected with the machine, and the economy of fuel arrived at, is indispensable. The chief peculiarities of the Cornish engines consist, 1st, in employing high-pressure steam (of forty or fifty pounds' pressure to the square inch of surface) *expansively*, by cutting off the communication with the boiler at one-fourth or one-fifth of the length of the stroke of the piston; 2d, in allowing a short interval between each stroke for the perfect condensation of the steam; 3d, in adopting every method whereby the radiation and loss of the heat from the boiler and the cylinder can be prevented. If the last particular can be accomplished, it is evident that in the same proportion a saving of fuel may be effected. The engine of Watt was first used as a substitute for that of Newcomen in draining mines, and its chief recommendation to mining companies was the alleged economy of fuel, of which Watt and his partner were so confident, and which they desired to make so prominent an advantage, that they only asked a profit in proportion to the saving which their engine effected, when compared with a common engine burning the same kind of coals; demanding that one-third of the saving should be paid them annually, or that the whole annual payments should be redeemed by paying ten years purchase-money at once, which in one instance we find, for three engines, exceeded £7,200 per annum.

The efficiency of a steam-engine for mining purposes is estimated by a standard which is termed *duty*, and which conveniently and accurately defines the work performed, with reference to the consumption of a given quantity of coal. By the duty of an engine is meant the number of pounds (always expressed in millions) of water which have been raised through the height of one foot by the consumption of a bushel of coal; the data for this calculation being the quantity of water discharged from the pumps in a given time, and the quantity of coal consumed by the engine in the same time. This was the mode of estimation first practised by Watt, who thus calculated the saving of fuel effected by his engine. In an old engine at Long Benton colliery, near Newcastle, out of sixty-three cubic feet of steam thirty-three were wasted, and the remainder, thirty feet, alone performed useful work; it was therefore clear that there was full scope for improvement.

In 1813, a system for the registration of the duty and other peculiarities of the performances of the engines working in Cornwall was organized, and the results, ascertained monthly, have since been published in the shape of monthly reports. In considering that some of the most powerful engines in Cornwall consume from three to four thousand bushels of coal per month, that

some mines employ several such engines, and that the mere expense of drainage is not unfrequently £12,000 or £13,000 per annum, the immense importance of the improvements, the results of which are just noticed, will be at once understood. The Messrs. Lean estimate the saving to the country effected since 1813, upon the whole number of engines reported, to amount to a hundred thousand tons of coal in the year, equivalent in value to £80,000 sterling per annum. The importance of the steam-engine to mines may be gathered from the instance of the Consolidated and United Copper Mines, where there are eight large steam-engines used in pumping, having cylinders of from 65 to 90 inches; one engine of 30-inch cylinder, and eight engines of about 20-inch cylinders, for drawing ore and other matter from the mines.

These great results have been arrived at by the adoption of the three methods above enumerated in brief, and by strict attention to the works connected with the pumps, in which a principal improvement is the use of one connected main-rod, with offsets to work each separate lift of pumps, instead of the old plan of a separate rod to each lift; to these must be added the adoption of the plunger-pole instead of bucket-pumps. These improvements have not been so much sudden discoveries as the effects of long and laborious investigation of the action of steam-engines, and a statement of the successive steps of improvement would in fact be a history of the improvements of the steam-engine.

Some idea of the quantity of water discharged by the engines in Cornwall may be gained by adducing an instance. In 1837, in the month of January, 62 engines discharged, per minute, 17,143 gallons; in June, 60 engines discharged 15,152 gallons per minute; in December, 56 engines discharged 12,891 gallons per minute. The greatest quantity of water is generally found in the mines after the winter months, which is produced by percolation from the top, or from surface water; the waters that rise from beneath being more constant in their supply.

The ventilation of metal mines is another most important matter of arrangement; but as it resembles that of coal mines, we include both under that head.

Support of Excavations.

A very considerable item in the expenses and difficulties of a mining establishment is that of the support of the excavations made in the works. The extent to which such support is necessary will naturally depend very much on the nature of the rock passed through, which may be either so hard and compact as to stand securely of itself, or so soft and friable as to crumble and crush together, unless the workings are effectually propped up.

As noticed above, masses of the rock, containing little or no productive ore, are generally left, which serve the purpose of pillars, and adequately keep up the roof; but where the whole is extracted, recourse must be had to *timbering* or *walling;* that is, to woodwork or brickwork, of which the former is in many respects the most suitable. In the sinking of the shaft, four pieces of timber of the requisite strength are framed into each other, and fixed within the shaft at intervals of about four feet apart, the intervening ground being supported by driving thin boards between each set of timbers and the rock. Passages and levels are usually supported by three pieces of timber, placed in the form of a doorway, rather narrower above than below, and framed together at the top in the strongest manner. These doorways are in figure something like those frequent in Egyptian sepulchral architecture. A succession of them, with intermediate supports and braces, will fully keep up the passages. The large open excavations, or *gunnies*, from which the ore has already been taken, are kept open by strong pieces of timber placed across them, and pressing against the two walls of the vein, which they thus prevent from closing together, as might be the case where the vein is much inclined, and consequently a great pressure existing in the unsupported inclined well.

The spaces formed by excavation are very useful for the reception of the *deads* and rubbish continually accumulating under ground, when the workings are carried on in the rock or in unproductive portions of the vein. It would be useless and expensive, except as far as is indispensable, to raise such rubbish to the surface, and therefore a *stull* is formed by placing strong timbers in the backs of the levels, upon which boards are laid, so as to make a close covering on which the *deads* and *attle*, or rubbish, are then thrown, till the space above has been entirely filled up. This mass becomes sufficiently solid to support the walls or sides of the vein in an effectual manner, and is a very cheap and convenient mode of fortification. Attention must be paid to the wood employed for timbering, as it is desirable that it should be of the strongest kind. Resinous wood, like the pine, lasts a much shorter time than the oak, the beach, and the cherry, although larch has been used with advantage. Oak has been known to last upwards of forty years; while the resinous woods commonly decay in ten years and upwards. It is also necessary that the wood should retain its whole useful force of resistance, and therefore only those pieces are squared which absolutely require it. The spars of the frames in the shafts and galleries are deprived merely of their bark, which, by retaining moisture, would accelerate the decomposition of the wood.

In many mines it is found more advantageous to support the excavations by brick or stone walling and building, constructed either with or without mortar. Such erections are indeed more costly than wooden ones, but they last very much longer, and need far fewer repairs. Sometimes the two sides of a gallery are lined with upright walls, and its roof supported by a vault or arch.

Dressing Ores.

On bringing ores to the surface, the first thing done is to separate the valuable material from the refuse, and then subject it to the smelting process.

With respect to copper ores, the dressing commences by riddling the pieces, after which they are broken or crushed by mechanism contrived for the purpose. A further separation of the more valuable portions of the pulverized ore from that which is less so, is effected by an operation termed *jigging*, which consists in keeping the whole of the mineral particles suspended in water for a time sufficient to allow of the subsidence of the more ponderous portion. This is accomplished by the agitation of the water in a sieve, in which the broken ore is placed, the more pulverized part passing through the interstices of the sieve, and the heavier and larger pieces occupying the bottom of it, after which separation the light and worthless stone may be removed from the top with a piece of wood. The agitation of the water was formerly entirely, and is at present extensively, effected by hand labour, in which boys were commonly employed. Machinery has, however, in a large proportion of the more considerable works, been applied to this process in two different arrangements, by one of which a succession of sieves are kept in motion under water by means of a connection with a water-wheel or steam-engine; by the other, the water itself, in which a number of sieves are immersed, is kept in agitation by the motion of a body in the centre.

An idea of the labour attendant upon the dressing of copper ores, and of the necessity for it, may be formed from the fact, that the average quantity of copper contained in the ore is rather less than 9 parts in 100. In these processes, and indeed in all the operations for

dressing, many of the minutest particles are carried away whenever a stream of water is employed by the flow of the liquid. A waste of this kind in an extensive mine would be considerable, and it is therefore arranged that all such water shall pass into successive reservoirs termed *slime-pits*, in which the metallic particles fall to the bottom, and are from time to time collected and subjected to such treatment as to obtain them in a tolerably fine state. The great principle upon which all the varied apparatus and processes which are employed in different mines in all parts of the world depends, is the difference in specific gravity between earthy and metallic matter, the one being generally double that of the other. The dressing-floors of a mine are always arranged as near the mouths of the principal shafts as possible, the ore being conveyed to them by a small railway. The floor itself is paved, and there are one or two side-ranges of sheds for the workers, and buildings containing the apparatus employed, an adequate supply of water being provided by an artificial channel or *leat*. Of course, from very rich veins ore can be obtained which scarcely requires any other dressing than one reduction by hammer, and it is in proportion to the poorness of the vein that the operations of this nature extend.

The dressing of lead ores is exhibited on the largest scale in the lead mines of Northumberland and the neighbouring counties. The processes differ in many respects from those just described. *Grating* is the first operation performed with the contents of the vein. A large grate receives the ore, on to which a feeder of water runs, an adult being present to direct the operations of the young boys by whom this business is accomplished. The smallest of the pieces run through the grate into a *trunking* box, which is placed underneath for their reception, and out of which they are subsequently thrown on one side to be *hotched*. Hotching is the agitation, by a boy, of the ore in a large square brake-sieve, to which a long lever or arm is attached. The brake-sieve being balanced or fixed at one point, the boy, by means of this handle, shakes the contents so as to separate the ore. The small pieces of ore thus hotched into a tub below, are wheeled from this to a *running buddle*, which is a small space of excavated ground paved with a stone floor. Water being caused to flow gently over this, the ore is placed in it, and stirred by a *colrake*, until a considerable purification takes place, and the pure ore is ready for delivery to the smelter. This final process is termed *buddling smiddum*, and does not prevent the passing away in the water of fine particles of lead. The water is therefore directed into *sludge* and *slime-pits*, and several further operations are performed to obtain these particles; but this proceeding is only adopted in large concerns. About forty years ago, crushing-mills were introduced, by which, in nearly all cases at present, the pieces of ore are in the first instance reduced, and then submitted to the processes above briefly noticed.

Tin ores require somewhat modified processes from those performed upon copper and lead ores. Being very minutely and intimately disseminated in the vein-stone, or rock, a more complete pulverization is requisite for its separation from it. The pieces are therefore generally reduced, in the first instance, in a *stamping-mill*, by means of heavy weights or hammers, lifted by machinery, and allowed to fall upon the ore; while a stream of water constantly passes through the mass, and washes away the portion which is bruised sufficiently small to pass through an iron plate pierced with holes, and forming one side of the box in which the stampers work. The ore thus obtained is submitted to the *jigging* and other operations, which are usually more numerous and more carefully attended to in the case of tin ores than in copper and lead, and they may be so prolonged as to yield a produce of 50 or 60 per cent. of tin.

In Germany and France they are somewhat in advance of the Cornish miners in the machinery employed in dressing ores, their *shock-frame* being superior to any thing of the kind used in Cornwall.

Thus are the three principal metals dressed at the surface of the mines. We have somewhat minutely detailed the processes, inasmuch as, from their being conducted around the top of the shafts, they commonly attract more of the attention of strangers and visiters than the other operations of mining.

The ores of the precious metals require a peculiar treatment, from their existence in a state of minute subdivision, mixed with a large quantity of earthy matter Gold ores are generally stamped, and silver ores are ground to an exceedingly fine powder; but, from the great value of the metals, the process of washing is differently conducted, and in some instances is altogether dispensed with.

Superintendence—Management.

The business of a mine is divided into several departments, namely, the under-ground operations, the pit-work, and machinery, the dressing and surface work, accounts and financial subjects, and the general control. Proper agents or superintendants are allotted to each department, and are all rendered subordinate to one general manager, who at stated periods communicates with the whole united body of shareholders or *adventurers*, or with a select committee chosen from them. This general manager, named the *purser*, is, in large concerns, a man of superior education and ability in reference to the duties of his office. The agents and subordinate officers are usually chosen from the most intelligent working miners, who, indeed, are peculiarly qualified for their tasks, by their thorough practical knowledge of the nature of the labour, and of the frauds which dishonesty might attempt. It is evident that such promotions act as a powerful stimulus upon the miners at large, and they are found to be in general an intelligent set of men. The agents are locally denominated *captains*, and there are the underground captains, and the *grass* or surface captains: their titles, however, like those of higher import, do not entitle them to take precedence away from their native districts.

The shareholders themselves usually form companies of 64, 100, 128, or several thousands in number, who hold grants or leases of the property from the mineral proprietors for a certain term of years—commonly twenty-one—renewable under certain conditions. The risk and responsibility of the undertaking entirely devolve upon this company, whom both the capital is provided and the management conducted, while the proprietors of the minerals receive a stipulated portion of the gross returns of the mine as a consideration for the use and deterioration of his property. This proportion of course varies accordingly with the risk and outlay of capital. Where the mines are easily and cheaply worked, as in the north of England lead mines, it amounts to an eighth or a tenth; but in Cornwall, where the mines are deep and most expensive, it seldom exceeds a fifteenth, an eighteenth, or a twenty-fourth, and is even as low in some instances as a thirty-second. This payment is termed the *royalty*, from the circumstance of all minerals having originally been the property of the king; and is subject to no fixed value, for it is often sound policy to reduce it, so as to enable companies to avoid the hazard of bankruptcy. It is well known that mining property is exceedingly liable to fluctuations in value, especially in metalliferous mines. The capital required to open mines in this country varies from £4000 to £150,000, and the profit upon this, in some instances, scarcely repays the capital expended; while in others, after paying back this sum, it amounts to two or three hundred thousand pounds. The duration of mines, too, in a working condition, is a matter of great uncertainty, some few being now in ope-

vation which are known to have been opened centuries since, but many are of modern origin, and cannot be expected to be wrought for more than a few years.

The Miners.

The total number of persons employed in and about the Cornish and Devon mines is estimated at 30,000. The captains are, upon the whole, a respectable and intelligent body of men. The miners themselves are of frank and independent manners, and though not often insolent, they are usually blunt, the younger ones affording, perhaps, the least favourable examples of behaviour. The adult miner earns at present from 40s. to 65s. per month by his own labour; and if he has both sons and daughters employed about the mine, may take from the mine, on their account and his own, £8 or £10 in the same period. The men now occupy decent cottages, frequently their own property, and in the last case they farm or garden a little. Generally speaking, the miners are a somewhat religious people, and frequently Methodists. There are, however, unfortunately, exceptions to this remark, and particularly amongst the younger persons. Taking Cornwall as a whole, crime is increasing more rapidly than population. The physical effects of the employment upon the workmen in the lead mines are very pernicious. Whether it result from any emanation of noxious gases from the lead and strata, or from the otherwise impure atmosphere of the mines, may be questionable; but Mr. Leifchild found, by an examination of the parish registers in the Northumbrian districts, that the average term of life was only 48 years and 5 months for the males, and 53 years and 1 month for the females; while for the people of the same districts otherwise engaged, it is 61 years. The disease to which the lead miners are subject is chronic asthma, generally terminating in pulmonary consumption. These men are, however, extremely attached to their dales, and there is no fear that any of them will be deterred from pursuing their calling by any supposition of its unhealthiness. No females are ever employed under ground in the Cornish mines, or in any of the metalliferous mines of England, that stigma having been confined to coal mines.

METALLURGY—METALS.

The processes of smelting and finishing metals, to render them suitable as marketable commodities, are usually treated of under the term Metallurgy; and to these we shall now advert.

Iron.—The various kinds of ironstones or ores are first roasted in large heaps in the open air, for the purpose of expelling the sulphur and arsenic with which they are commonly combined, and also to facilitate their reduction. The roasting is assisted by the combustion of coal or charcoal, and it is calculated that the stone loses from thirty to forty per cent. during the operation. The ore is then transferred to the blast furnace, which is usually a large pyramidal building, with arched openings at each side for the insertion of the blast pipes. Of late years blast furnaces have been built of a round shape, called the cupola furnace, which form is by many preferred. The inside is either cylindrical or square, widening from the top to near the bottom, when it is suddenly contracted, and terminates in the hearth or crucible in which the metal is received. The blowing pipes are situated a little above the hearth on each side, and the air is forced into the furnace by means of an engine adjoining the furnace. Into this furnace the ore, or *mine*, as it is called, is put, along with coke as the combustible agent, and lime to act as a flux. By the combustion of the coke an intense heat is raised, which softens the ore; the limestone combines with the earthy ingredients of the ore, and the metallic particles fall down into the hearth or crucible. When it is properly fused, a tap-hole is opened in the crucible, and the metal flows out into a fosse bedowed with water mixed with clay, which forms a coating to prevent the metal from sticking to the ground.

To obtain a ton of pig-iron by the above process, it is stated that 55 cwts. of roasted ore, 25 cwts. of limestone, and 40¾ cwts. of coal are required. The coal is put into the furnace first, the limestone on the top of the coal, and the iron ore last. At the end of about twelve hours, the metal is allowed to run from the hearth; the furnace is again charged, and the process may be carried on for an indefinite period without intermission. To make good iron, the ingredients must be justly proportioned, and the blast kept regular during the whole operation. Even the season of the year and the direction of the wind are said to affect the quantity and quality of the iron.*

Hot air is now universally used in the blasting furnaces, an improvement which has greatly lessened the expense of iron manufacture. The heating apparatus consists of two large cast-iron cylinders, the one being placed within the other, leaving a space between. The outermost cylinder is closed at both ends, but the innermost is left open, with nine rows of pipes, three in each row, which cross its interior, and communicate with the space between the cylinders. This apparatus is placed within the mouth of the furnace, the flames from which pass through between the pipes. The air from the blowing machine enters the space between the cylinders, and circulates by means of the cross pipes. By this invention the consumption of fuel at the Calder iron-works has been diminished in the proportion of 7 tons 17 cwts. to 2 tons 2 cwts.

Cast-iron, as it comes from the blasting-furnace, is full of impurities, such as fragments of charcoal, earthy matter, &c., which require to be removed by a refining process. There are three varieties of cast-iron, easily distinguished from each other. No. 1 cast-iron is of a dark colour, open in the grain, and is rendered fusible by comparatively little heat. No. 3 is very white in colour, excessively brittle, and does not melt freely. No. 2 is an intermediate variety between the other two, and possesses a combination of the properties of each.

The refining furnace is a small low building of brickwork, rising little above the surface of the ground. The hearth or crucible is composed of fire-brick, and is generally about three feet square. Coke is first placed upon the hearth, and the iron upon the coke, which is again covered in the form of a dome with coke. The fire is then lighted, and the hot-air blast applied about a quarter of an hour afterwards. While burning, a bluish flame is seen playing on the surface of the metal, which is formed by the combustion of carbon. When properly melted, the metal is run out into oblong moulds, and water cast upon it to render it brittle, and also partly to oxidize it. The metal thus suddenly cooled is very white, and possesses in general a fine radiated fibrous texture.

Cast and Malleable Iron.—Iron is made to assume two distinct forms, differing considerably in their nature, cast and malleable. Cast-iron articles are made by running iron in a state of fusion into moulds of fine sand or loam, according to the required shape. The mould is formed by means of a wooden pattern, which being sunk in the sand, and then withdrawn, leaves a cavity of the desired shape, into which the red-hot liquid iron is run from the furnace. Malleable iron is made from the metal in a state of fusion by means of what is called a *puddling furnace*, where it is raised to a very high temperature. After being stirred frequently to facilitate the combination of the carbon and oxygen, it gradually assumes the consistency of a stiff paste. It is then taken out and subjected to the action of a very large hammer, or the pressure of rollers, by which it becomes soft, ductile, and malleable. In this state it is called wrought, forged, or

* Encyclopædia Britannica

bar-iron, and is ready for the various operations of the blacksmith and machine maker.

Steel.—On malleable iron of a good quality being combined with carbon, it forms steel. The best steel is that made from Swedish and Russian iron. "The general method of forming steel is by the process of *cementation*. A furnace is constructed of a conical form, in which are two large cases or troughs of fire-brick, capable of holding some tons of iron. Beneath these is a long grate, on which the fuel is placed. On the bottom of the case is placed a layer of charcoal dust; over this a layer of charcoal powder, and the series of alternate layers of charcoal and iron is thus raised to a considerable height. The whole is covered with clay to exclude the air; and flues are carried through the pile from the furnace, so as to communicate the heat more completely and equally. The fire is kept up for eight or ten days. The progress of cementation is discovered by withdrawing a bar, called the *test bar*, from an aperture in the side. When the conversion of iron into steel appears to be complete, the fire is extinguished, the whole is left to cool for six or eight days longer, and is then removed. [The absorption of the carbon by the metal is when the interior of the troughs has attained 70° of Wedgewood's pyrometer.] The iron prepared in this manner is named *blistered steel*, from the blisters which appear on its surface. To render it more perfect, it is subjected to the action of the hammer, in nearly the same manner which is practised with forged iron; it is beat very thin, and is thus rendered more firm in its texture, and more convenient in its form. In this state it is often called *tilted steel*. When the bars are exposed to heat in a furnace sufficient to soften them, and afterwards doubled, drawn out, and welded, the product is called *shear steel*. Cast steel is made by fusing bars of common blistered steel with a flux of carbonaceous and vitreous substances, in a large crucible, placed in a wind furnace. When the fusion is complete, it is cast into small bars or ingots. Cast steel is harder and more elastic, has a closer texture, and receives a higher polish, than common steel. It is capable of still further improvement by being subjected to the action of the hammer.

"The most remarkable, as well as the most useful of the properties of steel, is the power which it has of changing permanently its degree of hardness, by undergoing certain changes of temperature. No other metal, says Thenard, is known to possess this property, and iron itself acquires it only when it is combined with a minute portion of carbon. If steel is heated to redness, and suddenly plunged in cold water, it is found to become extremely hard, but at the same time it is too brittle for use. On the other hand, if it be suffered to cool very gradually, it becomes more soft and ductile, but is deficient in strength. The process of tempering is intended to give to steel instruments a quality intermediate between brittleness and ductility, which shall insure them the proper degree of strength under the uses to which they are exposed. For this purpose, after the steel has been sufficiently hardened, it is partially softened, or let down to the proper temper, by heating it again in a less degree, or to a particular temperature, suited to the degree of hardness required, after which it is again plunged in cold water.

"Different methods have been pursued for determining the temperature proper for giving the requisite temper to different instruments. One method is to observe the shades of colour which appear on the surface of the steel, and succeed each other as the temperature increases. Thus, at 430 degrees of Fahrenheit, the colour is pale, and but slightly inclining to yellow. This is the temperature at which lancets are tempered. At 450 degrees a pale straw colour appears, which is found suitable for the best razors and surgical instruments. At 470 degrees, a full yellow is produced, suitable for penknives, common razors, &c. At 490 degrees, a brown colour appears, which is used to temper shears, scissors, garden hoes, and chisels intended for cutting cold iron. At 510 degrees, the brown becomes dappled with purple spots, which show the proper heat for tempering axes, common chisels plane irons, &c. At 530 degrees, a purple colour is established, and at this degree the temper is given to table-knives and large shears. At 550 degrees, a bright blue appears, used for swords and watch-springs. At 560 degrees, the colour is a full blue, and is used for fine saws, augers, &c. At 600 degrees a dark blue, approaching to black, has become settled, and is attended with the softest of all the grades of temper, used only for the larger kinds of saws.

"Another method of giving the requisite temper has been practised upon various articles. The pieces of steel are covered with oil or tallow, or put into a vessel containing either of these ingredients, and heated over a moderate fire. The appearance of the smoke from the oil or tallow indicates the degree of heat. If the smoke just appear, the temper corresponds with that indicated by the straw colour when the metal is heated alone. If so much heat is applied that a black smoke arises, this points out a different degree of hardness; and so on, till the vapour catches flame. By this method, a number of pieces may be done at once, with comparatively little trouble, and the heat is also more equally applied.

"A still more accurate method of producing any desired degree of temper, is to immerse the steel in some fluid medium, the temperature of which is kept regulated by the thermometer. Thus oil, which boils at about 600 degrees, may be used for this purpose at any degree of heat which is below that number of degrees. Mr. Parkes has recommended the employment of metallic baths, chiefly composed of lead and tin, in different proportions, which pass into fusion at definite temperatures, and which can be used for tempering steel as soon as they arrive at their melting points."*

Iron Articles.—The articles formed of iron and steel are so numerous as to be beyond calculation. The apparatus of steam-engines, machinery of all kinds, fire-arms, and agricultural implements, are among the variety of larger articles produced. In England, where iron manufactures are on the most perfect scale, it is customary to make each class of articles at a distinct factory or engineering establishment, by which division of labour the work is in all cases of the best order and of the newest inventions. Some of the largest manufactories of engines and machinery are established in Manchester, Leeds, London, and Glasgow; while articles of a smaller kind, including cutlery, are made principally at Birmingham and Sheffield.

The English cutlery manufacture is very extensive, and is excelled by that of no other country, though now nearly approached by that of Belgium. "The inferior kinds of cutlery are made of blistered steel welded to iron. Tools of a better quality are manufactured from shear steel, while the sharpest and most delicate instruments are formed of cast steel.

"The first part of the process consists in forging, and is varied according to the kind of article to be formed. Common table-knives have the blade forged of steel, and welded to a piece of iron, out of which the shoulder, and part which enters the handle, are made, the shape being given to them by hammering in a die and swage. They are afterwards tempered and ground. Forks are made by forging the shank, and flattening the other end to the length intended for the prongs. The prongs are made by stamping the metal at a white heat between two dies, the uppermost of which is attached to a heavy weight, and falls from a height. The shape is thus given to the fork, leaving, however, a flat thin piece of metal between the prongs, which is afterwards cut out with a

* Bigelow's Technology.

by press. They are subsequently filed, bent, hardened, and polished.

"Blades of penknives are forged from the end of a rod of steel, and cut off, together with metal enough to form the joint. The small recess in which the nail is inserted to open the knife, is made with a curved chisel, while the steel is hot. Razors are forged from cast-steel, much in the same manner as knives. The anvil is commonly a little rounded at the sides, for the purpose of making the sides of the razor a little concave, and the edge thinner. In forging scissors, the shape is given to the different parts by hammering them upon different indented surfaces, called *bosses*. The bows which receive the finger and thumb, are made by punching a hole in the metal, and enlarging it by hammering it round a tool, called a *beak* iron. The halves are finished by filing and grinding, and afterwards united by a joint. Saws are made from steel plates rolled for the purpose, and have their teeth cut and finished by filing, and set by a suitable instrument. Axes, adzes, and other large tools, are forged from iron, and have a steel piece welded on, of the proper size, to form the edge.

"To enable the steel to be wrought, it is brought to its softest state, but after the shape is given to the instrument, the steel is hardened and tempered by the methods already described. The remaining part of the manufacture consists in grinding, polishing, and setting the instrument, to produce a smooth surface and a sharp edge. The grinding is performed upon stones of various kinds, among which freestone is perhaps the most common. These stones are made to revolve by machinery, and move with prodigious velocity, so that the surface, in some cases, passes over six or seven hundred feet in a second, and stones have been burst by their own centrifugal force. For grinding flat surfaces, like those of saws, the largest stones are used; while for concave surfaces, like the sides of razors, smaller stones are used, on account of their greater convexity. The internal surfaces of scissors, forks, &c., which cannot be applied to the stone, are ground with sand and emery, applied with instruments of wood, leather, and other elastic substances. The last polish is given by a material composed chiefly of the oxide of iron. The edges are lastly *set* with hones and whet-stones, according to the degree of keenness required. The test used by cutlers for determining the goodness of the edge and point of a lancet is, that it shall pass through a piece of soft leather without sensible resistance. Needles are polished by tying them in large bundles with emery and oil, and rolling them under a heavy plank till they become smooth by mutual attrition. The shape is previously given, and the eye made with a steel punch."*

Lead.—When lead ore comes from the mine, the first operation is to wash and sort it into heaps of different qualities; this is done either by putting the ore into a trough and stirring it, or filling a sieve, the meshes of which are made of iron, and immersing it in a vat full of water. Another process is to put the ore upon an instrument called a *grid*, which consists of a number of bars of iron placed parallel to each other, about an inch apart. Over this grating a stream of water flows, which washes away all impurities, and also separates the small pieces of ore from the large. The smaller pieces are then collected into a finer sieve, and washed again, and all pure ore which may be still amongst them is carefully picked out with an iron scraper. This washing is greatly facilitated by the specific gravity of the metal. The ore containing most galena sinks first, and is found next the bottom of the vat; a second quality of ore will be found on the top of this, and the inferior kinds above it. When the sieve is immersed in the water, it is shaken pretty severely, which causes the ore in a manner to float, and allows the heavier pieces to sink to the bottom. The different qualities of ore thus obtained are separated from each other by the iron scraper called a *crimp*.

The mixed ore, that is, such as contains stone and other impurities in the lump, along with pure galena, is then sent to the grinding-mill. This consists either of solid uprights shod with iron, and moved up and down by a horizontal spindle furnished with arms, or a pair of fluted cylinders, through which the ore is made to pass, and it is afterwards ground to the requisite fineness by smooth rollers. The mixed ore, after being ground, is again washed, and the pure galena separated from the impurities.

There are two kinds of furnaces used in the smelting of lead ore—a reverberatory furnace, called a *cupola*, and the other known by the name of the *Scotch furnace*. The first, in the interior, is generally eight feet long, six feet wide, and two feet high at the centre. The fire is placed at one extremity, and is separated from the smelting part by a wall, which is built about half the height of the furnace. The hearth upon which the ore is placed is composed of furnace slags, and it slopes from the wall which separates it from the fire to the other end of the furnace, and is hollowed from the sides to the centre. This is enclosed by an arched roof, in the middle of which is a small aperture for admitting the ore from a hopper placed above it.

About 20 cwts. of ore are usually put into a furnace at a time, which is spread equally over the hearth with a rake. For the first two hours, no regular fire is made, a gentle heat merely being kept up by putting small coal on the furnace, the doors of which are kept shut. This is called the roasting process, which is formed principally for the purpose of dispelling all sulphureous vapours from the ore. At the end of two hours the fire is raised, and the metallic lead soon begins to flow from the ore. The smelter and his assistant now stir the ore at intervals, and a shovelful of quick lime is thrown in. This is done in order to liberate the oxide of lead from the ore, and allow it to react upon any sulphuret which may have resisted the roasting. The heat is again increased, and the stirring continued. In about four hours from the commencement, the furnace receives its greatest heat, after which a tap-hole is opened, and the lead runs into an outer basin. From this it is cast in semi-cylindrical moulds, and receives the name of bars.

The Scotch furnace is much of the same nature as the above, except that the hearth, sides, and sole-plate, are made of cast iron, from two to three inches thick. The roasting is performed with peat and coke, and the furnace is urged by wooden bellows. In advance of the furnace a basin is placed, for the reception of the lead as it flows from the furnace.

The quantity of lead obtained from the mines of Great Britain, annually, has been estimated at nearly 40,000 tons.

The articles made from lead are *sheet-lead*, which is cast on large tables, and smoothed and thinned by rollers; *lead-pipes*, which are generally made by drawing through a mandril; and *leaden shot*, which is formed by dropping melted metal in a shower from a great height. Towers for making shot are conspicuous objects in London.

Copper.—The ores are roasted by a low heat, in a furnace with which flues are connected for collecting the sulphur which is volatilized. The carbonates of copper reduced by fusion, afford a pure copper; and this is an easily wrought metal, useful for many purposes. Copper alloyed with zinc forms brass, which is extensively used for articles of ornament by brass-founders.

Tin.—The ore of tin, when melted in furnaces and run like iron, is shaped into blocks or pigs. The uses of tin are very numerous, and so well known that they scarcely need to be pointed out. A very important ap-

* Bigelow's Technology.

plication of tin is in the coating of other metals, such as those of iron and copper, which have been formed into vessels. The silvering of looking-glasses, and the fabrication of a great variety of vessels and utensils for domestic and other uses, are among the advantages derived from this metal.

COAL MINES.

As explained in our article GEOLOGY, coal belongs to the secondary order of rocks, in which it is defined as the *carboniferous group*. With respect to its origin and character, it is entirely a mass of vegetable matter, which has accumulated in certain situations, and afterwards been covered over and pressed into a hard consistence under other strata—generally mud or sand—which in time has become layers of limestone or sandstone. Coal is not found in veins or deposits resembling metalliferous substances; it is discovered in large basin-shaped patches in different parts of the world, and always in the same position with relation to adjoining strata. Geology being almost unknown as a practical science some years since, frequent trials were made to obtain this fuel, where we now know nature never intended that it should be found; although blackish, charred, woody and peaty substances led to the expectation of its presence, and caused the useless expenditure of large sums of money. The coal-seams, together with their alternating strata, are usually called the *coal-measures*, and the basin-shaped deposits in which these lie are termed the *coal-fields*. In either form, coal is found in vast abundance in various parts of England, Scotland, and Ireland, and constitutes the most valuable of all our mineral products, for without it most others would be nearly useless. The entire British coal-fields may be classified as follows:—

The coal of Scotland.—The coal-fields of Scotland are of great extent and value, indeed sufficient of themselves to furnish the whole empire with an adequate supply of this mineral for a long series of years. Coal is found in several districts of Scotland, as in Dumfriesshire and Roxburghshire, in the more southern counties; but the great field of Scotch coal stretches from south-west to north-east across the centre of the kingdom; and it is to be found in greater or smaller quantities in the counties of Haddington, Edinburgh, and Linlithgow, Stirling, Clackmannan, Kinross, Fife, part of Perth, Ayr, Renfrew, Lanark, Dumbarton, and part of Argyle. Its average breadth is thirty-three miles, and its length upon the mainland of Scotland ninety-eight miles; so that its total area is 3234 square miles. If from this we deduct 360 miles for the space covered by the Frith of Forth, there will remain 2874 square miles of territory, in most parts of which coal is found at different depths and of various qualities, whilst in about 600,000 acres of the same space it may be worked with advantage. The depth of coal varies, but in general it seems to be rather nearer the surface in the western than in the eastern division of the country. There is also a great variety in the number of its seams or strata, as well as in their thickness. The greatest thickness in the island is at Quarrelton, where five contiguous strata are upwards of fifty feet thick. Seams less than eighteen inches are not deemed equivalent to the expense of working them.*

The coal of Ireland is found in seventeen counties of that country. The chief district is that of Munster, which occupies a considerable portion of Limerick, and Kerry, and also a part of Cork; next are the Connaught and Leinster districts. Some of the coal-fields are of the carbonaceous, while others are of the bituminous quality. Comparatively little is raised, and almost all the coal used in Dublin, Belfast, and other towns, is imported from England.

* General Report of Scotland.

The coal of England and Wales may be thus classified:—1. The great northern district, including all the coal-fields north of the Trent. 2. The central district, including Leicester, Warwick, Stafford, and Shropshire. 3. The western district, which may be subdivided into north-western, including north Wales; and south-western, including south Wales, Gloucester, and Somersetshire.

Coal is found in these fields in strata of various thicknesses, alternating with clay, slate, and sandstone, the alternations being frequently and indefinitely repeated. These beds or measures commonly repose upon millstone grit, and shale, which sometimes exceed 120 fathoms in thickness. Under this series is the carboniferous or mountain limestone, varying in thickness up to 900 feet; and this is again succeeded in the descending order by the old red sandstone, ranging from 200 to 2000 feet in thickness. These four different series are generally comprehended in the term *coal-formation*, although the three last do not form an essential and invariable part of it, being sometimes absent. A general resemblance in their structure is observable in all the English coal-fields, but they greatly differ in minor particulars.

By far the most important and best known of all the English coal-fields is undoubtedly that of Northumberland and Durham, the pits of which ship their produce by the rivers Tyne, Wear, and Tees. The coal raised from these mines is of the most valuable character for domestic purposes, and as such has obtained a notoriety throughout the civilized world. There are three principal kinds of coal found in Great Britain:—1. The *caking* coal (distinguished by various provincial designations), yielding about 40 per cent. of bitumen, the quantity of which is the chief recommendation to a household coal. This is the prevailing kind in the Northumberland and Durham mines. 2. The *cannel* coal, called in Scotland *parrot* coal, which occurs in Lancashire, and contains about 20 per cent. of bitumen. 3. The *stone* coal, known also under many other names, which is the ordinary coal of the Staffordshire and Scotch collieries, and is largely consumed in manufacturing processes.

This great northern coal-district commences near the mouth of the river Coquet on the north, and extends nearly to the Tees on the south. As far as Shields, the sea is the boundary on the east; but from that point it leaves a margin of a few miles between it and the sea, and extends about ten miles west from Newcastle. Its greatest length is 58 miles, and its greatest breadth about 24. It supplies a very large portion of England, including the metropolis, part of Scotland, and many foreign countries. The coal-measures of this field rest upon the millstone grit and shale, and lie, in the south Durham portion, under the magnesian limestone, the northernmost point of which projects near the mouth of the Tyne. In consequence of the basin or boat-shaped disposition of the coal, the beds at some places appear at or crop out to the surface, while, in the central parts of the concave or basin, they lie at great depths. The beds of this series of coal-measures are 82 in number, and consist of alternations of coal, sandstone, and slate clay, forming an aggregate thickness of 1620 feet. The number of really workable and productive seams of coal in this field are 17; but of these only about four or five yield the best coal. These are variously named as the High Main and the Low Main, the Bensham and the Hutton seams, the last extending over the whole of the eastern part of Durham, and ranging in thickness from 4 to 5½ feet, of which, however, 2 feet frequently turn out to be coarse coal, unfit for the market, and suitable only for mending the horse roads. It seems probable that more accurate and complete knowledge will establish the identity of some of those seams which are now distinguished by different names.

The extent of the whole surface of this coal-field is a subject of dispute; but, according to the most received approximation, Northumberland contains 243 square miles, and Durham 594 square miles, making 837 square miles for the two counties. Of this the portion already excavated is computed to be about 105 square miles; and from a minute calculation, it has been deduced that, according to the present issue of coal from the chief parts in this field, there remains enough to warm and cheer our posterity for 1700 years to come. It should be mentioned, however, that Professor Buckland, in 1830, limited the supply, at the existing rate of consumption and waste, to 400 years. This last calculation, however, assumed as one of its elements the continuance of the practice of screening coal at the pit's mouth, by which from one-third to one-fourth of the quantity of coal drawn was separated into small coal heaps, and ultimately consumed in the most wanton manner. The present regulation, however, of selling coal by weight instead of measure, has done away with this abuse to a great extent. Great misconceptions prevail upon the available quantity of coal in each seam. The actual quantity of coal in the Newcastle coal-field does not amount to more than a twenty-fifth part, or 4 per cent., of the whole mass of strata accompanying it, of which mass various kinds of sandstone form about 36 per cent., and strata in which siliceous earth predominates about 44 per cent. Again, when the seam of coal itself is gained, all is not marketable coal that looks black, in the same way as "all is not gold that glitters." There is much impurity even in the most valuable seams, in the shape of what is termed by the pitmen *band*, *swad*, and *foul coal*. In a seam producing one of the most approved coals for the London market, we found the *good coal* to be only 2 feet 3 inches in thickness, while the whole seam of coal was 5 feet 6 inches thick.

Coal Shafts and Workings.

Coal mines are reached by circular shafts, as in metal mines; and the sinking of these forms a large item of expense, for the operation involves the erection and working of a steam engine to draw off the water, and the blasting of any rocky matter that intervenes. The working beneath, to form the necessary excavations, is also liable to great impediments from the occurrence of *dykes*. These are generally of the character of dislocations in the strata, a seam of coal being all at once stopped by a barrier of stone, and continued at a different level. But although the dykes thus impede operations, they are useful in forming walls to prevent the intrusion of water. The cutting of a dyke or fault of any extent is carefully avoided by coal-miners, as the penetration of this barrier, which nature seems to have interposed by way of a warning to the ardour of the excavator, would often admit a rush of waters from the other side, and cause the inundation of the mine; for these interruptions assume the office of coffer-dams in stopping the passage of the water in many cases. At Gosforth colliery, about two miles north of Newcastle, the manager described to us, while standing nearly over the 90-fathom dyke, that, about the year 1825, a shaft was attempted to be sunk on what turned out to be the wet side of this great dyke, but it was speedily abandoned, in consequence of the perpetual influx of water. The adventurers then merely crossed the dyke by advancing a few yards; and having thus reached the dry side, they sank the present shaft, in which they were compelled by this short journey to descend nearly 200 fathoms before they could reach the coal; this, however, they succeeded in doing without any obstruction from large quantities of water.

Shafts vary in depth, according to the situation of the stratum or seam to be reached. The deepest are those in the Newcastle district. The writer of the present article descended and inspected twelve of the principal pits in this field, selecting such as were deepest and largest, or otherwise peculiar and important. Three of the shafts of these were each five hundred and odd feet deep, three were each eight hundred and odd feet, and three others, each one thousand and odd feet deep. The deepest shaft in this coal-field, and probably in any other, is one thousand six hundred feet deep, and we were about four minutes in descending. This is the celebrated Monkwearmouth shaft, the difficulties encountered in sinking which were perhaps as formidable as any upon record. This is generally believed to be the deepest perpendicular shaft in the world, if the level of the sea is regarded. We find it, however, stated of one near Namur, in the Netherlands, that it is two thousand four hundred feet in depth, although no particulars are given whereby to judge of its relative depth below the level of the sea, or of its perpendicularity. The readiest method of forming an idea of the depth of such a shaft as the Monkwearmouth, is to consider that it would contain the Monument of London piled eight times upon itself!

In Lancashire, the deepest shafts are about eight hundred feet, and in Yorkshire they are about the same, but seldom more than three or four hundred feet in either district, and in many instances very shallow. The steam-engine is not commonly erected in the collieries of these parts, unless, indeed, on a very small scale, and of a very imperfect kind. The *horse-gin* and *turn-wheel*, or *roller*, are the machines commonly used in these inferior collieries for the purposes of winding or lifting the coal. The horse-gin is the same kind of machine as that usually known by the name, and is generally worked by horses who have seen better days, and indeed now see no days at all, being blind, wind-galled, or spavined. The turn-wheel is the least expensive and most dangerous mode of winding. It is, in fact, nothing more than a common well-winch with a fly-wheel, which is wound by an old woman or boy, on whose equanimity the ascendants and descendants are entirely dependent.

The men and boys commonly descend and ascend by inserting one leg into a loop at the end of the pit-rope, and winding the other round the rope, to which also they cling with both arms and hands. Two men commonly go at one end of each of the two ropes, when the loops are used. When the baskets (corves) are employed, three or four, or more, may descend together. Eight persons may descend the Monkwearmouth shaft in a large iron bucket. The number of boys going up and down at one time is sometimes five or six, and they cling to the ropes with as much tenacity as possible, presenting the appearance of a string of onions. The men take the youngest boys on their knees, holding them fast, which, after work, is necessary, for they are sometimes asleep when they arrive at the top. A modern improvement in shaft-machinery is the substitution of iron frames (cages), sliding upon vertical rods or rails, which traverse the shaft perpendicularly; the transit of this plan is easy, steady and safe. In some collieries it is the practice to descend and ascend by the upcast shaft, which is in fact going down or up a long smothering chimney. We have descended three upcast shafts, each of more than a thousand feet in depth. The celebrated Monkwearmouth shaft is an upcast, and we shall not readily forget our descent of this, during the whole of which we were subjected to the suffocating vapours of the smoke of the flaming furnace at the bottom, and of the vitiated return air. The ropes of this shaft cost £550 per pair, and weigh 5¼ tons, only lasting, however, about ten months. Many of the ropes in these collieries are flat, and all are of a superior character. The chief danger in ascending is that of being drawn up too high and over the pulleys upon which the ropes run, and which are erected upon wooden frames over the

shaft. A bell is hung, by mechanical contrivance, when the men arrive near the surface, but this has sometimes failed; and in the summer of 1842, a pitman was killed by such a failure at a pit in county Durham.

The method of excavating the coal from the mines is not always the same in different places, but may, in a general sense, thus be described:—The pit is either level or sloping, according to the seam of the coal, and the process of excavating it furnishes material for sending to the surface up the shafts. A pit may vary from three or four to six feet in height, from the floor upwards; the roof, which is a hardish part of the strata left, being supported by pillars consisting, for the greater part, of unexcavated coal. Sometimes wooden props are used, but these are less safe than the substance of the coal. It may easily be supposed, that great care is required in leaving a sufficiency of these natural props; for cases have been known in which the superincumbent pressure has forced down the roof, and the land on the surface, with houses upon it, has sunk.

In excavating, hewers are employed to dig out with picks the masses of coal; and as they proceed in their labours, they cut out evenly-formed apartments, or galleries, all connected with each other, and divided by the rows of pillars which it has been necessary to leave standing. In some instances, the miners must recline or stoop to effect their purpose; and when we remember that they are incommoded with water and foul air, and working in darkness only illuminated by feeble lamps, it must be allowed that their occupations are irksome, and far from being either pleasant or safe. Other persons remove the coal as it is dug, in some cases by means of small wheeled carriages, which they draw, and in others by carrying it in baskets on their back. Being in either way removed to the bottom of the shaft, it is there put in the buckets, or corves, and wound to the surface.

Ventilation of Coal Mines.

The temperature in coal-pits varies in general from sixty to seventy degrees in deep mines. In one of the Hetton pits, it is sixty-six degrees at the shaft bottom and seventy degrees in the workings. In the deep Monkwearmouth pit, it ranges from seventy-eight to eighty, and even to ninety degrees. The Newcastle coal-pits generate gases more largely than any other. The chief component part of inflammable pit-gases is carbureted hydrogen gas, mixed with unequal quantities of olefiant, carbonic acid, and nitrogen gases. They exhibit a very different degree of inflammability when mixed with atmospheric air, according to the different proportions they contain of nitrogen, carbonic acid, and olefiant gases. The two first gases diminish, the last increases, their inflammability. The most readily explosive mixture of this inflammable compound with common air is one measure of the gas to seven or eight of air.

The great objects of ventilation are to dissipate the noxious gases issuing from the coal, frequently at all pores, and to supply the miners with fresh air. Its agent is the difference between the weights of two columns of air, one of which is at the natural temperature, and the other rarefied by the heat of a furnace. (See article VENTILATION). Both by means of doors in the galleries, and the furnaces erected for the purpose, ventilation is carefully attended to, so that a current of fresh air is almost always playing along the passages. In cases where it is presumed that the return or escaping current of air is so impregnated with the inflammable gases of the mine that it would take fire by coming into contact with the flames of the furnace, the air is carried over the furnace through a close brick-work channel (termed a dumb furnace), which opens into the upcast shaft *above* the fiery furnace; thus the heat of the fire is made to produce the draught, while the flame does not communicate with the vitiated return air. One of the very highest rates of circulation afforded a result of 59·030 cubic feet of air per minute coursing through the pit, which amount was subdivided into eleven different currents, being an average of 5·366 cubic feet to each current. The ordinary circulation is much below this, but the higher it is raised, the safer and fresher the pit.

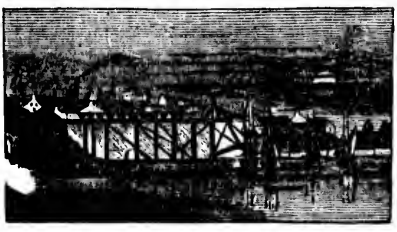
Notwithstanding all the precautions used, explosions of foul air and accidents will occur. No colliery district, we believe, has been more fertile in explosions of a terrific character than the Newcastle coal-field. At the very lowest calculation, no less than 1500 lives have been sacrificed in or about the collieries of the Tyne and Wear, in little more than the last forty years, and the greater portion of these have been lost by explosions of inflammable gases. Mr. Leifchild describes a catastrophe of this nature, the effects of which he witnessed, that occurred in April, 1841; and by this calamity thirty-two persons were killed, some of them being fearfully mutilated or scorched to cinders. The acknowledged cause of this explosion, and of many others, was the temporary neglect of the little boy who kept one of the most important doors in the pit. It is supposed that he left this door for a short time to play with another doorkeeper, or *trapper*, and consequently the current of ventilation became deranged. Whenever such a derangement takes place, the contact of a candle-flame explodes the pit either wholly or partially, and with more or less havoc. In this instance the pit was shattered to a great extent, but in others it is sometimes not much broken up. In 1839, an explosion occurred in which fifty-one persons were killed; and in 1835, at Wallsend pit, 102 human beings were destroyed by one.

Very few persons are unacquainted with the nature of the *Davy-lamp*, or safety-lamp, invented by Sir Humphry Davy, and introduced to the miners in 1816. As shown in the adjoining figure, it consists of an oil-lamp enclosed in a wire-gauze cylinder, of which the apertures are extremely minute—a square inch of the surface containing 625 openings. Through apertures so small, flame will not pass, and the lamp may therefore be carried into the most explosive atmospheres without risk. Its safety depends upon the cooling agency of the wire-gauze, exerted on the portion of gas burning within the cylinder or lamp. When the fire-damp is to the air in the proportion of 1 to 5, 6, or 7, the cylinder is filled with the flame; but even though the wire-gauze should become red hot, the exterior air is not kindled. It is perhaps possible, by certain chemical arrangements, to force the flame through the gauze, if a strong current be employed, but no instance of such an event ever having occurred naturally in a mine is, we believe, recorded; and therefore the Davy-lamp in its original form is esteemed perfectly safe, notwithstanding the numerous *improvements* proposed for it. If the miners would always employ this safeguard instead of candles, there can be little doubt that fewer explosions would occur; but the feeble light which it affords renders it unacceptable, and men will actually, and without dispute, frequently risk their lives for the sake of a little more light and the avoidance of a little trouble. Many mines have been conducted since the introduction of this lamp, which, without it, must have been closed, and some have been re-opened that could not be worked in safety with the old *steel-mill*—a machine of revolving steel and flint, employed before the Davy-lamp in dangerous pits. This is especially the case in what are termed the pillar-workings of the pit, where the ventilation becomes more difficult, and in almost all pillar-workings the *Davy*, as the pitmen call it, is in requisition. In many pits a *locked* Davy is delivered to the pitmen, who return it before they leave the pit.

A considerable number of lives are lost, singly or in small numbers, by what may be considered as the ordinary casualties of mining, such as the fall of stone from the roof, which is a frequent cause of calamity. In the inferior coal-fields, numerous deaths occur by the breaking of ropes and shaft apparatus, all which are of a much more costly and durable character in the Newcastle collieries. And this leads us to speak of the ascent and descent of these pits.

Colliers.

The number of men and boys employed above and under ground in the Tyne, Wear, and Tees collieries, or what may be termed the Newcastle coal-field, approximates to 30,000, which may probably be the maximum. To speak more definitely, nearly 13,000 are engaged in the collieries on the Tyne (which are the oldest), 9000 in those on the Wear, the number in those on the Tees being uncertain. The pitmen appear to be a tolerably healthy race of men, of somewhat diminished stature, and of a rather peculiar bodily configuration. Their legs are sometimes bowed, and their backs rather bent, as the results of their constrained position in hewing the coal; while, as a set-off, their muscular development is considerable, and, being spare, they recover readily from accidents. The hewers earn, in fair times, from 18s. to 20s. per week, or more, and enjoy a cottage and fuel free of payment. The cottages are built in long rows, and form distinct villages. The lads and boys are also well paid, but the *putters* undergo in many instances very severe labour, which the oldest of them bear well, but it tells visibly upon the youngest. The education of the men, women, and boys, is very defective; few can read at all readily, and fewer still can write. They are, in fact, not long emerged from a state of semi-barbarism. Thirty years ago, their Sunday costume was remarkably gay and singular, and their manners equally so. At present, they may be considered to be, when viewed externally, a tolerably well-behaved, shrewd, hard-working, hard-feeding community—not long since, we might have added *hard-drinking*, but temperance societies are encouraged by them, and a considerable number of them are Methodists. A special government commission has inquired, during the year 1841, by means of visiting assistant commissioners, into the circumstances of the employment of females (none being found in the Newcastle pits) and children in coal mines. The results of this commission have occupied a large share of public attention; and Lord Ashley's bill, founded upon them, excludes females altogether from coal-pits, and limits the age of boys employed in them. It is very satisfactory to have ascertained that (lead mining excepted) all mines appear to be *capable* of being worked by men without any serious diminution of their health. The occupation may, by liberal and judicious management, be rendered far from disagreeable to those accustomed to it.



Surface-works—Consumption of Coal.

The surface-works at a coal mine are less complicated than those at the metal mines, where smelting has to be performed; still, they are frequently very extensive, and include steam-engines for drawing the coal, pumping the water, and also departments in which much of the apparatus connected with the pits is made and repaired. From the pits in the Newcastle and Durham districts, railways are laid in communication with the banks of the Tyne; and overhanging the river may be seen many of the terminations of these railways adapted for shooting the coal from the wagons on board the vessels lying ready to receive it. The apparatus suited for emptying the wagons into the vessels is called a *staith*, and one of these is sketched in the preceding figure.

The cost of coal on being raised from the pit is always very much below the selling price to the consumer, a large addition being made by the merchants through whose hands the article passes, in the shape of dues for freight, carriage, commission, &c. Good coal in Scotland may be had for about 10s. or 11s. per ton; but in London, the expense of the sea-carried Newcastle coal is enormous; the coal, in general, which originally cost 12s. to 14s. per chaldron, being raised to about 50s. to the consumer. Speaking of the abuses of the coal trade, Mr. M'Culloch, in his "Dictionary of Commerce," makes the following statements:—"Abuses have insinuated themselves into most departments of the business; and to such an extent have they been carried, that it takes, at this moment, a larger sum to convey a chaldron of coal from the *pool*, a little below London Bridge, to the consumers in the city, *than is sufficient to defray the entire cost of the coal in the north*, including the expense of digging them from the mine, their conveyance to the shore, landlord's rent, &c.! The following statement shows the various items that made up the price of coal to the London consumer in October, 1830, distributed under their proper heads. They have been carefully abstracted from the evidence before the parliamentary committees.

CHARGES UP TO THE TIME OF ARRIVAL IN THE PORT OF LONDON.

Coal Owner.			
Paid coal owner for coals		£0 14 0	
Deduct river duty paid by him for improvement of Sunderland harbour		0 0 3	
			£0 13 9
Coal Fitter.			
Keel dues, and fittage (including seven miles' water-carriage)		0 2 3	
Ship Owner.			
For freight, including insurance of ship and cargo, pilotage, seamen's wages, wear and tear of the ship and materials, discharging ballast, &c.		0 8 6½	
Municipal Dues.			
River duty, as above	£0 0 3		
Pier duty, lights, &c, paid by ship	0 0 5½		
		0 0 8½	
			0 11 8½
CHARGES IN THE PORT OF LONDON.			
Government Tax		0 6 0	
Municipal Dues.			
Trinity and Nore Lights, tonnage duty, Trinity-House for ballast, &c.	0 0 5		
Entries, &c.	0 0 2½		
Corporation of London metage	0 0 4		
Ditto orphans' dues	0 0 10		
Ditto meter's pay and allowance	0 0 4		
Ditto market dues	0 0 1		
Ditto Lord Mayor's groundage, &c.	0 0 0½		
Ditto land metage	0 0 6		
Ditto undertaker	0 0 1		
Coal-whippers	0 1 7		
		0 4 4½	
Coal Factor.			
Factorage and *del credere* commission		0 0 4½	
Coal Merchant.			
Buyer's commission	0 1 0		
Lighterage	0 2 0		
Carriage	0 6 0		
Credit	0 2 0		
Shoorage	0 1 3		
Add for even money	0 0 3		
	0 12 6		
Add for discount, *scorage*, and *ingrain*	0 2 2½		
		0 14 8½	
			1 5 8½
Making the price paid by the consumer			£2 10 7½

Which is thus apportioned:			
Coal owner for coal - - - -	0	13	9
Ship owner, &c., for voyage to London	0	11	5½
Government duty, corporation charges and London coal merchant - -	1	5	5½
	£9	10	7½

Of these charges, but little reduction need be looked for in those incurred in the rivers Tyne and Wear, and in the rate of freight; and as the government duty of 6s. per chaldron has been abolished, the charges that admit of further reduction are the municipal dues, and those attending the delivery of coal to the consumers; and in these, certainly, there is ample room for retrenchment.

The most important item, in those forming the charges in the port of London, is the fee of the *coal-whipper*, or coal-heaver—that is, the deliverer of the coals from the ship to the barge or lighter. This fee is about 1s. 7d., and is at least *five* times as great as it ought to be. At Newcastle and Sunderland, the filling of a chaldron of coal into the wagon costs 1½d. to 1¾d.; and admitting that to raise coal from the hold is a little more difficult, still, if 4d. were allowed, it would be a most liberal payment. But the truth is, that this item should be struck off altogether. It is occasioned by *a regulation peculiar to the Thames, which prevents the crews of colliers from performing this indispensable part of their peculiar duty.* In the outports, to which, luckily, this preposterous regulation does not extend, the crews act as coal-heavers, and they do so without either asking or obtaining additional wages. And there certainly is no reason whatever for supposing that the case would be materially different in the port of London, were it not for the regulation referred to. In 1829, the total amount of money paid to the coal-heavers was £107,566, 13s.; of which at least £90,000 may be saved to the citizens by simply *allowing* the crew to perform the function of coal-heavers.

The consumption of coal in Great Britain, according to a statement made by Mr. Taylor, an experienced individual in the coal trade, and laid before a committee of the House of Lords, was as follows:—

The annual vend of coal carried coastwise from	Tons.
Durham and Northumberland is - - - - -	3,300,000
Home consumption, say one-fifth - - - - -	660,000
	3,960,000
Which quantity supplies 5,000,000 persons; and supposing the whole population to amount to 15,000,000, the estimate will therefore be - -	11,880,000
Consumed in iron-works - - - - - - -	3,000,000
Annual consumption of Great Britain - - - -	14,880,000
Exported to Ireland - - - - - - - -	900,000
Total - - - - - - - - - -	15,780,000

Since this statement was made, the consumption is believed to have greatly increased, and, including the coal exported to Ireland and to foreign countries, the total quantity raised annually is not less than 23,000,000 of tons, the price paid for which is reckoned to be eight millions sterling a-year.

SALT MINES.

Deposits of salt are chiefly found amongst secondary rocks; and rock-salt is almost invariably accompanied by clay, sandstone, and gypsum (from which last plaster of Paris is made, either above or below it, sometimes both; and the countries containing salt deposits are for the most part flat. It is found either in the form of rock-salt, or disseminated in brine springs in many countries; but some, as the capitals of Hindostan, are so destitute of it, that, in the shape of stamped cakes, it once passed as money, according to some authorities.

Perhaps the most extensive deposition of rock-salt in the world is found at Wielitska, near Cracow, in Poland. It has been worked as a mine since the year 1251, and its excavations are said to extend more than a league from east to west; the salt produced being of an iron-gray colour, in which are enclosed cubes of a pure white. After being let down by a rope for 230 feet, the visiter is led through galleries perfectly dry, and of considerable height and breadth, until he arrives at two chapels composed entirely of salt, and hewn out of the solid mass. Images, as well as pillars and ornaments of the same material, adorn the place, and reflect the rays of light issuing from the lamps of the guides, producing a beautiful and novel appearance. Descending lower by ladders, the visiter finds himself in an immense hall or cavern of salt cut with great regularity, and many hundred feet in length. A thousand persons might dine in it without inconvenience; and when illuminated by flambeaux, its splendour is not inferior to that of a palace hall.

There are some extensive beds of rock salt in England; two found in Cheshire are known to extend a mile and a half north-east and south-west, and upwards of three-quarters of a mile in width. The surface of the lower bed is about 220 feet from that of the ground, and this bed has been penetrated to the depth of 132 feet, without any appearance of its base. Some of the upper strata in this series are very porous, and permit 360 gallons of water to rise through them per minute, a circumstance that greatly impedes the sinking of pits. The salt of these mines is commonly of a reddish hue, and is often so hard that the blast by gunpowder is necessary to extract it. The lower portion of the lower bed is the purest, and in it occurs considerable cavities, sometimes 16 feet high. The mines are worked by galleries, masses of salt being left as pillars to support the roof. When illuminated by candles, numerously fixed on the sides, the effect produced is exceedingly brilliant. Of the Cheshire mines many yield 16,000 tons of salt per annum for home consumption, and 140,000 tons are annually exported from Liverpool.

Salt is also obtained in our own country from brine springs, the chief of which are situated at Droitwitch, in Worcestershire. They are four in number, all situated within a square furlong, and seem to issue from a bed of rock-salt. The quantity of brine rising from these pits is immense; and although that which is used bears but a small proportion to that which runs to waste, nevertheless the quantity of salt annually made from these four pits, or springs, is about 16,000 tons, two-thirds of which are consumed in England. The brine is perfectly limpid, and contains about one-third its weight of salt, which is separated from it by evaporating processes.

Salt Mine.

Among the most interesting accounts of the English salt-mines is that of Sir George Head, in his "Tour through the Manufacturing Districts of England in 1835." While at Northwich, he visited the Marston

pit which has been worked for a period of sixty years, and may be considered inexhaustible. "Having waited (says he) with my conductor a few minutes, till the engineer had put a little steam on, we both stepped into a round tub, and, standing upright, holding by the chains, were let down very easily. I cannot express the delight I felt at the scene around me, which surpassed any thing I had anticipated: creating those sensations I remember to have felt when first I read of the pyramids and catacombs of Egypt. Here was a magnificent chamber, apparently of unlimited extent, whose flat roof presented an area so great that one could not help being astonished at its not having long since given way. Yet there was no apparent want of security, it being sound and durable, as if formed of adamant. Here and there pillars, in size like a clamp of bricks in a brick-field, tendered their support, presenting to the view an array of objects that broke the vacancy of uniform space. My idea of the extent was, as if an area, equal to the site of Grosvenor Square, were under cover. In the mean time, the glistening particles of crystal salt on the walls, and the extreme regularity of the concentric curved lines, traced by the tools of the workmen, were very remarkable. Occasionally, the mark of the jumper-chisel was observable where recourse had been had to blasting the solid rock. I made a few blows against the side of the mine with one of the heavy pointed pickaxes in ordinary use, and found it as hard as freestone. Under foot the whole surface was a mass of rock-salt, covered with a thick layer of the material, crushed and crumbled to a state that exactly resembled the powdered ice on a pond that has been cut up by skaters.

"Experiments have been made by boring to a depth of seventeen yards, but they have neither perforated the rock-salt, nor do they at present know the thickness of the stratum. The height of this excavation is about fifteen feet, within which space the salt is estimated as being of the best quality. Above, it is somewhat inferior. I was informed that thirty-five thousand tons of salt were annually dug out of the different levels, and that the area of the whole together amounted to forty-eight statute acres. A considerable quantity of this salt is exported to Prussia.

"At one part there is a vista of two hundred yards in length, which has been dignified with the name of Regent Street. Here occasionally pic-nic parties are celebrated; and on a large table of coarse deal-boards, were the evidence of deeds of wassail performed at a feast of this description, which had taken place a few months before. An empty jug and sprig or two of evergreen lay forlorn and neglected, while I observed natural tokens, indisputable and abundant, of mice that had joined in the revelry. These little animals invariably establish their residence under ground, wherever men lead the way. At the coal-pits of Whitehaven, for instance, they are plentiful at a depth of one hundred and forty fathoms, being brought there originally, probably, in bundles of horse provender. Were it possible, within this mine, to provide against the inconvenience of smoke, there not being any efficacious outlet for its egress, I cannot conceive a place better calculated, with proper appendages and decorations, to give effect to a fête on a magnificent scale.

"Every one who descends this pit ought to bring a good Bengal light. For ordinary purposes, we had recourse to common tallow candles.

"Having wandered a long way, through vast space, but almost in darkness, we came again to the foot of the shaft. Previous to ascending, my guide went a little out of the way, in order to carry a pail of water to an old horse, who, as the workmen were absent for the whole day, was standing by himself in perfect solitude, and, till we came, without any light at all. Alone and in darkness, he must, poor fellow, from necessity, live for many hours in the year, and pass thus neglected a very considerable portion of his time. He loudly expressed his gratitude for the water, and I took an opportunity of examining his condition while he was drinking. I was surprised to find it particularly good; unlike the flaccid though fine-coated state of horses in coal-pits, his was that of a firm crest and perfect health, a fact I attribute especially to the salubrious effects of the salt. His stall was comfortable and dry, as was the whole space below contained in this pit. I saw no appearance whatever of water during the whole time I was below.

"The salt, after being prepared by the solution of the rock, and evaporation, is formed by wooden moulds, with holes at the bottom, to allow the remaining water to pass through, into cubical blocks, and in this state shipped either by the river Weaver and canal to Western Point, and thence into the Mersey, or by the canal southward.

"A considerable quantity is prepared from the brine springs, some of which are so strongly saturated as to hold in solution the greatest possible quantity of salt. To the water of some of these springs rock-salt is added while boiling in the pans. From these springs the water, or brine, is raised by a shaft sunk, and a pump worked by an ordinary steam-engine."

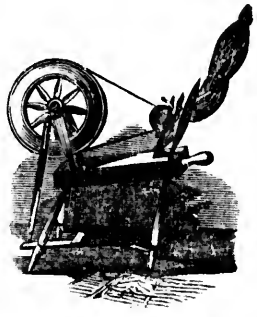
MISCELLANEOUS ARTS AND MANUFACTURES.

TEXTILE FABRICS.

All kinds of cloth formed of spun or woven threads fall under the title of textile fabrics, and the manufacturing of these, in the departments of linen, cotton, woollen, and silk, is now the most important branch of industry in Great Britain and Ireland.

LINEN.

The fabrication of linen cloth, to which we may first advert, commences by the preparation and spinning of the raw material, lint. Lint is the fibrous bark of the flax plant, which grows in temperate climates to a height of from three to four feet. When ripe, it is pulled and steeped to soften the substance of the stalks; on being dried, it is *skutched*, or bruised, to free the fibres from the waste of the stalks. It is next *hackled*, or cleaned, by being drawn over and among sharp iron spikes; the refuse in hackling is called *tow*, and is employed for coarse sacking. The hackled lint is a collection of fine smooth fibres, ready for being spun. The mode of spinning is now very different from what it once was. In ancient times it was customary to spin by the distaff, an exceedingly simple apparatus, consisting of a spindle, or bobbin, twirled by the twisting of the lint, as it came from a staff of lint held by the operator; the finger and thumb were the sole instruments for twisting. A female could not twist a spindleful of thread, though engaged a whole day in the labour. This rude process was at length superseded by the introduction of a machine called the *spinning wheel*, a representation of which is given in the annexed engraving. A female sat with her left hand towards the *rock*, or staff, on which the lint was placed; her right foot moved the paddle-board below, and this affecting the upright crank, turned the wheel. A band communicated to the spindle, and on this the thread was fed from the rock. In drawing out the lint, the finger and thumb were frequently wetted by touching the lips, and this had an effect in consolidating and smoothing the thread, which no purely mechanical process has since been able to imitate. Spinning in this manner with the wheel formed a very common employment for females, particularly those who were aged, and whose time was of little or no value. Although the motion of the wheel was rapid, in comparison of the feeble operation of the distaff, the process was very insufficient, except for home-made linens, and something very different was required for manufactures conducted on a large scale.



The introduction of machinery in the manufacture of cotton led to the application of similar mechanism in the linen manufactory; and for many years hand-labour has been entirely abandoned. All steps in the preparation and spinning of the flax are on a large scale. The flax is imported in vast quantities from Holland and other countries, and is dressed and spun in factories at Leeds, or some other great seat of manufacture. The machinery is extremely beautiful and ingenious, and the making of it alone is a principal trade. On being brought to one of these factories, the flax is from 30 to 36 inches in length, and the first step "is to take a quantity of it, and divide it into three lengths; the part nearest to the root being coarse and strong, the middle part fine and strong, and the upper part still finer, but not so strong. Thus each length being divided into three, and all those of the parts from the bottom, middle, and top, being collected into separate heaps, three distinct qualities of thread are to be formed.

"The separation of these first lengths into three is effected by a very ingenious machine, consisting of a number of vertical wheels, and a centre wheel, furnished with a kind of teeth. The length of flax is held transversely against these wheels, and is passed between two, one on either side, while the centre wheel tears it across, by separating but not cutting the fibres. This cuts off the bottom part of the length of flax; the remaining part is then submitted to the same process, and the middle part cut from the top, each sort being collected in one heap, so as to effect a separation of the three qualities above named. Each division, from what has been before seen, will be, of course, about ten or twelve inches in length. In the next stage, these lengths are fixed in a sort of vice at one end, spread out to a breadth of six or seven inches; several of these are fixed on a sort of revolving drum, at distances of about a foot from each other, their unsupported ends falling on an internal drum covered with strong cards, the internal drum revolving one way with considerable velocity, and the external in the opposite direction rather slowly, and thereby the lengths of flax are rendered very smooth and straight; they are then dexterously removed by an attendant, generally a girl, and placed with their other side downwards in the next machine, and again removed. It should be remarked, that these only pass over the upper part of the internal drum; for it is obvious, if they passed below, their weight would cause them to fall from and not upon the carding roller.

"These several operations being performed, the next step is to place these pieces of flax, one just reaching the other, on a feeding cloth, and by the hand slightly to combine their ends; the first end is then passed between two card-rollers, or rollers furnished with teeth, which carry the whole forward, while the extreme end passes between two rollers of iron, the latter moving with considerably greater velocity than the former, in some cases 30 to 1, and consequently the flax is now lengthened 30 to 1, and its thickness reduced accordingly. In passing from the roller the flax receives no twist, but comes out flat, and of about the breadth of narrow tape, and is caught in a cylindrical tin can placed below to receive it; when a certain length has been received, sufficient to fill the can, a bell rings, an attendant breaks the flax, removes the can, and places another. The flax in the full can is then taken to another machine, where it is again lengthened, and so on to different degrees, according to its intended fineness. After it is properly reduced in the flat state above described, it receives in its last stage a very slight twist, so as to reduce it to a round thread. It is then received on bobbins, and is in a proper state for spinning; the process of which differs only in degree from that described in relation to the cotton manufacture."*

The yarn produced in these spinning-mills is purchased

* Encyclopædia Metropolitana, article *Manufactures*.

cy manufacturers, who employ weavers to convert it into the various fabrics of linen, damask, and cambric.

Weaving.—This is an art of great antiquity, and has undergone little improvement till recent times. The process is founded on a simple principle. A certain number of threads drawn out alongside of each other, constitute the *warp*. This is evenly wound on the beam of a loom, and is thence extended to another beam at the opposite end. The warp is two threads in depth, and by means of heddles, and other apparatus, these are caused to rise and fall so as to cross each other. Every time that the threads are opened, a shuttle containing the *woof* or *weft* is thrown across from one side of the warp to the other, and the thread of woof thus left is driven home by a lay, or properly by a comb-like process of reeds, which the lay brings forward. A reversal of the warp makes another opening, which is similarly crossed by the shuttle, and so on, the fabric gradually assuming the character of cloth. Plain cloth of all descriptions is formed by this species of operation. *Twilled* cloth is formed by causing the thread of the woof to pass alternately over four and under one of the threads of the warp, and performing the reverse in its turn. Jeans, dimities, serges, and other fabrics, are thus woven. For this, and all kinds of ornamental weaving, an expensive, or at least complex harness is required. The machinery for weaving lace and gauze is very ingenious and beautiful, but would require to be examined minutely to be properly understood.

Bleaching and Calendering.—These processes follow that of weaving, and in both there are now great improvements. Bleaching linen is performed by spreading the cloth on a bleaching-green, where an abundance of water can be obtained, and exposing it to the action of the atmosphere in a wet condition. Some submit their cloths to artificial bleaching by chemical detergents, but these are allowed to be somewhat injurious to the texture. With respect to brown linen, "being first unfolded from the firm and compressed shape in which each *piece* or web is received from the manufacturer, it is cast, loosely knotted, into a wooden boiler capable of containing some two or three hundred pieces, and nearly filled with a weak solution of potash or barilla. After the linen has been boiled in this liquid for several hours, it is removed from the boiler by a crane and net-work of rope, and almost immediately transferred, in separate quantities, to the *wash-mills*. Here it is placed in a trough, through which jets of spring-water are constantly passed, and kept fully exposed to the action of the water by means of two large beams suspended above the troughs, and termed *feet*, the lower ends of which are alternately drawn back and permitted to fall against the linen with considerable force. This motion is produced by the revolving of a cylinder situated directly beneath, and having projecting spars which catch and raise, at intervals, the extremity of the feet. From the wash-mills the linen is removed to the green, where it is carefully spread upon the grass, the several pieces being attached together, and their ends secured to the ground by small wooden *pins*. After remaining two or three days upon the grass, it is again brought to the bleach-house, to be boiled and washed as before. The operations of boiling, washing, and spreading upon the green continue, thus successively repeated, till the linen has fairly assumed a whitish hue, when two additional forces are introduced. The first is that of passing the linen through the *rub-boards*. These boards, which are fixed in a frame, and moved by simple machinery, have portions of their inner surfaces furnished with plates of *lignum-vitæ*, or other hard material, completely channelled with narrow parallel grooves, the plates of the upper board being placed immediately over those of the under. Between these plates the linen, having been first plentifully soaped, is slowly passed, so that the entire web is submitted to the friction. The second process is that of steeping, for a certain number of hours, in *rieves*, or cisterns, containing water acidulated with sulphuric acid. After the introduction of the additional processes, the earlier continue unchanged, excepting that the use of the former alkalis in boiling is abandoned, soap being now employed.

"By these several means, the bleaching is at length completed, when the *finishing* or prepairng for market immediately begins. The linen is first starched and blued, after which it is suspended in a *drying-loft*, where it is exposed to the air till completely dry. It is then taken down and stretched, and submitted to the *beetles*. These are a succession of weighty wooden billets, ranged in a frame, above a slowly-revolving cylinder, round which the linen is wound. The machinery being set in motion, the billets are raised and successively dropped, with great rapidity and force, on the cylinder beneath. This is continued for several hours, and the operation repeated till the fabric is sufficiently compressed, and the requisite smoothness obtained. The linen is then *lapped*, or folded, and sent to the assorting-room. Here each piece is carefully measured, again firmly lapped, and subjected to the pressure of an hydraulic-press. The peculiar stamp of the merchant is finally applied, and the linen is ready for the market."*

Hemp is a coarser plant than flax, and its fibres, when skutched and hackled, are spun into yarn suitable for being woven into canvas or bagging. The manufacture of these fabrics has been long settled at Dundee and the adjoining districts, to which the raw material is readily imported from the continent of Europe. Ropes, cordage, and twine, are made from the same strong material.

COTTON.

Cotton is the wool produced in the pods or fruit of the cotton plant, which is indigenous to all the tropical regions of Asia, Africa, and America. When the pods are ripe, they burst and disclose the cotton wool, mixed with seeds. After the cotton is gathered, it is exposed to the rays of the sun till it is perfectly dry; the seeds are then separated by a peculiar skutching apparatus, and being picked and compressed into bales, is in this state sent to Europe. The chief seats of import are Glasgow and Liverpool, where it arrives in large oblong bales, and in this state is carted off to the factories in which it is to be spun.

The relative value of raw cotton depends on the length of its staple, the delicacy of its fibre, and its freedom from dirt and seeds. The cleanest, we believe, is the American; but however careful its preparers have been, "it never comes to England in a state fit for immediate use; some seeds remain after the most careful cleaning, and the pressure to which it is subjected in packing, forms hard matted lumps, and some of the coarser and heavier wool is unavoidably mixed with that of superior quality. The first operation in the process of manufacture is consequently the cleaning of the cotton. It is put into the blowing-machine, where the cotton is torn open by revolving spikes, and subjected to the action of a very powerful blast, produced by the rapid turnings of a fan; the light wool is thus blown to some distance from the heavier portions—the dirt, seeds, &c. This process is continued in the skutching-machine, where the cotton is beaten by metallic blades making from 3000 to 5000 revolutions in the minute; these completely open the fibre, and separate the fine wool from the waste, which falls to the ground through a frame of wire-work.

"The cleaning process is generally called *willowing*, which is either a corruption of *winnowing*, or perhaps derived from the willow frames on which the cotton was cleaned by beating, before blowing-machines were invented. Previous to this improvement, the cotton was

* Mr. and Mrs. Hall's Ireland. London: 1842.

placed upon willow-hurdles, or upon cords stretched over a wooden frame, and then beaten with smooth switches. This operation, technically called *batting*, though very fatiguing, and we believe unwholesome, from the dust, &c., which was scattered about, was usually performed by women; it is now very rarely practised, except when some remarkably fine cotton is required for the manufacture of lace, when it is of importance to preserve the length of the staple, which might be injured by machinery.

"The Hindoos open the fibres of their cotton by a bow similar to that which hatters use in raising wool; the same contrivance appears to have been employed in America, for we find the term *bowed cotton* still employed in the language of commerce. Judging from its effects on wool and fur, we should think that the bow is an effective machine for cleaning and opening the fibres, but it would be far slower and less productive than the willow.

"When cleaned, the cotton is brought to the lapping or spreading-machine, where a given weight of the wool is spread over a determinate surface of cloth, and being then slightly compressed by a cylinder, it is lapped round a cylindrical roller, so as to be in a fit state for feeding the carding-machine. It is a singular fact, illustrating the accuracy with which machinery works, that the weight of the cotton spread on the cloth in this process regulates the fineness of the thread ultimately produced, and that there is rarely any great amount of error in the calculation.

"The next process, that of carding, is one of the most beautiful in the whole of the cotton manufacture. An explanation of the object to be attained is necessary for those who have not paid some attention to the subject. In order that any material should be spun, that is, should have its fibres twisted together, it is essential that these fibres should be straight and parallel with each other. After having been subjected to the action of the willow, the fibres of the cotton are blown about in every direction, and, if compressed, would be entangled with each other. This, which is the object to be gained for the process of felting, is precisely that which must be carefully avoided for spinning. In order to straighten the fibre, the cotton is made to pass between cards or brushes of wire, one of which is stationary, and the other in motion; the wire teeth catch the fibres, and, by their continued action, pull them nearly into parallel directions.

"This process was anciently, and in some rural districts both of England and Ireland is still, effected by hand-cards, which might be described as two brushes with handles, having short wires instead of hairs. The labour was usually performed by women, who placed one of the cards on the knee, holding it firm with the left hand; and then spreading the cotton or wool in small quantities over the wire, drew the other card repeatedly over it with the right hand, until the fibres were deemed sufficiently straight. When thus prepared, the cardings were taken off in a roll by the hand, and laid so as to be united into a continuous roving by the spinning-wheel.

"The first great improvement in this process was to fix one of the cards to a table, and suspend the other from the ceiling, so that the workmen could move it without having to sustain its weight. Such a contrivance allowed *stock-cards*, as they were called, to be made of double the size of hand-cards, and consequently to double the quantity of work produced. We have seen stock-cards in some rural districts, where there is still a domestic manufacture of woollens; but they are daily becoming of more rare occurrence. In nearly all manufactures, they have been superseded by the cylindrical cards, which Mr. Baines has shown to be the invention of Mr. Lewis Paul of Birmingham, about the year 1748. About 1760, the process, which seems to have been either neglected or disused, was revived by Mr. Morris of Wigan, and applied to the carding of cotton. The perfecting of the machine has been claimed for Sir Richard Arkwright, but the originality of his invention has been very fiercely contested. Without entering into the controversy, we shall proceed to describe briefly the machine in its present state.

"The carding-machine has the appearance of a cylindrical box, into which cotton is given by the roller, round which it was wrapped in the spreading operation. Its wooden covering is a series of narrow panels; and if one of these be lifted, it will be seen that each of them is a card, and that a cylinder covered with cards occupies the interior of the box, between which and the panel-cards the cotton is rapidly passed. At the opposite side of the box is a second cylinder, the cards on which, instead of being placed horizontally, are wound spirally round the cylinder, which is called a *doffer*, so as to remove the carded cotton in a continuous fleece. The cotton is slipped from the doffer by the action of a slip of metal, finely toothed like a comb, which, being worked against the cylinder by means of a crank, beats or brushes off the cotton in a fine filmy fleece. The cloud-like appearance of the carded cotton, as it is brushed from the doffer, or finishing cylinder, by the crank and comb, is singularly beautiful—a breath seems to disturb the delicacy of its texture, and to the touch it is all but impalpable. The filmy fleece is gradually contracted as it passes through a funnel, by which it is forced to assume the shape of a roll or sliver. It then passes between two rollers, by which it is compressed into the shape of a ribbon of considerable tenacity, in which state it coils itself up in a deep tin can.

"Looking at the various parts of this interesting machine, the attention is first engaged by the feeding cylinder, which supplies the cotton to the cards more regularly and continuously than could be effected by hands. The successive cards on the concave and convex cylinder are seen to subject the wool to several successive cardings at each revolution of the wheel; and to prevent the necessity of stopping the machine to remove the carded cotton, it is stripped off by the doffer, which removes the cotton, not in successive portions, but in one continuous fleece. Again, the removal of this fleece from the doffer, which would be both tedious and imperfect if attempted by hand-cards, is completely accomplished by the simple agency of the crank and comb.

"Carding is not the only operation employed to straighten the fibre of the cotton. It may easily be conceived that the teeth of the cards will frequently lay hold of a fibre by the middle, and thus double it together, in which state it is unfit for spinning. This evil is corrected in the drawing-frame—an important part of the spinning machinery, for it executes work which could scarcely have been effected by human hands. The essential parts of the drawing-frame may be easily understood from description. Each drawing-head consists of three pairs of rollers, the upper one of each pair being smooth and covered with leather, the lower being fluted longitudinally. They are placed at a distance from each other, which is regulated by the staple of the cotton; that is to say, the distance between each pair of wheels is generally a very little more than the length of the fibres subjected to their action. The loose ribbon formed by the carding-machine is pulled through these rollers, and as they revolve with different velocities, the fibres pull out each other, and reciprocally extend each other to their full length.

"But a not less important object of the drawing-frame is to equalize the consistency of the cardings. One carding, notwithstanding all the precautions that have been taken, will be found to have more or less of substance than another, and it is necessary to counteract this inequality by combining several of the carded ribbons, technically called *card-ends*, into one sliver. Eight card-ends are usually brought to the first drawing

head, and after passing through the rollers, they combine to form one sliver of the same density as each of them separately, thus increasing eight-fold the chances of uniformity in the sliver. Four of these slivers are again subjected to the same process, and thus the chances of uniformity are two-fold those of the original card-ends; and this is continued until the last sliver may be regarded as containing parts of 300 card-ends; but for very fine spinning, the doubling of the fibres, as the process is called, is multiplied more than 60,000 times.

"The drawing-frames are fed from the tin cans containing the card-ends, and the chief duty of those who attend them is to mend or piece the feeding slivers when one of them is broken, or when one of the cylindrical cans is exhausted. A contrivance has been recently introduced to abbreviate this labour; a cylindrical weight is made to fall at intervals into the receiving can, and by pressing down the sliver, to force it to hold more than double the quantity which it would contain if the sliver were left to coil itself loosely. In the mills for fine spinning, great attention is paid to this process, because any defects left by the drawing-frame cannot be cured in subsequent operations. The labour of attending to the machines is the lightest in the cotton-mill, but there are few parts which require more vigilance and care.

"The next operation is the making of a roving or thin sliver, about the thickness of a candlewick, and giving it only so much of a twist as will enable it to hold together. The attenuation of the sliver is accomplished by rollers acting in the same way as in the drawing process, but various contrivances have been devised to give the roving just so much tension as is necessary, and no more. Arkwright invented the can-roving-frame, in which a slight twist was given to the roving by making the receiving-can revolve upon a pivot. It was necessary that the rovings, after this operation, should be wound off upon bobbins, a process injurious to their delicate texture; to obviate this evil, the jack-frame, or jack-in-the-box, was contrived, which wound the roving on a bobbin as it received its twist, instead of leaving it to coil in the can. At present, the process of roving is generally performed by the bobbin and fly-frame, an ingenious piece of mechanism.

"It is not necessary to enter into any examination of the many ingenious contrivances which have been devised to render the roving-machines more perfect and automatic; the reader will best appreciate the difficulty of the operation, by bearing in mind that the process of twisting by the spindle, and winding on the bobbin, though connected in fact, are quite independent in principle, and that there is therefore a necessity for the nicest adjustment, in order that the one should be accommodated to the other.

"Twist of low numbers, called water-twist, because it was originally worked in Arkwright's water-frame, is spun by the throstle, a machine probably deriving its name from its singing noise. It is in principle nearly the same as the drawing-frame which has been just described; it extends the rovings by the action of rollers into slender threads, and twists them by the rotation of spindles and flyers. The machinery, however, is far more simple, because the hard-twisted throstle thread does not require such tender manipulation as the delicate roving."

The most interesting part of the manufacture is mule-spinning, which is more common than throstle-spinning. "Let the reader," continues our authority, "imagine himself in the room, a part of which is represented in the accompanying cut, and it is probable that the circumstances worthy of his notice will present themselves in nearly the following order:—He will see a carriage about a yard in height, and of very considerable length, varying in different mills, bearing a row of spindles between its upper rails; it has generally three wheels which traverse on the same number of iron guiding bars, so as to allow of its drawing out to a distance of more than four feet from the stationary frame; as it

recedes from the frame, it draws with it and elongates the threads, or rather rovings delivered to it through rollers, by a series of bobbins in the creels or stationary rails. The threads, as they are elongated, are twisted by the spindles; and should any of them break, it is the duty of a boy or girl, called a piecer, to join the disunited ends as the carriage moves from the upright frame. A girl in the act of piecing the yarn is represented in the cut. When the carriage has receded to its full extent, the spindles continue to revolve until the requisite quantity of twist is communicated to the yarn. The spinner then causes the spindles to revolve backwards, until he has unwound the portion of thread which has coiled spirally round it from the point to the nose of the cop, and at the same time he lowers a faller wire, supported by hooks, as seen in the cut, so as to regulate the winding of the yarn on the cop in a proper spiral. There is great nicety required in regulating the pushing back of the carriage, for it is necessary that its rate of travelling should be commensurate with the revolution of the spindles. Three simultaneous and delicate movements have thus to be effected by the spinner as the carriage returns; he must guide the faller wire so as to insure the regular winding of the yarn on the cop; he must regulate the rotation of the spindles, of which there are often a thousand to one mule; and he must push the carriage at such a rate as to supply precisely the exact amount of yarn that the spindles can take up.

"The little piecers can only take up the ends when the carriage is within a foot or two of the delivering-roller, and they have therefore an interval of rest, while the carriages traverse backwards and forwards. The spinner, too, has a brief respite while the carriage is moving outwards from the frame. The time taken to make a stretch, that is, to draw out a thread equal in length to the range of the carriage, increases with the fineness of the yarn, and varies, also, according to the completeness of the machinery and the skill of the operative. The breaking of the threads depends not merely on the machinery, but to a very great extent on the atmosphere and temperature. We were in a mill during the prevalence of a sharp drying east wind, and found that it produced such an effect on the fibres of the cotton, that the threads broke faster than the piecers could mend them, and that the spinning of very high numbers at such a time was all but impossible. The rooms in which fine yarn is spun are kept at a temperature of 70 to 80 degrees, which is not so high as to produce much inconvenience."*

By the processes now described, the cotton has been attenuated into fine yarn on bobbins, and is now ready

* England in the Nineteenth Century—Lancashire. London How and Parsons. 1842.

for being *warpea*, or made into webs for the weaver. Formerly, all was wove by the hand; but the introduction of the power-loom, by which the work is altogether done by machinery, has superseded hand-loom weaving, except for some particular fabrics. "In one respect," observes the above authority, "the power-loom has a very obvious advantage over the hand-loom; the batten, lathe, or lay, to which the reed is attached, drives home the weft to the rest of the web, after it has been shot from the spindle; now, a weaker or stronger blow of this lathe alters the thickness of the cloth, and after any interruption, the most experienced weaver finds it difficult to commence with a blow of precisely the same force as that with which he left off. In the power-loom, the lathe is easily adjusted to give a steady certain blow, and when once regulated by the engineer, it moves with unvarying precision from the beginning to the end of the piece. Hence power-loom cloth is always of a more equable and regular texture than that woven by hand. Power-looms are generally placed in long apartments, and lighted from the top by a single range of windows to every row of looms. The weavers, or rather the tenters, have very little to do besides watching the machinery, and correcting any defects in the materials to be woven. As the labour is light, it is usually performed by women, or young persons; and we are informed that the business is so simple as to be easily learned in a month or six weeks." In the annexed engraving is pre-

sented a view of the interior of a power-loom apartment. All the looms are of iron, and moved by belts from shafts, the shafts being turned by steam or water-power.

SILK.

Silk is the produce of an insect called the silk-worm, or bombyx, but which is properly a caterpillar, which undergoes several changes during the short period of its life. The animal is produced from eggs laid in summer by a grayish kind of moth. These eggs are about the size of a grain of mustard seed; their colour, when first laid, being yellow, but afterwards becoming of a bluish hue. In temperate climes, and with proper precautions, these eggs may be preserved a long time without hatching or rotting. The three successive states of being of the silk-worm are those of the caterpillar, the chrysalis, or aurelia, and the moth; and in addition to these, it undergoes five other distinct modifications of being. When first hatched, it is a small black worm, about a quarter of an inch in length. On being brought forth, it almost immediately begins searching for its natural food (the leaves of the mulberry tree), which it devours with avidity. In about eight days, the head grows much larger, and the worm is attacked by its first sickness. This lasts for three days, during which time it refuses food, and remains perfectly motionless. It then begins to cast its skin, which it accomplishes after much pain and exertion. So complete is this moulting, that not only the covering of the body, but of the feet, the skull, the jaws, and even the teeth, is cast off. The insect then begins to feed with recruited appetite, and continues for five days, when a second moulting takes place, exactly like the first, and so on through a third and fourth course, the animal progressively increasing in size. After the last moulting it feeds voraciously, and increases rapidly in size during ten days, when it has attained its full growth—being then generally from two and a half to three inches long. At this period, it begins to leave off eating, and soon entirely ceases—becomes restless and uneasy, and looks out for a convenient place to commence its spinning labours. Its colour is now a light green; but as the material for forming the silk gets digested, it becomes glossy, and somewhat transparent. The silky substance is secreted in the form of a fine yellow transparent gum in two vessels, which are wound, as it were, on two spindles in the stomach. When the animal has found a suitable angle, or hollow, for the deposition of its silken ball, or cocoon, it begins to spin thin and irregular threads at first, the silk being drawn through two minute apertures beneath the jaws. In four days the cocoon is completed, the labourer remaining, of course, always on the inside of the sphere it is forming. The cocoon resembles a pigeon's egg in shape and colour, but is not quite so large. As may be imagined, the insect, from the continual emission of the gummy silk, together with the want of food, gradually contracts in size; and if the cocoon be opened after it is finished, the animal will appear in the form of a chrysalis, with a smooth brown skin—its former covering lying beside it. The silkworm goes through all the transformations above mentioned in the space of from twenty two to thirty days, according to the temperature to which it is exposed. The cocoons containing the insects intended to be preserved for laying eggs are left undisturbed, and the chrysalis gradually undergoes a transformation into the state of a moth. This change is accomplished in the space of about twenty days; and the moth, by great labour and ingenuity works its way through the cocoon, but without injuring it, and sets itself at liberty. It then appears as a large moth, of a grayish-white colour, furnished with four wings, two eyes, and two black horns, or antlers, of a feathery appearance. This moth enjoys its existence only a very short time. It remains almost entirely fixed to one spot, the wings never being used for the purpose of flying, but only in assisting it in fluttering while seeking its mate. When this object is attained, the female deposits her eggs, and both end their being in the course of two or three days afterwards. The number of eggs laid by the female varies from 250 to 500; and these eggs, in about six months after, produce larvæ as before. It will scarcely be credited, but is nevertheless true, that in a few short weeks—that is to say, from its being hatched to the period of its full-grown size—the weight of the silkworm is increased more than nine thousandfold. The greater part of the raw silk introduced into England is from China, India, Italy, and some other warm countries.

The cocoons being prepared and assorted, the material is ready for being *reeled*. The great point in reeling is to make the thread of as even a thickness as possible; *perfect equality* is scarcely attainable. An experienced reeler, with the assistance of a girl to turn the wheel, can with ease wind off a pound of silk in a day. Six or eight pounds may be wound off in a day, but a coarse, foul and ordinary silk, will be the produce. The modes of reeling silk in Italy and France are very different, but that of the former is reckoned the best. The floss, or inferior silk, of the cocoons is not reeled, but spun, after being mixed with the silk of the injured or inferior cocoons.

After reeling, the next process for preparing the

raw silk for the weaver is that of *throwing*. It has already been mentioned that this branch of the art was introduced by Sir Thomas Lombe into England, in 1718, from models surreptitiously obtained by him at Piedmont. Considering the remarkable perfection now attained in this country in the science of mechanics, it will not appear strange that these throwing-mills have been long since superseded in Great Britain by subsequent improvements.

Raw silk, preparatory to weaving, must be made to take one of three forms, respectively termed *singles*, *tram*, or *organzine*. *Singles* is merely the raw silk twisted, in order to give more firmness to its texture. All raw silk, for whatever manufacture designed, must undergo this process. *Tram* is formed by twisting together, not very closely, two or more threads of raw silk, and this generally forms the weft, or transverse threads of the web. *Organzine*, which is principally used for warp, is produced by a very elaborate process, of which it would be impossible to convey any correct idea to the general reader without the aid of a diagram. The principle of the process, however, may be generally stated to be like that of making rope, where the combined strands are twisted in an opposite direction to that given to the separate threads, and this is accomplished by giving a reverse motion to the machinery; whereas singles and tram are twisted only in one direction, similarly to twine, or to the individual strands of which the larger rope is made. Silk thread intended for organzine is in the first process twisted in a left hand direction. The organzine, when finished, is transferred to reels instead of bobbins, whence it is made up into skeins, and sorted for sale or use. Previously to this, however, the reels are subjected to a process of steaming for two or three minutes, in order to prevent any after crinkling. The silk thus thrown is called hard silk, and must be boiled for some hours with a quantity of soap, in order to discharge the gum, and thereafter well washed in a current of clear water to discharge the soap, after which the silk appears soft and glossy.

Silk is woven into various fabrics, plain and figured, by the Jacquard loom, and also into velvets. The fine soft pile of velvet is produced during the process of weaving, by inserting short pieces of thread doubled under the shoot or weft, and which stands upright in such a way, and so close together, as entirely to conceal the interlacings of the warp and shoot. In the production of every yard of velvet, six yards of pile at least are used. The loops of the double threads intended for the pile are supported by grooved wires, and the loops are afterwards divided by running a sharp instrument, called a *trevel*, along the groove. This is done by the hand, and, of course, requires great dexterity, as the slightest deviation from the proper line would infallibly injure, if not wholly destroy, the silk. It is considered a good day's work for one man to weave one yard of plain velvet, for which he is paid about five times as much as for weaving plain silks.

WOOLLEN.

The wool of sheep, cleaned and dressed, has from the earliest ages been employed in the fabrication of cloths. Until comparatively recent times, however, the manufacture was conducted in a homely manner, and on a small scale. As in the case of flax, it was customary to spin the wool by means of a wheel and spindle superintended by a female, who made little progress during a whole day's labour. This plan has now been almost entirely laid aside, and wool is generally spun in factories by machinery for the purpose. After being spun, the yarn is woven into cloth, which is fulled or thickened, and then dressed on the surface by teasles, and an apparatus for shaving the pile. The best cloth is dyed in the wool before weaving; but much is dyed after it has assumed the form of cloth.

The woollen manufacture of England is carried on in three different modes—that of the master clothier, who buys his own wool from the importer, and afterwards gives it out to be manufactured either in factories or private houses; the factory system, by which every process of the manufacture is carried on under the same roof; the last is the domestic system, in which private weavers purchase wool from the dealer, and employ themselves, wives, children, and sometimes several journeymen, in the various manufacturing processes under their own roofs. The factory system is evidently the one best adapted for carrying the manufacture to its utmost extent.

The mode of disposing of the various woollen cloths is different in Yorkshire and the west of England, but in both upon a scale in keeping with the magnitude of the manufacture and the commercial importance of the kingdom. In the west of England, the goods are exposed at periodical markets or fairs; in Yorkshire, in cloth-halls, of which there are three at Leeds, besides others at Halifax, Bradford, Huddersfield, Wakefield, &c. These halls consist of long walks or galleries, through the whole length of which the master-manufacturers have their stands in double rows. Between these the merchants pass, and make their purchases. At a certain hour a bell rings, and the market closes, those goods which are purchased being then carried to the merchants' quarters, and those unsold remaining in the stands. The goods are bought in their undressed state, the merchant afterwards getting them finished off himself. Dressing and finishing has of late years become a business entirely distinct from the manufacturing department, and in which to attain perfection has been the chief aim of the Yorkshire merchants. So proficient, indeed, have they become, as to defy any but the most experienced judges to distinguish their cloths from the more costly fabrics of the west of England.

Besides the manufacture of cloth, blankets, and flannels, the department of woollen fabrics comprehends *carpets* and *hosiery*, two very distinct but important branches. Three kinds of carpets are usually made—Venetian, Kidderminster, and Brussels. Venetian carpeting is a plain fabric, composed of thick linen woof on a woollen warp, and is employed chiefly for stair or lobby coverings. The Kidderminster carpeting is by far the most common. It consists of two woollen webs, woven together, and intersecting each other at particular parts, so as to produce definite figures of different colours. The manufacture of this species of carpets has been long carried on with advantage in different parts of Scotland. Brussels carpets possess a basis of strong linen threads, on which the pattern in woollen is thrown up in loops, which are kept firm by small rods. When the web is woven, the rods are pulled out, leaving a soft surface of the closed ends of loops. Latterly, a great improvement has been made in Brussels carpet-weaving, and which has also been adopted for shawls. Instead of using threads of any particular colour throughout, and throwing up the threads as they were required to form the pattern, the custom is now to dye the threads with different colours suitable to the pattern required. Thus, a single thread may be dyed in patches of red, yellow, black, or any other colour, and it performs its part in the pattern through its entire length; the saving of material by this ingenious and piebald mode of dying is immense.

When wool is twisted to a certain degree of hardness, it receives the name of *worsted:* and the manufacture of certain fabrics of this kind is as extensive as that of soft woollen goods. Many of the variegated cloths, called *tartans*, are made of worsted, and so likewise are *tapestries*, and some kinds of *stockings*. The stocking or hosiery manufacture, generally, is conducted by means of stocking-frames and hand-labour; the frame having been in universal use since it drove knitting out of fashion about seventy years ago. The cheap hand-labour

Germany acts as a constant check on the progress of the British hosiery manufacture.

PAPER-MAKING.

The earliest kind of paper, or material on which writing was performed, of which we have any account, was the *papyrus*, used by the ancient Egyptians, and hence our modern word *paper*. The papyrus was a plant, from which thin fibrous membranes were stript, and being pressed together, they formed a rude species of small sheets. The Chinese are said to have understood the art of making paper from the pulp of rags in very early times; but whether the European mode of making paper was derived from that quarter, is not clearly known. The art was introduced amid the obscurities of the middle ages, and most likely through the ingenuity of the Arabians. In the beginning of the fourteenth century, a paper-mill was established at Nuremberg, in Germany; and in 1588, a mill was erected at Dartmouth, in England. Little progress was made, however, in the manufacture of paper in this country, it being supplied, till within the last seventy years, principally from France and Holland.

The principle on which paper is made is very simple. A portion of linen cloth is ground to pulp; this pulp is shaken in a fine wire sieve, so as to settle in a thin cake, or sheet; the sheet is pressed in order to squeeze out the liquid; and, when dry, we have a sheet of paper. Instead of new linen cloth, rags, for the sake of economy, are always employed; and the more substantial the rag, so is the paper the stronger in texture. The quantity of rags produced in Great Britain and Ireland being altogether insufficient to supply the demand for paper, large importations take place from continental Europe, chiefly Germany. Cotton rags, or the refuse cotton of factories, are also employed in the paper manufacture; but only for inferior papers, or as an alloy, which is not always justifiable. The processes of preparing the rags, making by hand, and making by machine, may be respectively noticed.

Preparing the Rags.—After the rags arrive at the mill, they are picked and sorted into four or five qualities. All substances not suited for paper-making, or which might injure the machinery, such as pins, buttons, pieces of silk and woollen cloth, must be carefully removed. This greatly facilitates the work of the cutters, who have also to see that the rags are sorted into their proper parcels. In cutting, small table frames are used, the upper surfaces of which are composed of wire-cloth, containing about nine meshes to the square inch. In the centre of these tables a knife or short scythe is fixed, in a slanting direction. Against this knife the females at the tables draw the rags, cutting them into pieces of about four inches square, when they are put into boxes according to the fineness of their texture. During this operation, much dust is beat out of the rags, which falls through the meshes of the wire-cloth. It is calculated that a woman will cut a hundredweight of rags by this method in a day. After the rags are cut, they are put into a cylinder of wire-cloth, measuring about four feet in diameter and five in length. An axis runs through the centre of the cylinder, which is furnished with spokes about a foot long, attached at right angles to the axis. The machine being set in motion, the spokes beat and toss the rags about, which frees them from any dust that may remain after the cutting. When the rags are very dirty, it has been found advantageous to put them into the duster before being cut, which renders that operation easier and more cleanly for the people engaged at the work.

The next operation is that of boiling the rags in an alkaline ley. Sometimes this is done by simply putting the rags into open vats containing the ley, with a fire underneath. Others, however use close boilers, into which steam is admitted by means of a pipe from the top. The alkaline ley is composed of from four to ten pounds of the carbonate of soda to the hundredweight of rags, according to their quality, and a third part additional of quicklime, to render it caustic. Some manufacturers use lime alone, and others pot and pearl ashes, for the purpose of bleaching; but soda and quicklime are the substances generally employed. The rags are boiled for about eight hours in this solution, and are then allowed to cool gradually, it having been found that when the cooling takes place too rapidly, any dirt upon the rags is apt to be indelibly fixed.

After being boiled, the rags are carried to the first washing-engine, which consists of a large oblong stone trough, into which a stream of water is allowed to flow and to escape by the other end. This cleans the rags most effectually, the run of water carrying away any impurities that may still adhere to them. On one side of this trough is an engine, which again washes and grinds the rags, and is termed by the workmen the *breaking-in machine*. This powerful apparatus consists of an elliptical-shaped trough, made generally of wood lined with lead or copper; within it, a grooved roller revolves horizontally over the surface of a sharply-grooved plate, by which the rags are torn to shreds. The grooves on the roller, and those on the plate, act upon the pieces of rags much in the same manner as cutting with a pair of scissors. The trough is half filled with water, which comes in at one end and escapes through holes at another part. The engineer puts the rags into the engine, spreads them with his hands, and by means of agitators at the bottom of the trough, no piece is allowed to escape the action of the roller. These troughs are about ten feet in length, four and a half in width, and two and a half in depth, being capable of holding from 112 to 120 lbs. of rags. The operation of *grinding*, as it is called, occupies about an hour and a half; and when the rags are sufficiently reduced to a pulp, the stuff is passed down from the trough to the draining boxes, by means of a pipe six inches in diameter. This pipe is furnished with a valve at the bottom of the trough, which the engineer opens by means of an iron hook, and through this the pulpy matter flows freely. On reaching the draining boxes, the water is allowed to run off from the pulp previous to the bleaching process.

In the grinding operation a great improvement has lately been effected. It was found that the constant flow of water through the agitated trough of the engine carried off a considerable proportion of the finer particles of the stuff, and thus caused a serious loss. A plan has been invented to lift the waste water by a revolving sieve, which admits the water alone and excludes the stuff, thereby effecting a most important saving to the manufacturer.

Bleaching is sometimes performed by subjecting the pulp to the action of chlorine, which is manufactured from sulphuric acid, sea salt, and the black oxide of manganese. The chamber in which this is performed must be close, so that the chlorine may not escape. A more common method of bleaching, however, is to steep the pulp in a solution of the chloride of lime, by which the fibres are not so much injured as when chlorine is used. In bleaching, great care should be taken that the solution is not too powerful, or the texture of the paper may be materially injured by the process.

The bleaching-house consists of a long apartment, furnished with stone chests about three feet deep, ranged on each side, and capable of containing about fifty-seven cubic feet. These chests have false bottoms pierced with small holes, which can be opened at pleasure, to allow the solution to escape. When the water is drained off the pulp is carried to the bleaching-chests, and about one hundredweight put into each, along with from six to eight pounds of Tennant's saturated chloride of lime

and about twelve gallons of water. The stuff is allowed to steep for twenty-four hours, being frequently stirred in the interval, so that every part may be equally bleached. After bleaching, the pulp is again put into a washing-machine to free it thoroughly from the bleaching-liquor. This process is similar to that previously described, except that the roller is screwed down closer to the fluted plate, so as to reduce the pulp to a finer consistence. In making what is called machine-paper, the size is now added, the addition or the want of which constitutes the chief difference between the paper for the reception of ink and the other sorts. The kinds of size principally used consist of either white soap, starch, glue, or dissolved rosin, with the addition of a few pounds of alum. The size is strained through a sieve into the beating-engine, and there mixed with the pulp.

From the second washing or beating-machine, the pulp is passed down to a large tun or vat called the *stuff-chest*, which is merely a reservoir to keep the pulp till it is put into the machine which converts it into paper. This vat is furnished with agitators at the bottom to keep the pulp of an equal thickness, which now bears a strong resemblance to curdled milk. Previous to being put into the vat, however, it is now almost universally the practice to strain the pulp through bars of brass. These are planed perfectly smooth at the edges, and placed so closely together, that the fibrous part of the matter must pass through longitudinally. By this means, knots, &c., are kept out, which it formerly cost considerable trouble to scrape from the surface of the paper after it had been manufactured.

Making Paper by Hand.—This is the old method of making paper, which is now completely exploded, except for some kinds of writing and coarse packing papers. The pulp is prepared without size, that being imparted afterwards to the sheets by dipping them in a tub. Properly prepared, the pulp runs into a vat, at one end of which stands the vatman with two frames or moulds beside him, made of brass wires or wire-cloth, fixed upon a wooden frame, of the size of the sheet to be made. The vatman holds in his hand a frame of wood called a *deckle*, which fits exactly all round the edge of the mould, for the purpose of giving a clean edge to the paper. For making what is called wove paper, a wire-cloth is required. For laid or corded papers, however, the mould is made of brass wires lying longitudinally, crossed by wooden bars placed underneath, and interlaced by cross wires somewhat thicker than the longitudinal ones.

The vatman, laying the deckle upon the mould, dips it into the vat, and takes up a quantity of the pulp. If he considers there is too much in the mould, he throws off part of it, and then, holding the mould horizontally, he shakes it to and from him, which connects the fibres together, and renders the fabric of an equal thickness throughout. The water flows through between the wires, and as soon as the pulp has attained a degree of consistence, the vatman lifts off the deckle, and hands the mould to the coucher, who stands at the other corner of the vat. The coucher places the mould in an inclined position for a few seconds, so that as much water may flow from the pulp as possible. He then puts a piece of felt or blanketing upon a wooden board, and turning the mould over upon this, the pulp adheres, and the mould is handed back to the vatman. Another felt is placed upon the top of the pulp laid down, and the process is continued until what is termed a *post* is completed. A strong board is then placed upon this, and the whole is put under severe pressure, in order that the water may be thoroughly extracted. When the paper is taken out of this press, it may be handled, and the sheets are taken from between the felts and placed by themselves. Another pressing is then given, slighter than at first, for if too severe, the sheets are apt to stick so closely together that they cannot be afterwards parted without injury. After this pressing, the sheets are carefully separated from each other, and again pressed, previous to being sent to the drying loft. In making the finest writing-paper, this separation and pressing is performed twice, which considerably improves the texture of the paper.

The next process is drying, which is done in a loft containing a number of spaces filled with hair-ropes fixed into spars of wood, the ends of which slide up and down upright posts at the corners of each space. Five or six sheets of paper are hung together upon these ropes and allowed to dry. The air is freely admitted by the sides of the loft, which are sparred with shutters, to close out the air entirely, in case of bad weather; and each loft is provided with pipes, which go round the room, and can be filled with steam, so that the drying process may go on at all times.

When the paper is quite dry, it is sent to the sizing house, where it is made suitable for receiving ink. The size is made from the parings of skins, &c., which are boiled for about ten hours to reduce them to a gelatine. The gelatine is carefully strained; about a fourth of its weight of alum is then added, and the mixture is allowed to congeal. When used, it is diluted with water, and an additional supply of alum put in. The workman then takes about six quires of paper in his hand, and dips it into the tub containing the size, where it is allowed to remain for a few minutes, so that every sheet may be well soaked. The sheets are carefully lifted out one by one, and put into a press, which is slightly screwed down, that the surplus size may flow out. In order that the sheets may be easily separated, the edges are washed with hot water; and when taken out of the press, each sheet is laid between woollen clothes, in the same manner as when the paper was first taken from the mould. When strongly sized, the sheets are again separated carefully, and kept about forty-eight hours before being hung up to dry.

When sized and dried, the paper is taken to the finishing-house, where it undergoes several pressings to smooth the surface. It is then sorted and put up in reams, consisting of twenty quires of twenty-four sheets each, or 480 sheets.

Making Paper by Machines.—From the vat or stuff chest, the pulp, prepared as already described, is let out by a sluice into a pipe which leads it to one end of the *making-machine*. The opening from this corresponds exactly with the breadth of the machine, and the quantity and thickness of the stuff admitted into the latter is regulated according to the kind of paper to be made.

The machine now in general use for the making of paper is the invention of Mr. Louis Robert, and was brought to this country about forty years ago, by a M. Didot, who, with the assistance of MM. Fourdrinier, and Mr. Dorkin the engineer, greatly improved the invention, and obtained a patent for it.

The first part of the machinery upon which the pulp comes is a brass wire-cloth, of so fine a texture that there are seventy wires in the inch, and which is woven in the same way as linen. This wire-cloth may be described as a sort of belt without any break, which is kept continually revolving, but in such a way that the upper side upon which the stuff is received preserves a flat and horizontal surface. The wire-cloth moves upon a number of small copper rollers, which have an agitating horizontal motion, and this distributes the stuff equally over the cloth, giving a uniform strength and thickness to the paper. After passing between a pair of rollers, where it delivers the stuff, it is led backwards again under the frame; and so goes on in a continuous revolution. Movable sides are attached to the upper surface of the wire, which regulate the breadth of the sheet to be manufactured.

The first pair of rollers through which the stuff passes

are called the couching rollers. The under roller is simply cast-iron, while the upper one is covered with woollen cloth of a peculiar texture, manufactured for the purpose. It is upon this upper one that the stuff is delivered. The pressure from these rollers is slight; and the pulp is next led on to an endless felt, and passes between two cast-iron rollers. The machinery of this felt must be so regulated, that it will go with the same speed as the wire-cloth and couching rollers, otherwise confusion would ensue. In passing through the first pair of rollers, only one side of the stuff is rendered smooth; but in the second pair it is reversed, and the rough side is now pressed. These rollers are closer than the first pair, and the pressure being greater, the sheet is now more dry and firm. It often happens that, in passing from these rollers to those that succeed them, the paper breaks, and adheres to the woollen cloth; in the event of which, should the broken parts be carried round on the surface of the roller, they would inevitably injure the part of the sheet which follows. To prevent this casualty, there is affixed lengthwise, along the upper surface of the roller, a large knife, called the *ductor*, resembling in breadth and sharpness a common scythe, the edge of which, being placed in a sloping manner, like the blades of a wright's plane, is brought so close to the roller, as effectually to shave off any substance that may chance to adhere to it.

The sheet next passes through two other pairs of rollers, which press out the water, and render the paper smooth and firm. It is then carried to the drying cylinders, which are hollow and filled with steam, introduced by pipes placed at both ends of their axes. When these cylinders are too hot, the paper will be observed to shrivel; and by an ingenious contrivance, the extra steam can be let off, so as to reduce the temperature. The water which collects in the cylinder is carried off by means of an instrument shaped like a cork-screw, and which is wrought by the machinery. The paper is again passed through a pair of rollers, to smooth it after being dried, and is then wound upon a reel. As one reel is filled, it is taken off and another put on in its place; and it is evident that the paper can be made of any length the reel is large enough to hold.

The whole machinery upon which the process we have described is performed, is about fourteen feet in length, and moves at the rate of from twenty-five to forty feet per minute. At one end is seen running in a stream of liquid resembling curdled milk, and at the other comes out a finished fabric, the time required for manufacturing thirty feet of which is little more than a minute. Near the extremity of the machine is usually placed an apparatus for receiving the reels of paper in web, and drawing out and cutting the web into sheets according to the regulated size. The sheets are then sorted and packed up in the usual manner.

By the operations now described, all the printing papers and also letter papers of an ordinary kind are now made, and that to an immense extent. "Suppose," says a writer on this subject, in the "Encyclopædia Britannica," "that a machine makes ten yards lineal of a web per minute, or 600 in the hour, this is equal to a mile in three hours, or four miles per day of twelve hours. The paper is generally made about fifty-four inches wide. Reckoning that there are 300 machines in Great Britain, and that they work twelve hours a day on an average (many go both by day and night), the length of web would altogether be equal to 1200 miles, and the area of what was made would be about 3,000,000 yards daily."

GLASS MANUFACTURE.

The origin of glass manufacture is involved in the greatest obscurity, and has given rise to much ingenious speculation, upon which little or no dependence can be placed. Glass beads have been found on the bodies of Egyptian mummies, which are known to have been embalmed three thousand years ago. Pliny says, that the art of glass-making was accidentally discovered by some shipwrecked Phœnician mariners, whose vessel was laden with fossil alkali, a component part of glass. On kindling a fire on the sand to prepare some food, and placing their cooking vessels on pieces of the substance just named, the sand, by the agency of the fire and its union with the alkali, became vitrified, and hence, according to this authority, the discovery of the art of glass-making.

The first glass manufactory of any note was established at the village of Murano, near Venice. The glass produced here was superior to any in Europe, and for a long time the principal supply was obtained at this place. The Venetians were long celebrated for making mirrors, which they brought to considerable perfection. Window-glass appears to have been made in England in the middle of the fifteenth century, but it was of an inferior description. In 1557, the finer sort of window-glass was manufactured at Crutched Friars in London. The first flint-glass was manufactured at Savoy House in the Strand; and the first plate-glass for mirrors, coach-windows, &c., was made at Lambeth in 1673, by Venetian workmen brought over by the Duke of Buckingham. Glass-making was introduced into Scotland by James VI.

The art of staining or colouring glass is believed to be coeval with the discovery of the article itself. It is certain that it was known in Egypt several thousand years since, and tradition gives the honour of the discovery to an Egyptian king. The art of combining colours so as to produce pictures is of more recent date. The early specimens of stained glass exhibit a series of different pieces of various colours, joined together like mosaic work, so as to bring out the representation desired. This can now be done on one entire sheet. For a long period, the pictured glass used in cathedrals, &c., was merely painted on the surface, and was consequently liable to be rubbed off. The colours now are incorporated by fusion, and cannot be obliterated but by the destruction of the glass itself. The discovery of this art is ascribed to a painter in Marseilles, who went to Rome during the pontificate of Julius II. It was afterwards greatly improved by Albert Durer and Lucas of Leyden.

All the pigments used in painting on or staining glass are oxides of metals or minerals, as gold, silver, cobalt, &c., which, after being laid on, are subjected to a strong heat, until they penetrate into the body of the glass, or become fixed on its surface, and thus give out their fullest brilliancy and transparency. Animal and vegetable matters, which are freely used as colouring in ordinary painting, are wholly excluded in this, as the operation of the fire would entirely destroy their colouring properties. The colours that are meant to penetrate into the glass for the purpose of staining it are wholly transparent, while those which are merely fixed upon the surface are only semi-transparent. Any colour or tint can be communicated to the glass in this way, and the art is at present practised with great success. The description of glass best adapted for painting upon or staining, is the finest crown or window-glass.

A glass-house is usually built in the form of a cone, from 60 to 100 feet high, and from 40 to 80 feet in diameter at the base. The furnace is placed in the centre of the building, and is generally of an oblong figure, although sometimes circular. Below the furnace is an arched gallery, extending right across the building, and terminating in folding-doors, large enough to admit a barrow for carrying out the ashes. In the sides of the furnace are apertures called working-holes, through which the materials are put into the pots, and the blowing-tubes inserted. In a crown-glass manufactory, the furnace generally contains from four to six pots; but this will also

gether depend upon the size of the building. The stone used in constructing glass furnaces must be of the finest grain, that called fire-stone, got from Coxgreen, in the neighbourhood of Newcastle, is considered the best for this purpose.

Crown or window-glass is usually composed of kelp and fine white sand, but pearl ashes and other alkalies are sometimes used instead of the former. Kelp is made by burning sea-weed, which is cut from the rocks for this purpose in the months of May, June, and July. After being spread out and allowed to dry for some time, it is gathered together and thrown into a pit, where it is reduced to a state of fusion by fire. When cool, the kelp is a hard solid mass, and must be broken into portable pieces for convenience. In preparing the kelp for glass-manufacture, it is broken by a machine called a *stamper*, afterwards ground in a mill, and then passed through a hair sieve. The best kelp is said to be that made in the Orkneys; and it is also manufactured in large quantities both in the West Highlands and in Ireland.

The best sand for glass-making is that which contains most transparent particles, and this is found in large quantities in that brought from Lynn Regis in Norfolk, and the western coast of the Isle of Wight. The sand is put into a large vat, and boiling or cold water poured upon it until the water runs off clear. It is then subjected to a red heat for twenty-four hours, and immediately on being taken out is plunged into cold water, which divides the particles of sand, and makes it unite more readily with the alkali. Some put nitre amongst the sand during this process, which consumes any sulphur or other extraneous matter which may be present. The sand and kelp are next mixed together, in the proportion of eleven parts of the former to seven or eight of the latter. It is now, however, becoming very common to use the carbonate of soda and lime instead of kelp in the manufacture of crown-glass; and from these alkalies being much purer than kelp, a better article is produced.

When the sand and alkali are properly mixed together, the compost is put into the calcining arch or reverberatory furnace, where it is reduced by heat to a semi-fluid state. This process requires from three to four hours, and the *frit*, as it is now called, is taken out, placed upon an iron plate, and cut into cakes before it becomes quite cold. The calcining furnace is generally about ten feet long, seven feet wide, and two feet high. The sides and top are built of fire-brick, and the rest of common brick; and the bottom must be carefully cemented, to prevent the frit from oozing through the seams. It is the opinion of most glass manufacturers, that the frit should be kept for about six months before it is used. If glass is made from new frit, it is full of what are called seeds, the presence of which depreciates the quality of the ware.

The frit is next put into the melting pot, along with a proportion of what is called cullet, which is nothing more than broken crown-glass. The melting pot is formed of the finest clay, that obtained at Stourbridge, in Worcestershire, being considered the best adapted for this purpose. The clay is freed from all extraneous particles, which, if allowed to remain, would injure the pot, and about a fourth part of old crucibles ground into a fine powder is added. Pots made from this mixture resist heat much better than when altogether formed of the virgin clay. The pots are very gradually dried, being generally kept for nine or twelve months at a temperature of about fifty degrees. They are afterwards tested in a furnace before being used, and last upon an average for from eight to ten weeks.

When the frit and cullet are put into the pots, the furnace is heated to as high a temperature as possible, until the metal is reduced to a liquid state. It is then skimmed of all extraneous substances which may be floating on the surface, and is fit for the operations of the workmen. An iron tube, six or seven feet in length, thicker at one end than the other, is heated and dipped into the liquid metal. A portion of glass adheres to the end of the rod, which, being allowed to cool a little, is again dipped in, and gathers more. The rod is then taken out and hung perpendicularly, that the metal may be equally distributed on all sides, and also that it may be lengthened out beyond the rod. The metal is next rolled upon a smooth iron plate called the *marver*, and afterwards blown out slightly, so as to resemble a pear in shape. The blower then heats the metal twice, blowing it out between the heatings, when it is brought to a globe shape. The glass is then allowed to cool a little, and a rod of iron, called the *punty rod*, is attached to the side immediately opposite to the tube. This is done by dipping the end of the rod in the liquid metal, which adheres readily to the half-cooled glass, and the tube is detached by touching it with a piece of iron dipped in cold water, leaving an aperture in the glass about two inches in diameter. The glass is again put into the furnace until it has become sufficiently ductile to yield readily to any impression. The workman then twirls the globe round slowly at first, but afterwards with great velocity, during which the aperture formerly mentioned gradually widens until it reaches a certain point, when the globe suddenly flies open with a loud ruffling noise, and becomes a plane or circular sheet of glass, about fifty inches in diameter. This is an exceedingly beautiful operation, and requires considerable skill on the part of the workmen. The circular motion is still continued, until the sheet is sufficiently cool to retain its form, when it is carried to the annealing arch to be tempered. The punty rod is detached by means of large shears, and the sheet of glass is lifted on a wide-pronged fork, and set up edgewise in the kiln. A kiln will hold from four to six hundred sheets. When full, the mouth is built up, the fire withdrawn, and the kiln allowed to cool as gradually as possible. The glass is taken out, the circular sheets cut into halves, and assorted into different qualities, known by the names of *firsts*, *seconds*, and *thirds*.

SHEET-GLASS.

The process we have described is altogether applicable to crown or window-glass, but the manufacture of sheet-glass is somewhat different. In making sheet-glass, the same materials are used as in crown-glass, the difference being in the manner of forming the sheet. When the metal is melted, the workman dips his tube into the pot, and when he has gathered a sufficient quantity of the liquid glass upon it, he places it in a horizontal position upon a hollowed block of wood. He turns the rod round in his hand, with the metal resting upon the hollowed block, which forms it into a solid cylindrical mass. Water is poured upon the block during this operation, the action of which upon the glass gives great brilliancy to its surface. If the glass was only red hot, on coming in contact with the water it would crack, but at the great heat at which it must be kept so as to be ductile, no injury takes place. When the metal is sufficiently formed and cooled, the workman blows into the tube until he perceives the diameter to be of the dimensions required, which depends upon the size of the sheet to be made. The metal is again put into the furnace, and when softened, the workman swings it round his head, reheats and continues to swing it, until the cylindrical mass has attained what he thinks a sufficient length. He then fills the tube with air, and closes up the hole, so that none may escape; after which the metal is again put into the furnace, and as it becomes soft, the air bursts from the end opposite to the tube, leaving an aperture. The cylinder is then turned round very quickly, which renders it perfectly straight; and then, by applying cold iron to the end of the glass next the tube, a sudden contraction takes place, which separates the cylinder of glass from the iron tube. The cylinder thus formed is allowed to cool for about five seconds, and it is then split up lengthwise by

drawing a red-hot iron rod along the inner side. The glass has next to be flattened, which is done by softening it in a furnace upon a smooth plate, where, as it begins to melt, it gradually opens, and is smoothed with a piece of charred wood. It is then put into the annealing furnace to be tempered, in the same manner as crown-glass.

Sheet-glass may be made of any thickness, and possesses considerable advantages over crown-glass. It has none of that wavy appearance too often seen in crown-glass, and a larger square can be obtained when the sheet is formed. It is difficult to get a sheet of crown-glass which will yield a square 34 inches by 22, whereas the common size of sheet-glass is 40 inches by 30.

PLATE-GLASS.

The manufacture of plate-glass requires greater care than either of the two preceding kinds, and the process is different—the plate-glass being moulded, and not blown, as is the case with other kinds of glassware. The sand made use of must be the finest that can possibly be obtained, and requires to be well washed, to free it from impurities, and passed through a fine sieve, previous to being mixed with the other ingredients. At St. Gobin, in France, crystallized carbonate of soda is used as the alkali; and at Ravenhead, near St. Helen's, Lancashire, the soda is obtained by treating sea-salt with pearl-ash, the result of which is carbonate of soda and muriate of potash. The latter body is easily got rid of, as it crystallizes at a higher temperature than the carbonate of soda. The soda thus prepared is exceedingly pure, and well adapted for glass manufacture. To these are added dry slaked lime carefully sifted, and cullet, as in crown-glass making. The following proportions are stated by Dr. Ure to have uniformly yielded a beautiful glass:—"Sand, 7 cwt.; quicklime, 1 cwt.; dry carbonate of soda, 2 cwts. 37 lbs.; and about the same quantity of cullet as there is sand."

These materials are generally fritted before being melted; but at St. Gobin, in France, this is sometimes dispensed with. Two kinds of crucibles are required in the manufacture of plate-glass; namely, the pots in which the materials are melted, and the basins from which it is poured upon the moulding plate. These crucibles are made from a clay entirely free from iron and lime, and which is dried, ground, picked, washed in water, and passed through a fine hair sieve. Old crucibles ground to a powder are mixed with the clay in proportions according to its quality. This composition, when prepared, is called *slip*, and is also used for cementing the furnaces.

The materials of which the glass is composed are first put into the pots to be fused, which occupies about sixteen hours, and then transferred to the basins. The transfer of the melted glass from the pots to the basins is called *lading*, and is performed by ladles of wrought iron furnished with long handles. This second melting is called *refining;* and the glass is allowed to remain other sixteen hours, which is necessary for the disengagement of the air-bubbles introduced by the transferring, and for giving the metal the proper consistence for casting. For three hours previous to the casting, all the openings in the furnace are closed—an operation called *stopping the glass*, or *performing the ceremony*. The glass is tried; and if found of the proper consistence, and free from air-bubbles, the basins are carried to the casting table.

This table was formerly made of copper or bronze, but cast-iron is now found to answer the purpose better. It is about ten feet long, five feet broad, and from six to seven inches thick, supported by a wooden frame which rests on iron wheels. Along the sides of the table are two parallel bars of bronze, which support the roller in its progress, and determine the thickness of the glass. The roller is made of bronze, and is run along the table after the glass is poured on, to spread it equally. When the liquid glass is poured upon the table, two men run the roller slowly and steadily from one end to the other and after two plates have been formed, the rollet is allowed to cool. The plate of glass is next inspected, and if any air-bubbles appear, it is cut through, and is then put into the annealing furnace, where it remains for fifteen days.

When tempered and cooled, the rough edge is cut off the glass by means of a diamond, and the plates are sorted according to their sizes; it being necessary, when air-bubbles occur, to cut a larger piece from one than from another. The next step is the grinding of the surface, which is done by cementing the glass upon a horizontal table made either of freestone or wood. One plate is then reversed and suspended over another, and ground flint is introduced between them. The suspended plate is fastened upon a conical stone, with a ball at the top for the workman to hold it by. When machinery is used for this process, the upper plate is fastened to a square of cast-iron, which receives a rotary motion similar to that communicated by the hand. When one side has been sufficiently ground, the plates are reversed, and the same operation performed on the other. By this grinding, the plates have been rendered perfectly level, but they have still to be smoothed before receiving their polish. For this purpose, they must be again ground with emery powder, of increasing degrees of fineness. The glass is then polished on both surfaces by means of a piece of wood covered with layers of woollen cloth. The glass is fixed, as before, upon the stone table, and a quantity of the red oxide of iron (the colcothar of commerce) is laid on, and the surface is well rubbed with the covered wood. Plate-glass is extensively manufactured into mirrors, which is done by applying a layer of tinfoil alloyed with mercury to their posterior surface.

FLINT-GLASS, OR CRYSTAL.

Flint-glass, or crystal, is composed of Lynn sand, which is calcined, sifted, and washed for the purpose; red lead or litharge, and refined pearl-ash. It was formerly made of calcined flint, but the finest Lynn sand has been found to produce a clearer ware, and is therefore preferred. The proportion of these materials varies in almost every manufactory, but the following receipts are stated, on good authority, to produce an excellent article:—

1.	Fine white sand	300 parts.
	Red lead or litharge	200
	Refined pearl-ashes	80
	Nitre	20
	Arsenic and magnesia a small quantity.*	
2.	Siliceous sand	3 parts.
	Minium (litharge)	2
	Carbonate of potash	1½

To these must be added a considerable quantity of cullet, or broken crystal—about a third or a fourth of the weight of the whole being thought necessary.

A flint-glass furnace varies little from those described for other kinds of glass, except that it is round in the top. The pots in which the glass is melted are larger at the top than the bottom; and the top is arched over that no dust may fall in, with a hole at the side for the insertion of the tube. When the glass is sufficiently melted, the tube is inserted, and a quantity lifted out upon its point in the same manner as for crown-glass. After being rolled upon the marver, the glass is blown out to a globe shape, when the punty rod is attached, and by means of an instrument resembling a pair of sugar-tongs, the glass is moulded to the form required. The shapes into which flint-glass is manufactured are so numerous, that it would be almost impossible to describe them all. The operations are extremely simple and beautiful, and are performed with a rapidity which is truly astonishing. The workman is furnished with a pair of compasses and a graduated scale, to measure the article which he is making, by which they are kept to a uniform size. When finished, the articles are all weighed, to see that the right quantity

* Ure's Dictionary of Arts.

of glass has been used in their manufacture, and after this they are put into the annealing furnace.

A very beautiful kind of crystal vessel has been made recently, which is clear in the inside and coloured without. This is done by dipping the tube into a pot of clear glass first, which is blown out and allowed to cool a little. The globe thus formed is then immersed in coloured glass, which readily adheres when it is made into the shape required. Small white figures are also sometimes put on to the sides of vessels. This is done by placing the figure upon the glass while hot, and covering it with a thin layer of liquid crystal, through which the white figure shines. Optical glasses are made from crystal, in which case the utmost care is necessary to keep the metal entirely free from waves, otherwise the glass will be useless.

What is called glass-cutting, or grinding, is a separate trade from blowing in all glass manufactories. The cutting-wheel is driven by means of a belt proceeding from a large drum attached to an engine or other moving power. Above the cutting-wheel is a conical box, from which wet sand drops upon it, while another is placed below to receive the sand as it falls from the wheel. The wheels used are three in number: the first is made of cast-iron, by which the rough glass is ground; the second of Yorkshire stone, by which the vessel is smoothed; and the third of willow-wood, by which the final polish is communicated. For this latter purpose, the wooden wheel is dressed with rotten-stone or pumice-stone; and for imparting the highest degree of polish, putty powder is used. These wheels are of various forms, according to the shape of the vessel to be cut: they may be broad or narrow, flat-edged, two-edged, concave, convex, &c. The cutter holds the glass to the wheel while it is revolving, and the most beautiful and regular figures are engraved in this manner with astonishing rapidity.

BOTTLE-GLASS.

Bottle-glass is composed of the coarsest materials, generally soap-makers' waste and sand. The following receipt is recommended by Dr. Ure as producing a fine dark-green glass:—Dry glauber salts, 11 lbs.; soaper salts, 12 lbs.; half a bushel of waste soap ashes; sand, 56 lbs.; glass skimmings, 22 lbs.; green broken glass, 1 cwt.; basalt, 25 lbs. The furnaces for preparing bottle-glass are similar to those used for crown-glass.

When the metal is melted the pots are skimmed, and the workman introduces his tube. When sufficient is gathered upon the end of the tube, the blower rolls the glass upon a stone, blowing into it at the same time. He then puts the metal into a brass or iron mould of the shape of the bottle to be made, and blows through the tube until it comes to the desired form. This mould is so contrived as to open down the middle by means of a spring which the blower works with his foot. The mould is open when he puts in the metal at first; it is then immediately closed, and opened again when the bottle is formed, which is handed over to the finisher. The finisher detaches the tube from the mouth of the bottle, and fixes the punty-rod to the bottom. He then warms the bottle at the furnace, and takes out a small quantity of metal, which is turned round the upper part of the neck, and forms the rim usually seen on bottles. The finisher next employs a pair of shears to give the right shape to the neck: on one of the blades of the shears is a piece of brass resembling a cork, by which the inside of the neck is formed. The bottles thus finished are sent to the annealing arch, which is kept a little below melting heat until full, when the fire is allowed to die out.

The instrument universally employed in cutting window-glass is the diamond, which is set into a metal socket attached to a wooden handle for this purpose. The cutting point of the diamond must be a natural one; artificial points, as well as those produced by breaking the diamond, only scratch the glass, without producing the deep cut which is necessary. The best diamonds for cutting glass are called *mother sparks*, which are sometimes cut down into a number of small sparks, with a natural point to each. It is thought better that a cutting diamond should be made of a large spark, for when one point is worn out, it can be turned and reset, when another fresh point is obtained. The diamonds used are known by the technical name of *bort*—that is, all such pieces as are too small to be cut, or have a bad colour, and are consequently unfit for ornamental purposes.

MANUFACTURE OF EARTHENWARE, OR POTTERY.

Pottery may be generally defined as the art of making vessels from clay, or from other mineral substances ground and rendered plastic like that body. The manufacture of porcelain or china is not included in this definition, inasmuch as it is semi-vitrified, and becomes translucent in the kiln. Stoneware with a painted gluze seems to have been first attempted by the Arabs in Spain, about the ninth century. Soon after, it found its way into the island of Majorca, where considerable progress was made in the art. From Majorca, it was introduced into Portugal, Italy, and France, and from the last into Holland. In the seventeenth century, a pottery was established at Burslem, in Staffordshire, at which, however, only the coarsest articles were manufactured. In 1690, two Dutchmen of the name of Elers introduced the method of glazing ware by the vapour of salt, which they cast in by handfuls amongst heated articles in the kiln. The late Josiah Wedgewood, however, was the first who made any great improvement in this branch of manufacture. It was he who erected the first large factories in Staffordshire, and who, from his extensive chemical and mechanical knowledge, has made the stoneware manufactures of this country superior to those of every other.

The best clay for stoneware manufacture is obtained in Dorsetshire, and another of a quality somewhat inferior is got in Devonshire. These clays are both well suited for the potter, being easily worked, standing the fire well, and becoming very white when burnt. According to an analysis of Mr. Wedgewood, the porcelain clay of Cornwall contains sixty parts of alumina, or earthy matter, and twenty of silica. When dug from the pit, the clay should be cleaned as much as possible with the hand, and freed from stones. At the factory it is cut to pieces and put into a cast-iron cylinder, about four feet high and twenty inches in diameter. An upright shaft or axis revolves in this cylinder, from which knives radiate in all directions, being so placed that the shaft with the knives attached somewhat resembles a screw. In the sides of the cylinder knives are also fixed, which reach nearly to the shaft and remain inactive. When the shaft moves round, the active blades cross the passive, and operate like shears in cutting the clay, which is by this process reduced to a fine pulp. When well ground in this manner, the clay is of the consistence of cream, and is run off through sieves of wire, lawn, and silk, so that none of the grosser parts may enter into the composition of the ware. This liquid clay is then diluted to a standard density, and set aside in cisterns to be used as required.

Vessels made from clay alone, however, are found to crack upon being put into the kiln; and to prevent this, it is necessary to add some siliceous substance, incapable of contraction, to the clay. Ground flint is most commonly used for this purpose. It is prepared by cleaning the flint found imbedded in chalk, subjecting it to a red heat, and throwing it in this state into water, by which it becomes comparatively soft. It is then broken by being placed under an upright shaft, which moves up and down in a frame, and is called a *stamper*. The broken

flint is next transferred to the flint-mill, which consists of a strong wooden tub, built round a circular bottom composed of flat pieces of horne-stone. On the top of these, similar flat stones are laid, which are attached to and driven by strong wooden arms projecting from an upright shaft in the centre of the box. Into this tub the flint is put, and a stream of water is constantly running in which greatly facilitates the grinding. When the flint is reduced to about the consistence of cream, it is passed through sieves in a similar manner to the clay.

The flint and clay liquids are then mixed together in such proportions that the flint powder will be to the dry clay as one to five or six, according to the plasticity of the clay. Sometimes a little Cornish stone is also added; and the following are the proportions generally adopted in one of the principal Staffordshire factories:—

For cream colour—

Silex, or ground flint - - -	20 parts.
Clay - - - - - -	100
Cornish stone - - - - - -	2

The mixture is put into oblong stone troughs called *slip kilns*, bottomed with fire-tiles, and placed above a furnace flue. Heat is then applied and the water gradually evaporated, the liquid being constantly stirred during the operation. By this process the mixture is formed into a fine uniform doughy mass, which is cut into pieces and heaped together in a damp cellar, where they lie for the space of about six months. The clay here becomes black, exhales a fetid odour, and is supposed to undergo a slight degree of fermentation. The longer the clay is kept the finer it is in the grain; and vessels made from it when old are not so apt to crack as the ware formed from newer paste.

Another operation, called *sloping*, or *wedging*, greatly assists in forming a fine quality of clay. This consists in seizing a mass of clay in the hands, tearing or cutting it into two pieces, and striking them together again with a force sufficient to make them adhere. This is repeated about twenty or thirty times, by which the parts of the clay are completely intermingled. In large establishments, this operation is performed by means of a tub, with an upright revolving shaft, on which blades are fixed, the machine being similar to that used when the clay comes first from the pit. The clay is forced by the downward pressure of the blades through a pipe, and is cut into equal lengths, and again returned to the cylinder until the parts are blended together. It is sometimes the practice to beat the clay with wooden mallets; this practice is common in France, and the stuff is afterwards trodden by the feet on a clean floor. In China and Sweden, oxen are made to tread upon the clay, to form it into a proper dough.

A process called *slapping* is performed by cutting a large mass of clay with a wire, and striking the two pieces together with considerable force. This is generally done as the clay is to be used, either in the same apartment in which the manufacturing process is performed, or in an adjoining one.

The clay being thus completely kneaded, is put upon the potter's lathe, where it is formed into articles of various shapes. This lath consists of an upright iron shaft, the lower point of which turns in a socket, and the upper is fixed in a broad wooden disc. Near the top the shaft passes through a socket attached to the framework of the lathe. In the centre is a pulley with grooves of different circumference, by which the speed of the shaft can be increased or lessened as circumstances require. This shaft is driven by a fly-wheel, from which an endless belt passes to the pulley.

The clay is weighed out and handed to the workman at the lathe, called the *thrower*, who dashes the mass upon the revolving wooden disc. He then dips his hands frequently into a dish of water placed beside the lathe, and pressing the clay with both hands, it gradually assumes an irregular conical form. By pressing one hand upon the top of this cone, it is again flattened down to a cake, by which operation all air-bubbles are extricated. He next lessens the speed of the shaft by shifting the belt from a small to a larger groove in the pulley, and forms the clay into the shape of the vessel required. This operation is called *throwing*; and when performed, the vessel is cut off from the disc by a wire attached at each end to a piece of wood. The vessel is then allowed to dry gradually, until it arrives at a certain point called the green state, after which it is put upon the turning-lathe. Here it is turned to its proper shape by a sharp tool which also smoothes it, and after this it is burnished with a steel surface.

In the green state, also, are attached handles and other appendages to vessels, this being the point at which the clay possesses its greatest tenacity, till it is burned. Handles of teapots, &c., are formed by squeezing the dough through different shaped orifices, which, as it issues, is cut into proper lengths and bent into the desired forms. These, being formed, are attached to the vessels by a paste called *slip*, and the seams are smoothed off with a wet sponge. The ware is next placed in an apartment heated to about 90° Fahrenheit, and fitted all round with shelving. When completely dry, they are rubbed over with hemp, and are then ready for the kiln.

The articles made in the manner above described are all of a round form; but there are many which are of a different shape, and require a different process in the manufacture. Oval-shaped vessels are formed by what is called press-work, which is done in moulds made of plaster of Paris. One-half of the pattern is made in the one side of the mould, and the other half in the other side. The parts are formed to fit each other exactly, and are joined in the same manner as the handles are to vessels. Imitations of flowers and foliage are executed in moulds of plaster of Paris. The clay is poured into the mould in a thin state, and is left in the mould for a certain time. The plaster soon absorbs the water, which renders the clay tough; and its thickness depends upon the time it is allowed to stand in the mould. These *furnishings*, as they are called, are then dried to the green state, and fastened on with slip.

When the ware is ready for the kiln, the articles are placed in baked fire-clay vessels called *saga*, or *saggers*. These vessels are made by the workmen during the intervals of their work, and are from six to eight inches deep, and from twelve to eighteen in diameter. The sags are packed full of the dry ware, and are then piled above each other in the kiln, the bottom of one sag forming the lid of another. These dishes are necessary to prevent the ware from being suddenly and unequally heated, and also to protect them from the smoke of the kiln.

The body of a pottery kiln is generally formed of a conical shape, and inside of this is the fire-kiln, which is circular and round at the top. When the kiln is filled with the sag, the door-way [illegible] and fire applied to the furnaces. The heat is [illegible] gradually, from the time the fire is put on till the ware is found to be properly burnt. To ascertain this, the workman draws from the kiln what is called a watch, and if this is found to resemble in colour a previously burned vessel, he allows the kiln to burn a little longer, and then opens the doors of the furnaces carefully, so as to lower the heat by slow degrees. The burning, or *baking*, as it is called, usually lasts from forty to forty-two hours, after which the kiln is allowed to cool very slowly. When the ware is taken out of the sags, a child makes the pieces ring with the handle of a brush used for dusting them, and then immerses them in the glazing material. The glaze is kept in a large tube, into which the articles are put by the child, and lifted out by a man who shakes them in the

air, and places them on a board to be conveyed to the glazing kiln.

"Three kinds of glazes are used in Staffordshire—one for the common pipe-clay or cream-coloured ware, another for the finer pipe-clay ware, to receive impressions, called *printing body*: a third for the ware which is to be ornamented by painting with the pencil. The glaze of the first, or common ware, is composed of 53 parts of white lead, 16 of Cornish stone, 36 of ground flints, and 4 of flint-glass: of the second, 26 parts of white felspar, fritted with 6 parts of soda, 2 of nitre, and one of borax; to 20 pounds of this frit, 26 parts of felspar, 20 of white lead, 6 of ground flints, 4 of chalk, 1 of the oxide of tin, and a small quantity of the oxide of cobalt, to take off the brown cast and give a faint azure tint, are added. As to the stoneware which is to be painted, it is covered with a glaze composed of 13 parts of the printing colour frit, to which are added 50 parts of red lead, 40 of white lead, and 12 of flint; the whole having been ground together."*

The above compositions make a very clear, hard glaze, which is not affected by vegetable acids, and preserves its lustre for an indefinite time. When covered with the glaze, the vessels are put into sags, which have been previously glazed, with a composition of 13 parts common salt, and 30 parts potash. They are then put into the glazing kiln, which is usually smaller than the biscuit kiln, the sags being piled in the same manner as at the first burning. The heat of the glazing kiln is very low at first, but gradually increases until it reaches the melting-point, when great care is necessary to prevent the temperature from suddenly falling. To ascertain when the temperature is high enough, balls of red clay coated with fusible lead enamel are employed. When these balls become of a slightly dark-red colour, the temperature is sufficient to glaze ordinary pipe-clay ware. The fire is kept on for about fourteen hours, after which very little fuel is added, and the kiln is gradually allowed to cool. The vessels are again tried by being slightly struck by a small wooden hammer, when, if they ring freely, they are sound.

There are two ways of colouring pottery ware—either before glazing or after. The printing under the glaze is generally performed by means of the oxide of cobalt, which is purified either by calcining or boiling it in nitric acid. The cobalt is mixed with a certain quantity of ground flints and sulphate of baryta, by which the shade wanted is produced. To fix this compound upon the vessels, it is mixed with a flux composed of ground flints and broken flint-glass. The colouring is ground upon a porphyry slab, with a varnish prepared from a pint of linseed oil boiled very thick, 4 ounces of rosin, half a pound of tar, and half a pint of the oil of amber. This varnish is very tenacious, and requires to be liquefied by heat before being used.

The figure to be fixed upon the vessel is engraved in the usual manner upon a copper plate, which is rubbed over with a colouring matter prepared as above, and the impression is taken upon paper of a yellow colour, made very thin, and unsized. The printed paper is placed upon the vessel, and is rubbed with a roll of flannel about an inch and a half in diameter. After this the vessel is set aside for a little, to allow the figure to become fixed, when it is dipped in water, and the paper washed off with a sponge. The impression being transferred, the vessel is dipped into a strong alkali to destroy the oil, and is then immersed in the glazing matter.

Colouring above the glaze is performed by covering the copper plate with the colouring matter as before, and brushing off what is superfluous. A cake of glue, stiff enough to be handled, is then laid upon the plate, which receives the impression of the figure. The glue cake must be very cautiously lifted off from the plate, and transferred to the surface of the glazed ware which it is intended to print. The same cake will answer for transferring several impressions, by simply washing its surface.

The ornaments on common stoneware vessels are made in relief in France, and hollow in England, by means of a mould in relief which is made to pass over the article. These hollows are filled with a clay paste of the colour required, while the vessel is turning upon a lathe. Net-work and variegated decorations are made in this way by passing different layers of coloured clay over each other.

Metallic lustres, from gold, platina, copper, iron, &c., are produced by dissolving any of these metals in aqua regia, and applying it to the vessels. Over the metallic solution a glaze composed of 60 parts of litharge, 30 of felspar, and 15 of flint, is put, in the vessels burned as before.

Stoneware of the Wedgewood colour is a semi-vitrified ware, which is not susceptible of a superficial glaze. It is composed either of barytic earths, which act as a flux upon the clay, and form an enamel, or by the clay being rubbed over with a compound-vitrifying paste. Semi-vitrified ware undergoes an operation called *smearing*, by which the vessels do not require to be immersed in glaze. They are merely put into the glazed sags, which communicate by reverberation a lustre nearly equal in brilliancy to glaze itself.

PORCELAIN, OR CHINA.

Porcelain is a fine-grained, compact, very hard, faintly translucid ware, of which there are two kinds, one called hard, and the other tender. Hard porcelain is composed of a clay containing silica, which is infusible, and preserves its whiteness in a strong heat, and of a flux consisting of silica and lime. The glaze of this ware is earthy, and admits of no metallic substance or alkali. Tender porcelain consists of a vitreous frit, which is rendered opaque by the mixture of a calcareous clay. It is glazed with artificial glass, into the composition of which silica, alkalies, and lead enter.

Kaolin clay is the largest ingredient in porcelain ware. It is composed of alumina and silica, and is obtained in large quantities in China, Germany, France, and in the county of Cornwall, in England. Kaolin is very friable in the hand, and is with difficulty formed into a paste or dough which will bear to be worked. That found in Cornwall is whiter than the foreign clays, and more unctious to the touch. In France, the clay is washed at the pit, which is repeated after it arrives at the manufactory, and it is also passed through fine sieves. When in this state, felspar rock is added, by the addition of which it is rendered fusible. The felspar is calcined, broken with stampers, and afterwards ground in a horne-stone mill, to render it as fine as possible. This mixture is poured into shallow plaster pans, which absorb the water, leaving a thick paste, which is placed in damp cellars for some months to ripen. The paste is again put into the plaster pans, and cut into small pieces, which are thoroughly dried and ground to a fine powder. It is then moistened and troddon by workmen, who walk over it in every direction.

The clay is now ready for working, which is done either upon the lathe or by casting in moulds. The materials for making porcelain ware are much less plastic than those of other pottery ware, and consequently greater care must be bestowed on its manufacture. When vessels are made upon the lathe, the operations are exactly the same as for stoneware, but they must be performed with greater caution. It is stated by Dr. Ure, that a good workman at Sevres, in France, makes no more than from 15 to 20 porcelain plates in a day; whereas an English workman, with two boys, makes from 1000 to 1200 plates of stoneware in the same time.

When formed, the vessels are allowed to dry very

* Ure's Dictionary of Arts.

slowly, and are then put into the kiln, which is nearly the same as that used for burning stoneware. In this kiln they receive a certain degree of heat, by which the vessels are rendered capable of being handled, and the clay loses its property of forming a paste with water. The vessels are then dipped in the glaze, which consists of felspar rock ground to a fine powder, and formed into a paste with water mingled with a little vinegar. When taken out of the glaze, the vessels are inspected, and the glazing matter applied with a hair-brush to any parts which may remain uncovered. A quality peculiar to porcelain is, that it softens in the fire, for which reason one piece cannot be piled above another in the sags, as is done with stoneware. Every porcelain vessel requires a sag for itself, with a piece of level stoneware in the bottom, covered with sand. This prevents the vessels from warping. The sags are piled above each other in the kiln, and wood put into the furnaces. The heat is gradually increased for fifteen hours, at the end of which time the inside of the kiln has a cherry-red colour. The temperature is then greatly increased by putting small chips of aspen wood into the furnace, which is continued for from thirteen to fifteen hours. The whole firing occupies from thirty to thirty-six hours, when the porcelain is baked. The kiln is allowed to cool gradually for three or four days; and when taken out the bottom of the vessels are covered with the sand put into the sag, which is removed by friction.

Porcelain vessels are very brittle, and are easily damaged, which accounts in some degree for the high price at which they are sold. It is calculated that after being manufactured, one-third of the articles are damaged, most of which takes place in the kiln.

MANUFACTURE OF LEATHER.

Leather making is the art by which the skins of animals are rendered impervious to the action of those external agents which would otherwise decompose them. This effect is brought about by steeping the skins in a certain astringent principle called *tannin*, and may be performed either with the hair on, or, as is generally the case, when it is taken off the skins. Tannin is obtained from the bark of a number of trees, particularly the East India catechu, the common oak, the Spanish chestnut, the Leicester willow, &c. It is found in the largest quantities in catechu—one pound of this, according to Mr. Purkis, being equal to seven or eight pounds of oak bark. Tannin is also obtained, by a peculiar preparation, from the gall nuts of the Levant oak.

When the bark of trees is to be used for tanning, it should be stripped from the trunk and branches in the spring, when the sap flows most freely. The trees should not be less than thirty years old, for it has been found that the bark possesses more tannin when old than when in a young state. The bark, when dried, is ground in a mill, to reduce it to a rough powder, after which it is ready to be used.

The first process which the skins undergo is steeping in lime-water, which is continued for a longer or shorter time, according as the skins are dry or fresh. Sometimes the skins are salted when they are imported from abroad; and in this case they require to be steeped, beaten, and rubbed, until they are brought to a fresh state. The horns are then cut off, and the skins put in heaps for a day or two, after which they are hung up in a shed. During this process, a slight putrefaction takes place, by which the hair on one side, and the fleshy matter on the other, are easily removed. This is done by a blunt knife, or scraper, the skins being stretched upon a wooden beam called a *horse*. The skins are then immersed for about forty-eight hours in water mixed with a little sulphuric acid, which has the effect of distending the fibres, causing the skins to swell. This process is called *raising*, and by it the tannin principle more easily reaches the inner fibres. When sufficiently raised, the skins are put into a pit with a layer of bark in the bottom. On this skins are laid, and then bark and skins alternately. The pit is filled up with a strong decoction of bark, and the whole is allowed to lie undisturbed for about six weeks. At the end of this time, it will be found that the tannin has become entirely exhausted, when the skins must be taken out, and put again into the pit, along with fresh bark. In this they are allowed to lie for three months; and this process is repeated two or three times, according to the quality of the leather required. From six to eight months in all are sufficient to complete the tanning of the commonest kind of sole leather, called *crop* by the trade; but for the better kinds of sole leather, from a year to a year and a half will be required. *Bend leather* is the strongest of all sole leather, and in manufacturing it, the tanning process is continued for a longer period than is necessary for crop. The best and thickest skins, also, are selected for this kind.

When properly tanned, crop leather is hung up in an airy house to dry, which is performed slowly, and the article is then fit for the market. Bend leather, after being dried, is beaten into a firm consistence, so that when cut, the edges present a glossy appearance. The instrument with which bend leather is beaten is a broad brass hammer; and this kind of leather may be easily distinguished from its being darker in the colour, in consequence of lying longer in the tannin.

A coarse kind of upper leather is also made from cowhides, the weakest and thinnest being selected for this purpose. When taken out of the lime-water, and the hair scraped off, these hides are immersed in a solution of the ordure of pigeons, which has the effect of neutralizing the lime. They are then stretched upon a board, and from the inner or fleshy side slices are taken with a sharp knife, until the operator thinks it is reduced to a proper thickness, an operation which is technically called "shaving in the bait." The skins are then put into the tan-pits, where they remain for about six months, after which they are sent to the currier. The skins of seals, calves, &c., are manufactured into upper leather in the same way, except that an equal extent of shaving is not required.

Several improvements have been made in the manufacture of leather, by which the tannin principle is more readily admitted to the inner fibres of the skins. One of the improved methods is that of Messrs. Herapath and Cox of Bristol, and consists in using a machine of two rollers, which is placed in the middle between two tan-pits. The hides, having been previously divested of the hair, &c., are fastened together, and put into the tan-pit in regular folds. After lying in this for a certain time, the end of the belt of hides is laid upon the under roller, which, being set in motion, carries the belt over to the other tan-pit. This is done without pressure; but when the hides have become soft, the upper roller is pressed down against the under one. The hides are again passed through between the rollers, which press out the exhausted tannin, and prepare them for being submitted to a fresh infusion. By the old method, the hides were taken from one pit to another without receiving any pressure, and consequently a quantity of exhausted tannin must have remained in them when put into the fresh liquor. By using this machine, however, this is altogether obviated; and leather may now be tanned in four months, a process which formerly took from eight to twelve. The material is also said to be of a firmer texture, and remains longer waterproof than that produced by the old system.

The most recent improvements are those of Mr. John Cox of Gorgie Mills, near Edinburgh, and for which he has obtained patents. He announces six improved p o

cesses of tanning, any of which may be adopted. His great object is to force the liquid tannin into the vesicles of the skin, and this he proposes to do as follows, in his *fourth* process, which he considers the most suitable in ordinary circumstances. The skin is to be sewed into the form of a bag, and immersed in tanning liquor, while the interior is also filled and compressed from a supply of liquor through a pipe from a cistern placed a few feet above the pit:—"The hide or skin bag being tied tightly at the neck-end to the feeding tube (which tube should be long enough to dip a little down amongst the liquor in the pit in which the bag is to be immersed), tanning liquor is to be supplied to the feeding cistern, when the bag will swell until it can contain no more liquor, when percolation will commence, and be continued with a vigour proportionally to the height of the liquor in the feeding cistern above the liquor in the pit of immersion. As the bag fills with liquor, the pit (having been previously full) will overflow, unless the liquor is supplied from the pit of immersion; and therefore a run-way must be made for the liquor to flow to a reservoir, from which it may be pumped or lifted again to the feeding cistern; and as the percolation goes on, the liquor will flow to the reservoir, again to be raised and circulated as before. The hides or skins tanned according to this process may also be confined in compartments, or jammed against each other for the sake of saving room and quantity of liquor necessary at a time, as described as being practicable in the atmosphere; but I prefer that each bag should have ample room for swelling out as far as its dimensions will permit, as the tanning goes on rather more rapidly and equally in all the parts; while the tension generated by the hydrostatic pressure is more equal, rendering the leather more equal in texture and quality. In this process of tanning there is a double hydrostatic pressure exerted—a greater, which is exerted inside of the bag, and a lesser, which is exerted outside of the bag; and it is the surplus pressure (which is equal to all parts of the bag) of the one above the other that causes the percolation of liquor from within outwards. In all these four processes now described, I prefer that the grain side of the hide or skin be outwards, though I do not confine myself thereto; and I also prefer that some bark or other solid tanning ingredient be introduced into the bags, so as to help to keep up the strength of liquor, and to stop up any holes or apertures that may be in the hide or skin." For further particulars, we refer to Mr. Cox's Specification of Patents. We understand that, by any of his processes, a hide may be as effectually tanned in a week as it was by the old tan-pit method in twelve months, while there is at the same time a saving of tanning material and gelatine.

Skins intended for the manufacture of gloves require in the first place to be washed with pure water. This is done in a cistern placed, if possible, near a running stream; and immediately after being washed, the skins must be worked, or they are liable to become marked with indelible spots. They are next rubbed upon a convex beam, and the rough parts removed with the fleshing-knife. The fleshy sides of the skins are then covered with a cream of lime, and piled together with the wool sides of each pair outermost. They are left in this state for from four to six days, or until the wool is found to come easily off. The skins are then washed in a running water, to free them from the lime, and the wool is taken off by means of small spring tweezers. After this they are fleeced smooth by a rolling-pin, or by rubbing with a whetstone.

The next operation to be performed is steeping the skins in a strong solution of lime, for the purpose of swelling and softening them. They are then put into weak lime-water, and drained upon inclined tables; which is repeated several times, the process occupying about three weeks. The outsides are then rubbed with a whetstone, to remove any wool which may still remain; and the skins are then fit for what is called *branning*. Into twenty gallons of water forty pounds of bran are put, and the skins are steeped in this mixture until they sink, which they will generally do in about two days in summer and eight in winter. During the branning process, the skins must be frequently stirred, that each may get a due share of the liquid. They are next steeped in a solution of alum and sea-salt, which is called the *white stuff*. From twelve to eighteen pounds of alum, and about three pounds of salt, are put into a copper with twelve gallons of water. This mixture is dissolved by heating the copper; and when about to boil, three gallons of the solution are poured into a basin, in which twenty-six skins are worked one after another. The twelve gallons are thought sufficient for one hundred skins; and when all have been worked, they are allowed to steep for about ten minutes. The skins are then taken out, and fifteen pounds of wheat flour are added to the solution. This is next run out of the copper vessel, and the yokes of fifty eggs put into it, in which the skins are worked and afterwards allowed to steep for a day. They are then taken out, stretched upon poles, and allowed to dry.

By this operation the leather is rendered very white and soft, which enables it to bear the working of the softening-iron. This consists of a plate of iron about a foot broad, mounted upon an upright beam thirty inches high, which is fixed to the end of a plank three and a half feet long. This plank is heavily loaded; and the skins having been previously wetted, they are rubbed with the iron upon a board. The skins are sometimes stretched upon the horse, and well rubbed with a blunt two-edged knife, and afterwards polished with pumice-stone. They are then worked upon the stretching-iron, and afterwards smoothed with a hot iron.

Sheep-skins are frequently dressed for household purposes, and on this account are technically called housings. For this purpose, those skins are selected which have the longest and most beautiful fleece. They are first well washed and steeped in water, to render them soft, and then thinned with the fleshing-knife, after which they are put into the bran-pit for four days. The same process as for glove leather, of steeping in alum water and rubbing with paste, is then performed. The skins are next worked upon the horse, stretched upon the stretching-iron, and then dried in the sun with the fleecy side outermost.

Chamois leather is prepared by washing, steeping in lime-water, taking off the fleece, and then branning the skins as before described. The outer skin, or epidermis, is next cut off upon the horse, which removes all excrescences, and renders the skins equal in thickness. They are then branned for a short time, the liquid wrung out of them, and then well beat in a fulling-mill. The next process is to oil the skins, which is done by sprinkling and rubbing over them any cheap animal oil. The skins are afterwards oiled and beat several times, and are then subjected to a fermenting process; after which they are washed in potash ley, and then dried.

Morocco leather is manufactured from goat-skin, but a spurious article is frequently sold under this name, which is made from sheep-skin. The process is much the same as for glove leather, except that the washing is performed offener, and the skins are salted previous to being dyed. Morocco leather is dyed with cochineal, about an ounce being required for each skin. The cochineal is boiled for a few minutes in water along with a little alum, and is then filtered into a cask. Each skin is sewed together edgewise, the grain side outermost, and agitated in the dye liquor for half an hour; after which it is beat and again put into the cask. The skin is next tanned in a decoction of sumach. The tanning is performed twice the process requiring about twenty-four hours. The skins

are then rubbed hard with a copper blade, and hung up to dry. The cochineal gives a scarlet colour to morocco leather; but other colours may be given to it, such as black, by using the red acetate of iron; blue, by indigo; yellow, from the roots of the barberry.

Currying is the process by which the newly-tanned rough leather is converted into the soft, flexible, and jet-coloured article from which the upper leathers of shoes are made. The currier first steeps the leather, and then places upon it a piece of basket work, upon which he treads, in order to soften it. He then shaves the leather by means of a double-edged knife with a horizontal handle at each end. The edges of this knife are curved, and in cutting, it is held nearly at right angles to the leather, which is thrown over an upright beam. The currier stands behind this beam and scrapes downwards. By this means all inequalities are removed, the leather being rendered uniform in thickness and firm in the texture. What is called a stretching-iron is also used, which still further firms the grain; and cleaning knives to make the surface smooth.

The leather is then pommelled by an instrument grooved on the under side and with a cross strap on the top, under which the hand of the workman goes. The leather is folded with its grain side in contact, and rubbed strongly with the pommel, which gives it a granular appearance and greater flexibility. It is then conveyed to the drying-house, where grease is applied to soften it. The grease employed is a mixture of tallow and cod-oil, called *dubbing*, and is applied to the leather by means of hard brushes upon a large broad table. When well greased, the leather is hung up to dry, in order that it may thoroughly imbibe the oily matter. It is then well scraped, to free it from all superfluous oil, which would otherwise injure its appearance and prevent it from receiving the colour readily. The leather is then rubbed on the flesh side with a brush dipped in a composition of oil and lamp-black, until it is thoroughly black. It is then black-sized with a brush or sponge, rubbed again with the oily matter, and afterwards scraped with glass. When coloured upon the grain side, a solution of sulphate of iron or copperas is employed. The leather is then wetted with stale urine, and afterwards rubbed with an iron, to render the grain as fine as possible.

Cow-hides, when dressed for upper leather, are called *neat's* leather, and the shoes made from it are coarse. Common shoes are in general made from calf-skin, which is prepared in the same manner. The uppers of boots are all made from calf-skin, the best part for this purpose being the back and flank. This also applies to cow-skin leather. A considerable quantity of shoes are made from a description of leather called *kip*, which is prepared from the hides of young cattle. It is neither so fine nor so soft as that made from calf-skin, but is superior to the leather of full-grown cow-hides. Horses' hides were formerly much used for making leather, but they are now almost entirely superseded by cow-hides, which are greatly preferred. They were prepared much in the same manner, and when dressed, were generally known by the name of *cordovan hides*. Besides what is supplied by the home markets, this country annually imports large quantities of hides from abroad.

MUSIC—ART OF SINGING.*

It is the object of the following pages to exhibit such a view of the principles and practice of music as may be calculated for popular information and use. The path to musical knowledge has for the most part been rendered rugged and toilsome by the interposition of many needless difficulties. Things really plain and simple have been invested with an air of mystery; and the great principles and leading rules of the art, though in themselves easily explained and easily understood, have been buried beneath a mass of useless technicalities. The conviction that this is the case has sometimes led to the opposite extreme; and the study of music has been apparently simplified by short-hand methods and mechanical contrivances, devised to diminish the labour of reflection and memory. But there is no "royal road" to music any more than to mathematics. Skill in its practice is to be gained only by a clear understanding of its principles. All that the instructor can do is to divest those principles of unnecessary obscurity, and to present the rules of practice in their simplest and most comprehensive form. The rest must be done by the intelligence, attention, and perseverance of the student.

The musical artist, whether as a composer, a singer, or an instrumental performer, requires a very different degree of knowledge and skill from the amateur, who cultivates the art as an elegant accomplishment and as a refined and intellectual pastime—an innocent and salutary relaxation from the severer cares and occupations of life. In this point of view, there is no station or degree of society in which music may not be cultivated with advantage. And the experience of the present day has shown, and is showing more and more, that even the classes who earn their daily bread by the sweat of their brow may find in music a recreation within their reach, full of innocent enjoyment, and pregnant with moral and social benefits. It has been found that the highest pleasures which it can impart—pleasures derived from the knowledge of its noblest productions—are accessible to the humblest as well as the highest, and that it is to the toil-worn artificer, mechanic, and labourer, that music dispenses its best and dearest blessings.

Those, however, whatever may be their station in society, who are to derive such benefits from music, must acquire a knowledge of it *as an art*, whose principles and rules afford exercise to the intellect, and whose lofty and beautiful productions exalt and purify the mind. Many tribes, in a very rude state of society, exhibit much sensibility to music, and derive much pleasure from the simple strains in which, taught by nature alone, they give expression to their feelings; and there is no doubt, that even to their untutored minds, music, such as they possess, is a source of much higher and better enjoyment than the mere gratification of sense. But it is only, we repeat, where music has become an art, and where its exercise is invested with the dignity of an intellectual pursuit, that its effects as an instrument of civilization and moral improvement become evident and striking.

There is no country in which the moral and social

* The editors think it proper to mention that the present treatise is the composition of Mr. George Hogarth, author of "Musical History," and "Memoirs of the Musical Drama."

agency of music is so remarkable as in Germany. In the various countries which compose that wide region, the national character has been much refined and softened in the course of a few generations; and, in this progress, the operation of music can be palpably traced. Its effects in this point of view are described with equal truth and eloquence by M. Mainzer, in the introduction to his work of popular instruction, entitled, "Singing for the Million." After describing the measures pursued in the principal states of Germany for the diffusion of musical knowledge among the people, this writer says—"As may be naturally supposed, from all that we have here stated, in the boarding-schools for the upper classes, singing and the art of music are cultivated with still greater care, and the instruction therein given assumes a high and artistical character. In gymnasiums, singing and drawing are considered as important as the classics, history, and mathematics; art and its principles are studied equally and simultaneously with science. In the military schools, which every common soldier is compelled to attend for the purpose of obtaining instruction in reading, writing, arithmetic and the fundamental principles of the art of war, the elements of singing are likewise taught. Hence, the soldiers may be frequently heard performing songs in four parts in the streets in front of their barracks; whole battalions sing when marching in the morning to the place of exercise, and, on their return, no fatigue prevents them from singing their chorusses in full voice, and thus enjoying a useful and agreeable recreation. If any one visit the orphan asylums for both sexes, he will find that the lessons begin and end with singing: in the churches to which they belong, the children sing with a fervour of soul which elevates them to those spheres of happiness where the cruel destiny that but too often clouds their dawning existence is for the time forgotten. In Germany, more than any other country, it may be seen how peculiar a charm singing gives to the existence of children, and how much animation to the manners of the people; how happy is the influence it exerts on schools and national festivals; and how much, on the whole, it contributes to the welfare of the nation."

The French have never been regarded as a particularly musical people, and yet the effects produced among them by the systems of popular instruction introduced by M. Mainzer and M. Wilhem have been very considerable. In Great Britain both these systems are now in operation. Our government, following the example of the French, has bestowed its patronage on the method of Wilhem, which has been adapted to English use by Mr. Hullah; while M. Mainzer, in carrying on his system, relies wholly on the support of the public. Both systems are already widely spread, and both are likely to be very efficient. As usual in such cases, a spirit of partisanship has been excited regarding them, and the advocates of the one seem to think it necessary to depreciate the other. Any such feeling we utterly disclaim; we have carefully examined both systems, to which we shall specially refer in the sequel, and have here only to observe, that being convinced of the benefits which both may confer in a country which presents an ample field for their operation, they have our hearty wishes for their success.

It is, of course, to the more wealthy and educated classes of society that the attainment of scientific knowledge and technical skill in music has been hitherto confined. At this day, even these classes in this country have little to boast of in this respect; much less, indeed, than they had two or three centuries ago. In the sixteenth and seventeenth centuries, the music chiefly cultivated in England consisted of *vocal harmony*, and the performance of the inimitable *madrigals* of the Italian and English masters of that age was regarded as a most elegant pastime, in which every one who had pretensions to the habits and manners of good society was supposed capable of participating. Every musical student, as far as his means and opportunities permit, ought to follow the example set in these times, and study both the theory and practice of harmony; for it is impossible either to acquire a respectable degree of proficiency in the practice of music, or to derive real pleasure from it as a liberal and intellectual pursuit, without that expansion of mind which is derived from a knowledge of its principles.

This study ought to be conjoined with the practice of singing or performance on some instrument. Great facilities will be afforded by being able to play ever so little on the pianoforte; to do which, in so far as to realize to the ear the effect of successions of chords and combinations of harmony, is a matter of no difficult attainment. People will prosecute the study in different ways, and carry it different lengths, according to their different dispositions, opportunities, and views. But we may say in general, that a familiarity with the principles which we shall attempt to develop, combined with moderate skill and readiness in singing or playing on an instrument, will produce that enlargement of view which is requisite for the full comprehension and enjoyment of the noblest productions of the art. We may add, that the study of harmony will be more pleasantly and successfully followed as a domestic and social pastime than as a solitary pursuit. Members of a family may follow it together; or a circle of friends and companions may form themselves into a little class for the purpose. Supposing them to have profited by the methods of instruction, now so easily accessible, so as to be able to sing from the notes vocal passages of the simplest kind (if with a pianoforte, so much the better, though it may be dispensed with), they will find little difficulty in mastering the contents of the following pages. And they will find it equally improving and interesting to discover the application of the various rules and principles of harmony which they are thus acquiring, in every grand or beautiful composition in the performance of which they may have occasion to join.

With these prefatory remarks, we proceed to an account of the theory of music, commencing with

THE SCALE.

Music is composed of sounds produced by the human voice, or by instruments constructed for that purpose, varying in pitch according to certain fixed and determinate degrees. The gradation of these sounds, from the lowest, or most grave, to the highest, or most acute, forms what is called the *musical scale*, a scale evidently derived from nature, since, though it has been found to be more or less complete in different times and places, it is the same in its principal degrees in all parts of the world. By using the different sounds or notes of this scale in succession, in such a manner as to give pleasure to the ear, *melody* is produced; by using two or more of them at the same time, in such a manner as to be agreeable, *harmony* is formed. Melody, in its simpler forms, is immediately dictated by nature, as no people or tribe, however rude, seems ever to have been destitute of it. Harmony, though its effects, as well as those of melody, must be founded in nature, has never been found to exist unless where music has received a considerable measure of artificial culture.

The natural scale of musical sounds, though its extent is limited only by the bounds of the human voice, or of the different instruments, consists only of seven notes, for it is found that if, after singing or playing these seven notes, we continue the series, we repeat another scale similar to the first, and so on, as far as the extent of the voice or the instrument will go.

To express these sounds by means of notation, various expedients, in the progress of music, have been resorted to, which have been gradually improved, till the

now in use has been adopted. It consists in drawing five parallel lines, and in placing on them, and in the spaces between them, marks representing the notes of the scale. At the same time, the notes have received distinguishing names, either letters of the alphabet, or syllables used for that purpose. Thus:

C D E F G A B C
Do Re Mi Fa Sol La Si Do

There are only seven letters or syllables, because, as already mentioned, there are only seven notes in the scale. In the above figure, the last note bears the same name as the first; and if the series of sounds is carried further, the same names will be repeated. The last of the above notes, C, being the eighth from the first, is called its *octave;* and the whole series, of which it forms the beginning and the end, is called an octave.

In examining the above series of sounds or octave, from C to C, it will be found that the steps of the scale are unequal; the distance between the third and fourth notes, E and F, and between the seventh and eighth, B and C, being smaller than the others. In singing the scale, this is at once felt to be the case. While, therefore, the interval between C and D, D and E, F and G, G and A, and A and B, is called a *tone*, the smaller interval between E and F, and between B and C, is called a *semitone*.

The scale, therefore, to whatever extent it may be carried, from the gravest note that can be produced to the shrillest or most acute, consists of a series of octaves; and in each octave, the interval between the third note and the fourth, and between the seventh and eighth, is a *semitone*, while the other intervals between a note and that next it are *tones*.

It is easy to perceive that the five lines (or *staff*, as it is called) above described, can comprise but a small portion of the musical scale, which is of indefinite extent, and limited only by the capacities of the human voice, or of instruments. The explanations now to be given are applicable to the voice, the original musical instrument, from which all others are derived.

The voices of women and boys are more acute, higher in pitch, than those of men. If a man or a woman sing the same tune, they will, if untaught, suppose that they are singing the same notes, or in unison, whereas the one is singing an octave above the other. It is for this reason that a note and its octave are designated by the same letter or syllable.

The great divisions of the voice, then, are into the *male* and the *female*. But males, as well as females, differ in the pitch of their voice; and this difference produces a subdivision. The male voice of the highest pitch is called the *tenor;* of the lowest pitch, the *bass*. The female voice of the highest pitch is called the *treble* or *soprano;* of the lowest pitch, the *contralto*.

Persons possessed of each of these varieties of voice have, generally speaking, pretty nearly the same range or compass of notes. Each voice, at an average, may be said to contain eleven or twelve notes, some more, and some less. Were we to draw a staff of *eleven* lines, placing the notes upon the lines, and in the spaces between them, we could comprehend the whole extent of the ordinary vocal scale, from the lowest note of the bass to the highest note of the treble, thus:—

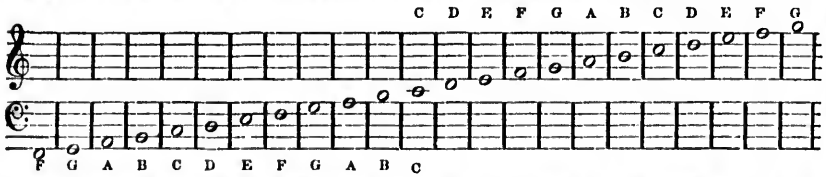
F G A B C D E F G A B C D E F G A B C D E F G

But it is evident that this would be cumbrous, and that the number of lines would produce confusion to the eye. It is found that five lines are generally sufficient for the extent of any one voice, by adding the simple expedient, when a note happens to go either above or below the five lines, of drawing an additional little line for that note, which is called a *leger* line. By this means the staff, when necessary, may be increased to six, seven, or more lines; but too many leger lines must be avoided, as they render the notation confused.

Five lines, therefore, are taken out of the above eleven, to form a staff for any one voice; but each voice will require a different set of lines. The two great divisions of voice are the bass and the treble; for the bass we take the five lowest lines, for the treble the five highest. In order to distinguish these staves from each other, we employ two arbitrary marks, the one for the bass, and the other for the treble; thus:—

The first is called the *bass*, or F clef, because it is placed on the line which has the note F. The other is called the *treble*, or G clef, because it stands on the line which has the note G, as seen in the above eleven lines.

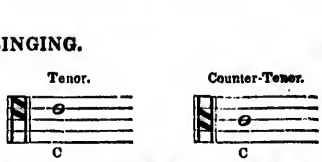
Of these eleven lines, the five lowest being used for the bass staff, and the five highest for the treble staff, one line remains in the middle, which is common to both, and may be represented by a leger line above the bass staff, or below the treble staff.



This is precisely the same as the above diagram of eleven lines, except that the middle note, C, is placed on a leger line instead of a line prolonged like the others.

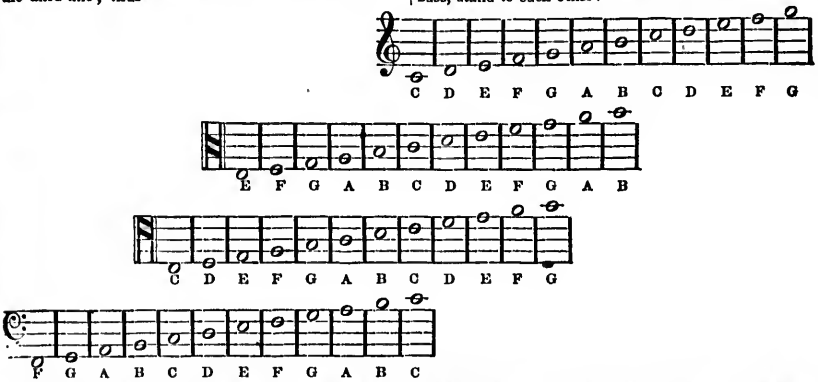
The above are the two clefs most generally used in music, and were there no other than bass and treble voices, no other clefs would be necessary. But we have seen that there are also *tenor*, and *contralto* (or *counter-tenor*) voices: the range or compass of the tenor being four or five notes higher than the bass, and the compass of the counter-tenor being about an octave higher than

the bass. The tenor part might be written on the bass clef, but the notes would not be spread over the five lines. The lower lines and spaces would be left empty, while the higher notes would require leger lines. The same inconvenience would arise from writing the counter-tenor part on the treble clef. Two other staves, or sets of five lines, therefore, are used for the tenor and counter-tenor parts. Both of them are distinguished by a mark called the C clef; but this mark, for the tenor, is placed on the fourth line, and, for the counter-tenor, on the third line; thus—

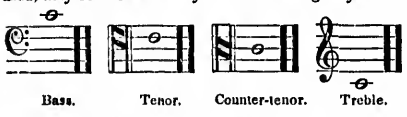


The C, in both these staves, is the same; and it is moreover, the C which stands on the leger line between the treble and base staves.

The following diagram will show the relation in which the different clefs, the treble, counter-tenor, tenor, and bass, stand to each other:—



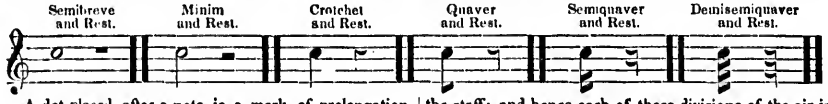
This, we apprehend, explains itself. The notes which are perpendicular to each other express the same sound. As, for example, the middle C, according to the clef used, may be written in any of the following ways:—



It is requisite to observe, however, that, though the above clefs are necessary for the clear and correct notation of music for different voices, yet in music printed for popular use, the use of the *tenor* and *counter-tenor* clefs is now very generally dispensed with, the parts for these voices being written in the treble clef, an octave above the real notes intended to be sung. But the learner should not neglect the knowledge of these clefs, as they are always used in music of a high class. In the examples of harmony given throughout the following pages, the treble and bass clefs only are used, the harmony, even when in four parts, being written in two staves. But the learner will find it a useful exercise to write out these examples in as many staves as there are parts, giving to each part its proper clef.

TIME.

Thus much for the notation of sounds, in relation to their pitch. But musical notes are not only high and low, they are also *long* and *short;* and their relative proportions to each other in this respect are expressed by differences in the form of the notes. The longest note in modern use is represented by a circle, as in the previous examples, and is called a *semibreve*. A note of half its length is called a *minim;* a quarter, a *crotchet;* an eighth, a *quaver;* a sixteenth, a *semiquaver;* and a thirty-second, a *demisemiquaver*. They are written thus—



A dot placed after a note is a mark of prolongation. A dotted semibreve is equal to three minims instead of two; a dotted minim to three crotchets; a dotted crotchet to three quavers: a dotted quaver to three semiquavers; and a dotted semiquaver to three demi-semiquavers.

Measure, or *rhythm*, is one of the essential attributes of music. Everybody knows the meaning of *beating time* to a tune. By beating time, the tune or melody is divided into a number of equal parts, which in musical notation are marked by lines or bars, drawn across the staff; and hence each of these divisions of the air is called a *bar*.

Each portion of the melody, comprised within the limits of a bar, is also divided into *equal* parts. Sometimes the bar is divided into *two* equal parts, and sometimes into *three*. In the former case, the melody is said to be in *common time;* in the latter, in *triple time*.

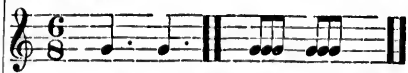
There are various kinds of *common* as well as of triple time. The first kind of common time consists of *one semibreve* (or shorter notes equal to one semibreve) in each bar. It is marked C; thus—

The second kind of common time consists of one *minim* (or shorter notes equal to one minim) in each bar. It is marked $\frac{2}{4}$, meaning, that it contains two fourth-parts of a semibreve (or two crotchets) in a bar:—

The third kind of common time is marked $\frac{6}{4}$. It consists of six crotchets in a bar: but these are divided into two equal parts, each of which is equal to a *dotted minim*, or what is called a *triplet* of three crotchets.

These six crotchets are divided into two triplets by *accenting* the first note of each triplet, or sounding it a little more strongly than the others. This species of time is now rarely used.

The fourth kind of common time is marked $\frac{6}{8}$. It consists of six quavers in a bar, divided into two equal parts, each of which is a dotted crotchet, or a triplet of three quavers.



Each of these triplets may be divided into six semiquavers.

The last kind of common time is marked $\frac{12}{8}$, and consists of four dotted crotchets, each of which may be divided into a triplet of three quavers. The bar of $\frac{12}{8}$ is just two bars of $\frac{6}{8}$ thrown into one.

Triple time consists, first, of a *dotted semibreve*, divided into three equal parts, each of which is a minim, or two crotchets, or four quavers. This is now seldom used.

Secondly, of a *dotted minim*, divided into three equal parts, each of which is a crotchet, or two quavers, or four semiquavers, and marked $\frac{3}{4}$.

Thirdly, of a *dotted crotchet*, divided into three equal parts, and marked $\frac{3}{8}$.

Lastly, of *three dotted crotchets*, and marked $\frac{9}{8}$.

Although the dot is used for indicating the division of a note into three (instead of two) equal parts, yet it is common to divide notes into triplets without the use of the dot. Thus, in common time of a semibreve in a bar, it may be divided thus—

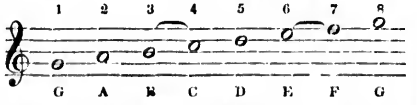
And in $\frac{2}{4}$ time—

In these cases, the notation of C time is similar to $\frac{12}{8}$; and $\frac{2}{4}$ to $\frac{6}{8}$. When a note, without being dotted, is thus divided the triplet is frequently marked with a small figure 3, but this is not always done.

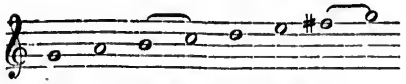
DIVERSITY OF KEYS.

It has been already shown that the scale consists of a series (more or less extended) of *octaves*; and that in each octave the intervals between the third and fourth note, and between the seventh and eighth, are *semitones*; all the other intervals between two adjoining notes being *tones*. It is this inequality in the intervals which produces the tune or melody of the scale.

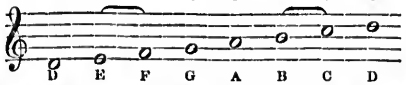
In singing this scale, we may begin upon any note at pleasure; and this note, whatever it may be, is called the *key-note*. But on whatever note we begin to sing the scale, we must, in order to preserve its tune or melody, place the *semitones* in the positions already mentioned; that is, between the third and fourth notes, and between the seventh and eighth. We have already exemplified the scale, as commencing on the note C. Take it now upon another note—suppose G.



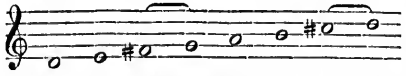
But one of the intervals in this scale is not in its proper place. The interval from E to F, which (as we have seen) is a semitone, is here between the sixth and seventh instead of being between the seventh and eighth; while the interval between the seventh and eighth is a tone, instead of being (as it ought) a semitone. The other semitone, from B to C, is in its right position. To correct this, it is only necessary to *raise the pitch* of the note F, so as to make it a whole tone higher than E and consequently a semitone lower than G. A new note is thus obtained, called F *sharp*, which is distinguished by a particular mark, as under—



Again, commence the scale on the note D—

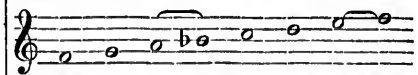


Here two of the semitones are out of their proper places, as may be seen at a glance. But we correct the position of the first semitone by raising the pitch of the note F, as in the previous example, and we correct the position of the second semitone by raising the pitch of the note C. Thus—

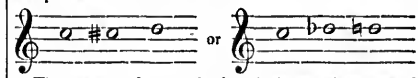


Take now the note F as the key-note or foundation of the scale.

Here the first semitone is misplaced, being between the fourth and fifth instead of the third and fourth. The other semitone is rightly placed. To correct this, it is necessary to *depress* the pitch of the fourth note B, in order to bring it nearer to the A; and the new note thus obtained is called B flat, distinguished by a mark, as under—

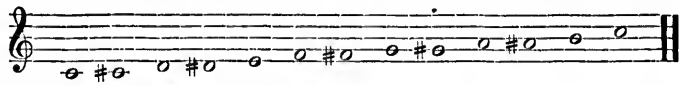


In this manner the learner may form a new scale on every note of the octave, and we recommend it to him as a useful exercise. In doing so, he will find that every interval of a tone may be divided into two semitones, by placing between the two notes a third note, at the distance of a semitone from each. And this third note may be obtained by raising the pitch of the lower of the two notes, or by lowering the pitch of the higher. Thus, the tone between C and D may be divided into two semitones, by inserting between these notes either a C sharp or a D flat.

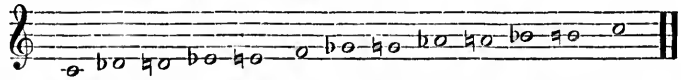


The mark prefixed to the last D is called a *natural*. When the pitch of a note has been raised or lowered by a sharp or a flat, this mark indicates that the note so altered is restored to its natural pitch.

By thus dividing every tone into semitones, a new scale may be formed, consisting entirely of semitones. In the first place, it may be formed by raising the pitch of each note, excepting where semitones already exist—



Or it may be formed by depressing the pitch of each note—



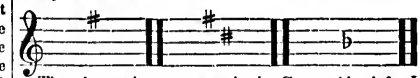
In both these scales, the intervals between E and F, and between B and C, being semitones at any rate, undergo no alteration.

The scale which thus proceeds entirely by semitones is called the *Chromatic* scale, to distinguish it from the natural, which is called the *Diatonic* scale.

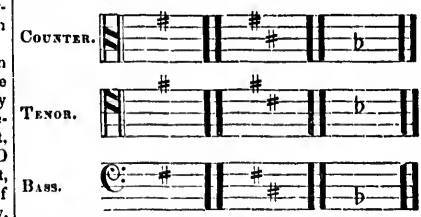
The chromatic scale, formed by *sharps*, is not precisely the same as that formed by *flats*, as the interval called a semitone is not the exact half of a tone. But the difference is so minute as to be in some measure disregarded in practice; and on keyed instruments (the organ and pianoforte) the two chromatic scales are played in the same way; the C sharp and D flat, D sharp and E flat, &c., being considered the same sounds. But though these sounds may seem the same to the ear, it is evident, from the preceding account of the formation of the scale, that they must not be confounded in musical notation.

By the formation of the chromatic scale, we obtain *twelve* notes in each octave; and upon every one of these notes a scale may be formed; or, in other words, every one of these notes may be taken as a key-note. Moreover, as several of the notes appear in a double aspect, though identical in sound (as C sharp and D flat, D sharp and E flat, F sharp and G flat, G sharp and A flat, and A sharp and B flat), each of these double forms of the same note gives rise to a different scale or key, which, though consisting of the same sounds, must be differently noted.

Each scale or key is distinguished by a *signature*, pointing out the notes which have been altered from the natural scale, by means of sharps or flats. The scale commencing on G, for example, contains one altered note, F sharp; and the signature placed at the beginning of a piece of music in the key of G, shows that wherever F occurs, it is sharp. The signature of the key of D shows that F and C, wherever they occur, are sharp. The signature of the key of F shows that the B is always flat, and so on.



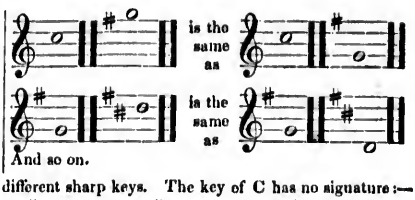
The above signatures are in the G or treble clef. In the C, or tenor and counter-tenor, and F, or bass clef, they must vary according to the clef.



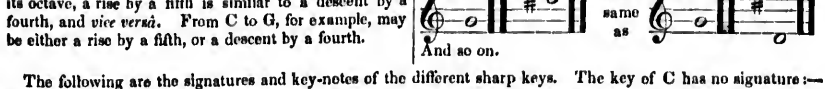
In the *sharp* keys, the series of key-notes proceeds from the natural key of C *upwards by fifths*. G, the fifth above C, has one sharp; D, the fifth above G, has two sharps; A, the fifth above D, has three sharps, &c. In

the *flat* keys, the series of key-notes proceeds from C *downwards by fifths*. F, the fifth below C, has one flat; B flat, the fifth below F, has two flats; E flat, the fifth below B flat, has three flats, &c.

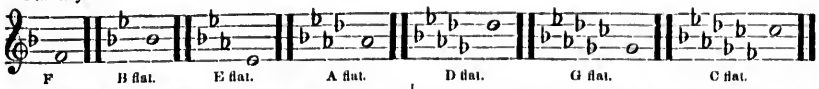
Observe that, from the similarity between a note and its octave, a rise by a fifth is similar to a descent by a fourth, and *vice versâ*. From C to G, for example, may be either a rise by a fifth, or a descent by a fourth.



The following are the signatures and key-notes of the different sharp keys. The key of C has no signature:—

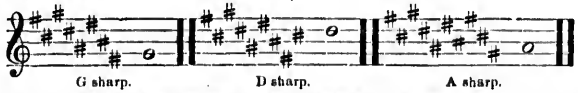


Flat keys—



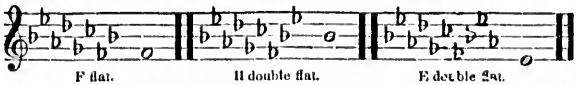
From what has been said, it will appear that several of these scales, though differently noted, are played on the pianoforte with the same keys. Thus, C sharp, with seven sharps at the signature, is the same as D flat, with five flats; C flat, with seven flats, is the same as B with five sharps; and F sharp, with six sharps, is the same as G flat with six flats.

The above are the principal sharp and flat keys, with the use of which it is necessary to be familiar; but there are others occasionally but rarely used. And, indeed, the series, whether of sharp or flat keys, may be carried out indefinitely. To the sharp series we may add—



In the key of G sharp, the F is raised two semitones; in D sharp, the F and C are each raised two semitones; and in A sharp, the F, C, and G, are each raised two semitones. The notes thus doubly raised are marked, when they occur, with a ×, called a *double sharp*. But it is hardly ever necessary to use keys with such a multitude of sharps; because, by using flat signatures, the same notes may be much more simply expressed. A passage in the key of G sharp, with eight sharps, may be written in A flat with four flats. For D sharp, with nine sharps, we can substitute E flat, with three flats; and for A sharp, with ten sharps, we can substitute B flat, with two flats.

To the flat series we may add—

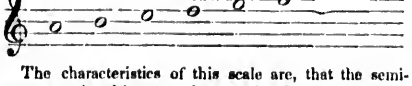


But these may be more simply written with sharp signatures. For F flat, we may substitute E natural (the same sound), with the signature of four sharps; for B double flat, we may substitute A, with three sharps; and for E double flat, we may substitute D, with two sharps. Nevertheless, it is necessary to be acquainted with these out-of-the-way keys; because, though entire pieces of music are never written in them, yet transient passages belonging to them are met with in learned and complex compositions.

THE MINOR SCALE.

The scale hitherto described, in which the semitones stand between the third and fourth, and between the seventh and eighth, is called the *major* scale, to distinguish it from another, called the *minor* scale.

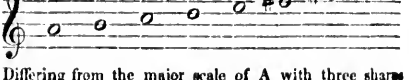
If we commence on the *sixth* note of the scale already described, and ascend to its octave, without altering the natural notes, we have the minor scale. Taking A, as he sixth note of the scale of C, we have—



The characteristics of this scale are, that the semitones are placed between the *second* and *third* notes, and between the *fifth* and *sixth*. In singing this scale, it will be felt that this position of the semitones gives the tune or melody a melancholy expression, which distinguishes it from the major scale.

It is, especially, the difference between the interval of the *third* in the two scales which is their distinguishing feature. In the major scale, as we have seen, the interval between the key-note and the third consists of two tones; in the minor scale, the intervals between the key-note and third consists of a tone and semitone. The one kind of third is called a *major third*, the other a *minor third*.

The other marks which distinguish the above minor scale from a major scale, namely, the semitone between the fifth and sixth, and the whole tone between the seventh and the eighth, are not always preserved. It is one of the refinements of modern music, that in rising from the seventh to the eighth, we always do so by a semitone, whether the scale be major or minor. When this is done, the sixth note of the scale is also raised a semitone: so that the *ascending* minor scale generally stands thus:



Differing from the major scale of A with three sharps only in the circumstance that the *third* is minor.

The minor scale thus admits of some variety. It may be written in either of the above ways, or, while the

seventh is sharpened, the sixth may remain unaltered. But the scale, whether ascending or descending, is considered as consisting of the notes given in the first example. The minor scale of A, therefore, has no signature at the clef, the sixth and seventh notes being marked with sharps only when they occur, so altered, in the course of the piece.

Every minor scale, being formed on the sixth note of a major scale, is said to be *relative* to the major scale on which it is so formed.

Thus, the minor scale of A is relative to the major of C

The minor of E to the major of G

.. .. B .. .. D

.. .. F♯ .. .. A

.. .. C♯ .. .. E

.. .. G♯ .. .. B

.. .. D♯ .. .. F♯

.. .. A♯ .. .. C♯

Flat keys—

The minor of D is relative to the major of F

.. .. G .. .. B♭

.. .. C .. .. E♭

.. .. F .. .. A♭

.. .. B♭ .. .. D♭

.. .. E♭ .. .. G♭

.. .. A♭ .. .. C♭

The signature of every minor key is the same as that of its relative major. Thus, C major and A minor have no sharp or flat at the clef; G major and E minor have one sharp; D major and B minor have two sharps; F major and D minor have one flat; B flat major and G minor have two flats; and so on. Let the learner, as an exercise, write all the relative major and minor keys, with their proper signatures.

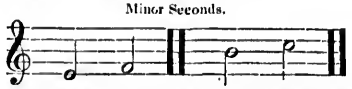
INTERVALS OF THE SCALE.

The next object of attention ought to be the *intervals* of the diatonic scale. This scale may be called the alphabet of music; as from the various successions and combinations of these sounds the beauties of melody and harmony are derived.

The intervals of the scale are expressed by numbers, and are called the second, third, fourth, fifth, sixth, seventh, and eighth, or octave. Each of them is of different kinds.

The *second* is *major* and *minor*. The *minor second*, or *semitone*, is the interval between the third and fourth notes of the scale, and between the seventh and eighth. In the key of C, these intervals are—

Minor Seconds.



The *major second*, or tone, is the interval between any other note of the scale and that immediately adjoining, as between C and D, D and E, F and G, &c.—

Major Seconds.

The third is *major* and *minor*.

The *major third* consists of two tones; as between C and E, F and A, G and B—

Major Thirds.

The *minor third* consists of a tone and a semitone; as between D and F, E and G, A and C, B and D—

Minor Thirds.

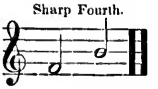
The *fourth* is *perfect* and *sharp*.

The *perfect fourth* consists of a major third and a semitone, or of a minor third and a tone; as between C and F, D and G, E and A, G and C—

Perfect Fourths.

The *sharp fourth* consists of a major third and a tone, or of three tones (whence it is sometimes called the *tritone*); as between F and B.

Sharp Fourth.



The *fifth* is *perfect*, and *imperfect* or *flat*.

The *perfect fifth* consists of a major and a minor third or of three tones and a semitone; as between C and G, D and A, E and B, F and C—

Perfect Fifths.

The *imperfect* or *flat fifth* is the perfect fifth diminished by a semitone; as between B and the F of the next octave, or between any of the above perfect fifths, after the lower note has been raised, or the upper note depressed by a semitone; as between C sharp and G, D sharp and A, E sharp and B, F sharp and C; or between C and G flat, D and A flat, E and B flat, or F and C flat—

Imperfect Fifths.

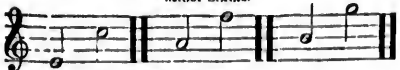
The *sixth* is *major* and *minor*.

The *major sixth* consists of a perfect fifth and a tone; as between C and A, D and B, F and D, G and E.

The *minor sixth* consists of a perfect fifth and a semitone; as between E and C, A and F, B and G—

Major Sixths.

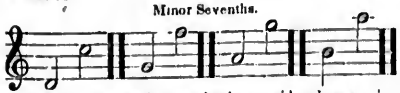
Minor Sixths.



The *seventh* is *major* and *minor*.

The *minor seventh* consists of a major sixth and a *semitone*; as between D and C, G and F, A and G, B and A

Minor Sevenths.



The minor seventh may also be considered as a minor sixth and a tone, or as a fifth and a minor third, or as an octave wanting a tone.

The *major seventh* consists of a major sixth and a tone; as between C and B, F and E –

Major Sevenths.

The major seventh is an octave wanting a semitone.

The octave is from a note to another of the same denomination; as from C to C, D to D, &c.

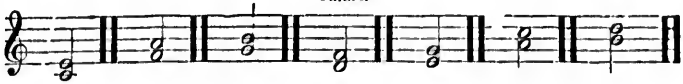
Intervals which extend beyond an octave are, the *ninth*, *tenth*, *eleventh*, *twelfth*, &c., though it is seldom found necessary to extend these denominations further. From the relation between a sound and its octave, it follows that similar relations exist between these larger intervals and those already enumerated. Thus, the *ninth* is considered as corresponding to the *second*, the *tenth* to the *third*, the *eleventh* to the *fourth*, and the *twelfth* to the *fifth*.

The above are all the intervals which are derived from the *diatonic scale*. There are several others derived from the *chromatic scale*; but to these it is not necessary to advert at present. A familiar acquaintance, however, with those already enumerated, is absolutely necessary, as their names and properties occur at every step of the learner's progress.

Intervals are considered as being, not only between two notes sounded successively, but between two notes sounded together. In the one case, they are intervals of melody; in the other, they are intervals of harmony. Intervals of melody are written as above, intervals of harmony as under—

Seconds.

Thirds.



Fourths. Imperfect.

Fifths. Imperfect.

Sixths

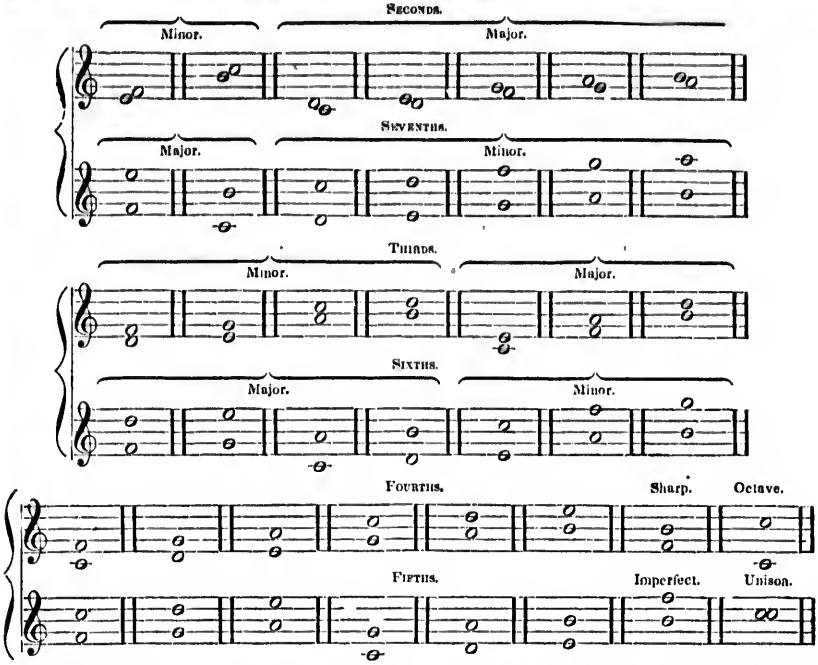
Sevenths.

Octaves.

Intervals may be inverted; that is, the lower note, by being raised an octave, may be placed uppermost; or the upper note, by being lowered an octave, may be placed undermost.

By inversion, a second is changed to a seventh, and a seventh to a second; a third is changed to a sixth, and a sixth to a third; a fourth to a fifth, and a fifth to a fourth.

Major intervals are changed to minor, and minor intervals are changed to major. A minor second becomes a major seventh, and a major second becomes a minor seventh. A major third becomes a minor sixth, and a minor third becomes a major sixth; and so on, as in the following examples:—



Intervals are divided into *Consonant* and *Dissonant*.

When two (or more) notes are heard at the same time, it is found that some of these intervals are agreeable and others disagreeable to the ear. The intervals which form the agreeable combinations are called *consonant*, the others *dissonant*. Harmony is not confined to the use of consonant intervals or *concords* only. On the contrary, the admixture of dissonant intervals, or *discords*, produces many of its greatest beauties.

The consonant intervals are the *major* and *minor third*, the *fifth*, and the *octave*, with their *inversions*; namely, the *major* and *minor sixth*, and the *fourth*. The *unison* also may be included; because, though it cannot properly be called an interval, yet it is the inversion of the octave; and when used by two or more voices, is agreeable to the ear, and of use in harmony.

It must, however, be remarked, that, though the inversion of the third (the sixth) is as agreeable to the ear as the third itself, yet this is by no means the case with the inversion of the fifth (the *fourth*); which is so much less agreeable than the fifth, that it requires (as will be afterwards shown) some of the precautions required in the use of discords.

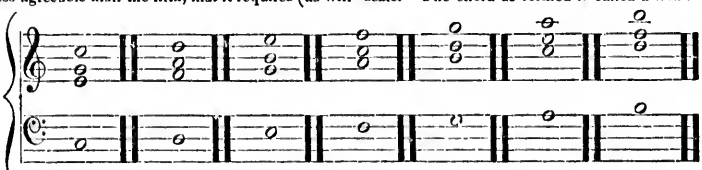
The dissonant intervals are the *major* and *minor second*, the *sharp fourth*, the *imperfect fifth*, and the *major* and *minor seventh*.

The *major* and *minor ninth* (the octave of the second) are also dissonant intervals.

CLASSIFICATION OF CHORDS.

Where any note is heard, along with its third (major or minor), its fifth, or its octave, or with all these together, the combination (called a *chord*) thus produced is agreeable to the ear—

Such a chord may be formed upon every note of the scale. The chord so formed is called a *triad*—



The above chords will be found to be of three kinds.

The first kind consists of the fundamental note, with its *major third*, *fifth*, and *octave*, and is formed upon the *key-note*, the *fourth*, and *fifth* of the scale. It is called the *major triad*.

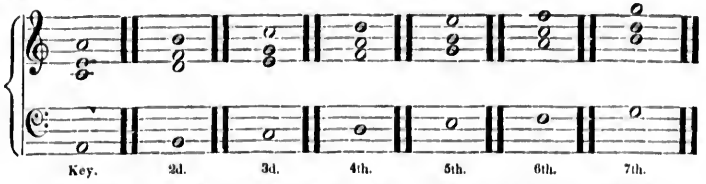
The second kind consists of the *minor third*, *fifth*, and *octave*, and is formed upon the *second*, *third*, and *sixth* notes of the scale. It is called the *minor triad*.

The third kind consists of the *minor third*, the *imperfect fifth*, and *octave*, and is formed on the *seventh* note of the scale. As this chord contains a dissonant interval (*imperfect* fifth), it is much more sparingly used, and with greater precautions, than the others. It is called the imperfect *triad*.

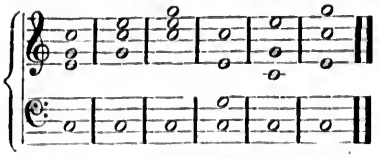
Triads.

The above triads are formed upon the scale in the key of C major. It would unnecessarily multiply examples to exhibit the formation of the triads in the other keys. This the learner can do for himself; and it may be added (once for all), that the examples and exercises given in the sequel ought to be written by the learner in a variety of keys, in order to make him familiar with the practice of transposition.

The *minor scale* will give the same triads, but differently placed—



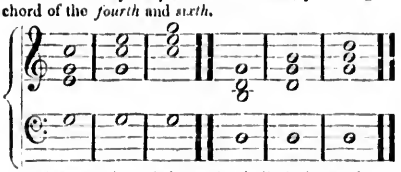
The notes of which a triad consists may be taken in different *positions*; for example—



In changing the *position* of a triad, the fundamental note remains in the lowest place, or in the *bass*. But the triad may also undergo different *inversions*, by placing the third or the fifth in the lowest place, or bass.

The *third* may be placed in the bass, producing the chord of the *third* and *sixth**—

The fifth may be placed in the bass, producing the chord of the *fourth* and *sixth*.



And every other triad may be similarly inverted.

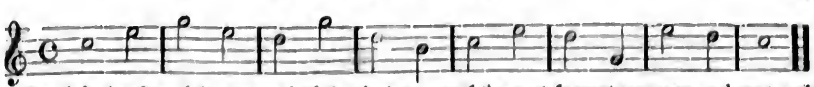
Progression of Chords.

Although every note of the scale may thus be made the foundation of a triad (or *common chord*, as it is also called), yet, in forming a harmonious series of triads, they cannot be made to follow each other at pleasure; but their succession must depend on certain rules deduced from the position of their fundamental note in the scale to which it belongs.

In every scale, the most essential note is the *key-note*, or *tonic*. The note, or one of the notes contained in its triad, begins and ends every strain of melody or harmony, and recurs so frequently that its impression is never lost upon the ear. Melodies frequently consist entirely of the notes of this triad—

Next to the key-note, or tonic, the most essential note is the *fifth* of the scale, called, from its importance, the *dominant* or ruling note. By adding this note, and the notes of its triad, to those of the tonic, a larger field of melody and harmony is thrown open.

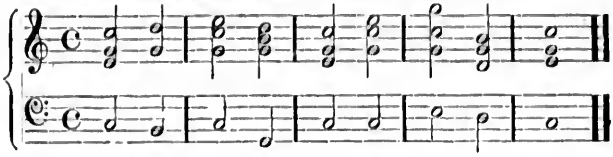
* In the present treatise, we make no use of the method of marking the different positions and inversions of chords by means of what are called *thorough bass figures*. It is a rude and clumsy contrivance, invented in the very infancy of the art of harmony, superseded by a better system of notation, and entirely discontinued in modern practice. It still continues to encumber books of instruction, because its acquirement is considered useful in order to read old music still extant, in the notation of which the figures were used. But this reason is becoming weaker every day, as most of the classical compositions of the old masters have been (or are being) reprinted in the modern manner of notation.



The triads, therefore, of the *tonic* and of the *dominant* are of the most frequent occurrence, and most easily alternate with each other.

Alternations between the *tonic* and *dominant*, in different *positions*—.

Alternations between the *tonic* and *dominant*, in different *inversions*—

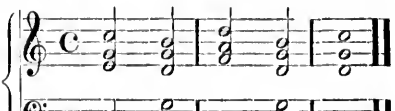


After the tonic and dominant comes the *fourth* of the scale, called the *subdominant*, with its triad—

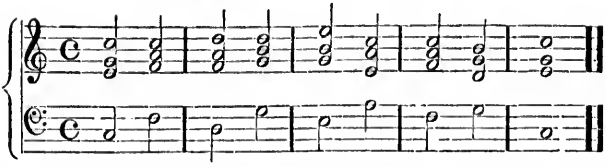
Alternations of the tonic, dominant, and subdominant triads, in different *positions*—

Alternations of these three triads, in different *inversions*—

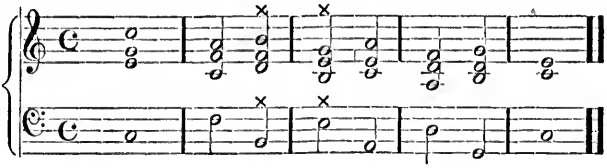
The triad on the second note of the scale (called the *supertonic*) is the next, in frequency of use, to the preceding three. Its employment may be understood from the following example:—



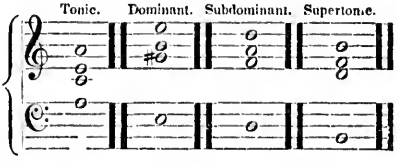
The above four triads—the tonic, dominant, subdominant, and supertonic—are the most essential. But the triads upon the *third* and the *sixth* notes of the scale (E and A in the scale of C) are also in frequent use, blended with the others; as follows—



The only remaining triad is that on the *seventh* note of the scale, or the *imperfect* triad. One of its intervals (the imperfect fifth) being dissonant, it is much less frequently used than any of the other triads. In order to diminish its harshness, the dissonant note must fall, in the following chord, to the note immediately below it. Thus F, the dissonant note in the triad of B, must fall to E. This is called *resolving* the discord—

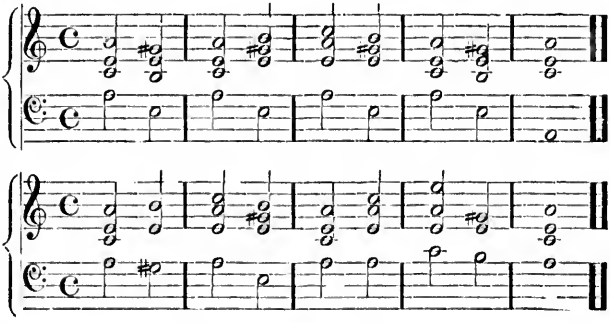


In the *minor* scale, the principal triads are placed on the same notes, and in the same order, as in the major; that is, on the *tonic*, *dominant*, *subdominant*, and *supertonic*. In the key of A minor, the *relative* to C major, these triads are—



Here, it will be observed, the *tonic* and *subdominant* are *minor* triads. The *dominant* is a *major* triad, and *supertonic* an *imperfect* triad. The following examples will show how they are employed:—

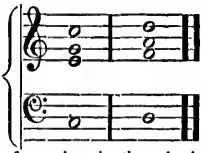
Alternations between the tonic and dominant, in different *positions* and *inversions*—



Alternations between the four triads—

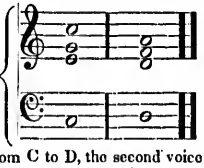
In forming progressions of chords, several considerations must be attended to. A chord must be regarded as a harmonious combination of notes sounded at the same time by several voices or instruments; and a series of chords must be regarded as a succession of notes sounded by several performers and forming several different parts or melodies, heard at the same time. Care, therefore, should be taken that the notes of each part follow each other smoothly, as in the examples already given. It will be observed, in general, that the bass moves by larger intervals than the upper parts of the chord. The following is an example of the smoothest form in which a progression of triads can be arranged:—

It is not permitted to make any two parts ascend or descend together by *consecutive fifths*, or *consecutive octaves*.



Take, for instance, the progression from the tonic to the supertonic—

Suppose these notes sung by four voices, in the order in which they stand. While the bass sings C, D, the second voice will sing G, A, each note being a fifth (or octave of the fifth, which is the same thing) higher than the notes in the bass; and the highest voice will sing C, D, each note being an octave above the bass. But both of these are prohibited, and may be avoided thus—



Here, while the bass rises from C to D, the second voice falls from G to F, and the highest voice falls from C to A. The progression of the triads is the same, with a different motion of the parts. This motion, when one part rises while the other descends, is called *contrary motion*. When both parts rise or fall, the motion is called *similar*; when one part rises or falls while the other part is stationary (that is, repeats or continues the same note), the motion is said to be *oblique*.

It is not easy to explain why two-fifths, heard consecutively in similar motion, should produce a bad effect, seeing that the fifth is, next to the octave, the most perfect consonance. But the fact is sufficiently ascertained by experience. The prohibition of two octaves in succession is of a different kind. They are not offensive in themselves, and are prohibited only when they would produce a poor and meagre harmony; for a note and its octave being considered as the same, if two parts move in octaves, one of them is, in respect to fulness of harmony, thrown away. There is, consequently, no harm in making two parts move in octaves when the harmony is otherwise as full as is requisite. A whole strain of music may be performed in octaves (as when a man and a woman sing together apparently the same notes); but this is not regarded as harmony at all, in the technical sense of the term.

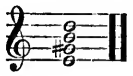
CHORDS OF THE SEVENTH.

Besides the chords called *triads*, or *common chords*, there is another class of chords, called *chords of the seventh*. From these two classes, every chord used in harmony is derived.

The principal *chord of the seventh* is formed on the dominant, or fifth note of the scale. It is formed by adding a minor seventh to the major triad on the note—

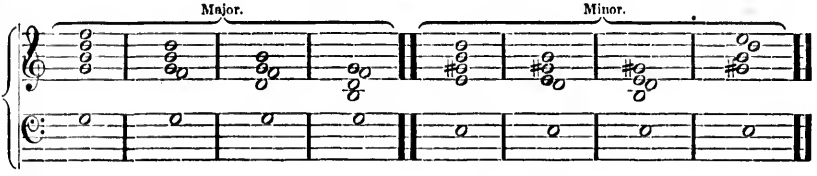
Dominant of C major.

Dominant of A minor.



This chord may be taken in four *positions*—

Major. Minor.



The dominant seventh is generally followed by the tonic. The dissonant note (the seventh) is *resolved* by falling a semitone, into the *third* of the tonic, and the third of the dominant chord rises one semitone into the tonic—

Major. Minor.

Alternations between the dominant seventh, its four *positions*, and the tonic—

Major.

MINOR.

The dominant seventh admits of three *inversions*, formed by placing the different notes of the chord in the bass They are as follow, alternating with the tonic:—

MAJOR.

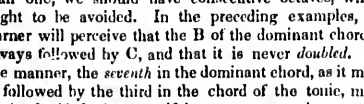
MINOR.

The first inversion of the chord of the seventh is called the chord of the *sixth* and *fifth;* the second inversion is called the chord of the sixth, fourth, and third (or, for shortness, *six-four-three*); the third inversion is called the chord of the sixth, fourth, and second (or, *six-four-two*). These names will be evident from looking at the chords.

In passing from the chord of the dominant to the chord of the tonic, the third in the dominant chord, which is the major seventh, or *leading-note*, of the scale, must ascend by a semitone into the key-note. Thus, in the key of C, the note B, in the chord of the dominant, must always be followed in the same part by C, the key-note, in whatever manner the chords may be inverted. Further, the third in the dominant chord ought not to be *doubled*, or sounded in more than one part; because, as this note must be followed by the key-note, if this were done in more parts than one, we should have consecutive octaves, which ought to be avoided. In the preceding examples, the learner will perceive that the B of the dominant chord is always followed by C, and that it is never *doubled*. In like manner, the *seventh* in the dominant chord, as it must be followed by the third in the chord of the tonic, must not be doubled; because, if it were, consecutive octaves would likewise be produced.

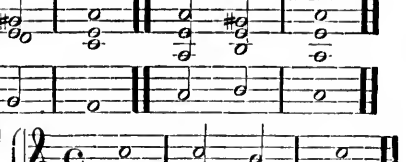
Another chord of the seventh, next in importance to the dominant, is formed upon the second note of the scale, or supertonic.

Supertonic of C major. Supertonic of A minor.



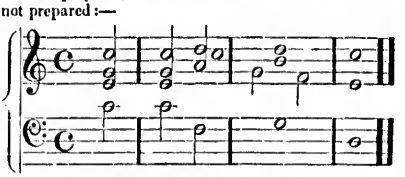
This chord may be taken in four *positions*, and admits of three inversions, analogous to those of the dominant. The learner will write it in these different forms.

In the chord of the seventh on the *dominant*, the seventh, which is the discord, must be *resolved*, as already mentioned. In the chord of the seventh on the supertonic (and in every other chord of the seventh), the seventh must be not only resolved, but prepared; that is, this note must be heard, as a consonance, in the preceding chord—

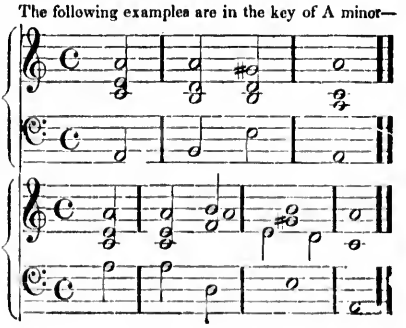


Here the C, which is the seventh of the supertonic, is *prepared* by being heard as the octave in the preceding chord, and *resolved* by falling to B in the following chord. The F, which is the seventh of the dominant, is also, in this case, both prepared and resolved. But the seventh of the dominant is not *necessarily* prepared; as may be seen by the examples already given, where it is resolved, though not prepared.

In the following example, the seventh of the supertonic is prepared, while the seventh of the dominant is not prepared:—



The following examples are in the key of A minor—



These two chords (the dominant and supertonic) are the principal chords of the seventh; but chords of the seventh (like triads) can be formed on every note of the scale. They are of four kinds; namely,

The *chord of the dominant seventh*, on the fifth note of the key consisting of a *major* third, a fifth, and a minor seventh.

The *minor chord of the seventh*, on the supertonic, the third and the sixth notes of the key; consisting of a *minor* third, a fifth, and a minor seventh.

The *chord of the major seventh*, on the tonic and subdominant; consisting of a major third, a fifth, and a *major* seventh.

The *imperfect chord of the seventh*, on the seventh note of the scale; consisting of a minor third, an *imperfect* fifth, and a minor seventh.

Of these chords of the seventh, the *dominant* (as already mentioned) is the most frequently used. Next in frequency are the minor chords of the seventh, namely, the chords on the supertonic, the third, and the sixth. More rarely used are the chords of the major seventh, on the tonic and the fourth; and, most seldom of all, the imperfect chord of the seventh, on the seventh.

In *every* chord of the seventh, the dissonant note must be *resolved* by descending one degree. In every chord of the seventh (*excepting the dominant*), the dissonant note must also be prepared, by being heard as a consonance in the previous chord.

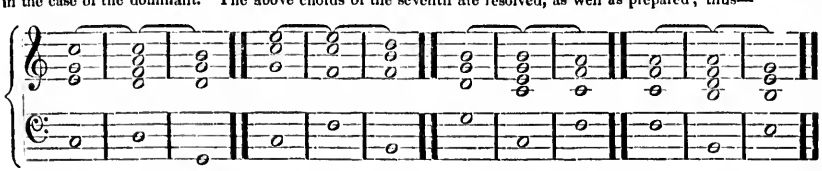
In order that these conditions may be complied with, the fundamental note of every chord of the seventh must descend by a fifth (or rise by a fourth) to the fundamental note of the following chord.

Thus, the chord of the *dominant must* be followed by the chord of the *tonic;* of which progression examples have already been given. It is not necessary, however (as has also been already shown), that the fundamental note of the chord shall stand in the lowest position. By *inversion*, any of its notes may be placed undermost but, whatever be the inversion, the fundamental progression is considered the same.

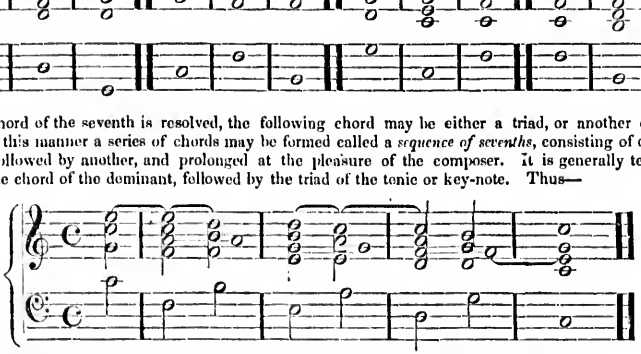
In regard to the other chords of the seventh, the fundamental progression to the chord must be such, that the note which forms the *seventh* in the second chord shall be a third, fifth, or octave, in the first. In other words, the dissonant note in the second chord must be previously heard as a consonant note in the preceding chord. This is called *preparing* the dissonance.

The following are *preparations* of various chords of the seventh:—

Every chord of the seventh must be *resolved*, by its fundamental note falling a fifth or rising a fourth, as shown in the case of the dominant. The above chords of the seventh are resolved, as well as prepared; thus—



When a chord of the seventh is resolved, the following chord may be either a triad, or another chord of the seventh. In this manner a series of chords may be formed called a *sequence of sevenths*, consisting of one chord of the seventh followed by another, and prolonged at the pleasure of the composer. It is generally terminated by arriving at the chord of the dominant, followed by the triad of the tonic or key-note. Thus—



The above series commences with the triad in the key of C, and ends with the same triad, preceded by the chord of the dominant. The intermediate chords are all chords of the seventh, in which the dissonant note (the seventh) is first *prepared* by being heard as a consonance in the preceding chord, and is then *resolved* by falling a single degree. The preceding passage is more elegantly written thus—

It must be observed that, in passages of this kind, the chords are not usually inverted, as their effect depends on the fundamental notes being distinctly heard in the bass.

CHORDS DERIVED FROM THE DOMINANT.

That most important note, the *dominant*, may not only be made (as has been already shown) to carry a triad, or a chord of the seventh, but also several secondary chords derived from the above.

By adding the *ninth* to the chord of the seventh, on the dominant, we have the chord of the *ninth* and *seventh*—

This chord must be followed by the triad of the tonic; and as it contains two dissonant notes, both of them must be resolved by descending into the notes of the following chord:—

In the relative minor key, this chord of the ninth and seventh will be resolved thus:

This chord of the ninth and seventh is frequently used *without* its lowest or fundamental note. It then assumes the appearance of a chord of the seventh, on the seventh note of the scale. But in this case, it is treated as if the fundamental note were understood and will be resolved into the chord of the tonic—

Major.

Minor.

The above chord, when minor, is called the chord of *the diminished seventh*, as it has the appearance of a chord of the dominant, in which the interval of the seventh has been diminished by raising the lowest note a semitone

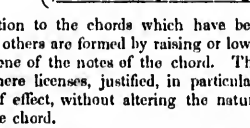
These two chords may be *inverted* by placing any of their notes in the bass—

MAJOR.

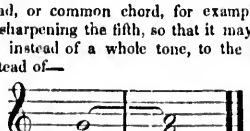
MINOR.

In addition to the chords which have been already explained, others are formed by raising or lowering, by a semitone, one of the notes of the chord. Those alterations are mere licenses, justified, in particular cases, by elegance of effect, without altering the nature or treatment of the chord.

The triad, or common chord, for example, may be altered by sharpening the fifth, so that it may ascend by a semitone instead of a whole tone, to the subsequent note. Instead of—

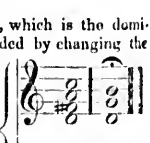


we may have



The most important of these altered chords, is that which is called *the extreme sharp sixth*. It is derived from the chord of the dominant. Suppose we have the following phrase, in the key of C:—

The close or stop on the last chord, which is the dominant triad, may be made more decided by changing the preceding chord, which is the minor chord of the seventh on the second note of the scale of C, into the chord of the dominant seventh on the fifth note of the scale of G, and resolving it into the triad of G, considered as a new tonic—



Take this chord in its *second* inversion, and then *flatten* the lowest note, so that it may fall by a *semitone* to the note following; and we have—

But as this chord, containing a *sharp fourth*, as well as an extreme sharp sixth, is too harsh, the sharp fourth is left out, and it is taken thus—

Or, instead of the sharp fourth, the perfect fifth is inserted—

There are here *consecutive fifths*; as, while in the bass A flat descends to G, in the second part E flat descends to D. In this case, the consecutive fifths have no bad effect, and are admitted by the best composers; though others, more scrupulous, avoid them thus—

SUSPENSIONS, &c.

The chords already described are all the *real* or *essential* chords used in harmony. But great varieties of harmony may be produced by blending the notes of one chord with those of another. If, after passing from one chord to another, one or more notes of the first chord are prolonged, so as to be heard at the same time with the notes of the second chord, this is called a *suspension*.

Take, for instance, the common progression from the dominant to the tonic—

The notes peculiar to the dominant may be prolonged into the tonic, thus—

The notes thus prolonged or suspended become *dissonances* when they are heard in the second chord; but they are rendered agreeable by being *prepared* and *resolved*. This is perfectly plain, from inspecting the preceding example.

Suspensions may be formed upon any of the progressions from one chord to another which have been already explained. To give examples of these in all their variety, within our limits, is impossible; but the following specimen will give the learner an idea of the manner in which they are used. Let him compare the following progression of chords, without suspensions, with the same progression in which suspensions are introduced:—

Without suspensions—

With suspensions—

Such passages are usually written more elegantly, thus—

The suspension may be placed in any part of the chord, either upper or under, the suspended note being **always** prepared and resolved. For example, in the bass—

Suspensions are sometimes, but rarely, resolved by *ascending*. This generally happens when the seventh, or leading note of the scale, rises to the key-note—

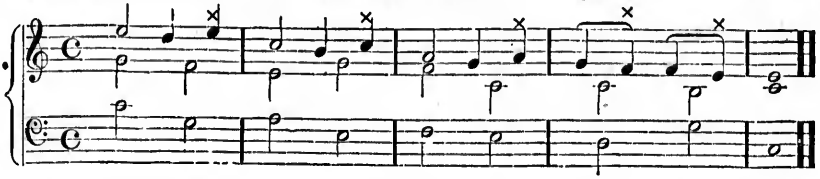
Passing notes are notes introduced to give a melodious smoothness to the passage from one chord to another, and which, though not belonging to the chord, are yet harmonious to the ear. For example—

Here the notes marked with a cross do not belong to the chords, but serve as connecting links to those which do belong to them.

The passing notes are generally unaccented notes, though sometimes they are *accented*; as—

The following is an example of passing notes placed in the bass:—

Anticipation is another mode of introducing notes not belonging to the chords. It is done by anticipating a note by sounding it before the chord to which it belongs is struck, as in the following passage;—



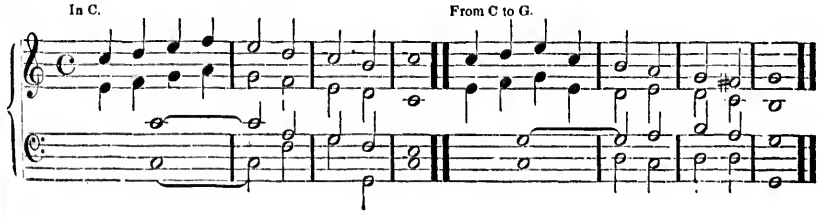
Lastly, harmony by notes not belonging to the chords may be produced by *pedal notes*. A pedal note (so called from its being generally played on the organ by the *pedals*), is a note in the bass, held on for several bars, while a series of different chords is heard along with it. It is chiefly used in the tonic or the dominant—

MODULATION.

Modulation is the art of passing from one key to another. A short tune, or melody, generally remains in one key; but in more extended works, it is necessary, for the sake of variety, to diverge into different keys, according to the character and style of the composition. The field of modulation is of almost boundless extent and inexhaustible fertility in musical resources; but their use requires much skill and judgment, and is regulated by certain laws and principles indispensable for the preservation of unity and consistency.

The following simple phrases, all commencing in the key of C, show how a melody may pass into other keys.

The foregoing examples may show how a melody may pass from one key to another. By harmonizing them, we see how the chords of one key pass to those of another. It will be observed that the chord of the new key is always preceded by the chord of its *dominant*—



The above are the keys into which we can pass most easily from the key of C major. If the original key is A minor, the keys into which we can pass most easily are, C major, E minor, G major, D minor, and F major—

The learner may exercise himself in making transitions from A minor to the other keys above mentioned.

In modulating from the key of C to the key of any other note of the scale, the new key will be major or minor, according as the third in the scale of the new fundamental note is major or minor. Thus, the keys of F and of G (as well as C) are major; while the keys of D, E, and A, are minor. We do not mention the key of B, as this key, in modulating from the key of C, is very rarely used. This note, besides having a minor third, has an *imperfect* fifth, F natural; and, to make it the fundamental note of a key, whether major or minor, its fifths must be made *perfect*, by changing F to F sharp—which is not in the scale.

In the above examples of transitions from C major, or A minor, to other keys, these notes must be understood as standing for *any* major or minor key, from which transitions may be made in the same manner. Thus, taking G as the original major key, transitions may be made to D and C major, and to A, B, and E minor; and, taking E as the original minor key, transitions may be made to G major, B minor, D major, A minor, and C major. The learner should exercise himself in writing similar modulations in all the different keys.

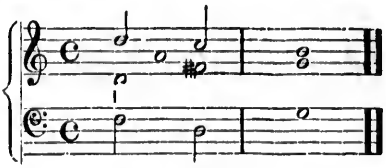
The smoothest and most gradual modulation is effected by means of a chord which is common to both keys that is, which belongs both to the original key and to the new key—

In the first of these examples, the first triad of G belongs both to the original key of C and to the new key of G. In the second example, the triad of F (of which A is the bass) belongs both to the original key of C and to the new key of F.

Modulation is less gradual (though it may be perfectly admissible), although the chord which immediately precedes the new key is not common to both keys—

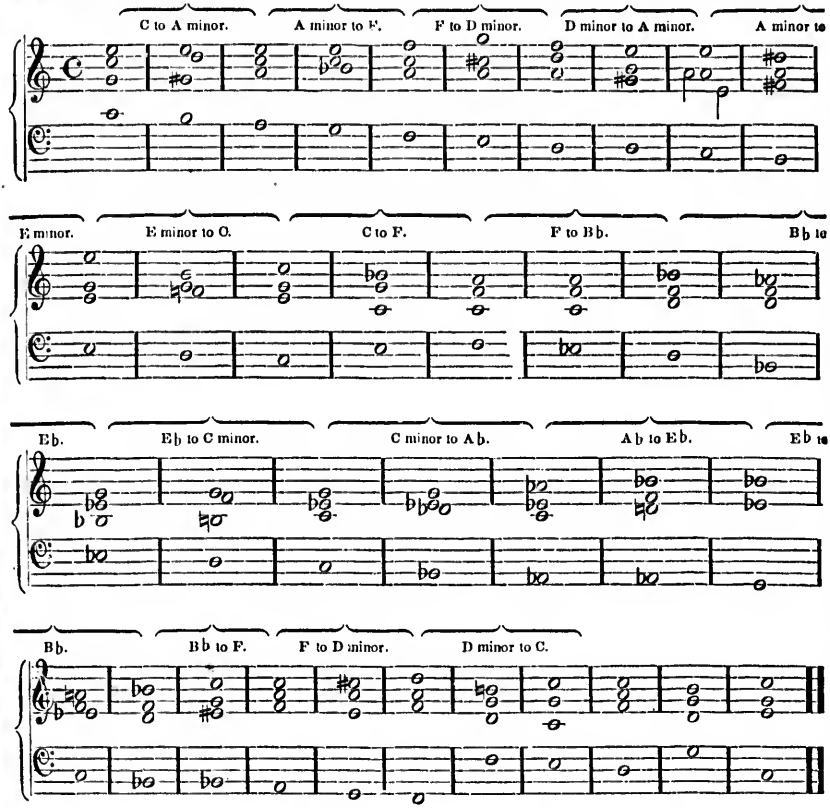
In the first example, the triad of F belongs to the original key of C, but not to the new key of G. In the second example, the triad of G belongs to the original key of C, but not to the new key of F. This kind of modulation generally produces a *chromatic* melody, or a melody containing an *accidental* semitone in one of the parts; as from F to F sharp, or from B to B flat, as above.

When a chord is succeeded by another, in such a manner that one of the notes of the first chord appears in the second chord, altered by a sharp or a flat, the note must be followed by its alteration *in the same part*, so as to make a chromatic melody, as in the preceding examples. When the note of the first chord appears in one part, and the altered note of the second chord appears in another part, this produces a fault, called a *false relation;* as, for example—

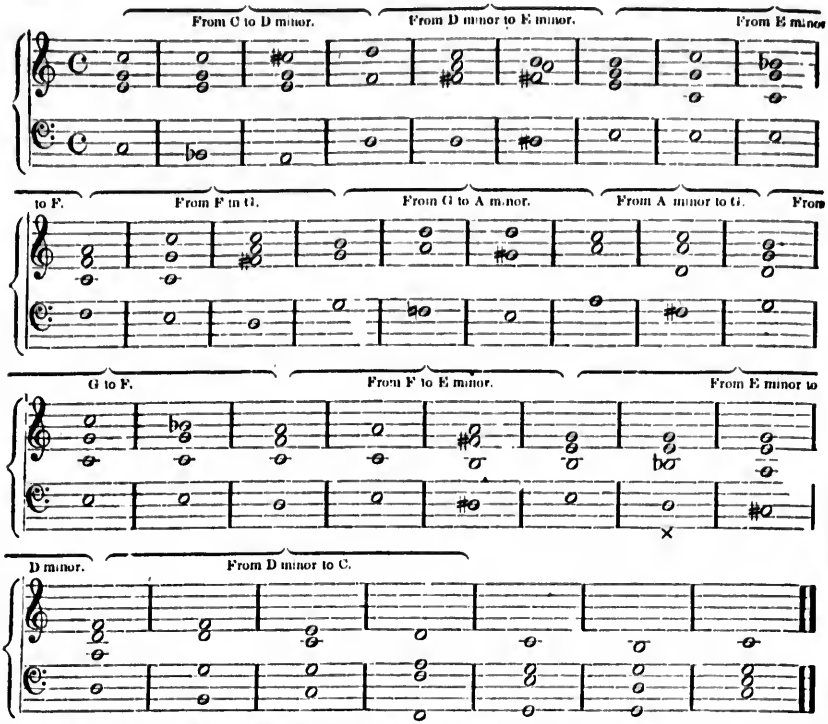


To be avoided thus—

The following example is a chain of modulations, in which every key is *relative* to that which precedes it. All the modulations are effected by an intermediate chord, which is the dominant seventh, generally employed in one of its inversions—



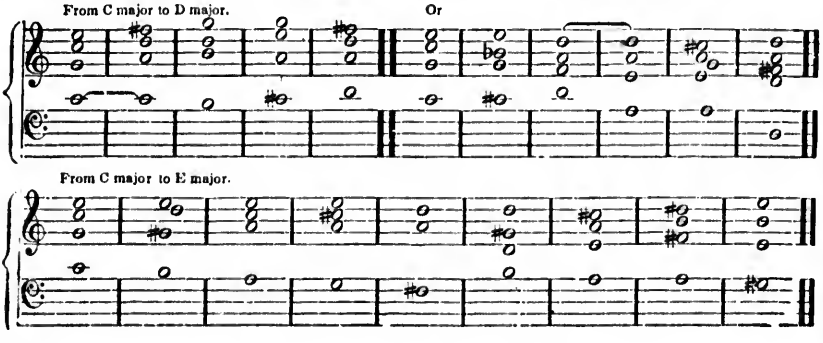
We may modulate into a key which is not relative to that which precedes it (or its antecedent), provided that both keys are relative to the primitive key or the principal key which predominates in the piece of music. Thus, when the principal key is C, we may modulate from D minor to E minor; because, though these keys are not relative to each other they are relative to the key of C. Supposing the primitive key to be any note, we may modulate immediately from its second to its third, from its third to its fourth, from its fourth to its fifth, from its fifth to its sixth, and from its second to its fifth, and *vice versa;* these modulations will be generally effected by means of two intermediate chords, as in this example—



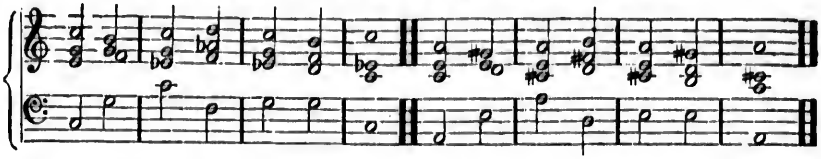
Observe that the D in the bass, marked with a cross, does not belong to the harmony of the chord, but must be regarded as a passing note, leading from the bass-note of the preceding to that of the following chord.

In modulating in this way from a key to another which is not relative to it (as from F to G, or from E to F), we must take care that the *primitive* key, to which both the keys are relative (though not relative to each other), be well determined; for it is only when this precaution is taken, that such modulations can be properly employed. We can easily modulate from G major to F major, by means of two intermediate chords, in a piece of music of which the principal key is C major, while we could not do so if the principal key were D or E minor. What is good in the one case might be bad in another; and all the above-mentioned modulations—from the second note of the scale to the third, from the third to the fourth, &c. —can only be used under the above condition.

When the primitive key is minor, in like manner, we may modulate from the fourth note of the scale to the fifth, from the fifth to the sixth, from the sixth to the seventh, from the fourth to the seventh, and *vice versa*. The learner may exercise himself in finding examples of this rule, similar to those given above. In the above modulations into the keys of different notes of the scale, the keys are major or minor according as their thirds, as they stand in the scale, are major or minor, as already shown; as we modulate from C to D minor, E minor, &c. We may also, though more seldom, modulate from C to D major, E major, &c.; but this must be done by a longer chain of intermediate chords, so as to prepare the ear gradually for the transition. For example—



We may pass from a major to a minor key on the same note, and *vice versa*—



We may likewise modulate from a given key to notes which are not in the scale of that key; as, for example, from C to E flat, B flat, A flat, &c. These modulations ought to be gradually effected, by passing into some intermediate key, which is relative to the keys which precede and follow it. Thus, in order to modulate from C to B flat, we may pass first from C to F, and then from F to B flat—

In order to modulate from C to E flat major, we may pass first from C major to C minor, and then from C minor to E flat; and to modulate from C to A flat major, we may pass from C major to C minor, and thence to A flat—

It may be laid down as a general rule, that, as we may pass from a major key to a minor key on the same note (as from C major to C minor), or from a major key to the minor key of its subdominant (as from C major to F minor), we may pass from a major key to all the keys which are relative to these two other keys. Thus from C major we may pass to all the relative keys of C minor, or to all the relative keys of F minor.

Modulations from C major to the relative keys of C minor—

From C to E flat.

From C to F minor.

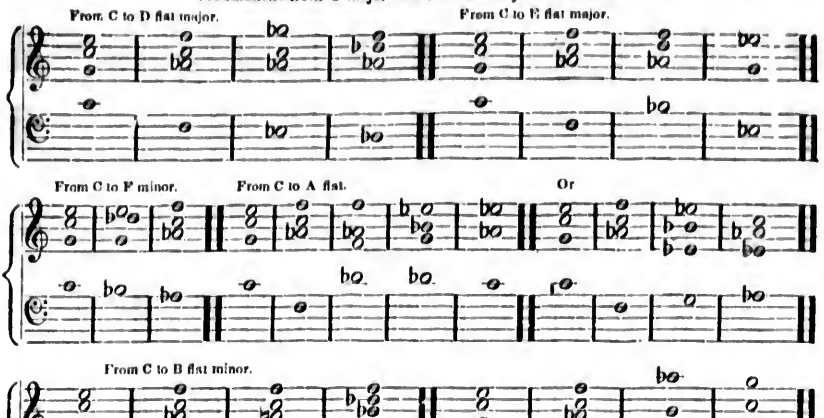
From C to G minor.

From C to A flat.

From C to B flat.

From C major to C minor.

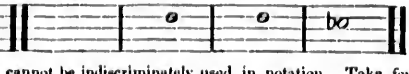
Modulations from C major to the relative keys of F minor—



The above rules and examples embrace the principal varieties of gradual, or regular modulation. But composers, in order to produce uncommon or striking effects, make *abrupt* or *irregular* transitions, by passing from one key to another not related to it (as, from C to B flat, or E flat, or D major, &c.), without the intervention of any intermediate chord. In such cases, the abruptness of the transition is frequently softened by making a pause before striking the chord of the new key; or the same effect is sometimes produced by sustaining a single note, without any harmony, for a little time, and striking a new chord containing this note in its harmony. But the use of the sudden and abrupt transitions cannot be reduced to any rule; it must be gathered from the works of the great masters. They must be cautiously and sparingly used; as departure from rule can be justified only by the effect produced.

There is one kind of sudden modulation which, from its importance, requires especial notice. This is *Enharmonic Transition.*

The diatonic scale (as has been already explained) consists of five tones and two semitones. By dividing all the tones into semitones, we have a scale of semitones, called the *chromatic* scale. In thus dividing the tone, the intermediate sound may be regarded either as the lower extremity of the tone raised, or as its upper extremity depressed; as, the intermediate note between C and D may be either C sharp or D flat. Thus, two chromatic scales are formed—a scale by sharps, and a scale by flats. The tone is not divided into two exact halves, but the difference is so minute as to be disregarded in practice; C sharp is treated as being the same sound as D flat, and on keyed instruments is produced by striking the same key. But, though the intermediate sound between C and D is regarded as the same, whether it is expressed by the name of C sharp or of D flat, yet these names cannot be indiscriminately used in notation. Take, for instance, the chord E, G, B flat, D flat; and then take the chord E, G, B flat, and C sharp. These chords are struck on the same keys of the pianoforte, yet are essentially different in their character and treatment. The chord E, G, B flat, D flat, is a chord of the diminished seventh, which requires to be resolved into the triad of F; the chord E, G, B flat, C sharp, is an *inversion* of a *different* chord of the diminished seventh (C sharp, E, G, B flat), in which the C sharp is removed from the bottom to the top of the chord; and it must be resolved into the triad of D—

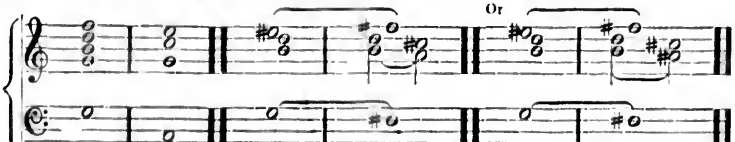


Here, then, we have the means of effecting an unexpected modulation. If, while in the key of F, we have the above chord with D flat, we may, by changing that note into C sharp (the sound remaining in the same), come at once into the key of D.

Enharmonic transitions may be made by means of three chords—the *dominant seventh*, the *extreme sharp sixth*, or the *diminished seventh.*

The chord of the dominant seventh may be changed into the chord of the extreme sharp sixth; and, *vice versa*, the chord of the extreme sharp sixth may be changed into the chord of the dominant seventh.

If we are in the key of C, for example, by changing the F, the dominant seventh, into E sharp, the extreme sharp sixth, we may come at once into the distant key of F sharp, either major or minor.



And, of course, we can reverse this progression, by changing the chord of the extreme sharp sixth into the chord of the dominant.

The chord of the diminished seventh is that whereby enharmonic transitions are most frequently made. Any chord of the diminished seventh may be written in four different ways, its sounds always remaining the same—

In the first of these, the leading note is F sharp, leading to G; in the second, the leading note is D sharp, leading to E; in the third, the leading note is B sharp, leading to C sharp; and in the fourth, the leading note is A, leading to B flat. Thus—

And, as each of these triads of G, E, C sharp, and B flat, may be either major or minor, we have here eight different keys into which we may pass from one chord.

The great facility with which many unexpected transitions may be made in this manner, is a temptation which young composers are seldom able to resist. They crowd their music with crude and disagreeable modulations, imagining that they are displaying learning and skill, while they are doing what is in reality very easy. The remarks on this subject by the celebrated Piccini, one of the greatest masters of the Italian school, ought to be kept in remembrance by every student of music—"To modulate," says this illustrious musician, "is to take a route which the ear will follow willingly. It even asks to be led; but only on condition that, when arrived at the point to which you have conducted it, it may there find something to repay it for its journey, and may enjoy some repose. If you keep it constantly going on without granting what it demands, it becomes weary, and will follow you no longer. To modulate is not difficult in itself; there is a routine for that as well as all other occupations. The proof of this is found in those *enharmonic modulations* which appear to the ignorant the height of science, and are, after all, the mere sport of learners. To create melody from a given modulation, to quit it only by legitimate means, to return to it without harshness or insipidity, to make the change of modulation a just means of expression, and of judicious variety—these are the real difficulties. But to quit a key almost as soon as we have entered it, to become extravagant without reason or end, to proceed by jumps and skips, merely because we do not know how to remain where we are—to modulate, in short, for the sake of modulating, is to prove that the artist is ignorant of the end of his art, as well as of its principles; and that he affects a superabundance of imagination and learning, in order to conceal the want of both the one and the other."

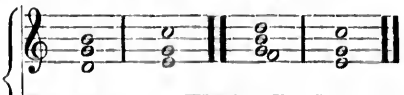
The musical instructor can explain the means by which the different kinds of modulation can be effected; but in the use of these means, the musician must be guided by the dictates of ear, taste, and feeling. It may be said, in general, that the principal key, in which the piece begins and ends, ought to occupy the largest portion of it; and that, in modulating into other keys, those which are most nearly related to the principal key may be dwelt upon at greater length than those which are more distantly related to it. But the varieties in the course of modulation are infinite; and the succession of keys, in any composition, must be the result of judgment matured by experience.

CLOSES OR CADENCES

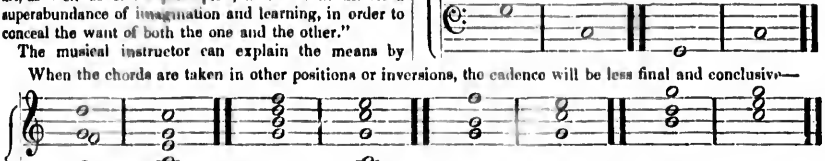
There is an analogy between music and language, in regard to *punctuation*. A strain of music is divided into periods, and these are subdivided into clauses; these periods and their subdivisions being marked by closes, or cadences, more or less complete. These closes, or cadences, are found either in melody or in harmony; but the closes of a melody are more strongly marked and defined by the harmony with which they are accompanied.

The principal cadences are those which end on the tonic, or key-note.

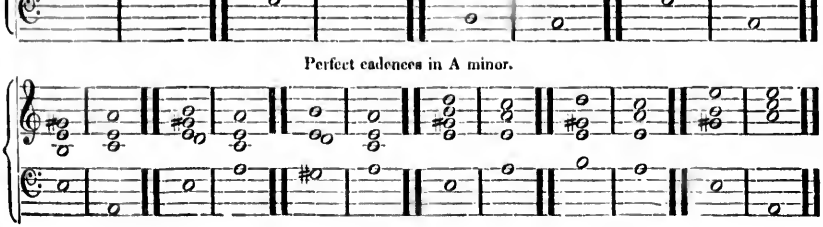
The *perfect* cadence takes place when the chord of the tonic is preceded by the chord of the dominant. Its most complete and final form is when the tonic itself is the last note of the melody, and when the fundamental notes of the chords are placed in the bass. The dominant may be either a triad, or a chord of the seventh—



When the chords are taken in other positions or inversions, the cadence will be less final and conclusive—



Perfect cadences in A minor.



The tonic may be preceded by the subdominant—

C major. A minor.

This cadence, from the subdominant to the tonic, is not used as a final close, except occasionally in old ecclesiastical music.

In the final cadence, from the dominant to the tonic, the seventh note of the scale (or leading note) must always be heard in one of the parts, and followed by the key-note. In minor keys (as well as major), this seventh or leading note, must always be the major third of the dominant chord, and must ascend to the tonic by a semitone.

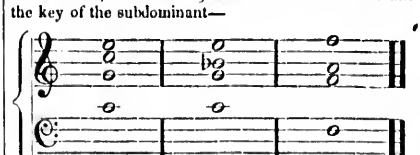
The next class of cadences are those which end on the *dominant*, and are called *imperfect*. The dominant may be preceded by various chords—most frequently by the tonic; but also by the subdominant, or the supertonic—

These closes on the dominant are never final; something else is always expected to follow them. A close on the dominant may be rendered more determined by making the preceding chord a dominant, and thus rendering the closing chord a temporary tonic. This is a transient modulation into the key of the dominant of the original key. In the key of C, the chord of D, the supertonic, will be converted into the dominant of the key of G—

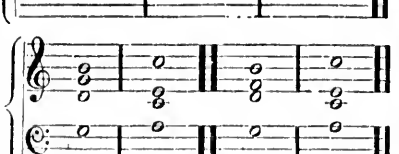
Or the chord preceding the close may be one of the chords derived from the dominant; the chord of the *diminished seventh*, or the chord of the *extreme sharp sixth*—

A cadence may take place by passing from the tonic to the *subdominant*—

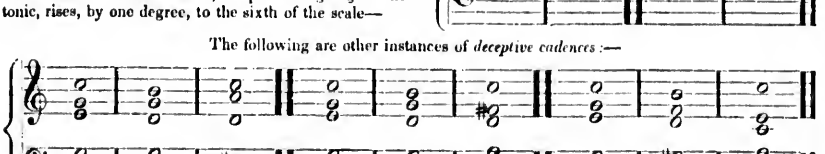
This may be made more decided by converting the tonic into a temporary dominant, by adding the minor seventh to its chord; thus making a transient modulation into the key of the subdominant—



When we expect a perfect cadence from the dominant to the tonic, the ear may be disappointed or deceived, by passing from the dominant to some chord different from the tonic. The most common of these is the *interrupted cadence*, in which the fundamental note of the dominant chord, in place of going to the tonic, rises, by one degree, to the sixth of the scale—



The following are other instances of *deceptive cadences*:—



The use of such cadences is to prevent the strain from coming to a final close, by disappointing the ear of the expected termination, and leading it to expect something more. This is well exemplified in the national air of "God save the Queen." The first part consists of six bars; at the end of the fourth, the melody comes to a close upon the key-note; but, in the bass, this close is *interrupted* by rising from the dominant to the sixth—

The following examples also show how, by such means, variety may be given to the repetition of the same notes in a simple melody :—

COUNTERPOINT.

Counterpoint is the art of composition in two or more vocal or instrumental parts, in such a manner as to render each separate part smooth and melodious, and at the same time to combine them in the purest harmony. This art is to a great extent deduced from the principles of harmony already explained; but, in its practice, various considerations and rules must be attended to, in order to prevent the music from being harsh, and unnecessarily difficult of execution. Many persons can heap together full chords on the organ or pianoforte, who cannot write, with purity and elegance, a simple duet for two voices.

The rules of counterpoint depend, in some measure, on the number of voices or instruments for which music is written. The fewer the parts, the stricter are the rules applicable to them. In two parts, things are prohibited which are admitted in three or four. We shall, therefore, give the principal rules of counterpoint, as applicable to composition in two parts; and shall afterwards show how they may be relaxed when the parts are more numerous.

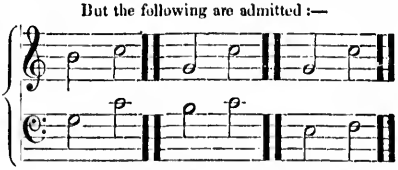
Counterpoints in two parts.

Two fifths, or two octaves, are not to be used in succession. This rule, which has been already explained, is of rigorous application in this species of counterpoint.

It is improper to proceed to a *perfect concord* by *similar motion*, except when one of the parts proceeds by a semitone. It is necessary to explain, that the octave and the fifth are called *perfect concords*, and the third and the sixth *imperfect concords*.

It is wrong, therefore, in two parts, to use such progressions as these—

But the following are admitted :—

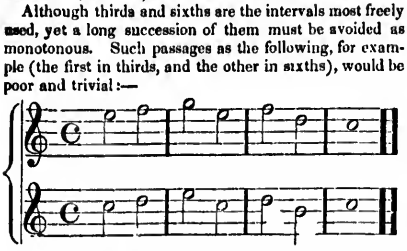


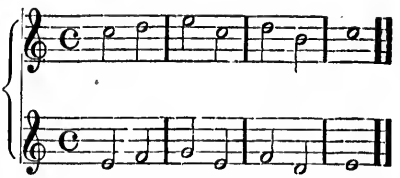
In the melody of each part, considered separately, the intervals ought, as much as possible, to be smooth and easily taken by the voice. This is a rule more of taste than of grammar, and the strictness of its application must depend on the nature of the composition. The ancient masters, who wrote for voices unaccompanied by instruments, did not admit into their melodies the intervals of the sharp fourth, the diminished fifth, nor the seventh. But in modern music, where the voices are supported by instruments, all these intervals are admitted. The *principle* of the rule, however, ought never to be lost sight of, especially in vocal music.

In considering the two parts together, the same principle should be observed in regard to the intervals of harmony. The intervals most freely used are the *major and minor third*, and *major and minor sixth*. The *unison* and *octave* are used seldom, as their frequent use would render the harmony meagre; their use is therefore chiefly con-

fined to the beginning and end of a passage. The *fifth* is used more frequently than the unison and octave, but by no means so freely. The *fourth* must be used sparingly, and generally with the precaution of being prepared and resolved; and the same thing is the case with the second, seventh, and other dissonant intervals.

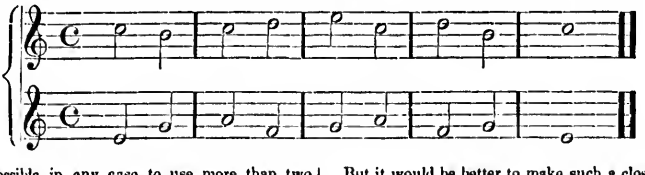
Although thirds and sixths are the intervals most freely used, yet a long succession of them must be avoided as monotonous. Such passages as the following, for example (the first in thirds, and the other in sixths), would be poor and trivial:—



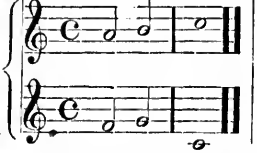


On this account, it is laid down as a rule, that no more than three thirds, or three sixths, ought to be used in immediate succession.

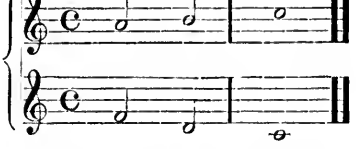
The monotony above exemplified is avoided, and an agreeable harmony produced, by using thirds and sixths so blended together as to prevent the recurrence of too many of the same kind in succession, thus—



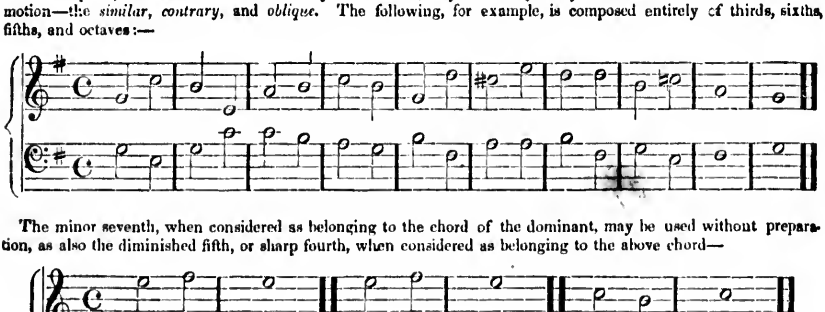
It is impossible, in any case, to use more than two major thirds in succession; and even two major thirds in succession can be tolerated only in one case, which is, when the two upper notes are the sixth and major seventh of the scale, immediately preceding a close; as—



But it would be better to make such a close thus



Counterpoint, even when it consists merely of concords, may be diversified by the use of the different kinds of motion—the *similar*, *contrary*, and *oblique*. The following, for example, is composed entirely of thirds, sixths, fifths, and octaves:—



The minor seventh, when considered as belonging to the chord of the dominant, may be used without preparation, as also the diminished fifth, or sharp fourth, when considered as belonging to the above chord—

Our limited space prevents us from going further into this branch of our subject, and passing over counterpoint in more than two parts, we arrive at

IMITATION, CANON, DOUBLE COUNTERPOINT, AND FUGUE.

The preceding pages contain an exposition of the principles of harmony, which are applicable to every species of composition. It remains to point out several resources which are found essential to the production of beauty and variety; as, without a general knowledge of their nature, so as to be able to perceive them when they are used, it is impossible to comprehend and enjoy the works of the great masters.

Of these resources, the principal are *imitation*, *canon*, *double counterpoint*, and *fugue*.

Imitation is the repetition, in one part, of a phrase or passage which has already been heard in another part. The imitation may be made either in the unison or octave, or in some other interval above or below.

imitation may be made by *contrary motion;* that is, when descending intervals in the one part are imitated by ascending ones in the other, and *vice versa;* and by *retrograde motion*, when the imitation begins at the end of the imitated passage, and goes backward.

Imitations are likewise made by *augmentation:* that is, when the given passage is imitated in notes of double length; and by *diminution*, when this process is reversed. Imitation is *strict*, when the passage is precisely imitated in every interval; and *free*, when the figures of the notes are imitated, so as to produce a general resemblance, without an exact imitation of the intervals.

Canon is that species of composition in which two or more parts are heard successively, in strict imitation. Canon is based upon imitation; but imitations are introduced and abandoned at the pleasure of the composer; whereas the whole piece or movement, called a canon, must be in strict imitation. Canon being just strict imitation, it follows that there are as many kinds of canon as of imitation—in all the different intervals, by contrary and retrograde motion, by augmentation and diminution.

Canons may be in any number of parts; but they are generally in two, three, or four. When they are so constructed as to close with a perfect cadence, they are called *finite*, in opposition to those called *endless* or *perpetual*, which go on till the performers think proper to leave off.

The most admired canon extant is the famous "Non nobis Domine" of William Byrd. It is for three voices (or in three choral parts), the subject, in the first part, being imitated in the second part a fourth below, and, in the third part, an octave below.

The canon, when discreetly used by a musician of real learning and genius, is a fruitful source of beauties. But this species of composition has been grossly abused by musical pedants, in whose hands it has degenerated into a mere trick of inventing and solving riddles and conun[illegible]

[illegible] *interpoint* is that species of counterpoint which is capable of being *inverted* in such a way that the upper part may be made the under, and the under the upper, without detriment to the goodness and regularity of the harmony. This inversion may take place most easily in the octave; that is, an under part, by being raised an octave, may often be placed uppermost, even though the parts had been written without this intention. But if the inversion is made in any other interval—that is, if the under part is raised a ninth or tenth, an eleventh or a twelfth—many precautions must be taken to render the parts capable of being so inverted. Next to double counterpoint in the octave, that in the tenth, and that in the twelfth, are the most practicable and frequently used.

Fugue is the most complex and difficult branch of composition. A general explanation of its principles, however, will enable the student to understand the construction of the choruses of Handel, and the other great ecclesiastical composers, in whose works the grandest specimens of it are to be found.

Fugue consists of a *theme* or subject, given out by one part, and imitated by the others according to certain laws, and carried on with that mixture of unity and variety which these laws are calculated to produce. These laws, moreover, though derived from the practice of several centuries, are by no means arbitrary, but founded on sound principles of reason and taste. The fugue is pre-eminently calculated to express the feelings and sentiments of a great multitude; and its noblest examples are to be found in sacred music—in the oratorios of the great German masters, and the anthems of the English cathedral service.

The fugue consists of certain constituent or elementary parts. First, the *theme* or *subject*, which is a leading phrase or melody, constantly heard, in various forms or imitations, throughout the whole piece. Next, the *answer*, which is the imitation of the subject taken up by another part. The correctness of the answer depends on many considerations, which cannot here be entered into. But the great principle on which it depends is the division of the scale into two portions or phrases; the one extending from the tonic to the dominant, and the other from the dominant to the tonic; the one embracing the interval of a *fifth*, and the other the interval of a *fourth*.

POPULAR METHODS OF TEACHING SINGING AND THE ELEMENTS OF MUSIC.*

Within these few years a considerable change has taken place in the method of teaching music, but particularly vocal music, to large bodies of people. Formerly, a master was employed to teach each person individually: now, the number instructed at the same time is almost unlimited. This, however, could only be effected by a system which would enable *all* to understand what was taught; and this has been attempted by two different plans—that of Mr. Joseph Mainzer, and of Mr. Bocquillon Wilhem.† The plan of Mr. Mainzer is the most simple of the two, but this simplicity may be said to amount to meagreness; for it fails, as far as we can understand, to instruct the pupil in raising or sustaining notes without the assistance of an instrument, and conveys a less perfect knowledge of the theory of music than the other; still, it is a great advance in methods of popular instruction, and we wish it every success. The plan of Mr. Wilhem, which has received the favour of the Committee of Privy Council on Education, and is now extensively taught under the auspices of Mr. Hullah and others, amounts to a regular system of music. Wilhem's method has at least two leading peculiarities. 1st, He uses no musical instrument whatever. 2d, He makes thorough musicians of his pupils as they proceed, not teaching them merely to imitate the sounds given by the pianoforte, flute, or violin; but he teaches how far the voice is to be raised or lowered, from one sound to another, by actual measurement, if such a term may be used.

He has based his method on three great principles: 1st, That the human voice is the origin of all music, and therefore the model for every musical instrument known. Experience has proved, that if we take any given sound as a foundation, and raise our voices by degrees (to us most natural), we can produce seven distinct sounds, each different from the other, and following each other by a regular and definite succession. It is the aim of all instruments to imitate, as nearly as possible, these seven sounds. 2d, Sympathy of voices in large bodies of people. This sympathy has not yet been sufficiently explained; yet the most acceptable of many theories on this point is that of Dr. Arnott, that the vibrations caused in the atmosphere by a large number of voices has the remarkable effect of bringing all to one pitch, and what is still more interesting, that all will follow or be led by those that are correct, and never a correct voice yield to one that is wrong, but maintain its position.

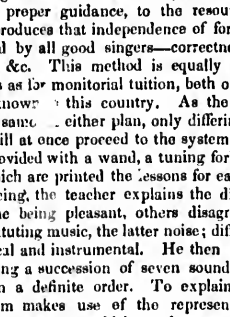
* For this section, Mr. Hogarth, the composer of the preceding pages, is not responsible. It has been appended by the Editors.

† Mr. Wilhem was a professor at the Conservatoire Musical at Paris, and died in the beginning of 1842.

3d, That the study of an art should always be arranged on the constructive or synthetic, not on the analytical method. The constructive method is understood as commencing with the most simple facts, and ascending to the general, through a series in which every step of the progress is distinctly marked, and which enables the pupil, without straining his faculties, to arrive at results which might otherwise have been difficult of attainment.

By making use of no instrument, and leaving every thing, under proper guidance, to the resources of the learner, he produces that independence of foreign aid, so much desired by all good singers—correctness of intonation, time, &c. This method is equally adapted for simultaneous as for monitorial tuition, both of which are sufficiently known in this country. As the instruction given is the same on either plan, only differing in minor details, we will at once proceed to the system itself. The teacher is provided with a wand, a tuning fork, and large sheets on which are printed the lessons for each evening. On commencing, the teacher explains the difference of sounds—some being pleasant, others disagreeable—the former constituting music, the latter noise; different kinds of music, vocal and instrumental. He then proceeds to the scale, being a succession of seven sounds, following each other in a definite order. To explain this more fully, Wilhem makes use of the representation of a ladder (*l'escalier vocal*), which renders sensible to the sight some abstract notions of the first elements of music; namely, the tones and semitones, the diatonic scale, the twelve semitones of the chromatic, the intervals formed by combinations of these tones and semitones, &c. &c.

Major Diatonic Scale.



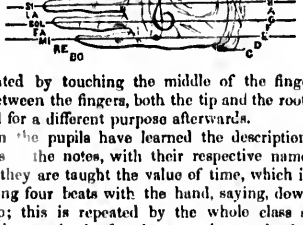
These truths in elementary music are conveyed in a manner calculated to keep the attention of the pupils constantly alive. Sometimes the teacher illustrates his meaning by singing a few notes; at another, by pointing to the large sheets, and then interrogating the pupils individually, to ascertain whether the real meaning has been clearly understood. In the representation of the ladder, there are eight bars, of which the third and fourth, and seventh and eighth, are nearer to each other than the first and second, second and third, fourth and fifth, fifth and sixth, or sixth and seventh; the semitones falling between the third and fourth, and seventh and eighth; the remainder of the spaces representing the tones. To impress on the mind of the pupil the fixed situation of the tones and semitones in the major diatonic scale, he makes use of *manual* signs, the hand being opened to represent the tones, and closed for the semitones, which the pupils imitate, and sing, repeating these manual signs. As sounds are invisible, and cannot therefore be seen, we have certain signs to represent these sounds. These signs, called notes, are next explained, as also the rests, according to their relative values. The pupils are then taught the position of the notes on the stave. The entire compass of the human voice (comprising the voices of men, and those of women and children) is explained by the large stave of eleven lines. This large stave of eleven lines is divided into three parts by the use of clefs, each clef representing certain five lines taken from the large stave.

The Sol clef, being most frequently used, is first learned and practised. To insure the remembrance of the names of the notes, and also the production of the correct sound, the hand is again employed, but in a different manner. The whole hand represents the stave of five lines, each finger a line. The teacher touches each finger, and mentions the name of the relative line in the stave, and which is repeated by all the pupils. The names of the notes in this method are not the same as the English, as it is more convenient to make use of little words, although without meaning, to the letters of the alphabet.

C	D	E	F	G	A	B
Do	Re	Mi	Fa	Sol	La	Si

When the pupils are perfectly conversant with the names and situations of the notes, both on the stave and hand, they learn the sounds according to situation. Many musicians object to the hand, yet Wilhem has considered the preparatory exercises of singing by the hand as of the greatest importance. Each pupil is desired, in Solfaing the exercises, to touch on his fingers the position which the teacher points to, and in this manner the *sight*, the *touch*, the *ear*, and the *voice*, are all equally practised, and so impressed with the sound emitted, and with the position of that particular sound on the stave, that, on again touching or pointing to a similar position, the same sound is immediately recalled to the memory with an astonishing correctness and precision. There is another advantage in the use of the hand; it saves the time of the teacher in practising any difficult passages, by his immediately referring to the position on the hand, repeating the particular passage until it be correctly performed, and having his eye on the pupils, and his ear attentive to their singing, while he is pointing to the notes he desires to have repeated.

Jean Jacques Rousseau attributes to Guido d'Arezzo, in the eleventh century, the first use of the hand to represent music. The principal masters who followed Guido d'Arezzo were Elias Solomon, who flourished about 1274, and Engelbert, in 1331. The hand of the ancients was somewhat different from that now used; but it is unnecessary to state in what the difference consisted. We confine ourselves to the hand, as at present employed, which is as follows. The sounds or notes are



represented by touching the middle of the fingers, or space between the fingers, both the tip and the root being required for a different purpose afterwards.

When the pupils have learned the descriptions and positions of the notes, with their respective names and sounds, they are taught the value of time, which is done by making four beats with the hand, saying, down, left, right, up; this is repeated by the whole class several times; then again the four beats, saying on the first beat semibreve; again four beats, saying minim on the first and third beats; then again four beats, saying crotchet on each beat; but as the word crotchet is rather difficult to repeat quickly, the last syllable is dispensed with, and crotch alone used. Thus, the relative value of each note is more firmly impressed on their minds than before; namely, that a crotchet, being of the value of one beat, the minim two beats, and the semibreve four beats, the minim must be twice as long as the crotchet, and the semibreve twice as long as the minim. The teacher now proceeds to the division of musical passages into

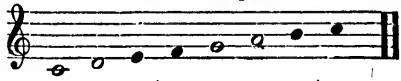
small portions, called bars or measures; some passages being divided into portions, of which each contains four beats; others, into portions or bars, containing three beats, &c.; but as the common time, or four beats in each bar, is the most simple, it is first practised. The pupil is also taught the signatures of the different times; thus, common time, or four beats in the bar, marked C; all others according to the value in the bar, $\frac{3}{4}$, $\frac{6}{8}$, $\frac{12}{8}$, &c. In the exercises on time, &c., no note is used of smaller value than the crotchet, until the pupils have overcome that and a few other difficulties.

Harmony and melody are next proceeded with, the former being different sounds sung at the same time; the latter being different sounds, sung one after the other: the former requires several voices; the latter can be sung by one voice; thus these parts are explained in the most simple manner. To show the difference between harmony and melody, the whole class is desired to give the sounds Do, Mi, Sol, Do, in succession, being the first, third, fifth, and eighth, of the major diatonic scale, forming melody. Having done so, the class falls into four divisions, each division singing one of these sounds; then the whole sing together, each their own notes, and thus produce harmony, forming the common chord of the scale of Do.

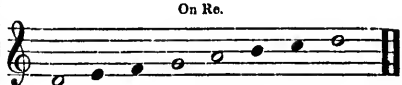
The pupils now commence the study of the Intervals, but before proceeding further, a few directions are given as regards the articulation, the production of sound, the manner of inspiration, &c., which are referred to occasionally. The three different kinds of exercises used after this are, 1st, Solfaing—to sound each note of a passage to its name of sound. 2d, Vocalizing—to sound each note to the same vowel. 3d, Singing—to articulate words while sounding the notes. The teacher now explains that the intervals are named according to the degrees which they contain, as from Sol to La, two degrees, a second; from Sol to Do, four degrees (Sol, La, Si, Do), a fourth; from Sol to Fa, seven degrees (Sol, La, Si, Do, Re, Mi, Fa), a seventh, &c. The pupils are put on their guard respecting the difference between "a unison," and "when in unison." A unison is no interval, and as therefore the practice of the unison would be merely a repetition of one note, its practice is mixed with the interval of the second. The pupil also learns that of each interval, except the octave; we have two kinds, larger or smaller; that they are larger or smaller according to the number of tones and semitones which they contain; thus a second may be major or minor, the former being the tone, the latter the semitone; a third, major or minor, the major containing two whole tones, the minor a tone and a semitone; a fourth, perfect or sharp, the perfect containing two tones and one semitone, the sharp three tones, hence also called a tritone, &c. To each of these intervals exercises are attached for the practice of that particular interval, mixed with exercises on time, accentuation, and others; when the pupils understand each interval, and can sing all the exercises correctly, a song is given, arranged with no interval greater than that just learned, but including all that has preceded it. As a consequence of this arrangement, some of the first songs employed must be very simple indeed; yet as it is for the benefit of the learner that it should be so, no objection ought to be raised to it on that account. Having arrived at the intervals of the fourth, the quaver is first introduced, with a few exercises; again the pupils are desired to make the four beats, but with this difference, that two notes are given or sounded to each beat instead of one, as formerly; showing that two quavers belong to each beat in place of one crotchet, as before. Thus the interest of the learner is always kept alive, and difficulties gradually introduced to enable him to overcome them, without straining his faculties too much. Here and there are introduced other subjects, such as the different Italian words used in music to denote loudness or softness; again, others expressive of quickness or slowness; others, marks of accentuation, the inversions of the different intervals, &c. &c. After having overcome all the intervals from the second to the eighth, there are recapitulary exercises, in which all that the pupil has hitherto learned is indiscriminately mixed together, the major and minor intervals, time, expression, accentuation, inversions, &c. &c.; and strict injunctions are given to the teacher on no account to proceed further until the pupils thoroughly understand and perfectly perform all that has gone before.

All that the pupils have as yet learned has been in the major diatonic scale of Do, but they have also been taught that every musical passage is in *some* particular scale; this sentence alone would imply that there were *many others;* he is now told that each note of the original may become a foundation or a commencement of another scale, and be called the first of that scale; this *first* note of any scale is called the tonic. He also knows that every major diatonic scale must have a succession of tones and semitones in a regular definite order; thus, tone, tone, semitone, tone, tone, tone, semitone. But were he to commence on Re, the note immedistely above Do, and consider it as the tonic, he will find that the tones and semitones do not follow as before—

Scale commencing on Do.

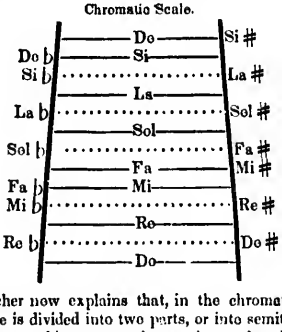


On Re.



The pupil must remember that the semitones fall between Mi and Fa, or the third and fourth sounds of the scale, and Si and Do, or seventh and eighth of the scale; but on examining the scale of Re, as above, the pupil will find that the semitone falls between the second and third, and the sixth and seventh of *that* scale, which is incorrect. To make this be understood, Wilhem again recurs to the vocal ladder, but a little different from the former—

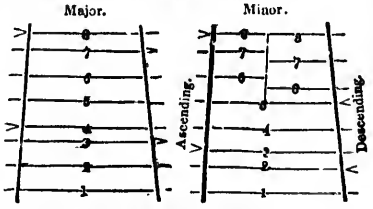
Chromatic Scale.



The teacher now explains that, in the chromatic scale, each tone is divided into two parts, or into semitones, by which means thirteen sounds can be produced, each a semitone apart from the other; that a tone can be divided into two semitones in two ways, either by lowering the upper sound or raising the lower; thus, Sol may be depressed or Fa raised a semitone, for which purpose certain characters or signs are required, which, being placed before any given note, raise or lower that note one semitone, namely, the ♯ (sharp), to raise, and the ♭

flat), to lower; but as it is sometimes desired to bring such a sharp or flat sound to its natural state, another character is used, the ♮ (natural). Now, the pupil will observe, that if he place a sharp before Fa, in the scale of Re, it will raise that sound a semitone; and if he place a sharp before the Do, it will also raise it a semitone—

By placing the sharp (♯) before Fa, he has raised Fa a semitone above what it was before, making the difference between Mi and Fa a tone, the difference between Fa ♯ and Sol being altered as a natural consequence to a semitone, by which the regular order is in this instance obtained. Again, in the same manner with the ♯ before Do, the semitone is transferred from between Si and Do to between Do and Re; thus the semitones fall between the third and fourth (Fa ♯ and Sol) and seventh and eighth (Do ♯ and Re) sounds of the major diatonic scale of Re. In this manner the pupil is taught to place the tones and semitones in their proper positions in all the scales. To practise the divisions of the tones, &c., the hand is again employed, the tips of the fingers representing the flat sounds, and the roots the sharp sounds. The teacher now shows that every minor interval can be made major, and every major interval minor, by placing a sharp or a flat before *one* of the notes composing it; also that an interval does not change its character when *both* the notes composing it are made sharp or flat. In practising these intervals, the manual signs representing the tones and semitones are again employed. The various pieces of music to be sung or Solfaed after this, have a more varied character, and consist of rounds, canons, solfeggios, songs, &c., in two, three, or four parts. Some of the airs are written in different keys, to show the effect, and to accustom the pupils to transposition from one key to another. The distinction between the diatonic and the chromatic semitone is next explained; the former being formed by two notes a semitone apart, standing on *different* degrees; and the latter by two notes a semitone apart, but standing on the *same* degree, and bearing the *same* name. The diatonic semitone is therefore a *minor second*; the chromatic semitone a sort of exaggerated *unison*. The pupil now proceeds to the order in which the major diatonic scales follow each other, according to the number of sharps or flats required to place the semitones in their proper positions. A table is then presented to him, showing the order, commencing on Do, ascending by fifths requiring sharps, and descending by fifths requiring flats. This table is used for occasional reference by the pupil. The teacher next explains the minor scale, the difference between the major and minor scales in the succession of tones and semitones ascending and descending, &c.; for which purpose Wilhem employs the vocal ladder, showing that, in the minor scales, the third of the scale is always minor; hence the name. The tones are marked —, semitones <.



Then follows a table with the major scales and their *relative* minors, having the same signatures.

Having hitherto only learned *common time*, with an even number of beats in each bar, the pupil's attention is now directed to time, with an uneven number of beats in the bar, called *triple time*, to practise which three beats are made in each, but in an opposite direction from the former. In the commencement of the study, the pupil is taught the three clefs, but only one has been practised, namely, the Sol clef. Having advanced thus far, Wilhem again introduces the large stave of eleven lines, with its principal divisions, by the Sol, Do, and Fa clefs, and also shows that the large stave of eleven lines can be subdivided into seven staves of five lines each, according to the extent of the different voices. The pupil is next taught how to transpose any piece of music from one scale to another, by changing the signatures, and using different clefs; but it is unnecessary here to present examples of the manner in which this is done; for full information on the subject, we refer to the accessible works of Wilhem and Hullah.

ACCOU[illegible] OF THE HUMAN BODY.

THE external appearance of the human body is necessarily familiar to all. Its internal structure, however, and the manner in which its different functions are performed, are not understood as they ought to be by the generality of people. The more fully that we comprehend the structure of our frame, the more attentive shall we be to its preservation in a state of health, and the more capable of accomplishing that all-important object. The present treatise will therefore be devoted to a description of the human body, in language as popular as the subject will permit, and as concise, at the same time, as possible.

Zoological science places the human being in the class of *Mammalia*, or suck-giving animals, and in the order of *Bimana*, comprising the two-handed creatures of that class. An erect posture is the peculiar characteristic of man, and it is one which gives to his aspect that dignity becoming his high place in creation. By the adaptation of an erect structure, also, his hands are left disengaged, and ready for the numerous operations to which he is inclined by his judgment or urged by his wants. His general stature is between five and six feet. A combination of hard and soft parts forms the material of his frame, the soft portions being arranged, generally speaking, upon and around the more solid parts of the structure. These latter parts consist of a beautiful framework of bones, formed the *skeleton*, which naturally occupies the first place in our description. *Muscles* and *tendons*, which are the organs of locomotion; the *brain* and *nervous system*, or organs of sense, feeling, and intellect; the *lungs*, for respiring the air essential to the maintenance of the principle of life; the *stomach* and *digestive organs*, for the supply of nourishment; the *heart*, *blood-vessels*, and *absorbents*, for the circulation of vital fluids through the body;—these and other important parts will fall to be described after the solid framework on which they rest has received its due share of our attention.

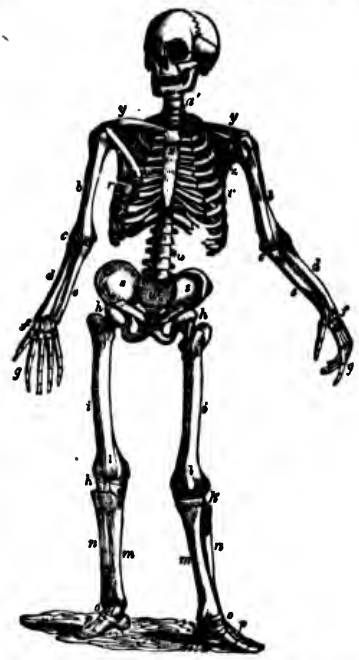
The skeleton comprehends three main divisions, the head, trunk, and extremities, which consist, in all, of 254 bones, joined together in a manner combining great strength with ease and freedom of motion. The whole of the bones are composed of nearly the same materials, namely, earthy matter, chiefly lime, and gelatine or animal glue. The lime gives them hardness and solidity, while the animal matter cements or binds them together, and renders them not easily broken. They differ to some extent in solidity and weight. A middle-sized adult skeleton, weighed all together, ranges between 160 and 200 ounces, or from 10 to 13 pounds avoirdupois. The heaviest bones in the body, in proportion to their size, are the bones of the skull, extremities, and pelvis, or under part of the trunk. Their surface is for the most part smooth, and the interior, beneath a cake or coating of more condensed substance, is porous and spongy. The bones of the extremities are hollow, like pipes, by which arrangement they are rendered at once light and strong. The marrow is contained in the internal cavity. Compact as they are, the bones are nevertheless pervaded by blood-vessels, which, indeed, are essential to their vitality.

The crown or summit of the osseous fabric is occupied by the cranium or skull, which is composed of eight bones, the *frontal*, the *occipital*, and the two *parietal*, constituting the greater part of the outward skull, before, behind, and laterally. The two *temporal* or temple bones, on the under part of each side, and the sphenoid and ethmoid bones, placed at the base of the skull internally, are the remaining bones of the head. The union of these bones is remarkably firm and strong in the adult being. In some cases, the osseous plates are joined by serrated or ragged edges, like the teeth of a saw. In other instances, they overlap each other, like the ridge of a house; the arrangement, in each case, being precisely the one best fitted to ensure strength and stability in the particular part. Altogether, an arch of the most powerful kind is formed, for the safe protection of the important organ within, the *brain*. The bones of the face, situated below and before the cranium, are numerous. Among the facial bones are reckoned the two upper *maxillary* or jaw bones; two *malar* or cheek bones; two *nasal* or nose bones; two small bones, attached to the nose internally, called the *turbinated* bones; two *palate* bones; the two *lacrymal* bones, situated in the orbit; the *vomer*, or ploughshare bone, forming a part of the basis of the nose; and the single lower jawbone or *maxillary* bone of the lower jaw.

The bones of the skull and face rest upon the top of the spine or backbone, which consists of twenty-four separate pieces, called *vertebræ*, firmly and curiously jointed the one into the other. The column of the spine is curved in several places, the most prominent being a curve forwards near the middle of the back. Seven of the vertebræ are called *cervical*, twelve *dorsal*, and five *lumbar*, from being situated respectively in the neck, back, and loins. Each vertebra has various projections and depressions, to admit of a firm union with those adjoining it; and, by the junction of the whole, a long hollow or canal is made, for the reception of the spinal marrow. In the annexed figure, the upper part of the vertebral column is marked *d*, and the lower *a*. The second of the vertebræ of the neck sends upwards a projecting pinion or tooth, which is received into a corresponding depression in the one above, thus forming the pivot upon which the head turns.* The bones of the spine rest upon the *pelvis*, *s e*, a hollow, basin-shaped cavity, which is formed of two large bones, and composes the lower part of the trunk, giving to it firmness and stability. The spine rests on it by means of the *sacrum*, a series of five imperfect vertebræ, consolidated into one piece in advanced life, which sink like a wedge between the pelvic bones of each side. The sacrum terminates in a loose osseous peak, called the *os coccygis*. The strong, hollowed, cup-like bones of the pelvis, are marked by large round depressions on the outer and under surface of each, which form sockets for the two upper bones of the leg. At the top of the spine, immediately below the vertebræ of the neck, are situated on each side the collar-bones or *clavicles*, *y y*, which are long and narrow in shape, and pass in a semicircle or arch from the front of the chest backwards, or, in other words, from the *sternum*, *x* (breast-bone), to the top of the shoulders. On the back of the ribs, at each side, lie the shoulder-blades or *scapulæ*, which are thin flat bones, of a triangular shape. They rest loosely on the back, having scarcely any attachment except by muscles to any of the neighbouring bones. By this means they have a

* A ligamentous band keeps the tooth-like projection of the second vertebra in the depression of the first. Nothing can better show how completely our life, during every instant of its duration, depends on the maintenance of every single part, however minute, in order. If this ligament, scarcely thicker than strong paper, were to give way, instant death, from pressure on the spinal marrow, would ensue. A porter, carrying a burden, dropped down dead. On examination, no cause of death could be found, till this apparently petty ligament was noticed to have given way, producing instantaneously the fatal result.

free and easy motion, and also communicate the same property in part to the arms, the upper bone of which is



attached, on each side, to the scapula. A very small cavity in the latter bone admits the round ball-like head of the humerus, giving to it the most unconfined play of movement, whether of a rotatory kind, upwards, downwards, or sideways. Nothing can be more beautiful than the whole arrangements for permitting the arm to perform the multifarious motions which man requires from it. The *humerus*, a single bone in each arm, *b b*, cylindrically shaped, is united at the elbow-joint, *c c*, to the two bones of the fore-arm, termed the *radius*, *d d*, and *ulna*, *e e*. One of these, the ulna, is attached to the humerus, by a hinge-joint (like that of a common door), while the radius is connected to the same bone by a round button-like head, which, being slightly concave, receives a projecting knob of the humerus, and admits of rotatory movements being performed by the lower part of the arm. These peculiarities of structure are essential to the free use of the hand. At the wrist, the position of the radius and ulna is in some measure reversed, the radius forming with the *carpal* bones, *f f*, a joint like that of a door-hinge, while the ulna is in a measure left loose. The carpal or wrist bones are eight in number. They are of small size, and lie in two rows, being jointed together in a manner that combines great strength with a certain degree of mobility. In the direction of the points of the fingers, they are united with the *metacarpal* bones, forming the palm of the hand, and to which the *phalanges*, *g g*, or finger bones, are attached. Each finger has three bones in it; the thumb has only two.

As has been said, the bones of the pelvis, on each side, are marked by deep cup-like concavities, which receive the heads of the thigh-bones, *h h*, *i i* (*femur*), the upper bones of the lower extremities. As was required by the different nature of the purpose to be served, the ball and-socket joint of the leg is much stronger than that of the arm and permits of much less freedom of motion. The *femur* or thigh-bone is a rounded cylindrical bone, terminating at the knee in a connection with the *tibia*, *m*, the principal bone of the inferior part of the lower extremity. The knee-joint is a hinge one, but permits of a slight rotatory motion when the leg is bent. The tibia has a smaller bone, the *fibula*, *n n*, placed by its side, and over the knee-joint is situated a small bone called the *patella*, *l l*, or knee-pan, to which the principal muscles that move the joint are attached, and which serves to protect the parts against injury. The tibia and fibula form a union at the ankle, *o o*, with the bones of the tarsus, which are seven in number, and constitute the heel or back part of the foot. These again are united to the *metatarsal* bones, *p p*, forming the body of the foot, and five in number. To these again are joined the *phalanges* of the foot, fourteen in all, two being attached to the great toe, and three to each of the others.

The *costæ* or *ribs*, *r r*, proceed from the vertebræ or backbones, and are twelve in number on each side. They bend round in a circular manner from their point of union behind, and seven of them, called the *true ribs*, are joined directly by gristle or cartilage to the breastbone, while the remaining five terminate anteriorly in a common cartilage, which unites with the sternum below. Altogether, the ribs form a large hollow space for the reception of the lungs, heart, and other organs, and protect them from injury. The ribs move in an easy joint formed with the backbone, and, with the intercostal muscles, contract and expand to suit the motions of the lungs.

These are the principal bones forming the skeleton of the human being. All animals have not this osseous framework; it is only found in a certain number of classes, including man, quadrupeds, birds, reptiles, and some fishes, all of which, from the principal feature in their structure, are called vertebrated animals. Some of the other tribes of beings have their framework, corresponding in purpose to bones, on the outside of the body, in the form of a coat of mail. This is the case with the shellfish, as the lobster, and with many insects that have a hard external covering, as beetles.

THE MUSCLES.

The soft fleshy substance of the body, which gives plumpness and form to the whole, is the muscular part, or *muscles*. These are the instruments of motion. And when we consider the various positions which the body and its members assume, the agility and quickness with which the most intricate movements are made, the ceaseless play of the heart, the heaving of the lungs, and the singular rapidity of articulation and speech, we need not be surprised that these muscles, upon which all such movements depend, should be many in number, and deemed important agents in the animal economy. The muscles are of a reddish brown colour; they are composed of accumulated threads or fibres, arranged sometimes in layers, sometimes in a straight position, and sometimes obliquely. They are of an elastic nature, somewhat like a piece of India rubber, and, at the impulse of the will, are lengthened and shortened alternately. A muscle is generally thick or swelled out in the middle; it gradually gets thinner towards the extremities, and, in many instances, passes at one or both ends into a tendon, or tough white substance, which is attached to a bone, and serves the same purpose as a rope or cord, to fix the muscle to the point from which it is intended to act. These tendons are most numerous about the joints, especially the larger joints, where they allow of free and unrestrained action, and yet occupy little space in situations where a large swelling muscle would have been inconvenient. About the larger joints of the body, also, such as the knee, elbow, and shoulder-joints, there are numerous glands, which pour out an

ony substance, that serves to lubricate the joints, and facilitates the play of the tendons. There are from four to five hundred muscles in the human body, all necessary for performing the various movements and operations of the complicated machine. On each side of the backbone there are several layers of strong muscles, which are fixed by tendons to every projection of the numerous bones composing the spine. These muscles keep the trunk of the body erect, and also permit of the various motions of the back. There are a multitude of small muscles about the face, head, and eyes, whose various action imparts that expression to the human countenance which indicates the prevailing feelings and passions of the individual. The tongue is also supplied by intricate muscular fibres, giving to it that amazing volubility of action by which the vast number of sounds composing language are expressed. Many are attached to the lower jaw; but two in particular, the temporal muscles, proceed upwards through an arch formed by a projecting arm of the temple-bone, and are fixed to the tendons of the head. These two muscles are the most powerful in moving the jaws in the operation of chewing the food, and are very large in several animals of prey. Another flat muscle inside the cheek is called the trumpeter-muscle, because it assists in blowing from the mouth and in sounding wind instruments. The chest is supplied with numerous muscles, which move the ribs upwards and downwards in the action of breathing. A large flat muscle, called the diaphragm, stretched across the trunk from side to side, and separating the hollow of the chest from that of the belly, also contributes mainly to the process of breathing. The arm and hand are rolled inward and outward by a set of muscles, which are placed on the outer and inner sides of the respective bones; thus, the outside muscles act in a contrary manner to the inside, and reverse motions may be alternately performed. The muscles of the fore-arm are fixed to the scapula or shoulder-blade, to the cheat, and to the clavicle, at the upper end, and to the bone of the arm at the other. The fingers are moved by muscles situated in the forepart of the arm, and have long slender tendons, by which they are attached. Two beautiful provisions of nature are here observed: at the wrist, a circular ring of tendinous substance binds down the long tendons, which would, in their various motions, otherwise start up from their places. This ring at once keeps them in place and permits their free and unhampered play. The other provision is seen in the construction of the tendons of the fingers. There are two principal muscles which move the joints of the fingers, and two sets of tendons, which are inserted, the one into the middle bones of the finger, the other into the third row of bones, or the extremities of the finger. In order to preserve their free action, and to make them lie in the most convenient manner, there is a loop or slit in the shorter tendon, by which the other passes through to its insertion in the point of the finger. By this means, the longest and strongest muscle moves the extremities of the finger, where the greatest power is wanted, without impeding the action of the other. The muscles which move the lower extremities are thicker and more powerful than those of the arms. Several large muscles, acting in opposition to each other, are situated around the thigh-joints, and move them. They are fixed, one end to the trunk of the body, some pretty far up, especially two, which are spread upon the front of the abdomen or belly, on each side of the spine, while the other ends are attached to the thigh-bone. Several thick muscles, also, are situated at the back of the trunk. Two large muscles compose the calf of the leg, and join to form the tendon of Achilles, which is fixed to the heel-bone; these muscles act powerfully in bending the ankle and in supporting the body in walking. The foot and toes are moved by several long slender muscles, situated in the leg, which have tendons attached to them, and terminating on the toes, exactly like those of the hand and fingers. The pelvis and lower limbs of man differ greatly from those of all other animals in their superior proportional strength, and in the number and fulness of the muscles. This was necessary, as man has been evidently intended by nature for the erect position. In the monkey tribe, whose general form approaches nearest to that of man, the narrowness of the pelvis or hip-bones, and the smallness of the muscles of the lower extremities, clearly show that they were not destined by nature for the erect attitude; in fact, all animals of this class are furnished with four *hands* or *paws*, the hinder pair exactly resembling those in front. When they attempt to walk on the hind extremities, they cannot put the sole to the ground, but press on it edgeways. By the nice balancing of the muscles, and the great force which they exert, man is enabled to stand erect, and to maintain a firm position, or move forward at pleasure, notwithstanding that the body diverges from the perpendicular line of the centre of gravity. The head is also balanced upon the neck by means of strong muscles, whose constant though unobserved exertion is necessary to maintain it in its position; for in young children, when the muscles are as yet weak, and in persons asleep, the head has an inclination to droop, and in the dead body it falls down on the shoulder or breast. The muscles of the neck, therefore, may be said to exercise a power in some degree involuntary, or not under the command of the will, as the majority of the muscles of the body are. But there are other muscles still more distinctly removed from under the guidance of the will. The heart is nothing else than a hollow muscle, which contracts and expands without the consciousness of the being; and, in like manner, the muscles which perform the act of respiration are not moved by the will. This division of the muscles into two classes shows, as perfectly as any thing could do, the care with which our frame is constructed. Had those muscles on which respiration and the action of the heart depend, been placed under the control of the being, their functions would have been liable to be impeded, at every turn, by circumstances. Now, these organs cannot cease to act for the most trifling period of time, without fatal consequences. The arrangement, therefore, which renders their operation involuntary, is one to be admired as essential to life and comfort.

THE BLOOD—BLOOD-VESSELS.

The Blood.—The blood is the medium by which all the solid and fluid parts of the body are supplied with nourishment. In its composition, therefore, will be found the majority of the substances of which the body is composed. The blood consists of a solid coagulable matter, called *fibrin;* of a series of *red globules* which form the colouring matter; and of *serum*, or whey-like matter, which gives the whole the necessary fluidity. From the heart, the centre of the circulation, the blood is conveyed through the body by vessels called *arteries*, and is brought back to the same part by *veins*. The purpose of its thus making the circuit of the whole body, is to supply the necessary materials for increasing the bulk and repairing the daily waste which takes place by perspiration and the perpetual operation of the numerous excretory organs. The blood is restored to its nutritious state by the chyle, a juice formed in the stomach and intestines from the digested food; this chyle reaches the heart by one of the large veins called the left subclavian; from the right side of the heart it goes along with the venous blood to the lungs, and there it is mixed with the oxygen, or vital portion of the atmospheric air, by which process it is converted into bright red arterial blood. In short, there are two distinct circulations of the blood in the system. By the one, the blood is conveyed and distributed over all parts of the frame, imparting, at every pulsation of the heart from which it issues, new life and nourishment to

the whole. After traversing the body, it returns to the heart, deprived of its nutritious properties, and changed in colour from a bright to a dark red. Here the second circulation, which is through the lungs, commences. The blood is poured from the right side of the heart, which has divisions for the purpose, into large vessels which carry it to the lungs, and, spreading out into countless branches, penetrates and permeates their whole substance. Collected again by other vessels of equal number and extent, it is conducted by them to the left side of the heart, to be propelled anew through the frame, restored to its bright red hue, and repossessed of all its vivifying qualities. Both these changes are effected in the lungs. The chyle, which may be called the essence of our food in a liquid state, is conveyed from the stomach through the chest by a duct, which empties itself into one of the veins, immediately before the blood is transmitted through the lungs. It is in these organs that the chyle is thoroughly mixed up with the circulation; and it should be remembered, that this chyle is the only benefit, the only real food, extracted from all the substances received into the stomach, the remainder being entirely useless and excrementitious. From the chyle comes the material of the bones, of the fleshy or muscular parts, of the brain and nervous cords, of the hair, nails, enamel of the teeth, and, in short, of every different structure of the system. The average quantity of blood contained in an ordinary-sized person, is calculated at about 30 lbs. weight. The coloured globules of blood do not enter into the smallest vessels of the body, but only the thinner part of it, which has no colour; thus, in the eye, there are numerous blood-vessels, but these are so minute as not to admit the red parts of the blood; and this is a necessary provision of nature, in order that these organs may retain their pure transparency for the purpose of vision. In inflammation of the eyes, when these vessels are much enlarged, the red globules sometimes enter, and the eyes are then said to be blood-shot. What is called the pulse, is the flow of the blood through the arteries, which is caused partly by the impulse of the heart's contractions or beatings, and partly by the contractions of the coats of the arteries. The rate of pulsation in a person in the prime of life, is from 65 to 75 beats in a minute. In childhood the pulse is much quicker—from 100 to 140 beats; and in old age it again becomes slower than the medium standard. In fevers, inflammations, and other diseases of excitement, the action of the heart is increased sometimes to form 100 to 140 pulsations in a minute.

Blood-Vessels.—These consist of the heart, with its arteries and veins, that branch out through every part of the body, and carry the blood, by constant circulation, through them. The heart is placed in the left side of the chest, a cavity divided into two parts by a thin membrane running perpendicularly down the centre, and supported below by the diaphragm. It is of a round or conical shape, with the base or broad part uppermost, and the point slanting downwards and towards the front surface of the chest. It is of a thick muscular substance, with hollow cavities inside, and numerous cords or pillars of fleshy or tendinous substance stretching through these to give them support. In man and all the more perfect animals that breathe air through the lungs, it is double, or has two distinct sides, each performing separate offices. In fishes, again, the heart is single; in insects there is no proper heart, but a vessel that runs along the back; somewhat like an artery, through which the fluid corresponding to blood circulates through their bodies; other animals, still more simple in structure, have no trace of heart or blood-vessels. For these ends, the heart in man has two sides, a right and left; and each of these sides contains two hollow cavities—the one called an auricle, from its fancied resemblance to a dog's ear; the other a ventricle, or belly. The manner in which the circulation of the blood is effected may thus be described in detail:—Two large veins, one from the upper part of the body, the other from the lower, enter the right auricle of the heart, and carry the blood, which has made the round of the body, into this cavity. Here it is of a dark purple colour, and it is called venous blood, from its coming from the veins. From the right auricle it is sent, by a sudden contraction or forcing together of the two sides of the cavity, into the right ventricle, immediately below the auricle, and communicating with this by a small opening furnished with a valve; by the right ventricle contracting, it is conveyed by the pulmonary arteries into the lungs, the two large cell-formed substances on each side of the chest, surrounding the heart. After passing through the lungs it is returned by the pulmonary veins to the left auricle of the heart; from this it is sent into the adjoining left ventricle; and, by a powerful contraction of this muscular cavity, it flows out by the great artery of the heart, the carotid, which distributes it through every part of the body, again to be returned by the veins: and thus the round of circulation is continually going on.

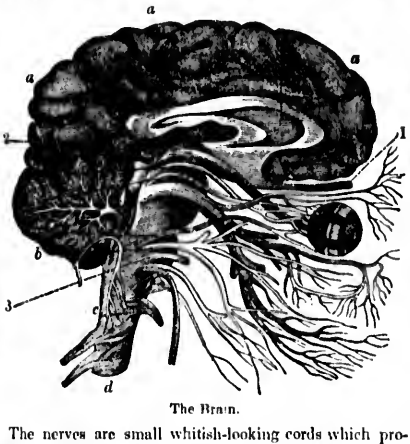
The heart being an extremely thick muscle, the force with which it contracts is very considerable. The left ventricle of the heart, too, although somewhat smaller, is much thicker and more muscular than the right, it having to send the blood through the whole of the body. A beautiful provision is observable in the heart, to prevent the flowing back of the blood into its different cavities during their alternate pulsations. In the passage of communication between the left auricle and ventricle are placed valves, which, when the ventricle contracts to send the blood through the aorta, close accurately, so as to prevent a reflowing into the auricle. There is the same provision between the right auricle and ventricle, and also at the mouth or commencement of the aorta and pulmonary arteries, and the veins which communicate with the right auricle. Some of these valves are of beautiful structure; they are composed of three flaps that join accurately over each other; and to prevent their being pushed by the impetus of the blood beyond their proper position, they have little tendinous cords attached, of exactly the length required. In the child before birth, as it cannot breathe, and therefore the lungs are not used, there is a small hole or communication between the right and left auricles, by which the blood from the veins flows directly through the arteries, and thus avoids going to the lungs; this hole closes up whenever the child begins to respire. The aorta, or great artery of the body, after it leaves the heart, passes upwards in the form of an arch, when it gives off the carotid branches to supply the brain, and face, and arteries to the arms and chest. It then bends downwards, and gives off branches to the stomach and other viscera; and when it comes to the lower part of the belly, it divides into two main parts, which become the arteries of the pelvis, thighs, and legs. The arteries of the body are composed of three coats or coverings, the principal one being a thick muscular ring, which encircles the artery, and which contracts and expands so as to assist in sending the blood onwards. The principal trunks of the arteries lie deep in the fleshy parts of the body, but their ramifications are so numerous and minute, that they pervade every particle of the human structure—bones, gristle, and every other texture. These extreme branches of the arteries being so minute, anatomists have had great difficulty in tracing the exact point at which they pass into veins. That they do so, however, is undeniable, and is partly seen on the surface of the brain. The veins are another system of vessels, which return the blood from the extremities of the body to the heart. They are larger and more flaccid than the arteries, and are distinguished from them by having no pulsation. A large vein generally accompanies the corresponding artery, but the great proportion of the veins lie more towards the surface, and are easily distinguished, swelling out under the skin. The numerous veins from the lower extre-

cities join into one trunk in the belly, which vein, after passing through the liver, as will be afterwards described, joins the right auricle of the heart, the blood from the upper half of the body joining also by another similar vein. In the veins of the extremities that hang downwards, and are apt to be gorged with blood, there are inserted numerous valves, at short distances, which prevent reflux of any kind.

THE BRAIN—NERVES AND NERVOUS INFLUENCE.

The brain, as already mentioned, is contained in the cranium. It is a soft mass of matter, enclosed in certain protecting membranes beneath the bones of the skull. As the organ by which mind acts, and chief seat of the nervous energy, the brain may be described as the most important and dignified of man's bodily parts, and well deserves the most careful investigation. The brain is divided by strong membranes into two main sections—the cerebrum or proper brain, which lies in front beneath the brow and on the top and sides of the head, and the cerebellum or lesser brain, which lies behind. Both are longitudinally divided into halves or hemispheres, and also into lesser parts called lobes. The annexed figure offers a lateral representation of the different parts of the brain, as it lies beneath the skull, with its beautiful and minute radiation of nerves proceeding to the eye and other external instruments of the organs of sense.

The cerebrum or principal part of the brain is indicated by the letters *a a a*. The cerebellum, distinguished by the letter *b*, terminates below in the *medulla oblongata*, *c*, the cylindrical pulpy cord by which a union is formed between the brain and *spinal marrow*, *d*. The latter part is the long cord of soft matter formerly mentioned as lying in the canal formed by the range of the spinal bones. It is round, of the thickness of the finger, of the same kind of substance as the brain, and formed of smaller nervous cords, running parallel to each other: it runs along the whole length of the back down to the pelvis.



The Brain.

The nerves are small whitish-looking cords which proceed from the brain and spinal marrow, and spread out in innumerable branches to every part of the body. A large branch of a nerve generally accompanies every large artery, and every important part of the body has a branch of a nerve sent off to it. The nerves for supplying the organs of smell (1), of seeing (2), of hearing (3), together with the great sympathetic nerves, which give branches to the heart, lungs, stomach, and other important viscera, proceed directly from the brain. The nerves of motion and sensation sent to the various parts of the trunk and extremities, take their origin, with a few exceptions, from the spinal cord. Two sets of nervous branches proceed from the cord on each side, corresponding nearly to the junction of every vertebral bone: and it is found that a branch of these nerves imparts motion, and the other sensation or feeling. The brain has a covering of three thin membranes; the outward one strong and thick, the inner extremely thin and delicate. The nerves, which are soft and pulpy inside, have also a thin external covering which protects them. The nervous branches are never seen or felt in the living body, and what are vulgarly called nerves are the tendons of the muscles, the erroneous title being given chiefly to those about the wrists, fingers, and ankle-joints. Their great numbers and minute divisions are manifest, however, because we cannot prick any part of the body with the sharp point of a needle, without wounding some of them, and thereby causing the sensation of pain. When the nerves are injured in their powers by disease, the sense of feeling in the part is entirely lost. The brain in the lower animals is not generally so large in proportion to their bulk, as in man; and the cerebrum, or upper brain, is often smaller in them than the cerebellum, or lower brain. In many classes of the inferior animals there is no distinct brain, but only nerves running along their bodies and joining into knots or ganglions. The nervous system of insects and worms is of this description. In the polypus and some other similar animals, a distinct nervous system can scarcely be traced.

It may be proper here to make some observations on the functions of the brain, considered abstractly from its anatomy. Man surpasses all other animals in the height and proportions of the forehead, and in the comparative mass of brain in the upper part of the skull. In the human head the lower parts of the face bear a smaller proportion to the forehead than in the brutes. The face is placed in nearly a perpendicular line with the forehead, instead of projecting outwards into a snout, as in the lower animals. The brute face is merely suited for the purpose of animal wants and for defence; the jaws are long and narrow, supplied with thick, strong muscles, and short teeth; there is not the elevated nose which in man forms a distinguishing feature—the arched eyebrows—the exquisitely formed lips, and the rounded chin; above all, there is not that play of varied expression, that air of intelligence, and that indescribable emanation of a rational mind, that ray of divinity, at the appearance of which the most wild and ferocious of the brute creation are awed and subdued. But, besides, the Creator seems to have allotted characteristic external signs to express the passions of the mind, that in social life man might not easily impose on his fellow-man; for the various muscles of the face express the several passions of the mind so faithfully, that they may be even represented in painting. This is said to be the natural expression, and would appear to be understood even by animals; for a dog, on looking to the countenance of his master, easily recognises the mute expressions either of commendation or dissatisfaction. From the action of these muscles being so often repeated, physiognomy arises; the action of the prevailing muscles fixes an enduring expression on the features; and thus traces of frequent anger often remain in the countenance after the passion itself is gone off. With the power of speech and reason, man has also the means of expressing his feelings and passions by laughter and weeping, manifestations which are not found in the lower animals. Weeping proceeds from a deep emotion of the mind, and seems an effort of nature to relieve the system of grief. It usually begins with deep inspirations of the lungs, after which follow short alternate inspirations and expirations, and it is finished with a deep long-drawn expiration, which is immediately followed by an inspiration. When moderate, it certainly relieves the distress arising from grief. Laughter has its rise from some ludicrous ideas impressed upon the mind, and would seem to arise directly from a sort of titillation

conveyed to the branches of certain internal nerves, probably those of the diaphragm; immediately to this succeeds a number of imperfect inspirations and expirations, which seem to be checked by the contraction of the glottis in the throat or larynx Laughter in a moderate degree may be conducive to health, as it gives impulse to, and ultimately promotes the circulation; carried to excess, however, it may prove dangerous, from accumulating too much blood in the lungs. Sneezing consists of one deep inspiration, succeeded by a powerful single expiration, and seems to consist of a convulsive effort of the muscles of breathing to throw off some cause of irritation in the sensitive membrane of the nostrils. The common hiccup is a spasmodic action of the muscles of the stomach, caused by something irritating the stomach itself. Some of the causes by which our mental happiness is either increased or diminished, proceed entirely from the bodily sensations. Any gentle stimulus applied to a nerve seems to cause a feeling of pleasure; strong stimuli, or any causes disturbing seriously the natural condition, produce pain. Itching is akin to pleasure, and in both cases the flow of blood is increased into the part in which either pleasure or titillation is perceived; but when farther increased, it degenerates into pain, or excessive sensations in the nerves. Anger violently excites the motion of the spirits, increases the motion of the heart, the frequency of the pulse, and the strength of the muscles; forces the blood into the extreme vessels; and even sometimes bursts the smaller vessels themselves: passion also increases the secretion of bile. Grief weakens the strength of the nerves and action of the heart, retards the pulse, destroys the appetite, and frequently produces paleness, 'oseness of the bowels, indigestion, and those slow or lingering diseases that take their rise from an interruption of the secreting glands, and a disease of their structure. Fear diminishes the force of the heart, weakens the muscular motions, relaxes the whole system, and, if long continued, causes a general sinking of the body. Excessive terror often increases for the moment the muscular strength, even to convulsions; excites the pulse, interrupts the course of the blood, and in not a few instances has produced sudden death. Love, hope, and joy promote all the salutary actions of the body, gently quicken the pulse, promote circulation, increase the appetite, and aid the cure of diseases. Excessive and sudden transports of joy, however, often prove fatal, by increasing the motion of the blood, and exciting a fit of apoplexy. Shame in a peculiar manner retains the blood in the face, as if the veins were obstructed; when felt in an extreme degree, it has also been known to prove the cause of sudden death.

THE LUNGS OR BREATHING APPARATUS.

In the highest part of the cavity of the chest, on each side of the breast-bone, the lungs are situated. A membrane passing from the breast-bone to the back, divides them into two portions, the right lung and the left lung. The right lung consists of three sections called *lobes*, the upper, middle, and lower; the left lung, rendered smaller in bulk by the presence of the heart in the same cavity, has only an upper and a lower lobe. The lungs have a dark bluish appearance, a familiar example of which is afforded in the *lights* of sheep, that part generally appended to the heart and wind-pipe. Inside they are composed of an immense number of cells, which alternately inflate or collapse as the lungs are filled and emptied of air. When an inspiration is made, and the lungs are filled with air, these cells become expanded; and the blood sent from the right side of the heart and spread over the cells, is exposed through an extremely thin membrane to the air. An important change, as formerly alluded to, here takes place on the blood: from being of a dark purple colour, it immediately changes to a bright

having absorbed or taken up all the oxygen or vital part of the air, and parted with a corresponding volume of carbonic acid gas or fixed air, which it had acquired in its circuit through the vessels of the body. So essential is the matter imparted by the air to the blood for sustaining animal existence, that the breathing cannot be suspended even for a very short period without extinguishing life. It is probable, too, that the heat of the body is generated and constantly kept up, in some way or other, by means of this process of breathing, and the change which the blood undergoes. We know, at least, that the evolution of carbonic acid cannot go on, in ordinary chemical processes, without an accompanying discharge of heat; and hence it is presumed that the vital warmth derived by the body from the blood, may be in this way produced. The lungs, like every other internal organ, are covered with a thin transparent membrane called the *pleura*: this membrane, as well as the substance of the lungs themselves, is liable to inflammation; and hence the name of the disease called pleurisy. The trachea or wind-pipe, the communication between the mouth and the lungs, is a hollow tube, having a series of cartilaginous rings passing round it, to prevent the possibility of its being compressed either by external means, or from the food in the act of swallowing, and, in consequence, the breathing obstructed. It takes its rise from the bottom of the mouth, and passes down in front of the neck, where its strong cartilage may be seen and felt. At its lower part it divides into two parts like the prongs of a fork, one going to join the right section of the lungs, the other the left. Lungs for breathing air are only found in the higher classes of animals. Fishes are furnished with gills, those comb-like substances which lie within a flap on each side of the head; over them a stream of water is constantly sent by inhaling it at the mouth in a similar manner to breathing. The air, which is always present in considerable quantities in water, is thus absorbed by the blood-vessels while ramifying over the gills, and all the purposes of breathing are answered. In insects there are no lungs, nor do they breathe by the mouth, but along the sides of their bodies, by means of numerous holes with small tubes or spiracles leading to a longer middle tube, by which the air enters and mixes with their fluids. When we descend lower in the animal scale, even this substitute for breathing ceases, and probably the vital air is absorbed by such animals by simple pores or openings in the skin.

THE TEETH.—DIGESTING APPARATUS.

The first process performed in connection with the supply of nourishment to the body is that of masticating the food, and this is the office of the teeth.

The Teeth.—These are placed in the upper and lower jaw, to which they are attached by roots, which sink into the porous sockets of the jaw, somewhat in the same manner as a nail is fixed in a piece of wood, though they are retained in place chiefly by the softer parts around. The teeth are composed of bony matter, covered externally with a thin coat of an extremely hard substance, called enamel. The teeth are furnished with nerves and blood-vessels, and have thus vitality like the rest of the body, although possessing it in a less perfect degree than most other parts of the structure. Hence they are very liable to disease and decay. In decaying teeth a blackish spot is first perceived upon the outer crust or enamel; this substance gradually gives way, and then the bone below proceeds to rapid decay. The irritation of the air and particles of the food inflame the nerves and soft pulpy parts inside, and thus the excruciating pain of toothache is produced. The first set, or temporary teeth, begin to make their appearance in the child about the fifth or sixth month, and towards the end of the eighteenth month the whole set of temporary teeth, consisting of twenty, have generally cut through the gums. These teeth continue till about the sixth or seventh year, from which time, till

about the twelfth or thirteenth year, they gradually fall out one by one, and are succeeded by the second or permanent teeth. The roots of the temporary teeth are much smaller, and sink less deep into the jaw than their successors. The rudiments of the second set of teeth begin to form early in cavities below the others, and, gradually growing and pressing upward, displace them. The number of the permanent teeth is thirty-two, consisting of sixteen in each jaw. The four front teeth are called the incisors, and have one long root; on each side next to these is one eye or dog tooth; then there are placed two small grinders on each side, having double roots, and three large grinders, or molar teeth. The last of these is called the wisdom tooth, from its making its appearance latest in the jaw, from the seventeenth to the twentieth year, or even later. By this change and gradual succession of teeth, we have a beautiful provision of nature for permitting the jaws to increase in size, and, at the same time, for preserving the relative positions and regularity of the different teeth; for had the first teeth of childhood been permanent, it is impossible that the jaw could have increased in growth without deranging the order and position of the whole. The teeth of various animals differ according to the kind of food on which they live. In carnivorous, or flesh-feeding animals, the teeth are sharp-pointed, and adapted for tearing their prey to pieces; in those animals called graminivorous, that live on grasses and other herbage, the teeth are of a rounded form, with broad surfaces, and the grinders are furnished with several layers of the hard enamel, following each other in succession, with a slight layer of common bone interposed; so that, when the grinder is worn down by the friction of chewing, it is not rendered useless, but a new layer of the enamel is presented at the worn-down surface. Some animals, as the hare, rabbit, beaver and mouse, have the front teeth of a chisel shape, with enamel only on the outer side of them. These animals are called gnawers, because they chew or gnaw down their food in this particular manner; and by the inner soft part of the tooth being liable to be worn down, while the outer is harder, the enamel is thus always kept with a sharp edge. Some animals have large projecting tusks for defence, as the elephant, wild-boar, &c.; others, as fishes, are provided with teeth, more for holding fast their prey than for mastication. Many have no proper teeth at all, as birds, worms, and other soft formed animals. Man is characterized by having all his teeth set close to each other in a half circle; they are of a medium form, between that of carnivorous and herbivorous animals; the front teeth are adapted for cutting; the canine are sharp, though not of undue length; and the grinders are suited for masticating vegetable and farinaceous matters, as nuts, &c. In short, the form of the teeth of man evidently points out that he is adapted to live on a mixed kind of diet, or a conjunction of vegetables and flesh.

Stomach.—Behind the windpipe, taking its rise also from the bottom of the mouth, lies the œsophagus, or tube which passes into the stomach. This tube expands at the top into what is called the pharynx, forming the whole of the upper part of the throat immediately behind the tongue. Into this cavity the windpipe opens, and, to guard against any particle of the food or drink passing into the windpipe instead of into the passage to the stomach, there is a little tongue or valve which closes accurately over the mouth of the windpipe every time food or drink is swallowed. When the substances have passed, the valve again springs open and admits of free breathing. To show how accurately and precisely every part of the human machine performs its duties, a celebrated writer has instanced this same valve, which, in a multitude of persons dining together, not one time out of a hundred in any one individual instance is at fault. When a drop of fluid or particle of food does by chance insinuate itself into the windpipe, so sensitive is this tube, that a convulsive cough is excited till it is again expelled. There is another little tongue or flap attached to the roof of the palate, and seen above the tongue when the mouth is opened. This, which guards the passage to the nose, is not, however to be confounded with the other, which is farther down the throat, and invisible. The œsophagus, or gullet, passes down through the chest, traverses a ring in the diaphragm, that large muscle which stretches across the lower ribs, and which assists so materially in breathing. Immediately below this muscle, on the left side, is situated the stomach, which is partly sustained in its place by being attached to the œsophagus, or tube from the mouth. The stomach is an oval bag of considerable size, occupying a slanting position immediately below the heart, with its right side overlapped by the left edge of the liver, and extending to the lower end of the breast-bone. The stomach has three coats—an external membranous one, a muscular, and a soft villous inner covering. The upper passage, by which this bag communicates with the œsophagus, is called the *cardiac* opening; the lower, where the first gut commences, is called the *pyloric* orifice.

Digestion.—One of the most important operations in the animal economy is that of digestion, whereby the various substances used for food are dissolved in the stomach, and undergo changes, by which they are formed into matter fit for entering into the composition of the different parts of the body, to nourish its growth, and supply the daily waste which takes place in the system; for such is the constitution of animal bodies, that the substances of which they are composed are liable to constant waste; the solid parts are worn down, and a large quantity of fluid is constantly given off by the exhalent vessels, both from the skin and the surface of the lungs. This is manifest in the sweat and the vapours exhalations constantly passing off by the mouth; and there is also an imperceptible perspiration regularly proceeding from the surface of the body, which has been computed to amount to several pounds in the course of a day. It must be evident, therefore, that if this waste was allowed to proceed but for a very short period, the body would soon be reduced to a state of complete decay. A constant supply of new material is therefore daily needed, to replace that which is wasted; and thus it has been supposed that a human body changes its whole materials many hundred times from the period of its birth till death; and that an individual, as regards his mere corporeal structure, is not at all the same at the period of manhood to what he was when a boy, nor in old age what he was in his prime. Although this change then is complete, even to the bones and most solid parts of the frame, it is brought about so gradually, and with so regular and minute substitution of one particle for another, that it is never perceptible. Man has been called, with relation to his diet, omnivorous, from his being adapted to live on every kind of food, whereas most other animals are confined to one particular description. The carnivorous animals live on flesh alone, the graminivorous on grass and green herbs, and the granivorous on grains and other smaller seeds. These animals never change their respective diets; nor, from the construction of their teeth, stomachs, and intestines, were they ever intended to do so. But in man it is plainly evident, from his anatomical structure, that he was intended to feed on every sort of food promiscuously, or that he could adapt himself to either animal or vegetable fare, as habit or necessity impelled him. Man also differs from brutes in resorting to the arts of cooking, whereby the food is put into a state more fitted for digestion, and for yielding a sufficiency of nutritious aliment. The food being received into the mouth, is broken down and masticated by the teeth. It is here also

reduced into a soft pulp by the saliva, which flows into the mouth by the salivary glands; and thus being sufficiently broken down and softened, it passes into the stomach. The stomach has numerous glands situated on its inner coat or surface, which secrete a peculiar fluid called the gastric juice, which is clear and colourless, with little taste or smell, or sensible qualities. On this fluid depends the important office of digestion. It has the power of coagulating substances in the stomach, of preventing the contents of the stomach from passing into a state of fermentation or putrefaction, and of dissolving the whole into one homogeneous mass. When the stomach is first filled with food, it appears to remain there for a short period without undergoing any change; gradually, however, successive portions of the food, as they come into contact with the gastric fluid, are dissolved; till at length, in a shorter or longer period, the whole is collected into a thin grayish paste, called chyme. In the upper or left division of the stomach, it would appear, from some recent observations, that the food is freed from its superabundant moisture, which drains off by some undiscovered means to the blood-vessels, and from thence to the kidneys. The chyme then, as it is gradually formed, moves to the other extremity of the stomach, called the pyloric, where it passes out to enter the intestinal canal. It would appear, also, that the pylorus, or lower mouth of the stomach, has a sensitive power, whereby it freely permits the digested chyme to pass out, but refuses exit to the undigested matter. The chyme having passed into the first part of the intestines or duodenum, is then mixed with the bile from the gall-bladder, and with the pancreatic juice. Both these substances, especially the bile, seem essential for the conversion of the chyme into proper alimentary matter, but their peculiar action has not yet been satisfactorily explained. That the liver and bile ducts are of the utmost importance, however, cannot be doubted, from their magnitude, and the care with which they are supplied with numerous vessels, and from their being universally present in a great proportion of animals. The chyme having passed through the duodenum, and having been mixed with the bile and pancreatic juice, now changes its appearance and properties, and becomes the chyle, or nutritious matter destined to supply the various parts of the system with nourishment. The digested mass is passed gradually along the course of the small intestines, urged forward by what is called their *peristaltic* motion, which is effected by a successive contraction of their fibrous coats. Here the minute mouths of the lacteal vessels, opening on the inner surface of the small intestines, take up the chyle, and carry it, as has already been described, to the receptacle of the chyle, and then by a duct running up the chest along the spine, called the thoracic duct, it joins the blood-vessels. The refuse of the aliment which has not been taken up by these lacteal vessels passes on through the large intestines, and at length is ejected from the body. Digestion is not brought about, as has by some been supposed, by any mechanical means, as by the grinding powers of the coats or sides of the stomach, nor by heat alone, nor fermentation, nor by the simple resolution of the food into a fluid; but it is evident that it undergoes a series of chemical actions in the stomach and bowels, whereby its nature and properties are completely changed; and thus animal and vegetable substances, however different, are reduced to one peculiar kind of fluid, the chyle, which, though it may be found to vary slightly according to the kind of food, is, in its general properties, always the same. The gastric juice varies in different animals. In those which feed on vegetable matter, it dissolves these substances only; whereas grain and vegetables pass through the stomach of a purely carnivorous animal without undergoing any change. The gastric juice has this singular property, too, that though it readily dissolves dead animal matters, and reduces them in a short time to a thin pulp, it will not usually act on the living fibre; so that, after death, the coats of the stomach have been found dissolved into holes, by the same juice, which, in the living body, had no such effect. This forms a most important fact in medical jurisprudence. A stomach of some kind or other is found in all animals; for it is by this organ that nutrition and growth are solely promoted. There are some very simply formed animals whose whole body consists of an oval hollow bag, or stomach, with a simple outlet for the mouth to take in nourishment, and no other organ whatever. The common polypi have simply a mouth and hollow stomach, with several tentacula, or arms, by which the creature seizes the worms and grubs on which it feeds; these it swallows, abstracts their juices, and then voids the remainder from its mouth. The common leech has its whole body divided into a number of small cells, like a piece of honey-comb; and these receive the water, and sometimes blood, on which it feeds. Flesh-feeding animals have a simple bag for a stomach, and their food is easily and soon digested. Those animals, again, that feed on grass, which is of more difficult digestion, have three and four stomachs, into which the food successively passes after it has been masticated or chewed a second time in the mouth. This is the case with cows, sheep, deer, &c. Birds that feed on grain have first a sap-bag, or crop, into which the food enters, and remains for a considerable time, mixed with a juice somewhat like saliva; here it is softened and rendered moist, preparatory to its passing into the true stomach, or gizzard, which is an extremely strong muscular bag; in this, with the assistance of a number of sharp-pointed pebbles, which such birds always swallow, it is ground down and acted on by the gastric juice. This compensates for the deficiency of teeth in fowls. Crabs and lobsters have no teeth in their mouths; but in their stomachs will be found three or more teeth, which assist in grinding down the tough sea-weed on which they feed. By domestication, the qualities of the gastric fluid may be so changed, that animals accustomed to live entirely on flesh will exist and thrive on a vegetable diet. This is the case with dogs, and many birds. All these peculiarities in the natural history of animals illustrate, at least directly, the uses of the digestive organs in the human being.

THE LIVER, ETC.

The Liver.—Opposite the stomach, on the right side, lies the liver, a large flat substance, of a dark brown colour, divided into two lobes. The liver has a round, convex, upper surface, and is hollow or concave below; it is also thick and solid at the back part, and its edge becomes thinner towards the front, where it lies over a portion of the stomach and bowels. It is suspended in its place by several ligaments attached to the surrounding parts. In the under side of the liver, in a small hollow, is situated the gall-bladder, a small oval bag which contains the bile. A tube from this bladder, called the bile-duct, passes into the upper portion of the bowels, carrying the bile there. The liver is supplied by several branches of an artery in the usual way that the other organs are, but it has also a peculiarity which no other organ of the trunk possesses. The large veins, which return the blood from the lower part of the bowels, before going to the heart, enter the substance of the liver, and there spread into innumerable branches throughout its whole surface. From this venous blood the bile is supposed to be secreted, and after having yielded this substance, the vessels collect again into one large trunk, and join the large vein which carries the blood to the heart. The liver weighs, on an average, from three to four pounds weight, and the quantity of bile which it secretes, taking into account its large supply of blood,

must be very considerable. The greater proportion of animal beings are provided with an apparatus of some kind or other for preparing a supply of bile, and in many the liver bears a large proportion to the other contents of the belly. In some animals, as the horse, the gall-bladder is awanting, there being merely a duct to convey the bile into the intestines. In the lowest classes of animals, all traces of liver or gall-ducts disappear.

The Spleen.—This substance is situated below the stomach, on the left side, betwixt it and the ribs. It is in shape a flat oval, and of a dark iron colour. No duct or opening has been discovered proceeding from it, nor has its use been as yet accurately ascertained. It possibly serves to relieve the stomach of its surplus quantity of blood while this organ is distended with food; and the splenic vessels have also been held by some to contribute to the secretion of the gastric juice. The spleen, it is remarkable, has been frequently cut out from living dogs, without causing any apparent derangement in the health or digestion of these animals.

The Pancreas.—This substance, known under the name of the sweetbread, is a large oblong gland (or *secreting* organ), lying across the back part of the belly, extending between the spleen and the middle of the liver. This gland pours out a substance something like the saliva or spittle of the mouth; and by means of a small duct or canal, empties it into the upper bowels, along with the bile from the gall-bladder, both these substances aiding in digestion, and the preparation of the nutritious fluid to be afterwards mentioned.

Lacteal Vessels.—These are innumerable small tubes, proceeding from the ileum or small intestines, along their whole course, and spreading along the mesentery, where they form an immense number of small knots, or glands, by joining together. These are the vessels which take up the fluid chyle, or milky-like substance, after it has been digested and properly prepared in the stomach and bowels. From these mesenteric glands, the chyle is conveyed by these ducts or canals to another large gland, situated in the loins, on the right side of the aorta, and immediately below the diaphragm, called the receptacle of the chyle. From this receptacle the thoracic duct arises, and passing upwards by the side of the aorta, or great artery of the body, it joins the left subclavian vein, lying under the left clavicle or collar-bone, and thus pours the whole of the chyle into the general circulation.

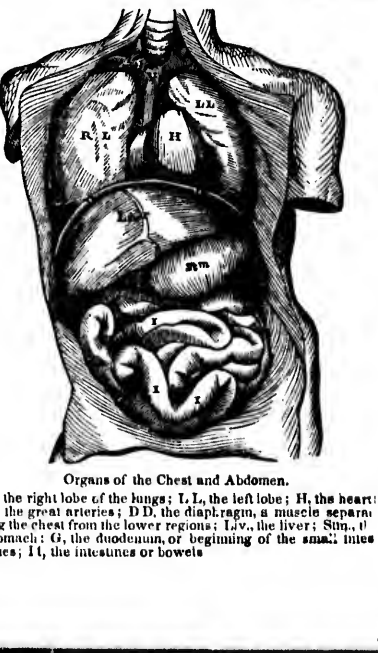
The Kidneys.—These are situated in the loins, one on each side of the back-bone, about one-third up the spine. They are in shape somewhat like a French bean, and their internal structure consists of a number of minute porous tubes. They each at the middle hollow part receive a large artery, and their use is to filter from the blood the superabundant fluid, and salts and juices unnecessary for the system, and transmit these, by means of two small tubes, called the ureters, to the urinary bladder. These tubes enter the back part of the bladder in a slanting direction, which serve the purpose of valves, preventing a flowing back of the fluid when the bladder is full. The bladder is situated in front, immediately above the bone of the pelvis, called the pubis.

The whole cavity of the belly is lined by a thin membrane, called the peritoneum, which is double, being reflected from the sides of the cavity over the whole of the intestinal organs. This peritoneum is liable to inflammation, in the same manner as was mentioned of the pleura, which produces a very violent disease. The coats of the intestines, too, are also subject to the same affection. Dropsy may arise from water being formed between the two folds of the peritoneum.

The Lymphatic Vessels.—These are another distinct set of vessels spread over all the inner cavities of the body, and also throughout the skin, on which they open by innumerable small mouths. Their office appears to be to take up from the blood a thin lymph, which they convey into the receptacle of the chyle and thoracic duct, and also to exhale or carry off from the skin the superfluous moisture of the body. This moisture forms the sweat, and several pounds of fluid are daily drained off from the body in this manner, even when little or no bodily exercise is taken, for perspiration continually goes on insensibly. These vessels are composed of a series of extremely small tubes, and, joining and interweaving, form numerous glands, especially in the groin, armpits, and neck; when swelled by disease, they harden and enlarge, forming knots like a pea or bean. But they are no less numerous on the surface of the inner cavities of the body as on the skin; they are found in the brain, or on the surface of the lungs, where they give out a large proportion of vapour at every expiration of the breath, and in the abdomen or belly. It is a disease or sluggishness of these vessels, whereby they do not perform their necessary duty of taking up all the superabundant fluids, that causes accumulations of water in the chest, belly, and legs. The branches of the lymphatics of the lower half of the body join the receptacle of the chyle; those of the upper part enter the thoracic duct just before the latter pours its contents into the subclavian vein.

THE BOWELS.

From the lower or pyloric orifice of the stomach, the duodenum, the first portion of the intestinal canal, takes its origin. This gut passes below the liver and receives the bile-duct, and the duct from the pancreas, when it terminates in the jejunum, which again passes into the ileum, or principal portion of the small intestines. These are of great length, and occupy a great part of the abdomen, being folded and twisted backwards and forwards in many intricate windings. At the end of the ileum, the colon, a large gut, makes an arch upwards towards the right side, and across the belly, and descending at the back part, ends in the short bag, called the cæcum, which joins the rectum, the termination of the intestinal canal. The whole length of the intestines in man is generally about six times that of his average height, or from thirty to thirty-six feet. In all animals that feed on vegetables, the intestines are of great length; whereas, in those that derive their nourishment from animal food, they are of much shorter proportions. Two membranous substances,



Organs of the Chest and Abdomen.

R L, the right lobe of the lungs; L L, the left lobe; H, the heart; V, the great arteries; D D, the diaphragm, a muscle separating the chest from the lower regions; Liv., the liver; Stm., the stomach; G, the duodenum, or beginning of the small intestines; I I, the intestines or bowels

called the omentum and mesentery, run along nearly the whole length of the intestines, and serve as a means of their attachment and proper suspension in their places. The bowels have three coats—an external one, common to them with the other viscera, a muscular coat, and an internal mucous covering.

It is of the greatest importance to health that the bowels, through which all rejected matter from the stomach is to pass, should be kept in an easy open condition, and that there should be a free passage through them once every day. When nature fails in this respect, a small quantity of medicine, under proper advice, may be taken; and the irritation which it causes usually leads to the desired result.

THE SENSES.

Man possesses five senses—sight, hearing, smell, taste, and touch, each of which acts through the medium of appropriate instruments, and all regulated by and acting in connection with the brain.*

Sight—the Eye.—The eye is the exterior instrument of sight, and is a most beautiful and ingeniously constructed object. The eye may be compared in its structure to a telescope, the purpose of both being to collect the rays of light proceeding from the surface of bodies, to concentrate these rays, by means of a refracting lens, into a focus, and, therefore, to form a very small image or picture of the object before them. The human eye is placed in a large hollow or socket in the upper bones of the face, surrounded by fatty substance, and the various muscles necessary for moving the eyeball and eyelid. At the upper and outer angle of the eye-socket is placed a gland, which secretes the tears that serve to moisten the delicate surface of the eye, to wash off any dust or other substance, and to keep the eye continually wet and transparent, for the purpose of perfect vision. The tears, after spreading over the eyeball, collect at the inner angle, where, at each corner of the eyelid, both above and below, there is a small opening visible, which carries the tears down a passage into the nose. The edges of the eyelids are also supplied with glands, which pour out a mucous that prevents them from adhering together; and these, when irritated and inflamed, are often the seat of disease. The membrane which covers and imparts the white colour to part of the eyeball in front, is called the sclerotic coat. The middle transparent part of the eye in front is called the cornea, which is filled with the aqueous humour of the eye. Immediately behind the cornea is seen a circular fringed-like substance, which varies in colour in different individuals, being blue, black, hazel, &c.; and hence it is called the iris, or rainbow curtain. This iris has the property of opening and closing, according to the quantity of light which falls upon the eye; and thus the pupil, a black circle contained within the iris, is enlarged or lessened. Behind the iris is situated the crystalline lens, in shape resembling the small lens or ground glass of a common telescope, but of unequel swell on each side, being more flattened before than behind. This lens is contained within a capsule, or thin covering of delicate membrane. A familiar example of the lens of a fish's eye is presented every day in that white globular substance found in such eyes after boiling. The heat coagulates the lens, which is of the same nature as the white of an egg; and in the fish it is nearly a circular body, to adapt the animal's vision to the dense medium of water. The lens is the substance which receives the rays of light entering the eye, and refracts or bends them inwards, whereby they are collected into one point upon the back chamber of the eye, or retina, and thus a minute pictur of the object seen is formed. If a bullock's eye is taken when fresh, and a hole cut in the skin covering the back part, and then presented to the light with a piece of white paper put opposite the hole, a representation of the objects in front of the eye will be distinctly traced on the paper. When through disease the lens becomes of an opaque white colour, and will not transmit the rays of light, the affection is known as the cataract, producing blindness. The fluid filling the lens is called the crystalline humour. Behind the lens is the back chamber of the eye, filled with a fluid, called, from its thickness, the *crystalline* humour. Over this back chamber the retina is spread out like a lining or covering. It is covered over with a black pigment, the better to prevent the intermixture or reflection of the rays of light. On this membrane the optic nerve, which comes from the front part of the middle brain, and enters the eyeball at the back part, spreads out in numerous branches; and here the small images of the outward objects presented to the eye are painted in mininture. All these objects are painted on the retina in a reversed position, or turned upside down, the same as happens in a common microscope; and how they are perceived in their upright position through the medium of sensation, is a curious question, not easily admitting of explanation. Each eye, too, forms a distinct impression of every object, and yet things are not seen double, but both eyes combine to give one impression to the brain or seat of perception. Besides the numerous muscles which roll the eyeball in various directions, to adapt it to the various positions of vision, there seems also a power, in the cornea or front portion of the eye, whereby it can flatten or become more convex according as the object viewed is at a greater or less distance from the eye, thus adapting itself to the focus of vision in a similar manner as the joints of a telescope are drawn out or pushed inwards. When the cornea is, from its natural form, of too rounded or convex a structure, distant objects are always seen imperfectly, hence causing what is called nigh-sightedness; on the other hand, when it is too flat in form, near objects are then seen indistinctly. This change occurs generally to the cornea as old age approaches, and hence spectacles, or artificial rounded lenses, to aid the flatness of the eye, are in such cases made use of with the desired effect. From the different densities of the three humours composing the eye, the refraction, or breaking of the light into the various coloured rays, is avoided. This for a long time was a great objection to telescopes, till different kinds of glass were joined together in the lenses, thus imitating the resources of nature in the eye. The eyes are supplied by two large optic nerves, proceeding by separate trunks from the brain; they join together for a short space within the cranium, where they again separate, and each entering an opening at the back part of the orbit, spreads out into branches over the retina. Sometimes these nerves lose their power of sensibility, and total blindness is occasioned without any perceptible disease of the eye: this is called *amaurosis*, and is in most cases incurable. All the larger and more perfect animals are possessed of eyes. Birds have in general very acute vision, especially birds of prey, to enable them to distinguish their victims at a great height in the air. They have also a third eyelid, or transparent membrane which covers the eyeball when they are darting suddenly through the air, and which thus protects the delicate organ of the eye from injury, at the same time that it allows the transmission of a sufficient quantity of light. Fishes have eyes of a somewhat different

* What may be called a *sixth* sense is almost if not altogether demonstrated, namely, the *muscular sense*, or that by which we are made sensible of the condition of our muscles, as acted upon, for the moment, by gravitation and the resistance of matter, in order to enable us by our powers of voluntary motion to command these muscles. Sir Charles Bell has thrown much light on this subject by his discovery of distinct origins for the nerves of feeling and motion, although they are found undistinguishable, in their substance, in the same sheath. Hunger and thirst are *sensations* also, and so perfectly different from all others, that they have been held by some to be the effects of a seventh sense.

form from land animals, to adapt their vision to the denser medium of water, through which the rays of light pass to their eyes. Insects have great numbers of small eyes clustered together, and most probably they are of microscopic structure. Many of the inferior animals, as shellfish, worms, &c., have no eyes.

Hearing.—The ear is the instrument of this sense. The outer part of the ear is formed so as to collect and transmit the currents of air into the passage which leads to the drum. This passage is of a winding description, and, besides being defended at its mouth by a number of small hairs growing up in it, there is also a waxy substance constantly secreted, which keeps the whole moist, and is an effectual bar to the entrance of insects or other offensive substances. At the inner end of this winding passage is the thin membrane or drum, which is stretched out on four small bones, and which, by its vibrations, conveys, through the medium of the nerves, the sensations of sound. There are also attached to these small bones several muscles, which, by their contraction and relaxation, modify the tension of the thin membrane, and prevent sounds from acting too strongly on it, or render it tighter, in order to be even sensible to feeble vibrations. Behind the cavity of the tympanum, or drum, there is another passage which leads from the ear to the mouth, called the *Eustachian tube*, the object of which is most probably the same as the holes in the common drum, to allow the air to escape from behind, and thus promote the vibration of the membrane of the tympanum; for it is found, that if such holes are not made in a drum, little or no sound will be produced; and in the human body, when this tube, leading to the mouth, is choked up by the inflammation of a common cold, deafness is produced. There is another cavity called the vestibule of the ear, covered over also by a thin membrane: on this membrane the nerves of hearing are expanded, and convey the sensations of sound to the brain. The sense of hearing is very acute in some animals, especially those that live by prey. In the lower orders of beings the sense is awanting, but is compensated in a considerable degree by the extreme acuteness of feeling, or touch, which is so diffused over their bodies as to make them sensible of the least agitation in the air by which they are surrounded.

Smell.—The nose is the instrument of smell, and is of comparatively simple structure. The bones forming its inner cavity are of a spongy nature, or rather are composed of a number of very thin plates, covered with a soft membrane, over which the branches of the nerves of smell are minutely exposed. The effluvia proceeding from bodies, and which imparts their peculiar odour, must pass in a stream or current through the nose before the odour is perceptible. If the air is perfectly still, and no current allowed in the nose by suspending the breathing through that organ, the strongest smells will make no impression. In some animals the sense of smell is acute and powerful, beyond the conception of human beings; thus a dog, by the acuteness of this sense, will distinguish the footsteps of his master amid those of a hundred other people, and can thus trace him for miles, although he has been a long while out of sight; pointers also scent game at a great distance. On the other hand, this sense is entirely denied to many of the lower animals. In man it is in many cases very imperfect, and may be blunted, or even extinguished, by disease. In colds affecting the delicate membranes lining the nostrils, the smell is very much diminished.

Taste.—The sense of taste is nearly allied to that of smell. The nerves of taste are spread over the upper surface of the tongue, and are raised up in innumerable small points, like the pile of velvet. In the lion these papillæ are very large, and easily distinguishable. No other part of the mouth is endowed with the property of tasting, except the tongue, as may be proved by touching any part of it with a piece of salt or sugar, when no sensation of taste will be communicated until the tongue has come in contact with the part so touched. That the taste or flavour of many bodies is heightened by the accompanying effects on the organ of smell, is evident; because, if the nose is stopped up so as to prevent the exercise of its functions, many substances having different flavours will tas alike. This is the case with the various kinds of wines, but especially with the ardent spirits. It is almost impossible to distinguish between the flavours of different kinds of spirits if they be tried in the dark, and with the passage to the nose accurately shut up. The tongue and whole cavity of the mouth and throat are kept moist by the saliva, or spittle, which continually flows into them from repositories placed around the cheeks and under the tongue, called salivary glands, which communicate with the mouth by means of small ducts. This saliva flows in greatest quantity during meals, and may even be excited by the sight of food when the appetite is good. It is of essential service in moistening the food, and preparing it for the process of digestion in the stomach. The sensation of taste is in all probability diffused among every class of beings, however low in the scale of existence, although it is probable many animals possess little of it in their mouths, especially when these are formed of hard, horny, or even earthy substances, as in many insects—the lobster, crab, &c. —and where any organ corresponding to a tongue is wanting. Even many birds that feed on grain and hard bodies, not chewed or broken down in the mouth, must have little sensation of taste.

Touch.—The sensation of touch is diffused more or less over every part of the body, but is most perfect at the points of the fingers, which in man are generally used to examine the figure and texture of bodies. For this purpose they are furnished with a large supply of very minute blood-vessels and nerves. It would appear that there are different nerves that convey the sensation of touch, distinct from those which are the nerves of motion; and that these proceed in pairs from the spinal marrow; and that, moreover, the sensation of heat or cold may be perceived very distinctly, in cases where the pricking of a needle or contact of other bodies is never felt. The sense of touch may be said to belong to every animated being, and is one great characteristic of animal existence. Vegetable bodies possess a certain degree of life, and show what is called irritability of their fibres; but they have no sensation, properly so called; they are not sensible of pain or injury, as the lowest and simplest sentient animal is; neither have they the compensating perceptions of pleasure. It is probable, however, that sensation is not by any means equally acute in all animals; some feel more intensely than others, and it is a happy provision of nature that it should be so. The lower insects and reptiles, from their structure and habits, are continually exposed to injury; and did they feel it as acutely as the larger animals, the degree of animal suffering throughout nature would be excessive. Many animals bear the loss of limbs with impunity, and have the power of restoring these lost members in a very short time. It is probable that, according to the perfection of the nervous system, is the acuteness of animal sensation.

On thus reviewing the different parts of the human body, it will be observed that most of its organs are double. On a line being drawn in the middle, on each side will be found parts which are exactly similar to the corresponding side. This is the case with the brain, which is a double organ, having two series of nerves proceeding out from each side of it to go to the respective sides of the body. There are two eyes also, each reflecting a distinct image on the retina; yet the nerves communicate so that only one impression is conveyed to the sense The arms are double to suit the various purposes for which they are employed, and so are the lower limbs, as

essential requisite for the support of the body, and for progressive motion. The lungs, too, may be said to be double, having two distinct lobes; and it sometimes happens that one of them is entirely shrunk or diseased, and yet the important office of respiration is still carried on. The stomach, the liver, and some of the other viscera of the abdomen, are, however, single, their several offices being common to the whole body.

THE HAIR AND NAILS.

The hair grows out from the skin somewhat in the manner of a vegetable production. Hairs are fixed by roots in the skin, from whence, by a series of minute vessels, they drew nourishment, and continually increase in length. They possess no sensibility, however, and unlike the other parts of the frame, may be cut off without producing the least pain. Hair is of different colours in different individuals—is fair in those of light complexion, and deep black in the swarthy. As old age approaches, and even in many young persons, where there is a particular disease in the hair, or dryness in the skin, this colour changes to gray and white. The colouring matter of the hair is contained in the centre, which is of a hollow form, and consists of an oily substance, in which carbon or charcoal, in minute particles, is more or less mingled. The nails are somewhat like hair in their production and composition; they are, like hairs, insensible to the touch, and may be cut or pared without producing pain. They receive nourishment from the blood-vessels of the extremities, and have a constant growth or renewal of their substance. Nails serve as a defence to the tender parts of the fingers; in animals they form formidable weapons of attack. The horns of cattle are exactly of the same nature as nails, and are chiefly composed of animal gelatine.

The manner in which the various secretions take place in the system, that are to form hair, nails, wax for the ears, blood, perspiration, &c., cannot but excite our admiration; for the whole is a chemical process of the most perfect kind, and such as art possesses no power to imitate.

THE SKIN.

An external compact membrane or skin covers the whole body. The outer skin, or cuticle, is unprovided with any blood-vessels or nerves, and consequently is insensible; in this manner it is well suited for a protection to the parts beneath; it is pierced by innumerable minute pores, which are the mouths of the exhalant vessels: it is thicker in the palms of the hand and soles of the feet than in any other parts of the body. Below the outer skin is a thin membrane, called the *rete mucosum*, which, assuming different hues in different nations, gives rise to the variety of colour in the human race. Some have held this membrane to be double, but this is not established. In Europeans it is white, passing into yellowish brown; in native Americans, of a copper colour; in Negroes, of a deep black. The common belief is, that climate has the effect of modifying the colour of the skin, as the black skin only occurs in tropical regions, and it is found that there it is a protection against the scorching influence of the sun's rays. Negroes will remain cool and comfortable exposed to a sun which would be intolerable to a white-skinned person. Their free perspiration seems to be of great service. Immediately below this network is the *cutis*, or true skin, an extremely sensible membrane, so thickly studded with minute blood-vessels and branches of nerves, that the smallest-pointed needle cannot prick it without touching many of them. On the points of the fingers, lips, and other parts of the body, these vessels are very numerous; and hence these parts are endowed with exquisite feelings of touch. Below the skin is situated the cellular membrane, which is a network, whose interstices are filled with fat, and it thus serves to fill up the spaces between the muscles, and to make up the shape, and preserve the symmetry, plumpness, and beauty of the whole frame. In cases of emaciation, this fatty matter is sometimes entirely taken up by the absorbent vessels—as after a tedious fever or other lingering disease—when the rough outlines and indentations of the muscles, and the projections of the bones, become painfully apparent.

SLEEP.

The various functions of the body are divided into voluntary and involuntary. When we eat we perform a voluntary motion, but digestion is performed without the action of the will, or is involuntary. The whole interior functional operations are involuntary, and go on whether we are awake or sleeping.

As a constant supply of food is necessary to repair the waste of the grosser parts of the body, so sleep is essential for the repose and renovation of the finer and more subtile nervous energy. Mere rest alone will not recruit the animal frame, but sleep, or a profound oblivion of feeling and sensation, and of every external circumstance, seems essentially necessary at every periodical revolution of the day. Toward the close of a day of exertion, the muscular powers which have been employed in motion, and in sustaining the body erect, begin to suffer particularly; the eyes become dim and heavy, and the eyelids close involuntarily; the lower jaw falls down; the circulation of the blood through the lungs is sluggish, hence frequent yawning is caused; the head nods forwards; all external objects affect us less and less; the thoughts become confused; and at last the profound oblivion of sleep ensues. We are unconscious of the exact moment when we pass into sleep, but occasionally it happens that immediately afterwards we are awaked by a convulsive start, which is caused by the sudden breaking in of the powers of volition, when as yet but newly and imperfectly lulled to rest. Sleep is quite essential to existence. Deprive a person of sleep, and the body sinks under the privation more rapidly than under famine. Indeed, no circumstances, however urgent, will prevent the approaches of sleep for any length of time; and under the severest calamities, and even while in the hour of battle, or when suffering from extreme fatigue, or cold, or hunger, sleep steals upon us to steep the senses in oblivion. Healthy sleep is so performed as to resemble, in all that regards self-consciousness, death itself. Sometimes, however, the mind exerts its activity, though it is but a partial exertion; and hence dreams, or thoughts of sleep, are made up of all incongruous associations, such as thoughts of the past day and incidents of long bygone years; scenes of actual experience, and others totally imaginary, being all mixed up and jumbled together. In sleep the heart continues to beat with regularity, and the circulation of the blood is carried on throughout the body; the lungs perform their functions, the stomach digests, and the bowels, and all the glands for secretion, carry on their operations; in short, every thing is carried on connected with the sustenance of the body and the existence of the vital powers; but for the most part all other powers, such as those over which we have a control in our waking hours, are at rest. This is not always the case, however, as walking during sleep, or somnambulism, is a peculiarity to which some individuals are liable. Dreams are most common when the sleep is imperfect or too long continued, and thus they occur frequently towards morning, or through the night, if the stomach is loaded and oppressed with food, or the mind harassed and deeply impressed with cares and solicitudes. In a state of health and serenity of spirits, the most profound and most refreshing sleep is during the first period of the night. When asleep, the circulation and breathing are both somewhat slower than when awake, hence the animal heat becomes diminished; and this is the reason why more clothing is required in bed than during the day. This is the reason, too, why a pe

son lying down to sleep out of doors, or on a sofa, with the usual allowance of clothes, feels chill and uncomfortable on awaking. Digestion, too, would appear to go on less vigorously during sleep; and hence the impropriety of going to bed with a full stomach. During the night and darkness is the most natural and obvious time to select for repose, and it is only the absurd encroachments of fashion that have wellnigh turned day into night. By going early to bed the damps and colds of night are avoided, which is of essential consequence, especially for the delicate. There is also a natural connection of the functions of the body with the periods of day and night, which makes sleep taken in the first part of the night peculiarly refreshing. The absence of every irritation of the head and other parts of the body—the perfect rest of the mind and external senses—have also great influence in promoting sleep. Again, a variety of causes which weaken and debilitate the body incline to sleep; such as great losses of blood, cooling medicines, purgatives, coldness of the atmosphere; and narcotics, such as opium and tobacco, drinking largely of wine or spirituous liquors, by first causing great excitement, and afterwards a corresponding debility of the system, also predispose to profound and lethargic sleep. Injuries of the head, by pressing on or otherwise interrupting the functions of the brain, also induce sleep; and great corpulency, by retarding the return of blood through the veins, and thus keeping up a pressure upon the head, is generally accompanied by a disposition to sleepiness.

The period required for sleep, by different individuals, depends much upon temperament and peculiarities of constitution, as well as on mode of life and habit. While some cannot sleep beyond five, six, or seven hours, others, again, cannot well do with less than eight or nine hours. Children sleep more than half of their time, and require it, and thrive under it; while adults need much less repose. On a general average, eight hours has been reckoned a good allowance. Certainly sleep beyond this does no good, and often does harm. In order to enjoy grateful and uninterrupted sleep, it is necessary that due exercise shall have been taken during the day; that temperance in food and drink shall have been observed; that strong tea or coffee, which have a stimulating effect on the system, shall not have been taken within an hour or two of going to bed; and that there has been no supper, or a light one. It is true, gluttony and intoxication produce sometimes deep sleep, but it approaches more to an apoplectic stupor than the calm repose of the temperate.

THE SEXES.

In almost all animals the sexes are distinguished by a difference of form and texture of their bodies; and in many, a superior gloss of colour in the hair or fur, or a superior brilliancy of the plumage, very generally characterizes the male of the species. In most animals, too, the males are of superior size, and endowed with greater muscular strength. In the human species man is marked by a larger and more muscular body than the female; his chest is square and capacious, and particularly at the shoulders, whence it tapers gradually downwards; his bones are large, and his joints firm and sinewy; his muscles are round, tense, and conspicuously marked: his limbs thick and fleshy, and his arms powerful; his skin is firm and tense, and his hair strong, crisp, and often curly. The female figure, again, is smaller, less powerful, and, in every respect, more delicately formed; the bones are less projecting, the muscles softer, less conspicuous, and more smoothly blended one into the other; the shoulders are narrow and rounded; the greatest breadth of the body being at the pelvis, from whence it gradually tapers upwards; the skin is soft and delicate; the hair smooth, and of a silken appearance. The mental qualities and dispositions differ somewhat also. Man is commanding, resolute, daring, adventurous, addicted to deep and abstract thought, as well as to high and imaginative speculations. Woman is gentle, submissive, timid; with a mind, perhaps, little inferior in compass to man, she is more commonly distinguished for acute penetration, nice and delicate discrimination, refined and chastened taste, and elegant and playful fancy. It was the opinion of Plato, that, with regard to the mind, there is no natural difference between the sexes, but in point of strength. "When the entire sexes are compared together," says he, "the female is doubtless the inferior but in individuals, the woman has often the advantage of the man." With warm and tender attachments, pure morals, and high religious feelings, she is admirably calculated for the sacred charge of watching over and training up the young, and of instilling into their tender and susceptible minds the beautiful lessons of early wisdom —of faith, truth, and charity. All nations, as they have advanced in civilization, have uniformly increased in that respect and refined attention which is due to the softer sex; and one of the most powerful minds and of the most splendid endowments has been the foremost to appreciate those superior qualities which are to be found in a gentle and unsophisticated female. The late Professor Dugald Stewart thus introduces a quotation from a well-known traveller, which affords a just and beautiful estimate of the tender disposition of woman:—"From the greater delicacy of their frame, and from the numerous ailments connected with their temperament, combined with their constant familiarity with distresses which are not their own, the sympathy of woman with the sufferings of others is much more lively, and their promptitude to administer relief, wherever it is possible, is much more eager than the generality of men. To the truth of this remark every day's experience bears witness; and, from the testimony of travellers, it appears that the observation extends to women in all the different stages of society."

TEMPERAMENTS.

There are certain conditions of the bodily frame which evidently give rise to varieties of the human constitution, and which have been called temperaments. These have been peculiarly the object of attention to Dr. Spurzheim, and others of the phrenological philosophers. As their views on this subject seem to us of a very clear order, a passage is here extracted from one of the journals devoted to that science. "Dr. Spurzheim," says the journalist, "recognises four primary or cardinal temperaments, to which he considers all individual cases may be advantageously referred, either as pure, or much more frequently consisting of two or more combined. I shall first give Dr. Spurzheim's brief Description of them, and shall afterwards enlarge upon each in detail.

"'1. The lymphatic, or phlegmatic temperament, is indicated by a pale white skin, fair hair, roundness of form, and repletion of the cellular tissue; the flesh is soft, the vital actions are languid, the pulse is feeble, and the whole frame indicates slowness and weakness in the vegetative, affective, and intellectual functions.

"'2. The sanguine temperament is proclaimed by a tolerable consistency of flesh, moderate plumpness of parts, light or chestnut hair, blue eyes, great activity of the arterial system, a strong, full, and frequent pulse, and an animated countenance; persons thus constituted are easily affected by external impressions, and possess greater energy than those of the former temperament.

"'3. The bilious temperament is characterized by black or dark hair, yellowish or brown skin, black eyes, moderately full but firm muscles, and harshly expressed forms. Those endowed with this constitution have a strongly-marked and decided expression of countenance; they manifest great general activity and functional energy.

"'4. The external signs of the nervous temperament are fine thin hair, often inclining to curl, delicate health,

general emaciation and smallness of the muscles, rapidity in the muscular actions, vivacity in the sensations. The nervous system of individuals so constituted preponderates extremely, and they exhibit great nervous sensibility.'

"The pure lymphatic temperament is characterized by a pallid complexion, soft skin, and mostly free from hairs, the hair flaxen, the pulse weak and low; a general tendency to corpulence, and a deficiency of expression in the face. Instances of pure lymphatic temperament are more rare than either of the others, and perhaps are never to be found, except amongst females and habitual invalids, when past middle age, who, from the want of exercise, have lost all trace of some other temperament which they may have possessed in youth. The mental characteristics of the lymphatic temperament are soon told; an insurmountable tendency to indolence, an aversion to exertion of either body or mind, form the hopeful traits. It is, therefore, obvious that the restraining faculties, Cautiousness and (in some of its manifestations) Secretiveness, are the only organs with the operation of which it will correspond; while all the other propensities, and the intellectual faculties, will be enervated and restrained by it.

"It has been generally supposed that the sanguine constitution is produced by the perfection or redundancy of the circulatory system: and it seems such a natural supposition, that it is difficult for us to allow its proper force to the fact, that individuals of other temperaments are frequently found who can bear loss of blood, by phlebotomy or otherwise, as well as those of sanguine constitutions, and in many instances much better. There is, however, one anatomical peculiarity which appears always to attend the sanguine. Their skin is much less disposed to transpiration than the bilious or nervous; and, in consequence, Dr. Prichard in a work lately published, considers that individuals possessing it are much better calculated to bear cold than others. The Fins, who, as a nation, are decidedly sanguine, bear extraordinary cold winters much better than their more bilious neighbours the Laplanders. Dr. Prichard adds, that as the sanguine temperament is very rare in those warmer countries, near the spot where man was first placed by his Creator, he considers the sanguine temperament as the result of a natural adaptation to external circumstances, analogous to the white hares and other animals of northern regions; but, if this is the case, it is difficult to imagine how it is that Laplanders should continue tawny, while the Fins, situated farther south, are fair. The most striking moral feature of the sanguine temperament appears to be a tendency to enjoyment of the present time, with little inclination to regret the past or to dread the future; and, in general, to look at either past or future no more than is necessary to happiness. The bilious temperament is characterized by a decided cast of features, complexion inclining to brown, dark eyes, and black or dark brown hair, with the muscles firm and well marked, and the figure, in general, expressive of vigour, with every motion significant and decided. In combination, it is frequently traced in a slight yellowness of the skin, which can only be detected by comparison, or an extraordinary acute perception of colours; for example, you may frequently find two persons, particularly ladies, the one with dark hair and eyes, the other with flaxen hair and blue eyes. The complexions of both would be denominated fair; on observing them near each other, however, it will be seen that the fairness of the dark-haired one differs considerably from the clear snowy whiteness of the sanguine.

"With respect to the nervous temperament, it manifests itself in a remarkable quickness to learn and readiness of comprehension, but little tendency to sensual gratification, and an extraordinary power of passing from one subject to another."

MAN ADAPTED TO LIVE IN ALL CLIMATES.

Man has this superiority over all other animals, that he can inhabit every different region of the globe, however extreme the degree of temperature. He is found under the scorching sun and amid the arid plains of Africa, as well as in the frost-bound regions of Spitzbergen; and he is found to live and thrive under these different extremes, not only after a gradual naturalization of ages, but can even move from one country to another, and undergo a vicissitude of climate with comparative impunity. Thus we see, even from our own country, emigrants going forth, and naturalizing themselves amid the cold regions of the north, onward to the very verge of the equator. The Esquimaux and the Canadian savage will prosecute their usual employments of the chase in a temperature where mercury freezes into a solid mass, and where even brandy congeals to ice in apartments containing fires; while the African negro, again, feels quite at his ease in a burning climate, where the thermometer in the shade ranges from 90° to 100°, and upwards. Man has an equal facility in adapting himself to the pressure of the atmosphere attendant on low or elevated situations. In Mexico, he is found living in elevated regions, from 6000 to 8000 feet above the level of the sea; and the hamlet of Antisana, in Quito, is 15,500 feet above the level of the ocean. On the contrary, we find almost all animals only adapted to live in the regions in which they are naturally found; and if they are removed from such localities, they seldom enjoy the natural period of their lives. Even the dog and the horse, the domesticated companions of man, degenerate and change their natures under extreme varieties of temperature; and the monkey tribe, which, in the structure of their bodies and in the substances on which they feed, approach the nearest to man, become sickly and diseased, and never propagate their species, when removed into any of the colder regions of the globe. In order to enable man thus to subsist in regions having such a diversity of natural productions, he is endowed with the power of feeding on and digesting every possible variety of food—he is, as compared to other animals, in respect to diet, omnivorous. We thus find the Greenlanders and inhabitants of frozen regions living almost exclusively on the fat and flesh of land and sea animals, the only species of food which the barren and ungenial nature of the climate affords, but one, nevertheless, which, from its stimulating and nourishing nature, is the very best for enabling them to live under such an extreme depression of temperature. The inhabitants of hot countries, again, will be found living on rice, fruits, and other vegetable substances, which the warm and genial soil produces in abundance, and which, from their nature, are less heating and stimulating than an animal diet. In the intermediate and temperate regions, a mixed diet of animal and vegetable food is preferred. Much discussion has arisen whether man be more a flesh-feeding or herb-eating animal; experience demonstrates that he is equally adapted to become both—that he will live on an almost purely animal diet, as well as on one purely vegetable; although, were we strictly to compare the form of his jaws and teeth, and the general structure of his intestines, with those animals that live on nuts and other fruits, and farinaceous or mealy substances, as, for instance, the monkeys, the near approach of these to the human structure would indicate to us that at all events a farinaceous diet is the most suitable to his natural organization. We thus find among all civilized nations that bread, and the grains and mealy roots, in some shape or other, have always a preponderating share in every meal. But the art of cooking, which man exercises even in the first dawnings of civilization, enables him to change the nature of his various food, and to render it more suitable both for digestion and the purposes of nourishment, and thus gives him a

wonderful superiority over all the rest of the animated world. Indeed, it is by this improved mode of preparing his food, perhaps, as much as by original strength and perfection of frame, joined to the other comforts of civilization, that he is enabled to brave the vicissitudes of climate, and to prolong his life to a longer period than the great majority of other animals.

Man has been formed with a naked skin, with the evident intention that he should clothe himself by his own labour and ingenuity. Almost all the larger and more perfect animals have a covering of hair, of feathers, or of down, which is at stated periods renewed, and in some animals in greater length and abundance at particular seasons, to suit the variations of temperature. But man can always adapt his clothing to the climate he inhabits, or to the varying alterations of the seasons; and he can at all times, by his own industry, vary or renew his suits. Man, too, builds for himself a comfortable habitation, to protect him from the inclemency of the weather, and is not contented with a burrow under ground, or the casual shelter of the woods and coppices, as is the case with the animals of the forests. It is true the architecture of bees, and some other animals, is curious, ingeniously combined, and admirably suited to their necessities; but in comparative taste, splendour, or even convenience, how far are all these surpassed by the houses, and temples, and cities of mankind! Though man is naturally defenceless and unarmed, how soon does his ingenuity enable him to obtain a mastery over the beasts of the field and forests, and furnish him with weapons of defence against all his enemies! How soon does his ingenuity enable him to improve and cultivate the soil—to drain marshes, cut down woods, level mountains—to select and cultivate the best species of grain, and the most wholesome and nourishing vegetables, for food—to invent tools and engines, by which he acquires a command over the sea and land, by which he erects bridges, constructs machinery, and launches the towering vessel upon the wide ocean! And, lastly, with what skill he constructs instruments of art and science, by which he can examine and investigate the most minute objects of nature, as well as bring within his sphere of observation other planets and other suns in the vast dome of the universe.

INFANCY.

At the moment of birth, the infant begins to exercise an independent existence, whereas before it formed a part, and was nourished by the vessels, of its parent. A general similarity takes place in the embryo growth of most animals, and the familiar instance of the chick in the egg may be taken as an example. The egg is composed of a centre part, or yolk, and of the albumen, or white part surrounding it. In this white part, a small darker speck may be seen floating, from whence the first rudiments of the chick are derived. In a few days after the hen has sat on the egg to impart to it the necessary heat, a small whitish spot will be observed, which is the first rudiments of a brain; in a few days more, vessels will be seen spreading out from a central heart, and forming a network all around; gradually an appearance of a head is seen, with indications of brain and spinal marrow; the eyeballs next are formed, then the several parts of the [illegible], the projections of the wings and legs, and [illegible] the skin and rudiments of the future feathers. During these periods of incubation, the chick has been nourished by the yolk of the egg, which has gradually been absorbed by its vessels for this purpose. At last, when its growth is perfected, and the whole contents of the egg converted into the materials of its body, the little animal begins to pick a hole in the shell, and, by repeated efforts, bursts from its shelly prison, and assumes an independent life. The infancy of man is of much longer duration, and of a much more helpless nature than the same state in any other animals. A child cannot walk till it is at least twelve months old; and even for a considerable time after that period, it has to be fed and tended with the utmost care; whereas, after a very short time, the young of most animals are able to provide for themselves; in a great many, a few minutes after birth they are able to walk about, to search for and distinguish the teat of their mother, and to pick up the food that is suitable for them; and having remained under their maternal protection for a short space, they leave their parents, and never know or distinguish them more. It is very different with the infant: during a long and helpless period of childhood, it is tended by a fond mother, who anticipates all its wants; while it, on the other hand, watches her smiles, and imitates her most minute actions; and thus a reciprocal bond of union is established, by which not only every species of knowledge and experience is acquired for the conduct of after-life, but those moral ties and affections established which constitute the great boast and solace of human society. Man proceeds from infancy to maturity by a slower and more gradual expansion of the bodily structure than any other animal, and this may be one reason of his superior organization, his greater fitness for supporting labour and fatigue, and the longer period to which his life is extended. From infancy upwards, the mental powers also gradually expand. This is also different from animals; for in them the faculty of instinct at once is perfected, and never afterwards increases or undergoes any change. In childhood, the mental faculties are constantly active, and on the alert to catch new information, inquisitive to know every thing, and imitate every gesture. The facility with which children acquire the knowledge of words, and in a few months master a language, is very astonishing, when we reflect for a moment how much time and pains it takes a grown-up person to become a proficient in any unknown language: and our astonishment will be heightened when we consider, that, in the case of children, they have not only to acquire the words and their proper applications, but even to master the articulation of sounds, with all their infinite combinations. The age of puberty, or that period when boyhood terminates and manhood commences, varies somewhat in different climates, according to their high or low temperature; the mean period may be reckoned about fourteen years; and, between twenty and twenty-five, the growth of the body generally terminates. About the age of thirty, man may be said to be in his full vigour, with his mental and bodily powers completely developed. Females arrive earlier at a state of maturity than males: in warm climates females are full grown as early as their ninth or tenth year; in more temperate regions, about their fifteenth or eighteenth year. The proportion of male children born to that of females, is as 21 to 20; there is thus a small superabundance of males; but, from various causes, it so happens that there is generally rather a superabundance of females actually existing in society. Among these causes may be mentioned, the greater hardships and labours to which men are exposed, the effects of war, and, on the whole, the longer life enjoyed by females. This regular proportion of male and female births throughout mankind in all ages, and in all parts of the world, shows the admirable design and precision of an unerring nature.

OLD AGE.

We have seen that there is, within the animal frame, a system of operations, by which a constant supply of nourishment is afforded to make up for the daily waste and decay, and that every part is constantly undergoing a renewal. To view a man in the full vigour of life, then, we might suppose that, excepting accidents, he was calculated to go on, in the course of existence, for an indefinite period. The principle of life, however, seems to

have limits set to its duration, beyond which it fails to keep in healthy motion the animal faculties. The apparatus of life is evidently destined but to last for a certain time. Old age creeps on apace, and the vital flame burns fainter and fainter, till at last it sinks in the socket, and is seen no more. The commencement of decay is perceptible even in youth itself. The child at first grows quickly, from the soft and yielding state of all its vessels; but gradually these begin to thicken and get harder—a greater proportion of earthy matter is adding to the bones. The extremities grow large, while the heart itself does not increase in an equal degree; hence the circulation becomes less and less quick, till the period of full growth. When the growth of the body can proceed no farther, a degree of fatness not unfrequently occurs. This proceeds from the superabundant nourishment produced from the food, which, from the impetus or force of the circulation being more lessened by the greater extension and resistance of the body, accumulates in the cellular textures and by the sides of the extreme vessels. In every part of the body, the induration produced by approaching age becomes conspicuous—in the bones now wholly brittle, in the skin, in the tendons, in the glands, in the arteries, and in the brain itself, which gets firmer and drier. Moreover, the arteries continue to get denser, narrower and even shut up in their minute branches. At the same time, the nerves become more and more callous and insensible to the impressions of the senses, and the muscles to irritation; thus, the contractile force of the heart, and the frequency of its pulsations, are diminished, and, of consequence, every force which impels the blood into the ultimate vessels. The quantity of humours is diminished in the denser body; the moisture which lubricates the solid parts everywhere manifestly decreases. Nor is the quantity of humours only diminished; they themselves likewise become vitiated. They were mild and bland in children; they are now acrid, salt, and fetid, and loaded with a great quantity of earthy matter. This circumstance of the superabundance of earthy matter is evident in the gouty concretions in the joints of old people, in the frequency of stone, and in the arterial tubes, and even the heart itself, being frequently converted into real bone. The rigidity of the whole body, the decrease of the muscular powers, and the diminution of the juices, constitute old age, which sooner or later comes upon all men—sooner, if subjected to violent labour, or addicted to pleasure, or fed upon a too scanty or unwholesome diet; but more slowly, if they have lived quietly and temperately, or if they have removed from a cold to a moderately warm climate. There are three obvious divisions of human life—a period of youth, including the period before the age of 30; of maturity, from 30 to 50; and of old age, commencing about the period of 50 or 60. David speaks of the age of man being, in his time, only threescore years and ten, or in rare cases fourscore years, which may be reckoned the average limit of human existence. After the period of 50 or 60 years, varying of course in different constitutions, the marks of old age begin to make their appearance. The skin becomes more lean and shrivelled; the hair changes to a gray colour, or baldness occurs; the teeth drop out, and, in consequence of this, the lower parts of the face, about the mouth and jaws, incline inwards; the muscular motions of the body become less free and elastic—this is especially seen in walking, old people generally treading on the whole base of the feet, and hence have a shuffling gait; the blood circulates slowly; the animal heat is diminished; the pulse occasionally intermits, and the whole energies of the animal frame become lessened; the eyesight begins to fail, and dulness gradually comes over all the senses; the memory undergoes a remarkable change—while recent events pass through the mind and make no impression, the occurrences of early life continually suggest themselves, and are minutely called to remembrance.

Although usually seventy years is the extreme period of human life, yet a small proportion of those born ever reach even this; a few rare instances occur where one hundred years or upwards are attained. The famous Parr lived to the age of 150 years; he married at the age of 120, and, when 130, was able to thrash, and to do every description of farmers' work. He was at last brought from the pure air and the homely diet of the country, into the family of the Earl of Arundel, in London, where he drank wine and lived luxuriously. The sudden change of diet and circumstances, however, proved quickly fatal to him. Henry Jenkins, another poor man, lived to the astonishing age of 169 years, and retained his faculties entire. Some time ago, a statement appeared of the ages of the resident pensioners of Greenwich Hospital, which contained at the time 2410 inmates. Of this number, 96 had attained to or passed the age of 80; one only was above 100; 15 were 90 or more; and 80 were 80 or upwards. About 42 of the 96 were of aged families, and in some of this number both parents had been aged. Longevity has in a great number of cases been found to be hereditary. Eighty of the 96 had been married; 79 were in the habit of using tobacco in some form or other, and 48 had drunk freely; 20 were entirely without teeth; 52 had bad, and 14 good teeth. But the oldest man in the house, who was 102, had four new front teeth within the five preceding years. The sight was impaired in about one half, and hearing only in about a fifth part of the number. Old people are not generally inclined for much exercise, nor is it suited to their stiff joints and impaired vigour; for the same reason they cannot endure much cold. Cheerful company, especially the company of the young, is peculiarly grateful to old people. Innocent amusements and recreations are also of great consequence, and the mind should be exercised in some useful or amusing pursuit. Cities, or at all events constant and agreeable society, are favourable to the condition of old age. In lonely, secluded country places, the mind sinks prematurely into a total gloom and blank, for want of sufficient stimulus and variety to keep up the vigour of thought and play of ideas. Few deaths occur from what is commonly called old age, or a gradual and simultaneous decay of all the functions. It may be said to happen when the powers gradually decay, first of the voluntary muscles, then of the vital muscles, and, lastly, of the heart itself; so that, in an advanced age, life ceases through mere weakness rather than through the oppression of any disease. The heart becomes unable to propel the blood to the extreme parts of the body; the pulse and heat desert the feet and hands, yet the blood continues to be sent from the heart into those arteries nearest to it, and to be carried back from them. Most commonly, however, some one part gives way, and disease gradually coming on, cuts off the lingering flame of existence. Thus the body, after having grown up to maturity, and flourished in its prime, sinks to the earth, and moulders into the elements of which its several parts are composed.

CONCLUSION.

The admirable structure of the body of the human being—its superiority in every respect to that of the lower animals—afford a most perfect proof of design in the all-wise Creator, and is one of the most striking instances of the impossibility of our formation being the result of blind chance. Paley, after going over a great number of examples of this kind of design in a Creator, proceeds to state that, in all instances wherein the mind feels itself in danger of being confounded by variety, it is sure to rest upon a few strong points, as per

baps upon a single instance. Among a multitude of proofs, it is *one* that does the business. If we observe in any argument (he continues), that hardly two minds fix upon the same instance, the diversity of choice shows the strength of the argument, because it shows the number and competition of the examples. There is no subject in which the tendency to dwell upon select or single topics is so usual, because there is no subject of which, in its full extent, the latitude is so great, as that of natural history applied to the proof of an intelligent Creator. Perhaps the most remarkable instances of mechanism in the human frame are—the pivot upon which the head turns, the ligament within the socket of the hip-joint, the pulley or trochlear muscles of the eye, the epiglottis, the bandages which tie down the tendons of the wrist and instep, the slit or perforated muscles at the hands and feet, the knitting of the intestines to the mesentery, the course of the chyle into the blood, and the constitution of the sexes as extended throughout the whole of the animal creation. To these instances, the reader's memory will go back, as they are severally set forth in their places; there is not one of the number which I do not think decisive; not one which is not strictly mechanical; nor have I read or heard of any solution of these appearances, which in the smallest degree shakes the conclusion that we build upon them.

The works of nature require only to be contemplated. When contemplated, they must ever astonish by their greatness; for, of the vast scale of operation through which our discoveries carry us, at one end we see an intelligent Power arranging planetary systems, and, at the other, concerting and providing an appropriate mechanism for the clasping and reclasping of the filaments of the feather of the humming-bird. We have proof, not only of both these works proceeding from an intelligent agent, but of their proceeding from the same agent; for, in the first place, we can trace an identity of plan, a connection of system, from Saturn to our own globe; and, when arrived upon our globe, we can, in the second place, pursue the connection through all the organized, especially the animated, bodies which it supports. We can observe marks of a common relation, as well to one another as to the elements of which their habitation is composed. Therefore one mind hath planned, or at least hath prescribed, a general plan for all these productions. One Being has been concerned in all."

VEGETABLE PHYSIOLOGY.—BOTANY.

GENERAL ECONOMY OF VEGETATION.

EVERY one is acquainted with the usual forms of vegetables, either as herbs or trees, for they exist in all situations suitable to their growth and constitute not only a highly ornamental covering provided by nature for the exposed surface of the earth, but, as is well known, are an inexhaustible source of nourishment to the animal races.

Plants are in the main easily distinguishable from animals, and the consideration of them falls under different sciences. Yet it is not easy to say where the animal world ends, and the vegetable world begins. The two seem to melt into each other in the class of existences called *zoophytes*, which appear a combination of both plant and animal.* We are not, however, to suppose that the highest class of plants are thus connected with the lowest or simplest class of animals, and that the organic world is consequently one continuous chain. The two systems may be rather said to be united at a point near the base of both, above which they rise side by side. Apart from this connection, plants are to be distinguished from animals by not only certain external appearances, but by the absence, in them, of what animals possess, an *internal principle* not easily described, but traceable in certain very remarkable results, namely, motion from place to place, a selection of advantageous circumstances, and a power of adapting means to ends.

Of the nature of life, or the vital principle, science does not profess to be able to give an explanation. In using the term, we only mean that power or quality resident in certain structures, by which they are enabled to incorporate with themselves those nutritive particles of matter which they require, and to reproduce structures of their own species or type. The most simple forms of life are observable in plants whose economy is limited to mere absorption of nutrition and reproduction; and it is only when we come to the link that unites vegetables with animals, that we find any thing sensitive, a nervous energy, or spontaneous locomotion. With respect to the powers of reproduction, it must be carefully impressed, that neither plants nor animals come into existence without a parentage. It was at one time supposed that some kinds of animals, as, for example, maggots, locusts, and myriads of smaller creatures, were produced from external causes alone, such as putridity, or a certain state of the atmosphere; but such notions have long been abandoned by men of science, and it is placed beyond the possibility of doubt that all animals and vegetables whatsoever, notwithstanding any mystery that may attach to their appearance, are the offspring of others of their own type.

The method of reproduction, as will be afterwards shown, is different in different plants, but, as a general principle, it may here be stated that the parent vegetable is charged with the function of liberating germs or seeds, which vegetate as soon as brought into a condition fitted for their growth. A seed is like an egg in character, for it possesses in itself that amount of nourishment which will enable it to subsist in the ground during germination, or until it draws the means of existence from the soil and atmosphere. Most kinds of seeds, being contained in husks or shells for their preservation, are able to retain their vegetative power for a long period of time, if entirely excluded from heat, air, and moisture; thus, on turning up soil that had been covered centuries ago, a new order of vegetation is always observed to arise from the long-buried seeds.

It may be further mentioned, as a provision in the economy of vegetation, that, while each species of plants is incapable of being transformed by reproduction into any other, it is possible, in some instances, as in the animal species, to produce a hybrid or mixed breed, and, with the additional means afforded by cultivation, plants and fruits may be improved in quality to a very high degree. Thus, the common sour crab, growing wild in our fields and hedges, is the uncultivated original of the different varieties of the apple. Yet, to sustain this improvement, constant culture, transplanting, crossing, or grafting are required. The plant is only improved as

* See art. ZOOLOGY.

respects itself, and if its seeds be allowed to grow up without culture in a poor soil, they will produce plants exactly resembling their humble original.

The term of vegetable existence, from the period of germination till the final decay of the plant, is extremely various: some plants are annuals, or grow but for one year or season; while others are perennial, and continue their growth from year to year; trees are among the longest lived plants, some being known to exist for upwards of two thousand years. The reproductive powers of plants are likewise very varied; but it may be stated, in general terms, that in each case nature has provided effectual means of perpetuation, either by means of roots or seeds, or by both. This power of reproduction is strikingly observable in such plants as the potato, which propagates by oviparous seeds pendant from its stalks, and by the tubers clinging to the roots in the ground. In most instances, the artificial deprivation of the seeds before they arrive at maturity, incites the reproductive powers of the roots, and they increase in bulk, or throw up new plants at a distance from the parent stem. When annuals have ripened their oviparous offspring (grain in the ear, for instance), the object of their growth is accomplished, and they forthwith droop and decay.

The development of vegetable life is greatly dependent on certain concurring agents, among which, in a particular manner, are included *heat*, *air*, *moisture*, *light*, and *soil*. Each of these agents, however, is limited to a certain range, and this range is different in different plants, so that excessive heat and excessive cold, and also the extremes of drought and humidity, are always unfavourable to vegetation generally, though not to all kinds of vegetables. Thus some mosses and other plants, whose parts are few and little developed, continue to grow in very cold weather, and even under the snow; others which generally contain much juice in their substance, but which are covered with an epidermis so compact that it resists the action of heat, and prevents any evaporation of the juice of the plant, live in situations where the heat is extreme, and during that part of the year when excessive drought renders the common vegetation as inactive as it is in polar countries during the depth of winter.

The condition of the atmosphere as respects temperature, moisture, and other qualities affecting vegetable life, is comprehended in the term *climate*. No two places at a distance from each other can be said to have the same climate, because each is subject to particular influences not affecting the other to the same degree. That district will possess the most genial climate, and be best adapted for the perfection of vegetable life, which at once lies most fair towards the sun, and is exposed to the action of refreshing rains, or is moistened in some other way. A free exposure to the sun throughout the year is equal to several degrees of latitude nearer the equator, other circumstances being favourable. The more free the exposure, the more readily will most plants blossom, and yield a rich fruit; so well is this understood in the grape countries on the Rhine, that the right bank of that river, which faces the sun, is reckoned to be much more valuable than the left, and commands a higher price for its wines.

The character of the vegetation in tropical and extreme northern and southern climates, is of the most opposite kind—the one luxuriant and continuous, the other only for a short period during summer. In the tropical regions there is always about twelve hours of sunshine, and nearly the same length of darkness; and when the air is clear, the action of the sun is generally sufficient to occasion a suspension of the powers of many vegetables, or what is sometimes called *a sleep of plants*, during the heat of the day. But, unless for local circumstances, the chief of which are alternate successions of drought and rain, there is nothing in the mere solar action which can affect vegetation there very much more at one time of the year than at another; and therefore, considered with reference to the sun alone, the vegetation there is not only generally ever-green, but ever growing, ever-flowering, and ever-ripe and in fruit.

In the extreme northern and southern latitudes, a portion of one half of the year is continual day, and a corresponding portion of the other half continual night; and when the continual day approaches, if part of the heat of the sun were not occupied in melting snow and ice, and turning into vapour the water which clouds the atmosphere and mitigates the ardour of the solar heat, the action of the sun in those high latitudes would at these times be excessive. As it is, vegetation, during the short period that it acts, is more vigorous in such parts of the polar countries as are out of the range of the cold produced by melting snow or ice, than it is in any other part of the world; and even in Lapland, we have the expansion of the bud, the blowing of the flower, the ripening of the fruit, and the preparation of the new bud, in little more than half the time in which these operations take place in the temperate climates. This state of things requires a suitable character in the vegetables placed in those countries—they must be capable of withstanding equally the ardour of summer and the rigour of winter. For this purpose, such vegetables as stand exposed to the air at both seasons, form complete buds, encased in a hybernaculum, composed of a number of scales of a resinous or gummy consistency, with thin strata of dry air between them; and buds so shielded are proof against the utmost severity of cold. The more lowly plants of such places are defended by the snow which covers the ground; and thus, though the action of the vegetable world is limited in its annual period, and also in the number of species in which it is displayed, it is as perfect in its system, and as secure in its continuance, as in the tropical regions. Between these extremes, there is a regular gradation; and taking that and local observation along with us, we are in possession of at least the elements upon which a geography of plants may be formed.

While heat, variously modified, serves as a prime exciting cause of vegetable life, air and moisture, or water, are elements in which the vegetables feed and exist. The soil in which the plants have their roots, and the atmosphere in which their branches and leaves flourish, are the great laboratories of nature, whence these elements are drawn. To understand properly how plants derive nourishment from these sources, it is necessary to appeal to *chemistry*, or that branch of science which recognizes the elementary properties of matter. The following are a few leading principles, briefly stated:—

"The substances which constitute the principal mass of every vegetable are compounds of carbon with oxygen and hydrogen in the proper relative proportions to form water. Woody fibre, for example, is composed of such compounds of carbon with the elements of water. In another class of substances containing carbon as an element, oxygen and hydrogen are again present; but the proportion of oxygen is greater than would be required for producing water by union with the hydrogen. The numerous organic acids met with in plants belong, with few exceptions, to this class. A third class of vegetable compounds contain carbon and hydrogen, but no oxygen, or less of that element than would be required to convert all hydrogen into water. These may be regarded as compounds of carbon with the elements of water and an excess of hydrogen. Such are the volatile and fixed oils, wax, and the resins. The juice of all vegetables contains organic acids, generally combined with inorganic bases or metallic oxides; for these metallic oxides exist in every plant, and may be detected in its ashes."*

* Liebig's Organic Chemistry.

Nitrogen also forms a portion of most plants, being an important ingredient in the substance called gluten, or the starchy material of farinaceous vegetables. It is chiefly drawn in the form of ammonia from the soil to which animal manures have been applied. In general, carbon is the fundamental and principal element in plants, and this is derived chiefly from the atmosphere. The carbon exists in the atmosphere in the form of carbonic acid, or in a state of union with oxygen; and therefore, before appropriating the carbon, plants must necessarily decompose the atmosphere. This process is actually performed by the vegetable kingdom. Plants possess the power of separating the carbon of the carbonic acid from the oxygen, and, seizing upon the carbon, return the oxygen to the atmosphere.

The process of decomposition and appropriation is performed by the leaves and other green parts of plants, these constituting the breathing apparatus. But, for the performance of this remarkable chemical action, aid from the sun's light is necessarily required. While vegetables are in a considerably darkened shade during the day, and in darkness during the night, carbonic acid is accumulated in all parts of their structure; and the assimilation of the carbon and the exhalation of oxygen commence from the instant that the rays of the sun strike them. As soon as a young plant breaks through the surface of the ground, it begins to acquire colour from the top downwards, and the true formation of woody tissue commences. Plants thus improve the air by the removal of carbonic acid, and by the renewal of oxygen, which is immediately applied to the use of man and animals.

The growth of plants, and their transformation of elementary properties in the soil and atmosphere, must hence be regarded as a protracted and various process in the chemistry of nature, proceeding on fundamental laws. In order that the process may not be defeated, pure atmospheric air, and also the sun's light, must be allowed in their proper proportions, independently of pure water. The air best adapted for robust vegetable growth is that of an ordinary density, near the sea's level. Generally speaking, the more elevated the station of the plant is, its action is the less, because the air is the less dense, therefore colder, and is understood to have greater evaporative power; but mountainous countries are generally much better supplied with humidity than plains; and therefore the dwarfed growth of plants in such situations must be considered as resulting much more from their diminished action than from any excess of evaporation. Hence, as we ascend the slopes of mountains which are of sufficient elevation for having their summits covered with perpetual snow, we find upon them plants resembling those of a succession of latitudes, gradually getting colder than the mean temperature of that which answers to the level of the sea, in the same latitude as the mountain. So that, upon very lofty mountains near the equator, the Andes in upper Peru, for example, we meet with something resembling the succession of plants in the whole quadrant, from the equator to the pole. But it is a resemblance only, and not an identity; because, although it be possible to find upon the side of such a mountain places which have the same mean temperature for the year as is found in every parallel of latitude, yet both the daily and the seasonal distribution of the sun's action are very different; and it necessarily follows that the habits, and even the characters, of the vegetables are equally so.

Humid air supplies some vegetables with all the nourishment which, from their situations, they can possibly obtain; and therefore we may conclude that it is capable of affording some nourishment to every vegetable. But the air also acts as a drain upon vegetables, in removing out of their structure a portion, and sometimes a very large portion, of that water which is necessary for the purposes of growth; and in proportion as the air is more humid, it must perform this function less perfectly. We must therefore suppose that there is a certain degree of moisture, and of evaporative power jointly, in the air, which is best adapted to the healthy action of plants, but what this is must depend upon the nature of the plant, and must therefore be ascertained by direct observation. Indeed, this is one of the circumstances which tends to the local distribution of the different kinds of plants, as we find them in a state of nature; but, like the others, we cannot so separate it from co-operating causes as to obtain the law of its action. There is one other circumstance connected with the air which is worthy of notice, and that is, whether it be more generally stagnant or in motion. It is perfectly evident, that the action of stagnant air upon a plant must be every way less than that of moving air, whether we suppose the action to be of one kind or another; and therefore, up to a certain point, motion in the air must be favourable to the growth of vegetables. Of this there have been proofs by direct observation, in the same part of the world; and when we examine different parts of the world, we find proofs which are much more striking: thus, for instance, the trade wind of the Atlantic sets constantly against the shores of Brazil and Guinea, and up the valley of the Amazon, until its motion is gradually destroyed by the dense mass of vegetation over which it passes.

The Oriental isles, and the southern part of the Malay peninsula, are in like manner exposed to a constant current of the air; and those two regions are, in respect of the number, the variety, the beauty, and the activity of their vegetable productions, the very gardens of the two hemispheres. Even when the current of air is an alternating one, the return of which is actually unfavourable to vegetation, such a situation is still highly favourable upon the whole. Of this we have striking examples in the valley of the Mississippi, the Malabar coast of India, and even in the British islands, and, generally speaking, along the whole of the west coast of Europe, where the advantage is not counteracted by some local cause.

Winds are therefore to be considered as performing an important part in the economy of nature. From northern and southern latitudes, where there is a small supply of sun's light during winter, with weak vegetation, and consequently a superabundance of carbonic acid in the atmosphere, the winds convey the deleterious material to tropical regions, where, by means of the brilliant sun's light and strong vegetation, it is readily and profitably consumed. Streams of wind in a contrary direction, or from the equator to the poles, in the same manner bring to us the superabundance of oxygen produced from tropical plants. While heat, moisture, air, and light, variously modified in the multifarious climates on the globe, produce the extraordinary diversity of vegetable growth, another set of circumstances affect the life of plants, and these relate to the nature of the soil in which they are placed. Although properly belonging to GEOLOGY, we shall present a short exposition of what soils usually consist.

The soil is mainly composed of particles which have been disengaged by various means in the course of time from the rocks on which it rests. In some instances, and more particularly on hills, it is composed chiefly of pulverized materials from the rocks immediately at hand or beneath; but in many others, the pulverized matter has been washed down from high into low grounds, or transported by floods from great distances. The action of the air and water on rocks in dissolving them, and the power of the latter element in transporting the disengaged particles, are the principal causes of the present arrangement of the soil.

Notwithstanding the different appearances which the earthy covering of the globe exhibits, it is composed

almost entirely of four substances, formed by an original union of simple elementary matters. These four substances, washed at a former period from rocks, and more or less compact from influencing circumstances, are called primitive earths, and are named *clay*, *sand*, *lime*, and *magnesia*. Clay is variously named alumine or argillaceous earth; sand is sometimes termed silex, silica, or silicious earth; and lime is commonly called calcareous earth. The distinctive characters of all these substances are well known. Besides these four earths, which either in a soft or hard state constitute the soil and subsoil, the upper stratum or mould contains the relics of decayed vegetable and animal substances, also certain metallic bases, generally oxide of iron. The particles of decayed vegetable matter, sometimes termed *humus*, and known as food for new vegetation, are understood to be in reality a deposit of carbon gained by plants from the atmosphere. Ammonia, as already said, is also an ingredient in fertile soils.

The whole of these circumstances, modified in a variety of ways, influence vegetable growth, and require to be studied by the cultivator of plants. It has long been remarked that plants have a tendency to exhaust the soil in which they grow, and to exchange their situation for one more suitable to their wants. The following propositions on this subject have been laid down by two eminent French chemists, Yvart and Pielet:—1. That every plant has a natural tendency to exhaust the soil; 2. That all plants do not exhaust the soil equally; 3. That all plants of different kinds do not exhaust the soil in the same manner; 4. That all plants do not restore to the soil the same quantity nor the same quality of manure; 5. That all plants differently affect the growth of weeds. From these fundamental principles the following conclusions are drawn:—1. However well a soil may be prepared, it cannot long nourish crops of the same kind in succession, without becoming exhausted; 2. Every crop impoverishes a soil, in proportion as more or less nutritious matter is restored by the plant cultivated; 3. Perpendicular rooting plants, and such as shoot horizontally, ought to succeed each other; 4. Plants of the same kind should not return too frequently in a circle of cropping; 5. Two plants equally favourable to the growth of weeds ought not to succeed each other; 6. Such plants as greatly exhaust the soil, as grains, should only be sown when the land is in good heart; 7. In proportion as a soil is found to exhaust itself by successive crops, plants that are least exhausting should be cultivated. It may be added, that a successive change of crops has a tendency to destroy noxious insects, as those which are produced by one crop cannot be supported by another of a different description.

Nature, when unassisted, invariably makes an effort to change the crops of plants. When a forest in North America is burnt down by accidental fires in the summer season, trees of quite a different kind spring up from long concealed seeds in place of those which have been destroyed. When, in ordinary circumstances, one kind of plant has exhausted the soil in its neighbourhood, it pushes its roots to as great a distance as possible in quest of food, and there sends up shoots, while a new race of plants grows upon the spot which it has vacated. The seeds of certain plants, such as the dandelion, thistle, &c., are furnished with downy wings, by which they are rendered buoyant, and carried away from the parent plant by the slightest wind. The seed-vessels of other plants, such as the whin, when ripe, burst open with considerable force, and scatter the seeds to some distance from the place where the old plant grows. In these, as in a thousand other circumstances, we find that one of nature's great primary laws is that of perpetual change—an alteration from one condition and appearance to another, in endless succession and variety. In the artificial cropping of the ground, the farmer, for his own sake, is impelled[*] to take a lesson from nature, and to study what species of plants he can most advantageously produce in succession from his fields. Hence, *ration*, or the *rotation of crops*, as it is differently termed, is a matter of first importance in husbandry.

A long course of experience and scientific inquiry have proved that all soils are capable of being improved by art, and supplied with restoratives suitable to the demands of the proposed vegetation. These artificial restoratives receive the name of *manures*, and are commonly in the form of animal excrements, these containing ammonia, one of the bases of vegetable structure, in greater or lesser abundance. Some idea of the powers of restoration from substances of this nature in a due state of putridity or decomposition, is obtained from the fact, that, from every pound of ammonia which evaporates, a loss of sixty pounds of corn is sustained. Potash, soda, gypsum, and other materials, also constitute manures, or bases, whence are drawn fertilizing principles in vegetation.*

CLASSIFICATION OF PLANTS.—LOWER FORM OF VEGETATION.

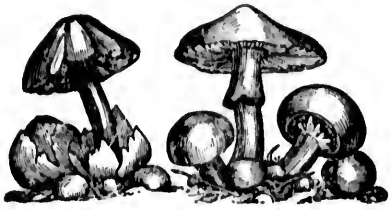
According to the latest researches of naturalists, about 80,000 plants of distinct specific forms have been discovered, but it is believed that as many more remain to be made known, and additions to the list are constantly taking place. For the sake of order and classification, as in the case of the Animal Kingdom, all plants, from the lowest to the highest forms of vegetation, are arranged in a progressive series of groups or families, the members of which possess a common resemblance, or are otherwise allied in character. This very necessary classification belongs to Botany—a term from the Greek, signifying a plant—and an outline of the plan adopted is given in the latter part of the present article. Here it is only necessary to mention, that, according to the Linnean system, the whole Vegetable Kingdom is arranged in two grand divisions, namely, plants having visible flowers (*Phænogamia*), and plants having no visible flowers (*Cryptogamia*). The whole are also divided into classes, orders, genera, and species, each species containing a number of varieties.

The lowest forms in which vegetables make their appearance are those of the *cryptogamia*,† among which are included the *fungi*, the *musci* (mosses), *hepaticæ* (liverworts), *lichines* (lichens), *algæ* (seaweeds), and *filices* (ferns), &c. The fungi, which may be placed at the very bottom of the vegetable scale, are observable in a great variety of forms, and, among others, mushrooms, toadstools, puff-balls, the fungous dry-rot, fermentation, mildew, and mould. We may take the last mentioned as about the lowest in the group. Mould, as most persons are aware, makes its appearance on the surface of various familiar objects—decaying paste, fruit-preserves, cheese, and old shoes. It never appears on any thing which is new or fresh, but is always a harbinger of decay, and may be considered a first step towards the decomposition of the substance into its constituent elements. How vegetation should appear in so secluded a situation as the inner cracks in cheese, or in a jar of preserves placed carefully away in a cupboard, or on the leather of an old boot in the remote corner of a bedcloset, is at first sight incomprehensible; but a consideration of the reproductive powers of fungi at once explains the circumstance. The whole of the fungous tribe possess the most extraordinary productive powers.

* To students who desire full information on this highly important branch of vegetable economy, and particularly all who are to be engaged in agricultural pursuits, we recommend the careful study of "Organic Chemistry," by J. Liebig: to be had of G. H. Zieber & Co., Philadelphia.

† A term signifying *hidden marriages*, or, by a liberal interpretation, plants whose means of reproduction are concealed, not obvious, as in the case of flowers.

Instead of propagating by the ordinary and slow process of elaborating and throwing off seeds, they increase by the dispersal of their entire substance. Every particle in their mass is a germ, or technically a *spore*, which, though smaller in bulk than a particle of fine dust, and



Fungi.

generally so minute as to be invisible to the naked eye, is the embryo of a new plant, and will develop its powers of vegetation as soon as placed in an appropriate situation for its growth. In this manner, a toad-stool, having performed its office and exhausted its means of nourishment, shrinks, dries, and dissolves in millions of atoms, which, being liberated and floated away in the atmosphere, are deposited in every imaginable situation. Some are inhaled into the lungs of animals, while others enter into the fabric of trees and herbs, and, in short, they find admission into every exposed and penetrable substance. There is, however, a distinct principle in fungous vegetation, that it can develop itself only in decaying bodies. Decay, or liability to decay, is necessary for its fructification; and when this condition ensues, and other circumstances are suitable, the embryo expands and rises with surprising rapidity into notice.

A very remarkable kind of fungous vegetation is known to make its appearance in wine cellars, the substance which supplies the growth being the vapour from the wine in the casks or bottles. If the cellar be airy and dry, the vapour escapes, and no fungous vegetation is manifested; but if it be somewhat damp and secluded from air and light, the fungous growth becomes at once apparent. Round every cork a mould-like vegetation will exhibit itself, and the vapour from the casks rising to the vaulted roof, will there afford nourishment to great festoons and waving banners of fungi. In the wine vaults of the London docks, this kind of vinous fungi hangs like dark woolly clouds from the roof, completely shrouding the brick arches from observation. On a small piece being torn off and applied to the flame of a candle, it burns like a piece of tinder. Should wine escape from a cask in a moist and ill-ventilated cellar, it will altogether resolve itself into fungi of a substantial kind. A circumstance of this nature once came under the notice of Sir Joseph Banks. Having a cask of wine rather too sweet for immediate use, he ordered that it should be placed in a cellar to ripen. At the end of three years, he directed his butler to ascertain the state of the wine; when, on attempting to open the cellar door, he could not effect it, in consequence of some powerful obstacle. The door was therefore cut down, when the cellar was found to be completely filled with a firm fungous vegetable production, so substantial as to require an axe for its removal. This appeared to have grown from, or to have been nourished by, the decomposed particles of the wine, the cask being empty and buoyed up to the ceiling, where it was supported by the surface of the fungus.

The disease called rust, which affects grain in the ear, particularly in moist seasons, is well known to be a fungous vegetation, proceeding from germs which had previously existed in the substance of the plants. In a dry season, and on a favourable soil, rust rarely makes its appearance; certain conditions are necessary for its development, and it is to obviating these that the farmer must look for exemption from this destructive malady in his crops. It is now placed beyond a doubt that rust arises in many cases from the over-manuring of fields; the grain is overloaded with nourishment, and the dormant fungi, brought into a condition of development, speedily show their destructive properties. The tendency to rust may be neutralized by steeping the seeds before sowing in a corrosive solution, or strong brine, but the same end may be better secured by not over-manuring, or by a free use of saline manures. Salt, as is well known, is an enemy to corruption, and, when applied to the soil, it prevents the injury which plants receive from the fungus tribe. Skilful agriculturists are now fully aware of these facts.

Offensive in appearance as nearly all fungous vegetables are, and injurious as they may sometimes be to the crops of the husbandman, they perform a highly useful office in creation. Existing only by the absorption of fœtid exhalations, and rapidly depriving them of their insalubrious properties, they execute duties analogous to those of certain tribes of insects (maggot-flies, for instance), and in this respect have been appropriately associated with these animals as the "scavengers of nature." On this point in their economy, a naturalist observes as follows:—

"The peculiarity of their agency consists in their power of suddenly multiplying their numbers, to a degree which could only be accomplished in a considerable lapse of time by any larger beings; and then as instantaneously relapsing, without the intervention of any violent disturbing cause, to their former insignificance. If, for the sake of employing on different but rare occasions a power of many hundreds or thousands of horses, we were under the necessity of feeding all these animals at a great cost in the intervals when their services were not required, we should greatly admire the invention of a machine, such as the steam-engine, which should be capable at any moment of exerting the same degree of strength, without any consumption of food during the periods of inaction; and the same kind of admiration is strongly excited when we contemplate the powers of insect and fungous life, in the creation of which nature has been so prodigal. A scanty number of minute individuals, only to be detected by careful research, and often not detectable at all, are ready, in a few days or weeks, to give birth to myriads, which may repress or remove the nuisances referred to. But no sooner has the commission been executed, than the gigantic power becomes dormant; each of the mighty host soon reaches the term of its transient existence; and when the fitting food is used in quantity, when the offal to be removed diminishes, or fewer of the spores find soil on which to germinate; and when the whole has been consumed, the legions before so active all return to their latent unnoticed state, ready, however, at a moment's warning, again to be developed; and, when labour is to be done again, again to commence their work either in the same districts, or to migrate in clouds like locusts to other lands. In almost every season there are some species, but especially in autumn there are many, which in this manner put forth their strength; and then, like the spirits of the poet, which thronged the spacious hall, 'reduce to smallest forms their shapes immense.'"

It will now be understood that mould is a fungous vegetation, produced by a previous deposit of germs in the tissue or on the surface of the object on which it grows. The proximate cause of its development is generally damp, and, without this condition, the embryo remains in a dormant state. Still, it may be asked, how cheese happens to have green mould at its very centre: the reply is, that the fungous germs floating in the atmosphere had various opportunities of finding admission into this article of diet.

They may have been deposited on the grass of a field; the grass was eaten by the cow, and the germs were so lodged in the milk; or, what is more probable, the germs fell upon the curd, and there lay concealed till a certain dampness in the cheese brought their vegetative powers into operation. It is well known that the exposure of curd for a day to the atmosphere will have the effect of producing cheese liable to mould. The mouldiness of Stilton cheese is produced, we believe, by practising this device. Those who wish to make sweet cheese, not readily liable to mould, should avoid exposing the curd to the atmosphere.

A fully more surprising instance of fungous vegetation in a secluded situation, is that which occurs in the fermenting of yeast, and other substances. Fermentation is, in a respect, a chemical process, forming a first step towards dissolution, but the action is also vegetative. The whole mass of matter gradually assumes the condition of active vegetative growth. The fungous germs which had been incorporated in the material, begin to live and expand, each being a plant which grows and gives rise to new plants of the same species. A popular author observes of fermentation at this stage in its progress—"If a small portion of the fluid be examined at intervals with a powerful microscope, it is seen that each of the little vesicles contained in it puts forth one or more prolongations or buds, which in time become new vesicles like their parents; these, again, perform the same process: so that within a few hours the single vesicles have developed themselves into rows of four, five, or six. This is not the only way, however, in which they multiply; for sometimes the vesicles are observed to burst, and to emit a number of minute granules, which are the germs of new plants, and which soon develop themselves into additional cells. By the time that five or six vesicles are found in each group, the fermentation is sufficiently far advanced for the purposes of the brewer; and he then takes measures to check it, by which the vegetation of the yeast is suspended. The groups of vesicles then separate into individuals resembling those which first constituted the yeast; and thus, a greatly increased amount of this substance is the result of the process."*

We may learn from these observations that the germs of fungi, necessary to produce dry rot, mould, fermentation, and other species, are dispersed throughout all organic matter. Every thing we eat, drink, taste, or which ministers to our wants, contains the germs of fungi, and all that is required to bring them into visible operation are certain conditions of decay, heat, and moisture.

It is generally allowed that the algæ embrace the most minute forms of vegetation (not of a fungous character). One of those forms is that which has vulgarly been called *red snow*, or *bloody rain*. A shower of red-coloured rain or snow is by no means a rare phenomenon in the northern parts of Europe, or within the arctic circle; and the tinging matter, which has been accurately examined, is found either to proceed from the incorporation of vegetables or animalcules, both too small to be seen by the naked eye. The colouring vegetable matter is an aggregation of an infinitude of plants either sucked up by a water-spout into the atmosphere, or overtaken while carried along by the winds, and brought down by the falling drops. On the stones by the side of brooks, we may sometimes observe a similar reddish colouring matter, which, if not caused by metallic ores, will generally be found to be a primitive kind of vegetation. When touched, it feels slippery, and on examination by a microscope, it is observed to consist of myriads of plants, each consisting of a small vesicle or globule, which, on arriving at maturity, expands, bursts, and liberates plants of its own species. This excessively humble plant is classed with algæ, as being the nearest to it in character, although these plants are for the most part of a large size, and grow principally on rocks in the sea.

The object which nature has in view by the germination and dispersal of the algæ, mosses, and lichens, is clearly that of preparing the way for a higher order of vegetation. It cannot possibly escape our observation, that the tendency to vegetate is a power restless and perpetual. We hew a stone from the quarry and place it in a damp situation, on the ground or in a wall, it is all the same which, and shortly a green hue begins to creep over it. This is the commencement of a vegetable growth, produced by germs floated in the atmosphere, and being attached at random to the stone, have been brought to life through the agency of the moisture. Other stones equally exposed, but in dry situations, have also received a clothing of these germs, but circumstances not being suitable, they have not been developed: give the moisture, and they will immediately appear. We hew another stone from the quarry, and build it into the pier of a bridge just within the surface of the water. Shortly, the same kind of green algæ will appear; but the wet being in greater abundance and more continuous, the growth will become more luxuriant. Instead of the simple green hue, we have the addition of long filaments resembling green hairs, which float and accommodate themselves to the water around. This kind of plants, which are known to naturalists as the confervæ, propagate, like others of the cryptogamia, by a rupture of their tissue, and the liberation of germs, which become plants of the same species. Of course there cannot be a doubt that all open ponds, lakes, and running waters, abound in germs capable of producing this green filamentous vegetation.

The inquiry may perhaps here be made—supposing that nature designs this species of growth to be a forerunner of a higher order of vegetation, how is that result to be brought about? To answer this, we must take an expansive view of the subject, and not confine ourselves merely to one department of science. Nature is incessantly working out vast ends by humble and scarcely recognisable means. It seems to be a principle that nothing shall remain stationary or unchanged. The whole surface of our planet is every instant altering in its features. Mountains are being washed down into the plains, rocks are mouldering into soil, the sea is filling up at one place and encroaching on the land at another, and water-courses are constantly shifting their outlines. The duty of filling up seas, ponds, lakes, and rivers, is consigned to divers means within the animal and vegetable economy, and one of these is the growth of algæ and other aquatic plants. Take a pond of water, and shut off its means of supply from rivulets and springs, and then observe what an effort nature will make to fill it up. The sides and bottom become speedily covered with a luxuriant crop of confervæ; other plants, which grow only in water, begin to make their appearance, their seeds being wafted thither by winds; at length the superficial matting of herbage is able to support the weight of birds, grass grows, there is alternate vegetation and decay, and finally the pond is filled up. This routine is observable in many small lakes which are fed by weak springs, and, except for an artificial clearing out occasionally, they would in a short time become dry land. What, indeed, are the extensive peat-mosses but lakes and pools choked with vegetable matter, which remains in a half-consumed condition. Thus we see that the green hair-like ooze which grows upon stones in the water, humble and apparently insignificant as it is, performs a distinct part in creation necessary to work out the important designs of Providence.

The algæ are the vegetation of the deep, and grow as immense forests in the rocky bed of the sea, where they furnish food for animals, and assist in filling up and altering the channels. On being decomposed, they afford an alkali to soap manufacturers, and are exceedingly useful

* Popular Cyclopædia of Natural Science.

in furnishing iodine, a substance which is now used in medicine for reducing glandular swellings.

Algæ.

Lichens are a numerous family of plants, and put on various appearances. Their usual aspect is a dry scaly crust of a grey or yellow hue, and their appropriate place of growth is on old walls, gravestones in churchyards, and rocks; they are also seen growing on the trunks of old trees. Their structure is very simple; each plant consists of a membranous scale, or *frond*, divided into lobes, and they cling to the object on which they grow by means of small filamentous roots, which insinuate themselves into the most minute crevices. Growing usually as parasites on some kind of hard substances, they derive their nourishment exclusively from the atmosphere, and only require pure air and sun's light, with a fair proportion of moisture, for their subsistence. Their whole economy being rudimental and simple, they are capable of living at great altitudes on mountains, where the air is too thin for the growth of the higher orders of plants; on this account the lichens are found flourishing beyond the limits of every other kind of vegetation, even to the very verge of perpetual snow. At these great heights they cannot be said to be of any service in preparing soil for plants of a superior order, but they at least help to bray down their rocky beds, and level mountains with the grounds beneath. From the atmosphere they have the power of secreting oxalic acid, which, acting chemically on their rocky base, causes small hollows sufficient to gather rain from the atmosphere; and the moisture finding its way into crevices, the rock is split by frost, and in time moulders into fragments. The tenacity with which they adhere to their situation, renders it difficult to scrape them from stones by art; but as light and air are essential to their subsistence, they may be easily removed by covering them over for a short time with a turf or quantity of earth. Gravestones, whose inscriptions have been obliterated by lichens, may by this expedient be completely cleared from their growth. Liverworts are a superior kind of lichens, possessing leafy fronds, and expanding to greater dimensions; they also seem to grow best in situations somewhat damp.

Lichen.

In our comparatively mild climate, we have little experience of the lichenous family of plants which appear to flourish best in those cold regions of the globe where almost every other living thing would perish. In the extreme northern parts of the American continent, there are found on the rocks a kind of lichen called by Canadian voyageurs *tripe de roche*, from its resemblance, when boiled, to tripe, and in which cooked state it forms a meal when more nutritious food is wanting. Another kind, called reindeer moss, is common in the arctic regions, where it grows to a foot in depth, and is the chief resource of the reindeer. The celebrated Iceland moss is also abundant in these regions, and may be reduced by cooking to a fine mucilaginous substance.

The name *moss*, however, is misapplied to these and most other lichens and liverworts. Mosses are plants a stage higher in structure and functions, and generally require a greater quantity of heat, air, moisture, and soil for their growth. With moss, plants commence the rudimental characters of root, stem, branches, and leaves. Mosses have a bright green colour, a proof of the activity of their leaves or breathing apparatus; and their slender stems, with minute feathery branches, are among the most elegant structures of vegetable growth. Mosses fructify in a peculiar manner. On examining a soft green mass of moss, we may at certain seasons observe a forest of small thin stalks raised considerably above the general level. These are the seed stems. At the top of each is a small pouch containing the seed, and covered over with a lid or veil, which drops off when the fructifying matter is ripe, and suffers it to escape. By being elevated in this manner, and freely exposed to the wind, means are afforded of scattering the seeds over the recumbent moss, and for their being blown to places at a distance. The object seems to be, to keep up an active fresh vegetation on the surface of the moss, while a corresponding decay is going on beneath, and adding deposits of new soil. The whole economy of the plant is beautiful, and it will be remembered that it so much affected the feelings of Mungo Park, in one of his moments of desolation in the wilderness, as to inspire him with an energy sufficient to carry him over his difficulties.

Moss.

HIGHER FORMS OF VEGETATION.—PHYSIOLOGICAL STRUCTURE.

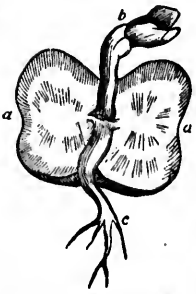
From the humble class of cryptogamous plants, we ascend to the second great division in the vegetable kingdom, called the PHÆNOGAMIA, or plants which flower, and possess the attributes of distinct seeds, roots, stems, branches, and leaves.

Seeds.—A seed, upon being placed in the ground, in due time sends forth two shoots, one ascending and forming the stem, and the other descending and forming the root. The annexed figure gives a representation of the germination of a dicotyledonous or two-lobed seed: *a a* the seed lobes, *b* the leaf-germ, *c* the root spreading into fibres.

The time required for vegetation varies much in different species; thus the mustard takes little more than one day, whilst the rose, the hazel, &c., require two years. When a seed begins to germinate, it enlarges until it bursts its shell. As soon as the embryo stem has reached the open air, its leaflets are expanded, and begin to perform all the functions of leaves.

Roots.—The root (*radix* in Latin) is commonly defined to be that part of a plant which attaches itself to the soil where it grows, or to the substance on which it feeds, and is the principal organ of nutrition. Exceptions to this definition occur, as in the case of some vegetables which grow floating loosely in water, as duckweed and others, having no root at all. As the nourishment of a plant is derived from the earth, the root is that part which grows in an opposite direction to the stem, and is buried in the ground. A root consists of several parts, which have been called the body or *caudex*, the collar or life-knot, the branches or radicles, when such exist, and the

rootlets or small fibres, which seem to be indispensable in all roots. The body of the root assumes various forms; it may be globe-shaped, as in the turnip; conical or tapering gradually from the collar to the attenuated fibre, as in the carrot; fusiform, or tapering at both ends, as in the radish; this latter may be abrupt, that is, as if the lower end had been cut off, exemplified in the devil's bit scabious; fibrous, or consisting of small thread-like fibres,



which proceed directly from the collar, as may be seen in most grasses; tuberous, when the fibres bear globe-shaped bodies filled with starchy matter, as in the potato; fasciculated, when the fibres swell slightly in the middle; bulbous when the round lobe consists of coats or layers, such as may be seen on cutting an onion across. A corm is similar in form to a bulb, but is not composed of layers; a palmated root consists of a number of oblong tubers proceeding from the collar like the fingers from the body of the hand, as in the dahlia. Tuberous roots, such as the potato, are considered by some modern botanists as merely underground stems, from the circumstance of their having eyes, or buds, from which branches will spring. The crown, collar, or life-knot, as it is variously called, is that part which lies between the stem and the root. It is the most essential portion of the whole; for, if it be removed or seriously injured, the plant will inevitably die; whilst the small fibres or rootlets, although an essential part of a plant, may be destroyed at pleasure, so long as the crown remains, for it readily reproduces them. When it is of a slender make, as the seed form, it dries up and the plant soon dies. Such plants are termed annuals, as the poppy, mignonette, and others. The crown, however, in some cases, by proper treatment, may be rendered so strong that annuals can be brought to grow two years, when they are termed biennials; or for three years, when they are called perennials. The fibrous root consists of a quantity of long thin fibres, of different lengths and thicknesses, and having still finer ones springing from them, as in the case of wheat, barley, and most grasses. These small fibres or rootlets bear a resemblance to the branches and leaves of the stem. Fibrils consist of a central fasciculus of vessels, enclosed by a cellular cortex and cuticle. Like the leaves of trees that are not evergreen, they are annually produced; in some cases dying and falling off like leaves, in others becoming thicker, harder, and forming radicles or root-branches. The spongelets, as they are called, which take up nourishment from the soil, are situated at the extremity of these rootlets. They are minute spongy bodies, of an oblong shape. We have an instance of rootlets falling off like leaves in those arising from bulbs—such as the lily, the onion, the tulip, &c., which are pushed off and perish like leaves by buds containing the rudiments of the rootlets to be evolved next season.

Roots have a remarkable tendency to grow downward, or in the direction of the earth's centre, and, from experiments, it is likely that this tendency is an effect of gravitation. The precise direction, however, is very much influenced by the condition of the soil. Both root and rootlets extend as if in quest of food, and this will penetrate sideways or obliquely to great distances. When plants are by any means prevented from fructifying by seeds, they almost invariably increase by extending their roots, from distant points of which new plants will spring up

The stem or stalk.—When a plant shows itself above the ground it evidently manifests a strong tendency to the light. Light, in fact, is essential in bringing it to maturity, and in giving the green colour to its leaves The stem, with a few exceptions, is always above ground, and is the perpendicular pillar from which various lesser growths, such as branches, shoot off laterally. "The stem," says Rennie, "is divided from the root by the part called the crown or collar. The space between the collar and the first leaf or bud is termed the bole; but the great body of a stem is called the trunk. The stem of grapes, corn, and reeds, is termed the straw; the stem of palms, ferns, mushrooms, and sea-weeds, is termed the stalk; the stem of such flowers as the primrose, the daisy, the snowdrop and the lily, is termed the scape, though flower-stalk is certainly better; the running stem, as in the strawberry and cinquefoil, is termed a runner; a shorter runner that does not root, as in the house-leek, is termed an offset; a longer one that does not root, as in the cucumber, a violet; and a small stem proceeding laterally from a root or stool, a sucker."

The stem, it will be observed, assumes many forms and characters as to bulk, structure, position, place, and duration. It appears as a tuber (*Gladiolus*, 1), a bulb (the onion, 2), a scape (*Dodecatheon*, 3), a culm (*Arundo*, 4), or as a woody column (the palm, 5). It varies in size from that of a bristle to a trunk of many feet in diameter.

When a trunk bears permanent or perennial branches, the plant is termed a tree; when permanent branches arise, not from a trunk, but from the root, the plant is termed a shrub; when small and much branched, a copse shrub; when furnished with woody branches that are not permanent, as in the tree mignonette, it is termed an under-shrub; and when the whole stem is not woody, and dies down every year, at least as far as the crown of the root, the plant is termed an herb; when a trunk is formed like the underground stem of the iris, of the hardened bases of leaves which have withered and fallen, and is not taper, but all of one thickness, giving off no branches, as in the date and cocoa, the plant is termed a palm.

Buds, which have various forms, but are generally oval or roundish, consist of the young shoots either of leaf, flower, or twig, and proceed from what is called the axil of a leaf. They are usually formed either early in summer or in autumn, and are so contrived as to preserve from injury the delicate foliated structure within. The outside is composed of tough scales, which are frequently covered with a gummy resin, and they are internally kept warm by a downy substance interposed between the leaves. Buds are in most respects like bulbs, the scales being composed of cellular tissue, with distinct fasciculi running through it. This separation of the vascular fasciculi is the feature which distinguishes these scales from leaves. The inner scales perform the functions of leaves, until these are perfected and fully expanded, when they drop off; but in some trees, as in the apple and the almond, they are converted into leaves; whilst in others, as the rose, they are converted into the pellicles, or foot-stalks of the real leaves which spring out

of them. When the central part of a bud contains leaves only, it lengthens upwards as it expands into a branch; thus a leaf-bud and a branch-bud may be said to be the same. When it contains a flower, this is situated as in the bulb of the tulip, in which small bulbs are formed on the edges of the crown of the root between the scales, which gradually enlarge at the expense of the scales, are detached, become perfect bulbs, and send up leaves and flower-stalks. With respect to the manner in which the leaves are folded—they may be plaited, as in the palm or birch; doubled, as in the rose and oak; embracing, as in the iris and the sago; double embracing, as in valerian, teasel, &c.; double compound, as in carrot, mimosa, &c.; rolled inwards, as in grasses; tiled, as in privet, lilac, &c.; rolled outwards, as in rosemary, primrose, &c.; rolled lengthways, breadthways, rolled from the tip to the base, or wrapped round the stalk.

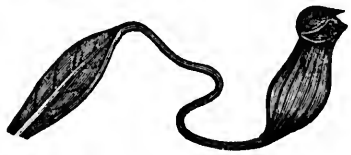
The buds of trees, being in a state of great sensibility, and feeling the first warmth of the sun, the vitality of the continued shoot is roused into action; it attracts the moisture contained in the neighbouring cells charged with nourishing matter; the rising sap also enters its vessels; it gradually swells, and bursting the enclosing scales, pushes into the light and air, unfolding its leaves successively as it advances, until the whole tree becomes green.

Leaves.—Leaves are the grand ornament of plants, and from their numbers, position, and delicacy of organization, they are designed to effect an important office in the vegetable economy. Springing from the branches, and exposed in profusion to the atmosphere, they perform the functions of a breathing apparatus analogous to that of the lungs or gills of animals. A similar purpose, at least, is designed, for the circulatory sap of plants, like the blood of animals, requires to be exposed to the atmospheric influence, in order that it may be suitable for nutrition. This purpose is accomplished by the agency of the leaves, to which the sap, on rising from the roots, through the stem and branches, is propelled or attracted, and there both air and light exercise their beneficial influences. Gaseous qualities, however, are emitted as well as inhaled by the leaves; and that they allow the escape of aqueous fluid is well known. Leaves are thus indispensable to the growth of plants, and care should be taken not to injure them; for defoliation either naturally, or by art or accident, instantly arrests the growth, and the failure or diminished expansion of foliage is a certain sign of debility.

A leaf consists generally of two parts, the petiole, or leaf-stalk; and the lamina, or that part which is broad and thin. Sometimes, however, as in the rose tribe, stipules are attached to the base of the petiole. The leaf-stalk is that part which connects the leaf with the branch, and at the base will be found slightly hollowed, in which a bud rests. Sometimes the leaf-stalk is wanting, as in the sow-thistle and catch-fly, and in this case the leaf is said to be sessile or sitting. The lamina, or broad part of the leaf, is frequently of a different colour on the under side to what it is on the upper. This is exemplified in the common silver-weed (*Potentilla anserina*), the leaves of which are hoary on the lower side and green on the upper. Leaves are either *caducous*, falling in summer; *deciduous*, falling in autumn; *persistent*, remaining till pushed off in the following spring; or *perennial*, when of still longer duration, as in evergreens.

Some leaves are of a very remarkable shape, which none of the foregoing characters can describe. The most remarkable of these is the pitcher plant (*Nepenthes distillatoria*), which is seen in the annexed cut. The leaves of this plant are sheathing at the base, and at the end of the proper leaf is a petiole or stalk, several inches long, which is terminated by a bladder-like vessel furnished with a lid. This vessel is always filled with water, which appears to be distilled from the plant itself.

With regard to the manner in which leaves project from the branches, and their distribution over the woody cylinder to which they are attached, every possible variety may be observed. They may be opposite, that is, two leaves growing on either side of the branch, the one directly opposite to the other; alternate, when one leaf springs out on one side of the branch, and another on the opposite side a little above it, and so on; whorled or *verticillate*, when a number of leaves grow round the stem from a common knot or joint, as in the bed straw. The distribution of alternate and opposite, however, is not regular; for in some instances it will be found that the leaves on the lower part of the stem are alternate, whilst those on the upper part are opposite.



The leaves of most plants possess a power of motion, which is the effect of what is termed irritability or vitality. Thus the leaves of the aspen (*Populus tremula*), from a peculiar formation of the petiole, never rest; and those of the sensitive plant (*Mimosa pudica*) close themselves up on the slightest touch. The flowers of many plants also possess this irritability, closing when night approaches. There is a numerous description of plants which have few or no leaves, as the torch and melon thistles; but their stems are much dilated, presenting a large superficies of parenchymous exterior to the air and light; or they are profusely covered with spines, which, no doubt, conjointly do the office of leaves. It may be remarked, that such plants as the common garden rhubarb, which requires much moisture, are provided with very broad leaves, which catch the rain that falls upon them, and also, by their umbrageous quality, preserve the ground round the stalks from being parched by drought.

Green is the most general colour of leaves, but some are red, or purple, or yellow; some appear nearly white, in consequence of being clothed with short woolly or silky hair. They differ much in substance and structure; some are immensely thick and fleshy, as those of the genus aloe, others remarkably thin, as those of the beech. The texture of the surface is also very dissimilar; some are rough, prickly, and wrinkled, others smooth and glossy. Whatever be their form or appearance, it is found, by minute microscopic observation, that the interior of the fine membranous substance consists of cells and passages suitable to the due exposure of the sap, the inhaling of air, and the absorption of humidity from the atmosphere. The fine downy hair which grows on the leaves is understood to be of service in collecting dew at night, and supplying it to the plant.

Glands.—It is doubtful whether the bodies which usually receive this appellation (*glandulæ*) really exist in the vegetable system. There are, however, minute organs, differing in structure from the common texture of the part where they are situated, which separate some peculiar matter from the ordinary proper juice, and which may be regarded as glands. If this be admitted, these glands occupy the interior and exterior of stems and leaves, vary greatly in form and attachment, and perhaps in structure, although any attempt to demonstrate this can scarcely be depended upon. Internal vegetable glands are generally seated in the substance of leaves, with a small excretory duct or channel opening upon the surface of the leaf. These furnish the little drops of essential oil found on many leaves, as, for instance, that of the black currant. In some leaves, when the cells are swelled with fluids

nese d icts are pressed upon and closed, so that the leaf exhales no odour, although a powerful odour is exhaled as soon as the withering of the leaf opens the ducts. This is the case in sweet-scented meadow-grass, whence new hay derives its odour. External vegetable glands are either with or without a foot-stalk; and all these glands are cellular, with the cells more regular than those in the substance of the leaf, and arranged in circles: a cord of vessels can generally be traced into the substance of the gland. Bristles are sometimes the excretory ducts of glands, as exemplified in borage, the nettle, &c.

Flowers.—A flower consists of several distinct parts, the calyx, corolla, stamens, disk, nectarium, pistillum, and receptacle. A flower is essentially constituted by the presence of sexual organs, either male or female. When there is only one of these present, the plant is termed unisexual; but more commonly these organs are both present in the same flower, which is in this case termed a hermaphrodite. In some instances, although the same plant bears both male and female organs, it is not hermaphrodite, as these organs occur in different flowers; in others, again, the male and female flowers exist only in different plants. Lastly, male, female and hermaphrodite flowers are sometimes found mingled together, either on the same or on different foot-stalks. Sometimes the male or female organs alone, protected in a small scale, constitute the flower; but in general they are surrounded and protected by the corolla and calyx. All these are commonly borne on a stalk called the peduncle (from *pedo*, to prop or support), which, expanding at its extremity, forms the receptacle or torus, as it has been called, upon which the whole of the parts above mentioned are supported. What is called the berry in strawberries, appears to be nothing more than the receptacle bearing the naked seeds on its surface. It is called common, when a number of florets rest on one receptacle. The round button which is exposed when the downy seeds are blown from the head of the dandelion, is an instance of the common receptacle.

The *calyx* is the external leafy envelope surrounding the flower, and in which it rests as in a cup. Sometimes it is entire, but more frequently it is divided into segments (*sepals*), which are more or less separated from each other. It is most commonly green, but in some flowers it is highly coloured.

The *corolla* is the true flower or blossom, and consists of several divisions or leafy parts, called *petals*, which are almost all articulated at the base, and consequently fall off at the earliest manifestations of maturity or decay. The extensive variety of tints in the flowering part of plants, is a remarkable circumstance of vegetable economy; and what may be the precise use of such gayety of colour, has formed the subject of philosophic inquiry. Independently of the exceeding beauty to the eye, which is certainly a matter for pleasing gratulation, it is believed that the lively colours are useful in attracting insects, these creatures incidentally performing an office in the reproductive economy, and in carrying off saccharine exudations.

The lower part of the single petal of a corolla is called the claw, corresponding to the stalk of the leaf; and the broad part is called the limb. The corolla is frequently furnished with certain appendages, attached either to the throat or to the base of the petals, called nectaries. These are placed in different parts of the corolla; in the common auricula they surround the edge of the throat; in the ranunculus or butter-cup tribe, they appear like scales at the bottom of the claw; and in the monkshood, in the form of a spur behind the corolla. They receive the name of nectaries from the supposition that they secrete honey, and they are always found to contain a clear, sweet-tasted fluid.

Stamens, &c.—Within the beautiful corolla are observed several small filamentous objects, on some of which are particles of fine coloured matter like dust. These are parts of the reproductive organization, and consist of stamens and pistils. In general, a stamen consists of two parts, in most cases of a filament (from *filum*, a thread), which is usually white, and always of an anther, which is usually yellow or purple. It has been shown that the stamens are always next to the petals, that is, between their base and the base of the seed-organ. It is upon the number and arrangement of the stamens that systematic botanical arrangements have principally been founded. The following are a few characteristics of the number, length, position, direction, &c., of the stamens. The number of stamens in each flower varies from one to twenty, or more. In length, they are equal or unequal, and this disproportion is sometimes symmetrical, sometimes not. In position they may be opposed to the divisions of the petals, or they may alternate with them. Sometimes they protrude beyond the corolla, at other times they are wholly included within it. Their direction may be erect, pendant, or horizontal, and their summit is variously inclined to or reflected from the centre of the flower. The filament which supports the anther is most commonly straight and filiform; sometimes, however, it is otherwise. It varies, from being as small as a hair to be large and flat like a petal, and its summit is either pointed or obtuse. On the summit is that essential part the *anther*, which is generally formed of two small membranous sacs, attached immediately to each other, or united by an intermediate connecting body. In form, anthers are subject to great variety, and, like the filaments, they sometimes cohere so as to form a sort of tube. Their colour is often yellow, orange, violet, white, &c., but never green or truly blue.

The pollen contained in the anthers consists of numerous regularly-figured small particles, which possess in different plants a very different figure, size, and colour. The number of particles in a cell, which is very small, sometimes amounts to many thousands. In some flowers the pollen consists of transparent grains; in others

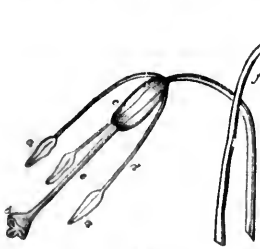


Fig. 9.

Fig. 10.

f Peduncle. *g* Calyx. *h* Corolla.

they are of a white, purple, blue, or brown, and more frequently of a yellow colour. When a grain of pollen is dropped into water, it swells and bursts, and a minute quantity of matter escapes, which is supposed to be the fecundating principle of the pollen.

We may illustrate the action of the pollen from the anthers, by referring to the annexed small engraving. *a* is the filament or stalk of the stamen, *b* is the anther on its summit, and *c* is the pollen or dust in the act of being shaken down upon the stigma or upper part of a pistil, of which we observe three in a group.

In this figure, it may be remarked, that the anther is a roundish-shaped body, delicately poised on the filament, and ready to vibrate and shake its dust on objects beneath or near it.

In the larger engraving, figs. 9 and 10, the different parts of the flowering structure are combined, as they are frequently seen in nature.

The pistil is a kind of tube with a communication from the stigma, through its style or stalk to the ovary or seed-bag beneath, and down this the pollen is permitted to exercise its influence. The seed-organ or ovary occupies almost always the inferior part of the pistil, and it is there that the process of fructification is fully effected. When cut open it exhibits one or more cavities or cells, in which are contained the rudiments of the seeds or ovula; and it is in it that the change of the ovula into perfect seeds is effected. It is of various forms, but most commonly ovoidal. It is generally seated upon the receptacle, together with the stamens, but frequently it is placed below the flower. Its cavity consists of one or more cells, in which the ovula or rudimentary seeds are found. It may be remarked, that the pistils spring from a nectary or disc in the centre of the flower, and surrounded by the stamens.

The precise mode of fructification is nowhere clearly stated. The stigmatæ are in all cases moistened with a clammy fluid, which causes the grains of pollen to swell, burst, and discharge their minute granules. Some suppose that these are taken up by spongelets in the summit, similar to those of the root, while others allege that the fluid matter in which the granules float is sucked up. It has been discovered that the grains of pollen, when shed on the summit, in a few hours shoot out one or more delicate tubes, which by some philosophers are supposed to extend down as far as the seed-organs, and to expand around and between the nascent seeds. Some believe them to convey thither the granules, which at least enter into the tubes; others, however, deny that this is the case. The seed-organ lies at the base of the pistil, and contains the seeds either nascent or advanced to maturity. It bears a very strong resemblance to the egg-organ of birds and insects, and its parts have accordingly received from naturalists the same scientific names. The seed-organ is usually of an egg-oblong form, and is always composed of an outer membrane, a middle membrane, and an inner membrane, all intimately united. As every seed derives its nourishment from the inner membrane, there must be a communicating point; and this point being always on the verge of the membrane, may be so termed; that on the seed being termed the seed-scar, but popularly, though improperly, named the eye. In some species the verge bears a number of smaller verges, to each of which a seed is attached, by means of the verge cord or seed-stalk. All these parts are obvious in an unripe pea or bean.

Fig. 11.

Fig. 12.

Seed-vessels are various in form; as, for example, in the case of the pea, fig. 11, the vessel is a shell or pod, and in the case of the apple, fig. 12, it is the body of the fruit.

All fruits, in reality, are but so many vessels or receptacles for the seeds, and the various forms in which they appear are individually suitable to the purposes of their growth.

Structural arrangements.—Vegetable, like animal structures are composed of solid and fluid parts. Few of the latter are considered simple in their composition, as they contain more or less of a gelatinous matter, which frequently imparts to them a consistency approaching to that of a solid body. The gum which we often see exuding from trees, is an instance of the viscidity of vegetable fluids. Many of them, also, contain minute globules of matter, which thicken them to a considerable degree. It has next been discovered that these often cohere and form solid masses, or unite in lines so as to constitute fibres. These, again, collect together, and compose various kinds of texture. The solid parts of a vegetable are membrane and fibre, which form the tissues referred to, and their varied combinations in the bark, wood, pith, and medullary or marrow rays. The fluid elements are watery solutions of the soluble materials of the soil, which, by chemical and mechanical agency, as well as the influence of the principle of life, are decomposed, and again united in different proportions, so as to form new substances, or, in other words, the solid components, the textures, and secretions of the vegetable.

The elementary parts of the vegetable structure appear to consist of minute bags, bladders, or vesicles, the coats of which are transparent membranes of extreme tenuity. If a very thin slice of the stem of any plant be put into a drop of pure water, and examined by the microscope, it will be found to consist chiefly of these cells. Their size differs very considerably, from even the thousandth part of an inch to the thirtieth. Although in their original state they possess an oval or globular form, yet, by being variously compressed, they are made to assume other forms, such as twelve-sided figures, or six-sided, like a honey-comb, and pass by insensible gradations into the tubular structure. These various modifications of the same elementary texture have received separate technical names, which, however, it is unnecessary to specify. By the concurring observations of modern botanists, these cells consist of separate vesicles closed on all sides, and destitute of inlet or pore. It seems to have been satisfactorily established, that the partitions which separate them, however thin, must consist of a double membrane, formed by the adhesion of the coats of the two contiguous vessels, and that the fluids gain access not by means of regular apertures, for none can be detected, but by exuding through the substance of the membrane. As from the shape of the cells the coats cannot be supposed to unite at every point, the spaces thus formed have been called *intercellular passages*, *canals*, &c., and they are supposed to perform an important part in the function of nutrition. The nature of the matter contained in the cells and the intercellular spaces, differs according to the part in which it exists, and the peculiar powers of the plant. Sometimes they are filled with certain liquids, the products of vegetable secretion; at other times the contents are simple watery sap, and occasionally they are only filled with air. Air tubes and cells are most frequently met with in the centre of stems and in leaves, rarely in roots, and never in the woody part of plants. Although some plants consist entirely of cells, yet as already observed, the greater number of them have, in addition to these, numerous

ducts or vessels, consisting of membranous tubes of considerable length, interspersed throughout every part of the system. With regard to the origin of these, Dr. Roget observes: "There can be little doubt, indeed, that the vessels of plants take their origin from vesicles, which become elongated by the progress of development in one particular direction; and it is easy to conceive, that, where the extremities of these elongated cells meet, the partitions which separate their cavities may become obliterated at the points of junction, so as to unite them into one continuous tube with an uninterrupted interior passage. This view of the formation of the vessels of plants is confirmed by the gradation that may be traced among these various kinds of structures. Elongated cells are often met with applied to each other endwise, as if preparatory to their coalescence into tubes. Sometimes the tapering ends of fusiform cells are joined laterally, so that the partitions which divide their cavities are oblique. At other times their ends are broader, and admit of their more direct application to each other in the same line, being separated only by membranes passing transversely; in which case they present, under the microscope, the appearance of a necklace of beads. When, by the destruction of these partitions, their cavities become continuous, the tubes they form exhibit a series of contractions at certain intervals, marking their origin from separate cells. In this state they have received the names of *moniliform*, *jointed*, or *beaded vessels*. Traces of the membranous partitions sometimes remain where their obliteration has been only partial, leaving transverse fibres. The conical terminations occasionally observable in the vessels of plants also indicate their cellular origin."

Those parts of plants which do not exhibit the form of either membranes or cells, are comprehended in what is called the *vascular system*, which constitutes almost the entire bulk of the more solid parts of trees. If a branch be cut transversely early in spring, the sap will be found to exude, and cover the whole of the cut surface, which, if examined, will be found to consist of a vast number of exceedingly small fibres, vessels, or pipes, through which the liquid portions of the vegetable ascend or descend. These are, as it were, the veins and arteries of the plant. Indeed, whilst the tissue of cells above described may be said to constitute the flesh of plants, the tissue of fibres may be said to stand for the bones and other firm parts of the system. In animals, the fluids are conveyed to and from a central reservoir called the heart; but such an organ does not exist in the vegetable kingdom. The fluids enter by innumerable mouths at the root, and are conveyed by the vascular system to all parts of the plant fitted to receive them. There is little variation in the diameter of the vessels, and their general form is cylindrical. Their minuteness is quite astonishing. In a piece of oak of about the size of 1-19th of an inch, 20,000 vessels have been reckoned to exist. Hedwig measured the largest vessel in the stem of a gourd; it appeared 1-12th of an inch in diameter through his instrument, which magnified 290 times; so that its real diameter was the 3480th part of an inch. The vessels of plants do not, like those of animals, exist single, but are collected in bundles, or fasciculi as they are called, which sometimes contain hundreds of vessels. They occasionally also ramify; that is, some vessels shoot off from one parcel to unite with another, and afterwards return to that which they had left. By this ramification a reticulated appearance is frequently produced, especially in the bark and leaves of plants. They do not ramify like the vessels of animals from greater into less; but, by the division of a greater fasciculus into several smaller fasciculi, they at last become single, and thus their ramification is effected. It is generally supposed that they do not open into one another; that is, actually unite and be lost in each other, forming that kind of connection which anatomists call inosculation or anastomosing (from a Greek word which signifies to open the mouth.)

These vessels have been named according to the functions which they perform, or the appearances which they assume. There appear to have been two kinds of vessels discovered in plants, the straight and the spiral. Grew describes the former as straight hollow threadlets, fifty times finer than a horse hair, forming a larger tube, as if we should suppose a walking-cane composed of small straws. Leuwenhoeck describes them as composed, like the quills of birds, of two transparent tissues, one placed lengthways and the other across, with no lateral communication. It is the opinion of the highest authorities that both fibres and straight vessels take their origin from spiral vessels. The first is called the simple spiral. If the fleshy scale of any bulb, for instance, that of the lily, be cautiously broken, and the parts separated, the spiral vessels will be observed like screws, partially unrolled. They consist of opaque silvery shining fibres, twisted in a spiral manner, so as to form a hollow cylinder, the spires being generally in contact. This hollow tube is sometimes formed of one continuous fibre, sometimes of several parallel fibres adhering together. The fibres are tenacious, and in some plants elastic. They differ much in size in different plants, and at different stages of the growth of the same plant. They stretch through the whole of its length, from the roots to the leaves and flowers, following the various curvatures of the stem. Grew found that they alternate with the straight vessels in every part of the wood, and surround and ensheath them in the leaf-stalk, the leaf, the flower, and the fruit. The straight vessels are said to be formed in spring, the spiral vessels in summer. These spiral vessels undergo various transformations. In many cases the inner fibres of the tube, instead of forming a continuous spiral, appear in the shape of rings succeeding one another at regular intervals, and constituting what are called annular vessels (from *annus*, a ring). This is considered a primary form of vessel, and, from the two simple varieties of vessels described, more complex forms are elaborated as the plant advances in age. In the punctuated vessel the spires are separated to nearly equal distances from each other, and the intervening spaces are filled up with a membrane sprinkled over with small obscure points or dots.

This is the largest with respect to the diameter of the vegetable vessels; it is at first transparent, but becomes opaque by age. A fourth variety of vessel, which has the same origin as the last, being formed of rings, is that in which the separations are not filled with membrane, but with small productions proceeding from these rings themselves. These ramifications often have the appearance of network, whence they derive the name of *reticulated* spiral vessels. It is impossible, in the present limited treatise, to go into a definition of the varieties and purposes of these vessels; and it will suffice to say that the spiral vessels, in all their variety, serve the office of conveying the sap throughout the whole of the plant. Besides the vessels already enumerated, vegetables contain certain organs denominated *glands*, which are composed of closely-compacted cells, and which perform the function of *secretion*; that is, the conversion of the nutritious joices into particular products for various purposes in the economy of the plant.

Among the parts associated with or arising from the elementary structure already mentioned, are the pith, the wood, the bark, and the epidermis or skin. The pith is that soft, light, and spongy sort of substance which occupies the centre of the stem (hence sometimes called the heart), where it is commonly surrounded by a circle of vessels, which construct for it an appropriate canal. When seen in its most perfect form, it is found to consist entirely of cellular tissue rather loose in texture, as

in the alder, or compact, as at the knot of the ash. The wood (*lignum*) is that hard cylinder which immediately surrounds and envelops the pith, and is enclosed by the bark. It is essentially composed of vessels, and of cellular tissue combined in an infinite variety of ways, and exhibiting every diversity of form. If a tree of several years' standing be cut transversely and examined, it will be found to consist of a number of cylinders, enclosing one another like so many layers or concentric circles disposed around an axis. By the number of these the age of the tree may be determined.

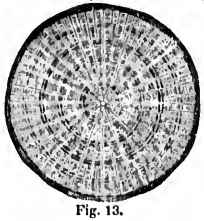

Fig. 13.

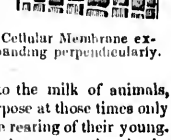
Fig. 13 is a section of a stem five years old, having the pith in the centre, and a cylindrical layer for every year of the growth, and the bark on the outside. The outermost layer, which is spongy and less durable than the inner or heartwood, is called alburnum. The whole are traversed by rays or lines diverging from the centre of the stem to its circumference. These are called medullary rays, or silver grain, and they are composed chiefly of large cells, extending transversely, or in the direction of the diameter of the tree, and composing by their union continuous vertical planes the whole length of the trunk. They are called medullary (from *medulla*, marrow), because they were supposed to be processes of the pith, or a continuation of it, which is not the case. Their use appears to be to keep upen the communication between the bark and the pith, which the formation of the wood would otherwise have destroyed. The bark resembles wood in its component parts, being made up like it of vessels and cellular tissue, intimately connected with each other. As in trees a new layer of vessels is annually added to the wood, so a similar but much thinner layer is also made to the bark, to which the name of *liber*, or inner bark, is usually applied, the old layer being pushed outwards. Between the vessels thus annually produced, a considerable portion of cellular tissue is interposed, the cells being commonly filled with juices. The whole is surrounded by an outer zone or envelope, to which the name of skin, epidermis, cuticle, or rind, has been given. It is an extremely thin membrane, and extends over the surface of every part of the plant excepting the spongelets of the roots, and the summit of the pistil in flowers. The rind of plants is similar to the skin of animals in the functions in which it performs. It is, no doubt, intended to protect the more sensible organs beneath. As the scarf-skin of the hand becomes indurated by hard labour, so the rind of the tree, if exposed to a stormy climate, becomes rough, whilst the rind of the same species of plant, if reared in a sheltered situation, like the hands of a delicate lady, remains smooth. As the plants grow, the rind stretches, and sometimes to a considerable extent; but in cases in which it is not easily stretched, as in the elm, it breaks up into innumerable cracks. The birch, and some other trees, "cast their bright skin yearly, like the snake." The rind is transparent and colourless where it is very thin; but it is usually of a brown or gray colour when thick. Various opinions are entertained respecting the origin and structure of this membrane. Some philosophers hold it to be continuous with the bark, and formed of the outer side of its cells. Others describe it as a separate membrane, composed of minute cells, or "bladders," as Grew calls them, which shrink and are dried up as the plant grows older. This opinion is now supported by the highest authorities. There has in some instances been found a very delicate, transparent, and apparently inorganized, membrane on the outside of the rind. Whether it possessed pores, or, as they are sometimes termed, glands, was long a disputed point, but their existence has lately been incontestibly proved. They are a sort of minute bags opening on the outside by an oval slit with a raised border, which contract when water or moisture is applied, and expand in dry air, or when exposed to sunlight.

Having already defined what constitutes the chemical elements of plants, as well as the nature of the food which they derive from the atmosphere and soil, nothing more need here be said on the subject, and we pass on to a short account of the methods by which the ascent and descent of the sap are effected.

The various matters held in solution by the fluid enter the plant in a perfectly crude state. The liquid rises in the stem of the plant, undergoing little or no perceptible change in its progress, and is in this state conducted to the leaves, where it experiences various important modifications. By causing the roots to imbibe coloured liquids, the general course of the sap has been traced with tolerable accuracy, and it is found to traverse principally the ligneous substance of the stem; in trees, its passage is principally through the alburnum, that is, the wood last formed, and not through the bark, as was at one time believed.

The course of the sap varies under different circumstances at different periods of vegetation. At the time when young buds are preparing for their development, which usually takes place after the genial warmth of spring has penetrated beyond the surface of the earth, and expanded the fibres and vessels of the plant, there is created an urgent demand for nourishment, which the roots are actively employed in supplying. As the leaves are not yet completed, the sap is at first applied to purposes somewhat different from those it is destined to fulfil at a more advanced period, when it has to nourish the fully expanded organs; this fluid has, accordingly, been called the nursling sap. It does not rise through the alburnum, but through the wood which is immediately contiguous to the pith, and thence passes, by unknown channels through the layers of wood, to the buds, which it nourishes. In this circuitous circulation it is supposed to undergo a change, or becomes assimilated, in which state it is fitted for entering into combination with the plant, or becoming incorporated with the new organization. This nursling sap has been compared to the milk of animals, which is prepared for a similar purpose at those times only when nutriment is required for the rearing of their young.



Cellular Membrane expanding perpendicularly.

The nutrient sap, which, as we have seen, rises in the stem, and is transmitted to the leaves without any change in its qualities or composition, is immediately by the medium of the stomata, or orifices which abound in the surface of those organs, subjected to the process of exhalation. The proportion of water which the sap loses by exhalation in the leaves, is generally about two-thirds of the whole quantity received: so that it is only the remaining third that returns to nourish the organs of the plant. It has been ascertained that the water thus evaporated is perfectly pure, or at least does not contain more than a 10,000,000th part of the foreign matter with which it was impregnated when first absorbed by the roots. The water thus exhaled, being dissolved by the air the moment it escapes, passes off in the form of invisible vapour. Hales made an experiment with a sun-flower, three feet high, enclosed in a vessel, which he kept for fifteen days, and inferred from it that the daily loss of the plant by exhalation was twenty ounces; and this, he computes, is a quantity seventeen times greater than that lost by insensible perspiration from an equal portion of the surface of the human body.

The comparative quantities of fluid exhaled by the same plant at different times are regulated, not so much by temperature, as by the intensity of the light to which the leaves are exposed. It is only during the day, therefore, that this function is in activity. De Candolle has found that the artificial light of lamps produces on the leaves an effect similar to that of the solar rays, and in a degree proportionate to its intensity. As it is only through the stomata that exhalation proceeds, the number of these pores in a given surface must considerably influence the quantity of fluid exhaled.

By the loss of so large a portion of the water, which in the rising sap had held in solution various foreign materials, these substances are rendered more disposed to separate from the fluid, and to become consolidated on the sides of the cells or vessels, to which they are conducted from the leaves. This, then, is the first modification in the qualities of the sap which it undergoes in those organs.

The sap having undergone in the leaves the double processes of exhalation and aëration, is thereby elaborated into a fluid corresponding to the blood of animals, and fitted for becoming incorporated with the vegetable organs. The crude fluid which enters the leaves is called the ascending sap; and after it leaves them, in order to be distributed throughout the plant, it has been called the returning sap. It still contains a considerable quantity of water, but a large proportion of that which has not been exhaled by the leaves, and its elements, oxygen and hydrogen, has combined with certain other substances, so as to form proximate vegetable products, of which gum is the simplest, and generally the most abundant. The returning sap descends from the leaves through two different structures. In exogenous plants, the greater portion finds a ready passage through the liber, or innermost layer of bark, and another portion descends through the alburnum, or outermost layer of the wood. With regard to the exact channels through which it passes, the same degree of uncertainty prevails as with regard to those which transmit the ascending sap. De Candolle maintains, that in either case the fluids find their way through the intercellular spaces; other physiologists, however, are of opinion that particular vessels are appropriated to the office of transmitting the descending sap. The nature of the forces which actuate the sap in its descent from the leaves, and its distribution to different parts, as well as those powers which contribute to its motion from the roots to the leaves, are involved in equal obscurity. The hypothesis that it resulted from capillary attraction is now generally abandoned.

SECRETION AND EXCRETION IN VEGETABLES.

The modifications which the returning sap undergoes, and its conversion into gummy, saccharine, amylaceous, or ligneous products, are effected by the simpler kinds of cells. But there are other cellular organs in which greater changes take place in its nature, the agents for effecting which are unknown, and are therefore referred generally to the vital energies of vegetation. The process is termed secretion, and the organs by which it is conducted, glands. The matter secreted is sometimes retained in the cells, and sometimes appears on the outside as an excretion, for the plant has the power of throwing out by the root those superfluous or noxious matters which, if retained, would injure it. This explains the fact why plants render the soil where they have long been cultivated less suitable to their continuance in a vigorous condition than it originally was; and also why plants of a different species are frequently found to flourish very well in the same situation, where this apparent deterioration of the soil has taken place.

The vessels in which the fluid secretions are contained are of a peculiar kind, and exhibit ramifications and junctions resembling those of the blood-vessels of animals. We may also discover, by the aid of the microscope, that the fluids contained in these vessels are moving in currents with considerable rapidity, as appears from the visible motions of their globules; and they present, therefore, a remarkable analogy with the circulation of the blood in some of the inferior tribes of animals. This curious phenomenon was first observed by Schultz in the chilidonium, in the year 1820; and he designated it by the term *cyclosis*, in order to distinguish it from the real circulation, if, on further inquiry, it should be found entitled to the latter appellation.

The circular movements which have been thus observed in the milky juices of plants, have lately attracted much attention among botanists; but considerable doubt still prevails whether these appearances afford sufficient evidence of the existence of a general circulation of nutrient juices in the vegetable systems of those plants which exhibit them; for it would appear that in reality the observed motions of the fluid are in every case partial, and the extent of the circuit very limited. The cause of these motions is not yet known: but probably they are ultimately referable to a vital contraction of the vessels, for they cease the moment that the plant has received an injury, and are more active in proportion as the temperature of the atmosphere is higher.

BOTANY.

Various eminent individuals have attempted the classification and naming of plants, each of whose arrangements is called a *system*, and possesses certain peculiar features. The three systems which have been most esteemed, and wholly or partly adopted, are those of Tournefort (1656—1708), Linnæus (1707—1778,) and Jussieu (1699—1777).

THE SYSTEM OF TOURNEFORT.

Tournefort founded his system on the absence or presence, the figure, situation, and proportion, of the *corolla*. This part of the flower is always, when present, the most conspicuous and imposing, and attracted the notice of the earlier botanists, as it does that of children now, more than it really deserved; because, in fact, no part of the flower is more subject to incidental change than the corolla. He divided the vegetable kingdom into two principal parts, namely, herbs and trees; the primary divisions he subdivided into twenty-two classes, the first seventeen of which comprise the herbs, and the other five the ligneous vegetables; these are again separated into one hundred and nineteen sections, but without names or titles being applied to them, as in those of other botanists. The characters of the sections were not always sufficiently defined; and consequently the young botanist often met difficulties in arranging plants in their proper places. Though now known to be imperfect, the system of Tournefort possesses great merit. His labours, considering the state of the science when he lived, were indeed great, and far surpassing those of either Linnæus or Jussieu. In fact, Tournefort was pioneer to both, and amassed, and in many cases assorted to their hands, the materials of which both their systems are formed.

THE LINNÆAN, OR SEXUAL SYSTEM.

The sexuality of plants had been discovered long before the time of Linnæus; but, as far as is now known, he was the first who suggested the idea of classifying plants according to the numbers, connection, and stations of the male and female organs. From the moment the idea occurred to him, he was indefatigable in the completion of a system which, no doubt, he fondly flattered himself was founded in nature. His great acquirements as a scholar, his love of natural history, his station among learned men, and his connection with many learned so

stics, eminently fitted him for achieving this great and laborious work.

The plan of the Linnæan system of botany was intended to comprehend the whole vegetable kingdom, which was arranged in two grand divisions, namely, plants having visible flowers (*Phænogamia*), and plants having no visible flowers (*Agamia* or *Cryptogamia*). The whole are included in twenty-four classes; and these classes are subdivided into orders, genera, and species. The terms used to express the classes are compounded of the Greek numerals and the word *andria*, signifying man. These classes are subdivided into orders, which are designated from their number of pistils by Greek numerals also, with the addition of the word *gynia*, which signifies woman. The following is a summary of the distinguishing traits of the respective classes:—

1. Monandria, with one stamen—Marestail.
2. Diandria, with two stamens—Speedwell.
3. Triandria, with three stamens—Grasses.
4. Tetrandria, with four stamens—Bed-straw.
5. Pentandria, with five stamens—Primrose.
6. Hexandria, with six stamens—Snowdrop.
7. Heptandria, with seven stamens—Water plantain.
8. Octandria, with eight stamens—Heath.
9. Enneandria, with nine stamens—Flowering-rush.
10. Decandria, with ten stamens—Pink.
11. Dodecandria, with eleven to nineteen stamens—Agrimony.
12. Icosandria, twenty or more, inserted into the calyx—Rose.
13. Polyandria, twenty or more, inserted into the receptacle—Poppy.
14. Didynamia, two long and two short—Foxglove.
15. Tetradynamia, four long and two short—Wallflower.
16. Monadelphia, filaments combined in one set—Geranium.
17. Diadelphia, filaments united into two sets—Pea.
18. Polyadelphia, filaments united into more than two sets—St. John's Wort.
19. Syngensia, anthers united into a tube, flowers compound—Thistle.
20. Gynandria, stamens situated upon the style, above the germen—Orchis.
21. Monœcia, stamens and pistils in different flowers on the same plant—Spurge.
22. Diœcia, stamens and pistils in separate flowers on different plants—Willow.
23. Polygamia, stamens and pistils united or separate, on the same or on different plants, and having two different kinds of perianth—Orache.
24. Cryptogamia, stamens and pistils not visible—Moss.

A more minute analysis of the system is as follows:—

Flowers with stamens of a fixed number, and equal in length.

First Class, or Monandria, having one stamen.—If they have one pistil, they are of the first order, or Monogynia; if two pistils, they are of the second order, or Digynia.

Second Class, or Diandria, having two stamens.—If they have one pistil, they are of the first order, or Monogynia; if they have two pistils, they are of the second order, or Digynia; and if three, they are of the third order, or Trigynia.

Third Class, or Triandria, having flowers with only three stamens.—If they have one pistil, they are of the first order; if two, they are of the second order, and if three, of the third order.

Fourth Class, or Tetrandria, having flowers with only four stamens equal in length.—If they have one pistil, they are of the first order; if two, of the second; three of the third; and if four, of the fourth order, or Tetragynia.

Fifth Class, or Pentandria, having flowers with only five stamens.—Those having from one to four pistils are named as in the preceding classes; those having five pistils belong to the fifth order, or Pentagynia, and if they have many pistils, to the sixth order, or Polygynia.

Sixth Class, or Hexandria, having flowers with six stamens.—As they have one, two, or three pistils they belong to the first, second, or third orders; if they have six pistils, to the fourth order; and if many pistils to the fifth order.

Seventh Class, or Heptandria, those having only seven stamens.—If they have one or two pistils, they are classed as before; if four pistils, they belong to the third order; and if seven pistils, to the fourth order.

Eighth Class, or Octandria, having flowers with only eight stamens.—If they have from one to four pistils, they rank in the order corresponding to the number.

Ninth Class, or Enneandria, those having only nine stamens.—If they have one pistil, they belong to the first order; if three, to the second; and if six, to the third.

Tenth Class, or Decandria, having only ten stamens.—If they have one, two, or three pistils, they belong to the first, second, or third orders; if five, to the fourth; and if ten, to the fifth order.

Flowers with stamens of rather uncertain number, but of fixed insertion.

Eleventh Class, or Dodecandria, having flowers with from eleven to nineteen stamens inserted into the receptacle.—If they have from one to five pistils, they belong to the orders corresponding to these numbers; and if they have about twelve pistils, they belong to the sixth order.

Twelfth Class, or Icosandria, having flowers with twenty or more stamens inserted into the flower-cup or the blossom.—If they have one, two, or three pistils, they belong to the first, second, or third orders; if five, to the fourth order; and if many pistils, to the fifth order.

Thirteenth Class, or Polyandria, those having flowers with from twenty to one hundred stamens inserted into the receptacle.—If they have from one to six pistils, they are classed as before; if they have many pistils, they belong to the seventh order.

Flowers with two of the stamens shorter.

Fourteenth Class, or Didynamia, having flowers with four stamens, two longer and two shorter, inserted on a one-petalled blossom.—If the four seeds appear not to be in a seed-vessel, they belong to the first order, or Gymnospermia; but if they appear to be concealed in a seed-organ, they belong to the second order, or Angiospermia.

Fifteenth Class, or Tetradynamia, having flowers with six stamens, four longer and two shorter, the blossom with more petals than one.—If the seed-organ is a short pod, they belong to the first order, or Siliculosa; and if a long round pod, to the second order, or Siliquosa.

Flowers with stamens united by their filaments.

Sixteenth Class, or Monadelphia, having flowers with the filaments of all the stamens united at the base into one bundle.—If there are three stamens, they belong to the first order, Triandria; if five stamens, to the second order, Pentandria; if seven stamens, to the third order, Heptandria; if eight stamens, to the fourth order, Octandria; if ten stamens, to the fifth order, Decandria; if eleven stamens, to the sixth order, Endecandria; if from twelve to twenty stamens, to the seventh order, Dodecandria; and if more than twenty stamens, to the eighth order, Polyandria.

Seventeenth Class, or Diadelphia, having flowers with the filaments of all the stamens united into two bundles.—If they have five stamens, they belong to the first order, Pentandria; if six stamens, to the second order, Hexandria; if eight stamens, to the third order,

Octandria; and if ten stamens, to the fourth order, Decandria.

Eighteenth Class, or Polyadelphia, having flowers with the filaments of all the stamens united into three or more bundles.—If there are from twelve to twenty-five stamens unconnected with the flower-cup, they belong to the first order, Dodecandria; if the bundled stamens are inserted in the cup, to the second order, Icosandria; and if there are more than twenty-five stamens unconnected with the flower-cup, to the third order, Polyandria.

Flowers with stamens united by their anthers.

Nineteenth Class, or Heptandria, having flowers composite, with all the anthers in a floret united into a tube, whilst their filaments are not united. If all the florets are equal, they belong to the first order, Polygamia æqualis; if the florets of the circumference have pistils without stamens, to the second order, Polygamia superflua; if the florets of the circumference have neither stamens nor pistils, to the third order, Polygamia frustranea; if the florets of the circumference have pistils without stamens, and those of the centre stamens without pistils, to the fourth order, Polygamia necessaria; and if the florets have a partial flower-cup all within a general flower-cup, to the fifth order, Polygamia segregata.

Flowers with the stamens and pistils united.

Twentieth Class, or Gynandria, having flowers with the stamens inserted upon the style or seed-organ. If they have one stamen, they belong to the first order, Monandria; if two stamens, to the second order, Diandria; if three stamens, to the third order, Triandria; if four stamens, to the fourth order, Tetrandria; if five stamens, to the fifth order, Pentandria; if six stamens, to the sixth order, Hexandria; and if eight stamens, to the eighth order, Octandria.

Flowers of only one sex.

Twenty-first Class, or Monœcia, having flowers, some with pistils only, and some with stamens only, on the same plant. There are nine orders, taken from the number and bundling of the stamens, as before.

Twenty-second Class, or Dioecia, having flowers with pistils only, or with stamens only, on two separate plants of the same species. There are nine orders, founded as in the preceding class.

Twenty-third Class, or Polygamia, having flowers with both stamens and pistils, and also with only one of these, both on the same and on separate plants of the same species. There are three orders.

No flowers apparent on the plants.

Twenty-fourth Class, or Cryptogamia. Stamens and pistils, if present, cannot, from being very minute, be ascertained. The class contains five orders—Ferns, *Filices;* Mosses, *Musci;* Liverworts, *Hepaticæ;* Seaweeds, *Algæ;* and the Mushrooms, *Fungi.*

To these Linnæus added another class, or rather appendix, which he called *Palmæ*, the flowers of which were not sufficiently known in his time to admit of their being properly placed in the system. They are now distributed into the various classes and orders of the sexual system; they are still kept separate by Jussieu, who has, as Linnæus did, arranged them into an order by themselves, under the old name. In fact, the genus *Palmæ* is of all others the least associable with the Linnæan plan of arrangement; being as distinct a tribe of plants in their structure, forms, and manner of growth, as can be found in the whole vegetable kingdom. Still there were stations provided for them in the sexual scheme, where they have been placed by late writers; but, as already observed, they do not associate well with the genera among which they are ranked. For instance, who would imagine that the cabbage palm (*areca oleracea*) and the Scotch pine (*pinus sylvestris*) were any way allied to each other? Yet the Linnæan botanist must unite them, because their flowers are respectively monœcious, and their stamens are united in one brotherhood.

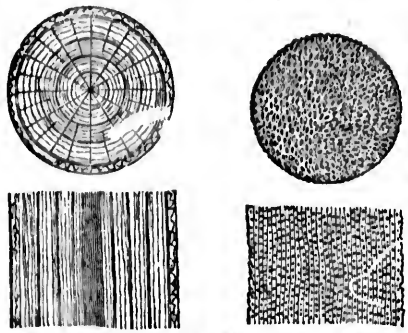
THE JUSSIEUIAN, OR NATURAL SYSTEM.

The author of this new system of botany has taken a very comprehensive view of the vegetable kingdom, and has been fortunate in fixing on those greater characteristics of plants which distinguish them from each other, and which at the same time are the least variable. On examining closely the vegetable membrane, he found it was either uniformly simple, that is, consisting of tissues of cells of nearly equal size and consistence, or of tissues of which the cells were of various sizes intermixed with each other, and formed into fibres lying in straight or in spiral positions, and forming tubes and openings of different structure and consistence. This evident difference of structure served to divide the vegetable kingdom into two parts; the first he called *Cellulares* or *Acotyledoneæ*, that is, plants formed wholly of cellular membrane, and rising from their seeds, or sporules, destitute of cotyledons or seed-leaves. Among these Acotyledoneæ are embraced the lower grades of the vegetable creation—the Filices, the Musci, the Hepaticæ, the Algæ, the Fungi—being placed, as it were, at the bottom of the scale, and exhibiting, in their outward aspect as well as in their internal structure, nothing of that loveliness of form, and but rarely that brilliancy of colouring, by which some of the other divisions of plants are distinguished. They are the first and rudest types of vegetable life, many of them consisting merely of a cluster of minute cells, or of minute threads, as in the case of *proto-coccus* and *byssus;* and many of them being, in fact, nothing more than a mere slime or mucus, as in the *moulds* and *nostocs*. Yet these minute and apparently insignificant tribes of vegetables, as already stated, are by no means useless or superfluous in the scale of nature.

Germination of Dicotyledonous and Monocotyledonous Plants.

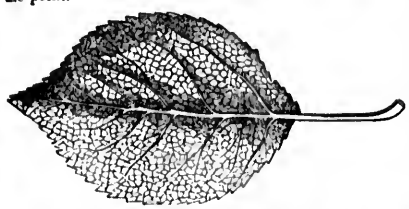
The plants composed of the second description of membrane, Jussieu named *Vasculares* or *Cotyledoneæ*, because the organization was more complicated, consisting of cells of various size, lying in various positions, in denser or looser laminæ or partitions, and being invariably fibrous; and, moreover, rising from their seeds furnished with cotyledons or seed-leaves. Of these, some presented one seed-leaf only, but the great majority presented two; hence the latter were called *Dicotyledoneæ*, and the former *Monocotyledoneæ*. This difference in the development of the seedlings of *Vasculares*, served as a basis for the two classes into which it is divided and named, as above stated.

But besides the difference in the germination of vascular plants, they also differ materially in the manner of their growth. The first class, *Dicotyledoneæ*, is annually increased in bulk by additions of bark and wood on the outside, hence it is also called *Exogenes;* whereas the second class, *Monocotyledoneæ*, is enlarged by the expansion of the interior parts of the stem, and therefore is also called *Endogenes*. These are very striking characteristics of the two classes, as regards their manner of growth; but there is another very obvious distinction, not only in the structure of their stems, but in



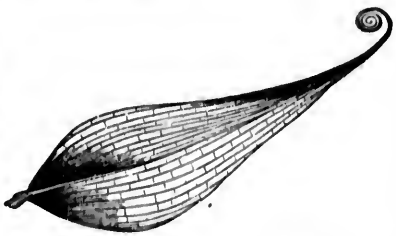
Sections of Dicotyledonous and Monocotyledonous Stems.

leaves. In a leaf of the first class, the petiole, or foot-stalk, is extended directly through the web or face, and is branched pretty regularly from the mid-rib (*costa*) to the margin; whereas in a leaf of the second class, there is no very conspicuous costa or mid-rib, the petiole being pretty equally divided at the base of the leaf into several branches, which run in nearly parallel lines to the point.



Dicotyledonous Leaf of the common Apple-tree.

By these obvious distinctions in the manner of the germination of the seeds, the modes of accretion, and in the structure of the stems and foliage, the two classes of *Cotyledoneæ*, or vascular plants, are clearly marked. But as there are great differences with respect to the stations, connections, and numbers of the floral members of the plants included in this first division, the author of the system found it expedient, in order to facilitate the study of the science, to separate it, as already stated, into two classes; namely, *Dicotyledoneæ* and *Monocotyledoneæ*; the former being again separated into two subdivisions, namely, *Dichlamydeæ*, that is, plants whose flowers have two coats or coverings, the calyx and corolla being distinct; and *Monochlamydeæ*, that is, plants whose flowers have one coat or covering, the calyx and corolla not being distinct, but blended in one, as exemplified in those of the mezereon.



Monocotyledonous Leaf of the Glorioss Superba.

In so limited a treatise it would be impossible, even were it desirable, to mention all the features and characteristics of the Jussieuian system, as comprehended in its ramified divisions, subdivisions, orders, genera, and species; and, indeed, to acquire any thing like useful knowledge on the subject, it must be studied practically in the garden and fields, under the instructions of a master. It is generally allowed that the minute complexity of the divisions and orders is most perplexing to the student, and a simplification in this respect, as well as in the nomenclature, would be very desirable. It is well known that there are many genera which run on the confines of two orders, with neither of which they exactly agree. In such cases, uniting the neutral with one or other of the more decidedly marked orders, would surely be better than constituting a new order, merely for the purpose of more completely or scientifically identifying one unsociable plant. It appears that Jussieu himself was strongly impressed with the desire of limiting the number of his orders, as well as the genera; nevertheless, almost all the improvements which have been recently made in the system by his followers, are divisions of orders, and subdivisions of genera, thus expanding rather than simplifying the system.

It cannot be denied, however, that there are many persons engaged in the cultivation of plants who would rejoice at seeing a new scheme of scientific botany by which the orders of the natural system would be reduced, and the number of genera diminished. Such a thing is not so impracticable as may be imagined; a master mind to contrive, and a few talented practical botanists to sanction the scheme, and fix the nomenclature, would be a work well worth the attention and labours of some universal botanical society instituted for this special purpose.

Botany, as well as every other science, has lately been greatly advanced by that friendly and highly commendable intercourse and interchange of social and scientific communion between home and foreign professors; and no doubt, whatever may be its defects, a union among its professors will speedily supply a remedy.

NATURAL THEOLOGY.

NATURAL THEOLOGY is that branch of logical science which comprehends the discovery of the existence and tributes of a Creator, by investigating the evidences of design in the works of the creation; and, in an enlarged sense, it refers to the probable intentions of God with regard to his creatures, their duty, and conduct.

It cannot but appear to every rational mind, that a subject involving such important views and considerations is full of the deepest interest, and may be made the agent of much intellectual improvement. It is incumbent on us to read the wisdom of God, and his admirable contrivance, in all that we see around us and above us, and which pertains to the universe to which we belong. Independently of the pleasure, and perhaps worldly advantage, which the study of Natural Theology will produce, it will be equally serviceable in keeping alive feelings of piety and devotion. As Lord Brougham has properly remarked, "even the inspired penmen have constant recourse to the views which are derived from the contemplation of nature when they would exalt the Deity by a description of his attributes, or inculcate sentiments of devotion towards him. 'How excellent,' says the Psalmist, 'is thy name in all the earth! thou hast set thy glory above the heavens. I will consider the heavens, the work of thy fingers; the moon and stars which thou hast ordained.'"

It is worthy of remark, as showing the depth and solidity of the foundation on which rests the existence of a supreme, intelligent, and beneficent First Cause, that the further we push our discoveries, the more clearly are the Divine perfections exhibited. It is not merely true that, on a superficial view, we perceive the necessity of believing that a limited and changing world, such as that on which we dwell, could neither exist without being produced, nor be the author of its own existence; and that there must, therefore, be, beyond the range of our senses, an independent and uncreated Essence, without beginning, without bounds, incapable of change, intelligent, ever-active, all-pervading; but it is also certain, that those views are not only uncontradicted, but fully established by the most minute survey of the objects within the sphere of our vision; so that he who penetrates the deepest into the secrets of nature, only multiplies proofs of that most sublime and most animating truth, that "verily there is a God" who made and rules the universe. It is difficult to understand that strange moral obtuseness which has induced a certain class of writers to reject this; for grant but one assertion, which is—and it is not easily to be questioned—that there exist in nature indisputable traces of design, planned with wisdom, directed by goodness, and accomplished by power, and it follows that there also of necessity must have been a *wise, a good, and a powerful Designer.*

Let us suppose ourselves cast ashore upon some island previously unknown to us; we immediately proceed to examine the appearances which present themselves, in order to discover if any traces exist of human inhabitants. To ascertain if such beings there existed, it would not be necessary that they should actually be seen by us. In our wanderings we might come upon a hut bearing all the marks of occupation; we might see the roots of the trees which had been felled to form it, and other tokens of the recent presence of man upon the spot; and did we desire to discover something of their character and habits before we presented ourselves to their notice, it is most probable that sufficient data would be also afforded on which to found an opinion. Were the habitations we discovered merely wigwams, or rude enclosures destitute of the conveniences of civilized life; or were the furniture, the weapons, or the instruments in and around them, such as barbarous nations generally use, we might reasonably argue that we had found the dwelling of an untamed savage. But if, instead of this, we find the surrounding land trenched, enclosed, and cultivated; should we find the common articles of European husbandry, and the common utensils of an European household, we should naturally draw the inference that we had reached the abode of an emigrant, who had thus reared around him the attributes of civilized life. Much more a few additional observations might reveal to us, and enable us to form conjectures, bearing the aspect of probability, concerning the people among whom we had fallen. Now, it is in this way alone that we can argue respecting the Author of all things, and discover proofs and demonstrations of a first supreme Cause. To prove that the formation of all things was the result of DESIGN, it is only necessary to show that they are in general, or in so far as we can discover, admirably suited to the uses and purposes to which they are to be applied—that their arrangement is perfectly harmonious—and that it is impossible that any chance could have thrown them together in a way so happy. To discover if this design can be evidenced or demonstrated, it is necessary to seek through the various works of creation with which we are surrounded; and the more minute we make our inspection, the more likely shall we be to perceive the deduction. If there be some departments to which our senses have a readier access than to others, and which we can therefore more readily examine, from these especially we ought to deduce our results. It may be that we shall find many things, which, from the deficiency of our observing faculties, we cannot understand, nor discover the uses or consequent design which they display; but still, if, in the course of our inspection, we find every part admirably adapted for a specific purpose, and teeming with the most convincing evidences of design, then we may with safety and true philosophy infer that in those objects, which, from their nature and our imperfection we cannot so completely investigate, a greater degree of light would tend to confirm the result to which our previous observations, among other things, had led us.

DESIGN IN THE PLANETARY SYSTEM.

To the uninstructed eye, the earth which we inhabit appears on a clear night to be surrounded by a numerous host of radiant points, which, rising in the east, move majestically through the sky until they reach the western horizon, when they set or disappear; and so completely does this idea commend itself to the mind of an observer, that it requires a considerable effort to conceive how it can be otherwise. But science has taught us that this is a mere illusion, and the discoveries of Copernicus and Sir Isaac Newton have established the truth suggested by Pythagoras upwards of 2000 years before the time of either of them, that the apparent motion of the heavens is the consequence of the real revolution of the earth every twenty-four hours upon its axis; that, with relation to the earth, the sun is stationary, while the earth every year completes a journey round him; that the planets are globes similar to our own, revolving at once upon their own axis, and round the sun; that the moon is a satellite or attendant upon the earth, accompanying it in its course, and at the same time describing every month a circular orbit round it; and that to several of the planets are attached similar

moons or satellites, bearing to them a corresponding relation.

By turning to our article ASTRONOMY, in which the number of the planets, and their distances from the sun, with other particulars, are noted, it will be seen that the earth which we inhabit is but a very small point, even in the solar system (as the concourse of planets round the sun has been called), and that it forms but a part of one magnificent and resplendent whole. But to ascertain the marks of a designing mind in this mighty maze of brilliant wonders, let us turn our attention to some of those particulars regarding them, with which we are acquainted; and it must be confessed, that, if we are to suppose them mere masses of matter unclothed with aught bearing analogy to our vegetable productions, and uninhabited by beings either sentient or rational, it will be difficult to see why any of the arrangements connected with these bodies, so far at least as they themselves are concerned, and apart from their attractive influence upon our own world, should be either beneficial or the contrary. It is solely on the *conjecture* that there are organized beings on their surface to be warmed, and nourished, and upheld, that we can argue regarding such arrangements; and making this conjecture, we shall find that there are some very remarkable apparent contrivances for ministering to their comfort and happiness. It has been supposed that a planet so far distant as Herschel, or even Jupiter or Saturn, must suffer from an extreme deficiency both of light and heat; and hence it has been argued that they are necessarily unfit for the sustenance either of animal or of vegetable life. But when we consider that even Herschel, the most distant from the sun, possesses 248 times the light afforded by our full moon, it will not be difficult to believe, that, with a somewhat more acute power of vision than we possess, the inhabitants of that planet, if formed like ourselves, may be quite able to engage in employments which require considerable minuteness of perception. Besides, to compensate for the deficiency of light derived directly from the sun to this planet in common with Jupiter and Saturn, there is afforded the subsidiary benefit of several moons or satellites to reflect light upon the surface when the sun has withdrawn his beams; neither is it probable that the inhabitants should miserably perish from cold; for putting out of view the possibility that they may be formed with constitutions adapted to a more frigid climate than that of any portion of our world, we must remember that heat is not dependent altogether upon the body from which it originates, but is regulated in a very great measure by the nature of the body to which it is transmitted. Keeping this in view, the planet Mercury may be as cool, and Herschel as warm, as our own globe, although they be at such different distances from the great source of heat. This, however, can be the subject of conjecture alone; and it is only valuable, as showing that we have no reason to suspect the goodness of the Creator in having placed some of his worlds in situations which, at first sight, might be supposed necessarily incapable of affording even the most essential accommodations to organic existences.

Of all the planets, Saturn presents us with the most singular example of design in reference to this subject. When viewed through a telescope, this beautiful orb is seen to be surrounded by a double circle 30,000 miles distant from any part of its surface. This apparatus consists of two concentric rings, separated from each other by a space nearly 3000 miles in breadth, and moving round the planet at the extraordinary rate of a thousand miles a minute. Now, there is one use of this appendage, whatever may be its other purposes, which is very apparent; it must contribute much to enlighten and beautify the globe to which it is attached; and a very little reflection will show the effect it must have in this respect. What a magnificent brilliant spectacle must these rings present to the inhabitants of Saturn! During its more than fourteen years of summer, the night must be enlivened by the bright reflection of this brilliant arch extending its luminous curve from the eastern to the western horizon; while even during the day, the sun must be materially aided by it in shedding light upon the world to which it belongs. "There is no planet in the solar system," says a late writer, "whose firmament will present such a variety of splendid and magnificent objects as that of Saturn. The various aspects of his seven moons, one rising above the horizon while another is setting; a third approaching the meridian; one entering into an eclipse, and another emerging from it; one appearing as a crescent, and another with a gibbous phase, and sometimes the whole of them shining together in one bright assembly; the majestic motions of the rings, at one time illuminating the sky with their splendour, and eclipsing the stars; at another, casting a deep shade over certain portions of the planet, and unveiling to view the wonders of the starry firmament—are scenes worthy of the majesty of the Divine Being to unfold, and the rational creature to contemplate." Of the other planets it is unnecessary individually to speak; our knowledge of them is extremely limited, and we may simply remark, that, in most of them, the same causes exist which in our globe produce the various seasons. To the causes of the seasons, further than that they are the result of the influences of the celestial bodies, we will not here allude. To the arrangement of these, and to the forethought and all-pervading knowledge and goodness of him who designed them, are we, in a word, indebted for the opening beauties of spring—the full glow of summer, arrayed in flowers and clothed with verdure—the sober and sear leaves of autumn, with its aureate fields and happy harvests—and the cold but not desolate winter, which even in its frigidity serves a valuable purpose in the scheme of the natural world.

In these arrangements we see proofs of the care, the power, and the beneficence of that great Being who was the cause of all things. To what else, indeed, shall we trace the primary fact, that, of all the heavenly bodies connected with our system, the sun alone, situated as he is in the centre, possesses undivided light, while the planets which surround him are all dark bodies receiving their light from him? There is no reason, in the nature of things, why a body placed in the centre of a system should give forth light and heat, while those revolving round it should be destitute of them. And yet we find it to be so: and we perceive the consequence of this arrangement to be not only most beneficial, but absolutely indispensable to the existence of the organized beings with which these orbs may be clothed or peopled.

But there is another view of the system of worlds to which our earth belongs, that strongly corroborates the existence of a creating and presiding Being. We mean the provision which is made for its perpetuity, notwithstanding the existence of so many conflicting forces—any one of which, if the system were differently arranged to what we find it to be, might in the course of ages derange the relations which the different bodies composing it possess towards each other, and precipitate the whole into confusion, only equalled by that chaos from which, by might and power, it was called. It will hardly be necessary minutely to explain the causes by which the earth and the other planets are kept in a continual state of rotation round the sun; but as perspicuity is one of the chief objects at which we aim, a few words on this subject will not be out of place. Let it be understood, then, that in every body of matter there exists a certain tendency to rush towards every other body, and that the larger, and denser, and nearer, any two bodies are, the greater is that tendency, and it will easily be comprehended that the sun, the largest of all the bodies in our system, should attract every other

orb with a degree of force regulated by the size, the density, and the distance of each; so that, had all these bodies at first been placed in a state of rest in the universe, they would immediately have begun to move towards the sun, and thus, in the course of time, would, one after the other, have reached and been amalgamated with him in the form of one vast and irregular mass. But at the creation, this result was prevented by communicating to the planets an impulse at right angles to the diameter of their orbits, which, combining with the force of attraction—that is, the power of the sun in drawing or attracting the planets towards himself—caused the planets to revolve round the sun. If each of the planets, however, were to revolve round the sun, with no other prevailing power to interfere with their motions except these two, viz., the attraction of the sun, and the original impulse at creation, they would of course continue as they are throughout all ages; but this is not the case. In the words of Mr. Whewell, "each of them is acted on by all the rest. The earth is constantly drawn by Venus, by Mars, by Jupiter, bodies of various magnitudes perpetually changing their distances and positions with respect to the earth. The earth, in return, is perpetually drawing these bodies. What in the course of time will be the result? The cause acts perpetually, and it has the whole extent of time to work in. Is it not, then, easily conceivable, that, in the lapse of ages, the derangements of the planets may accumulate, their orbits may change their form, their mutual distances may be much increased or much diminished? Is it not possible that these changes may go on without limit, and end in the complete subversion and ruin of the system?" What might have been the case had the balance of power, so to speak, in our system, been differently disposed, it is not easy to say; but that all which is here suggested as possible, would actually take place, were a capricious or ignorant hand to interfere in the distribution of these forces, may assuredly be affirmed. We should soon have "years of unequal length and seasons of capricious temperature; planets and moons of portentous size and aspect, glaring and disappearing at uncertain intervals; tides like deluges sweeping over whole continents; and, perhaps, the collision of two planets, and the consequent destruction of all organization in them both." As the solar system exists, however, so nicely is it adjusted, that the deep inquiries of several of the philosophers of the last century, founded on the most complicated calculations, have shown that its arrangements are stable—that although there are and may be perturbations, there are invariably proportionate compensations; so that, whenever a maximum has been reached in the derangements of the system, it must necessarily begin to revert to its ancient order, and the restoration must in the end be as complete as was the derangement. It would require a hardihood greater than we can easily conceive to exist in the human mind, to view this subject, and to deny, after all, that a perfectly wise, beneficent, and powerful being, originally made and has since sustained and governed all things; for had the original impulse of which we have spoken been a little stronger or a little weaker—had the relative inclination of the orbits of the planets to one another been greater—had one or more of them moved in a direction opposite to the rest—had any one of these causes operated, the whole solar system must sooner or later have been precipitated into chaotic confusion. Will any man, then, deny the proof here afforded of design and skill?

It is proper, before leaving the heavenly bodies, to advert to the fixed stars. If little be known respecting the planets, still less has been ascertained regarding these more distant bodies; but it is by no means an unedifying employment to contemplate, through them, the immensity of creation, and, thus elevated, to draw the conclusion that the Being by whom they originated must indeed be infinitely glorious. Had there been no other design on His part than thus to strike the mind of man with a sense of His magnificence and grandeur, no surer method could have been adopted to impart the lesson. The mind is bewildered when it dwells upon the glories which astronomy developes; and it cannot find words lofty enough to express its sense of the intelligence it discovers, or the proofs of the power and wisdom and goodness it perceives.

RELATIONS BETWEEN MAN AND EXTERNAL NATURE.

Leaving the evidences of design that are to be deduced from the contemplation of the heavens, let us regard some of the relations that exist between man and external nature, and consider the wonderful adaptations to each other which they exhibit. There can be no blank in nature, and, consequently, no body is isolated; all more or less influence each other, and it is of some of these relative influences that we are about to speak. Man is attached by the laws of gravitation to the earth which he inhabits, and is surrounded by an atmospheric medium capable of exercising certain influences upon him; these influences are modified by the Almighty Power to be subservient to his wants, and *designed* to be adapted not only to his necessities, but to those of every living thing, whether plant or animal, that exists. The air which surrounds us exercises, in consequence of its extent, a pressure on the human body equal to about 33,600 pounds. But why do we not sink and miserably perish beneath this immense weight? It is by the re-action of the elastic fluids contained within our bodies that we are enabled to support so enormous a pressure. Here we find a mutual relation between us and the air, which can not be interrupted without mutual injury. Suppose this weight to be withdrawn from our bodies, what would be the result? The expansibility of the fluids contained within us would have no restraint; they would dilate, burst through the solids which contain them, and destroy the individual. Place any animal beneath the receiver of an air-pump, and withdraw the air, the result is very apparent. One of the causes of the inconveniences that are experienced when on the summit of a very high mountain, is, that the air is less dense, and does not oppose so much pressure to the body; and this it is which occasions the violent bleedings from the ears, eyes, and mouth, that sometimes attack those so situated. The effect of a cupping-glass, when applied to the skin, has the same cause. We feel more or less the effects of any sudden change of atmospheric pressure, but still the density of the air is well adapted to the wants of men, had it been greater, our energies would have been oppressed as by an unnatural load; and if less, insufficiently sustained as by a defective support. The senses of hearing and smelling, too, which depend for their perfection on a medium density of the air, would have been either insupportably intense or defective. Again, the atmospheric pressure materially affects temperature. If a certain quantity of air contains a certain quantity of heat, it is clear that it must be equally diffused throughout it; and if the same air be contained in less bulk, or if the pressure be greater, the heat is increased in the same ratio. In the same manner, if the pressure be lessened, the air expands, and with it the heat is diffused over a greater surface. By compressing air, we can produce a sufficient concentration of heat to cause ignition. This influence of the air upon the body is as universal as the former, and the adaptation of the one to the other as constant. With the exception of some countries near the equator, and there only in the hot season and the middle of the day, the temperature of the atmosphere is always below that of man; and as heat always tends towards an equilibrium, it is obvious that a constant subtraction of heat from the body must be going on. Now

we are so organised as to allow of this universal subtraction; and, indeed, were it suddenly stopped, or even diminished, we should soon perish. Again, if the subtraction became increased, or went on more rapidly than the vital principle could replace it, our temperature would sink, our humours and fluids freeze, and in this case, too, we should soon perish. But there are intermediate points between these two extremes; and as we before said, our organization is such that it adapts itself to the degree. All organic bodies are capable of resisting to a great extent, and of modifying the action of heat and cold; indeed, this principle of self-preservation is in them so striking as to have been regarded from a very early period as the most essential attribute of life. The power possessed by the higher classes of animals, of preserving a more or less uniform degree of heat, is almost unlimited. In very cold climates the thermometer not unfrequently sinks to 50° or 55° below the freezing point, while in very hot ones it is sometimes 120° or 125° above it, making a difference of 170 or 180; still, however, the temperature of the body remains unchanged. What unanswerable evidence of design is this, and how limitless must be that Power who could create such wonderful adaptations!

If the atmospheric pressure produces in some measure the regulation of heat and cold, in no less degree does it affect moisture and its concomitants—clouds, mist, rain, snow, and hail; and thus we are dependent for many of our comforts, and for most of our necessities, upon the due adjustment of atmospheric influences. Winds, too, arise from any unwonted atmospheric pressure disturbing the equilibrium of the atmosphere, and are the efforts of nature to restore the balance. All the changes of weather, the most violent storms and tempests, own the same cause.

Connected with this subject, as evidencing design, is the composition of the air, which is precisely that best adapted to support respiration. It consists, besides small proportions of aqueous vapour and carbon, of two fluids, or gases, called oxygen and nitrogen. In a separate state these gases are inimical to life. Lavoisier proved by experiment that pure air, or oxygen gas, if respired for a certain time, rarifies the blood too much, and increases the rapidity of the circulation, the effects of which are violent fever, inflammation of the lungs, and death. Nitrogen is equally destructive to life, as not yielding that principle on which the purification of the blood depends. It is their combination that renders them salutary to the constitution, neither consuming life by too much stimulus and excitement, nor deadening its energies by a languid circulation and a depression of spirits. Why should the air have been composed exactly of twenty-one parts of oxygen and seventy-nine of nitrogen? Why were all other proportions excluded? It could not have been owing to a blind and fortuitous chance. The fact that we find two deadly ingredients so united as to become not only harmless but salutary, must strike every mind with an unanswerable evidence of design. Atmospheric air is absolutely necessary both to animal and vegetable life, and both classes of beings are fully adapted for its reception. The boldest Epicurean could scarcely imagine that so necessary a substance has by mere chance surrounded this globe for the support of its inhabitants, upon whom, without it, God would have bestowed his power and wisdom and goodness in vain; nay, even had men, according to the doctrine of Epicurus, sprung up like mushrooms from the earth without an atmosphere, they could not have existed upon it. Has not, then, the hand of a wise Creator been here visibly employed, or why were we supplied with instruments that render the air available to us?—enabling us to resist its dreadful pressure, and to avail ourselves of its unutterable advantages. If we contemplate for a moment the evils which would have followed had not divine intelligence presided at the constitution of our globe, and placed an atmosphere around it, how fearful and dreary it would have been! The moon has no atmosphere, and hence its climate must be very extraordinary; either the fiercest sunshine must reign, or the keenest frosts endure. If our earth had been similarly situated, no organic being would have adorned its surface; neither plant nor animal could have existed no reflection of light could have taken place no dawn or twilight would have prepared us for morning or for night; a dome blacker than darkness would have surrounded the earth, and light only have become manifest when the eye received it directly from the sun. The blue sky which now surrounds us, and which is owing to the thin watery vapours floating in the atmosphere, and reflecting peculiar rays of light, the blue and the violet, would not have been there. And where can we find such evidences of design as the blue colour which the sky exhibits! Of all hues we could imagine, is there any to surpass that mild and soft ethereal tint, harmonizing with all around us, and on which the eye, fatigued with more brilliant and dazzling objects, turns for relief and repose? The unbeliever may say that this colour was the result of chance; but suppose any other, a bright yellow, a dazzling white, a glaring red, a fearful colour, how uncomfortable and painful would it have been for the vision of man! Again, an atmosphere is necessary to hearing; it enlarges the field of vision, and contributes also to the means of smell; and not only do the beings on earth enjoy life through its means, but it contributes to the sustenance of the finny tribes, enabling them not only to exist, but to rest in the water, or ascend and descend in it in quest of food.

There are still other relations existing between man and external nature, to which we would shortly allude as illustrative of design; and they are such, that without them certain important functions could not be performed, and, consequently, man could not exist. These relations, which may be termed *organic*, are the more numerous and necessary to life, as the organization of the individual is the more developed or complete; and while they may be all included in the two functions of nutrition and sensation, they are the more multiplied as the operations of the former are more complex, and the extension of the latter greater; and hence they are more numerous in man than in any other animal. As in the physical relations, to some of which we have already alluded, so in the organic we must assign the first rank to the atmosphere, so necessary to life, and so admirably adapted to sustain it. It is the medium, also, through which we receive heat, light, and electricity, of which we appear to be as much in need as of that principle of air which purifies our blood, and fits it for the performance of its several operations. These matters are inherent in all living bodies; and if simple elementary bodies do exist, these are they. Many physiologists recognise the greatest analogy between the nervous fluid and electricity, and there is great reason for believing that it assists considerably in the maintenance of the vital phenomena. We know, however, that all these agents exercise a great influence upon life, from the demand that living bodies make upon them. Observe how plants languish and become weak when deprived of light, and how solicitously they move in the direction that will the most expose them to its invigorating influence. Nor is it less necessary to animal existence. Eggs cannot be hatched when deprived of it; and the transformations to which many insects are exposed, go on more slowly when in a darkened place. But let us suppose that this element was only given for the purpose of enlightening the earth, what a wonderful relation, then, does it bear to the eye which perceives it! No one who considers the eye attentively can resist the impression of the evidence of design and skill which its construction exhibits. At the same time, it must be obvious that this construction of the eye would not answer its purposes, unless the constitution of light corresponded to it. Light is an element of the most

peculiar kind and properties, and such an element can hardly be conceived to have been placed in the universe without some regard to its operations and functions. As the eye is made for light, so light must have been made, at least among other ends, for the eye. What we have said of light is equally applicable to heat. It is obvious that the vital energy of plants is much diminished, even suspended, during winter, while with the return of summer they again shoot forth their leaves and flowers; the same alternation obtains also among hybernating animals. Heat is evidently the cause of these changes; so much so, indeed, that vegetables may be forced to invert the order of the seasons. The climate in fact demonstrates the influence of heat. How stunted is both animal and vegetable life in polar regions, and how exuberant do the same individuals become under warmer skies! Electricity undoubtedly exists in the atmosphere in all its states; but we know very imperfectly the laws of this agent, and are still more ignorant of its atmospheric operation. The present state of science, while it permits us to hazard an opinion, does not enable us to perceive those adaptations of its laws to its uses, which we can discover in those cases where the laws and the uses are both of them more apparent. "It is at any rate very probable," says Whewell, "that electricity has its important purposes in the economy of the atmosphere. And this being so, we may see a use in the thunderstorm and the stroke of the lightning. These violent events are, with regard to the electricity of the atmosphere, what winds are with regard to heat and moisture. They restore the equilibrium where it has been disturbed, and carry the fluid from places where it is superfluous, to others where it is deficient. We are so constituted, however, that these crises impress every one with a feeling of awe. The deep lowering of the gloom of the thunder-cloud, the overwhelming burst of the explosion, the flash from which the steadiest eye shrinks, and the irresistible arrow of the lightning which no earthly substance can withstand, speak of something fearful, even independently of the personal danger which they may whisper. They convey, far more than any other appearance does, the idea of a superior and mighty Power, manifesting displeasure and threatening punishment. Yet we find that this is not the language which they speak to the physical inquirer; he sees these formidable symptoms only as the means or the consequences of good. What office the thunderbolt and the whirlwind may have in the *moral* world, we cannot here discuss; but certainly *he* must speculate as far beyond the limits of philosophy as of piety, who pretends to have learned that these work more of evil than of good. In the *natural* world, these apparently destructive agents are, like all other movements and appearances of the atmosphere, parts of a great scheme, of which every discoverable purpose is marked with beneficence as well as wisdom."

We think we have now sufficiently shown the wonderful adaptations and relations that exist between some of the phenomena of external nature and organized existences. It does not accord with our purpose to enter deeply or at greater length into the subject, but even the little we have said must, we hope, carry with it the conviction, that verily it is a God who made and rules the universe.

DESIGN IN THE STRUCTURE OF THE EARTH.

It is evident, even on a very casual inspection, that the surface or crust of the globe we inhabit has undergone many changes and these both great in extent and of long duration. Two agents, fire and water, have been mainly instrumental in their production. The ocean, the great source of aqueous influence, seems, from time immemorial, to have been engaged in a struggle to degrade or level the surface of the earth, not only by the direct action of its tides and currents upon coasts, but also by means of the clouds of vapour which it sends up into the atmosphere, and which re-descend on the earth in the shape of rain and snow, giving rise to numberless springs and rivers, all of which have some effect, less or more, in washing down the dry land. This system of detrition, carried on from age to age, would have produced a state of things very different from that which now exists, had it not been for the antagonizing agency of fire, which, working from the centre outwards, either by extensive convulsions or by slow upheavements, has elevated and repaired the earth's surface as fast as the waters have abraded it, and has compelled the ocean to give back to the light, in the form of continents and islands, the materials which it had before swallowed up.

In this reciprocal action and counteraction, and in their effects upon the earth's surface, we find abundant proofs of benevolent design. By these means have been produced those extensive irregularities—that diversity of hill and vale, ridge and plain—on which depends the fitness of the earth for the maintenance of all organic life, whether animal or vegetable. If the surface were level and smooth, the vapours raised from the sea by the sun would find no channel for their return, and the globe would necessarily become a stagnant marsh, unsuited for the residence of man and the greater part of the creatures that now tenant it along with him. But even if man could have inhabited the earth without its existing irregularities, how few comparatively would have been the advantages of his position! Had the matters carried down and deposited in the early seas, in the form of chalk-beds, limestone-beds, and coal-beds, with all the treasures of minerals and metals accompanying them, remained where they were first accumulated, man would have lost all the most essential elements of industry and civilization. The changes and disruptions which have taken place in the crust, have brought to light a fund of riches, without which he would have been poor in comforts and in arts. Looking to those vast coal-fields alone, which the crust of our globe contains, can we imagine for a moment that the great changes by which these ruined forests of the primeval world were first spread out and moulded into new forms, and then upheaved to the reach of man, to supply him with endless stores of heat, light, and wealth, were produced by blind chance, or by aught but a creative designer, a being equally great and good?

On examining further into the condition of the earth's crust, as established by the changes it has undergone, we find numerous other proofs of the wise foresight which has ordered and arranged the whole. We discover that all the successive mutations of our planet, extensive as they have evidently been, were rendered compatible with the existence and enjoyment of countless numbers of organized and sentient beings. All the rocky strata of the crust, with the exception of those which appear to be the oldest and deepest seated, are mixed up abundantly with organic remains, both animal and vegetable, and indeed some of the great limestone-beds are found to be entirely composed of the shells of insects. In short, whatever was the state of the surface at any given period of the revolutions fitting it for the ultimate residence of man, we find organized beings to have sprung up upon it, with such habits and peculiarities of structure as enabled them to exist and enjoy existence under the peculiar circumstances in which they were placed. Nothing can more distinctly show that our planetary revolutions had a noble scope and purpose, and were under the guidance of laws framed by a being as benevolent as wise.

DESIGN IN ANIMAL PHYSIOLOGY.

The earth, whose structure we have just briefly noticed, serves as the place of habitation for two kinds of existences—the animal and vegetable—to whose forms

tion and functions we discover the beautiful dispensations of Providence, extending on every side over a vast range of beings, and demonstrating the unity of plan on which organized creation has been devised. And, first, the whole circle of our knowledge does not afford greater evidence of design than comparative anatomy; in it we find innumerable contrivances for the comfort and happiness of the different tribes of beings adapted to the peculiarities of their condition; in each animal we see the same organ repeated, but modified to render it more available to the habits of its possessor; and among all the wonders of creation, there are none which strike the inquiring mind more forcibly than this change or modification of formation for the obvious purpose of accommodation to circumstances. Were all animals formed alike, or did the differences which exist between them bear no relation to their habits or destinies, it would be less easy to refute the doctrine which assigns all things to material causes, and excludes the designing hand of an intelligent Creator. Although even then the argument would be totally untenable, still the demonstration which disproves it would have been less satisfactory and perfect, as the surprising skill and beneficent care by which the structure of every animal is adapted to its individual habits and necessities, could not have been so well displayed. A single tool in the hands of the carpenter is a proof of contrivance, but that proof is much multiplied and rendered more forcible when we find the same instrument modified into a thousand forms to suit the different operations of the workman. Few of the functions of animated beings better illustrate this than that of alimentation, which we shall now briefly trace, through the humble zoophytes and worms up to birds and mammiferous animals. Nutrition is common to all animals without exception; and the numerous and varied modifications of the means employed to effect it are obvious proofs of the design and intelligence of the Creator. There are some animals so nearly allied to plants as to be scarcely distinguishable from them; and in these, as in plants, nutritive matter is introduced by mere imbibition. Fixed like plants to the spot where they grow, any other organs would have been superfluous; while to those which are not so attached, but seek their food and obtain it through their locomotive powers, organs for seizing and preparing it are necessary. In them, therefore, we find lips variously and curiously modified; glands about the mouth for furnishing fluids for lubricating dry alimentary matters; a tongue, or something analogous to it; teeth and jaws for breaking down hard substances, and rendering them fit for swallowing; with a passage called the œsophagus, or gullet, leading from the mouth to the stomach, in which the food is at last assimilated, and rendered fit for nourishing the animal. But it is not until we advance some way in the great chain of animal life that these parts become sufficiently obvious, or their offices clearly defined. In the very lowest orders, the mouth and stomach are one continuous tube, or all stomach, as it may be called, and so simple in construction that the animal may be turned inside out without detriment to it; that which was external being now internal, and performing, apparently with equal facility, all the offices of what was previously the stomach. As we advance, however, we find the nutritive organs ceasing to be a mere sucking apparatus, or a receptacle for imbibed fluids. In those whelks which are furnished with proboscides, we find a cavity occupied by the aperture of the œsophagus, a tongue, and teeth; while the snail possesses a perfectly formed mouth and lips. Among the worms, whose stomachs are generally membranous bags, we find examples of wonderful contrivance and design. Thus, the powerful stomach of one species contains three hard calcareous shells, by which the individual is enabled to bruise and masticate the shelled animals on which it feeds. The discoveries of Ehrenberg respecting the animalculæ inhabiting different vegetable effusions, have extended, in an extraordinary degree, our knowledge of the stupendous power of God; and the inimitable proofs of design displayed in beings to whom, in relative size, the mite is an elephant, afford astonishing displays of a minute and most beneficent attention to the preservation of these curious creatures, in whose organization and instincts new and admirable indications of creative wisdom are revealed. By the aid of the microscope, we are enabled to perceive the Creator of the universe minutely busy among the worlds of living creatures to which he has given birth on a blade of grass, or in a drop of water, and to discover fresh scenes of wonder, and interest, and evident design, among hosts of animated beings, infinite in number as in minuteness. These discoveries, of which an able analysis was lately given by Dr. Gardiner in the Edinburgh New Philosophical Journal, have dissipated the obscurity in which the animalculæ were plunged, and displayed the wonders of their organization. To render their digestive organs more conspicuous, he supplied them with coloured food, which communicated its tinge to the cavities through which it passed. The moment a minute particle of a highly attenuated solution of pure indigo was applied to the drop of water on the field of the microscope, in which were some of the infusory animalculæ, the most beautiful phenomena presented themselves. Presently their bodies, which had been hitherto quite transparent, became dotted with a number of spots of a dark blue colour, evidently produced by particles of indigo accumulated in these situations. In some species, particularly those which had a contracted part, or neck, between the head and body, these particles were to be traced in a continuous line in their progress from the mouth to these internal cavities. In this way, by the employment of colouring matters, Ehrenberg succeeded in ascertaining the existence of a system of digestive cavities in all the known species of this tribe of animals; one of the largest of which he found to possess a highly complicated structure with regard to many organs; with respect to the nutritive functions, he found a head provided with a regular apparatus for mastication, consisting of jaws having from two to six teeth, which were seen actively opening and shutting when the animal was taking its food.

As we ascend higher in the scale of existence, we find the digestive apparatus ceasing to be simple cavities, or canals hollowed out of the substance of the body, and becoming distinct organs formed by membranes and coats proper to each; and among these, the first example occurs in the sea anemone, in which we find spaces intervening between the coats of the stomach and the skin of the animal; here, however, the stomach is still a blind pouch, one aperture serving alike for receiving and ejecting the alimentary matters. In the *echini* or sea-urchins these organs are still more perfect. Those of mastication are peculiarly developed; an œsophagus or gullet also presents itself, and a stomach continued into a regular intestine, which takes two turns in the body before it terminates.

DESIGN IN THE FORMATION OF INSECTS.

In the digestive organs of insects we meet with a multitude of new and peculiar formations, while most of the simple forms found in the lower animals are here repeated. The organs of mastication, deglutition, and suction, present such remarkable differences, that the arrangements of modern systems of entomology have been chiefly founded on them. In this order of animals, nutrition by vegetable substances is much more common than in those below it; indeed, as Blumenbach has observed, the business of nutrition in insects does not seem to have for its object the mere preservation of the individual, as in most red-blooded animals, but chiefly the consumption of organized matter, which will appear

from considering the structure of their alimentary canal. In most of those which are subject to a metamorphosis, the stomach in the larva state is of great size in comparison with the short intestinal canal; while those, on the contrary, which take little or no nourishment in their perfect state, have this organ remarkably diminished, and, as it were, contracted. How beautifully does the great size and straight course of the intestinal apparatus of the animal, when in its caterpillar state, coincide with its enormous voracity and quick digestion! It has been computed that caterpillars sometimes devour and digest no less than three times their own weight of aliment in four and twenty hours. On the other hand, during the subsequent metamorphosis which the animal undergoes, no food is taken; but nature, or rather the God of nature, has wonderfully, and with beneficent design, provided against any necessity for this, by causing insects to become very fat, as observed by Malpighi, on the approach of these changes; so that this fat, being absorbed into the blood while these are going on, serves all the purposes of a supply of alimentary matters from without. The insects now under consideration exhibit at different periods of their existence the greatest contrasts, not only in external form, but also in their habits, instincts, and modes of subsistence. The larva, as we have seen, is remarkable for its voracity, requiring large supplies of food, and consuming enormous quantities of vegetable matter; the perfect insect or butterfly, having attained its full dimensions, is sufficiently supported by small quantities of a more nutritious food, consisting either of animal juices or of the fluids prepared by flowers, which are generally of a saccharine quality, and contain nourishment in a highly concentrated form. It is evident that the same apparatus which is necessary for the digestion of the bulky food taken in during the former period, would not be suited for the assimilation of that which is received during the latter; and that, in order to accommodate it to this altered condition of its function, considerable changes must be made in its structure. Who can believe that these changes are made without wisdom, or persuade themselves that all this is to be brought about by causes divested of knowledge and understanding? Dr. Roget, in his admirable Bridgewater Treatise, has beautifully illustrated the subject, by very clear and correct drawings by Mr. Newport, of the three different states of the entire alimentary canal of the privet hawk-moth (*Sphinx ligustri*): first, when a caterpillar; then as a chrysalis; and, lastly, as the moth: and of these, taking our text from Roget, or rather from Herold, we shall endeavour to give some account. We have seen that in the caterpillar the stomach forms by far the most considerable portion of the alimentary canal, bearing some resemblance in its structure and capacity to the stomachs of certain worms. This is followed by a large but short and perfectly straight intestine. In the chrysalis these organs have undergone considerable modifications; the whole canal, but more especially the stomach, being contracted both in length and width: the shortening of the intestine not being proportionate to that of the whole body, obliges it to be folded upon itself for a certain length. In the moth, the contraction of the stomach has proceeded much farther, and an additional cavity, which may be considered as a kind of craw, is developed; the small intestine takes a great many turns during its course, and a large pouch has been formed at the part where it joins the large intestine. "When we consider," say Kirby and Spence, speaking of the phenomena which we have detailed, "the adaptation of all these changes of form, the loss of old organs and the acquisition of new ones, to the functions and mode of life of the animal, we see evidently the all-powerful hand of that Almighty Being who erected the universe, upholding by his providence, and the law that he has given to every creature, the system that he at first brought into existence."

In insects, all parts concerned in digestion are in general smaller and less complicated in the carnivorous than in the herbivorous tribes, apparently from the matters on which the former subsist being already animalized, and requiring, therefore, less preparation before they are received into the blood; and it is no slight indication of design, to observe in them how admirably parts are adapted to the animal necessities. Thus, scorpions, spiders, millepedes, and others, which live for the most part on hard animal substances, are furnished with jaws of a firm horny texture, in many cases very large, when compared with the size of the animal; dragon-flies and beetles, particularly the stag-beetle, are examples in which the jaws are very large and manifest, often possessing tooth-like edges; and these, too, feed on smaller insects than themselves. In another description, of which the bee, wasp, and ant, are examples, we find the animal deserting the coarser kinds of food, living chiefly on juices; and in them also we again find the same mode of taking in nourishment, as in the lowest stages of the animal kingdom, viz., by means of organs of suction, which here, however, are combined with organs for mastication. These organs of suction are still more developed in insects, such as gnats, house-flies, &c.; in them they consist of a tube, of which the sides are strong and fleshy, and movable in every direction, like the trunk of an elephant, and having at its extremity a double fold, resembling lips, which are well adapted for suction. The gnat, and other insects which pierce the skin of animals, have for this purpose instruments termed *lancets*, from their shape and office. In the gnat they are five or six in number, finer than hair, exceedingly sharp, and generally barbed on one side; while in the house-fly they are flat, like the blade of a knife. In the butterflies, however, which are almost wholly independent of solid nutritive matter, these organs present themselves in the greatest perfection, and without any addition of teeth. The proboscis of this order of insects is a double tube, constructed by the two edges being rolled longitudinally till they meet in the middle of the lower surface, thus forming a tube on each side, but leaving also another tube, intermediate to the two lateral ones. This middle tube is formed by the junction of two grooves, which, by the aid of a curious apparatus of hooks, lock into each other, and can be either united into an air-tight canal, or be instantly separated at the pleasure of the animal.* It would be quite incompatible with the nature of this essay to enter at greater length into the evidences of design, deducible from the digestive apparatus of insects. "This immense class," say Cuvier, "in the structure of their alimentary canal, exhibit as many variations as those of all the vertebral animals together: there are not only the differences that strike us in going from family to family, and from species to species, but one and the same individual has often a canal quite different, according as we examine it in its larva or imago;† and all these variations have relations very exact, often easily estimable, with the temporary or constant mode of life of the animals in which it is observable." That this statement is correct, we have seen; and no one can be blind enough to deny that it evinces an origin of things quite incompatible with mere brute and uncertain chance.

DESIGN IN THE FORMATION OF FISHES.

Still ascending in the scale of creation, we come to the contemplation of fishes. We ask, was it by mere chance that the respiratory apparatus of fishes was so formed that their blood receives its vivifying principle from the air which is held in solution by the water in which they move? And who cannot, in this one instance, but discern the hand of a ruling Providence, adapting the structure of animals to the habits which are to characterize

* Roget, ii. 114. † Imago or perfect state

them? Was it by chance that, in the plaice, the sole, the turbot, and other flat fishes, the eyes are placed both on one side of the body, an isolated instance of a want of uniformity in the two sides? No; the design is obvious for as these animals are destined to continue always with one side in the mud at the bottom of the water, an eye on this side would have been superfluous and inconvenient to them. The same design and evident adaptation of structure to circumstances is apparent in the Surinam sprat. This singular animal generally swims so near the surface, that its eye is partly in and partly out of the water; and all its parts correspond with this strange peculiarity, the pupil being partly divided into an upper and lower portion, and the lens consisting of two globes, an upper and a lower one attached together. It appears that the superior part of the eye is, like that of terrestrial animals, adapted to refract rays transmitted by air, and the inferior part, like that of aquatic animals, those transmitted by water, and that the refracting power of the several parts of the eye is accordingly much less above than below. With regard to the function of hearing, we find in fishes the Creator still proceeding on one vast plan or unity of design; with the exception of one species, all the parts of the ear are buried within the skull, and send no process to the surface; and this is precisely what we should have looked for in beings destined to hear through the medium of water, the vibrations of which, being so much more powerful than those of air, would render the complicated apparatus requisite in terrestrial animals in them superfluous. In the class of fishes, we see the lowest condition of the alimentary canal as it is found in vertebral animals. Fishes, voracious to a proverb, subsist almost entirely on animal food. The ocean teems chiefly with animal life. It is a dense, and rich, and moving, and tempestuous element, where vegetation is comparatively small, contrasted with its development in the light and unresisting element of the atmosphere. This rich and resisting element of water abounds in every latitude and in every drop, with all forms of animated beings. Thus, fishes have the means of easily satisfying their voracious appetites with a selection of all kinds of food. Their teeth, more instruments of prehension than mastication, are sharp, recurved, dense, and pointed cones, adapted to grasp and retain every living thing that moves in the waters, and placed in all parts of the mouth of these all-devouring animals; their œsophagus or gullet is very wide and short, and directly opening into their capacious stomach. Thus, the food of fishes not being masticated in the mouth, does not dwell there; and as they are surrounded with an abundance of moisture, they require no salivary glands for lubricating the food, and they have none. Like larvæ, their stomachs are very large: and like them, also, they are chiefly intent upon the gratification of their appetites. All other senses seem to be absorbed in this. Their brain is very small, and their senses correspondingly obtuse.* The intestine of fishes varies considerably in length, according to the kind of food; but generally speaking, it is not longer than their bodies; whereas, in most reptiles—which compose the next class of animals in the ascending scale—it is considerably longer; a provision unnecessary in fishes, perhaps, from the matters on which they for the most part feed, being almost always of the same nature as their own bodies, and therefore requiring comparatively little preparation.

Relinquishing our plan of illustrating design by an account of the digestive apparatus, let us consider, in reptiles, the organs subservient to the function of respiration, which, though somewhat similar to the organs designed for that purpose in birds and mammiferous quadrupeds, differ from those in some remarkable particulars. In reptiles, indeed, as in birds and mammalia, there is a kind of lungs; but they are membranous and not fleshy; that is to say, the cells which they contain are so much larger as to give them a membranous and not a fleshy appearance; nay, in many reptiles the lungs consist of one membranous bag, very similar to the air-bladder of fishes. These lungs or bags are situated in the abdomen, and are loose and floating among the entrails; and they receive their supply of air, in general, not as in birds and mammiferous animals, in consequence of the formation of a vacuum around them, but by a process very similar to that of swallowing. Hence, reptiles, unlike the higher classes of animals, can still continue to breathe if their bodies are cut open, because they do not require a vacuum round the lungs. The air thus received is subservient to the purification of the blood in the usual manner; but it is not so immediately vitiated as air received into fleshy lungs, owing to the larger size of the cells, which do not immediately allow the whole of it to come into contact with their sides. This is one reason why reptiles can sustain an impediment to their respiration for a much longer time than birds and mammals; but another and a much better reason is to be found in the distribution of their blood-vessels, those going to the lungs not forming a necessary part of the general circulating system, but constituting, as it were, only an appendage to it, which may for a time cease to transmit blood without inconvenience. A fish was destined always to be in the water, and a bird or quadruped always in the air; and hence the structure of their respiratory, as well as circulating system, is such as to incapacitate them each for the other element.

DESIGN IN THE FORMATION OF BIRDS.

We come now to birds; and whether we consider their external form or anatomical structure, or in whatever light it is possible to view them, the same conclusion presents itself to the mind. Inexhaustible contrivance, vast and comprehensive intelligence, are everywhere conspicuous. Behold, in their pointed bill, and gradually enlarging head and neck, a means of penetrating the yielding air; then the prow-like breast, the flexible rudder tail, the equipoised wings, and feathers at once adapted for lightness, for strength, and for tenacity, and all bearing relations, not only to each other, but to the air in which the animal is to fly: the wise contrivance of these could not be the result of chance. The investing membranes of their lungs, prolonged from various parts of their surface in the form of tubes, and expanding into bags, enveloping almost all the entrails, so as to keep them constantly surrounded with air, and similar prolongations extending also into the cavity of their bones, serving to inflate these in the same manner—are not the peculiarities for the obvious purpose of giving lightness to the animal, and thus enabling it to support itself in the air?—and does not this palpable subserviency of one part of the structure of birds to the rest, irresistibly inculcate the truth that one master-hand has regulated the whole?

In the beaks or bills of birds, various as are their forms, we can trace an exact adaptation to the food of the species. In those that tear their prey, as the eagle and hawk—or bruise hard fruits, as the parrot—or penetrate the bark of trees, as the woodpecker—the bills are of extraordinary hardness, and, in form, intimately connected with the habits of the animal. In those to whom a sense of feeling in this part is necessary to enable them to find their food in mud or water, as the duck, it is very soft, generally flattened, and so constructed that fluids may filter through it, while the solid food is retained. A bill hooked at the end, with sharp edges, characterizes birds of prey. Another species of strong sharp-edged bill, of an elongated shape, but without a hook, serves to cut and break, but not to tear; and this is the form of the bill in birds which live upon animals which make resistance in the water; some of these are straight, as in the heron—others curved some downwards, some upwards

* Grant's Lectures

Some sharp-edged bills have their sides approximating, like the blade of a knife to its handle, and thus adapted to seize small substances; as the penguin. The small, conical, arched bill of poultry, serves only to take up grain. The bills of the smaller birds present all the varieties of the conical form, from the broad-based cone of the hawfinch to the thread-like cone of the humming-bird. Such of them as have strong short bills live on grain; those with long thin ones, on insects. Where the bill is short, flat, opening very anteriorly, as in martens and swallows, the bird seizes flies and butterflies in the air; and if it be long and curved, possessing some strength, we find it grubs up worms for its food. The same evidence of design which we discover in the bills of birds adapting them to procure the kind of food on which the individual is to subsist, is apparent also in the conformation of their digestive organs. As the food of birds varies from the softest animal matter to the hardest grain, so we observe every gradation in the structure of their stomachs, from the membranous sac of the carnivorous tribes to the true muscular gizzard of granivorous birds—varying according as the food consists of animal or vegetable materials, or presents more or less resistance from the cohesion of its texture.

In no branch of natural history do we find more remarkable evidences of design, than in the varieties of kinds of coverings of animals adapted to their wants and situations on the globe. The covering of birds, in particular, "cannot (says Paley) escape the most vulgar observation. Its lightness, its smoothness, its warmth:—the disposition of the feathers all inclined backward, the down about their stem, the overlapping of their tips, their different configuration in different parts, not to mention the variety of their colours, constitute a vestment for the body, so beautiful and so appropriate to the life which the animal is to lead, as that, I think, we should have had no conception of any thing equally perfect, if we had never seen it, or can now imagine any thing more so. Let us suppose (what is possible only in supposition) a person who had never seen a bird, to be presented with a plucked pheasant, and bid to set his wits to work how to contrive for it a covering which shall unite the qualities of warmth, levity, and least resistance to the air, and the highest degree of each: giving it also as much of beauty and ornament as he could afford. He is the person to behold the work of the Deity, in this part of his creation, with the sentiments which are due to it.

"The commendation which the general aspect of the feathered world seldom fails of exciting, will be increased by further examination. It is one of those cases in which the philosopher has more to admire than the common observer. Every *feather* is a mechanical wonder. If we look at the quill, we find properties not easily brought together—strength and lightness. I know few things more remarkable than the strength and lightness of the very pen with which I am writing. If we cast our eye to the upper part of the stem, we see a material, made for the purpose, used in no other class of animals, and in no other part of birds; tough, light, pliant, elastic. The pith, also, which feeds the feathers, is among animal substances, *sui generis*; neither bone, flesh, membrane, nor tendon.

"But the artificial part of a feather is the beard, or, as it is sometimes, I believe, called, the vane. By the beards are meant, what is fastened on each side of the stem, and what constitute the breadth of the feather: what we usually strip off from one side or both, when we make a pen. The separate pieces or laminæ of which the beard is composed, are called threads, sometimes filaments, or rays. Now, the first thing which an attentive observer will remark is, how much stronger the beard of the feather shows itself to be, when pressed in a direction perpendicular to its plane, than when rubbed, either up or down, in the line of the stem; and he will soon discover the structure which occasions this difference, viz. that the laminæ whereof these beards are composed are flat, and placed with their flat sides towards each other; by which means, whilst they *easily* bend for the approaching of each other, as any one may perceive by drawing his finger ever so lightly upwards, they are harder to bend out of their plane, which is the direction in which they have to encounter the impulse and pressure of the air, and in which their strength is wanted, and put to the trial.

"This is one particularity in the structure of a feather: a second is still more extraordinary. Whoever examines a feather, cannot help taking notice that the threads or laminæ of which we have been speaking, in their natural state, *unite*; that their union is something more than the mere apposition of loose surfaces; that they are not parted asunder without some degree of force; that nevertheless there is no glutinous cohesion between them; that, therefore, by some mechanical means or other, they catch or clasp among themselves, thereby giving to the beard or vane its closeness and compactness of texture. Nor is this all: when two laminæ which have been separated by accident or force are brought together again, they immediately *reclasp*: the connection, whatever it was, is perfectly recovered, and the beard of the feather becomes as smooth and firm as if nothing had happened to it. Draw your finger down the feather, which is against the grain, and you break, probably, the junction of some of the contiguous threads; draw your finger up the feather, and you restore all things to their former state. This is no common contrivance: and now for the mechanism by which it is effected. The threads or laminæ above mentioned are *interlaced* with one another, and the interlacing is performed by means of a vast number of fibres, or teeth, which the laminæ shoot forth on *each side*, and which hook and grapple together. A friend of mine counted fifty of these fibres in one twentieth of an inch. These fibres are crooked, but curved after a different manner; for those which proceed from the thread on the side towards the extremity of the feather, are longer, more flexible, and bent downwards; whereas those which proceed from the side towards the beginning or quill end of the feather, are shorter, firmer, and turn upwards. The process, then, which takes place, is as follows:—When two laminæ are pressed together, so that these long fibres are forced far enough over the short ones, *their* crooked parts fall into the cavity made by the crooked parts of the others, just as the latch that is fastened to a door enters into the cavity of the catch fixed to the door-post, and there hooking itself, *fastens* the door; for it is properly in this manner that one thread of the feather is fastened to the other.

"This admirable structure of the feather, which it is easy to see with the microscope, succeeds perfectly for the use to which nature has designed it; which use was, not only that the laminæ might be united, but that, when one thread or lamina has been separated from another by some external violence, it might be reclasped with sufficient facility and expedition.

"In the *ostrich*, this apparatus of crotchets and fibres, of hooks and teeth, is wanting; and we see the consequence of the want. The filaments hang loose and separate from one another, forming only a kind of down; which constitution of the feathers, however it may fit them for the flowing honours of a lady's head-dress, may be reckoned an imperfection in the bird, inasmuch as wings composed of these feathers, although they may greatly assist it in running, do not serve for flight.

"But under the present division of our subject, our business with feathers is, as they are the *covering* of the bird. And herein a singular circumstance occurs. In the small order of birds which winter with us, from a snipe downwards, let the external colour of the feathers

lour of the feathers

so what it will, their Creator has universally given them a bed of *black* down next their bodies. Black, we know, is the warmest colour: and the purpose here is, to *keep in* the heat arising from the heart and circulation of the blood. It is further likewise remarkable, that this is not found in larger birds; for which there is also a reason:—Small birds are much more exposed to the cold than large ones; forasmuch as they present, in proportion to their bulk, a much larger surface to the air. If a turkey were divided into a number of wrens (supposing the shape of the turkey and the wren to be similar), the surface of all the wrens would exceed the surface of the turkey, in the proportion of the length and breadth (or of any homologous line) of a turkey to that of a wren; which would be, perhaps, a proportion of ten to one. It was necessary, therefore, that small birds should be more warmly clad than large ones; and this seems to be the expedient by which that exigency is provided for.

"The *oil* with which birds prune their feathers, and the organ which supplies it, is a specific provision for the winged creation. On each side of the rump of birds is observed a small nipple, yielding upon pressure a butter-like substance, which the bird extracts by pinching the pap with its bill. With this oil or ointment thus procured, the bird dresses its coat, and repeats the action as often as its own sensations teach it that it is in any part wanted, or as the excretion may be sufficient for the expense. The gland, the pap, the nature and quality of the excreted substance, the manner of obtaining it from its lodgment in the body, the application of it when obtained, form, collectively, an evidence of intention which it is not easy to withstand. Nothing similar to it is found in unfeathered animals. What blind *conatus* of nature should produce it in birds? should not produce it in beasts?"

As we have entered so fully into this subject when treating of other classes of beings, we shall not here revert to it, or bring forward illustrations of the truth of our proposition; the facts already detailed seem sufficient to display the wisdom which the great Creator has evinced in this department of the animal world. Nothing can be more worthy of remark than the exhaustless contrivances by which every difficulty is obviated, and nature moulded to the will of its Almighty Author. How many obstacles were to be overcome before a heavy body, like that of an eagle or the mighty condor, could be rendered buoyant in the air, and made to track its adventurous course so high above the earth as to be almost lost to human gaze! How many conditions were necessary to give safety and enjoyment to the smallest of the winged tribes, even after the first obstacles were overcome! Yet how wonderfully simple and efficacious the means by which the whole has been accomplished! That man is indeed to be pitied who can turn even a transient glance on such a subject, without being lost in astonishment and admiration.

THE STRUCTURE OF MAN AND OTHER ANIMALS.

We now arrive at the consideration of the mammalia, or those animals which suckle their young; and at the head of this great class we find man proudly pre-eminent. We have already seen, that, as the materials on which the function of digestion is to be performed are numerous and diversified, so a difference exists in the parts which are subservient to it. Without altering the general plan of the function, or the essential parts of the organs concerned in it, nature makes such additional provisions, in the instincts by which the reception of food is guided, and in the organs by which it is assimilated, as are suited to the circumstances in which the animal is placed, to the food on which it is to subsist, and to the ulterior purposes which it is to serve in the world. Such evidences of design are very remarkable in the mammalia; and in few organs are they more powerfully instanced than in the teeth, between which, in form, structure, and position, and the kind of food on which each animal of this class is intended to subsist, the most intimate connections present themselves. These relations—which indeed may be also traced in the shape of the jaw, in the mode of its articulation with the head, in the proportional size and distribution of the muscles which move the jaw, in the form of the head itself, in the length of the neck and its position on the trunk, and, in fact, in the whole conformation of the skeleton—have been noticed from very early ages, and frequently described.

The purposes answered by the teeth are principally those of seizing and detaining whatever is introduced into the mouth, of cutting it asunder and dividing it into smaller pieces, of loosening its fibrous structure, and of breaking down and grinding its harder portions. Four principal forms have been given to teeth, which accordingly may be distinguished into the conical, the sharp-edged, the flat, and the tuberculated teeth; though we occasionally find a few intermediate modifications of these forms. It is easy to infer the particular functions of each class of teeth, from the obvious mechanical actions to which, by their form, they are especially adapted. The conical teeth, which are generally also sharp-pointed, are principally employed in seizing, piercing, and holding objects; such are the offices they perform in the crocodile and similar reptiles, where all the teeth are of this structure: and such also are their uses in most of the cetacea or whale tribe, where similar forms and arrangements of teeth prevail. The animals subsist on fish, and their teeth are therefore constructed very much on the model of those of fish; while those cetacea, on the other hand, which are herbivorous, as the manatus and dugong, have teeth very differently formed.

The sharp-edged teeth perform the office of cutting and dividing the yielding textures presented to them: they act individually as wedges or chisels; but when co-operating with similar teeth on the opposite jaw, they have the power of cutting like shears or scissors. The flat teeth, of which the surfaces are generally rough, are used, in conjunction with those meeting them in the opposite jaw, for grinding down the food by a lateral motion, in a manner analogous to the operation of millstones in a mill. The tuberculated teeth, of which the surfaces present a number of rounded eminences, corresponding to the depressions in the teeth opposed to them in the other jaw, act more by their direct pressure in breaking down hard substances, and pounding them, as they would be in a mortar.

The apparatus for giving motion to the jaws is likewise varied according to the particular movements required to act upon the food in the different tribes. The articulation of the lower jaw to the skull is somewhat similar to a hinge; but considerable latitude is given to its motions by the interposition of a movable cartilage between the two surfaces of articulation, a contrivance admirably answering the intended purpose. Hence, in addition to the principal movements of opening and shutting, which are made in a vertical direction, the lower jaw has also some degree of mobility in a horizontal or lateral direction, and is likewise capable of being moved backwards or forwards to a certain extent. In the conformation of the teeth and jaws, a remarkable contrast is presented between carnivorous and herbivorous animals. In the former, of which the tiger may be taken as an example, the whole apparatus for mastication is calculated for the destruction of life, and for tearing and dividing the fleshy fibres. The teeth are armed with pointed eminences, which correspond in the opposite jaws, so as exactly to lock into one another, like wheelwork, when the mouth is closed, and the muscles which close it are of enormous size and strength. In the herbivorous animals, on the contrary, as in the antelope, the greatest force is bestowed, not so much on the

motions of opening and shutting, as on those which are necessary for grinding, and which act in a lateral direction. The surfaces of the teeth are flattened and of great extent; and they are at the same time kept rough, like those of millstones, their office being in fact very similar to that performed by these implements of grinding. The *Rodentia*, or gnawing quadrupeds, are formed for subsisting on dry and tough materials, such as the bark and roots, and even the woody fibres of trees, and the harder animal textures; and their teeth are expressly adapted for gnawing, nibbling, and wearing away, by continued attrition, the harder texture of organized bodies. They are all furnished with two front teeth, generally very long, and having the exact shape of a chisel; while the molar or back teeth have surfaces irregularly marked with raised zig-zag lines, rendering them very perfect instruments of trituration. The beaver and rat are examples among omnivorous rodentia, and the hare and rabbit among those that are principally herbivorous.

The *Quadrumana*, or monkey tribes, approach nearer to the human structure in the conformation of their teeth, which are adapted to a mixed kind of food; while the other orders of mammalia exhibit gradations in the structure of their teeth corresponding to the varieties in the nature of their food. Thus the teeth and jaws of the hyæna are formed more especially for breaking bones, while those of the sea-otter have rounded eminences which peculiarly fit them for breaking shells.

"On comparing the structure of the digestive organs of man," continues Dr. Roget,* "with those of other animals belonging to the class mammalia, we find them holding a place in the series intermediate between those of the purely carnivorous and exclusively herbivorous tribes, and in some measure uniting the characters of both. The powers of the human stomach do not indeed extend to the digestion of either the tough woody fibres of vegetables on the one hand, or the compact texture of bones on the other; but still they are competent to extract nourishment from a wider range of alimentary substances than the digestive organs of almost any other animal. This adaptation to a greater variety of food may also be inferred from the form and disposition of the teeth, which combine those of different kinds more completely than in most mammalia. In addition to these peculiarities, we may also here observe, that the sense of taste in the human species appears to be affected by a greater variety of objects than in the other races of animals. All these are concurring indications that nature, in thus rendering man omnivorous, intended to qualify him for maintaining life wherever he could procure the materials of subsistence, whatever might be their nature, whether animal or vegetable, or a mixture of both, and in whatever soil or climate they may be produced; and for endowing him with the power of spreading his race, and extending his dominion over every accessible region of the globe. Thus, then, from the consideration of the peculiar structure of the organs of his frame, may be derived proofs of their being constructed with reference to faculties of a higher and more extensive range than those of any, even the most favoured, species of the brute creation."

There is one circumstance connected with the function of digestion, as displayed in certain of the mammalia, to which, as evidencing great and wonderful design and accommodation in structure to circumstance, we would particularly allude; it is the facility and power of the camel of abstaining long from drinking—a power which he is often necessitated to bring into effect during the long period of nine, ten, or even twelve days. In Arabia, the camel is the chief beast of burden; and in travelling through such a country, it is only at long intervals that water can be obtained; a country, as described by Buffon, without verdure, without water, possessing a burning sun, an air always parched, sandy plains, mountains still more scorched, which the eye runs over without perceiving a single animated being; a dead earth perpetually tossed with the winds, and presenting nothing but bones, scattered flints, rocks perpendicular or overturned; a desert totally void, where the traveller never breathes under a shade, where nothing accompanies him, nothing recalls the idea of animated nature; absolute solitude, more dreadful than that of the deepest forests, more solitary and naked, more lost in an unlimited void; he everywhere beholds space surrounding him as a tomb. The light of day, more dismal than the darkness of night, serves only to give him a clearer view of his own wretchedness and impotence, and to conceal from him the barriers of the void, by extending around him the immense abyss which separates him from the habitable parts of the earth; an abyss which in vain he should attempt to traverse, for hunger, thirst, and scorching heat, haunt every moment that remains to him between despair and death. Frightful as is this picture, the desire of lucre, or the gratification of curiosity, or a love of enterprise no less insatiable, often tempt men to traverse the sandy deserts of Arabia. For their own necessities they may provide, but no human means could afford the possibility of conveying water sufficient to satisfy the longings of a beast of burden which accompany these expeditions. It is by the singular structure of the camel's stomach that it is enabled to pass several days without drinking, and to take at a time a prodigious quantity of water, which remains in reservoirs pure and limpid, because these wells are so contrived that neither the fluids of the body nor of digestion can mix with it. What design is here!—and how redolent of wisdom, and how full of mercy! But let us endeavour to explain the nature of this structure which so evidently adapts the camel to be the inhabitant of the sterile and arid regions of the east:—Ruminating quadrupeds, or those which chew the cud, have two, three, or four stomachs, distinguished, when there are four, by the names of paunch, bonnet, many-plies, and caille. When the food is swallowed for the first time, it passes directly from the gullet into the paunch, where it undergoes some necessary changes, and it is then transmitted to the bonnet, to be mixed with the fluids of the cavity. This process is going on during the time the animal is grazing, when from the incessant occupation of nipping off the grass, for which its teeth are so admirably suited, it has not leisure to chew it sufficiently. When afterwards reposing itself, however, the half-chewed aliment is brought again in successive little balls, from the bonnet into the mouth, where it is subjected to a perfect mastication; and when again swallowed, it passes directly to the many-plies, thence, after some time, to the caille, and ultimately to the intestines. In the camel, however, the paunch has two deep cellular appendages; and the bonnet, or second stomach, has its internal membrane hollowed into numerous deep cells, serving as reservoirs of water, to be used only as occasion requires; while the third stomach is alone appropriated to the immediate necessities of the body. Between the end of the gullet, then, and the orifice of this third stomach, extends through the two first, a long muscle capable of drawing up the third stomach, so as to receive alimentary matters directly from the gullet, when the immediate wants of the animal are to be supplied; but when the fluid taken is meant to be used only in its long journeys through the deserts, this muscle is relaxed, and it is thus received into the two first stomachs, and transmitted onwards by these only at the necessary intervals. The Arabs who traverse these extensive plains, accompanied by these useful animals, are, it is said, sometimes obliged, when faint and in danger of perishing from thirst, to kill one of their camels, for the sake of the water contained in these reservoirs

* Bridgewater Treatise.

which is always found pure and wholesome. It is stated by those who have travelled in Egypt, that camels, when accustomed to go journeys during which they are for a long time deprived of water, acquire the power of dilating the cells, so as to make them contain a more than ordinary quantity, as a supply for their journey.

COMPENSATION OF PARTS IN ANIMATED NATURE.

The evidences of design in creation are beautifully developed in what is called the compensatory structure of animals. By this is signified the supplying the defects of one organ by the structure of another part or organ. Paley has summed up a few striking instances of this nature. "The short unbending neck of the elephant (says he) is compensated by the length and flexibility of his *proboscis*. He could not have reached the ground without it; or, if it be supposed that he might have fed upon the fruit, leaves, or branches, of trees, how was he to drink? Should it be asked, Why is the elephant's neck so short? It may be answered, that the weight of a head so heavy could not have been supported at the end of a longer lever. To a form, therefore, in some respects necessary, but in some respects also inadequate to the occasions of the animal, a supplement is added, which exactly makes up the deficiency under which he laboured.

"If it be suggested that this proboscis may have been produced, in a long course of generations, by the constant endeavour of the elephant to thrust out his nose (which is the general hypothesis by which it has lately been attempted to account for the forms of animated nature), I would ask, How was the animal to subsist in the mean time, during the process, *until* this prolongation of the snout were completed? What was to become of the individual while the species was perfecting?

"Our business at present is simply to point out the relation which this organ bears to the peculiar figure of the animal to which it belongs. And herein all things correspond. The necessity of the elephant's proboscis arises from the shortness of the neck; the shortness of the neck is rendered necessary by the weight of the head. Were we to enter into an examination of the structure and anatomy of the proboscis itself, we should see in it one of the most curious of all examples of animal mechanism. The disposition of the ringlets and fibres, for the purpose, first, of forming a long cartilaginous pipe; secondly of contracting and lengthening that pipe; thirdly, of turning it in every direction at the will of the animal; with the superaddition, at the end, of a fleshy production of about the length and thickness of a finger, and performing the office of a finger, so as to pick up a straw from the ground—these properties of the same organ, taken together, exhibit a specimen not only of design, (which is attested by the advantage), but of consummate art, and, as I may say, of elaborate preparation, in accomplishing that design.

"The hook in the wing of a *bat* is strictly a mechanical, and also a *compensatory*, contrivance. At the angle of its wing there is a bent claw, exactly in the form of a hook, by which the bat attaches itself to the sides of rocks, caves, and buildings, laying hold of crevices, joinings, chinks, and roughnesses. It hooks itself by this claw; remains suspended by this hold; takes its flight from this position: which operations compensate for the decrepitude of its legs and feet. Without her hook, the bat would be the most helpless of all animals. She can neither run upon her feet, nor raise herself from the ground. These inabilities are made up to her by the contrivance in her wing; and in placing a claw on that part, the Creator has deviated from the analogy observed in winged animals. A singular defect required a singular substitute.

"The *crane* kind are to live and seek their food amongst the waters, yet, having no web feet, are incapable of swimming. To make up for this deficiency, they are furnished with long legs for wading, or long bills for groping, or usually with both. This is *compensation*. But I think the true reflection upon the present instance is, how every part of nature is tenanted by appropriate inhabitants. Not only is the surface of deep waters peopled by numerous tribes of birds that swim, but marshes and shallow pools are furnished with hardly less numerous tribes of birds that wade.

"The common *parrot* has, in the structure of its beak, both an inconveniency and a *compensation* for it. When I speak of an inconveniency, I have a view to a dilemma which frequently occurs in the works of nature, viz., that the peculiarity of structure by which an organ is made to answer one purpose, necessarily unfits it for some other purpose. This is the case before us. The upper bill of the parrot is so much hooked, and so much overlaps the lower, that if, as in other birds, the lower chap alone had motion, the bird could scarcely gape wide enough to receive its food; yet this hook and overlapping of the bill could not be spared, for it forms the very instrument by which the bird climbs; to say nothing of the use which it makes of it in breaking nuts and the hard substances upon which it feeds. How, therefore, has nature provided for the opening of this occluded mouth? By making the upper chap movable, as well as the lower. In most birds the upper chap is connected, and makes but one piece, with the skull; but in the parrot, the upper chap is joined to the bone of the head by a strong membrane placed on each side of it, which lifts and depresses it at pleasure.

"The *spider's web* is a *compensating* contrivance. The spider lives upon flies, without wings to pursue them; a case, one would have thought, of great difficulty, yet provided for, and provided by a resource which no stratagem, no effort of the animal, could have produced, had not both its external and internal structure been specifically adapted to the operation.

"In many species of insects the eye is fixed, and consequently without the power of turning the pupil to the object. This great defect is, however, perfectly *compensated*, and by a mechanism which we should not suspect. The eye is a multiplying glass, with a lens looking in every direction, and catching every object; by which means, although the orb of the eye be stationary, the field of vision is as ample as that of other animals, and is commanded on every side. When this lattice-work was first observed, the multiplicity and minuteness of the surfaces must have added to the surprise of the discovery. Adams tells us that fourteen hundred of these reticulations have been counted in the two eyes of a drone-bee.

"In other cases the *compensation* is effected by the number and position of the eyes themselves. The spider has eight eyes, mounted on different parts of the head; two in front, two in the top of the head, two on each side. These eyes are without motion, but by their situation suited to comprehend every view which the wants or safety of the animal render it necessary for it to take.

"The Memoirs of the Natural History of Animals published by the French Academy in the year 1687, furnish us with some curious particulars in the eye of a chameleon. Instead of two eyelids, it is covered by an eyelid with a hole in it. This singular structure appears to be *compensatory*, and to answer to some other singularities in the shape of the animal. The neck of the chameleon is inflexible. To make up for this, the eye is so prominent, that more than half of the ball stands out of the head; by means of which extraordinary projection, the pupil of the eye can be carried by the muscles in every direction, and is capable of being pointed towards every object. But, then, so unusual an exposure of the globe of the eye requires, for its lubricity and defence, a more than ordinary protection of eyelid, as well as a

more than ordinary supply of moisture; yet the motion of an eyelid formed, according to the common construction, would be impeded, as it should seem, by the convexity of the organ. The aperture in the lid meets this difficulty. It enables the animal to keep the principal part of the surface of the eye under cover, and to preserve it in a due state of humidity without shutting out the light; or without performing every moment a nictitation which, it is probable, would be more laborious to this animal than to others.

"But the works of the deity are known by expedients. Where we should look for absolute destitution, where we can reckon up nothing but wants, some contrivance always comes in to supply the privation. A *snail*, without wings, feet, or thread, climbs up the stalks of plants, by the sole aid of a viscid humour discharged from her skin. She adheres to the stems, leaves, and fruits of plants, by means of a sticking plaster. A *mussel*, which might seem, by its helplessness, to lie at the mercy of every wave that went over it, has the singular power of spinning strong tendinous threads, by which she moors her shell to rocks and timbers. A *cockle*, on the contrary, by means of a stiff tongue, works for itself a shelter in the sand. The provisions of nature extend to cases the most desperate. A *lobster* has in its constitution a difficulty so great, that one could hardly conjecture beforehand how nature could dispose of it. In most animals, the skin grows with their growth. If, instead of a soft skin, there be a shell, still it admits of a gradual enlargement. If the shell, as in the tortoise, consists of several pieces, the accession of substance is made at the sutures. Bivalve shells grow bigger by receiving an accretion at their edge; it is the same with spiral shells at their mouth. The simplicity of their form admits of this. But the lobster's shell being applied to the limbs of the body, as well as to the body itself, allows not of either of the modes of growth which are observed to take place in other shells. Its hardness resists expansion, and its complexity renders it incapable of increasing its size by addition of substance to its edge. How, then, was the growth of the lobster to be provided for? Was room to be made for it in the old shell, or was it to be successively fitted with new ones? If a change of shell became necessary, how was the lobster to extricate himself from his present confinement? how was he to uncase his buckler, or draw his legs out of his boots? The process, which fishermen have observed to take place, is as follows:—At certain seasons, the shell of the lobster grows soft; the animal swells its body; the seams open, and the claws burst at the joints. When the shell has thus become loose upon the body, the animal makes a second effort, and by a tremulous spasmodic motion, casts it off. In this state, the liberated but defenceless fish retires into holes in the rock. The released body now suddenly pushes its growth. In about eight-and-forty hours, a fresh concretion of humour upon the surface, i. e. a new shell, is formed, adapted in every part to the increased dimensions of the animal. This wonderful mutation is repeated every year."

In the changing of the colour of the chameleon, we see one of the beautiful compensatory provisions of nature. This little animal, which is common in the East Indies, and some other Asiatic countries, lives upon flies, beetles, or other insects, which it catches by climbing up shrubs or trees, and darting out its tongue; but its pace is slow, and as insects have good eyes to perceive the approach of an enemy, they would be sure to make their escape in the present case, unless the chameleon approached them in disguise. This, therefore, it invariably does. As it passes among green leaves, it is of a green colour; and when it glides by any of a red or yellow tinge, so does it change its hue to red or yellow. So closely does it assume not only the shades and colours, but even the shapes of the leaves around, that a spectator might look at the tree for some minutes before discovering it. How wisely, therefore, has the Creator endowed this poor reptile with the wonderful gift of altering the colour of its skin; for if it were not possessed of such a property, it would inevitably die of hunger.

By carrying our observation upward from the mere physical organization of man, to the *mind* which he possesses, and is able to exert in reference to both sensible objects and abstract subjects, we have still greater reason to admire the proofs of design and goodness in an overruling Creator; for we all feel that this principle of mind—how constituted we do not here stop to inquire—is in harmony with the other works of creation around us. For example, how much are our minds suited to the recognition of what is beautiful in nature and art. This, however, admits of a few separate observations.

BEAUTY.

The wisdom of the great original Contriver is eminently manifested in that property of inanimate and animate objects which we call beauty. Here there is an evident fitness between the taste and habits of animals, human beings included, and what can be seen by the eye. We feel pleasure in contemplating the works of nature more obvious to our senses; and we cannot but remark, that that which is loathsome is not ordinarily presented to the eye. The splendid colouring of the vegetable kingdom, the smooth or spotted skins of the brute creation, and the lovely plumage of the feathered tribe, all give us delight in the contemplation. Consider, also, how beautiful is the outward appearance of the human form. Reflect on what the parts and materials are of which the fairest body is composed, and no further observation will be necessary to show how well these things are wrapped up, so as to form a mass which will be capable of symmetry in its proportion, and of beauty in its aspect; how the bones are covered—the bowels concealed—the roughness of the muscle smoothed and softened; how over the whole is drawn an integument, the skin, which converts the disgusting materials of a dissecting-room into an object of attraction to the sight, or one upon which it rests at least with ease and satisfaction.

The more minutely that we inspect the works of nature, the greater cause have we to wonder at the extraordinary perfection and beauty everywhere prevalent. The microscope develops splendours in the creation of insects which we can hardly comprehend. The back of a diamond-beetle exhibits an assemblage of brilliant colours and glittering gems more splendid than any artificial arrangement of the most precious stones. The colours of the feathers of birds in tropical climates, and the skins of the fishes of Ceylon, are incomparable for their beauty. And why is all this the case? Because it yields a pleasure to the sight, both of men and other living creatures; for the Creator has not denied the feeling of delight to the meanest reptile which crawls. All is beautiful, it would appear, in the estimation of one or other of living creatures. The most insignificant little flower, now blooming far from the haunts of men, in some remote wilderness, does not, as has been said, waste its sweetness on the desert air. It furnishes an object of pleasing gratification to some description of sentient creatures, perhaps so small as to be imperceptible to our naked eye.

Placing agreeableness of aspect entirely out of the question, there is another purpose answered by the skin, and that is concealment. Were it possible to view through this integument the mechanism of our bodies, the sight would frighten us much as it would disgust us. Durst we make a single movement, or stir a step from the place we were in, if we saw our blood circulating, the tendons pulling the lungs blowing, the humours filtrating, and all the incomprehensible assem-

blage of fibres, tubes, pumps, valves, currents, pivots, which sustain an existence at once so frail and so presumptuous?

In clothing the human frame with a covering of skin, the Creator has not omitted to vary its character according to local necessities. The skin is most beautiful on the face, because the face is most exposed to observation; it is softest where least liable to injury, and hardest or firmest in texture where it is most subject to be pressed upon. There is not less sign of contrivance in the manner in which it ceases at the extremities of the toes and fingers. A man has only to look at his hand, to observe with what nicety and precision that covering, which extends over every other part, is here superseded by a different substance and a different texture. Why do we find the skin cease at our fingers' ends, or on the back part of the fingers, and not the fore part? Because something hard or horny was required on these parts, by which we could hold fast or lift nimbly objects which we wished to grasp or seize upon. Nails therefore supersede the skin on such places. The same forethought is visible in the covering of our heads. What could have been a more beautiful or appropriate substance wherewith to cover the head and preserve the hard bony skull from injury, than the hair, a substance at once light, warm, and graceful?

DESIGN IN VEGETABLE PHYSIOLOGY.

In accordance with our intentions of glancing through most of the natural sciences, and bringing home to the main object of our labours treasures illustrative of design from them all, let us now turn our attention to those afforded by the vegetable kingdom of nature. And first, of the mutual relations that exist between animals and vegetables; in considering which, we shall find that these two great organized kingdoms of the creation are made to co-operate in the execution of the same design; each ministering to the other, and preserving that due balance in the constitution of the atmosphere, which adapts it to the welfare and activity of every order of beings, and which would soon be destroyed were the operations of any one of them to be suspended. "It is impossible to contemplate so special an adjustment of opposite effects, without admiring this beautiful dispensation of Providence, extending over so vast a scale of being, and demonstrating the unity of plan on which the whole system of organized creation has been devised." We said in a former part of this essay, that two principles of atmospheric air were oxygen and carbon; that the former was as essential to animal life as the latter was obnoxious to it; but that, on the other hand, carbon was indispensable to the continuance of vegetable organization. We will now endeavour to explain this by a short account of the phenomena of respiration as displayed in the two kingdoms. Among animals, the function of respiration is that by which the blood, received into its vessels from the alimentary canal, is, during its subsequent circulation, kept in a state of requisite purity. This is in all cases effected by bringing it, at intervals, into contiguity, either with atmospheric air alone, or with water containing this air diffused through it; when such is the mutual action of the blood and the air upon each other, that the former is purified and passes in general from a dingy purple to a bright scarlet colour, while the latter is in the same degree rendered impure, and after a time becomes inadequate to support either respiration or combustion. Now, whether the aërating organs be lungs or gills, it appears to be the object of nature, in their construction, to expose a large surface to the contact of air. This object is accomplished by their division into numerous cells or leaf-like processes, or by their extension on the walls of cavities, or the surface of pectinated ridges. The blood brought to these organs is there distributed by their terminating branches. Although still retained in vessels, it can nevertheless be easily acted upon by the air on the exterior. Priestley found the colour of blood changed by the air when enclosed in a moistened bladder, and the same effect was observed by Hunter when it was covered with goldbeaters' skin. It is scarcely possible to determine by direct observation what is the exact nature of the changes that the blood undergoes in its passage through the lungs; the most obvious is its change of colour; and the chemical differences between the dark purple blood in the veins before it has reached the lungs, and the bright vermilion colour it exhibits in the arteries after it has circulated through the lungs, and been exposed to the influence of the air, may be collected from the changes made in the air itself. Atmospheric air is known to consist of certain principles in definite proportions; when it has acted upon the blood, and is returned from the lungs, it is found that a certain proportion of oxygen which it contained has disappeared, and that the place of this oxygen is almost wholly supplied by an addition of carbonic acid gas and watery vapour. The exact quantity of oxygen which is lost in natural respiration, varies in different animals, and even in different conditions of the same animal. Birds, for instance, consume larger quantities of oxygen by their respiration, and hence require, for the maintenance of life, a purer air than other vertebrated animals. Vauquelin, however, found that many species of insects and worms possess the power of abstracting oxygen from the atmosphere in a much greater degree than the larger animals; thus, snails are capable of living for a long time in the vitiated air in which a bird had perished. Some insects which conceal themselves in holes, or burrow under ground, have been known to deprive the air of every appreciable portion of its oxygen. It is observed by Spallanzani, that those animals whose modes of life oblige them to remain for a great length of time in these confined situations, possess this power in a greater degree than others which enjoy more liberty of moving in the open air: so admirably have the faculties of animals been, in every instance, accommodated to their respective wants.

Now, bearing in mind that the air coming in contact with the blood of animals parts with its oxygen, and receives in its place carbonic acid gas, let us consider the function of respiration, or more properly aëration, as it occurs in vegetables. It was necessary that some means should be appointed by which this great quantity of carbon given out into the air by animals, and so injurious to animal life, should be removed from it. We have said that this principle was necessary to vegetable life; and here we find the means not only by which in a very considerable degree it is procured, but also by which it is removed from the atmosphere. The leaves of plants are analogous to the lungs of animals, and it is in them principally that the decomposition of the carbonic acid absorbed from the air is effected. When exposed to the action of the sun, they decompose that gas, retain its carbon, and disengage its oxygen. Solar light is an essential agent in effecting this chemical change; for it is never found to take place at night, nor while the plant is kept in the dark. That the carbon resulting from this decomposition of carbonic acid is retained by the plant, has been most satisfactorily proved by the experiments of Saussure, who found that this process is attended with a sensible increase in the quantity of carbon which the plant had previously contained. "Thus the great object to be answered by this vegetable aëration," says Dr. Roget, speaking at considerable length of this undeniable evidence of design to which we have thus shortly alluded, "is exactly the converse of that which we see effected by the respiration of animals; in the former it is adding carbon to the vegetable organization; in the latter, it is that of discharging the superfluous quantity of carbon from the animal system. On the whole, there

fore, the atmosphere is continually receiving from the vegetable kingdom a large accession of oxygen, and is at the same time freed from an equal portion of carbonic acid gas, both of which effects tend to its purification, and to its remaining adapted to the respiration of animals."

We have not much space to devote to the contemplation of vegetables, but we are unwilling to leave the subject without alluding to some other evidences of design which we find displayed in them. Among these, nothing more beautifully demonstrates that nature, or rather the Almighty Creator of nature, proceeds on a uniformity of plan and design, than the fact that plants as well as animals are possessed of the means of reproducing and continuing their species. The pistil which occupies the centre of the flower is destined to produce the seeds, while the stamens of the plant contain the dust necessary for fertilizing them, and without which the seeds would not produce young plants. Nature has guarded with nice care this precious dust, for on its preservation depends the continuance of the species. The apparatus by which in many flowers it is defended from injury, is very curious; nor are the means that are provided by which it comes in contact with the stigma of the pistil less demonstrative of a great, a wise, and a beneficent Providence. In some plants, where the organs are in the same flower, the stamens are placed above the stigma, upon which the dust, or pollen, falls by its own gravity; in others, we find the contrary is the case, the pistil being the longest; but here the flower is generally drooping. To assist the emission of the pollen, and its contact with the stigma, in many plants the stamens possess a very apparent moving power. When ripe, the ten stamens of the rue are seen alternately to bend down upon the stigma, deposit their portion of pollen, and return to their former position. The stalks or filaments of the pellitory of the wall are possessed of a remarkable elasticity, and thus forcibly scatter the pollen. This is very apparent if touched by the point of a needle; immediately it acts with a jerk, which dashes the pollen with some force on the stigma. The same arrangement is met with in the barberry bush, in which the six stamens remain sheltered under the concave tips of the flower-leaves or petals, till some extraneous body, as an insect in search of honey, touches the filament, which instantly contracts, and also dashes the pollen against the stigma. But all plants have not their stamens and pistils sheltered under the same veil; in many they are in different flowers, and in others even placed on different plants. Here, again, we have to admire the wise measure nature has taken for the accomplishment of her designs. In many the scattering of the pollen is effected by the winds; to favour the access of which, we find in some, as the hazel, the leaves are not evolved until after the seed has been perfected; or, if the plants be evergreens, the leaves are needle-shaped, so as to present very little obstacle to the passage of the pollen, which is secreted in much larger quantity than usual. Various species of insects, and especially the bee, are selected by nature for this purpose. In the pink we observe numerous small insects creeping to and fro, and thus depositing the pollen on the stigma. In flowers where the stamens and pistils are on different plants, often at a considerable distance from each other, bees, and other flying insects, are peculiarly accessory to the great end of nature. These insects, it is true, do not visit the flower for the purpose of scattering the pollen; they only seek for the sweet juice which exudes from its nectary. Their hairy body, which nature did not bestow without design, is seen covered with pollen, often in such quantities as to impede the progress of the animal; this, whenever they visit another flower, is rubbed against the stigma: and it is a fact, no less wonderful than calculated to fill us with admiration at the wise provision of nature, that many insects are peculiar to one flower, and that others, as the bee, will only visit one species in each journey from its hive.

The various methods which nature employs to disperse the different varieties of seeds over the earth, are truly wonderful. Many plants, when the seed is fully ripe, discharge it from its covering, with a jerk or elastic spring. The common oat is thrown out in this way, and the loud crackling of the pods of the broom in a dry sunshiny day, or, as Drummond has it, "bursting seed-balls crackling in the sun," is caused by their bursting and scattering about the contained seeds, and must have been frequently noticed. "Who has not listened," again asks Sir James Edward Smith, "in a calm and sunny day, to the crackling of the furze bushes, caused by the explosion of their elastic little pods; or watched the down of innumerable seeds floating on a summer breeze, till they are overtaken by a shower, which, moistening their wings, stops their farther flight, and at the same time accomplishes its final purpose, by immediately promoting the germination of each seed in the moist earth! How little are children aware, when they blow away the seeds of the dandelion, or stick burs in sport upon each other's clothes, that they are fulfilling one of the great ends of nature." These downy appendages, to which Sir J. E. Smith alludes, buoy up the lighter seeds, as the thistles, and carry them floating through the air to great distances. Then there are the currents of rivers which bear the seeds from one part of the country to another; and even seas and oceans, whose tides and currents float along the germs of vegetation to the various regions of the globe. Birds, too, by feeding on particular seeds, carry them to great distances, where, being often voided entire, they vegetate. There is evident design in this. It could not have been by mere chance, that in flowers which stand erect, the pistil is shorter than the stamens, permitting the pollen as it falls to descend upon the stigma; and when the flower is drooping, that the contrary arrangement is effected. And surely no one will be blind or hardy enough to assert that the mechanical means, to which we have alluded, for the dispersion of seeds, with all the beauty and aptitude of its arrangement, was not the result of divine wisdom—a wisdom which will be still more apparent when we extend our views from the power which called into being such various and beauteous existences, and gave the means of distributing them over the globe, and consider the laws that govern that distribution which we so much admire.

It is not here out of place to remark, that there is scarcely a vegetable production on which some species of animal does not subsist; and, generally speaking, wherever that peculiar production is to be found, there also is the animal to which it furnishes wholesome food. With some striking examples of this kind, the most uneducated man is acquainted; he knows that the partridge is on the plain, the woodcock in the forests, the grouse on the moors, and the ptarmigan on the loftiest peaks of the mountains. He knows, too, that other species migrate from country to country, seeking their food in distant regions, over trackless oceans, when it fails in their native haunts; and among the animal kingdom so universal is this, as to form an example of the wonderful adaptations which exist between it and the vegetable world. Vegetables, like animals, are adapted to varieties of climate and temperature; and when we consider their distribution over the globe, we shall find that those which are most essential to the maintenance of man, bear a variety of climate better than most others. This is the case with greens, carrots, potatoes, and many kinds of grain. Warm climates are much more favourable to vegetation than cold. In Spitzbergen, the whole number of plants with conspicuous flowers, natives of the country, is found by botanists scarcely to exceed thirty species; while in the warmer regions of the West Indies

in Madagascar and the coast of Coromandel, Willdenow enumerates from four to five thousand different species of indigenous plants. Now observe how admirably this distribution of plants corresponds with the wants and necessities of man. A vegetable diet is most suitable both to the tastes and the actual needs of the inhabitants of warm climates, and there we find that kind of food most abundant.

It is impossible for a reflecting individual to walk beside a field of growing barley, without being impressed with the conviction, that, in the economy of this description of grain, the design of a Creator has been wonderfully manifested. An ear of barley differs from one of wheat or oats. Each of the grains is furnished with a long slender bristle or beard, which is prickly to the touch, and seems to serve as a protection to the ear. These bristles form a roof, if we may so call it, to carry off the rain from the ear, and yet, by their elegant disposition, do not prevent the heat of the sun and the light from influencing the grain. And why should such be the case with barley, when the ears of wheat, oats, &c., do not possess any such protective process? Because barley is a grain easily injured by wet, which if not carried off would cause the ear to sprout even while on the stalk, and consequently be entirely useless to man.

In speaking of the economy of vegetable life, it should not pass unnoticed that there is a remarkable instance of creative wisdom in the means which have been arranged for the growth of plants from putrescent matter. All kinds of vegetable and animal substances, when deprived of life, as well as excrementitious matter, have a tendency to decomposition—that is, to resolve themselves into elementary gases of which they have been chiefly composed. This process of dissolution, as every one knows, produces a most disagreeable odour, which is often inimical to animal life. But this is not an evil; it displays a bountiful provision in nature; for it tells us, in a way not to be misunderstood, that the substance undergoing, or about to undergo, the putrefactive process, should be buried underground; and being there deposited, it immediately proceeds to supply its no longer useful gases to the infant plants and crops of grain which flourish on the surface. Thus do we see another striking evidence of the harmonious design which everywhere prevails between the animal and vegetable creation.

It has been said that a vegetable diet is preferred by the inhabitants of warm countries: to them sobriety is an easy virtue and a happy consequence of the climate. The people of northern regions, on the contrary, are voracious from instinct and necessity. They swallow enormous quantities of food, and prefer those substances which in digestion produce the most heat. Obliged to struggle incessantly against the action of cold, their life is but a continual act of resistance to external influences. Let us not reproach them with voracity, and their avidity for ardent spirits and fermented liquors. Those nations which inhabit the confines of the habitable world, in which man is scarcely able to withstand the severity of the climate, the inhabitants of Kamtschatka, the Samoiedes, &c., live on fish, that, in the heaps in which they are piled up, have already undergone a certain degree of putrefactive fermentation. In them there is a necessity for this inward excitement, which in our climate would be inevitably attended with disease, and probably death. The abuse of spirituous liquors is fatal to the European transported to the burning climate of the West Indies. The Russian drinks spirituous liquors with a sort of impunity, and lives on to an advanced age, amidst excesses under which an inhabitant of the south of Europe would sink.

The influence of climate not only affects alike the regimen of man in health, but of man in sickness; and it has been justly observed of medicine, that it ought to vary according to the places in which it is practised. A few substances, for the most part obtained from the vegetable kingdom, sufficed to Hippocrates in the treatment of diseases; and physicians who practise in a climate such as Greece, may imitate the simplicity of the father of medicine. Opium, bark, wine, spirits, aromatics, and the most powerful cordials, are, on the other hand, the medicines suited to the inhabitants of the north; and thus we are enabled to use freely those medicines which elsewhere would be attended with the utmost danger.

We are now prepared to understand the beautiful and wonderful harmony that exists between the distribution of man and plants over the globe; and no one, we think, can deny their meed of praise and admiration for the care and beneficence which this universal adaptation exhibits.

The frigid zone contains but few species of plants, and the verdure of those countries which lie within the polar circle are confined chiefly to the hills having a southern aspect, and the trees are of very diminutive growth. Besides mosses and lichens, there exist ferns, creeping plants, and some shrubs yielding berries of an agreeable flavour. The arctic regions of Europe are peculiarly favoured; for in certain parts of Lapland there are fine forests, and even rye and leguminous plants are produced.

In the high latitudes of the northern temperate zone are the pine and the fir, which show their adaptation to a cold climate by retaining their verdure in the midst of the regions of winter. To these, as advancing southward, succeed the oak, the elm, the beech, the lime, and other forest-trees. Several fruit-trees, among which are the apple, the pear, the cherry, and the plum, grow better in the northern half of this zone: while to its more southern parts, especially, belong the more delicate fruits, such as the olive, the lemon, the orange, and the fig, and, among trees, the cedar, the cypress, and the cork.

The space comprised between the 30th and the 50th parallels of latitude may be considered as the country of the vine and the mulberry. Wheat extends as far north as the 60th degree; oats and barley a few degrees farther. In the southern parts of this zone, maize and rice are more commonly cultivated.

The vegetation of the torrid zone is characterized by a wealth, a variety, and a magnificence, which are nowhere to be found in other regions of the globe. Under the beams of a tropical sun, the most juicy fruits arrive at perfection; and innumerable productions supply the wants and administer to the luxuries of man. There the grounds yield the sugar-cane, the coffee-tree, the palm, the bread-tree, the pisang, the immense baobab, the date, the cocoa, the vanilla, the cinnamon, the nutmeg, the pepper, the camphor, and numerous other fruits and aromatics. In South America is the remarkable tree called the *cow-tree*, which, when incisions are made in its trunk, yields abundance of a glutinous and nourishing milk.

CONCLUSION.

But we must hasten to conclude our interesting subject. Illustrations of design might be produced from the works of nature without end; every link in the chain of creation teems with proofs of it; in none can any one affirm with truth that it is wanting. Cursory as our remarks have been, they still must lead to the general conclusion, that not only design, but unity of design and identity of operation, pervade the works of nature, in as far as relates to organized existences; and even among those portions of creation which are not organic, there do we find the same evident desire and design to render them subservient to the wants and necessities of those which are. To several of these we have alluded, though it did not accord with our plan to allude to all, and we need only further draw attention to the remarkable uniformity in the plan of creation. The universe itself is a system; each part depending upon other parts, or being connected with other parts by some common law of motion, or by the presence of some common substance

One principle of gravitation causes a stone to drop towards the earth, and the moon to wheel round it. One law of attraction carries all the different planets round the sun. New countries are continually discovered, but the old laws of nature are always found in them—new plants, perhaps, or animals, but always in company with plants and animals which we already know, and always possessing many of the same general properties. We never get amongst such original or totally different modes of existence, as to indicate that we are come into the province of a new Creator, or under the direction of a different will. In truth, the same order of things attends us wherever we go. There is everywhere a perfect uniformity in the laws which regulate the phenomena of nature. And this very fact, while forcibly illustrating the unity of that power by whose instrumentality all that we see was ordered and originated, demonstrates most strikingly, at the same time, the surpassing wisdom of the same creative being. What agency, but one endowed with omniscience, could have educed results so mighty, from a few simple and uniform laws?—could have instituted and set in action these laws at the first, assured that, without change, or shadow of change, they would fulfil to the last all the great objects connected with the progressive development of the scheme of the universe? Thus, all that we behold around us, all that we can learn of nature, impresses us with a sense at once of the unity and greatness of the creative being. If these pages have tended to strengthen that conviction, they have attained their object. We cannot close them more fitly, perhaps, than by extracting a few lines from the powerful summing-up by the poet Young of the arguments on this very subject.

"What am I? and from whence?—I nothing know,
But that I am: and since I am, conclude
Something eternal: had there e'er been nought,
Nought still had been: eternal there must be,
But what eternal?—Why not human race?
And Adam's ancestors without an end?
That's hard to be conceiv'd. Yet grant it true,
Whence earth and these bright orbs?—Eternal too?
Grant matter was eternal, still these orbs
Would want some other father;—much design
Is seen in all their motions, all their makes:
Design implies intelligence, and art;
That can't be from themselves, or man: that art
Man scarce can comprehend, could man bestow?
Who motion, foreign to the smallest grain,
Shot through vast masses of enormous weight?
Who bade brute matter's restive lump assume
Such various forms, and gave it wings to fly?
Has matter innate motion? then each atom,
Asserting its indisputable right
To dance, would form a universe of dust:
Has matter none? Then whence these glorious forms
And boundless flights, from shapeless, and reposed?
Has matter more than motion?—has it thought,
Judgment, and genius?—is it deeply learn'd
In mathematics? Has it fram'd such laws,
Which but to guess a Newton made immortal?—
If so, how each sage atom laughs at me,
Who think a clod inferior to man!
If art to form, and counsel to conduct,
And that with greater far than human skill,
Resides not in each block—a Godhead reigns
And if a God there is, that God how great!"

HISTORY OF THE BIBLE—CHRISTIANITY.

Paul preaching at Athens.

OLD TESTAMENT.

The Bible is the most remarkable work now in existence. In the libraries of the learned there are frequently seen books of an extraordinary antiquity, and curious and interesting from the nature of their contents; but none approach the Bible, taken in its complete sense, in point of age, while certainly no production whatever has any pretension to rival it in the dignity of composition, or the important nature of the subjects treated of in its pages. The word *Bible* is of Greek origin, and, in signifying simply *the Book*, is expressive of its superiority over all other literary productions. The origin and nature of this every way singular work—how it was preserved during the most remote ages, and how it became known to the modern world in its present shape—form a highly interesting chapter of literary history.

The Bible comprehends the foundation of the religious belief of the Jews and Christians, and is divided into two distinct portions, entitled the Old and New Testament, the former being that which is esteemed by the Jewish nation, but both being essential in forming the faith of the Christian. The Old Testament is the largest department of the work, and appears a collection of detached histories, moral essays, and pious poetical compositions, all placed together in the order of time, or as they may serve for the purpose of mutual illustration. On taking a glance at the contents, the principal subject of narration seems to be the history of the Jews, commencing with an account of the creation of the world, and tracing their history, genealogically, through a series of striking vicissitudes and changes of situation. But when we examine the narratives minutely, it is found that there is another meaning than that of a mere historical elucidation. It is perceived that the whole train of events recorded, the whole of those lofty impassioned strains of poetry which distinguish the volume, are precursory and prophetic of a great change which, at a future period, was to be wrought on the moral character and fate of mankind, by the coming to the earth of a Messiah.

The authorship of the Old Testament has been universally ascribed, by both Jews and Christians, to pious men who were inspired or influenced by God to communicate to the world a correct knowledge of the foundations of religious belief and moral obligation. The Bible is hence called the Revealed Word of God, or the Sacred Scriptures. "We are to look to the Word of God, then, (says an able writer), as contained in the Scriptures of the

Old and New Testaments, for the only sure rule of faith and practice. But there is this singularity in the Sacred Scriptures, that we do not find in them a set treatise on any one of the interesting subjects which engage our attention as moral and religious beings. No attempt is made to prove the existence of a God; such an attempt would have been entirely useless, because the fact is universally admitted. The error of men consisted not in denying a God, but in admitting too many; and one great object of Scripture is to demonstrate that there is but one. No metaphysical arguments, however, are employed for this purpose. The proof rests on facts recorded in the history of the Jews, from which it appears that they were always victorious and prosperous so long as they served Jehovah, the name by which the Almighty made himself known to them; and uniformly unsuccessful, when they revolted from him to serve other gods. What argument could be so effectual to convince them that there was no God in all the earth but the God of Israel? The sovereignty and universal providence of the Lord Jehovah, are proved by predictions delivered by the Jewish prophets, pointing out the fate of nations and of empires, specifying distinctly the cause of their rise, the duration of their power, and the reason of their decline; thus demonstrating that *one* God ruled among the nations, and made them the unconscious instruments of promoting the purposes of his will.

"The writers, generally speaking, do not reason, but exhort and remonstrate; they do not attempt to fetter the judgment by the subtleties of argument, but to rouse the feelings by an appeal to palpable facts. But though there is no regular treatise in the Scriptures on any one branch of religious doctrine, yet all the materials of a regular system are there. The word of God contains the doctrines of religion in the same way as the system of nature contains the elements of physical science. In both cases, the doctrines are deduced from facts, which are not presented to us in any regular order, and which must be separated and classified before we can arrive at first principles, or attain to the certainty of knowledge; and in both cases, a consistent system can only be made out by induction and investigation. The very circumstance of no detailed system being given, renders it necessary to form one; for although a portion of religious and physical knowledge sufficient for the common purposes of life may be obtained by traditional information, and men may work conveniently enough by rules without possessing much general knowledge; yet they who would teach with profit must generalize, and they who would explain the ways of God must arrange, the materials which are so amply furnished, but which are presented apparently without order or plan."*

The periods when the act of writing all or greater part of the Scriptures took place, as well as most of the names of those who were instrumental in forming the work, have been ascertained with considerable accuracy, both from written evidence in the narratives themselves, and from the well-preserved traditions of the Jews. Generally speaking, it cannot be said that the books of the Old Testament are of a less antiquity than from two thousand three hundred to four thousand years—an antiquity considerably greater than that of any profane history. At whatever time, however, the different books were written, they were not collected from the sacred depositories of the Jews, where they had been carefully placed, till long after their immediate authors were deceased; and their present arrangement, as we shall afterwards explain, is of comparatively modern date.

From an early period, it was the custom of the Jews to divide the books of the Old Testament into three classes, which they respectively designated the *Law*, the *Prophets*, and the *Hagiographa*, or *Holy Writings*, which last division includes more particularly the *poetical* parts and some are of opinion that Jesus Christ alludes to this division of the Scriptures, when he says that "all things must be fulfilled that were written in the *Law of Moses*, and in *the Prophets*, and in *the Psalms*, concerning him." For by the book of *Psalms* they understood all the books of the third class. *The Law* comprehends the *Pentateuch*, that is, Genesis, Exodus, Leviticus, Numbers, and Deuteronomy—such including both a historical narrative, and the injunctions forming the legal code of the Jews. The prophetical books are eight: namely, 1. *Joshua*; 2. *Judges*, with *Ruth*; 3. *Samuel*; 4. *Kings*; 5. *Isaiah*; 6. *Jeremiah*; 7. *Ezekiel* and 8. *the twelve Lesser Prophets*. The first four books of this division are called *the Former Prophets*, and the last four *the Latter Prophets*. *The Hagiographa*, or *Holy Writings*, are nine, namely; 1. *Job*; 2. *the Psalms*, 3. *the Proverbs*; 4. *Ecclesiastes*; 5. *the Song of Songs*; 6. *Daniel*; 7. *Chronicles*; 8. *Ezra*, with *Nehemiah*; and 9. *Esther*.

According to the order in which the books of the Old Testament now stand, those of an historical nature are appropriately placed at the beginning. The first five books, having a chain of connection throughout, are Genesis, Exodus, Leviticus, Numbers, and Deuteronomy. These are styled the *Pentateuch*, such being the Greek compound for *five books*. They are likewise entitled the Books of Moses, from the belief that that enlightened Jewish leader composed them.

The Jews, or Hebrews, take the name of the sacred books from the first word with which each begins; but the Greeks, whom our translators generally follow, take the names from the subject-matter of them. Thus, the first book is called by the Hebrews *Bereshith*, which signifies *In the beginning*, these being the first words; but the Greeks call it *Genesis*, which signifies *Production*, because the creation of the world is the first thing of which it gives an account. It likewise contains an account of the increase of mankind; of their corruption of manners, and its cause; of their punishment by the Deluge; of the origin of the Jewish people from Abraham; of the manner in which God was pleased to have them governed; and, particularly, of the nature of the special superintendence vouchsafed to the Jewish nation by the Creator. This comprehensive narrative reaches from the creation of the world to the death of Joseph, or a period of 2369 years. (See article CHRONOLOGY.)

Exodus, the title of the second book of Moses, signifies in Greek, *The going out*, and was applied from the account which it gives of the Israelites going out of Egypt. In it are related the cruel Egyptian slavery under which the Jews groaned; their delivery by flight, and a passage through the Red Sea; the history of the establishment of their very peculiar law, and many remarkable transactions; concluding with the building of the Tabernacle, or place appropriated to the service of the Divinity. This book comprises the history of 145 years, from the death of Joseph till the building of the Tabernacle. The Hebrews call it *Veelle Shemoth*, that is, in English, *These are the names*, which are the words with which it begins.

The third book of Moses is called *Leviticus*, because it contains the laws which God commanded should be observed by those of the tribe of *Levi* who ministered at the altar. It treats at large of all the functions of the Levites; of the ceremonial of religion; of the different sorts of sacrifices; of the distinction of clean and unclean beasts; of the different festivals; and of the year of jubilee, or continued holiday. It likewise presents us with an account of what happened to the Jews during the space of one month and a half; that is, from the time the Tabernacle was erected, which was the first day of the first month of the second year after the Israelites came out of Egypt, till the second month of the same year, when God commanded the people to be num-

* Edinburgh Encyclopædia, article THEOLOGY.

bered. The Hebrews call this book *Vayicre*, that is, *And he called*, these being the first words; they call it also the *Law of the Priests*.

In the fourth book, which we call *Numbers*, Moses numbers the Israelites, and that, too, in the beginning of the book, which shows whence it had its name. The Hebrews call it *Voyedaber*, that is, *And he spake*. This book contains the history of all that passed from the second month of the second year after the Israelites came out of Egypt, till the beginning of the eleventh month of the fortieth year; that is, it contains the history of thirty-nine years, or thereabouts. In it we have also the history of the prophet Balaam, whom the King of the Midianites brought to curse the people of God, and who, on the contrary, heaped blessings upon the Israelites, and foretold the coming of the Messiah. It particularly mentions, also, the two-and-forty encampments of the Israelites in the wilderness.

The fifth book is called *Deuteronomy*, a Greek term, which signifies *The second law*, or rather, *The Repetition of the Law*, because it does not contain a law different from that which was given on Mount Sinai; but it repeats the same law, for the sake of the children of those who had received it there, and were since dead in the wilderness. The Hebrews call it *Elle-haddebarim*, that is, *These are the words*. Deuteronomy begins with a short account of what had passed in the wilderness, and then Moses repeats what he had before commanded, in Exodus, Leviticus, and Numbers, and admonishes the people to be faithful in keeping the commandments of God. After this, he relates what had happened from the beginning of the eleventh month to the seventh day of the twelfth month of the same year, which was the fortieth after their leaving Egypt. The discourse which is at the beginning of this book was made to the people by Moses on the first day of the eleventh month. According to Josephus, he died on the first day of the twelfth; and the Israelites, the Scripture says, mourned for him in the plains of Moab thirty days, and, consequently, during the whole of the twelfth month.

The Jews call the Pentateuch *the Law*, without doubt, because the law of God, which Moses received on Mount Sinai, is the principal part of it; and it is little to be doubted whether that great man was the writer of the Pentateuch. This is expressly declared both in Exodus and Deuteronomy. But as an account of the death of Moses is given in the last eight verses of this book, it is therefore thought that these verses were added either by Joshua or Ezra. The opinion of Josephus concerning them is very singular; he assumes that Moses, finding his death approaching, and being willing to prevent an error into which the veneration the people had for him might cause the Jews to fall, wrote this account himself; without which the Jews would probably have supposed that God *had taken him away*, like Enoch.

After the death of Moses, Joshua, by the order of the Divine Being, took upon himself the conducting of the Hebrew people, and succeeded Moses, to whom he had been a faithful servant, and by whom he had been instructed in what he ought to do. It is uncertain whether the book which contains the history of this successor of Moses be called *Joshua*, from the subject of it, or from his having been the writer of it. But it is certain that it contains an account of what passed from the death of Moses to that of Joshua. Nevertheless, there are several things in it which did not come to pass till after the death of this great man, and which, consequently, could not have been written by him. The common opinion as to the length of time it contains is, that Joshua discharged his office only for seventeen years, and that, therefore, this book contains no more than the history of that number of years.

After the death of Joshua, the Israelites were governed by magistrates, who ruled under the general designation of *Judges*; and the book which contains the history of these rulers is called the *Book of Judges*. This history begins with the death of Josnua, and reaches to that of Samson. We here see the people of God often enslaved in punishment of their crimes, and often wonderfully delivered from slavery. Towards the end of it, we have some instances of this people's inclination to idolatry, and of the corruption of their manners, even before they had been brought into slavery. Such are the histories of Micah, and of the Benjamites who abused the Levite's wife. This book contains the history of about three hundred years.

During the time of the government of Judges, there was a great famine in the land of Israel, which forced Elimelech, a native of Bethlehem, to retire into the land of Moab, with his wife Naomi and two children. Elimelech died there, as also his two sons, who had married two Moabitish women, one of whom was named Ruth. Naomi, after the death of her husband and her children, returned to Bethlehem, accompanied by Ruth, her daughter-in-law, who was there married to Boaz, Elimelech's near relation, and the heir to his estate. The book which contains this history is called the *Book of Ruth*. The beginning of it shows that it happened in the time of the Judges, but under which of them is not certainly known: some place it in the time of Shamgar or of Deborah. As to the writer of this book, some think that the books of Judges and Ruth were both written by Samuel; others attribute them to Hezekiah, and others to Ezra. The Jews place the book of Ruth among the five books which they usually read on all the festivals in the year. These five books are, the Song of Songs, Ruth, the Lamentations of Jeremiah, Ecclesiastes, and the book of Esther. In the Hebrew bibles they are printed or written apart by themselves, and are bound up together.

The four books following Ruth are called by the Greeks, and also in some Latin bibles, the *History of the Reigns*. Others call them all the *Books of Kings*, because they give an account of the establishment of the monarchy, and of the succession of the kings who reigned over the whole kingdom at first, and over the kingdoms of Judah and Israel after its division. At the beginning of these books is the history of the prophet Samuel, which gives light to that of the kings. The Jews call the first two of these books the *Books of Samuel*, perhaps because they contain the history of the two kings who were both anointed by Samuel, and because what is said of Saul in *the first*, and of David in *the second*, proves the truth of Samuel's prophecies. They give the name of the *Books of Kings* only to the other two, which in the Latin and French bibles are called the *third* and *fourth Books of Kings*.

The *first Book of Kings*, or the *first of Samuel*, contains the history of the high-priest Eli, of Samuel, and of Saul; and extends over a period of nearly eighty years.

The *second* contains the reign of David which is the history of about forty years. It is commonly believed that Samuel, Nathan, and Gad, were the writers of these two books; and indeed they are called, in the end of the first book of *Chronicles*, *David's historians*.

The *third*, or, according to the Hebrews, the *first Book of Kings*, begins with a relation of the manner in which Solomon came to the throne, and contains the whole of his reign. After that, an account follows of the division of the kingdom, and the history of four kings of Judah and eight kings of Israel. All these reigns, including that of Solomon, which occupies the first forty years, comprise the space of 126 years.

The *fourth* of these books contains the history of sixteen kings of Judah and twelve kings of Israel; and embraces a period of three hundred years. It likewise gives an account of the prophets who lived during this

time. It is quite uncertain who were the writers of the two last-mentioned books. They are, by some, attributed to Jeremiah or Ezra, but no very convincing proofs have been adduced in support of this opinion. It is evident, indeed, that these books form a varied collection of several particular histories.

The name of *Paralipomena*, which, in Greek, signifies the *history of things omitted*, is given to the two books which follow those of *the Kings*. These form, in fact, a supplement, containing what had been omitted in the *Pentateuch*, and the books of *Joshua*, *Judges*, and *Kings*, or rather they contain a fuller description of some things which had been therein only briefly related. Some give them the name of *Chronicles*, because they are very exact in mentioning the time when every transaction happened. We divide them into two books, as do also the Jews, who call them *Dibere Hayamim*, that is, an *Historical Journal*, the matters of which they treat having been taken from the Journals of the Kings. In the original language, however, the word *days* often signifies *the year*, and in this sense we may understand the term to signify properly *Annals*. The generally received opinion is, that Ezra was the compiler of these. In the *first* book, he begins with a succinct historical abridgment, from the creation of Adam to the return of the Jews from their captivity; and then he resumes the history of David, and carries it on to the consecration of Solomon, that is, down to the year before Christ, 1015. The history contained in the *second book* reaches down to the year before Christ, 536, when, upon the expiration of the seventy years of the captivity, Cyrus gave the Jews leave to return to their own country.

Ezra wrote the history of the return of the Jews from the captivity of Babylon into Judea. It is the history of about eighty-two years, from the year of the world 3468, when Cyrus became master of the eastern empire, by the death of his father Cambyses in Persia, and his father-in-law Cyaxeres in Media, to the year, 3550, which was the twentieth year of the reign of Artaxerxes, surnamed Longimanus. This book bears the name of Ezra, who was the writer of it.

The next book is a continuation of that of Ezra, and, therefore, it is by some called *the Second Book of Ezra*. It was Nehemiah, however, whose name it also bears, who wrote it, as is said, by the advice of Ezra. It contains the account of the re-establishment of Jerusalem, and of the Temple, and the worship of God. It is believed by some writers to be the history of about thirty-one years; but its chronology is exceedingly uncertain.

After this general history of the Jews, follow two histories of particular persons, namely, *Esther* and *Job*. The first contains the account of a miraculous deliverance of the Jews, which was accomplished by means of the heroine named Esther. The history of Job is not only a narration of his actions, but contains also the entire discourses which this pious man had with his wife and his friends, and is, indeed, one of the most eloquent and poetic books in the Holy Scriptures. It is uncertain who was the author.

Next to the *historical* books of Scripture, follow those of a moral nature. The first of these is the book of *Psalms*, which are likewise in some measure historical; for they recite the miracles which God had wrought, and contain, as it were, an abridgment of all that had been done for the Israelites, and that had happened to them. The Hebrews call them the *Book of Praises*, by which they mean, *of the praises of God*. The word *psalm* is Greek, and properly signifies the sound of a stringed instrument of music. The Hebrews sung the psalms with different instruments. We make but one book of them all, but the Hebrews divide them into five parts, which all end with the words *Amen*, *Amen*. Though the Psalms bear the name of David, yet they were not all composed by him: some of them are more ancient, and others are of a later date than his time; some of them being ascribed to Moses, Samuel, and Ezra. Speaking of the dedication of the second temple, Prideaux says, "In this dedication, the 146th, the 147th, and the 148th Psalms seem to have been sung; for, in the Septuagint versions, they are styled the *Psalms of Haggai and Zachariah*, as if they had been composed by them for this occasion; and this, no doubt, was from some ancient tradition; but in the original Hebrew, these psalms have no such title prefixed to them, neither have they any other to contradict it." It is not probable, however, that all those whose names they bear were the true authors of them: it is more likely that these are only the names of those to whom they were first given to sing.

After the Psalms are the *Proverbs*, which are a collection of moral sentences, of which Solomon was the writer. This name is given them by the Greeks, but the Hebrews call them *Misle*, that is *Parables*, or *Comparisons*; and the word may also signify *Sentences*, or *Maxims*. It is a collection of divine precepts, proper for every age and every condition of life.

The book which follows is also a *moral* one, and was likewise composed by Solomon. The Greeks call it *Ecclesiastes*, which answers to the name of *Koheleth*, which it bears in the Hebrew. Both these words signify, in our language, *a preacher*, or *one who speaks in an assembly*. In this book is given an admirable picture of the vanity of worldly expectations.

Among the *moral* books is also reckoned the *Song of Songs*; that is to say, according to the Hebrew manner of speaking, *a most excellent song*. It is an inspired production of Solomon, in the allegorical form of an *epithalamium*, or nuptial song significant of the marriage and fellowship between Christ and his people: "Its majestic style, its power on men's consciences to promote holiness and purity, the harmony of its language with that of Christ's parables, and of the book of Revelation; the sincerity of the bride in acknowledging her faults, and, in fine, its general reception by the Jewish and Christian church, sufficiently prove its authenticity."—*Brown*.

In regard to the Prophets, it may be observed, that all the Old Testament is considered to be in substance one continued prophecy of the coming of a Messiah; so that all the books of which it consists are understood to be in some sense *prophetical*. But this name is more especially given to those books which were written by persons who had a clearer knowledge of futurity, who forewarned both kings and people of what would happen to them, and who, at the same time, pointed out what the Messiah was to accomplish, whom they who are acknowledged to have been prophets had always in view; and this is what ought most especially to be taken notice of in their writings.

The Prophecies bear the names of those to whom they belong. Some learned men are of opinion that the Prophets made abridgments of the discourses which they had written, and fixed them up at the gates of the Temple, that all the people might read them; and that after this the ministers of the Temple might take them away, and place them among the archives, which is the reason why we have not the prophecies in the order in which they were written. But the interpreters of Scripture have long since laboured to restore that order, according to the course of their history.

The works of the Prophets are divided into two parts, the first of which contains *the Greater*, and the second, *the Lesser Prophets*. This distinction, of course, does not apply at all to the persons of the prophets, but only to the bulk of their works. *The Greater Prophets* are Isaiah, Ezekiel, Daniel, and Jeremiah. *The Lamentations* of Jeremiah make a separate book by themselves, containing that prophet's descriptions of the destruction

of the city of Jerusalem and of the captivity of the people. *The Lesser Prophets* are Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habbakkuk, Zephaniah, Haggai, Zechariah, and Malachi. They were formerly contained in one single volume, which the Hebrews call *Thereaser*, which means *Twelve*, or *the Book of the Twelve*.

The dates of many of the prophecies are uncertain, but the earliest of them was in the days of Uzziah, King of Judah, and Jeroboam the Second, his contemporary, King of Israel, about two hundred years before the captivity, and not long after Joash had slain Zechariah, the son of Jehoiada, in the court of the temple. Hosea was the first of the writing prophets, and Joel, Amos, and Obadiah published their prophecies about the same time.

Isaiah began his remarkable prophecies a short time afterwards, but his book is placed first, because it is the largest of them all, and is more explicit respecting the advent of Christ than any of the others. The language of this eminent writer is exceedingly sublime and affecting; so much so, that it has never been equalled by any profane poet either in ancient or modern times. It is impossible to read some of the chapters without being struck by the force of the prophetic allusions to the character and sufferings of the Messiah; and in consequence of these prevailing characteristics, the author is ordinarily styled the *Evangelical Prophet*, and by some of the ancients, a *Fifth Evangelist*. The Jews say that the spirit of prophecy continued forty years during the second Temple; and Malachi they call the Seal of the Prophecy, because in him the succession or series of prophets broke off, and came to a period. The book of Malachi, therefore, appropriately closes the sacred record of the Old Testament.

By referring to our historical sketch of the Jewish people,* it will be observed that the glory of Israel vanished at the period of the conquest and captivity of the nation, about six hundred years before Christ. As a consequence, though not an immediate one, the inspired writings of the Old Testament were concluded soon after this event, or probably four hundred years before the coming of the Messiah. Thus a period of from four to five centuries elapsed from the time when Malachi concluded his prophetic enunciations, till that in which the Evangelists penned the books descriptive of Christ's life and ministrations.

NEW TESTAMENT.

The second and lesser division of the Bible, as has been said, relates entirely to the Christian religion, or the fulfilment of that which was predicted and prefigured in the more ancient department of the work. This division of the Sacred Scriptures is generally styled the *New* Testament, or that which has been a later revelation and bequest; that portion of it which relates to the history of the life of Christ is called the *Gospel*, and by some the *Evangel*, both these words having the same meaning, and implying *good news*, or *glad tidings*, from the circumstance that the narratives contain an account of things which are to benefit mankind.

The New Testament, like the Old, is a compilation of books written by different inspired individuals, and all put together in a manner so as to exhibit a regular account of the birth, actions, and death of Christ—the doctrines to be promulgated—and the prophecies regarding the future state of the church which he founded. The historical books are the four *Gospels* and the *Acts of the Apostles*, all these being of the character of narratives of events; the doctrinal are the Epistles of Paul, and some others; the prophetic book is the last, and is called the *Revelations* or *Apocalypse of St. John*, having been written by that apostle while he was in the island of Patmos.

The four Evangelists, or writers, are Matthew, Mark, Luke, and John; these having, as is generally believed, been companions of Christ during his ministrations, and therefore personally acquainted with his life and character. Each of the four books is principally a repetition of the history of Christ, yet they all possess a difference of style, and each mentions some circumstances omitted by the others, so that the whole is essential in making up a complete life of the Messiah. These distinctions in the tone of the narratives, and other peculiarities, are always considered as strong circumstantial evidence in proof of their authenticity, and of there having been no collusion on the part of the writers. But, indeed, the events they record are detailed in so exceedingly simple and unaffected a manner, that it is impossible to suppose that they were written with a view to impose on the credulity of mankind. The veracity and actual belief of the Evangelists themselves are placed beyond a doubt.

The first book is written by Matthew, who was by birth a Jew, and exercised the profession of a publican—that is, a collector of the public tax or assessment imposed upon the Jewish people by their conquerors the Romans. Matthew, who was also called by the name of Levi, was one of the twelve apostles of Christ, and he is said to have written his narrative from thirty to forty years after the departure of his Master from the earth. Many of the ancients say that he wrote it in the Hebrew or Syriac language; but it is more probable that there were two originals—one in Hebrew, and the other in Greek, the former written A. D. 37 or 38, and the latter A. D. 61: and that these were respectively designed for the Hebrew and Gentile nations.

With regard to Mark, the writer of the second Gospel, it may be observed, that although Mark and Marcus was a common Roman name, there is reason to believe that this Evangelist was a Jew, who had changed his original appellation on being converted to the faith of Christ. Jerome says, that, after the writing of this Gospel, he went into Egypt, and was the first that preached the Gospel at Alexandria, where he founded a church, to which he offered an example of holy living.

The Gospel of St. Mark is much shorter than that of Matthew, not giving so full an account of Christ's sermons as that did, but insisting chiefly on his miracles; and in regard to these also, it is very much a repetition of what we have in Matthew, many remarkable circumstances being added to the incidents they related, but not many new matters. There is a tradition that it was first written in Latin, because it was written at Rome; but this is generally thought to be without foundation, and that it was written in Greek, as was St. Paul's epistle to the Romans, the Greek being the more universal language. The Gospel of Mark was written at a somewhat later period than that of Matthew.

Luke, the name of the third Evangelist, is considered by some to be a contraction of *Lucilius*; and he is said by St. Jerome to have been born at Antioch. Some think that he was the only one of all the penmen of the Scriptures that was not of the Israelites; that he was a Jewish proselyte, and was converted to Christianity by the ministry of St. Paul at Antioch; and that, after the coming of Paul into Macedonia, Luke was his constant companion. He had employed himself in the study and practice of physic; and hence Paul calls him *Luke the beloved Physician*. It is deemed probable that Luke wrote both his gospel and his narrative of the *Acts of the Apostles* at Rome, when he was there a prisoner with Paul, *preaching in his own hired house*—circumstances alluded to at the conclusion of the latter work. If this be the case, Luke's Gospel may be dated about thirty years after Christ's departure, or A. D. 63. Jerome

* See article HISTORY OF THE JEWS—HOLY LAND—ARABIA PETREA.

says that St. Luke died when he was eighty-four years of age and that he was never married. Dr. Cave observes, that "his way and manner of writing are accurate and exact, his style polite and elegant, sublime and lofty, yet perspicuous; and that he expresses himself in a vein of purer Greek than is to be found in the other writers of this sacred history." Thus he relates several things more copiously than the other Evangelists, and thus he especially treats of those things which relate to the priestly office of Christ.

The fourth Evangelist, John, was one of the sons of Zebedee, a fisherman of Galilee, the brother of James, one of the Twelve Apostles, and distinguished by the honourable appellation of *that disciple whom Jesus loved.* The Ancients tell us that John lived longest of all the Apostles, and was the only one of them who died a natural death, all the rest suffering martyrdom. It is now established that he wrote his Gospel about the year 97 or 98, when he was of an extremely old age.

After the Gospel or History of Jesus Christ, follows the history of what passed after his ascension and was transacted by the Apostles. The book, therefore, which contains this history, is called the *Acts of the Apostles.* It is a history of the rising church for about the space of thirty years. It was written, as has been already observed, by St. Luke the Evangelist, when he was with St. Paul at Rome, during his imprisonment there. In the end of the book he mentions particularly his being with Paul in his dangerous voyage to Rome, when he was carried thither a prisoner; and it is evident that he was with him when, from his prison there, Paul wrote his epistles to the Colossians and Philemon, for in both of these he is named by him.

Next to this come the *Epistles of St. Paul*, which are fourteen in number; one to the Romans; two to the Corinthians; one to the Galatians; one to the Ephesians; one to the Philippians; one to the Colossians; two to the Thessalonians; two to Timothy; one to Titus; one to Philemon; and one to the Hebrews. They contain that part of ecclesiastical history which immediately follows after what is related in the Acts. The principal matter contained in them is the establishment or confirmation of the doctrine which Jesus Christ taught his disciples. According as the difficulties which raised disputes among the Christians, or the heresies which sprang up in the church from the first age of it, required, St. Paul in these epistles clears up and proves all matters of faith, and gives excellent rules for morality. His epistles may be considered as a commentary on, or an interpretation of, the four books of the Gospel.

The epistle to the *Romans* is placed first, not because of the priority of its date, but on account of its superlative excellence, it being one of the longest and fullest of all, and, perhaps, also, on account of the dignity of the place to which it is addressed. It is gathered from some passages in the epistle, that it was written in the year of Christ 56, from Corinth, while Paul made a short stay there in his way to Troas. He was then going up to Jerusalem, with the money that was given to the poor saints there; which is spoken of in the fifteenth chapter of the epistle.

The two Epistles to the *Corinthians* were written about a year after that to the Romans, viz. A. D. 57; that to the *Galatians*, A. D. 56; to the *Ephesians*, A. D. 61; to the *Philippians*, A. D. 62; to the *Colossians*, A. D. 63; wo to the *Thessalonians*, A. D. 51 and 52; the first to *Timothy*, A. D. 64; the second to *Timothy*, A. D. 66; to *Titus*, A. D. 65; to *Philemon*, A. D. 62; and that to the *Hebrews*, A. D. 62. From which chronology it appears, that the epistles of St. Paul are placed in the New Testament rather according to the dignity of the cities to which they were sent, than according to the order of time in which they were written; for the epistles to the Thessalonians were those he wrote first, though that to the Romans is placed before them. Interpreters are agreed that the last epistle which he wrote was the second to Timothy.

St. Paul wrote to the churches of some particular places, or to some particular persons; but the other epistles which follow his are called *catholic*, that is (universal), because, with the exception of the second and third of St. John, they were not addressed to any particular church or individual, as his were, but to the whole church in general. These are—one of St. James; two of St. Peter; three of St. John; and one of St. Jude.

The date of most of these epistles is extremely uncertain, but the most generally received chronology of them is as follows:—That of St. James, A. D. 61; of St. Peter, A. D. 66 and 67; of St. John, A. D. 80 and 90; of St. Jude, A. D. 66.

It has sometimes occurred to the minds of well-disposed persons, that it would have been better for Christianity had there never been any other record of its origin and doctrines than the writings of Matthew, Mark, Luke, and John. But, however plain and satisfactory the histories of these Evangelists may be, and however little they admit of controversy, it may, on the other hand, be observed, that the strong arguments and illustrations brought forward in the epistles by Paul and others, were necessary in order to combat the sophistry of the Greeks and the self-sufficient philosophies of other nations. Paul, the chief of the epistle writers, who became a Christian by conversion, after Christ had departed from the earth, is the great champion of the faith, and exposes, in strong and perspicuous language, the hidden depravities of the human heart; so that, where the affecting discourses and sufferings of the Messiah failed to convert and convince, the reasoning of this great writer is calculated to silence and subdue those who stubbornly resist the benignant influence of the Christian faith.

Such, then, were the various books written to convey to posterity a faithful account of Christ's life and mission, and consequently of the religion which it was his purpose to institute. It will have been observed, that the whole were inscribed within the first century, and gradually accumulated in the hands of the primitive church, as an imperishable basis on which the faith of Christians should be founded.

AUTHENTICITY OF THE SCRIPTURES.—APOCRYPHA.

With respect to the authenticity of both the Old and New Testament books, as generally received, we of course look to the estimation in which they were respectively held by those with whom they had been deposited, and who unquestionably possess the best evidences of their credibility. The Jews, as is well known, were most scrupulous in preserving entire the works of their inspired writers, and of preventing the intrusion of literal errors into the copies which were from time to time transcribed. Of the fidelity of the original text, there cannot, we think, be any reasonable doubt, and although there are what are called various readings, these are of an exceedingly unimportant character. Referring to this subject, it is said by the learned Dr. Adam Clarke, "that all the omissions of the ancient manuscripts, put together, would not countenance the omission of any essential doctrine of the gospel, relative to faith or morals; and all the additions countenanced by the whole mass of manuscripts already collated, do not introduce a single point essential either to faith or morals, beyond what may be found in the Complutensian or Elzevir editions." Among other means adopted by the Jews to preserve the integrity of the Scriptures, was that of noting and recording the exact number of words, verses, points, and accents, in each book. The duty of doing so was the province of the Jewish doctors or learned men, called Masorites. By these acute grammarians, all

the verses of each book and of each section were numbered, and the amount placed at the end of each in numerical letters, or in some symbolical word formed out of them; the middle verse of each book was also marked, and even the very letters were numbered; and all this was done to preserve the text from any alteration, by either fraud or negligence. For instance, Bereshith, or Genesis, is marked as containing 1534 verses, and the middle one is at—"And by thy sword thou shalt live," (xxvii. 40.) The lines are 4395; its columns are 43, and its chapters 50. The number of its words is 27,713, and its letters are 78,100. The Masoritic notes, or Masorah, as the work is called, contain also observations on the words and letters of the verses; for instance, how many verses end with the letter *samech*; how many there are in which the same word is repeated twice or thrice; and other remarks of a similar nature.

It seems now generally agreed upon that the Masorites of Tiberias, during the fourth century of the Christian era, were the inventors of the system of the *vowel-points and accents* in the Hebrew Bible; and although they multiplied them very unnecessarily, it must be allowed that they were an improvement of considerable importance. From the *points* we learn how the text was read in their time, as we know they were guided in affixing them by the mode of reading them which then prevailed, and which they supposed to have been traditionally conveyed down from the sacred writers.

The respect which the Jews have uniformly paid to the sacred books, has been almost allied to superstition. They are directed to be written upon parchment, made from the skin of a clean animal, and to be tied together with strings of a similar substance, or sewn with goats' hair which has been spun and prepared by a Jewess. It must be likewise a Jew that writes the Law, and they are extremely diligent and exact in it, because the least fault profanes the book. Every skin of parchment is to contain a certain number of columns, which are to be of a precise length and breadth, and to contain a certain number of words. They are to be written with the purest ink, and no word is to be written from memory; it must be first orally pronounced by the copyist. The name of God is directed to be written with the utmost attention and devotion, and the transcriber is to wash his pen before he inscribes it on the parchment. If there should chance to be a word with either a deficient or a redundant letter, or should any of the prosaic part of the Old Testament be written as verse, or *vice versa*, the manuscript is vitiated. No Hebrew manuscript with any illumination is, on any account, admitted into a synagogue, although private individuals are permitted to have them ornamented for their own use; but in the illustrations, the resemblance of any animal denounced by the Jews as unclean cannot be admitted. Among the modern Jews, the book of Esther, in particular, is frequently decorated with rude figures of various kinds; but with respect to this book, it must be observed that, owing to its wanting the sacred name of God, it is not held in such repute for holiness as the other books are. The manuscripts for private use may be either upon parchment, vellum, or paper, and of various sizes. "There is," says Prideaux, "in the church of St. Dominic, in Bononia, a copy of the Hebrew Scriptures, kept with a great deal of care, which they pretend to be the original copy, written by Ezra himself; and, therefore, it is there valued at so high a rate, that great sums of money have been borrowed by the Bononians upon the pawn of it, and again repaid for its redemption. It is written in a very fair character, upon a sort of leather, and made up in a roll, according to the ancient manner; but its having the vowel-points annexed, and the writing being fresh and fair, without any decay, both these particulars prove the novelty of that copy."

To open and shut up the roll or book of the Law, to hold it, and to raise and show it to the people, are three offices, which are sold, and bring in a great deal of money. The skins on which the Law is written are fastened to two rollers, whose ends jut out at the sides beyond the skins, and are usually adorned with silver; and it is by them that they hold the book when they lift it up, and exhibit it to the congregation; because they are forbidden to touch the book itself with their hands. All who are in the synagogue kiss it, and they who are not near enough to reach it with their mouths, touch the silken cover of it, and then kiss their hands, and put the two fingers with which they touched it upon their eyes, which they think preserves the sight. They keep it in a cupboard, which supplies the place of the ark of the covenant, and they therefore call this cupboard *Aron*, which is the Hebrew name for the *Ark*; and this is always placed in the east end of the synagogue. He who presides chooses any one whom he pleases to read and explain the Scripture, which was a mark of distinction, as we see in the thirteenth chapter of *the Acts*, where we find *the rulers of the synagogue* desiring the Apostles, when they were in the synagogues, to make a discourse to the people. Ordinarily speaking, a *priest* began, a *Levite* read on, and at last one of the people, whom the president chose, concluded. He who reads stands upright, and is not suffered so much as to lean against the wall. Before he begins, he says with a loud voice, *Bless ye God*, and the congregation answers, *Blessed be thou, O say God; blessed be thou for ever*; and when the lesson is ended, the book is rolled up, and wrapped in a piece of silk.

Certain books, collectively termed the *Apocrypha*, are sometimes included in the Bible, and of these it is necessary to give a brief account. The term Apocrypha is Greek, signifying *hidden* or *concealed*, and is applied to those books whose origin is unknown, or the authenticity of which is either doubtful or absolutely denied. Some writers divide the sacred books into three classes—the canonical, the ecclesiastical, and the apocryphal. In the first they place those whose authority has never been questioned in the catholic or universal church; in the second, those which were not received at first, but which were nevertheless read in the public assemblies, as books that were useful, though they never placed them upon the same footing of authority as the former; and in the third, they placed the books which were of no authority, which could not be made to appear in public, but were kept *hidden*, and were therefore called *apocryphal*, that is, *concealed*, or such as could not be used in public. "Let us lay aside those books which have been called *apocryphal*," says St. Augustine, "because their authors were not known to our fathers, who have, by a constant and certain succession, transmitted down to us the authority and truth of the Holy Scriptures. Though some things in these apocryphal books are true, yet as there are in them multitudes of others which are false, they are of no authority."

The Apocrypha consists of *fourteen* books, namely, *First* and *Second Esdras*, *Tobit*, *Judith*, the rest of the chapters of the book of *Esther*, the *Wisdom of Solomon*, *Ecclesiasticus*, *Baruch*, the *Song of the Three Holy Children*, the *History of Susanna*, the *Story of Bel and the Dragon*, the *Prayer of Manasses*, and the *First and Second Book of the Maccabees*. Biblical historians assert that these books were of a later composition than the other parts of Scripture, never existed in the proper Hebrew tongue, and were at no time received by the Jews as the writings of inspired men. It is the general belief of such Scripture critics as have made this subject their study, that the whole or greater part of the Apocrypha was written between the time of the Babylonish captivity and the appearing of Christ, and by persons who had mixed with the Greeks and other foreign nations. The apocryphal books, it is observed, are never quoted in the New Testament, or by the Jewish writers Philo

and Josephus; and by the early councils of the Church they were formally excluded from the canon. On these points, however, as is well known, there exists a great difference of opinion—the Roman Catholic Church viewing the apocryphal books as canonical, and the Protestants entirely setting them aside, or using them only as works of ordinary edification, or for the light which they throw on the phraseology of Scripture and the history and manners of the East. With respect to the meaning and application of the term *canonical*, we have appended a note beneath.*

While attempts have been made to intrude uncanonical books into the authentic body of ancient Scripture, the New Testament has been exposed to similar vitiation. In the third and fourth centuries, there were gospels forged by divers sects, and published, one under the name of St. Peter, another of St. Thomas, another of St. Philip, &c. But they were never owned by the church, nor was any credit given to them, as the learned Dr. Whitby shows. And he gives this good reason why we should adhere to records written at or near the time of Christ—"Because," says he, "whatever the pretences of tradition may be, it is not sufficient to preserve things with any certainty, as appears by experience. For whereas Christ said and did many memorable things, which *were not written*, tradition has not preserved any one of them to us, but all is lost except what was written; and that, therefore, is what we must abide by."

What has been said of the integrity of the text of the Old Testament, may be applied also to the New, in as far as it may be charged with corruptions in consequence of the negligence of transcribers. Though it must be admitted that the New Testament text, by being more frequently transcribed than the Old, became liable to a greater proportion of various readings, originating from the mistakes of the transcribers, yet this very circumstance was likewise a sure protection against wilful perversion or corruption; for, in proportion as copies were multiplied, the difficulty of effecting a general corruption was increased. No such system as that of Masorites was ever adopted to preserve the purity of the New Testament text; but we have it in our power to use various means for ascertaining what is the true reading of the text, without having recourse to such a plan as that of the Masorah; and Concordances, which are now brought to an uncommon degree of perfection, are of great use in preserving it from corruption. It need only be added, that we have the consent of the church, in all ages and countries, to prove the fidelity of the New Testament Scriptures, and any variety occurring in the readings in modern times can arise only from heedlessness, or motives of an improper kind.

With respect to the credibility, on general grounds, of the New Testament writers, and that the books are of that antiquity usually assigned to them, there cannot be any reasonable doubt; in other words, the writers wrote the books in perfect good faith, believing that what they penned was true, and the very books are those now before us in the New Testament. On these points, an able divine remarks:—"It must be esteemed a strong circumstance in favour of the antiquity of the New Testament, that on a subject in which the chances of detection are so numerous, and where we can scarcely advance a single step in the narrative without the possibility of betraying our time by some mistaken allusion, it stands distinguished from every later composition, in being able to bear the most minute and intimate comparison with the contemporary historians of that period. The argument derives great additional strength from viewing the New Testament, not as one single performance, but as a collection of several performances. It is the work of no less than eight different authors, who wrote without any appearance of concert, who published in different parts of the world, and whose writings possess every evidence, both internal and external, of being independent productions. Had only one author exhibited the same minute accuracy of allusion, it would have been esteemed a very strong evidence of his antiquity. But when we see so many authors, exhibiting such a well-sustained and almost unexpected accuracy through the whole of their varied and distinct narratives, it seems difficult to avoid the conclusion, that they were either the eye-witnesses of their own history, or lived about the period of its accomplishment."*

A minor point in the history of the Bible now requires to be noticed. In the earliest times the writings of the Old Testament were divided into books and short paragraphs equivalent to verses; but the division into chapters and verses in which they now appear was of a much later date. The separation of both the Old and New Testament books into chapters and verses, is by some writers ascribed to Arlott, a Tuscan monk, or rather to Hugh Cardinalis in the thirteenth century; while others allege that, from the comments of Theophylact on the Gospel, this must have been effected two centuries earlier. The question is not very important, and it is sufficient for the purposes of general knowledge to be informed, that the divisions of the Scriptures into chapters and verses was the work of a Roman Catholic divine some time between the eleventh and thirteenth centuries.

---

* The meaning of this term will be gathered from the following explanations in the *Encyclopædia Americana* (Conversations Lexicon):—"The term *canon* (Greek) signifies a measure, rule, or standard; thence canon is used to denote the rule or standard of primitive Christianity. The same term is employed to designate the collection of books containing this rule, that is, the canonical books of the Holy Scriptures which the Church acknowledges. The canon of the books of the Old Testament, as drawn up by the Jews in the fourth century before Christ, receives in this form equal respect among all Christians, because Christ and his apostles have expressly appealed to them, and pronounced them writings inspired by God. The apocryphal books of the Old Testament, whose canonical character the Jews did not acknowledge, the Eastern [or Greek] Church has never received; but the Western [or Roman] Church declared them canonical, in the African council, about the end of the fourth century." What follows is said to be the explanation of a Catholic. "The Holy Scriptures are esteemed sacred by the Catholics, because the Church has transmitted them from age to age as sacred, and illustrative of revelation, as far as any writings can be. The Church has only declared what writings have been handed down as of divine origin. The catalogue of these Holy Scriptures is the canon; the writings themselves are called canonical books. In this sense, the Protestant Church has no canon; it rejects the authority of all traditions of the Church. Hence, in order to be consistent, it must leave every Protestant, on free investigation, to decide what books he will regard as canonical. But the Bible, the pillar of the Protestant faith, is made up of separate canonical books; and by pursuing such a course, the basis of the Protestant faith might be undermined. It has been agreed, therefore, however inconsistently, to adopt the New Testament canon of the Catholic Church. But, in fixing the canon of the Old Testament, the decisions of the Catholic Church have been rejected; and, contrary to the African councils and the usage of the Romish Church, established by the Council of Trent, part of Esther, also Baruch, Tobit, Judith, Wisdom, Ecclesiasticus, or Jesus the son of Sirach, the two books of Maccabees, the Song of the Three Youths in the Fiery Furnace, described in Daniel, together with the last two chapters of this prophet, are thrown out as uncanonical or apocryphal. It is worthy of mention, that a controversy on this subject broke off the negotiations for a union of the Catholic and Protestant Churches, which commenced in the beginning of the eighteenth century between Leibnitz, Molanus, and Bossuet." The above explanation is scarcely correct, as respects the Protestant idea of the canon of Scripture. The church of England, for example, does not implicitly adopt the Roman Catholic canon: it founds its rule of faith on that which is believed to have been the canon in the earliest centuries of Christianity. "The Church of England, in determining the sense of the Bible, listens with respect to the voice of the most ancient fathers and doctors; and not only with respect, but even with submission, where that voice is all but unanimous."—*Life of Jewel.* "The Council of Trent confirmed the decision of some previous councils, by which the books of the Apocrypha were declared to belong to the canon of the Old Testament; contrary to that of the council of Laodicea, A. D. 364, which, by an express canon, sanctioned the catalogue of the sacred books as received by Protestants."—*Josiah Conder's View of all Religions.*

* Edinburgh Encyclopædia, article CHRISTIANITY.

MODERN HISTORY OF THE BIBLE.

It will have been gathered from the preceding details, that the books of the Old Testament were originally written in the Hebrew language, that being the tongue spoken by the ancient Jewish people; and that the books were inscribed on rolls or sheets of carefully prepared parchment, and deposited only in the Temple, or preserved in the hands of the highest officers of religion. In this condition, and either in the Hebrew or Chaldaic tongue, they existed till translated into the language of the Greeks, under the name of the Septuagint. With respect to the exact period at which this translation was effected, history presents no uniform account. The translation is ordinarily assigned to seventy Jewish elders or interpreters—and hence the term *Septuagint*, which signifies seventy—who were employed by the Egyptian ruler, Ptolemy Philadelphus, to furnish a copy of the Scriptures in Greek, a language with which he and his people were acquainted. Whether the narration of this circumstance, which is said to have occurred 277 years before the Christian era, be conformable with credible history, it is at least certain that the translation called the Septuagint was effected by Jews skilled in the Greek tongue, at about the time specified, and it was afterwards held in high esteem by the Sanhedrim at Jerusalem. It may further be explained, that it was this Greek version of the Scriptures which was always quoted by our Saviour and his apostles, whenever they made an appeal to the sacred writings. With the earliest organization of the Christian church may be said to have commenced a new era in the history of the Bible. The Old Testament books, whether in the form of Hebrew, Chaldaic, or Greek versions, were still cherished by the Hebrew priesthood as they are at this day; but copies were likewise accessible to the early Christians, and by these pious apostles and disciples they were treasured as the prophetic testimony of God's eternal design for the salvation of mankind, in the grand event which had now actually occurred—the coming of Jesus Christ.

When the books of the New Testament were collected and authenticated by the early fathers and other members of the Christian church, they were held in equal esteem with those of the Old, and carefully preserved along with them. Though still in detached manuscripts, they were generally in the Greek tongue; but, during the first three centuries of our era, Latin, or the language of the Romans, came largely into use in literature, and, in the same manner as the modern European languages in later times superseded the Latin, so did the Latin supersede the Greek. Augustine (born 354—died 430) mentions that, previous to his time, there existed a great number of Latin versions of the Scriptural writings. "We know those who translated the Scriptures into *Greek*," says he, "and the number of them is not great; but the number of the *Latin* translators is infinite. When the faith came to be established, the first man who found a Greek copy, notwithstanding the little knowledge he had of the two languages, boldly undertook a translation of it." From another passage of his writings it has been generally concluded that there was one particular version, called "the Italian," in higher estimation than the rest, and which was the authorized version of the Roman churches. However this may be, it is certain that the Latin church required a version of the Scriptures formed directly from the Hebrew, as all the Latin translations in existence at that time had been taken from the SEVENTY. Jerome, who was the contemporary of Augustine, was in every respect best suited, of [illegible] of the learned men of that time, to the task of effecting a new translation, which he accordingly undertook. He began by correcting some books of the Old Testament in the Latin Bible, particularly the version of the Psalms, and marked those passages wherein any difference existed between the Latin version, the Greek of the Seventy, and the Hebrew original. He had early applied himself to the study of the Hebrew language, and at different periods had the assistance of five Jewish teachers; he had access, also, to the works of Origen, who published what is called the *Hexapla*, that is, the Bible in *six* different languages. From these he must have derived considerable assistance in the work he undertook—that of translating into Latin all the books of the Old Testament, to which he added a corrected edition of the common version of the New.

The work thus ascribed to Jerome (or St. Jerome, as he is ordinarily called) received the name of the *Vulgate*, and both by Christians and Jews has been considered a faithful translation. It was sanctioned by the Council of Trent, since which time corrected editions have been published under the authority of the Pope Sextus V. and Clement VIII. By the Roman Catholic body it is held in the highest esteem, and is reckoned equivalent in value to the Scriptures in the original tongues.

This seems to us the most proper place to notice—what must be clear to every one's comprehension—that, for the safe custody and verification of the Scriptures, from the period at which the New Testament books were collected, we are indebted to the Church, or, to speak more plainly, that series of ecclesiastical functionaries whose history is extended from the apostolic times till the present. Until the Bible, therefore, was secured to the people by the greatest of all mechanical applications, the art of printing, and in that respect placed beyond the reach of private interpolation or error, its safety, as a record, was dependent on the care and affection of the church, and for the faithful performance of that important service, no one surely will refuse a due meed of thankfulness and praise. From motives no doubt conscientious, many who have now the Bible in their hands may consider the Church a valueless institution; but to this incorporation are they unquestionably indebted for preserving the Scriptures through ages of persecution and civil uproar. From the era of Augustine and Jerome, when copies of the sacred books came into considerably greater request by the scattered branches of the Church, transcripts were effected by priests and latterly by monks, with a diligence and accuracy which demand our utmost esteem and approbation. In the cells of monasteries, surrounded by hordes of barbarous nobles and their serfs, learning found refuge from oppression; and there, in the darkest ages of European history, were humble and pious ecclesiastics engaged, certainly from no worldly consideration, in penning copy after copy of the Sacred Writings, and bequeathing them as memorials of their industry to future and more fortunate generations.

Both before and after the application of printing to multiply copies of the Bible, translations, either direct from the original tongues or from the Greek versions, were effected by almost every people to whom Christianity was introduced. Thus, copies of the Scriptures in Arabic, Persian, Sclavonic, and other tongues were produced. One of the most ancient of these is that translated for the use of the Armenian Christians in the fifth or sixth century.* [illegible] Scriptures are

* "For the more commodious comparison of different versions, many of them have been sometimes joined together. In his eightfold Bible, Origen placed, in different columns, a Hebrew copy, both in Hebrew and in Greek characters, with six different Greek versions. Elias Hutter, a German, about the sixteenth century, published the New Testament in twelve languages, namely, in Greek, Hebrew, Syriac, Latin, Italian, Spanish, French, German, Bohemian, English, Danish, Polish; and the whole Bible in Hebrew, Chaldaic, Greek, Latin, German, and a varied version. But the most esteemed collections are those in which the originals and ancient translations are conjoined, such as the Complutensian Bible, by Cardinal Ximenes, a Spaniard; the King of Spain's Bible, directed by Montanus, &c.; the Paris Bible, by Michael Jay, a Frenc

understood to have been translated into Anglo-Saxon, for use in the first British churches, as early as the sixth or seventh centuries; and the whole Bible was translated by Bede, an eminent Romish ecclesiastic, in the beginning of the eighth century. The first English Bible we read of was that translated by Wickliffe, one of the earliest English reformers, about the year 1360, but never printed. The part of the English Bible first printed was the New Testament, translated by William Tindal, assisted by Miles Coverdale; it was printed abroad in 1526, but, giving offence to the church, was bought up and burnt. "In 1532, Tindal and his associates finished the whole Bible except the Apocrypha, and printed it abroad: but while he was afterwards preparing for a second edition, he was taken up and burnt for heresy in Flanders. On Tindal's death, his work was carried on by Coverdale, and John Rogers, superintendant of an English church in Germany, and the first martyr in the reign of Queen Mary, who translated the Apocrypha, and revised Tindal's translation, comparing it with the Hebrew, Greek, Latin, and German, and adding prefaces and notes from Luther's Bible. He dedicated the whole to Henry VIII. in 1537, under the borrowed name of Thomas Matthews; whence this has been usually called *Matthews's Bible*. It was printed at Hamburgh, and license obtained for publishing it in England by the favour of Archbishop Cranmer and the Bishops Latimer and Shaxton. The first Bible printed by authority in England, and publicly set up in churches, was the same Tindal's version, revised, compared with the Hebrew, and in many places amended, by Miles Coverdale, afterwards Bishop of Exeter, and examined after him by Archbishop Cranmer, who added a preface to it; whence this was called *Cranmer's Bible*. It was printed by Grafton, was of large size, and published in 1540; and, by a royal proclamation, every parish was obliged to set one of the copies in its church, under the penalty of forty shillings a month; yet, two years after, the bishops obtained its suppression by the king. It was restored under Edward VI., suppressed again under Queen Mary, and restored again in the first year of Queen Elizabeth, and a new edition of it given in 1562. Some English exiles at Geneva, in Queen Mary's reign, namely, Coverdale, Goodman, Gilbie, Sampson, Cole, Whittingham, and Knox, effected a new translation, printed there in 1560—The New Testament having been printed in 1557—hence called the *Geneva Bible*; containing the variations of readings, marginal annotations, &c., on account of which it was much valued by the Puritan party in that and the following reigns. Archbishop Parker resolved on a new translation for the public use of the church, and engaged the bishops and other learned men to take each a share or portion. These being afterwards joined together, and printed with short annotations in 1568, in large folio, made what was afterwards called the *Great English Bible*, and commonly, the *Bishop's Bible*. In 1589, it was also published in octavo, in a small but fine black letter: and there the chapters were divided into verses; but without any breaks for them, in which the method of the Geneva Bible was followed, which was the first English Bible where any distinction of verses was made. It was afterwards printed in large folio, with corrections, and several prolegomena, in 1572: this was called *Matthew Parker's Bible*. The initial letters of each translator's name were put at the end of his part. The archbishop overlooked, directed, examined, and finished the whole. This translation was used in the churches for forty years, though the Geneva Bible was more read in private houses, being printed above twenty times in as many years."

Various editions of the Bishop's Bible were printed at London in black letter at the beginning of the seventeenth century; but notwithstanding the care that had been expended on it, the version was not very correct, and its language was often far from elegant. To amend these deficiencies, and to obtain a really excellent version, James I. ordered an entirely new translation, which is that now in common use throughout Great Britain. To effect this very important undertaking, forty-seven distinguished scholars were appointed, and divided into six classes. Ten at Westminster were to translate to the end of 2d Kings; eight at Cambridge were to finish the remaining historical books and the Hagiographa; at Oxford, seven were engaged on the Prophets, eight upon the four Gospels, the Acts of the Apostles, and the Apocalypse: the Apocryphal books were to be translated at Cambridge. Each individual translated all the books allotted to his class; the whole class then compared all the translations, and adopted the readings agreed on by the majority. The book, thus finished, was sent to each of the other classes. Three years were consumed in this arduous duty of translating and examining. Copies were then sent to London, one from each of the abovenamed places. Here a committee of six, one from each class, reviewed the whole, which was last of all revised by Doctor Smith, and Doctor Bilson, Bishop of Winchester. Having received the approbation of the king, himself no mean scholar, it was printed in 1611. We are not informed by any writer, whether the translation was effected from Hebrew copies of the Old Testament or the Greek Septuagint, or whether any transcriptions of the original manuscripts were consulted;* but it is allowed by all persons competent to judge, that the version possesses extraordinary merit, and is the most perfect ever produced.

CHRISTIANITY.—HISTORY OF THE CHURCH.

Early History.

At the period of Christ's appearance on earth,† the land of Judah had sunk to the condition of a Roman province, and its people, the Jews, were in a condition not only of civil but of great moral degradation. Their religion, as appears from all history, had degenerated from its ancient and lofty character, and existed only as a system of empty external observances in the hands of a priesthood to the last degree corrupt. The leaders of the people, and the chief priests, according to the account of Josephus, were persons of profligate manners, who had purchased their places by bribes or by acts of iniquity, and who maintained their authority, in subordination to the Roman civil power, by flagitious crimes. The multitude, affected by the example of their superiors, were not less corrupted in morals; and in a general sense it may be understood that the entire nation was

gentleman, in ten large folio volumes, copies of which were published in Holland, under the name [or sanction] of Pope Alexander VII., and that of Brian Walton, afterwards Bishop of Chester. This last is the most regular and valuable; it contains the Hebrew and Greek originals, with Montanus's interlineary version; the Chaldee Paraphrases, the Septuagint, the Samaritan Pentateuch, the Syriac and Arabic Bibles, the Persian Pentateuch and Gospels, the Ethiopic Psalms, Song of Solomon, and New Testament, with their respective Latin translations; together with the Latin Vulgate, and a large volume of various readings, to which is ordinarily joined Castel's Heptaglot Lexicon—all included in eight volumes folio."—*Brown's Dictionary of the Bible.*

Biblical scholars are now greatly assisted in their studies by the publication of polyglott editions of the Bible, containing in parallel columns versions in various ancient and modern languages. The word *polyglott* signifies many tongues.

* The most ancient manuscripts of the Bible, in the original Hebrew, are to be found among the Jews in Spain (or were so some years ago), but none of them is above seven or eight hundred years old: a manuscript in the Bodleian Library at Oxford is thought to be seven hundred years old; in the library of the Vatican at Rome there are manuscripts, we believe, of parts of the Old and New Testament, which are of considerable antiquity. The first edition of the entire Hebrew Bible was printed at Soncino in 1488: and the Brescian edition of 1494 was used by Luther in making his German translation.

† The term *Christ* is from the Greek, and signifies "the Anointed:" *Messiah*, from the Hebrew, has the same meaning.

in a state of lamentable disorder. To aggravate the distractions of the people, they were divided into a variety of sects, who, in proportion as they neglected the essentials of religious faith and practice, occupied themselves in disputes respecting matters of inferior concern. Of these sects, three in a great measure eclipsed the rest, both by the number of their adherents, and also by the weight and authority which they acquired: these were the Pharisees, the Sadducees, and the Essenes. The chief difference of opinion among these leading sects regarded the interpretation to be put on the *words* in the Holy Scriptures, and none of them seemed to have the interests of true piety at heart. The best of the three was the Essenes, who discountenanced ostentation in religious offices, and inclined to lives of secluded meditation. While the Jews, then, were thus broken up into contending sects, and were apparently in a state of profound ignorance of the true principles of religion, Jesus Christ appeared among them, to execute his divine mission, which referred not only to them but the whole human race. In the writings of the Evangelists we are furnished with so remarkably precise an account of the birth and public ministrations of Christ, as also of his death and passion, as to leave nothing to be said here on the subject; and we pass on to an enunciation of the principles which it was the object of his mission to accomplish, and an historical sketch of that universal society of believers, the Church, which he empowered to work out his designs.

Supposing Christianity, or the religion of Christ, to be reducible to a single principle, it might be described as an universal truth adapted to all mankind, and of a divine, all-uniting power—a principle of love and universal brotherhood, without respect of nation, age, rank, colour of skin, or any other exterior circumstance; in short, a system of faith and practice for the whole human race. A religion to be so universally applicable should necessarily embrace no tenet or observance which required special localization. Judaism required a periodic visitation to the Temple at Jerusalem; Mohammedanism requires the performance of pilgrimages to certain cities in Arabia, also attention to forms only suitable to the daily and seasonal influences of a warm climate; Hindooism enjoins constant ablutions in the Ganges, besides other local observances—all which mark these religions as but referable to certain nations and countries, and not compatible with modes of existence in all parts of the earth. Setting aside, for the present, all other considerations, Christianity, by including no obligation which could not be as well performed in one part of the globe as another, or as well in one age as another, is something very different from religions either temporary or local in their character. In this universal and eternal applicability, then, do we find one of the grandest features of the religion of Christ.

The promulgation of the principle of universal benevolence and love—the antagonism of every evil or violent emotion—was, whatever may be said of it, new to the Jewish people. True, they believed in one God, the Creator of all things, and so far had just views of the Source of religion; they also possessed the commandments of the Mosaic law; but when, on any occasion, did they view the Gentile nations, or foreigners, in any other light than as an inferior race of mankind, to whom their laws and usages had no sort of applicability? Practically, their religion narrowed the affections, while Christianity was all for widening them. "The Greeks, besides developing the principle of the beautiful in their works of art, had laid the foundations of valuable sciences applicable to the business of life. The Romans had established the principles of law and politics, administration, and proved their value by experience. These scattered elements of moral and intellectual cultivation, insufficient, in their disunited state, to bring about the true happiness and moral perfection of man, in his social and individual capacity, were refined, perfected, and combined, by Christianity, through the law of a pure benevolence, the highest aim of which is that of rendering men good and happy, like God, and which finds, in the idea of a kingdom of heaven upon earth, announced and realized by Christ, all the means of executing its design. His religion supplied what was wanting in these nations—a religious character to the science of Greece, moral elevation to the legislative spirit of Rome, liberty and light to the devotion of the Jews; and by inculcating the precept of universal love of mankind, raised the narrow spirit of patriotism to the extended feeling of general philanthropy. Thus, the endeavours of ancient times after moral perfection were directed and concentrated by Christianity, which supplied at the same time a motive for diffusing more widely that light and those advantages which mystery and the spirit of caste had formerly withheld from the multitude. It conveyed the highest ideas, the most important truths and principles, the purest laws of moral life, to all ranks; it proved the possibility of perfect virtue, through the example of its Founder; it laid the foundation for the peace of the world, through the doctrine of the reconciliation of men with God and with each other; and directing their minds and hearts towards Jesus, the Author and Finisher of their faith, the crucified, arisen, and glorified Mediator between heaven and earth, it taught them to discern the benevolent connection of the future life with the present."*

Systems of chronology differ with regard to the year of the crucifixion of the Saviour, some placing it in A. D. 30, and others in A. D. 33. In either case, as is known to the readers of the evangelical history, the apostles and disciples who had followed him while on earth began, shortly after his departure, those ministrations which they were commissioned to execute by their divine Master, and which had for their object the dissemination of the Gospel in all parts of the world. It will be further recollected, that, in consequence of the defection and death of the traitor Judas, the apostles were reduced to eleven in number—Peter, and Andrew his brother; James the son of Zebedee, and John his brother; Philip and Bartholomew; Thomas and Matthew; James the son of Alpheus, and Jude his brother; lastly, Simon the Canaanite. Afterwards, they elected Matthias in place of Judas. The number, however, was again reduced to eleven, by the murder of James, the brother of John, by Herod (A. D. 44).

The first society or church established by the apostles was at Jerusalem; and, from all that can be learned, it was on the most simple and unpretending scale, corresponding to the nature of the religion which they professed. One of Christ's most emphatic declarations had been that "his kingdom was not of this world," by which he signified that the Christian doctrines and graces referred exclusively to the mental affections, were a business of the heart, not of outward show or demonstration, and had in other respects no alliance with civil dominion. The humble but intrepid apostles, therefore, in the course of their preaching and teaching in Judea, and afterwards in other countries, took no part in any design to subvert temporal governments, or to bring them into contempt; neither did they seek to ally themselves with civil rulers, but confined themselves in all places to their proper functions of calling sinners to be converted to the faith of Jesus, comforting those who mourned, animating the piety of the dejected, and, in particular, assisting the poor and needy. Of the forms of Christian worship in this infant state of the Church, little is known; and, indeed, it appears that some time elapsed before the converted, or at least the pupils to the apostolic teachers,

* Encyclopædia Americana, article CHRISTIANITY

forsook the forms enjoined in the old Judaic mode of worship. According to Mosheim, they "held separate assemblies, in which they were instructed by the apostles and elders, prayed together, celebrated the holy supper in remembrance of Christ, of his death and sufferings, and the salvation offered to mankind through him; and at the conclusion of these meetings, they testified their mutual love, partly by their liberality to the poor, and partly by sober and friendly repasts, which thence were called *feasts of charity*. Among the virtues which distinguished the rising church in this its infancy, that of beneficence to the poor and needy shone in the first rank and with the brightest lustre. Having finished their work at Jerusalem, the apostles proceeded to other nations, and travelled over a great part of the known world, in a short time planting a vast number of churches among the Gentiles. Several of these are mentioned in the sacred writings, particularly in the *Acts of the Apostles*, though these are undoubtedly but a small part of the churches which were founded, either by the apostles themselves or by their disciples under their immediate direction."

It is not our design to enter into a formal detail of what constituted the various points of belief and religious practice in this early age of the Church. It will be understood that there was at first no body of written evidence answering as a fountain of doctrine and precept, such as we now possess in the collected books of the New Testament; and that apostles, and those who were raised up to assist them in their holy cause, were accordingly thrown much more on their own resources, and more dependant on God's inspiring power to teach and direct, than required to be the case in more advanced times. To use the words of Mosheim—"Among the first professors of Christianity there were but few men of learning; few who had capacity enough to insinuate into the minds of a gross and ignorant multitude the knowledge of divine things. God, therefore, in his infinite wisdom, judged it necessary to raise up, in many churches, extraordinary teachers, who were to discourse in the public assemblies upon the various points of Christian doctrine, and to treat with the people, in the name of God, as guided by his direction, and clothed with his authority. Such were the *prophets* of the New Testament."—(Rom. xiii. 6; 1 Cor. xii. 28; xiv. 3–29; and Eph. iv. 11.)

Much as we desire to do so, it is impossible for us to pass over a circumstance in the history of these early times, which has led to centuries of discord; we allude to the early form of church government. We shall allow a place to Mosheim's explanations on this subject. "Neither Christ himself, nor his holy apostles have commanded any thing clearly or expressly concerning the external form of the Church, and the precise method according to which it should be governed. From this we may infer, that the regulation of this was, in some measure, to be accommodated to the time, and left to the wisdom and prudence of the chief rulers, both of the state and of the Church. If, however, it is true that the apostles acted by divine inspiration, and in conformity with the commands of their blessed Master (and this no Christian can call in question), then it follows, that that form of government which the primitive churches borrowed from that at Jerusalem, the first Christian assembly established by the apostles themselves, must be esteemed as of divine institution. But from this it would be wrong to conclude that such a form is immutable, and ought to be invariably observed; for this a great variety of events may render impossible. In those early times, every Christian church consisted of the *people*, their *leaders*, and the *ministers*, or *deacons*; and these, indeed, belong essentially to every religious society. The people were, undoubtedly, the first in authority; for the apostles showed, by their own example, that nothing of moment was to be carried on or determined without the consent of the assembly, and such a method of proceeding was both prudent and necessary in those critical times.

"It was, therefore, the assembly of the people which chose their own rulers and teachers, or received them by a free and authoritative consent, when recommended by others. The same people rejected or confirmed by their suffrages the laws that were proposed by their rulers to the assembly, excommunicated profligate and unworthy members of the church, restored the penitent to their forfeited privileges, passed judgment upon the different subjects of controversy and dissension that arose in their community, examined and decided the disputes which happened between the elders and deacons, and, in a word, exercised all that authority which belongs to such as are invested with the sovereign power. The people, indeed, had in some measure purchased these privileges, by administering to the support of their rulers, ministers, and poor, and by offering large and generous contributions, when the safety or interests of the community rendered them necessary. In these supplies, each one bore a part proportioned to his circumstances, and the various gifts which were thus brought into the public assemblies were called *oblations*.

"The rulers of the church were called either *presbyters* or *bishops*, which two titles are, in the New Testament, undoubtedly applied to the same order of men. These were persons of eminent gravity, and such as had distinguished themselves by their superior sanctity and merit. Their particular functions were not always the same; for while some of them confined their labours to the instruction of the people, others contributed in different ways to the edification of the church. Hence the distinction between *teaching* and *ruling presbyters* has been adopted by certain learned men. But if ever this distinction existed, which I neither affirm or deny, it certainly did not continue long; since it is manifest that St. Paul requires that all bishops or presbyters be qualified and ready to teach and instruct.

"The Church was, undoubtedly, provided from the beginning with inferior ministers or *deacons*. No society can be without its servants, and still less such societies as those of the first Christians were. And it appears not only probable, but evident, that the *young* men, who carried away the dead bodies of Ananias and Sapphira, were the subordinate ministers, or *deacons* of the Church of Jerusalem, who attended the apostles to execute their orders. All the other Christian churches followed the example of that of Jerusalem in whatever related to the choice and office of the deacons.

"Such was the constitution of the Christian Church in its infancy, when its assemblies were neither numerous nor splendid. Three or four presbyters, men of remarkable piety and wisdom, ruled these small congregations in perfect harmony, nor did they stand in need of any president or superior to maintain concord and order where no dissensions were known. But the number of the presbyters and deacons increasing with that of the churches, and the sacred work of the ministry growing more painful and weighty by a number of additional duties, these new circumstances required new regulations. It was then judged necessary that one man of distinguished gravity and wisdom should preside in the council of presbyters, in order to distribute among his colleagues their several tasks, and to be a centre of union to the whole society. This person was at first styled the *angel* of the church to which he belonged, but was afterwards distinguished by the name of *bishop*, or inspector; a name borrowed from the Greek language, and expressing a principal part of the episcopal function, which was to inspect and superintend the affairs of the church. It is highly probable that the Church of Jerusalem, grown considerably numerous, and deprived of the ministry of the apostles, who were gone to instruct the other nations, was the first which chose a president or bishop. And it

is no less probable that the other churches followed by degrees such a respectable example. * * * A bishop, during the first and second century, was a person who had the care of one Christian assembly, which at that time was, generally speaking, small enough to be contained in a private house. In this assembly he acted, not so much with the authority of a *master*, as with the zeal and diligence of a faithful *servant*. He instructed the people, performed the several parts of divine worship, attended the sick, and inquired into the circumstances and supplies of the poor. He charged, indeed, the presbyters with the performance of those duties and services which the multiplicity of his engagements rendered it impossible for him to fulfil; but had not the power to decide or enact any thing without the consent of the presbyters and people. And though the episcopal office was both laborious and singularly dangerous, yet its revenues were extremely small, since the church had no certain income, but depended on the gifts or oblations of the multitude, which were, no doubt, inconsiderable, and were, moreover, to be divided between the bishops, presbyters, deacons, and poor.

"The power and jurisdiction of the bishops were not long confined to these narrow limits, but soon extended themselves, and that by the following means. The bishops who lived in the cities had, either by their own ministry or that of their presbyters, erected new churches in the neighbouring towns and villages. These churches, continuing under the inspection and ministry of the bishops by whose labours and counsels they had been engaged to embrace the gospel, grew imperceptibly into ecclesiastical provinces, which the Greeks afterwards called *dioceses*. But as the bishop of the city could not extend his labours and inspection to all these churches in the country and in the villages, so he appointed certain suffragans or deputies to govern and to instruct these new societies; and they were distinguished by the title of *chorepiscopi*, that is, country bishops. This order held the middle rank between bishops and presbyters, being inferior to the former and superior to the latter.

"The churches in these early times were entirely independent; none of them subject to any foreign jurisdiction, but each one governed by its own rulers and its own laws. For, though the churches founded by the apostles had this particular deference shown them, that they were consulted in difficult and doubtful cases, yet they had no juridical authority, no sort of supremacy over the others, nor the least right to enact laws for them. Nothing, on the contrary, is more evident than the perfect equality that reigned among the primitive churches; nor does there even appear in this first century the smallest trace of that association of provincial churches, from which *councils* and *metropolitans* derive their origin. It was only in the second century that the custom of holding councils commenced in Greece, from whence it soon spread through the other provinces."

According to these explanations, it would appear that the earliest constitution of the church was exceedingly simple, being in a great measure a confederacy of separate and independent religious instructors; that it gradually assumed the external features of Presbyterianism (equality of rank, but mutual jurisdiction); and that, finally, as Christianity spread, and the scattered societies of believers required the supervision and counsel of superiors, there arose a species of Episcopacy or superintendence by apostolic bishops. According to others, the bishops exercised a superintendence from the first, the earliest being the apostles; and it is reasonable to suppose that some such superior directors, exercising an authority in a spirit of perfect love, must have been necessary for the sake of order and uniformity of doctrine; it is at the same time certain that, whether in the capacity of equals or superiors, the apostles and early bishops performed the office ordinary teachers of religion. The commissioning of ministers of the gospel by ordination, or the symbol of laying on of hands, appears to have existed from the earliest ages of Christianity. The members of the church at Antioch, founded by Paul and Barnabas, were the first who received the name of *Christians*, having been previously called Nazarenes, by way of derision.

From about the conclusion of the first till the sixth century, there flourished a body of eminent men in connection with the Church, whose functions may be said to have generally united those of a professor of divinity and ethics with the pastoral office. These are known in Church History by the title of *Fathers*. They were of two chief classes—Greek and Latin fathers—and were alike distinguished for their erudition. The most celebrated among the Greek fathers was Clement of Alexandria (beginning of the second century), who was the first who philosophized on Christianity; Origen, at one time a pupil of Clement, celebrated for his homilies and writings illustrative of the Scriptures; Eusebius, who wrote the first history of Christianity; Athanasius (296–373), Bishop of Alexandria, and a man of invincible courage under persecution, whose writings exerted a considerable influence on the Christian dogmas; and Chrysostom (344–407), an ascetic, the most admired of ancient orators. The most distinguished among the Latin fathers were—Tertullian, born about the middle of the second century, and a writer of great originality; Augustine (354–430), a man of persuasive eloquence, exalted piety, and a warm encourager of the monastic life; Ambrose (340-397), Bishop of Milan, an eminent orator, and famed for his mild and humane character; and Jerome (331–420), one of the most learned writers and able expounders of the Scriptures, which, as formerly mentioned, he translated into the Latin tongue.

In the course of the second and third centuries, the history of the Church is painfully disfigured by the assumption of dominant powers by bishops; the division of the clergy into subordinate ranks and offices; the increase of ceremonial observances, fasts, and festivals; and, above all, differences of opinion among Christians on matters of belief. One main cause of the variety of opinion might be traced to the collateral influence of the Grecian philosophers, particularly that of Plato. Many converts had been educated in these philosophies, and though Christianized, they still retained the subtle speculative notions implanted in their minds, as well as divers Pagan usages. From disputing in the schools of Athens on questions in metaphysics, they betook themselves to controversies on the most abstruse points of theology. From controversy, the disputants naturally subsided into heresy and schism; and hence we find that, while the Christian Church was on all sides struggling against barbarous powers, it was itself torn by intestine division. In this general sketch, we can only mention that the leading sectaries at this period were the Manicheans, Hieracites, Sabellians, and Novatians; and in the fourth century the heresy of Arius broke out, and produced incalculable injury. Prior to this latter event, the external condition of the Church underwent an entire change.

For nearly three hundred years after the death of Christ, the Church, though gradually altering in internal organization, doctrinal belief, and ritual observance, was still an independent spiritual community, reposing on the simple but glorious basis on which it had been placed by its Divine Author, and in which condition it may be said to have been invulnerable. The conversion of Constantine the Roman Emperor, in 321,* at once altered the primitive state of the Church. "Before that important period, some churches had been liberally supported by the devotion and zeal of wealthy individuals: but yet the situation of the clergy was insecure and contemptible in the eyes of the Pagan world. Afterwards

* See HISTORY OF GREECE AND ROME in the present series

they lived in princely splendour, honoured and esteemed as the first rank of men in the empire. Formerly, they had been sunk in the gloom of obscurity, but now they basked in the broad sunshine of honour, wealth, and imperial favour. To a person who contemplates the aspect of the Roman empire in that age, a new world seems to appear. The system of polytheism and idol worship, which, from time immemorial, had, by its pompous ceremonies and splendid festivals, commanded the veneration of mankind, fell into disrepute: and Christianity, which had so long been the object of universal contempt, and frequently of cruel persecution, at last triumphed over all opposition, and became the established religion of the masters of the world. The Roman empire saw magnificent churches erected for the worship of the crucified God, whose name had been long despised, and the rites of the Christian religion celebrated with a pomp and solemnity equal, if not superior, to what had been displayed in the Pagan temples. A total revolution was taking place in the texture of religious opinions and the combinations of human ideas. What a scene would this have appeared to a Christian of the apostolic age, or of that which immediately succeeded it! What would a Christian whose mind had been formed, whose religious ideas had been modelled, by the simple and disinterested maxims of primitive Christianity, think, on seeing the ministers of the humble and lowly Jesus display the magnificence of sovereign princes! And what must have been his reflections on contemplating a system of honour and emolument, set up by the professed followers of one whose whole life was a continued scene of poverty and sufferings, and whose preaching and practice were entirely calculated to inspire all those who embraced his doctrine with a sovereign contempt for the things of this world! In the reign of Constantine the Church was enriched; but it evidently appears that the spirit of genuine Christianity was in a great measure extinguished. Ecclesiastical history, which had hitherto exhibited a horrible and sanguinary scene of the sufferings of the Church under Pagan persecutors, then began to display a not less disgusting view of the persecution of Christians by the hand of Christians, carried on with a cruelty little short, in some instances, of that which Pagans had before exercised against them."*

To extinguish, as far as possible, the heresy of Arius, and allay other causes of schism, Constantine convoked the celebrated Council of Nice (325), which consisted of 318 bishops, and other ecclesiastics to the number of 2048. After a session of two months, in which the emperor frequently assisted in person, the opinions of Arius, which went to a denial of the divinity of Christ, were condemned, the equality of the three Persons of the Holy and Undivided Trinity was declared the true doctrine, and, being comprised in a form of belief called the Nicene Creed, was published as the obligatory and only orthodox creed of the Christian Church.†

The deliberations of the Council of Nice failed in their main design, and the Arians, persecuted by the Church, dispersed themselves in distant nations, and there found a safe retreat. This may be viewed as the first great schism in the Church, which henceforth consisted, not in one, but in several distinct societies of believers. To trace minutely the progress of the respective branching-off communions, would lead us considerably beyond our limits; let it suffice to say, that in the fourth and fifth centuries, there were founded several important eastern churches. The Armenian Church dates its commencement from about the year 312. The Egyptian or Coptic Church originated in a heresy in the fourth century; and the Abyssinian Church shortly after branched off from it. The Syrian Church, in a similar manner, gave origin to the Syro-Indian Church, which still exists in Travancore and Cochin, and acknowledges as its head the Patriarch of Antioch. It is likewise to the fourth century that we must trace the origin of that great schism which afterwards divided the Church into the Western or Roman Church, and the Eastern or Greek Church. At this period, the Bishop of Rome occupied the first rank in the episcopal order, and on that account exerted a certain authority over all other bishops within the pale of the orthodox Church. "Constantine, by removing the seat of empire to Byzantium (Constantinople), raised up in the bishop of this new metropolis a formidable rival to the Roman pontiff. Accordingly, in a council held at Constantinople, in the year 381, by the authority of Theodosius the Great, the bishop of that city was, during the absence of the Bishop of Alexandria, and against the consent of the Roman prelate, placed in the first rank after the Bishop of Rome, and consequently above those of Alexandria and Antioch."—(*Mosheim.*) The rivalry and contentions of the bishops of Rome and Constantinople which ensued from this period, terminated in 1054 in a complete rupture. Each power excommunicated the other, and henceforth the Greek Church was entirely under the authority of the Patriarch of Constantinople. The other branch of the Church remained under the dominion of the Roman pontiff, and is that which is known by the name of the Roman Catholic Church.

Centuries before this latter event, the Church, under the generally recognised supremacy of the Bishop of Rome, had undergone the most extraordinary changes of condition. The legal establishment of Christianity as the religion of the state, and its consequent alliance with civil power, gave it a new character. That this authoritative recognition greatly aided in converting the pagan world, there can be no manner of doubt; but unfortunately, as we have seen, the wealth and authority conferred on churchmen naturally introduced evils gross in their nature; and in many respects the alliance with the civil government did infinitely more harm than good. Some writers aver that Christianity could scarcely have survived the dismemberment of the Roman empire and the barbarism that ensued throughout the middle ages, unless fortified by civil power; but this, we humbly submit, is but a timid view of the Christian dispensation, which surely required no such extraneous means of support. It is a lamentable truth, confirmed by every respectable historian, that the proceedings of Constantine (321), and afterwards of Theodosius (390), in establishing Christianity as the religion of the empire, laid the foundation of every species of ecclesiastical abuse, and directly caused the decay of that sublime but simple piety which was the ornament of the apostolic times. It is to

* Bigland's Letters on History.

† The Nicene Creed, after receiving some subsequent additions, stood as follows, and has for ages occupied a place in the Church service:—"I believe in one God, the Father Almighty, Maker of heaven and earth, and of all things visible and invisible: and in one Lord Jesus Christ, the only begotten Son of God, begotten of his Father before all worlds: God of God, Light of Light, Very God of Very God, being of one substance with the Father, by whom all things were made: who for us men, and for our salvation, came down from heaven, and was incarnate by the Holy Ghost of the Virgin Mary, and was made man, and was crucified also for us under Pontius Pilate: He suffered and was buried, and the third day he rose again according to the Scriptures, and ascended into heaven, and sitteth on the right hand of the Father, and he shall come again with glory to judge both the quick and the dead; whose kingdom shall have no end: And I believe in the Holy Ghost, the Lord and Giver of Life, who proceedeth from the Father and the Son, who with the Father and the Son together is worshipped and glorified, who spake by the Prophets: And I believe one Catholic and Apostolic church; I acknowledge one baptism for the remission of sins; and I look for the resurrection of the dead, and the life of the world to come. Amen."

With respect to the form of belief usually called the Apostles' Creed, it is believed to be of much less antiquity than the apostolic age, but there is great obscurity as to its authorship. It also has undergone alterations in the course of time. "The third creed, erroneously ascribed to Athanasius (who assisted at the Council of Nice, in 325), is affirmed to have been privately drawn up about the middle of the fourth century; and is rejected by all the Protestant churches (except the Anglican." —*Conder's View of all Religions.*

the arrangements consequent on the alliance of the Church with the civil power, that we have also to trace the origin of that new feature in ecclesiastical polity, the endowment of churches, cathedrals, abbeys, monasteries, and other institutions, with the functionaries belonging to them. But the most extraordinary change, both in the internal and external character of the Church, was the excess of power which, by the sanction of temporal princes, was accorded to the bishops of Rome. From early times, the occupant of the Roman primacy had been known under the title of *papas*, a Greek word signifying father, and hence the well-known terms, *papal* and *pope*. The pope, aided by his council, formed the head of the hierarchy, and acted as a supreme magistrate in all religious matters whatsoever. From the possession of the spiritual supremacy, a plea was easily found to assume the right of interfering in temporal concerns; and, as is known to the readers of history, the pope was allowed to exercise an almost unquestioned authority over the affairs of Christian princes for several centuries. It is at the same time proper to remark, that the lay and clerical members of the Church did not always agree in conceding this excessive power to the popes; the right of spiritual jurisdiction was not denied, but how far, and in what manner, that of a temporal nature, without the express sanction of general councils, should be allowed, formed a point of frequent debate, and we do not know that Catholics have yet arrived at a uniformity of opinion on the subject.

Another serious abuse which crept into the ecclesiastical affairs of the Church, was the establishment of monastic institutions—houses in which men secluded themselves from the world, and engaged themselves in religious offices. The practice of living as hermits, for the purpose of religious meditation, existed before Christianity, and was only engrafted upon it (in a regular manner) about the beginning of the fourth century; and in the course of the following hundred years, monasteries greatly increased in number. In the sixth century, the practice of taking vows of celibacy and rigid adherence to certain rules, was introduced by St. Benedict; from which period till the tenth century, monasteries are generally allowed to have been dwellings of piety, temperance, and the refuge of learning, driven to them for shelter from the troubles of the times. In the course of the tenth and eleventh centuries, the monasteries lost this valuable character. Idleness and luxury entered their walls, together with the vices of the world; their superiors, named abbots or priors, appointed by lay princes from among the nobility, set themselves above the jurisdiction of the bishops; and, in short, the whole monastic system, including convents for female devotees (nuns), became altogether corrupt. None of the religious orders rose to such eminence and power as the Society of Jesus, or Jesuits, founded by Ignatius Loyola (1491—1556), a Spaniard, and a man of great shrewdness and enthusiasm. The society was sanctioned by a bull (or ordinance) of Paul III. in 1560. Young men of ability and peculiar energy of character were alone admitted, and the trials of the novices were most severe. In addition to the usual vows of poverty, chastity, and implicit obedience to superiors, the members were bound to go, unhesitatingly and without recompense, whithersoever the pope should send them, as missionaries for the conversion of pagans and heretics, or for the service of the Church in any other way. This well-trained and formidable corps of spiritual combatants long exerted a powerful influence throughout Christendom, as well as in heathen countries; but as general intelligence advanced, they failed in their efforts; in 1773 their order was abolished by Clement XIV.; and latterly (though restored in 1814), they sunk into comparative obscurity.

The many flagrant corruptions of the Church began to excite the attention of reflecting men in the fourteenth century, and efforts were on divers occasions made by them to produce a reform, but without success. The abuses chiefly complained of were the scandalous lives of many of the clergy, particularly of the monastic and mendicant orders, the gross superstitious reverence generally paid to relics, the extravagant power of the pope, and the sale of indulgences. The exhibition of religious relics, with the view of exciting the piety of believers, had degenerated into a system of pure imposture. "The poor fragments of mortality, a skull, a bone, or the fragment of a bone, a tooth, or a tongue, were either mounted or set, according to the size, in gold and silver, deposited in costliest shrines of the finest workmanship, and enriched with the most precious gems. Churches soon began to vie with each other in the number and variety of these imaginary treasures, which were sources of real wealth to their possessors. The instruments of our Lord's crucifixion were shown (the spear and the cross having, so it was pretended, been miraculously discovered), the clothes wherein he was wrapt in infancy, the manger in which he was laid, the vessels in which he converted water into wine at the marriage feast, the bread which he broke at the last supper, his vesture for which the soldiers cast lots. Such was the impudence of Romish fraud, that portions were produced of the burning bush, of the manna which fell in the wilderness, of Moses's rod and Samson's honeycomb, of Tobit's fish, of the blessed Virgin's milk, and of our Saviour's blood!" —(*Southey.*)

The ludicrous extent to which the exhibition of relics was carried, and also the abstract claims of spiritual supremacy by the pope, might have been tolerated for some time longer; but the plenary power of selling immunities for transgressions roused the common sense of mankind. Leo X., famous for his love of splendour, commenced this odious traffic. Martin Luther (1483—1546), a monk of the order of Augustine, in Germany, was shocked with the effects of the system, as they appeared in his congregation at Wittemberg. "By far the most notable vender of indulgences was Tetzel, a Dominican, whose morals were on a par with his impudence. This man had popular talents: he was a ready, sonorous preacher; he was intimately acquainted with the human heart; and these advantages, joined to his dignity as prior of his order, pointed him out as the fittest person to sell these indulgences. He was accordingly made chief commissioner, and his success at the different towns he visited was prodigious. From the pulpit he declared indulgences to be the most sublime of God's favours; they had saved more souls than the efforts of all the Apostles; they would atone for every sin, however heinous; they were effectual in regard to future, no less than past transgressions; they stoned for the dead no less than the living; and whoever suffered his relatives to remain in purgatory, when a little money would release them, was guilty of the worst crime. Hence a blow was struck at all repentance: contrition of heart was out of the question, when pardon could be obtained on terms so much easier. The present recital would perhaps be disbelieved, if its truth were not virtually admitted by contemporary Roman Catholics. But good is often educed from evil; and this preaching of indulgences was one of the chief causes of the Reformation. There is reason to believe that the whole system struck Luther with horror from the very first; and that, coupled with the impiety which he had witnessed in the capital of Christendom, it provoked his doubts as to the infallibility of the papal authority. The effects of the indulgences were every day before his eyes; and, as one of the authorized confessors of the people of Wittemberg, he perceived them more clearly than other men. While seated in the tribunal of penance, he was amazed to hear what crimes had been committed, and still more, that no contrition was felt for them. He refused to absolve, unless

the criminals forsook their evil ways. They showed him their letters of impunity: no matter; he estimated these at their just value, namely, as so many pieces of waste paper. Being dismissed without absolution, and without admission to the sacraments, the deluded purchasers complained to Tetzel, who bellowed and threatened; but Luther was undaunted: he openly preached against the pernicious traffic; he attacked the very foundation on which it rested; he denied the power of pope or Church to remit the guilt of sin; and by his famous propositions, as everybody knows, rapidly produced the most gigantic change effected in this world since the origin of Christianity."*

The preaching of Luther, in exposing the error of indulgences, and in calling in question various traditional tenets and practices, speedily roused a large part of Germany; and as no symptom of relenting was shown by those in power, an extensive secession from the Romish Church became unavoidable. The year 1521 is to be regarded as the epoch of the Reformation in Germany; and from this period it became a political as well as religious movement—in a word, a movement in favour of civil and religious freedom. In consequence of a general *protest* being signed by the reforming party against a decree of the Diet of Spires, in 1529, they received, in 1541, the name of *Protestants*. Eleven years earlier, in 1530, a declaration of the principles of the reformers, drawn up by Melancthon, was presented to the Emperor of Germany at a diet held at Augsburg, and there solemnly read before the assembly; this famous declaration is known in history as the Confession of Augsburg. The Reformation spread from country to country with singular rapidity: the ancient church was deposed and one of a reformed character established in its place—in Switzerland and Genova in 1535; in Sweden and Denmark in 1536; in England in 1547; and in Scotland in 1560. In Austria, Italy, Spain, Portugal, and France, the efforts of the reformers were less successful, and in these countries the Roman Catholic Church has been established, or at least popular, till the present day.

CONCLUDING SUMMARY.

Christianity now exists, in one or other of its various forms, in all civilized countries, and numbers, as is believed, 260,000,000, out of 900,000,000, the entire population of the globe. Although originating in Asia, and flourishing for some time in the adjacent regions of northern Africa (Church of Alexandria, for example), it prevails only to a small extent in these continents, and is principally confined to Europe and the countries which have been peopled by European emigrants. Everywhere, it is the religion of *civilized man*, no other creed or form of belief being at all suitable to an advanced intelligence, or so directly calculated to inspire sentiments of refined piety, humanity, and justice. In the hands of uninstructed, ambitious, and intolerant men, its history abounds in the most odious crimes; but latterly, as its professors have fallen under the influence of a civilization to which it has itself largely contributed, and as the true principles of the Gospel have been better understood, our religion has not been outraged by indecent excesses either at home or abroad; while, by the earnest but unostentatious efforts of its supporters, of various denominations, it has been made favourably known in the most remote parts of the earth.

The forms in which Christianity is professed are very numerous, but the whole are comprehended in three leading systems—the Roman Catholic Church, the Eastern Churches, and the Protestant or Reformed Churches.†

With but one exception, all acknowledge the doctrine of the Trinity, the fall of man, salvation by the expiatory death of Christ, the resurrection, and a state of final rewards and punishments. Differences on other matters may be traced to two distinct causes of controversy: 1. Whether the rule of faith and practice is absolutely confined to the Holy Scriptures, or embraces a traditional revelation, sanctioned by councils and cherished by the

* Review of d'Aubigné's History of the Reformation.—*Athenæum* No. 571.

† *Roman Catholic Church.*—The doctrines and ritual of this body, as now professed, proximately rest in a great measure on the decisions of the Council of Trent (terminated 1563). According to these decisions, the Romish creed embraces the following points:—An admission of apostolical and ecclesiastical traditions; that the Holy Scriptures form only a part of revelation, and are to be interpreted only according to the sense in which they are held by the Church; that there are seven sacraments, necessary for the salvation of mankind, though not for every one—baptism, confirmation, eucharist, penance, extreme unction, clerical orders, and matrimony; that in the mass there is offered a true, proper, and propitiatory sacrifice for the living and the dead; and that in the holy sacrament of the eucharist, there is really, truly, and substantially, the body and the blood, together with the soul and divinity, of Christ (transubstantiation); that there is a place of purgation, or purgatory, into which souls proceed after death; that the saints, reigning together with Christ, are to be honoured and invoked; that they offer prayers to God for us, and that their relics are to be had in veneration: that the images of Christ, of the Virgin Mary, and also of the other saints, ought to be had and retained, and that due honour and veneration are to be given to them; that the power of indulgences was left by Christ to the Church, and that the use of them is most wholesome to the Christian people; that the Holy Catholic Apostolic Church is the mother of all churches, and that out of the Catholic faith none can be saved. To these principal matters of belief are added—the efficacy of prayers for the dead; auricular confession; celibacy of the clergy; the use of Latin in the public ministrations; signing with the cross; the rosary as an implement of devotion, &c.

The Roman Catholic Church is an episcopacy, or government by a hierarchy of bishops. The supreme control rests in the pope and his council at Rome, and thence radiates a system of management, most complete and effective, over all parts of Christendom. The church includes three distinct orders of clergy—bishops, priests and deacons; all others, such as cardinals (popes expectant), archbishops, deans, vicars, &c., belonging to one or other of these classes. The church claims the mark of true *apostolicity*, that is, an unbroken line of descent from the apostles and their divine Master. The ordination of priests is the engrafting them into this apostolic line of succession. Bishops alone ordain or communicate holy orders. In no church is the ritual of public worship so highly adorned, or rendered more imposing, by the dresses of the officiating priests, the waving of censers, crucifixes, pictures, images, and music. Although celebrated in an unknown tongue, it is observable that the public worship excites the greatest appearance of attention and decorum, as well as all the outward demonstrations of piety. The influence of the devotional feelings is said to be the object aimed at by the various outward insignia; the church (if we understand the argument) holding it to be of equal consequence whether the heart is touched, and feelings of piety and veneration are excited, by the exhibition of a crucifix or the preaching of a sermon. The Roman Catholic Church, though now only a remnant of its former self, is still the most numerous of the various Christian bodies: it includes within its pale, France, Belgium, Poland, Italy, the Mediterranean islands, Spain, Portugal, the greater part of the people of Austria and Ireland; about a half of the Prussians and Swiss, and the inhabitants of various German states; large numbers in the South American states and Mexico; also a part of the population of the United States, and nearly all the Lower Canadians; and a considerable number of the inhabitants of England and Scotland, besides those of inferior countries. Altogether the number of Roman Catholics is said to amount to 139,000,000.

The Eastern Church is divided into four leading communions, and several of a subordinate rank:—1. The Constantinopolitan or Orthodox Greek Church, comprising all who acknowledge the supremacy of the Patriarch of Constantinople. 2. The Russian Greek Church, which prevails over Russia, and in virtue of an ordinance of Peter the Great in 1700, was constituted the national church, having for its head the Russian emperor; it is governed by a council at St. Petersburgh. 3. The Anti-Byzantine or Monosphyte Churches, which have renounced communion both with the Constantinopolitan Church and Church of Rome, and differ from both in doctrine and ritual: these churches include the Syrian, Coptic, Abyssinian, Nestorian, Indo-Syrian, and Armenian Christians. 4. The Greek and other Eastern Christians, including the Maronites in Syria, who are in communion with the Church of Rome. The whole of these Eastern Churches are said to include 62,000,000 of members. Whatever be their peculiar differences, all recognise two sources of doctrine, the Holy Scriptures and Tradition, and are hierarchial episcopates in their form of government. The church service is in Greek. "The rites and ceremonies of the Greek church are exceedingly numerous, trivial, and burdensome. In all the services, except the communion, prayers and adorations are offered to the Virgin (styled the *Panagia*, all-holy), or to some of the multitudinous saints of the Greek calendar, almost as often as to the Deity. Every day in the year is consecrated to some saint, frequently to more than one: and every day of the week is appropriated in the church service to

church? 2. And who has the right to interpret the rule of faith—the church or individuals? On the exact determination of these points, rests a complex series of divisions, which at present appear to be as far from settlement to the mutual satisfaction of parties, as they were in the sixteenth century; and we may rationally conclude, that, humanly speaking, little or no advance to reconciliation can be effected, till education has dispelled the mists of prejudice, and enabled men to perceive and judge of abstract matters more equably.

some peculiar object of adoration."—*Conder*. This church does not resist the circulation of the Scriptures, and its clergy may be married men.

The Protestant Churches are either those which split off from the Church of Rome at the Reformation, or others which have since sprung from the reformed bodies. Protestantism owns two fundamental principles—that the Bible contains the sole rule of faith, and that it is the right of every one without respect of person, to judge of that rule with all the aids which divine grace, reason, and conscience, can inspire. At the same time, it may be noticed, that generally in practice each church possesses certain standards of belief to which it is expected its members will adhere. Rejecting traditional revelation and the decrees of all councils but those of an early date, Protestants admit only two sacraments, baptism and the Lord's supper. They reject transubstantiation and the sacrifice of the mass; deny the lawfulness of monastic vows, the holiness of celibacy, the merit of good works, the virtue of indulgences, the invocation of saints; reject the worship of images, auricular confession, extreme unction, purgatory, prayers for the dead, and the spiritual authority of the pope. Protestantism exists in three main divisions—Lutherans, Arminians, and Calvinists—each differing from the other in certain points of faith and church government; but there are, besides, innumerable sects which cannot be included in these bodies—as, for example, Quakers, or the Society of Friends, who reject the lawfulness of clerical functionaries, and disapprove of the sacraments and all ordinary forms of public worship—Baptists, a numerous body, with recognised pastors, who possess a very simple form of church government, repudiate infant baptism, and maintain the necessity of the baptism or immersion of adult believers—Moravians, a large and unobtrusive body, who, among other good qualities, display extraordinary ardour in the prosecution of missionary labours—Methodists, a numerous body in England, chiefly distinguished for their devotional fervour, the reformation of manners, and the instruction of the young in religious duties by means of Sunday-schools—and Unitarians, an intelligent and respectable body, but differing widely in doctrine from all other classes of Christians: who maintain, as their name imports, the absolute unity of God, in opposition to the doctrine of the Trinity, acknowledge no fixed creed or standard of faith except the Bible, and reject the doctrine of original sin, the vicarious sacrifice of Christ, and the eternity of future punishments. Unitarianism has made considerable progress in America during the last half century; and possesses a number of churches in Britain, Ireland, Geneva, Germany, and other parts of Christendom.

The total number of Protestants of all churches and sects is believed to be about 60,000,000.

Protestantism is professed in two chief forms—*Episcopacy*, or the government of the church by bishops, whose spiritual authority is derived from the apostles through the efficacy of ordination, both before and since the Reformation; and *Presbytery*, which rejects a hierarchy of bishops, and admits only the government of the church by a body of ministers all equal in rank. The body called *Independents*, or Congregationalists, only admit of each church being governed by its own members, on a primitive and simple model. At the head of the Protestant Episcopal churches may be placed the Church of England, whose doctrines are contained in the well-known Thirty-Nine Articles and in the Book of Common Prayer. The Church of England has for its basis a denial of the supremacy of the Bishop of Rome, and rejects the doctrine of purgatory, the doctrines concerning indulgences and pardons, the worship or veneration of images and relics, the invocation of saints, the sacraments of confirmation, penance, orders, matrimony, and extreme unction, transubstantiation, and the sacrifice of the mass. It retains confirmation as a religious ceremonial, ordination to the priestly office, the sign of the cross in baptism, burial service, kneeling at the communion, absolution of the sick, the whole hierarchical routine of officials—bishops, priests, deacons, prebends, archdeacons, rectors, vicars, &c., and numerous fasts and festivals. In its calendar affixed to the Book of Common Prayer, there are retained the names of about seventy saints of the middle ages, such as Hilary, Prisca, Valentine, Dunstan, &c. Practically, the church pays no attention to these, or to most of the authorized fasts, festivals, vigils, &c.

According to law, the reigning sovereign, whether king or queen, is the head of the church, and has the appointment of its bishops, who hold the dignity of spiritual peers, and are members of the legislature. From its strict connection with the state, the Church of England labours under the misfortune of possessing no power in itself to amend its formularies, which consequently remain what they were in the reign of Edward VI.; yet this great disadvantage is felt to be comparatively unimportant, on account of the extraordinary beauty and simplicity of the language of the prayers and litanies, as well as the elementary nature of the whole service, which admits of no alteration by officiating ministers. Latterly, a number of its clergy have manifested a strong desire to restore many forgotten ante-Reformation usages in the Church service—a circumstance which has given much offence to those of moderate views. Both in the United States of America and in Scotland, there are Episcopal communions deriving ordination from the Church of England, and having the same forms of worship. The Scotch Episcopal communion, in which the bishops officiate as ministers of congregations, and which is altogether dependent on the contributions of its adherents, is acknowledged to present the purest model of the Episcopacy which prevailed in the early ages of the Church.

Presbyterianism is established in Scotland, Holland, and some of the Swiss Cantons, and exists to a large extent in North America. Presbyterians generally follow the doctrines of John Calvin, rejecting the use of crucifixes, the sign of the cross, altars, liturgies, &c., and recognising no saints' days. Christmas and Easter are recognised by Presbyterians in Holland, but not by those in Scotland. The clergy, being equal in rank, are governed by provincial and general courts, constituted from their own body. Scotland possesses a numerous body of Presbyterian dissenters or seceders from the establishment; and, latterly, these have added to former causes of difference, by declaring their hostility to all connection between Church and State, and that Christianity, as was the case prior to the era of Constantine, should be entirely independent of civil government, and its ministers supported exclusively by voluntary contributions

LIFE AND MAXIMS OF FRANKLIN.

PARENTAGE AND BOYHOOD.

Benjamin Franklin was born at Boston, in New England, North America, on the 17th of January, 1706, and was the youngest but two of a family of seventeen children, two daughters being born after him. His ancestors, as far as they can be traced back (at least three hundred years), were petty freeholders at Eaton, in Northamptonshire; but if we may judge by the surname of the family—the ancient Norman appellative for a country gentleman—we may conclude they had originally been of some consequence. After the Reformation, the immediate progenitors of Benjamin continued zealously attached to the Church of England till towards the close of the reign of Charles the Second, when his father Josias, along with his uncle Benjamin, became dissenters. These men were both bred to the trade of silk-dyeing. Josias married early in life; and about the year 1682 he emigrated, with his wife and three children, to America, on account of the persecutions to which he was exposed for his dissenting principles. On arriving in New England, he embraced the occupations of soap-boiler and tallow-chandler, of which businesses he previously knew nothing, but only from their being at the time the likeliest to provide maintenance for his increasing family. He appears to have been a man of great penetration and solid judgment; prudent, active, and frugal; and although kept in comparative poverty by the expenses of his numerous family, was held in great esteem by his townsmen. In no respect was his practical good sense more conspicuous than in the education of his children; and his illustrious son frequently alludes, in terms of thankfulness and gratitude, to the many exemplary precepts and sound moral lessons he received while under the paternal roof. The following passage may be read with no little instruction by the heads and members of all families similarly circumstanced:—"He was fond of having at his table, as often as possible, some friends, or well-informed neighbours, capable of rational conversation; and he was always careful to introduce useful or ingenious topics of discourse, which might tend to form the minds of his children. By this means he early attracted our attention to what was just, prudent, and beneficial in the conduct of life. He never talked of the meats which appeared on the table; never discussed whether they were well or ill dressed, of a good or bad flavour, high-seasoned or otherwise, preferable or inferior to this or that dish of a similar kind. Thus accustomed from my infancy to the utmost inattention to these objects, I have since been perfectly regardless of what kind of food was before me; and I pay so little attention to it even now, that it would be a hard matter for me to recollect, a few hours after I had dined, of what my dinner had consisted. When travelling, I have particularly experienced the benefit of this habit; for it has often happened to me to be in company with persons, who, having a more delicate because a more exercised taste, have suffered in many cases considerable inconvenience; while, as to myself, I have had nothing to desire." Benjamin was at first designed to be a clergyman, and at eight years of age was put to the grammar-school with that view, having previously been taught to read. His uncle Benjamin, who had likewise emigrated, encouraged this project. This individual appears to have been an equally eccentric and ingenious man. He cultivated the Muses with a success that gave himself, at least, entire satisfaction. But what he was most proud of was a species of short-hand of his own invention, wherewith he had carried off from the conventicles in England several volumes of sermons whole and entire; and these he designed for his nephew's stock in trade, when he should set up as preacher. But young Franklin had not been a year at school when his father perceived that his circumstances were quite inadequate to the expenses necessary to complete his son's education for the clerical profession. He accordingly removed him from the more learned seminary, and placed him under an humbler teacher of reading and writing for another twelvemonth, preparatory to binding him to some handicraft trade.

APPRENTICESHIP.

When his term at school was expired, being then ten years of age, he was taken home to assist his father in his business; but he soon testified such repugnance to the cutting of wicks for candles, running errands, waiting in the shop, with other drudgery of the same nature, that, after a tedious and ill-borne trial of two years, his father became afraid of his running off to sea (for which he confesses to have had a predilection), as an elder brother had done, and resolved to put him to some other occupation. After much deliberation, therefore, he was sent on trial for a few days to his cousin (a son of Benjamin), who was a cutler; but that relative being desirous of a larger apprenticeship-fee than his uncle could spare, he was recalled. His brother James, a short time previous to this period, had returned from England, whither he had been sent to learn the printing business, and set up a press and types on his own account at Boston. To him, therefore, after no little persuasion, Benjamin at last agreed to become apprentice, and he was indentured accordingly for the term of nine years; that is, until he should reach the age of twenty-one.

The choice of this profession, as it turned out, was a lucky one; and it was made after much careful and correct observation on the part of the parent. He had watched his son's increasing fondness for books, and thirst for information, and that, too, of a solid and instructive sort; and he therefore judiciously resolved to place him in a favourable situation for gratifying this propensity in the youthful mind; while he would, at the same time, be instructed in a profession by which he

could always independently maintain himself, in whatever quarter his fortunes might lead him, within the bounds of the civilized world. Franklin thus speaks of his early and insatiable craving after knowledge :—

"From my earliest years I had been passionately fond of reading, and I laid out in books all the money I could procure. I was particularly pleased with accounts of voyages. My first acquisition was Bunyan's collection, in small separate volumes. These I afterwards sold, in order to buy an historical collection by R. Burton, which consisted of small cheap volumes, amounting in all to about forty or fifty. My father's little library was principally made up of books of practical and polemical theology. I read the greatest part of them. There was also among my father's books Plutarch's Lives, in which I read continually, and I still regard as advantageously employed the time devoted to them. I found, besides, a work of De Foe's, entitled An Essay on Projects, from which, perhaps, I derived impressions that have since influenced some of the principal events of my life." It seems to have been lucky for himself and mankind that the last-named author's most celebrated work, Robinson Crusoe, did not fall into his hands at this period.

By his assiduity Franklin soon attained great proficiency in his business, and became very serviceable to his brother. At the same time, he formed acquaintance with various booksellers' apprentices, by whose furtive assistance he was enabled to extend the sphere of his reading. This gratification, however, was for the most part enjoyed at the expense of his natural rest. "How often," says he, "has it happened to me to pass the greater part of the night in reading by my bedside, when the book had been lent me in the evening, and was to be returned the next morning, lest it might be missed or wanted!" His studious habits and intelligent conversation also attracted the notice of a wealthy merchant who was in the habit of coming about the office, who invited him to his house and gave him the use of an excellent library.

It is a singular peculiarity of all minds of an active and aspiring character, that they uniformly endeavour to do whatever others have done, and from which they themselves have derived enjoyment or benefit. Franklin, from the delight he took in the perusal of books, at last bethought him of trying his own hand at composition; and as has happened, we believe, with a great proportion of literary men of all ages, his first efforts were of a poetical nature. His brother, having come to the knowledge of his attempts, encouraged him to proceed, thinking such a talent might prove useful in the establishment. At the suggestion of the latter, therefore, he finished two ballads, which, after being printed, he was sent round the town to sell; and one of them, the subject of which was a recent affecting shipwreck, had, he says, a prodigious run. But his father having heard of the circumstance, soon let down the pegs of the young poet's vanity, by analyzing his verses before him in a most unmerciful style, and demonstrating, as Franklin says, what "wretched stuff they really were." This sharp lesson, which concluded with a warning that versifiers were almost uniformly beggars, effectually weaned him from his rhyming propensities.

Franklin immediately afterwards betook himself to the composition of prose, and the first opportunity of exercising his pen and his faculties in this way occurred in the following manner:—He had a young acquaintance of the name of Collins, who was like himself passionately fond of books, and with whom he had frequent and long arguments on various subjects. In narrating this circumstance, Franklin comments, in passing, on the dangerous consequences of acquiring a disputatious habit, as tending to generate acrimony and discord in society, and often hatred between the best of friends. He dismisses the subject with the following singular enough observation:—"I have since remarked, that men of sense seldom fall into this error—lawyers, fellows of universities, and *persons of every profession educated at Edinburgh*, excepted!" But to proceed: Franklin and his companion having as usual got into an argument one day, which was maintained on both sides with equal pertinacity, they parted without bringing it to a termination: and as they were to be separated for some time, an agreement was made that they should carry on their dispute by letter. This was accordingly done; when, after the interchange of several epistles, the whole correspondence happened to fall into the hands of Franklin's father. After perusing it with much interest, his natural acuteness and good sense enabled him to point out to his son how inferior he was to his adversary in elegance of expression, arrangement, and perspicuity. Feeling the justice of his parent's remarks, he forthwith studied most anxiously to improve his style; and the plan he adopted for this purpose is equally interesting and instructive.

"Amidst these resolves," he says, "an odd volume of the Spectator fell into my hands. This was a publication I had never seen. I bought the volume, and read it again and again. I was enchanted with it, thought the style excellent, and wished it were in my power to imitate it. With this view I selected some of the papers, made short summaries of the sense of each period, and put them for a few days aside. I then, without looking at the book, endeavoured to restore the essays to their due form, and to express each thought at length, as it was in the original, employing the most appropriate words that occurred to my mind. I afterwards compared *my* Spectator with the original. I perceived some faults, which I corrected; but I found that I chiefly wanted a fund of words, if I may so express myself, and a facility of recollecting and employing them, which I thought I should by that time have acquired, had I continued to make verses. The continual need of words of the same meaning, but of different lengths, for the measure, and of different sounds for the rhyme, would have obliged me to seek for a variety of synonyms, and have rendered me master of them. From this belief, I took some of the tales of the Spectator, and turned them into verse; and after a time, when I had sufficiently forgotten them, I again converted them into prose. Sometimes, also, I mingled my summaries together; and, a few weeks afterwards, endeavoured to arrange them in the best order, before I attempted to form the periods and complete the essays. This I did with a view of acquiring method in the arrangement of my thoughts. On comparing afterwards my performance with the original, many faults were apparent, which I corrected; but I had sometimes the satisfaction to think, that, in certain particulars of little importance, I had been fortunate enough to improve the order of the thought or style; and this encouraged me to hope that I should succeed in time in writing decently in the English language, which was one of the greatest objects of my ambition."

But it was not only by such rigorous self-imposed tasks that this extraordinary man, even at so early an age, endeavoured to chasten his mind, and make every animal propensity subservient to his sense of duty. He also began to exercise those acts of personal self-denial which the heyday of youth, the season for animal enjoyment, feels as the most intolerable of all restrictions. Having met with a work recommending a vegetable diet, he determined to adopt it. Finding, after some days' trial, that he was ridiculed by his fellow-boarders for his singularity, he proposed to his brother to take the half of what was now paid by that relative for his board, and therewith to maintain himself. No objection was, of course, made to such an arrangement; and he soon found that of what he received he was able to save one-half. "This," says he, "was a no fund for the purchase of

books, and other advantages resulted to me from the plan. When my brother and his workmen left the printing-house to go to dinner, I remained behind; and despatching my frugal meal, which frequently consisted of a biscuit only, or a slice of bread and a bunch of raisins, or a bun from the pastry-cook's, with a glass of water, I had the rest of the time till their return for study; and my progress therein was proportioned to that clearness of ideas and quickness of conception which are the fruits of temperance in eating and drinking."

Another remarkable instance of the resolute way in which he set about making himself master of whatever acquirement he found more immediately necessary to him at the moment, is the following:—Having been put to the blush one day for his ignorance in the art of calculation, which he had twice failed to learn while at school, he procured a copy of Cocker's Arithmetic, and went through it all, making himself completely master of it before turning his mind to any thing else! He soon after, also, gained some little acquaintance with geometry, by perusing a work on navigation. He mentions, likewise, his reading about this time Locke's Essay on the Understanding, and the Art of Thinking, by Messrs. du Port Royal. Having found, in some essay on rhetoric and logic, a model of disputation after the manner of Socrates, which consists in drawing on your opponent, by insidious questions, into making admissions which militate against himself, he became excessively fond of it, he says, and practised it for some years with great success, but ultimately abandoned it, perceiving that it could be made as available to the cause of wrong as that of right, while the prime end of all argument was to convince or inform.

About three years after Franklin went to his apprenticeship, that is to say, in 1721, his brother began to print a newspaper, the second that was established in America, which he called the New England Courant: the one previously established was the Boston News Letter. The new publication brought the most of the *literati* of Boston about the printing-office, many of whom were contributors; and Franklin frequently heard them conversing about the various articles that appeared in its columns, and the approbation with which particular ones were received. He became ambitious to participate in this sort of fame; and having written out a paper, in a disguised hand, he slipped it under the door of the printing-office, where it was found next morning, and submitted, as usual, to the critics when they assembled. "They read it," he says; "commented on it in my hearing; and I had the exquisite pleasure to find that it met with their approbation; and that in the various conjectures they made respecting the author, no one was mentioned who did not enjoy a high reputation in the country for talent and genius. I now supposed myself fortunate in my judges, and began to suspect that they were not such excellent writers as I had hitherto supposed them. Be this as it may, encouraged by this little adventure, I wrote and sent to press, in the same way, many other pieces which were equally approved—keeping the secret till my slender stock of information and knowledge for such performances was pretty completely exhausted." He then discovered himself, and had the satisfaction of finding he was treated with much more respect by his brother and his friends than heretofore.

The two brothers, however, lived together on very disagreeable terms, in consequence of the hasty and overbearing temper of the elder; and Benjamin anxiously longed for an opportunity of separating from him. This at last occurred. His brother was apprehended and imprisoned for some political article which offended the local government, and upon his liberation was prohibited from ever printing his newspaper again. It was therefore determined that it should be published in Benjamin's name, who had managed it during his brother's confinement with great spirit and ability. To avoid having it said that the elder brother was only screening himself behind one of his apprentices, Benjamin's indenture was delivered up to him discharged, and private indentures entered into for the remainder of his time. This underhand arrangement was proceeded in for several months, the paper continuing to be printed in Benjamin's name; but his brother having one day again broken out into one of his violent fits of passion, and struck him, he availed himself of his discharged indentures, well knowing that the others would never be produced a[gainst] him, and gave up his employment. Franklin afterwards regretted his having taken so unfair an advantage of his brother's situation, and regarded it as one of the first *errata* of his life. His brother felt so exasperated on the occasion, that he went round all the printing-offices, and represented Benjamin in such a light that they all refused his services.

PROCEEDS TO PHILADELPHIA.

Finding he could get no employment in Boston, as well as that he was regarded with dislike by the government, he resolved to proceed to New York, the nearest town in which there was a printing-office. To raise sufficient funds for this purpose, he sold part of his library; and having eluded the vigilance of his parents, who were opposed to his intention, he secretly got on board of a vessel, and landed at New York on the third day after sailing.

Thus, at the age of seventeen, Franklin found himself three hundred miles from his native place, from which he was in some sort a runaway, without a friend, or recommendation to any one, and with very little money in his pocket. To complete his dilemma, he found, on applying, that the only printer then in the town could give him no employment. That person, however, recommended him to go to Philadelphia, where he had a son, who, he thought, would give him work; and he accordingly set off for that place. His journey was a most disastrous one both by water and land, and he frequently regretted leaving home so rashly. He reached his destination at last, however, and in a plight which certainly did not bode over-auspiciously for his future fortunes. His own graphic description of his condition and appearance, on his first entrance into Philadelphia, is at once interesting and amusing:—

"I have entered into the particulars of my voyage, and shall in like manner describe my first entrance into this place, that you may be able to compare beginnings so unlikely with the figure I have since made. I was in my working dress, my best clothes being to come by sea. I was covered with dirt; my pockets were filled with shirts and stockings; I was unacquainted with a single soul in the place, and knew not where to seek a lodging. Fatigued with walking, rowing, and having passed the night without sleep, I was extremely hungry, and all my money consisted of a Dutch dollar, and about a shilling's worth of coppers, which I gave to the boatmen for my passage. At first they refused it because I had rowed, but I insisted on them taking it. A man is sometimes more generous when he has little than when he has much money, probably because he is, in the first place desirous of concealing his poverty.

"I walked towards the top of the street, looking eagerly on both sides, till I came to Market street, where I met a child with a loaf of bread. I inquired where he had bought it, and went straight to the baker's shop which he pointed out to me. I asked for some biscuits, expecting to find such as we had at Boston; but they made, it seems, none of that sort at Philadelphia. I then asked for a threepenny loaf; they made no loaves of that price. I then desired him to let me have threepence worth of bread, of some kind or other. He gave me three large rolls. I was surprised at receiving so much. I took

them, however, and having no room in my pockets, I walked on, with a roll under each arm, eating the third. In this manner I went through Market street to Fourth street, and passed the house of Mr. Read, the father of my future wife. She was standing at the door, observed me, and thought with reason that I made a very singular and grotesque appearance. I then turned the corner, and went through Chestnut street, eating my roll all the way; and, having made this round, I found myself again on Market street wharf, near the boat on which I arrived. I stepped into it to take a draft of the river water; and finding myself satisfied with my first roll, I gave the other two to a woman and her child who had come down the river with us in the boat, and was waiting to continue her journey. Thus refreshed, I regained the street, which was now full of well-dressed people all going the same way. I joined them, and was thus led to a Quakers' meeting-house, near the market-place. I sat down with the rest, and, after looking round me for some time, hearing nothing said, and being drowsy from my last night's labour and want of rest, I fell into a sound sleep. In this state I continued till the assembly dispersed, when one of the congregation had the goodness to wake me. This was consequently the first house I entered, or in which I slept, in Philadelphia."

Having with some difficulty procured a lodging for the night, he next morning waited on Mr. Bradford, the printer to whom he had been directed. That individual said he had no work for him at present, but directed him to a brother in trade of the name of Keimer, who, upon application, made him the same answer; but, after considering a little, set him to put an old press to rights, being the only one indeed he possessed; and in a few days gave him regular work. Upon this, Franklin took a lodging in the house of Mr. Read, his future father-in-law.

Franklin had been some months at Philadelphia, without either writing to or hearing from home, and, as he says, trying to forget Boston as much as possible, when a brother-in-law of his, a master of a vessel, having accidentally heard where he was, wrote to him, pressing his return home in the most urgent terms. Franklin's reply, declining compliance with the request, happened to reach his brother-in-law when the latter was in the company of Sir William Keith, governor of the province; and the composition and penmanship struck him as so much superior to the ordinary style of letter-writing, that he showed it to his excellency. The governor was no less pleased with it, and expressed the utmost surprise when told the age of the writer. He observed, that he must be a young man of promising talents, and said that if he would set up business on his own account at Philadelphia, he would procure him the printing of all the public papers, and do him every other service in his power. Franklin heard nothing of this from his brother-in-law at the time; but one day while he and Keimer were at work in the office, they observed through the window the governor and another gentleman (who proved to be Colonel French of Newcastle, in the province of Delaware), finely dressed, cross the street, and come directly for the office, where they knocked at the door. Keimer ran down, in high expectation of this being a visit to himself; "but the governor (says Franklin) inquired for me, came up stairs, and with a politeness to which I had not at all been accustomed, paid me many compliments, desired to be acquainted with me, obligingly reproached me for not having made myself known to him on my arrival in town, and wished me to accompany him to a tavern, where he and Colonel French were going to taste some excellent Madeira wine! I was, I confess, somewhat surprised, and Keimer was thunderstruck. I went, however, with the governor and Colonel French to a tavern at the corner of Third street, where, while we were drinking the Madeira, he proposed to me to establish a printing-house. He set forth the probabilities of success, and himself and Colonel French assured me that I should have their protection and influence in obtaining the printing of the public papers for both governments; and as I appeared to doubt whether my father would assist me in this enterprise, Sir William said that he would give me a letter to him, in which he would recommend the advantages of the scheme in a light which he had no doubt would determine him to agree to do so. It was thus concluded that I should return to Boston by the first vessel, with the letter of recommendation from the governor to my father. Meanwhile, the project was to be kept secret, and I continued to work to Keimer as before. The governor subsequently sent for me every now and then to dine with him. I considered this a very great honour; and I was the more sensible of it, as he conversed with me in the most affable, friendly, and familiar manner imaginable."

In pursuance of the above arrangement, Franklin set out on his return homewards, in the end of April, 1724, having been absent about seven months, during which time his parents and relations had heard nothing of him whatever, his brother-in-law never having written to inform them where he was. All the family, with the exception of his brother James, were delighted to see him; and not the less so, perhaps that he was apparelled in a complete new suit of clothes, had an excellent silver watch, and about five pounds sterling in his pocket. His father was exceedingly surprised when informed of the object of his visit, and still more at the contents of Governor Keith's epistle. After long deliberation, he came to the resolution of refusing compliance with the request, on account of his son being too young to undertake the management of such a speculation; adding, that he thought the governor a man of little discretion in proposing it. He promised, however, when his son had attained his twenty-first year, that he would supply him with what money he required to set him up in business, praising him highly, at the same time, for his industry and good conduct. Franklin, accordingly, was necessitated to return to Philadelphia with the news of his bad success, but left Boston, on this occasion, accompanied by the blessings of his parents. When he arrived at Philadelphia, he immediately waited upon the governor, and communicated the result of his journey. Sir William observed that his father was "too prudent;" but added, "since he will not do it, I will do it myself." It was ultimately arranged, therefore, that Franklin should proceed personally to London, to purchase every thing necessary for the proposed establishment, for the expense of which the governor promised him a letter of credit to the extent of £100, with recommendations to various people of influence.

SAILS FOR ENGLAND.

It had been arranged that Franklin was to go to England in the regular packet-ship; and as the time of her sailing drew near, he became importunate for the governor's letters of credit and recommendation, but the latter always put him off under various pretences. At last, when the vessel was on the point of departing, he was sent on board, under the assurance that Colonel French would bring the letters to him immediately. That gentleman accordingly came on board with a packet of despatches tied together, which were put into the captain's bag, and Franklin was informed that those intended for him were tied up with the rest, and would be delivered to him before landing in England. When they arrived in the Thames, accordingly, the captain allowed him to search the bag, but Franklin could find no letters directed either to himself or addressed as to his care; but he selected six or seven, which, from the directions on them, he conceived to be those intended for his service. One of these was to the king's printer, and Franklin accordingly waited upon that gentleman with it; but the latter had no sooner

opened it, than he exclaimed, "Oh, this is from Riddleden!—(a well-known rascally attorney at Philadelphia); I have lately discovered him to be an arrant knave, and wish to have nothing to do either with him or his letters." So saying, he turned on his heel, and resumed his occupation. In short, it turned out that none of the letters were from the governor; and he soon learned from a gentleman of the name of Denham, who had been a fellow-passenger with him, and to whom he explained his awkward situation, that the governor was a complete cheat, deceiving people, from vanity and a love of self-consequence, with promises which he neither intended nor was able to fulfil; and laughed at the idea of a man giving a letter of credit for £100 who had no credit for himself.

Franklin's situation was now even more desolate than when set ashore, ragged, hungry, and almost penniless, at Philadelphia, little more than a twelvemonth before. But the heart at eighteen is not naturally inclined to despond, and never was one less so than Franklin's. He immediately applied for and obtained employment in the office of the celebrated Mr. Palmer. Among other works on which he was set to work here, was a second edition of Wollaston's Religion of Nature. Conceiving some of the positions assumed in it to be weak or erroneous, he composed and published a small metaphysical treatise in refutation of them. This pamphlet acquired him considerable credit with his master as a man of talent; but that gentleman reprobated, with the utmost abhorrence, the doctrines maintained in his publication, which, truth compels us to say, were completely irreligious, so far as regarded the Christian faith, or any other acknowledged system of belief. Free-thinking, however, was then in fashion among the higher and more learned classes, and his pamphlet procured him the countenance of various eminent individuals; among the rest, of Dr. Mandeville, author of the Fable of the Bees, and Dr. Pemberton, Sir Isaac Newton's friend. He was likewise waited upon by Sir Hans Sloane, who had been informed of his bringing some curiosities with him from America; among others, a purse of asbestos—a natural substance which resists the action of fire, and then very little known—for which he paid Franklin a high price. From Mr. Palmer's office he removed to Mr. Watt's, for the consideration of a higher wage. Here he gave a striking proof of that resolute adherence to temperance, industry, and frugality, which were among the leading features of his character. While Mr. Watt's other workmen spent generally five or six shillings a week on beer, which was brought into the office to them during the day, he drank nothing but water; and they were surprised to see that he was much stronger than any of them, while he himself had the additional comfort and satisfaction of being always clear-headed. At first they ridiculed his abstinence, and conferred upon him the soubriquet of the *American Aquatic;* but as his character rose among them, his example, he says, "prevailed with several of them to renounce their abominable breakfast of bread and cheese, with beer; and they procured, like me, from a neighbouring house, a good basin of warm gruel, in which was a small slice of butter, with toasted bread and nutmeg. This was a much better breakfast, which did not cost more than a pint of beer, namely, three halfpence, and at the same time preserved the head clearer." His assiduous application to business, at the same time, together with remarkable quickness in *composing* (setting up the types), recommended him to his employer, and procured him all the most urgent and best-paid work: so that, with his frugal mode of living, he quickly laid past money.

RETURNS TO AMERICA.

After having been about eighteen months in London, much to his advantage in every respect—for, besides becoming more proficient in his business, he had stuck to his books as sedulously as ever, even though he frequently went to the play, made little pleasure excursions, and mingled a good deal in society—he was about to set out on a tour through Europe, with a young intelligent fellow-workman (designing to maintain themselves during their pilgrimage by means of their calling), when he accidentally met with Mr. Denham, before noticed as being his fellow-passenger from America. That gentleman was on the eve of returning to Philadelphia, to open a merchant's store, and offered Franklin the situation of his clerk, with a salary of £50 per annum. This sum was less than he was making as a compositor; but an anxious desire to revisit his native country induced him to accept of it. They set sail accordingly—Franklin now supposing that he had relinquished the composing-stick for ever—and arrived at Philadelphia on the 11th of October, 1726. Franklin had just entered his twenty-first year at this time; and he mentions having drawn up for himself in writing, during the voyage, a plan for the regulation of his future conduct. This interesting document was afterwards unfortunately lost; but he tells us himself that he pretty faithfully adhered to the rules thus early laid down, even into old age. Upon his arrival, he found that his old acquaintance, the governor, had been supplanted in his office, and was held in general contempt. They met several times, but no allusion was ever made by Franklin to the disgraceful imposture the other had practised on him.

Franklin's new employer had only been in business for a few months, when both were seized at the same time with a violent disorder, which carried off the master in a few days, and brought the clerk to the brink of the grave. On his recovery, being thus once more left destitute, he was fain to accept employment as a printer from his old master Keimer, who was now somewhat better off in the world, but still utterly ignorant of his profession. The whole charge of the office, with that of instructing four or five ignorant apprentices, devolved on Franklin. "I also," says he, "upon occasion, engraved various ornaments, made ink, gave an eye to the shop—in short, I was, in every respect, the *factotum*." But he likewise, at this time, gave another remarkable instance of his versatile ingenuity.

"Our press," says he, "was frequently in want of the necessary quantity of letter, and there was no such trade as that of letter-founder in America. I had seen the practice of this art at the house of James, in London, but had at the time paid it very little attention. I, however, contrived to fabricate a mould. I made use of such letters as we had for punches, founded new letters of lead in matrices of clay; and thus supplied, in a tolerable manner, the wants that were most pressing." Franklin's inventive mind would seem here to have obtained a distant glimpse of the principle of *stereotyping*, which has since been carried to such a height of usefulness and perfection, as exemplified in the various publications of the editors of this miscellany.

Keimer having engaged Franklin solely with the view of having his apprentices so far initiated in the art as that he could dispense with their instructor's services, took the first occasion to quarrel with him when he thought he had sufficiently attained his object. Upon their separation, one of Keimer's apprentices, named Meredith, who, like all the others, had conceived a great veneration for Franklin, proposed that they should enter into partnership together—Meredith's friends undertaking to furnish the capital necessary for purchasing the materials, &c. This offer was too advantageous to be refused, and types, press, &c., were forthwith commissioned from London; but while preparing to put their plan into execution, Franklin was induced, during the interval, to return again to Keimer, at the urgent solicitation of the latter. The motive for this humble entreaty

was that individual's having taken a contract for the printing of some paper-money for the state of New Jersey, requiring a variety of new cuts and types, which he knew well nobody in that place but Franklin could supply. This also presents us with a very striking instance of Franklin's remarkable gift of invention.

"To execute the order," says he, "I constructed a copperplate printing-press—the first that had been seen in the country. I engraved various ornaments and vignettes for the bills, and we repaired to Burlington together, where I executed the whole to the general satisfaction, and he (Keimer) received a sum of money for this work which enabled him to keep his head above water for a considerable time longer."

At Burlington, Franklin formed acquaintance with all the principal personages of the province, who were attracted by his superior abilities and intelligence. Among these was the inspector-general, Isaac Decon, "who," says Franklin, "was a shrewd and subtle old man. He told me that his first employment had been that of carrying clay to the brickmakers; that he did not learn to write till he was somewhat advanced in life; that he was afterwards employed as underling to a surveyor, who taught him his trade; and that, by industry, he had at last acquired a competent fortune. 'I foresee,' said he, 'that you will soon supplant this man (speaking of Keimer), and get a fortune in the business at Philadelphia.' He was wholly ignorant at the time of my intention of establishing myself there, or anywhere else."

ENTERS INTO BUSINESS.

Franklin had scarcely returned from Burlington, when the types commissioned for himself and Meredith, from London, arrived; and having settled matters with Keimer, the partners immediately took a house, and commenced business. They were in the act of opening up their packages, when a countryman came in to have a job done; and as all their cash had been expended in their various purchases, "this countryman's five shillings," says Franklin, "being our first fruits, and coming so seasonably, gave me more pleasure than any crown I have since earned." A number of young men having, during the preceding year, formed themselves, at Franklin's suggestion, into a weekly club for the purpose of mutual improvement, they were so well pleased with the beneficial results they experienced from their meetings, that, when the originator of their society set up in business, every one exerted himself more than another to procure him employment. One of them obtained from the Quakers the printing of forty sheets of a history of that sect, then preparing at the expense of the body. "Upon these," says Franklin, "we worked exceeding hard, for the price was very low. It was in folio, upon *pro patria* paper, and in the *pica* letter, with heavy notes in the smallest type. I composed a sheet a day, and Meredith put it to press. It was frequently eleven o'clock at night, sometimes later, before I had finished my distribution for the next day's task; for the other little jobs that came in kept us back in this work; but I was so determined to compose a sheet a day, that one evening, when my form was imposed, and my day's work, as I thought, at an end, an accident broke the form, and deranged two complete folio pages. I immediately distributed and composed them anew before I went to bed." This unwearied industry, which soon became known, acquired Franklin great reputation and credit among his townsmen, and business began rapidly to flow in upon them.

STARTS A NEWSPAPER.

The establishment and management of a newspaper seems to have all along been a favourite project with Franklin; probably because, from his former experience in it, and the consciousness of his powers of writing, he felt himself so well adapted for the task. The partners soon found themselves in circumstances to enable them to make the trial; but Franklin having incautiously divulged their intention to a third person, that individual informed their old master Keimer of the fact, who immediately took steps to anticipate them, and issued a prospectus of a paper of his own. The manner in which Franklin met and defeated this treachery is exceedingly characteristic. There was another paper published in Philadelphia by Mr. Bradford, which had been in existence for some years, but was such a miserable affair, that it only preserved its vitality because no other arose to knock it on the head. In order to keep down Keimer's publication, however, Franklin saw the policy of supporting the old one until prepared to start his own. He thereupon set about writing a series of amusing articles for it, which the publisher, Bradford, was of course very glad to insert. "By this means," says Franklin, "the attention of the public was kept fixed on that paper, and Keimer's proposals, which we burlesqued and ridiculed, were disregarded. He began his paper, however; and, after continuing it for nine months, having at most not more than ninety subscribers, he offered it to me for a mere trifle. I had for some time been prepared for it; I therefore instantly took it upon myself, and in a few years it proved very profitable to me." In fact, it obtained notoriety and applause at the very first number, in consequence of some observations therein by Franklin, on an important colonial question; and various members of Assembly exerted themselves so well in his behalf, that the printing of the House was speedily transferred from Bradford to his two young rivals. In the management of his newspaper, Franklin pursued a system of unflinching integrity. He steadfastly refused to give admission into his columns of any article containing personal abuse of particular individuals. Whenever he was requested to publish any thing of this sort, his answer was, that he would print the piece by itself, and give the author as many copies for his own distribution as he wished. He very wisely considered that his subscribers expected him to furnish them with useful and entertaining information, and not with personal slander or private discussions with which they had no concern.

COMMENCES BUSINESS BY HIMSELF.

Luckily for Franklin, almost at the commencement of the newspaper, an opportunity occurred of getting rid of his partner Meredith, who had become an idle, drunken fellow, and had all along been of comparatively little use in the concern. Meredith's father failed to implement the bargain for advancing the necessary capital to pay the demands of the paper-merchant, and other expenses necessarily attending their speculation, when they became due. A suit was accordingly instituted against the partners; and as Meredith's father declared his inability to pay the amount of the claims upon them, the son offered to relinquish the whole concern into Franklin's hands, on condition that the latter would take upon him the debts of the company, repay his father what he had already advanced, settle his own little personal debts, and give him thirty pounds and a new saddle! By the kindness of two friends, who, unknown to each other, came forward simultaneously and unasked to his assistance, Franklin was enabled to accept the offer. The agreement was carried into effect, and thus do we find this extraordinary man, at the age of twenty-four, and in the place where he had arrived penniless only seven years before, settled down in business, with a thriving trade proprietor of an extensively circulated newspaper, and a firmly established reputation of no ordinary kind. As this success, however, the result of his own good conduct, perseverance, and frugality, had no undue effect on his well-regulated mind, or could induce him to assume those airs of arrogant superiority and pretension, which

serve but too frequently blemished the character of those who have praiseworthily achieved their own elevation in society. On the contrary, he dressed more plainly, and deported himself more humbly, than ever; and to show that he was not above his business, he sometimes wheeled home on a barrow, with his own hands, the paper which he purchased at the stores.

Soon after getting the whole printing and newspaper concern into his hands, there was an outcry among the people for a new emission of paper-money. Franklin took up the cause, and by his arguments in a pamphlet which he published on the subject, contributed so greatly to the success of the proposal, and obtained himself so much popularity, that upon its being resolved to issue the notes, Franklin was selected to print them. He then opened a stationer's shop, and from his success in business, began gradually to pay off his debts. Meanwhile, his old master Keimer went fast to ruin, and with the exception of old Mr. Bradford, who was rich and did not care for business, he was the only printer in the place. He shortly afterwards married Miss Read, the lady named in a former part of this memoir. Franklin's behaviour to this young lady had not been altogether blameless. Previous to his sailing for England, he had exchanged pledges of affection with her; yet, all the while he was away, he only sent her one letter. Her friends and herself concluding that he either never meant to return, or that he wished to drop connection with her, she was induced to accept the hand of another suitor, and on his return to America Franklin found her married—an event that seems to have given him extremely little uneasiness. The lady's husband proved a great rogue, deserted her, and it was subsequently ascertained that he had still a former wife living. After being established in business, and rising in the world, the intimacy between Franklin and her family was renewed, and it was not long ere, despite her dubious situation, they hazarded a fulfilment of their early vows. The lady was about Franklin's own age, and proved, according to his own testimony, "an honour and a blessing to him."

In 1731, Franklin drew up proposals for a public subscription library at Philadelphia, being the first project of the sort that had been started in America. Fifty persons at first subscribed forty shillings each, and agreed to pay ten shillings annually; and the establishment was put under such judicious rules of management, that in the course of ten years it became so valuable and important as to induce the proprietors to get themselves incorporated by royal charter. This library afforded its founder facilities of improvement of which he did not fail to avail himself, setting apart, as he tells us, an hour or two every day for study, which was the only amusement he allowed himself. Several other companies were formed in the city in imitation of it, and the whole were finally united in one institution. A taste for reading was thus spread around, and libraries were formed throughout Pennsylvania.

Franklin was much gratified by the success of his scheme, and continued by his example to encourage habits of industry in the young, and to raise a taste for literary and other rational recreations. We now find him, at the early age of twenty-five or twenty-six, fairly embarked in life as a tradesman, citizen, and a lover of literary and scientific pursuits. His first consideration was scrupulous attention to business and to his family. He took care, he says, not only to be *really* industrious and frugal, but also to avoid every appearance to the contrary—was plainly dressed, and was never seen in any place of amusement: never went a-fishing or hunting; his only relaxation being in a game of chess, of which he was very fond. He devoted the greater part of his leisure time to self-examination and improvement. On instituting a rigorous examination into his conduct and character, he found that he possessed many faults, which he resolved upon amending, he even conceived the bold idea of seeking to attain *moral perfection*. With the view of carrying this project into execution, he fell upon the device of methodizing his time during the twenty-four hours of every day, and of laying down certain rules by which he should regulate his conduct and sentiments. He rose at 5 in the morning; the next three hours he appropriated to devotional exercise, study, cleaning of the person, and breakfast. From 8 till 12 he was at work. From 12 till 2 he read, did any desultory duties, and dined. From 2 till 5 he was again at work. From 6 till 10, he devoted to reading, conversation, intercourse with his family, and supper; and from 10 till 4 or 5 in the morning, to sleep; after which he arose and pursued the same routine as before. We thus see that early rising was a leading feature in his habits of life, and to this alone he doubtless owed much of his success.

Franklin's arrangement of his time was less remarkable than his plan of self-examination. We have said that he established certain rules for the regulation of his conduct. These were thirteen in number, and were called by him virtues or precepts to be kept in remembrance: they are thus summed up:—Temperance; silence, or abstaining from frivolous talking; order; resolution, or determination to perform promises and duties; frugality; industry; sincerity, or avoiding of all deceit; justice, or the wronging of no one; moderation; cleanliness; tranquillity of mind; chastity; and humility, in which was included an endeavour to imitate Christ, and also Socrates. It is mentioned by Franklin, that it required a constant care to avoid infringing upon these precepts, and that at length, to assist himself, he prepared a book to serve as a journal of his conduct and thoughts, in which he took pains to mark every error he committed. By this means he was able to observe how he advanced in virtue, and how far he abstained from error: it was his anxious wish to see the tables in his book free from any markings or indications of imperfection of character. To this journal of his conduct he attached certain mottoes; one of which was a verse from the Proverbs of Solomon, in which wisdom is eulogized:—"Length of days is in her right hand, and in her left riches and honour. Her ways are ways of pleasantness, and all her paths are peace." Another of his mottoes was in the form of a pious aspiration or prayer, in which he implored the divine blessing on his labours, and an increase of that wisdom which was most beneficial to him. One of his favourite passages which he occasionally repeated, was the beautiful address to the Deity in Thomson's poem on the Seasons:

> "Father of light and life, thou God supreme!
> Oh teach me what is good; teach me thyself!
> Save me from folly, vanity and vice,
> From every low pursuit; fill my soul
> With knowledge, conscious peace, and virtue pure,
> Sacred, substantial, never-fading bliss!"

He tells us that the most troublesome part of his prescribed task of self-regulation, was the obligation to preserve order in his line of duties—being most likely liable to distraction by trifling circumstances constantly interfering to mar his project. Nevertheless, he persevered, forced himself to be methodic, and was thus able to proceed with studies tending greatly to his mental improvement, and his increase in useful knowledge.

Of Franklin's intercourse with his family little has been made known, though it is ascertained, by a few scattered hints in his writings, that he was an affectionate husband and father, and placed much of his happiness in home. In his household affairs the most exact economy prevailed, and, for several years after his marriage, his breakfast consisted simply of bread and milk, which he ate from a twopenny earthenware porringer with a pewter spoon. Fortunately, his wife was as much disposed

to be industrious as he was; she assisted him in his business, folded the sheets of books which he printed, kept his shop, and executed other humble but useful duties. By following this industrious and economical plan of living, they gradually accumulated wealth, and were enabled to possess comforts and luxuries which were at first beyond their reach. Still, Franklin was not puffed up by prosperity, but continued to live in a style of simplicity agreeable to the notions he had formed at the outset of his career.

In conducting his business, he happily united the occupation of a printer with the profession of an author, and thus became the publisher of his own literary productions. No large work, however, was given by him to the world. His writings were chiefly of a minor character, such as detached pamphlets on subjects of local import, and short essays; and he did not, as it appears, write much that has been thought worthy of republication in a succeeding age. His newspaper was the Pennsylvania Gazette, which had been started by Keimor in 1728, and which, after about a twelvemonth's mismanagement, had come into the possession of Franklin and Hugh Meredith. By Franklin's ingenuity, the paper rose in general estimation.

Besides editing his newspaper, he conducted and published an almanac, which he began in 1732, and continued for a period of twenty-five years. This almanac bore the feigned name, Richard Saunders, and hence acquired the title of Poor Richard's Almanac, by which it became extensively known. The leading feature of the work consisted in an array of concise maxims and apothegms of an economical character, distributed here and there throughout the calendar, wherever space was left between the names of the holidays. When Poor Richard's Almanac was brought to a close, a considerable number of the maxims were collected in An address to the Reader, in the last number, and entitled The Way to Wealth. This admirable digest has been since translated into various languages, and is now widely known. We here subjoin a copy:—

THE WAY TO WEALTH.

I stopped my horse lately where a great number of people were collected at an auction of merchants' goods. The hour of sale not being come, they were conversing on the badness of the times; and one of the company called to a plain, clean old man, with white locks, "Pray, Father Abraham, what think ye of the times? Won't these heavy taxes quite ruin the country? How shall we ever be able to pay them? What would you advise us to?" Father Abraham stood up and replied, "If you have my advice, I'll give it to you in short: 'for a word to the wise is enough: and many words won't fill a bushel,' as poor Richard says." They joined in desiring him to speak his mind; and gathering round him he proceeded as follows:—

"Friends (says he) and neighbours, the taxes are indeed very heavy; and if those laid on by the government were the only ones we had to pay, we might more easily discharge them: but we have many others, and much more grievous to some of us. We are taxed twice as much by our idleness, three times as much by our pride, and four times as much by our folly; and from these taxes the commissioners cannot ease or deliver us, by allowing an abatement. However, let us hearken to good advice, and something may be done for us: 'God helps them that help themselves,' as poor Richard says in his Almanac.

"It would be thought a hard government that should tax its people one-tenth part of their time, to be employed in its service; but idleness taxes many of us much more, if we reckon all that is spent in absolute sloth, or doing of nothing, with that which is spent in idle employments, or amusements that amount to nothing. Sloth, by bringing on diseases, absolutely shortens life. 'Sloth, like rust, consumes faster than labour wears; while the key often used is always bright,' as poor Richard says. 'But dost thou love life? then do not squander time, for that's the stuff life is made of,' as poor Richard says. How much more than is necessary do we spend in sleep, forgetting that 'the sleeping fox catches no poultry, and that there will be sleeping enough in the grave,' as poor Richard says. 'If time be of all things the most precious, wasting time must be (as poor Richard says) the greatest prodigality;' since, as he elsewhere tells us, 'Lost time is never found again; and what we call time enough, always proves little enough.' Let us then up and be doing, and doing to the purpose; so by diligence shall we do more with less perplexity. 'Sloth makes all things difficult, but industry all easy,' as poor Richard says; and 'He that riseth late must trot all day, and shall scarce overtake his business at night; while laziness travels so slowly, that poverty soon overtakes him,' as we read in poor Richard; who adds, 'Drive thy business, let not that drive thee;' and,

> 'Early to bed, and early to rise,
> Makes a man healthy, wealthy, and wise.'

"So what signifies wishing and hoping for better times? We make these times better if we bestir ourselves. 'Industry needs not wish,' as poor Richard says; 'He that lives upon hope will die fasting.' 'There are no gains without pains; then help, hands, for I have no lands: or if I have, they are smartly taxed:' and (as poor Richard likewise observes) 'He that hath a trade hath an estate, and he that hath a calling hath an office of profit and honour;' but then the trade must be worked at, and the calling well followed, or neither the estate nor the office will enable us to pay our taxes. If we are industrious, we shall never starve; for as poor Richard says, 'At the working-man's house hunger looks in, but dares not enter.' Nor will the bailiff or the constable enter; for 'Industry pays debts, but despair increaseth them,' says poor Richard. What though you have found no treasure, nor has any rich relation left you a legacy? 'Diligence is the mother of good luck,' as poor Richard says: and 'God gives all things to industry: then plough deep while sluggards sleep, and you will have corn to sell and to keep,' says poor Dick. Work while it is called to-day; for you know not how much you may be hindered to-morrow; which makes poor Richard say, 'One to-day is worth two to-morrows; and, further, 'Have you somewhat to do to-morrow, do it to-day.' 'If you were a servant, would you not be ashamed that a good master should catch you idle? Are you, then, your own master? be ashamed to catch yourself idle,' as poor Dick says. When there is so much to be done for yourself, your family, and your gracious king, be up by peep of day: 'Let not the sun look down, and say, Inglorious here he lies!' Handle your tools without mittens; remember that 'The cat in gloves catches no mice,' as poor Richard says. It is true, there is much to be done, and perhaps you are weak-handed; but stick to it steadily, and you will see great effects: for continual dropping wears away stones, and by diligence and patience the mouse ate into the cable; and 'light strokes fell great oaks,' as poor Richard says in his Almanac, the year I cannot just now remember.

"Methinks I hear some of you say, 'Must a man afford himself no leisure?'—I will tell thee, my friend, what poor Richard says. 'Employ thy time well, if thou meanest to gain leisure; and since thou art not sure of a minute, throw not away an hour.' Leisure is time for doing something useful; this leisure the diligent man will obtain, but the lazy man never; so that, as poor Richard says, 'A life of leisure and a life of laziness are two things.' Do you imagine that sloth will afford you more comfort than labour? No; for, as poor Rich-

ard says, 'Troubles spring from idleness, and grievous toils from needless ease: many without labour would live by their own wits only; but they break for want of stock.' Whereas industry gives comfort, and plenty, and respect. 'Fly pleasures, and they'll follow you; the diligent spinner has a large shift; and now I have a sheep and a cow, everybody bids me good-morrow:' all which is well said by poor Richard.

"But with our industry, we must likewise be steady, and settled, and careful, and oversee our own affairs, with our own eyes, and not trust too much to others; for, as poor Richard says,

'I never saw an oft-removed tree,
Nor yet an oft-removed family,
That throve so well as one that settled be.'

And again, 'Three removes are as bad as a fire:' and again, 'Keep thy shop, and thy shop will keep thee:' and again, 'If you would have your business done, go; if not, send.' And again,

'He that by the plough would thrive,
Himself must either hold or drive.'

And again, 'The eye of the master will do more work than both his hands:' and again, 'Want of care does us more damage than want of knowledge:' and again, 'Not to oversee workmen is to leave them your purse open.' Trusting too much to others' care is the ruin of many; for, as the Almanac says, 'In the affairs of the world, men are saved not by faith, but by the want of it; but a man's own care is profitable; for,' saith poor Dick, 'Learning is to the studious, and riches to the careful, as well as power to the bold, and heaven to the virtuous.' And further, 'If you would have a faithful servant, and one that you like, serve yourself.' And again, he adviseth to circumspection and care, even in the smallest matters, because sometimes 'A little neglect may breed great mischief;' adding, 'For want of a nail the shoe was lost; for want of a shoe the horse was lost; and for want of a horse the rider was lost;' being overtaken and slain by the enemy, all for want of care about a horse-shoe nail.

"So much for industry, my friends, and attention to one's own business; but to these we must add frugality, if we would make our industry more certainly successful. A man may, if he knows not how to save as he gets, 'keep his nose all his life to the grindstone, and die not worth a groat at last.' 'A fat kitchen makes a lean will,' as poor Richard says; and,

'Many estates are spent in the getting;
Since women for tea forsook spinning and knitting,
And men for punch forsook hewing and splitting.'

"'If you would be wealthy (says he in another Almanac), think of saving, as well as of getting: the Indies have not made Spain rich, because her outgoes are greater than her incomes.'

"Away, then, with your expensive follies, and you will not have much cause to complain of hard times, heavy taxes, and chargeable families; for, as poor Dick says,

'Women and wine, game and deceit,
Make the wealth small, and the want great.'

And, further, 'What maintains one vice would bring up two children.' You may think, perhaps, that a little tea, or a little punch now and then, diet a little more costly, clothes a little finer, and a little entertainment now and then, can be no great matter; but remember what poor Richard says—'Many a little makes a mickle:' and farther, 'Beware of little expenses; a small leak will sink a great ship:' and again, 'Who dainties love shall beggars prove:' and moreover, 'Fools make feasts, and wise men eat them.'

"Here you are all got together at this sale of fineries and nic-nacks. You call them *goods;* but if you do not take care, they prove *evils* to some of you. You expect they will be sold cheap, and perhaps they may for less than they cost; but if you have no occasion for them, they must be dear to you. Remember what poor Richard says—'Buy what thou hast no need of, and ere long thou shalt sell thy necessaries.' And again, 'At a great pennyworth pause a while.' He means, that perhaps the cheapness is apparently only, or not real, or the bargain, by straitening thee in thy business, may do thee more harm than good. For in another place he says, 'Many have been ruined by buying good pennyworths.' Again, as poor Richard says, 'It is foolish to lay out money in a purchase of repentance;' and yet this folly is practised every day at auctions, for want of minding the Almanac. 'Wise men (as poor Dick says) learn by others' harms, fools scarcely by their own; but *Felix quem faciunt aliena pericula cautum.*' Many people, for the sake of finery on the back, have gone with a hungry belly, and half starved their families: 'Silk and satins, scarlet and velvets (as poor Richard says), put out the kitchen fire.' These are not the necessaries of life; they can scarcely be called the conveniences; and yet, only because they look pretty, how many want to have them! The artificial wants of mankind thus become more numerous than the natural; and as poor Dick says, 'For one poor person there are a hundred indigent.' By these and other extravagances, the genteel are reduced to poverty, and forced to borrow of those whom they formerly despised, but who, through industry and frugality, have maintained their standing; in which case it appears plainly, 'A ploughman on his legs is higher than a gentleman on his knees,' as poor Richard says. Perhaps they have had a small estate left them which they knew not the getting of; they think 'It is day, and will never be night; that a little to be spent out of so much is not worth minding.' 'A child and a fool (as poor Richard says) imagine twenty shillings and twenty years can never be spent; but always taking out of the meal-tub, and never putting in, soon comes to the bottom:' then as poor Dick says, 'When the well is dry, they know the worth of water.' But this they might have known before, if they had taken his advice: 'if you would know the value of money, go and try to borrow some; for he that goes a-borrowing goes a-sorrowing, and, indeed, so does he that lends to such people when he goes to get it in again.' Poor Dick further advises, and says,

'Fond pride of dress is sure a very curse:
Ere fancy you consult, consult your purse.'

"And again, 'Pride is as loud a beggar as Want, and a great deal more saucy.' When you have bought one fine thing, you must buy ten more, that your appearance may be all of a piece; but poor Dick says, 'It is easier to suppress the first desire than to satisfy all that follow it.' And it is as truly folly for the poor to ape the rich, as the frog to swell in order to equal the ox.

'Vessels large may venture more,
But little boats should keep near shore.'

"'Tis, however, a folly soon punished; for, 'Pride that dines on vanity sups on contempt,' as poor Richard says. And in another place, 'Pride breakfasted with Plenty, dined with Poverty, and supped with Infamy.' And, after all, of what use is this pride of appearance, for which so much is risked, so much is suffered! It cannot promote health, or ease pain; it makes no increase of merit in the person; it hastens misfortune.

'What is a butterfly? At best
He's but a caterpillar drest;
The gaudy fop's his picture just'—

as poor Richard says.

"But what madness must it be to run in debt for these superfluities! We are offered, by the terms of this sale,

six months' credit and that perhaps has induced some of us to attend it, because we cannot spare the ready money, and hope now to be fine without it. But, ah! think what you do when you run in debt. You give to another power over your liberty. If you cannot pay at the time, you will be ashamed to see your creditor; you will be in fear when you speak to him: you will make poor, pitiful, sneaking excuses, and by degrees come to lose your veracity, and sink into base downright lying; for, as poor Richard says, 'The second vice is lying; the first is running in debt.' And again, to the same purpose 'Lying rides upon debt's back;' whereas, a free-born Englishman ought not to be ashamed nor afraid to speak to any man living. But poverty often deprives a man of all spirit and virtue. 'It is hard for an empty bag to stand upright,' as poor Richard truly says. What would you think of that prince, or that government, who would issue an edict, forbidding you to dress like a gentleman or gentlewoman, on pain of imprisonment or servitude? Would you not say that you were free, have a right to dress as you please, and that such an edict would be a breach of your privileges, and such a government tyrannical? And yet you are about to put yourself under that tyranny when you run in debt for such dress! Your creditor has authority at his pleasure to deprive you of your liberty, by confining you in jail for life, or by selling you for a servant, if you should not be able to pay him. When you have got your bargain, you may perhaps think little of payment: but 'Creditors (poor Richard tells us) have better memories than debtors;' and in another place he says, 'Creditors are a superstitious sect, great observers of set days and times.' The day comes round before you are aware, and the demand is made before you are prepared to satisfy it; or if you bear your debt in mind, the term which at first seemed so long, will, as it lessens, appear extremely short. Time will seem to have added wings to his heels as well as at his shoulders. 'Those have a short Lent (saith poor Richard) who owe money to be paid at Easter.' Then since, as he says, 'The borrower is a slave to the lender, and the debtor to the creditor,' disdain the chain, preserve your freedom, and maintain your independence: be industrious and free; be frugal and free. At present, perhaps, you may think yourselves in thriving circumstances, and that you can bear a little extravagance without injury; but

> 'For age and want save while you may,
> No morning sun lasts a whole day,'

as poor Richard says. Gain may be temporary and uncertain; but ever, while you live, expense is constant and certain; and 'It is easier to build two chimneys, than to keep one in fuel,' as poor Richard says. So 'Rather go to bed supperless than rise in debt.'

> 'Get what you can, and what you get hold;
> 'Tis the stone that will turn all your lead into gold,'

as poor Richard says. And when you have got the philosopher's stone, surely you will no longer complain of bad times, or the difficulty of paying taxes.

"This doctrine, my friends, is reason and wisdom; but, after all, do not depend too much upon your own industry, and frugality, and prudence, though excellent things; for they may be blasted without the blessing of Heaven; and therefore ask that blessing humbly, and be not uncharitable to those that at present seem to want it, but comfort and help them. Remember Job suffered, and was afterwards prosperous.

"And now, to conclude, 'Experience keeps a dear school; but fools will learn in no other, and scarce in that; for it is true we may give advice, but we cannot give conduct,' as poor Richard says. However, remember this, 'They that will not be counselled cannot be helped,' as poor Richard says; and further, that 'If you will not reason, she will surely rap their knuckles.'"

Thus the old gentleman ended his harangue. The people heard it, and approved the doctrine, and immediately practised the contrary, just as if it had been a common sermon; for the auction opened, and they began to buy extravagantly, notwithstanding all his cautions and their own fear of taxes. I found the good man had thoroughly studied my Almanacs, and digested all I had dropped on those topics during the course of twenty-five years. The frequent mention he made of me must have tired every one else; but my vanity was wonderfully delighted with it, though I was conscious that not a tenth part of the wisdom was my own, which he ascribed to me, but rather the gleanings that I had made of the sense of all ages and nations. However, I resolved to be the better for the echo of it; and though I had at first determined to buy stuff for a new coat, I went away, resolved to wear my old one a little longer.

As Franklin advanced in worldly prosperity, he endeavoured to make his personal acquirements keep pace with his upward progress in society; and among other accomplishments, applied himself sedulously to the study of the dead and modern languages, of which, besides his native tongue, he as yet scarcely knew any thing. The following is his own account of his private *curriculum*:—

"I had begun in 1733 to study languages. I soon made myself so much a master of the French, as to be able to read the books in that language with ease. I then undertook the Italian. An acquaintance, who was also learning it, used often to tempt me to play chess with him. Finding this took up too much of the time I had to spare for study, I at length refused to play any more, unless on this condition, that the victor in every game should have a right to impose a task, either of parts of the grammar to be got by heart, or in translations, &c., which tasks the vanquished was to perform upon honour before our next meeting. As we played pretty equally, we thus beat one another into that language. I afterwards, with a little pains-taking, acquired as much of the Spanish as to read their books also. I have already mentioned that I had only one year's instruction in a Latin school, and that when very young, after which I neglected that language entirely; but when I had attained an acquaintance with the French, Italian, and Spanish, I was surprised to find, on looking over a Latin Testament, that I understood more of that language than I had imagined, which encouraged me to apply myself again to the study of it; and I met with the more success, as those preceding languages had greatly smoothed my way."

CIVIC PREFERMENTS AND DUTIES.

It was not to be supposed that a man of Franklin's comprehensive mind, and useful practical talents, would be allowed to remain long in the ranks of private life. Accordingly, in the year 1736, he was appointed clerk to the General Assembly of Pennsylvania. No opposition was made to his appointment the first year; but on the next election, a new member of the house opposed his return in a long speech. Franklin was, however, again elected, much to his satisfaction; for although the place was one of almost no direct emolument, it gave him an opportunity of making friends among the members, and ultimately to secure to himself the printing of most of the public papers, which was previously shared with his rivals. The new member who had resisted his re-election was a man of talents and character; and Franklin, although too independent to pay any cringing servility to him, perceived the propriety of gaining his good opinion; and the expedient he hit upon for this purpose affords another instance of his shrewdness and knowledge of human nature. Having learned that the gentleman possessed a very rare and curious book, he wrote

him a polite note, requesting that he would do him the favour of lending it for a few days. The book was immediately sent; and in about a week was returned by the borrower, with a short epistle, expressive of his gratitude for the favour. The member was so much conciliated by the circumstance, that the next time he met him in the house, he addressed him with great civility; manifested ever afterwards a great desire to serve him; and they became, in short, intimate friends. "This is another instance," observes Franklin, "of the truth of an old maxim I had learned, which says, 'He that has done you a kindness will be more ready to do you another than he whom you yourself have obliged.' And it shows how much more profitable it is prudently to remove than to resent, return, and continue, inimical proceedings." He was thereafter re-elected to the same post without opposition, for several years successively. In the following year, 1737, he supplanted his rival in trade, Bradford, in the office of deputy-postmaster for the state of Pennsylvania. These honourable preferments induced him to incline his thoughts to, and take a more active part in, public affairs than he had hitherto done.

He first turned his attention to the state of the city police, which was then in a shameful condition; and he soon effected a thorough reformation in the whole system. He suggested and promoted the establishment of a fire insurance company, the first that was projected in America. He afterwards successively exerted himself in organizing a philosophical society, an academy for the education of youth, and a militia for the defence of the province. In short, every department of the civil government, as he tells us, and almost at the same time, imposed some duty upon him. "The governor," says he, "put me into the commission of the peace; the corporations of the city chose me one of the common council; and the citizens at large elected me (1747) a burgess to represent them in assembly. This latter station was the more agreeable to me, as I grew at length tired with sitting there to hear the debates, in which, as clerk, I could take no part, and which were often so uninteresting, that I was induced to amuse myself with making magic squares, or circles, or any thing, to avoid weariness; and I conceived my becoming a member would enlarge my power of doing good. I would not, however, insinuate that my ambition was not flattered by all these promotions—it certainly was: for considering my low beginning, they were great things to me; and they were still more pleasing as being so many spontaneous testimonies of the public good opinion, and by me entirely unsolicited."

About this period (1739), the celebrated preacher Whitfield arrived at Philadelphia from Ireland. He was at first permitted to preach in some of the town churches; but the clergy soon took a dislike to him, and he was compelled to exercise his eloquence in the open streets or fields. This circumstance, however, like all displays of persecution in matters exclusively connected with private opinion, only rendered him the more popular; and the effects of his oratory speedily manifested themselves.

"It was wonderful," says Franklin, "to see the change soon made in the manners of our inhabitants. From being thoughtless or indifferent about religion, it seemed as if all the world were growing religious, so that one could not walk through the town in an evening without hearing psalms sung in different families of every street; and it being found inconvenient to assemble in the open air, subject to its inclemencies, the building of a house to meet in was no sooner proposed, and persons appointed to receive contributions, than sufficient sums were soon received to procure the ground and erect the building, which was one hundred feet long and seventy broad; and the work was carried on with such spirit as to be finished in a remarkably short time."

On leaving Philadelphia, Mr. Whitfield went, preaching all the way, through the colonies to Georgia. The settlement of that province had been recently commenced, and was attempted by people entirely unfit for such an experiment. They were unable to endure the fatigues and hardships of their situation, and perished in great numbers, leaving many helpless children with nothing to feed or clothe them. "The sight of their miserable situation," says Franklin, "inspired the benevolent heart of Mr. Whitfield, with the idea of building an orphan house there, in which they might be supported and educated. Returning northward, he preached up this charity, and made large collections; for his eloquence had a wonderful power over the hearts and purses of his hearers, of which I myself was an instance. I did not disapprove of the design; but as Georgia was then destitute of materials and workmen, and it was proposed to send them from Philadelphia at a great expense, I thought it would have been better to have built the house at Philadelphia, and brought the children to it. This I advised; but he was resolute in his first project, rejected my proposal, and I therefore refused to contribute.

"I happened soon after to attend one of his sermons, in the course of which I perceived he intended to finish with a collection, and I silently resolved he should get nothing from me. I had in my pocket a handful of copper, three or four silver dollars, and five pistoles in gold. As he proceeded, I began to soften, and concluded to give the copper. Another stroke of his oratory made me ashamed of that, and determined me to give the silver; and he finished so admirably, that I emptied my pocket wholly into the collector's dish, gold and all!"

At this time there was no military defensive force in Pennsylvania. The inhabitants were mostly Quakers, and neglected to take any measures of precaution against the dangers to which, from the French possessions in Canada, they were continually exposed. All the exertions of the governor of the province to induce the Quaker assembly to pass a militia law, proved ineffectual. Franklin thought something might be done by a subscription among the people; and to pave the way for this, he wrote and published a pamphlet called "Plain Truth." In this he clearly exposed their helpless and perilous situation, and demonstrated the necessity of cooperating for their mutual defence. The pamphlet had a sudden and surprising effect. A meeting of the citizens was held, at which proposals of the intended union, previously drawn up and printed by Franklin, were distributed about the room, to be signed by those who approved of them; and when the company separated, it was found that above twelve hundred signatures had been appended to the papers. Other copies were distributed through the province, and the subscribers at length amounted to upwards of ten thousand! All these individuals furnished themselves, as soon as they could, with arms; formed themselves into companies and regiments; chose their officers, and had themselves regularly instructed in military exercises. The women made subscriptions among themselves, and provided silk colours, which they presented to the companies, embellished with devices and mottoes furnished by Franklin. Such influence has one master-mind among his fellows in a time of emergency!

Franklin's modesty, however, was more than commensurate with his patriotism. The officers of the companies composing the Philadelphia regiment unanimously chose him for their colonel, but he declined the office in favour of a man of greater wealth and influence, who, on his recommendation, was immediately elected. These exertions of Franklin procured him great confidence from the governor and council, who consulted him on all their public measures. Notwithstanding, too, the passive principles of the Quakers, it was soon seen that

the precautions of military defence were any thing but disagreeable to them. A distinguished individual of their number, Mr. Logan, published an address declaring his approbation of defensive war, and supporting his opinion by able and elaborate arguments.

This gentleman, who came over from England when young man, as secretary to the famous William Penn, used to relate an anecdote respecting his old master, which is sufficiently amusing. During their voyage, they were chased by an armed vessel, supposed to be an enemy. Their captain prepared for defence, but told Penn and his company of Quakers that he did not expect their assistance, and that they might retire into the cabin. This notification they all complied with, excepting Logan, who remained on deck, and was quartered to a gun. The supposed enemy proved a friend, so that there was no fighting; but when the secretary carried the joyful news for his friends in the cabin, Penn reproved him severely for staying on deck, and lending his assistance in defence of the vessel, as being a breach of the principles of their society. Logan, nettled at this comment on his courageous conduct, which was made before the whole company, replied, "I being thy servant, why did thee not order me to come down? but thee was willing enough that I should stay and help to fight the ship, when thee thought there was danger!"

ELECTRICAL DISCOVERIES.

It would, perhaps, have been desirable to have followed Franklin through the remainder of his public and political career, without pausing to advert to other pursuits, entirely unconnected therewith, to which he devoted himself. We find, however, that the chronological violence of which we would in that case necessarily be guilty, would only serve to confuse our narrative. We will now, therefore, proceed to introduce him to our readers in an entirely new character from any in which they have yet seen him; for, in the language of the poet, his truly was

> "A mind so various that he seemed to be
> Not one, but all mankind's epitome."

Down to the close of the sixteenth century, all that was known of the principle of electricity, was the discovery of a power inherent in amber,* and one or two other substances, to attract to them, when rubbed, light bodies, such as small bits of paper, straw, &c. In the year 1600, Dr. Gilbert, of London, considerably enlarged the catalogue of these electrical or attractive substances, including the diamond and other precious stones, glass, sulphur, sealing-wax, rosin, &c. For above a century afterwards, however, electricity was little attended to, although Dr. Wall, Sir Isaac Newton, Guericke, and others (the latter of whom first observed the repulsive power and explosive quality of electricity), added some important facts. In 1728, it was discovered that electricity may be communicated from one body to another, even without these bodies being in contact.

The beginning of the year 1746 is memorable in the annals of electricity for the accidental discovery of the possibility of accumulating large quantities of the electric fluid, by means of what was called the Leyden jar, or phial. M. Cuneus, of that city, happened one day, while repeating some experiments which had been originally suggested by M. Von Kleist, Dean of the Cathedral in Camin, to hold in one hand a glass vessel, nearly full of water, into which he had been sending a charge from an electrical machine, by means of a wire dipped into it, and communicating with the prime conductor, or insulated non-electric, exposed in the manner we have already mentioned to the action of the excited cylinder. He was greatly surprised, upon applying his other hand to disengage the wire from the conductor, when he thought that the water had acquired as much electricity as the machine could give it, by receiving a sudden shock in his arms and breast, much more severe than any thing of the kind he had previously encountered in the course of his experiments. The same thing, it was found, took place when the glass was covered, both within and without, with any other conductors than the water and the human hand, which had been used in this instance; as, for example, when it was coated on both sides with tinfoil, in such a manner, however, that the two coatings were completely separated from each other, by a space around the lip of the vessel being left uncovered. Whenever a communication was formed by the interposition of a conducting medium between the inside and outside coating, an instant and loud explosion took place, accompanied with a flash of light, and the sensation of a sharp blow, if the conductor employed was any part of the human body. The first announcement of the wonders of the Leyden phial excited the curiosity of all Europe. The accounts given of the electric shock by those who first experienced it are perfectly ludicrous, and well illustrate how strangely the imagination is acted upon by surprise and terror, when novel or unexpected results suddenly come upon it.

The extraordinary phenomena of the Leyden jar, soon, of course, attracted the attention of Franklin, and his inquisitive mind set itself to find out the reason of such strange effects, which astonished and perplexed the ablest philosophers of Europe. Out of his speculations arose the ingenious and beautiful theory of the action of the electric influence which is known by his name, and which has ever been received as the best, because the simplest and most complete demonstration of the phenomena that has yet been propounded. His earliest inquiries were directed to ascertain the *source* of the electricity, which friction made manifest in the glass cylinder. This he demonstrated, by experiments, to be in the pores of the glass, and not in the coating, as previously supposed. After the cylinder, or phial (as it is frequently termed), was charged, he removed the coating and found that, by applying a new coating, the shock might still be received. He showed clearly, that, when charged, the cylinder contained no more electricity than before, but that as much was taken from one side as was thrown on the other, and that by making a communication between the inside and outside coating, by which, as has already been seen, a loud explosion was caused, the equilibrium was at once restored. In order to determine whether the virtue was created by the friction in the electric, or only communicated to it by other bodies, he resorted to the very simple experiment of endeavouring to electrify himself—that is to say, having insulated himself, and excited the cylinder by rubbing it with his hand, he then drew off his electricity from it in the usual manner into his own body. But he found that he was not thereby electrified at all, as he would have been by doing the same thing, had the friction been applied by another person. No spark could be elicited from him, after the operation by the presentment of a conductor. It was plain, therefore, that the electricity had passed in the first place out of his own body into the cylinder; which, therefore, in communicating it to him in the second instance, only gave back what it had received, and, instead of electrifying him, only restored him to his natural state. To prove this still farther, he insulated two individuals, one of whom he made to rub the cylinder, while the other drew the electricity from it. In this case, they were both affected; the one having given out as much electricity to the cylinder in rubbing it, as the other had drawn from it. In proof of this, he made them touch one another, when both were instantly restored to their usual state. The spark produced by their contact was also greater than that which took place when

* The term electricity is derived from the Greek word *electron*, amber

either of them was touched by an unelectrified person. From these results, then, Franklin constructed his theory, that everybody in nature has a natural quantity of electricity, which may be diminished or increased in the way we have just described. In the former case he regarded the body as *negatively*, in the latter as *positively*, electrified. In the one case it had less, in the other more, than its natural quantity of electricity; in either, therefore, supposing it to be composed of electricity and common matter, the usual equilibrium or balance between its two constituent ingredients was for the time upset or destroyed.

But to return to the Leyden phial: Franklin was not contented with merely ascertaining the principle of it. He made also a very happy application of this principle, which afforded a still more wonderful manifestation than had yet been obtained of the powers of accumulated electricity. Considering the waste that took place, in the common experiment, of the fluid expelled, during the process of charging, from the exterior coating, he conceived the idea of employing it to charge the inner surface of a second jar, which he effected, of course, by the simple expedient of drawing it off by means of a metal rod communicating with that surface. The electricity expelled from the outside of this second jar was conveyed, in like manner, into the inside of a third; and in this way, a great number of jars were charged with the same facility as a single one. Then, having connected all the inside coatings with one conductor, and all the outside coatings with another, he had merely to bring these two general conductors into contact or communication, in order to discharge the whole accumulation at once. This contrivance he called an *Electrical Battery*. The general sketch we have thus given will put the reader in possession at least of the great outlines of the Franklinian theory of electricity, undoubtedly one of the most beautiful generalizations to be found in the whole compass of science.

We now advert to another brilliant discovery by this illustrious philosopher, namely, the similarity between lightning and electricity. The Abbé Nollet had, before him, hinted his suspicions of this resemblance, but only in the most loose and distant way.

In a paper, dated Nov. 7, 1749, Franklin enumerates all the known points of resemblance between lightning and electricity. In the first place, he remarks, it is no wonder that the effects of the one should be so much greater than those of the other; for if two gun-barrels electrified will strike at two inches' distance, and make a loud report, at how great a distance will ten thousand acres of electrified cloud strike, and give out fire; and how loud must be that crack! He had known for some time the extraordinary power of pointed bodies, both in drawing and in throwing off the electric fire. The true explanation of this fact did not occur to him; but it is a direct consequence of the fundamental principle of his own theory, according to which the repulsive tendency of the particles of electricity towards each other, occasioning the fluid to retire, in every case, from the interior to the surface of bodies, drives it with especial force towards points and other prominences, and thus favours its escape through such outlets; while, on the other hand, the more concentrated attraction which the matter of a pointed body, as compared with that of a blunt one, exerts upon the electricity to which it is presented, brings it down into its new channel in a denser stream. In possession, however, of the fact, we find him concluding the paper we have mentioned as follows:—"The electric fluid is attracted by points. We do not know whether this property be in lightning; but since they agree in all the particulars in which we can already compare them, it is not improbable that they agree likewise in this. Let the experiment be made."

Full of this idea, his attention was one day drawn to a kite which a boy was flying, and it suddenly occurred to him that here was a method of reaching the clouds preferable to any other. Accordingly, he immediately took a large silk handkerchief, and stretching it over two cross sticks, formed in this manner his simple apparatus for drawing down the lightning from its cloud. Soon after, seeing a thunder storm approaching, he took a walk into a field in the neighbourhood of the city, in which there was a shed, communicating his intentions, however, to no one but his son, whom he took with him to assist him in raising the kite: this was in June, 1752.

The kite being raised, he fastened a key to the lower extremity of the hempen string, and insulating it by attaching it to a post by means of silk, he placed himself under the shed, and waited the result. For some time no signs of electricity appeared. A cloud, apparently charged with lightning, had even passed over them without producing any effect. At length, however, just as Franklin was beginning to despair, he observed some loose threads of the hempen string rise and stand erect, exactly as if they had been repelled from each other by being charged with electricity. He immediately presented his knuckle to the key, and, to his inexpressible delight, drew from it the well-known electrical spark. He said afterwards that his emotion was so great at this completion of a discovery which was to make his name immortal, that he heaved a deep sigh, and felt that he could that moment have willingly died. As the rain increased, the cord became a better conductor, and the key gave out its electricity copiously. Had the hemp been thoroughly wet, the bold experimenter might, as he was contented to do, have paid for his discovery with his life. He afterwards brought down the lightning into his house, by means of an insulated iron rod, and performed with it, at his leisure, all the experiments that could be performed with electricity. But he did not stop here. His active and practical mind was not satisfied even with the splendid discovery, until he had turned it to a useful end. It suggested to him, as is well known, the idea of a method of preserving buildings from lightning, which is extremely simple and cheap, as well as effectual, consisting, as it does, in nothing more than attaching to the building a pointed metallic rod, rising higher than any part of it, and communicating at the lower end with the ground. This rod the lightning is sure to seize upon, in preference to any part of the building; by which means it is conducted to the earth, and prevented from doing any injury. There was always a strong tendency in Franklin's philosophy to these practical applications.

Franklin's discoveries did not at first attract much attention in England; and, in fact, he had the mortification to hear that his paper on the similarity between lightning and electricity had been ridiculed when read in the Royal Society. Having fallen, however, into the hands of the naturalist Buffon, that celebrated man translated and published it in Paris, when it speedily excited the astonishment of all Europe. What gave his book the more sudden and general celebrity, was the success of one of its proposed experiments for drawing lightning from the clouds, made at Marley. This engaged the public attention everywhere. "The Philadelphia experiments," as they were called, were performed before the king and court, and all the curious of Paris flocked to see them. Dr. Wright, an English physician, being at Paris at the time, wrote to a member of the Royal Society of London, with an account of these wonders, and stating the surprise of all the learned men abroad of Franklin's writings being so little noticed in England. The society were thus in a manner compelled to pay more attention to what they had previously considered as chimerical speculations, "and soon," says Franklin, "made me more than amends for the slight with which they had before treated me. Without my having made any application for that honour, they chose

me a member, and voted that I should be excused the customary payments, which would have amounted to twenty-five guineas, and ever since have given me their Transactions gratis. They also presented me with the gold medal of Sir Godfrey Copley for the year 1753, the delivery of which was accompanied with a very handsome speech of the president, Lord Macclesfield, wherein I was highly honoured."

Although the numerous important public duties which Franklin was called upon latterly to discharge, chiefly engrossed his time, he still returned to his philosophical studies on every occasion that offered, and made several curious and interesting discoveries.

Perhaps no philosopher ever stood on a prouder eminence in the world's eye than Franklin during the latter half of his life. The obscurity of his origin served but to make his elevation the more brightly conspicuous; and honours were showered on him from all quarters of the civilized world. In 1757 he visited England, and before his return made a tour in Scotland, where he formed an intimacy with Lord Kames, and had the degree conferred upon him of Doctor of Laws by the University of St. Andrews. In 1764 he again visited England, from which he proceeded to the continent of Europe. In Holland, Germany, and France, he was received with the greatest testimonies of respect from all men of science and distinction. At Paris Louis XV. honoured him with the most distinguished marks of his favour.

POLITICAL CAREER.

This part of Franklin's life need only be very generally touched on, the scenes and transactions in which he bore a part having long since become matter of history, with which almost every individual is now more or less acquainted. We have before mentioned that he was elected a member of the General Assembly of Pennsylvania, as burgess for the city of Philadelphia, in 1747. Warm disputes at this time subsisted between the assembly and the proprietaries,* each contending for what they conceived to be their just rights. Franklin, a friend of the interests of *the many* from his infancy, speedily distinguished himself as a steady opponent of the claims of the proprietaries, and he was soon looked up to as the head of the opposition. His influence with the assembly is said to have been very great. This arose not from any superior powers of elocution; he spoke but seldom, and he never was known to make any thing like an elaborate harangue. "His speeches," says his intimate friend, the late Dr. Stuber of Philadelphia, "frequently consisted of but a single sentence, or of a well-told story, the moral of which was always obviously to the point. He never attempted the flowery fields of oratory. His manner was plain and mild; his style of speaking was, like that of his writings, simple, unadorned, and remarkably concise. With this plain manner, and his penetrating and solid judgment, he was able to confound the most eloquent and subtle of his adversaries, to confirm the opinions of his friends, and to make converts of the unprejudiced who had opposed him. With a single observation he has rendered of no avail an elegant and lengthy discourse, and determined the fate of a question of importance."

Franklin had conducted himself so well in the office of postmaster for the state of Pennsylvania, and had shown himself so well acquainted with the business of that department, that it was thought expedient to raise him to a more dignified station. In 1753, he was appointed deputy-postmaster-general for the British colonies. It is said that the revenue from this source, in Franklin's hands, yielded to Great Britain three times as much as that of Ireland. In 1754, Franklin drew up the celebrated "Albany Plan of Union," the purpose of which was the establishment of a general government in the colonies, to be administered by a president-general, appointed by the crown, and by a grand council, consisting of members chosen by the representatives of the different colonies; the whole executive authority to be committed to the president-general; the legislative to the grand council and president jointly; and all laws to be approved of by the king. This plan was unanimously approved of by the commissioners for the crown and the colonies appointed to consult on the question, but its final fate was singular. It was rejected by the ministry of Great Britain as too democratical, and by every local assembly as too despotic. These verdicts were, perhaps, the best proof of its excellence, and of its having steered exactly in the middle betwixt the interests of both.

The British government having thus rejected a proposal of internal defence in the colonies, they were soon obliged to adopt measures of another sort for their protection. Aggressive operations were again threatened by the French; and in 1754, General Braddock was despatched from England with two regiments of regular English troops to resist them. The troops were landed at Alexandria, and marched thence to Fredericktown in Maryland, where they halted for carriages to transport their baggage, ammunition, &c., to the frontiers. Great reluctance was manifested by the country people to supply these, and, in fact, so few were sent in, and so many other difficulties occurred, that the general was about to abandon the expedition altogether. In this dilemma he was fortunately joined by Franklin, who, aware of the necessity and importance of the expedition, asked General Braddock what recompense he would afford to the owners for the use of their wagons and horses. General Braddock referred the terms to himself; they were drawn up and accepted; and Franklin immediately published them in an advertisement, with an animated appeal from himself to the loyalty and patriotism of his countrymen. The consequence was, that, in two weeks, 150 wagons and 260 horses poured into the camp, the owners of which, however, declined the security of the British commander for compensation, and insisted on having the personal bond of Franklin. This he accordingly gave them, and even advanced several hundred pounds of his own in present payment.

The expedition accordingly set forward, and its disastrous issue must still be well remembered. Although a brave man, Braddock had far too much confidence in the prowess of his regular troops, and too much contempt for the Americans and Indians. About one hundred of the latter joined him on his march, who would have proved of the utmost use to him as guides and scouts, but he treated them so slightingly that they all left him. No appearance of the enemy was seen until the troops had penetrated far into the interior; and the first intelligence which they had of the approach of a foe, was in finding that they had fallen into an ambuscade, where they were mowed down in hundreds by invisible antagonists secreted among the trees and bushes. A general rout and confusion almost immediately ensued. The drivers cut their horses' traces and fled, abandoning the wagons, which also obstructed the retreat of the soldiers. The general was with difficulty brought off, severely wounded; and, out of eighty-six officers, sixty-three was killed or wounded, with seven hundred and fourteen privates killed, out of eleven hundred who fell in the snare. All the artillery and stores, of course, were left to the enemy.

As soon as the news of the defeat, and the loss of the wagons and horses, became generally known, the owners came in a body upon Franklin for the amount of their claims, for which he had given bond, amounting to nearly £20,000! It was with difficulty that many of these claimants were prevented from suing him, until government had time to examine into their charges and order

* The descendants of the original settlers who had received grants of land from the British government, who claimed exemption from all taxes, and other privileges.

payment; but the matter was at length satisfactorily settled.

The assembly now laid a tax, to raise money for the defence of the province, and Franklin was appointed one of the commissioners to dispose of it. He had also carried a bill through the house for establishing and disciplining a voluntary militia. To promote the association necessary to form the militia, he wrote a dialogue upon the subject, which was extensively circulated, and thought to have great effect. While the several companies in the city and country were forming and learning their exercise, the governor prevailed upon Franklin to take charge of the north-western frontier, which was infested by the enemy, and provide for the defence of the inhabitants, by raising troops, and building a line of forts. Franklin did not think himself very well qualified for the military, but was willing to be of all the service in his power. He received a commission from the governor, with full authority, and a parcel of blank commissions for officers, to be given to whom he thought fit. Five hundred and sixty men were soon raised and placed under his command.

The first place selected for the erection of a fort was Gnadenhutten, a small settlement of Moravians; and thither Franklin set out in the middle of winter, amid torrents of rain, and through almost impassable roads. Upon arriving at the village, he lost not a moment in planning and marking out the fort, with a circumference of 455 feet; and the men were instantly set to work with their axes to cut down trees for palisades. Seeing the trees fall so fast, Franklin had the curiosity to look at his watch when two men began to cut at a pine. In six minutes they had it upon the ground, and it was fourteen inches in diameter. Each pine made three palisades, of eighteen feet long, pointed at one end. While these were preparing, other men dug a trench all round, of three feet deep, in which the palisades were to be planted. When these were set up, the carpenters built within them a platform of boards all round, about six feet high, for the men to stand on and fire through the loopholes. They had one swivel gun, which they mounted, and fired as soon as it was fixed, that the Indians might know they had such pieces. Thus their fort, such as it was, was finished in a week, though it rained so hard every other day that the men were almost unable to work.

"This gave me occasion to observe," says Franklin, "that when men are employed they are best contented. For on the days they worked, they were good-natured and cheerful, and, with the consciousness of having done a good day's work, they spent the evening gayly. But, on our idle days, they were mutinous and quarrelsome, finding fault with the pork and the bread, and were continually in bad humour; which put me in mind of a sea captain, whose rule it was to keep his men constantly at work; and, when his mate once told him that they had done every thing, and there was nothing further to employ them about, 'Oh,' said he, '*make them scour the anchor.*'

"This kind of fort," he continues, "however contemptible, is a sufficient defence against Indians, who have no cannon. Finding ourselves now posted securely, and having a place to retreat to on occasion, we ventured out in parties to scour the adjacent country. We met with no Indians, but we found the places on the neighbouring hills where they had lain to watch our proceedings. There was an art in their contrivance of those places that seems worth mentioning.

"It being winter, a fire was necessary for them; but a common fire, on the surface of the ground, would by its light have discovered their position at a distance: they had therefore dug holes in the ground about three feet in diameter, and somewhat deeper; we found where they had, with their hatchets, cut off the charcoal from the side of burnt logs lying in the woods. With these coals they had made small fires in the bottom of the holes, and we observed among the weeds and grass the prints of their bodies made by their lying all round, with their legs hanging down in the holes to keep their feet warm, which with them is an essential point. This kind of fire, so managed, could not discover them either by its light, flame, sparks, or even smoke; it appeared that the number was not great, and it seems they saw we were too many to be attacked by them with a prospect of advantage.

"We had for our chaplain a zealous Presbyterian minister, Mr. Beatty, who complained to me that the men did not generally attend his prayers and exhortations. When they enlisted they were promised, besides pay and provisions, a gill of rum a-day, which was punctually served out to them, half in the morning and half in the evening, and I observed they were punctual in attending to receive it." Franklin advised that the rum should be distributed only just after prayers; and never were prayers more generally or more punctually attended.

Franklin's military career, was, however, a short one, for he had scarcely completed his defensive preparations, when he received a summons to attend the assembly, where his advice and assistance were found indispensable.

The disputes between the proprietaries and the people, before referred to, continued to increase in 1755 and 1756, although a war was then raging on the frontiers —the French having still possession of Canada. The popular assemblies insisted on the justice of taxing the proprietary estates; but the governors constantly refused to assent to such a measure. The assemblies at last resolved to appeal to the mother country; and a petition was accordingly made out, addressed to the king in council. Franklin was appointed to present this address, as agent for the province of Pennsylvania, and departed for England in June, 1757. During this time, the governor passed a law imposing a tax, in which no discrimination was made in favour of the estates of the Penn family which were immensely large. The Penns thereupon used their most strenuous exertions to prevent its passing into a law. After long debate and deliberation, a proposal was made that Franklin should *personally* engage that the proprietary estates should pay no more than a just proportion of the tax. This he agreed to do—the proprietaries withdrew their opposition, and tranquillity was once more restored to the province. The manner in which this dispute was terminated sufficiently evinces the high confidence entertained of Franklin's honour and integrity, even by those opposed to his political views. After this, Franklin remained some time at the British court, having, besides Pennsylvania, been also appointed agent for the states of Massachusetts, Maryland, and Georgia.

The French in Canada still continuing to molest and interrupt the trade of the other colonies, Franklin published his famous Canada pamphlet, in which he in a forcible manner pointed out the advantages which would result from the conquest of that province. An expedition was accordingly sent out under General Wolfe, the result of which is well known. At the treaty in 1762, France ceded Canada to Great Britain, and by her cession of Louisiana at the same time, relinquished all her possessions on the continent of America.

In the summer of 1762, Franklin returned to America, and received the thanks of the Assembly of Pennsylvania, as well for the faithful discharge of his duty to that province in particular, as for the many and important services done to America in general, during his residence in Great Britain. A compensation of £5000, Pennsylvania currency, was likewise decreed him for the services he had performed in England. He was also immediately re-elected to his seat in the assembly.

Upon the breaking out of the fatal disturbances in consequence of Mr. Grenville's Stamp Act, Franklin had again returned to England, as agent for Pennsylvania and other states. During his residence in England, he consulted, with unremitting industry, the best interests of his native country. He was everywhere received with respect, on account of his reputation as a writer and philosopher. Franklin was unwearied in his efforts to bring about a reconciliation. He had frequent interviews with Lord Howe and Lord Chatham, and other distinguished English statesmen, who entertained for him the highest respect and esteem. Most of the time during his present residence in England was occupied in these vain efforts. It is well known that the first violent demonstrations against the imposition of the Stamp Act, broke out in Franklin's native place, Boston, the capital of the state of Massachusetts. The governor, Hutchinson, and other functionaries, wrote to the home government, recommending the adoption of the most rigorous coercive measures, inveighing in unmeasured terms against the leading characters of the state. By some unaccountable means, these letters fell into Franklin's hands ere they reached their destination. He instantly transmitted them back to the assembly at Massachusetts, who, enraged at the conduct of the governor, sent a petition to the king, praying for his dismissal, and Franklin was appointed to present it. As might have been expected, the petition was dismissed as "frivolous and vexatious;" and Franklin incurred so much obloquy for his interception of the governor's despatches (the mode of which was never discovered), that he was dismissed from his office of deputy-postmaster-general. He still continued in England, however, and left nothing untried to effect a reconciliation between the mother country and the colonies; but finding all his endeavours unavailing, he returned to America in 1775. The day after his arrival, he was elected by the legislature of Pennsylvania as a delegate to Congress. Hostilities had then commenced; but it would be repeating a thrice-told tale to enter into any account of the protracted and bloody struggle that ensued, or the nature of its termination. In 1778, Franklin was sent as ambassador to the court of France, where he soon brought about an alliance between that nation and the North American states. When the British ministry at length saw the necessity of recognising the independence of the states, the definitive treaty to that effect was signed at Paris, on the 3d of September, 1783, by Dr. Franklin, Mr. Adams, and Mr. Jay, for the states, on the one hand; and by Mr. David Hartley, for Great Britain, on the other. Franklin continued at Paris for the two following years; but at last, by his own urgent request, was recalled. Shortly after his return, he was elected president of the supreme executive council, and lent all his still perfect energies to consolidating the infant government. Age and infirmities, however, claimed their usual ascendency; and in 1788 he retired wholly from public life.

DEATH.

Franklin's last public act—and it was one in beautiful accordance with the whole tenor of his life—was putting his signature, as president of the Anti-Slavery Society, to a memorial presented to the House of Representatives, praying them to exert the full powers intrusted to them to discourage the revolting traffic in the human species. This was on the 12th of February, 1789. From this day forward, he was confined almost constantly to bed with the stone, from which he suffered the most excruciating agony. Yet, when his paroxysms of pain drew forth, as they did occasionally, an irrepressible groan, he would observe, he was afraid he did not bear his sufferings as he ought—acknowledged his grateful sense of the many blessings he had received from the Supreme Being, who had raised him from small and low beginnings to such high rank and consideration among men, and made no doubt but his present afflictions were kindly intended to wean him from a world in which he was no longer fit to act the part assigned him. He latterly sunk into a calm lethargic state; and, on the 17th April, 1790, about eleven o'clock at night, he quietly expired. He was then aged exactly eighty-four years and three months. The following epitaph was written by himself many years previous to his death, [but only the simple inscription "Benjamin and Deborah Franklin, 1790," was placed upon the plain marble slab that covers his grave.—*Am. Ed.*]

"The Body of Benjamin Franklin, Printer, [like the cover of an old book, its contents torn out, and stript of its lettering and gilding], lies here food for worms; yet the work itself shall not be lost, for it will (as he believed) appear once more in a new and more beautiful edition, corrected and amended by The Author."

CHARACTER.

In looking back on Franklin's career, it is evident that the principal feature in his character was *worldly prudence*—not in the usual and selfish acceptation of the term, but that prudence, founded on true wisdom, which dictates the practice of honesty, industry, frugality, temperance, in short, all those qualities which may be classified under the name of "moral virtues"—as being the only certain means of obtaining distinction, respect, independence and mental cheerfulness. There is no other writer who inculcates lessons of practical wisdom in a more agreeable and popular manner, and we much regret that the limits of this sheet prevent our giving many extracts illustrative of this quality. His whole conduct and writings, indeed, present the somewhat singular union of great genius with practical good sense, and of singular worldly shrewdness with the loftiest integrity of principle. The greatest worldly honours—and few have attained higher—could not for a moment make him forget or deviate from the fixed principles with which he started in life. Ever keeping before his mind his own origin and rise, he justly considered every man to be originally on a par in as far as regarded real intrinsic worth; and equally, by precept and example, contributed more, perhaps, than any individual who ever existed, to breaking down these invidious bars to eminence and success in life which the conventional habits and artificial feelings of society had theretofore interposed to the elevation of those unblessed by birth and fortune.

As the present biography must be considered as more immediately instructive to the industrious and productive portion of mankind, we shall conclude it by giving the following "Advice to a Young Tradesman," written by Franklin at the time when his industrious and frugal habits were just beginning to be rewarded with independence and worldly respect.

"Remember that *time* is money. He that can earn ten shillings a-day by his labour, and goes abroad, or sits idle one-half of that day, though he spends but sixpence during his diversion or idleness, ought not to reckon *that* the only expense; he has really spent, or rather thrown away, five shillings besides.

"Remember that *credit* is money. If a man lets his money lie in my hands after it is due, he gives me the interest, or so much as I can make of it during that time. This amounts to a considerable sum where a man has a good and large credit, and makes good use of it.

"Remember that money is of a prolific generating nature. Money can beget money, and its offspring can beget more, and so on. Five shillings turned is six, turned again is seven and threepence; and so on till it becomes a hundred pounds. The more there is of it, the more it produces every turning, so that the profits rise quicker and quicker. He that kills a breeding sow

destroys all her offspring to the thousandth generation. He that murders a crown destroys all that it might have produced, aven scores of pounds.

"Remember that six pounds a year is but a groat a day. For this little sum (which may be daily wasted either in time or expense, unperceived) a man of credit may, on his own security, have the constant possession and use of a hundred pounds. So much in stock, briskly turned by an industrious man, produces great advantage.

"Remember this saying, 'The good paymaster is lord of another man's purse.' He that is known to pay punctually, and exactly to the time he promises, may at any time, and on any occasion, raise all the money his friends can spare. This is sometimes of great use. After industry and frugality, nothing contributes more to the raising of a young man in the world than punctuality and justice in all his dealings: therefore, never keep borrowed money an hour beyond the time you promised, lest a disappointment shut up your friend's purse for ever.

"The most trifling actions that affects a man's credit are to be regarded. The sound of your hammer at five in the morning, or nine at night heard by a creditor, makes him easy six month's longer; but if he sees you at a billiard-table, or hears your voice at a tavern, when you should be at work, he sends for his money the next day; demands it before he can receive it in a lump.

"It shows, besides, that you are mindful of what you owe; it makes you appear a careful as well as an honest man, and that still increases your credit.

"Beware of thinking all your own that you possess, and of living accordingly. It is a mistake that many people who have credit fall into. To prevent this, keep an exact account, for some time, both of your expenses and your income. If you take the pains at first to mention particulars, it will have this good effect—you will discover how wonderfully small trifling expenses mount up to large sums, and will discern what might have been, and may for the future be saved, without occasioning any great inconvenience.

In short, the way to wealth, if you desire it, is as plain as the way to market. It depends chiefly on two words—*industry* and *frugality*; that is, waste neither *time* nor *money*, but make the best use of both. Without industry and frugality nothing will do, and with them every thing. He that gets all he can honestly, and saves all he gets (necessary expenses excepted), will certainly become *rich*—if that Being who governs the world, to whom all should look for a blessing on their honest endeavours, doth not, in his wise providence, otherwise determine."

About forty years later, after a long life of experience, he penned the following similar admonitions, entitled, "Necessary Hints to those that would be Rich:"—

"The use of money is all the advantage there is in having money.—For six pounds a year you may have the use of one hundred pounds, provided you are a man of known prudence and honesty. He that spends a groat a day idly, spends idly about six pounds a year, which is the price for the use of one hundred pounds.—He that wastes idly a groat's worth of his time per day, one day with another, wastes the privilege of using one hundred pounds each year.—He that idly loses five shillings' worth of time, loses five shillings, and might as prudently throw five shillings into the sea.—He that loses five shillings, not only loses that sum, but all the advantages that might be made by turning it in dealing; which, by the time that a young man becomes old, will amount to a considerable sum of money.—Again, he that sells upon credit, asks a price for what he sells equivalent to the principal and interest of his money for the time he is to be kept out of it; therefore, he that buys upon credit, pays interest for what he buys; and he that pays ready money, might let that money out to use; so that he that possesses any thing he has bought, pays interest for the use of it.—Yet, in buying goods, it is best to pay ready money, because he that sells upon credit expects to lose five per cent. by bad debts; therefore, he charges, on all he sells upon credit, an advance that will make up that deficiency. Those who pay for what they buy upon credit, pay their share of this advance. He that pays ready money escapes, or may escape, that charge."

PRESERVATION OF HEALTH.

A HUMAN being, supposing him to be soundly constituted at first, will continue in health till he reaches old age, provided that certain conditions are observed, and no injurious accident shall befall. This is a proposition so well supported by an extensive observation of facts, that it may be regarded as established. It becomes, of course, important to ascertain what are the conditions essential to health, in order that, by their observance, we may preserve for ourselves what is justly esteemed as the greatest of earthly blessings, and dwell for our naturally appointed time upon the earth. A general acquaintance with these conditions may be easily attained by all, and to pay them obedience is much more within the power of individuals than is generally supposed.

The leading conditions essential to health may be thus enumerated:—1. A constant supply of pure air; 2. A sufficiency of nourishing food, rightly taken; 3. Cleanness; 4. A sufficiency of exercise to the various organs of the system; 5. A right temperature; 6. A sufficiency of cheerful and innocent enjoyments; and, 7. Exemption from harassing cares.

AIR.

The common air is a fluid composed mainly of two gases, in certain proportions; namely, oxygen as 20 and nitrogen as 80 parts in a hundred, with a very minute addition of carbonic acid gas. Such is air in its pure and right state, and such is the state in which we require it for respiration. When it is loaded with any admixture of a different kind, or its natural proportions are in any way deranged, it cannot be breathed without producing injurious results. We also require what is apt to appear a large quantity of this element of healthy existence. The lungs of a healthy full-grown man will inhale the bulk of twenty cubic inches at every inspiration, and he will use no less than fifty-seven hogsheads in twenty-four hours.

Now, there are various circumstances which tend to surround us at times with vitiated air, and which must accordingly be guarded against. That first calling for attention is the miasma or noxious quality imparted to the air in certain districts by stagnant water and decay-

ing vegetable matter. It is now generally acknowledged that this noxious quality is in reality a subtle poison, which acts on the human system through the medium of the lungs, producing fevers and other epidemics. A noted instance of its acting on a great scale is presented in the Campagna di Roma, where a large surface is retained in a marshy state. The air arising from that territory at certain seasons of the year, obliges the inhabitants of the adjacent districts of the city to desert their homes, in order to escape its pernicious influence. All marshes, and low damp grounds of every kind, produce more or less miasma, and it is consequently dangerous to live upon or near them. Slightly elevated ground should, accordingly, in all cases, be chosen for both single houses and towns. Tanks and collections of water of every kind are dangerous beneath or near a house, because, unless their contents be constantly in a state of change, which is rarely the case, their tendency is to send up exhalations of a noxious kind. A few years ago, the eldest son of an English nobleman—a youth of great promise, and who had recently become a husband and father—died of a fever which was traced to the opening of an old reservoir of water underneath the country-house in which he dwelt.*

Putrid matter of all kinds is another conspicuous source of noxious effluvia. The filth collected in ill-regulated towns—ill-managed drains—collections of decaying animal substances, placed too near or within private dwellings—are notable for their effects in vitiating the atmosphere, and generating disease in those exposed to them. In this case, also, it is a poison diffused abroad through the air which acts so injuriously on the human frame. This was probably the main cause of the plagues which visited European cities during the middle ages. In those days there were no adequate provisions for cleaning cities, and the consequence was, that large collections of filth were accumulated. The noxious air diffused by these means through the narrow streets and confined dwellings would tend to the most fatal effects. In old drains there is generated a gas (sulphureted hydrogen), which is calculated to produce dreadful consequences among those exposed to it. It has lately been discovered, that it is the presence of this gas in the sea near the eastern coast of tropical Africa, which causes the peculiar unhealthiness of that region. It is ascertained that small animals, such as birds, die, when the air they breathe contains one fifteen-hundredth part of sulphureted hydrogen, and that an infusion six times greater will kill a horse. It follows, that we can scarcely attach too much importance to measures for cleaning cities and improving drains. There are as yet no large towns in Britain kept in a state so clean as is desirable for the health of their inhabitants; and the metropolis itself is among those which are most defective in this respect.

The human subject tends to vitiate the atmosphere for itself, by the effect which it produces on the air which it breathes. Our breath, when we draw it in, consists of the ingredients formerly mentioned; but it is in a very different state when we part with it. On passing into our lungs, the oxygen, forming the lesser ingredient, enters into combination with the carbon of the venous blood (or blood which has already performed its round through the body); in this process, about two-fifths of the oxygen is abstracted and sent into the blood, only the remaining three-fifths being expired, along with the nitrogen nearly as it was before. In place of the oxygen consumed, there is expired an equal volume of carbonic acid gas, such gas being a result of the process of combination just alluded to. Now, carbonic acid gas, in a larger proportion than that in which it is found in the atmosphere, is noxious. The volume of it expired by the lungs, if free to mingle with the air at large, will do no harm; but, if breathed out into a close room, it will render the air unfit for being again breathed. Suppose an individual to be shut up in an air-tight box: each breath he emits throws a certain quantity of carbonic acid gas into the air filling the box; the air is thus vitiated, and every successive inspiration is composed of worse and worse materials, till at length the oxygen is so much exhausted that it is insufficient for the support of life. He would then be sensible of a great difficulty in breathing, and in a little time longer he would die.

Most rooms in which human beings live are not strictly close. The chimney and the chinks of the door and windows generally allow of a communication to a certain extent with the outer air, so that it rarely happens that great immediate inconvenience is experienced in ordinary apartments from want of fresh air. But it is at the same time quite certain that, in all ordinary apartments where human beings are assembled, the air unavoidably becomes *considerably vitiated*, for in such a situation there cannot be a sufficiently ready or copious supply of oxygen to make up for that which has been consumed, and the carbonic acid gas will be constantly accumulating. This is particularly the case in bedrooms, and in theatres, churches, and schools. An extreme case was that of the celebrated Black Hole of Calcutta, where a hundred and forty-six persons were confined for a night in a room eighteen feet square with two small windows. Here the oxygen scarcely sufficient for the healthy supply of one person, was called upon to support a large number. The unfortunate prisoners found themselves in a state of unheard-of suffering, and in the morning all were dead but twenty-three, some of whom afterwards sunk under putrid fever brought on by breathing so long a tainted atmosphere.

Although the vitiation of the air in ordinary apartments and places of public assembly does not generally excite much attention, it nevertheless exercises a certain unfavourable influence on health in all the degrees in which it exists. Perhaps it is in bedrooms that most harm is done. These are generally smaller than other rooms, and they are usually kept close during the whole night. The result of sleeping in such a room is very injurious. A common fire, from the draught which it produces, is very serviceable in ventilating rooms, but it is at best a defective means of doing so. The draught which it creates generally sweeps along near the floor between the door and the fire, leaving all above the level of the chimney-piece unpurified. Yet scarcely any other arrangement is anywhere made for the purpose of changing the air in ordinary rooms. To open the window is a plan occasionally resorted to, but it is not always agreeable in our climate, and sometimes it produces bad consequences of a different kind.

It would nevertheless be easy to produce an effective draught from any room in which a fire is kept. It is only necessary to make an aperture into the flue, near the ceiling of the room, and insert therein a tin tube, with a valve at the exterior, capable of opening inwards, but closing when at rest or a draught is sent the contrary way. The draught produced by the fire in the flue would cause a constant flow of air out of the *upper part* of the room (where most vitiated); and the valve would be an effectual protection against back-smoke, should there be the least tendency to it. This plan is adopted in Buckingham Palace. It could be applied to any existing house at a mere trifle of expense.

A more effectual plan, and one which operates when there is no fire in the room, is to establish a tin tube of two or three inches diameter out of each apartment to be ventilated, causing them all to meet in one general tube, the extremity of which passes into some active flue—for example, that of the kitchen, which is rarely cold. Thus there might be a constant passing of fresh

* Viscount Milton, son of the present Earl Fitzwilliam, was the person here alluded to

ah into and through every room of a large house, so that it would be at all times as healthy in this respect as the open fields. At the same time, the supply might, by means of graduated valves, be regulated to any degree which might be deemed agreeable.

FOOD.

The second requisite for the preservation of health is a sufficiency of nutritious food.

Organic bodies, in which are included vegetables as well as animals, are constituted upon the principle of *a continual waste of substance supplied by continual nutrition.*

The Nutritive System of animals, from apparently the humblest of these to the highest, comprehends an *alimentary tube or cavity*, into which food is received, and from which, after undergoing certain changes, it is diffused by means of smaller vessels throughout the whole structure. In the form of this tube, and in the other apparatus connected with the taking of food, there are, in different animals, varieties of structure, all of which are respectively in conformity with peculiarities in the quality and amount of food which the particular animals are designed to take. The harmony to be observed in these arrangements is remarkably significant of that Creative design to be traced in all things.

MAN DESIGNED TO LIVE ON A MIXED DIET.

Some animals are formed to live upon vegetable substances alone; others are calculated to live upon the flesh of other animals. Herbivorous animals, as the former are called, have generally a long and complicated alimentary tube, because the nutritious part of such food, being comparatively small in proportion to the whole bulk, requires a greater space in which to be extracted and absorbed into the system. The sheep, for example, has a series of intestines twenty-seven times the length of its body. For the opposite reasons, carnivorous or flesh-devouring animals, as the feline tribe of quadrupeds, and the rapacious birds, have generally a short intestinal canal. The former class of animals are furnished with teeth, calculated by their broad and flat surfaces, as well as by the lateral movement of the jaws in which they are set, to mince down the herbage and grain eaten by them. But the carnivorous animals, with wide-opening jaws, have long and sharp fangs to seize and tear their prey. These peculiarities of structure mark sufficiently the designs of nature with respect to the kinds of food required by the two different classes of animals for their support.

The human intestinal canal being of medium length, and the human teeth being a mixture of the two kinds, it necessarily follows that man was designed to eat both vegetable and animal food. As no animal can live agreeably or healthy except in conformity with the laws of its constitution, it follows that man will not thrive unless with a mixture of animal and vegetable food. The followers of Pythagoras argued, from the cruelty of putting animals to death, that it was proper to live on vegetables alone, and many eccentric persons of modern times have acted upon this rule. But the ordinances of Nature speak a different language; and, if we have any faith in these, we cannot for a moment doubt that a mixture of animal food is necessary for our well-being. On the other hand, we cannot dispense with vegetable food, without injurious consequences. In that case we place in a medium alimentary canal a kind of food which is calculated for a short one, thus violating an arrangement of the most important nature. A balance between the two kinds of food is what we should observe, if we would desire to live a natural and consequently healthy life.

RULES CONNECTED WITH EATING.

In order fully to understand how to eat, what to eat, and how to conduct ourselves after eating, it is necessary that we should be acquainted in some measure wi the *process of nutrition*—that curious series of operations by which food is received and assimilated by our system in order to make good the deficiency produced by waste

"Food is first received into the mouth, and there the operations in question may be said to commence. It is there to be chewed (or masticated) and mixed with saliva, preparatory to its being swallowed or sent into the stomach. Even in this introductory stage, there are certain rules to be observed. Strange as it may appear, to know *how to eat* is a matter of very considerable importance.

Many persons, thinking it all a matter of indifference, or perhaps unduly anxious to despatch their meals, eat very fast. If we are to believe the accounts of travellers, the whole of the mercantile classes in New England eat hurriedly, seldom taking more than ten minutes to breakfast, and a quarter of an hour to dinner. They tumble their meat precipitately into their mouths, and swallow it almost without mastication. This is contrary to an express law of nature, as may be easily shown.

Food, on being received into the mouth, has two processes to undergo, both very necessary to digestion. It has to be masticated, or chewed down, and also to receive an admixture of saliva. The saliva is a fluid arising from certain glands in and near the mouth, and approaching in character to the gastric juice afterwards to be described. Unless food be well broken down or masticated, and also well mixed up with the salivary fluid, it will be difficult of digestion. The stomach is then called upon to do, besides its own proper duty, that which properly belongs to the teeth and saliva, and it is thus overburdened and embarrassed, often in a very serious manner. The pains of indigestion are the immediate consequence, and more remote injuries follow.

The importance of the saliva has been shown in a striking manner, on several occasions when food was received into the stomach otherwise than through the mouth. A gentleman, who, in consequence of a stricture in the gullet, had his food introduced by an aperture into that tube, used to suffer severely from indigestion. It is recorded of a criminal, who, having cut his throat in prison without fatal consequences, required to get his food introduced by means of a tube inserted by the mouth, that, every time he was fed, there was an effusion of saliva to the amount of from six to eight ounces. We cannot suppose that a fluid of a peculiar character would have been prepared in such quantity, when water would serve as well merely to wet the food, if it had not been designed to act an important part in the business of nutrition. With regard to mastication, the evidence of its importance is still more clear. A few years ago, a young Canadian, named Alexis St. Martin, had a hole made by a shot into his stomach, which healed without becoming closed. It was therefore possible to observe the whole operations of the stomach with the eye. His medical attendant, Dr. Beaumont, by these means ascertained that, when a piece of solid food was introduced, the gastric juice acted merely on its outside. It was only when the food was comminuted, or made *small*, that this fluid could fully perform its function. When the stomach finds itself totally unable to digest a solid piece of food, it either rejects it by vomiting, or passes it on into the gut, where it produces an irritating effect, and is apt to occasion an attack of cholic or flatulency.

It is therefore to be concluded that *a deliberate mastication of our food is conducive to health, and that fast eating is injurious, and sometimes even dangerous.*

The food, having been properly masticated, is, by the action of the tongue, thrown into the gullet. It then descends into the stomach, not so much by its own gravity, as by its being urged along by the contractions and motions of the gullet itself. The stomach may be considered as an expansion of the gullet, and the chief part

of the alimentary canal. It is, in fact, a membranous pouch or bag, very similar in shape to a bagpipe, having two openings, the one by which the food enters, the other that by which it passes out. It is into the greater curvature of the bag that the gullet enters; it is at its lesser that it opens into that adjoining portion of the canal into which the half-digested mass is next propelled.

When food has been introduced, the two orifices close, and that which we may term the second stage in the process of digestion commences. The mass, already saturated with saliva, and so broken down as to expose all its particles to the action of the gastric juice, is now submitted to the action of that fluid, which, during digestion, is freely secreted by the vessels of the stomach. The most remarkable quality of this juice is its solvent power, which is prodigious.

The food exposed to this dissolving agency is converted into a soft, gray, pulpy mass, called chyme, which, by the muscular contraction of the stomach, is urged on into the adjoining part of the alimentary canal, called the duodenum. This is generally completed in the space of from half an hour to two or three hours; the period varying according to the nature and volume of the food taken, and the mastication and insalivation it has undergone.

In the duodenum, the chyme becomes intimately mixed and incorporated with the bile and pancreatic juices; also with a fluid secreted by the mucus follicles of the intestine itself. The bile is a greenish, bitter, and somewhat viscid fluid, secreted by the liver, which occupies a considerable space on the right side of the body immediately under the ribs. From this organ the bile, after a portion of it has passed up into the adjacent gall-bladder, descends through a small duct, about the size of a goose-quill, into the duodenum. The chyme, when mixed with these fluids, undergoes a change in its appearance; it assumes a yellow colour and bitter taste, owing to the predominance of the bile in the mass; but its character varies according to the nature of the food that has been taken. Fatty matters, tendons, cartilages, white of eggs, &c., are not so readily converted into chyme as fibrous or fleshy, cheesy, and glutinous substances. The chyme, having undergone the changes adverted to, is urged by the peristaltic motion of the intestines onwards through the alimentary canal. This curious motion of the intestines is caused by the contraction of the muscular coat which enters into their structure, and one of the principal uses ascribed to the bile is that of stimulating them to this motion. If the peristaltic motion be diminished, owing to a deficiency of bile, then the progress of digestion is retarded, and the body becomes constipated. In such cases, calomel, the blue pill, and other medicines, are administered for the purpose of stimulating the liver to secrete the biliary fluid, that it may quicken by its stimulating properties the peristaltic action. But this is not the only use of the bile: it also assists in separating the nutritious from the non-nutritious portion of the alimentary mass, for the chyme now presents a mixture of a fluid termed *chyle*, which is in reality the nutritious portion eliminated from the food. The chyme thus mixed with chyle arrives in the small intestines; on the walls of which a series of exquisitely delicate vessels ramify in every direction. These vessels absorb or take up the chyle, leaving the rest of the mass to be ejected from the body. The chyle, thus taken up, is carried into little bodies of glands, where it is still further elaborated, acquiring additional nutritious properties; after which, corresponding vessels, emerging from these glands, carry along the fluid to a comparatively large vessel, called the thoracic duct, which ascends in the abdomen along the side of the back-bone, and pours it into that side of the heart to which the blood that has already circulated through the body returns. Here the chyle is intimately mixed with the blood, which fluid is now propelled into the lungs, where it undergoes, from being exposed to the action of the air we breathe, the changes necessary to render it again fit for circulation. It is in the lungs, therefore, that the process of digestion is completed; the blood has now acquired those nutritient properties from which it secretes the new particles of matter adapted to supply the waste of the different textures of the body.

When food is received into the stomach the secretion of the gastric juice immediately commences; and when a full meal has been taken, this secretion generally lasts for about an hour. It is a law of vital action, that when any living organ is called into play, there is immediately an increased flow of blood and nervous energy towards it. The stomach, while secreting the bile, displays this phenomenon, and the consequence is, that the blood and nervous energy are called away from other organs. This is the cause of that chilliness at the extremities which we often feel after eating heartily. So great is the demand which the stomach thus makes upon the rest of the system, that, during and for some time after a meal, we are not in a condition to take strong exercise of any kind. Both body and mind are inactive and languid. They are so, simply because that which supports muscular and mental activity is concentrated for the time upon the organs of digestion. This is an arrangement of nature which a regard to health requires that we should not interfere with. *We should indulge in the muscular and mental repose which is demanded; and this should last for not much less than an hour after every meal.* In that time the secretion of bile is nearly finished: the new nutriment begins to tell upon the general circulation; and we are again fit for active exertion. The consequence of not observing this rule is very hurtful. Strong exercise, or mental application, during or immediately after a meal, diverts the flow of nervous energy and of blood to the stomach, and the process of digestion is necessarily retarded or stopped. Confusion is thus introduced into the system, and a tendency to the terrible calamity of dyspepsia is perhaps established.

For the same reason that repose is required after a meal, it is necessary, in some measure, for a little while before. At the moment when we have concluded a severe muscular task, such, for example, as a long walk, the flow of nervous energy and of circulation is strongly directed to the muscular system. It requires some time to allow this flow to stop and subside; and, till this takes place, it is not proper to bring the stomach into exercise, as the demand it makes when filled would not in that case be answered. Just so if we be engaged in close mental application, the nervous energy and circulation being in that case directed to the brain, it is not right all at once to call another and distant organ into play; some time is required to allow of the energy and circulation being prepared to take the new direction. It may, therefore, be laid down as a maxim, that *a short period of repose, or at least of very light occupation, should be allowed before every meal.*

It is remarkable that these rules, although the natural reasons for them were not, perhaps, well known, have long been followed with regard to animals upon which man sets a value, while as yet their application to the human constitution is thought of only by a few. Those intrusted with horses and dogs will not allow them to feed immediately after exercise; nor will they allow them to be subjected to exercise for some time after feeding. Experience has also instructed veteran soldiers not to dine the instant that a long march has been concluded, but to wait coolly till ample time has been allowed for all the proper preparations.

Although strong mental and muscular exercise should be avoided before, during, and immediately after a meal, there can be no objection to the light and lively chat which generally is indulged in when several are met to eat together. On the contrary, it is believed that

pound conversation is useful towards the process of nutrition. Dr. Combe, in one of his invaluable works, observes as follows:—"The necessary churning, or agitation of the food, is, from the peculiar situation of the stomach, greatly assisted by the play of the diaphragm and abdominal muscles during inspiration and expiration; and the diminution of the vivacity and extent of the respiratory movement which always attends despondency and grief, is one source of the enfeebled digestion which notoriously accompanies depression of mind. The same cause also leads necessarily to an unfavourable condition of the blood itself, which in its turn weakens digestion in common with every other function; but the muscular or mechanical influence is that which at present chiefly concerns us. On the other hand, the active and energetic respiration attendant on cheerfulness and buoyancy of spirits, adds to the power of digestion, both by aiding the motion of the stomach and by imparting to it a more richly constituted blood. If to these causes be added the increase of nervous stimulus which pleasing emotions occasion in the stomach (as in the muscles and organs of secretion generally), we shall have no difficulty in perceiving why digestion goes on so well in parties where there is much jocularity and mirth. 'Laughter,' says Professor Hufeland of Berlin, 'is one of the greatest helps to digestion with which I am acquainted; and the custom prevalent among our forefathers, of exciting it at table by jesters and buffoons, was founded on [accidentally in harmony with] true medical principles. In a word, endeavour to have cheerful and merry companions at your meals: what nourishment one receives amidst mirth and jollity, will certainly produce good and light blood.'"*

KINDS OF FOOD.

It has been shown by a reference to the structure of the human intestinal canal, that our food is designed to be a mixture of animal and vegetable substances. There is, it is to be remarked, a power of adaptation in nature, by which individuals may be enabled for a considerable time to live healthily on one or the other kind exclusively, or nearly so. The above is, nevertheless, the general rule, to which it is safest to adhere. It has been found, for instance, that field-labourers, including ploughmen, will live healthily for many years on a diet chiefly farinaceous—that is, composed of the farina of grain. But it is to be feared that the food, in this case, though apparently sufficient for health, is only so apparently; and that the constitution, being all the time not supported as it ought to be, breaks down prematurely in a great proportion of instances. It has been said, again, that the Irish labouring classes are a remarkably robust race, although their food consists almost exclusively of potatoes. The fact is overlooked, that the Irish eat a quantity of potatoes so enormous as could not fail to make up in some measure for the want of animal diet. It was found by the Poor-Law Commissioners, that the greater number of the peasantry of Ireland, women as well as men, take at their two daily meals, in general, about nine pounds' weight of this food! Such a case is rather to be ranked amongst instances of extraordinary adaptations to a particular kind of food, than as a proof that an unmixed potato diet is healthy. Climate has a remarkable effect in modifying the rule as to a mixture of animal and vegetable food. The former has most of a stimulating quality, and this quality is greater in beef, and flesh in general, than in fowl or fish. Now, the inhabitants of torrid countries are in their ordinary condition least in need of stimulus: hence they find a simple diet of rice and sago sufficient for them. Those, on the contrary, who dwell in cold countries need much stimulus: hence they can devour vast quantities of flesh and blubber, with scarcely any mixture of vegetable food.

Inquiries with respect to the comparative digestibility of different kinds of food, are perhaps chiefly of consequence to those in whom health has already been lost. To the sound and healthy, it is comparatively of little consequence what kind of food is taken, provided that some variation is observed, and no excess committed as to quantity. Within the range of fish, flesh, and fowl, there is ample scope for a safe choice. There is scarcely any of the familiar aliments of these kinds, but, if plainly dressed, will digest in from two to four hours, and prove perfectly healthy. One rule alone has been pretty well ascertained, with respect to animal food, that they are the more digestible the more minute and tender the fibre may be. They contain more nutriment in a given bulk than vegetable matters, and hence their less need for length of intestine to digest them. Yet it is worthy of notice, that between the chyle produced from animal and that from vegetable food, no essential distinction can be observed.

Tendon, suet, and oily matters in general, are considerably less digestible than the ordinary fibre; and these are aliments which should be taken sparingly. Pickling, from its effect in hardening the fibre, diminishes the digestibility of meat. Dressed shellfish, cheese, and some other animal foods, are avoided by many as not sufficiently digestible.

Farinaceous foods of all kinds—wheat, oaten, and barley bread, oaten porridge, sago, arrow-root, tapioca, and potatoes—are highly suitable to the human constitution. They generally require under two hours for digestion, or about half the time of a full mixed meal. The cottage children of Scotland, reared exclusively upon oaten porridge and bread, with potatoes and milk, may be cited as a remarkable example of a class of human beings possessing in an uncommon degree the blessing of health. Green vegetables and fruit, however softened by dressing, are less digestible, and less healthy as a diet. One important consideration here occurs. There is need for a certain bulk in our ordinary food. Receiving nutriment in a condensed form and in a small space will not serve the purpose. This is because the organs of digestion are calculated for receiving our food nearly in the condition in which nature presents it, namely, in a considerable bulk with regard to its nutritious properties. The same law applies with respect to the lower animals. When a horse is fed upon corn alone, it does not thrive. Nature did not contemplate that all horses should readily obtain a corn diet, but looked chiefly to grass and hay for their support. She therefore prepared the organs for the reception of something of considerable volume; and when a food of less volume is persisted in, her law is violated, and fatal consequences ensue. Civilized man is apt to pay little attention to this rule in his own case. Consulting taste alone, he is apt to refine his food overmuch, and reject what it were better for him to take. The present writer is much inclined to doubt the propriety of grinding off the coarse exterior of wheaten grain. It does not seem by any means likely that nature calculated the human alimentary cavity for the use of the white interior of the grain, exclusive of all the rest. Wheat forms so large a part of our daily food, that, if this be the case, we unquestionably make a departure of a very important kind from the laws of health. Experience is favourable to this view, for the effect of coarse bread in relaxing seems only comparable to that of white bread in constipating the bowels.

QUANTITY OF FOOD.—NUMBER AND TIMES OF MEALS

With respect to the amount of food necessary for health, it is difficult to lay down any rule, as different quantities are safe with different individuals, according to their sex, age, activity of life, and some other conditions. There is a general and probably well-founded opinion

* The Physiology of Digestion. By Dr. Andrew Combe. Edinburgh. 1836.

that most persons who have the means eat too much, and thereby injure their health. This may be true, and yet it may not be easy to assign to such persons a limit beyond which they ought not to go.

The best authorities are obliged to refer the matter to our own sensations. Dr. Beaumont, for example, says that we should not eat till the mind has a sense of *satiety*, for appetite may exceed the power of digestion, and generally does so, particularly in invalids; but to a point previous to that, which "may be known by the pleasurable sensations of *perfect satisfaction, ease, and quiescence of body and mind.*"

The number and times of meals are other questions as yet undetermined. As the digestion of a meal rarely requires more than four hours, and the waking part of a day is about sixteen, it seems unavoidable that at least three meals be taken, though it may be proper that one, if not two of these, be comparatively of a light nature. Breakfast, dinner, and tea as a light meal, may be considered as a safe, if not a very accurate, prescription for the daily food of a healthy person. Certainly four good meals a day is too much. No experiments, as far as we are aware, have been made with regard to the total amount of solids which a healthy person in active life may safely take in a day. It has been found, however, that confined criminals and paupers are healthiest when the daily solids are not much either above or below twenty-four ounces.* Of course, in active life there must be need for a larger allowance, but only to a small extent. We may thus arrive at a tolerably clear conviction of the reality of that excess which is said to be generally indulged in; for certainly most grown people who have the means, not excepting many who pursue very sedentary lives, eat *much more* than twenty-four ounces.

The interval between rising and breakfast ought not to be great, and no severe exercise or task-work of any kind should be undergone during this interval. There is a general prepossession to the contrary, arising probably from the feeling of freedom and lightness which most people feel at that period of the day, and which seems to them as indicating a preparedness for exertion. But this feeling, perhaps, only arises from a sense of relief from that oppression of food under which much of the rest of the day is spent. It is quite inconsistent with all we know of the physiology of aliment, to suppose that the body is capable of much exertion when the stomach has been for several hours quite empty. We have known many persons take long walks before breakfast, under an impression that they were doing something extremely favourable to health. Others we have known go through three hours of mental task-work at the same period, believing that they were gaining so much time. But the only observable result was to subtract from the powers of exertion in the middle and latter part of the day. In so far as the practice was contrary to nature, it would likewise of course produce permanent injury. Only a short saunter in the open air, or a very brief application to business or task-work, can be safely indulged in before breakfast.

With regard to the time for either breakfast or dinner, nothing can be said with scientific authority. Dr. Combe, who is by no means disposed to take lax or indulgent views with regard to dietary matters, while favourable to an early dinner hour, allows that he has himself changed his hours for both breakfast and dinner, from comparatively early to comparatively late periods, without any perceptible inconvenience. In rural life, it is found convenient to dine not long after the middle of the day; but in cities, where it is necessary to have a long uninterrupted space in the middle of the day for business, a late dinner-hour is scarcely avoidable. In such a case, a slight lunch serves to keep the strength from sinking; and, if dinner is taken not less than five or six hours before bed-time, it is not easy to see how any injurious consequences should follow. The changes that have taken place in meal hours from old times are more apparent than real. The present substantial lunch of fashionable life occurs nearly at the same hour as the Elizabethan dinner, and the present dinner is in all respects except name the same as the supper of those times. The only thing which the physiologist would much insist on is, that, between the two principal meals of the day, there should be no long fasts. If the interval be above seven hours, a biscuit should be taken after four of the seven hours have elapsed. When the interval amounts to nine hours, the lunch should be a little more substantial, but not of animal food, particularly if any has been taken at breakfast. A glass of wine is often added to a biscuit lunch, or wine alone is taken; but neither of these practices can be commended. While a small quantity of bread or biscuit gives real strength, and is quite sufficient for the occasion, wine only gives a stimulus, serving for the time, but making the case worse afterwards.

VARIETY OF FOOD.

A judicious variation of food is not only useful, but important. There are, it is true, some aliments, such as bread, which cannot be varied, and which no one ever wishes to be so. But apart from one or two articles, a certain variation of rotation is much to be desired, and will prove favourable to health. There is a common prepossession respecting *one dish*, which is more spoken of than acted upon. In reality, there is no virtue in this practice, excepting that, if rigidly adhered to, it makes excess nearly impossible, no one being able to eat to satiety of one kind of food. There would be a benefit from both a daily variation of food and eating of more than one dish at a meal, *if moderation were in both cases to be strictly observed*, for the relish to be thus obtained is useful as promotive of the flow of nervous energy to the stomach, exactly in the same manner as cheerfulness is useful. The policy which would make food in any way unpleasant to the taste, is a most mistaken one; for to eat with languor, or against inclination, or with any degree of disgust, is to lose much of the benefit of eating. On the other hand, to cook dishes highly, and provoke appetite by artificial means, are equally reprehensible. Propriety lies in the mean between the two extremes.

BEVERAGES.

The body containing a vast amount of fluids, which are undergoing a perpetual waste, there is a necessity for an occasional supply of liquor of some kind, as well as of solid food. It remains to be considered what is required in the character or nature of this liquor, to make it serve the end consistently with the preservation of health.

It is scarcely necessary to remark how men in all ages, and almost all climes, have indulged in liquors containing a large infusion of alcohol, or how widespread in our own society is the custom of drinking considerable quantities of wine, spirits, and beer, both at meals and on other occasions. Against habits so inveterate it is apt to appear like fanaticism to make any decided objection; yet the investigator of the laws which regulate health is bound to consider above all things how any particular habit bears upon the human constitution, and to state what is the result of his inquiries, however irreconcilable it may be with popular prejudice.

"The primary effect of all distilled and fermented liquors," says Dr. Combe, "is to *stimulate the nervous*

* See two papers on food, in Nos. 366 and 368 of *Chambers's Edinburgh Journal*.

system and quicken the circulation." They may thus be said to have a larger measure of the effect which animal food has upon the system. It is therefore the less surprising that those tropical nations which live most on farinaceous diet, are also found to be those which have the least propensity to the drinking of ardent spirits; while those northern nations which live most on animal food, have the exactly contrary inclination with respect to liquor, the Scandinavian tribes being notoriously the greatest sots that have ever been known. Dr. Combe admits that, in some conditions of the system, when the natural stimulus is defective, it may be proper to take an artificial supply in the form of ardent and fermented liquors. "There are," he says, "many constitutions so inherently defective in energy, as to derive benefit from a moderate daily allowance of wine; and there are many situations in which even the healthiest derive additional security from its occasional use. If, for example, a healthy person is exposed to unusual and continued exertion in the open air, or to the influence of anxious and depressing watchfulness, a moderate quantity of wine with his food may become the means of warding off actual disease, and enabling him to bear up uninjured, where, without it, he would have given way." But Dr. Combe at the same time declares, in the most decided language, that, when the digestion is good and the system in full vigour, the bodily energy is easily sustained by nutritious food, and "artificial stimulant *only increases the wasting of the natural strength.*" Nearly all physicians, indeed, concur in representing ardent liquors as unfavourable to the health of the healthy, and as being, in their excess, highly injurious. Even the specious defence which has been set up for their use, on the ground that they would not have been given to man if they had not been designed for general use, has been shown to be ill-founded, seeing that *vinous fermentation*, from which they are derived, is not a healthy condition of vegetable matter, but a stage in its progress to decay. Upon the whole, there can be little doubt that these liquors are deleterious in our ordinary healthy condition; and that simple water, toast water, whey, ginger beer, or lemonade, would be preferable (the first being the most natural and the best of all), if we could only consent to deny ourselves further indulgence.

CLEANLINESS.

To keep the body in a cleanly condition is the third important requisite for health. This becomes necessary in consequence of a very important process which is constantly going on near and upon the surface of the body.

The process in question is that of *perspiration*. The matter here concerned is a watery secretion produced by glands near the surface of the body, and sent up through the skin by channels imperceptibly minute and wonderfully numerous. From one to two pounds of this secretion is believed to exude through these channels or *pores* in the course of twenty-four hours, being in fact the chief form taken by what is called the waste of the system, the remainder passing off by the bowels, kidneys, and lungs. To promote the egress of this fluid is of great consequence to health; for when it is suppressed, disease is apt to fall upon some of the other organs concerned in the discharge of waste.

One of the most notable checks which perspiration experiences is that produced by a current of cold air upon the skin, in which case the pores instantly contract and close, and the individual is seized with some ailment either in one of the other organs of waste, whichever is in him the weakest, or in the internal lining of some part of the body, all of which is sympathetic with the condition of the skin. A result of the nature of that last described is usually recognised as a cold or catarrh. We are not at present called on particularly to notice such effects of checked perspiration, but others of a less immediately hurtful or dangerous nature.

The fluid alluded to is composed, besides water, of certain salts and animal matters, which, being solid, do not pass away in vapour, as does the watery part of the compound, but rest on the surface where they have been discharged. There, if not removed by some artificial means, they form a layer of hard stuff, and unavoidably impede the egress of the current perspiration. By cleanliness is merely meant the taking proper means to prevent this or any other matter accumulating on the surface, to the production of certain hurtful consequences.

Ablution or washing is the best means of attaining this end; and accordingly it is well for us to wash or bathe the body very frequently. Many leave by far the greater part of their bodies unwashed, except, perhaps, on rare occasions, thinking it enough if the parts exposed to common view be in decent trim. If the object of cleaning were solely to preserve fair appearances, this might be sufficient; but the great end, it must be clearly seen, is to keep the skin in a fit state for its peculiar and very important functions. Frequent change of the clothing next to the skin is of course a great aid to cleanliness, and may partly be esteemed as a substitute for bathing, seeing that the clothes absorb much of the impurities, and, when changed, may be said to carry these off. But still this will not serve the end nearly so well as frequent ablution of the whole person. Any one will be convinced of this, who goes into a bath, and uses the flesh-brush in cleansing his body. The quantity of scurf and impurity which he will then remove, from even a body which has changes of linen once a day, will surprise him.

Considering the importance of personal cleanliness for health, it becomes a great duty of municipal rulers to afford every encouragement in their power to the establishment of public baths for the middle and working classes, and to extend and protect all existing facilities for washing clothes, as well as for private supplies of water. Baths should neither be very cold nor very warm, but in an agreeable medium; and they should never be taken within three hours of a meal. Nature may be said to make a strong pleading for their more general use, in the remarkably pleasing feeling which is experienced in the skin after ablution.

EXERCISE.

The constitution of external nature shows that man was destined for an active existence, as, without labour, scarcely any of the gifts of providence are to be made available. In perfect harmony with this character of the material world, he has been furnished with a muscular and mental system, constructed on the principle of being fitted for exertion, and requiring exertion for a healthy existence. Formed as he is, it is not possible for him to abstain from exertion without very hurtful consequences

MUSCULAR EXERCISE.

With regard to merely bodily exercise, it is to be observed, in the first place, that we have no fewer than four hundred muscles, each designed to serve some particular end in locomotion or in operating upon external objects. A sound state of body depends very much upon each of these muscles being brought into action in proper circumstances and to a suitable extent. There is even a law operating within a certain range, by which each muscle will gain *in strength and soundness* by being brought into a proper degree of activity.

The process of waste and renovation may be said to be always going on in the body, but it does not go on with permanent steadiness unless the muscular system be exercised. Whenever one of the organs is put into exertion, this process becomes active, and the two opera

tions of which it consists maintain a due proportion to each other. A greater flow of blood and of nervous energy is sent to the organ, and this continues as long as it is kept in activity. When one state of action follows close upon another, the renovating part of the process rather exceeds the waste, and an accretion of new substance, as well as an addition of fresh power, takes place. On the contrary, when an organ is little exercised, the process of renovation goes on languidly, and to a less extent than that of waste, and the parts consequently become flabby, shrunken, and weak. Even the bones are subject to the same laws. If these be duly exercised in their business of administering to motion, the vessels which pervade them are fed more actively with blood, and they increase in dimensions, solidity, and strength. If they be little exercised, the stimulus required for the supply of blood to them becomes insufficient; imperfect nutrition takes place; and the consequences are debility, softness, and unfitness for their office. Bones may be so much softened by inaction, as to become susceptible of being cut by a knife. In a less degree, the same cause will produce languor and bad health.

It is of the utmost importance to observe, that the exercise of any particular limb does little besides improving the strength of that limb; and that, in order to increase our general strength, the whole frame must be brought into exercise. The blacksmith, by wielding his hammer, increases the muscular volume and strength of his right arm only, or, if the rest of his body derives any advantage from his exercise, it is through the general movement which the wielding of the hammer occasions. One whose profession consists in dancing or leaping, for the same reason, chiefly improves the muscles of his legs. The right hands of most persons, by being more frequently employed than the left, become sensibly larger as well as stronger. A still more striking illustration of the principle is to be found in a personal peculiarity which has been remarked in the inhabitants of Paris. Owing to the uneven nature of the pavement of that city, the people are obliged to walk in a tripping manner on the front of their feet; a movement which calls the muscles of the calves of the legs into strong exertion. It is accordingly remarked, that a larger proportion of the people of Paris are distinguished by an uncommon bulk in this part of their persons, than in other cities.

In order, then, to maintain in a sound state the energies which nature has given us, and still more particularly, to increase their amount, *we must exercise them*. If we desire to have a strong limb, we must exercise that limb; if we desire that the whole of our frame should be sound and strong, we must exercise the whole of our frame. It is mainly by these means that health and strength are to be preserved and improved. There are rules, however, for the application of these laws of our being.

1. In order that exercise may be truly advantageous, the parts must be in a state of sufficient health to endure the exertion. A system weakened by disease or long inaction must be exercised very sparingly, and brought on to greater efforts very gradually; otherwise the usual effects of over-exercise will follow. In no case must exercise be carried beyond what the parts are capable of bearing with ease; otherwise a loss of energy, instead of a gain, will be the consequence.

2. Exercise, to be efficacious even in a healthy subject, must be excited, sustained, and directed by that nervous stimulus which gives the muscles the principal part of their strength, and contributes so much to the nutrition of parts in a state of activity. To explain this, it must be mentioned that to produce motion requires the co-operation of the muscular fibre with two sets of nerves, one of which conveys the command of the brain to the muscle, and causes its contraction, while the other conveys back to the brain the peculiar sense of the state of the muscle, by which we judge of the fitness of the degree of contraction which has been produced to accomplish the end desired, and which is obviously an indispensable piece of information to the mind in regulating the movements of the body. The nervous stimulus thus created will enable a muscle in the living frame to bear a weight of a hundred pounds, while, if detached, it would be torn asunder by one of ten. It is what causes men in danger, or in the pursuit of some eagerly desired object, to perform such extraordinary feats of strength and activity. In order, then, to obtain the advantage of this powerful agent, *we must be interested in what we are doing*. A sport that calls up the mental energy, a walk towards a place which we are anxious to reach, or even an exercise which we engage in through a desire of invigorating our health and strength, will prove beneficial, when more of actual motion, performed languidly, may be nearly ineffectual.

3. The waste occasioned by exercise must be duly replaced by food; as, if there be any deficiency in that important requisite, the blood will soon cease to give that invigoration to the parts upon which increased health and strength depend.

KINDS OF BODILY EXERCISE.

Exercise is usually considered as of two kinds—active and passive. The active consists in walking, running, leaping, riding, fencing, rowing, skating, swimming, dancing, and various exercises, such as those with the poles, ropes, &c., prescribed in gymnastic institutions. The passive consists in carriage-riding, sailing, friction, swinging, &c.

Walking is perhaps the readiest mode of taking exercise, and the one most extensively resorted to. If it brought the upper part of the body as thoroughly into exertion as the lower, it would be perfect, for it is gentle and safe with nearly all except the much debilitated. To render it the more effectual in the upper part of the body it were well to walk at all times, when convenient, *singly* and allow the arms and trunk free play. It is best to walk with a companion, or for some definite object, as the flow of nervous energy will be by these means promoted, and the exercise be rendered, as has been already explained, the more serviceable.

Very long or rapid walks should not be attempted by individuals of sedentary habits, nor by weakly persons. Their frames are totally unprepared for such violent exertion. When a person who has been long confined at still employments finds himself at liberty to indulge his inclination for a ramble of a few days in the country, he should begin with slow and short marches, and be content therewith till his body is hardened for greater efforts. This is a rule followed in the army with respect to regiments which are about to undertake long marches. Every summer, many youths, from ignorance, do themselves great injury by undertaking pedestrian excursions much beyond their strength. Jaded to the last degree, and incapable of enjoying any thing presented to their observation, they nevertheless persist in making out some appointed number of miles per day, never once thinking of the outrage they are committing upon themselves, and only looking to the glory of executing their task, the only pleasure they find in the journey. Serious consequences—consumption not unfrequently—follow such ill-advised efforts.

With respect to very rapid walking, Dr. Johnson records some effects from it, of a remarkable nature, as occurring in his own case. "In my own person, says he, "I had some years ago, a very severe and alarming instance of the bad effects of too great muscular action, occasioned by a habit of walking very fast. After a day and night of unusual fatigue and rapid pedestrian exertion together with considerable mental anxiety, I was suddenly seized with an intermission of the pulse at

irregular periods. During each intermission, I felt the heart give a kind of struggle, as it were, and strike with great violence against the ribs, accompanied by a peculiar and most distressing sensation in the cardiac region, which I cannot describe." These symptoms became aggravated and lasted for eight weeks, "during which time," he continues, "I used horse-exercise, and kept, when at home, in a horizontal position. At length the heart gradually lost its morbid irritability; and at the end of fourteen or fifteen weeks I could walk as well as ever."

Running is an exercise which is intermediate between walking and leaping; it consists, in fact, of a series of leaps performed in progression from one foot to another, and the degree of its rapidity bears a constant proportion to the length of the individual and successive leaps. During this exercise the individual is obliged to take long inspirations, and make slow expirations; the air cells of the lungs are thereby distended, and the action of the heart being at the same time increased, and the circulation through the lungs much accelerated, a sense of oppression is felt on the chest, which is often exceedingly painful; when the violent action is discontinued, the heart palpitates with intermitting strokes, in the endeavour to recover its natural equilibrium of motion. Although this and other gymnastic exercises, such as leaping, wrestling, throwing heavy weights, &c., may, when judiciously had recourse to, invigorate the body, yet, from apprehension of the evils and accidents which may be so occasioned, young persons ought not to be permitted to engage extensively in such exercises, except under the care of some one well acquainted with gymnastics.

Fencing is of all active exercises that which is the most commendable, inasmuch as it throws open the chest, and at the same time calls into action the muscles both of the upper and lower extremities. Add to this, that it improves very much the carriage of the body; for which reason it may be considered a branch of polite education. The salutary effects of the other exercises which are taught in gymnastic institutions, such as exercises with the ropes, poles, pulleys, &c., in increasing the strength of the body, will be seen by consulting Mr. Roland's Treatise on Gymnastics, where will be found a table showing the amount of the increasing growth and strength of the body in a given time, during the employment of these exercises.

Dancing is exhilarating and healthful, and seems to be almost the only active exercise which the despotic laws of fashion permit young ladies to enjoy. We can scarcely consider modern quadrilles, elegant though they be, as exercise, seeing that they differ little from the most common walking movement. But country-dances, reels, and hornpipes, are genuine exercise, and their less refinement may be considered as amply compensated by the superior benefit which they confer upon health.

Riding is generally classed among the passive exercises, but in reality it is one which involves much action of the whole frame, and as such is very useful for health. Pursued solitarily, it has the drawback of being somewhat dull; but, when two or three ride in company, a sufficient flow of the nervous energy may be obtained.

The amount of bodily exercise which should be taken must vary according to the habits, strength, and general health of the individual. It was an aphorism of Boerhaave, that every person should take at least two hours' exercise in the day, and this may be regarded as a good general rule.

MENTAL EXERCISE.

Having thus explained the laws and regulations by which exercise may be serviceable to the physical system, we shall proceed to show that the same rules hold good respecting the mental faculties. These, as is generally allowed, however immaterial in one sense, are connected organically with the brain—a portion of the animal system nourished by the same blood, and regulated by the same vital laws, as the muscles, bones, and nerves. As, by disuse, muscle becomes emaciated, bone softens, blood-vessels are obliterated, and nerves lose their natural structure, so, by disuse, does the brain fall out of its proper state, and create misery to its possessor; and as, by over-exertion, the waste of the animal system exceeds the supply, and debility and unsoundness are produced, so, by over-exertion, are the functions of the brain liable to be deranged and destroyed. The processes are physiologically the same, and the effects bear an exact relation to each other. As with the bodily powers, the mental are to be increased in magnitude and energy by a degree of exercise measured with a just regard to their ordinary health and native or habitual energies. Corresponding, moreover, to the influence which the mind has in giving the nervous stimulus so useful in bodily exercise, is the dependence of the mind upon the body for supplies of healthy nutriment. And, in like manner with the bodily functions, each mental faculty is only to be strengthened by the exercise of itself in particular. Every part of our intellectual and moral nature, stands, in this respect, exactly in the same situation with the blacksmith's right arm and the lower limbs of the inhabitants of Paris: each must be exercised for its own sake.

The fatal effects of the disuse of the mental faculties are strikingly observable in persons who have the misfortune to be solitarily confined, many of whom become insane, or at least weak in their intellects. It is also observable in the deaf and blind, among whom from the non-employment of a number of the faculties, weakness of mind and idiocy are more prevalent than among other people. This is indeed a frequent predisposing cause of every form of nervous disease.

The loss of power and health of mind from imperfect or partial exercise of the faculties, is frequently observable in the country clergy, in retired merchants, in annuitants, in the clerks of public offices, and in tradesmen whose professions comprehend a very limited range of objects. There is no class, however, in whom the evil is more widely observable than in those females, who, either from ignorance of the laws of exercise, or from inveterate habit, spend their lives in unbroken seclusion, and in the performance of a limited range of duties. All motive is there wanting. No immediate object of solicitude ever presents itself. Fixing their thoughts entirely on themselves, and constantly brooding over a few narrow and trivial ideas, they at length approach a state little removed from insanity, or are only saved from that, perhaps, by the false and deluding relief afforded by stimulating liquors. In general, the education of such persons has given them only a few *accomplishments*, calculated to afford employment to one or two of the minor powers of the mind, while all that could have engaged the reflecting powers has been omitted. Education, if properly conducted, would go far to prevent the evils which befall this unfortunate part of the community.

On the other hand, excessive exercise of the brain, by propelling too much blood to it, and unduly distending the vessels, is equally injurious with its disuse. And not only are fatal effects to be apprehended from undue mental task-work, but also from that constant *stretch* of the mind which attends an unduly anxious and watchful disposition. The ancients had some notion of the impropriety of an incessant exertion of the mind, and rebuked it by their well-known proverb—*Apollo does not keep his bow always bent*. But they had comparatively little experience of the oppressive mental labours endured by large portions of modern society. Irrational, and in some respects dangerous, as many of the habits of our ancestors were, it is questionable if they suffered so much from these causes as their successors do from

virtuous but overtasking exertion. To maintain what such man conceives to be a creditable existence, now requires such close and vigorous exertions, that more, we verily believe, perish in the performence of duties in themselves laudable, than formerly sank under fox-hunting, toast-drinking, and the gout.

It is in large cities that this unintentional kind of self-destruction is most conspicuously exemplified. And it is in London, above all other places, that the frenzy is to be observed in its most glaring forms. To spend nine hours at a time in business, without food or relaxation, is not only not uncommon, but an almost universal practice, among the citizens of London: from a breakfast at eight to a chop at five, they are never, to use an expressive phrase, *off the stretch*. Upon a stomach enfeebled by exhaustion, they then lay the load of a full meal, which perfect leisure would hardly enable them to digest. But, far from waiting to digest it, they have no sooner laid down knife and fork, than away they must once more rush to business—not perhaps willingly, for nature tells them that it would be agreeable to rest; but then—but then business *must* be attended to. If nature were to punish the daily transgression by the nightly suffering, we should find few who, for the sake of pecuniary gain, would thus expose themselves to misery. But, unfortunately, she runs long accounts with her children, and, like a cheating attorney, seldom renders her bill till the whole subject of litigation has been eaten up. Paralysis at fifty comes like the mesne process upon the victim of commercial enthusiasm,* and either hurries him off to that prison from which there is no liberation, or leaves him for a few years organically alive to *enjoy* the fruits of his labours. A life thus spent is a mere fragment of what it ought to be. The means of obtaining pleasure have swallowed up the end. The glorious face of nature, with all its sublime and beautiful alternations; the delights of social life; the pleasures arising from the exercise of the finer feelings and the cultivation of the intellect; all that higher class of gratifications which nature has designed a moderate labour to place within the reach of *all* her creatures have been lost to such a man.

The absurdity of an ignorance or weakness of this kind is perhaps still more striking, when it occurs in individuals who make the acquisition of knowledge the chief aim of life. As the world is at present situated, it is possible to acquire learning upon almost every subject, and an infinite amount of knowledge, useful and otherwise, without even by chance lighting upon a knowledge of the most indispensable observances necessary for the preservation of a sound mind in a sound body. Half of the multiform languages of Asia may be mastered, while the prodigy who boasts so much learning knows not that to sit a whole day within doors at close study is detrimental to health; or, if he knows so much, deliberately prefers the course which leads to ruin. Leyden, an enthusiast of this order, was ill with a fever and liver complaint at Mysore, and yet continued to study ten hours a day. He eventually sank, in his thirty-sixth year, under the consequences of spending some time in an ill-ventilated library, which a slight acquaintance with one of the most familiar of the sciences would have warned him against entering. Alexander Nicoll, a recent professor of Hebrew at Oxford, of whom it was said that he might have walked to the wall of China without the aid of an interpreter, died at the same age, partly through the effects of that intense study which so effectually but so uselessly had gained him distinction. Dr. Alexander Murray, a similar prodigy, died in his thirty-eighth year, of over-severe study; making the third of a set of men remarkable for the same wonderful attainments, and natives of the same country, who, within the space of twenty years, fell victims to their ignorance of the laws of mental exercise. In 1807, Sir Humphry Davy prosecuted his inquiry into the alkaline metals with such inordinate eagerness, that, through excitement and fatigue, he contracted a dangerous fever, which he, in ignorance of the human physiology, ascribed to contagion caught in experimenting on the fumigation of hospitals. His physician was at no loss to trace it to his habits of study, which were such as would have soon worn out a frame much more robust. Davy at this time spent all the earlier part of the day in his laboratory, surrounded by persons of every rank, whose admiration of his experiments added to his excitement. Individuals of the highest distinction "contended for the honour of his company to dinner, and he did not possess sufficient resolution to resist the gratification thus afforded, though it generally happened that his pursuits in the laboratory were not suspended until the appointed dinner hour had passed. On his return in the evening, he resumed his chemical labours, and commonly continued them till three or four in the morning, and yet the servants of the establishment not unfrequently found that he had risen before them."* Over-tasked nature at length yielded under his exertions, and it was with the greatest difficulty that he was restored to health. Excessive application is known to have in like manner thrown Boerhaave into a species of delirium for six weeks, and to have on one occasion given a severe shock to the health of Newton. It unquestionably cut short the days of Sir Walter Scott, and also of the celebrated Weber, whose mournful exclamation in the midst of his numerous engagements can never be forgotten:—"Would that I were a tailor, for then I should have a Sunday's holiday!"

The premature extinction of early prodigies of genius is generally traceable to the same cause. We read that, while all other children played, they remained at home to study; and then we learn that they perished in the bud, and balked the hopes of all their admiring friends. The ignorant wonder is of course always the greater, when life is broken short in the midst of honourable undertakings. We wonder at the inscrutable decrees which permit the idle and the dissolute to live, and remove the ardent benefactor of his kind, the hope of parents, the virtuous and the self-devoted; never reflecting that the highest moral and intellectual qualities avail nothing in repairing or warding off a decided injury to the physical system, which is regulated by different laws. The conduct of the Portuguese sailors in a storm, when, instead of working the vessel properly, they employ themselves in paying vows to their saints, is just as rational as most of the notions which prevail on this subject in the most enlightened circles of British society.

It ought to be universally known, that the uses of our intellectual nature are not to be properly realized without a just regard to the laws of that perishable frame with which it is connected; that, in cultivating the mind, we must neither overtask nor undertask the body, neither push it to too great a speed, nor leave it neglected; and that, notwithstanding this intimate connection and mutual dependence, the highest merits on the part of the mind will not compensate for muscles mistreated, or soothe a nervous system which severe study has tortured into insanity. To come to detail, it ought to be impressed on all, that to spend more than a moderate number of hours in mental exercise diminishes insensibly the powers of future application, and tends to abbreviate life; that no mental exercise should be attempted immediately after meals, as the processes of thought and of digestion cannot be safely prosecuted together; and that, without a due share of exercise to the whole of the

* Of the frequent occurrence of premature paralysis, in consequence of the mode of life above described, we are assured by a metropolitan physician of the greatest eminence.

* Paris's Life of Sir Humphry Davy, p. 183.

mental faculties, there can be no soundness in any, while the whole corporeal system will give way beneath a severe pressure upon any one in particular. These are truths completely established with physiologists, and upon which it is undeniable that a great portion of human happiness depends.

REPOSE A CONDITION DEMANDED BY EXERCISE.

Exercise demands occasional periods of repose, and, in particular, that a certain part of every twenty-four hours be spent in sleep. After having been engaged in daily occupations for fourteen or sixteen hours, a general feeling of fatigue and weakness is induced; the motions of the body become difficult, the senses confused, the power of volition or *will* suspended, and the rest of the mental faculties, becoming more and more inactive, sink at length into a state of unconsciousness. The sense of sight first ceases to act by the closing of the eyelids; then the senses of taste and smell become dormant; and then those of hearing and touch. The muscles, also, dispose themselves with a certain reference to ease of position, those of the limbs having grown indolent before those that support the head, and those that support the head before those of the trunk. In proportion as these phenomena proceed, the respiration becomes slower and more deep, the circulation diminishes in impetus, the blood proceeds in great quantity towards the head, and all the functions of the internal organs become retarded. In this state, shut out, as it were, from the external world, the mind still retains its wonted activity, deprived, however, of the guidance of judgment and the power of *distinct* recollection; in consequence of which, it does not perceive the monstrous incongruities of the imagery which sweeps before it, and takes but faint cognisance of the time which elapses.

It may be laid down as an axiom, that the more uninterrupted sleep is, the more refreshing and salutary will be its effects; for, during this period, the body undoubtedly acquires an accession of nervous energy, which restlessness, however induced, must disturb; and therefore the state of the body before going to sleep, the kind of bed, and the manner of clothing, require especial attention. As the functions of the body are performed more slowly during our sleeping than our waking hours, a full meal or supper, taken immediately before going to bed, imposes a load on the stomach which it is not in a condition to digest, and the unpleasant consequence of oppressive and harassing dreams is almost certain to ensue. When the sleeper lies upon his back, the heart pressing, while pulsating, on the lungs, gives rise to a sense of intolerable oppression on the chest, which seems to bear down upon the whole body, so that in this painful state not a muscle will obey the impulse of the will, and every effort to move appears to be altogether unavailing. This constitutes *incubus* or *nightmare;* and it may be observed, that, as acidity on the stomach, or indigestion, gives rise to such dreams, so all dreams of this disturbed character are converse indications of indigestion; for which reason the great physiologist Haller considered dreaming to be a symptom of disease. It is certain that the dreams of healthy persons are the lightest and most evanescent.

The kind of bed on which we repose requires attention. Some are advocates for soft, others for hard beds; hence some accustom themselves to feather-beds, others to mattresses. The only difference between a soft and a hard bed is this—that the weight of the body in a soft bed presses on a larger surface than on a hard bed, and thereby a greater degree of comfort is enjoyed. Parents err in fancying that a very hard bed contributes to harden the constitution of their children; for which reason they lay them down on mattresses, or beds with boarded bottoms. A bed for young children cannot be too soft, provided the child does not sink into it in such a manner that the surrounding parts of the bed bend over and cover the body. The too great hardness of beds, says Dr. Darwin, frequently proves injurious to the shape of infants, by causing them to rest on too few parts at a time; it also causes their sleep to be uneasy and unrefreshing. The universal analogy derived from other animals evinces the truth of this doctrine, both in respect to the softness and due degree of warmth of their beds. Birds line the nests of their young with feathers; the eider duck and the rabbit pluck the down from their own breasts to increase the softness of the beds of their tender offspring, and brood over them with their wings, or clasp them to their bosoms, for the sake of warmth. For this reason, it is better that weak children should sleep with a bedfellow than alone; for, in this case, if any part of the body becomes cold, the child instinctively places that part in contact with the warmer body of its companion. So, also, it is better for a new-born infant to sleep with its mother in winter, or with its nurse, than in a solitary crib by the bedside. When in bed, the head should be always higher than the feet, and those subject to palpitation of the heart should lie with their heads very high. Night clothes should never consist of more than a chemise or shirt of cotton or linen, with a flannel shirt beneath. It is also highly improper to sleep in a bed overloaded with clothes; the body is thereby heated, and feverishness and restlessness induced. Accordingly, persons who complain of sleeplessness should look to the quantity of their bed-clothing; for the unnecessary addition of a single blanket may be the sole cause of the annoyance. It is also imprudent to lie with the head entirely within the bed-clothes; for, in this case the same air which has been already breathed must be again and again inhaled. For the same reason, the curtains should not be drawn closely round the bed. Washing the face and hands, and brushing the teeth, before going to bed, will be found to contribute materially to comfort. Whatever be the time chosen for sleep, it is evident that no person can with impunity convert day into night. Eight o'clock for children, and eleven for adults, may be recommended as good hours for retiring to rest. It is well known that children require more sleep than adults; and more sleep is requisite in winter than in summer. The average duration of sleep which may be recommended for adults is *eight* hours; but much depends upon habit, and many persons require only six. It is scarcely necessary to observe, that, on rising in the morning, the strictest attention should be paid to washing the face, neck, and hands; the mouth and teeth should also be well cleansed. The most simple powder for the teeth is finely brayed charcoal, a little of which will clear away all impurities, and preserve the teeth. On leaving the bedroom, the windows should be opened, and the clothes of the bed turned down, in order that the exhalations of the body during sleep may be dissipated. If, instead of this, the bed be made immediately after we have risen, these exhalations are again folded up with the clothes—a practice which is not consonant either with cleanliness or health.

TEMPERATURE.

The fifth important requisite for health is that the body be kept in a temperature suitable to it.

The degree of heat indicated by sixty degrees of Fahrenheit's thermometer, or that of a temperate summer day, is what the human body finds it agreeable to be exposed to when in a state of inactivity. In air much colder, the body experiences an unpleasant sensation, unless some warm clothing be worn, or a pretty active exercise be indulged in. When, either by natural or artificial means, the body is kept in a suitable state of warmth, the functions of the circulation and perspiration in the skin go on healthily; it is red, in consequence of the blood being urged into the capillaries or minute ves-

cels near the surface; it is also soft and moist, from the action of the glands for secreting the waste fluid and its free egress through the pores. This is a condition of great comfort, and the appearance of those who enjoy it conveys to others the notion that they are in good health. When, on the contrary, there is a much lower temperature, the functions of the vessels connected with the skin are apt to be considerably deranged. The vessels, in these circumstances, contract; the blood is driven inwards, where it sometimes occasions diseases of a dangerous nature; the perspiration, also, being prevented from passing out by its usual channels, catarrhal complaints ensues, sometimes ending in consumption.

It is of the more importance to make these facts generally known, as a notion prevails that exposure to a painful degree of cold tends to induce hardiness of constitution and to promote health. Undoubtedly, there may be harm from an opposite extreme, and we know well that excessive clothing and living in overheated apartments are detrimental to health. But safety lies in a medium between the two extremes. There is a degree of warmth which is both agreeable and healthy, and which it is desirable to have around us as constantly as possible.

There is no period of life at which warmth is of more consequence than in infancy. In a very young babe, the circulation is almost altogether confined to the surface, the internal organs being as yet in a very weak state. In such circumstances, to plunge the child into cold water, from an idea of making it hardy, as is customary in some countries, and among ignorant persons in our own, is the height of cruelty and folly; for the unavoidable consequence is, that the blood is thrown in upon the internal organs, and inflammation, bowel-complaints, croup, or convulsions, are very apt to ensue. A baby requires to be kept at a temperature above what is suitable to a grown person; it should be warmly, but not heavily clothed; the room where it is kept should be maintained at a good, but not oppressive heat; and it should never be put into other than tepid water. It should not be exposed to the open air for some days after its birth.

At all periods of life, it is most desirable to avoid exposure to very low temperatures, especially for any considerable length of time. To sit long in cold school-rooms or work-rooms, with the whole body, and especially the feet, in a chilled condition, is very unfavourable to the health of young people. It is not possible that a condition so adverse to the healthy action of the cutaneous vessels should not lead, if long persisted in, to very bad consequences. Those who are compelled to be sedentary, should make it their endeavour to obtain a sufficiently high temperature, either by warming their apartments sufficiently, or thickening their clothing. Common fires, though delightful from their cheerful look, are confessedly very inadequate, in most circumstances, to heat large work-rooms, school-rooms, or even the larger class of sitting-rooms; not to speak of the great objection which has been made to them on the score of economy, three-fourths of their heat being sent off through the chimney. It is most desirable that some means in which the public could have confidence were devised for thoroughly, and at the same time healthily, warming large apartments. Stoves enclosed in large iron-plate cases (Arnott's stoves), pipes of hot water or of steam, and blasts of heated air, are among the most conspicuous plans tried within the last few years. But none of these plans seems to have succeeded in obtaining the hearty approbation of the public, chiefly, we suspect, from their not being accompanied by what is peculiarly necessary where they are in operation, a means of ventilation. We can speak from some experience in favour of the plan of large steam-tubes, accompanied by a ventilating process; and have very little doubt that, with the latter requisite, this and several other of the recently suggested modes of heating might be found to serve the desired end. It is certainly of great consequence that some plan should be generally consented upon for warming the large rooms in which scholars and work-people spend so much time, as the chilliness there so generally experienced is a fatal underminer of the human constitution.

Clothing should be in proportion to the temperature of the climate and the season of the year; and where there are such abrupt transitions from heat to cold as in our country, it is not safe ever to go very thinly clad, as we may in that case be exposed to a sudden chill before we can effect the proper change of dress. Very fatal effects often result to ladies from incautiously stepping out of heated rooms in the imperfect clothing which they ludicrously style *full-dress*: all such injuries might be avoided by putting on a sufficiency of shawls, and allowing themselves a little time in the lobby to cool. The under-clothing in this country should be invariably of flannel, which is remarkably well calculated to preserve uniformity of temperature, as well as to produce a healthy irritation in the skin. While the value of comfortable clothing is fully acknowledged, we should never lose sight of the value of exercise for keeping up a kindly glow upon the surface, and for the support of a high tone of general health. Any one who, neglecting this, should live constantly in a warmed apartment, or only go out of doors muffled up in a load of clothes, would speedily suffer from a relaxed state of the system, and become so susceptible of damage from the slightest change of temperature in the atmosphere, that the most dangerous consequences might be apprehended.

Wet clothes applied to any part of the body, when it is in an inactive state, have an instantaneous effect in reducing the temperature, this being an unavoidable effect of the process of evaporation which then takes place. Hence it is extremely dangerous to sit upon damp ground, or to remain at rest for a single minute with wetted feet, or any other part of the body invested in damp garments. Dampness in the house in which we live has the same effect, and is equally dangerous. The chill produced by the evaporation from the wetted surface, checks the perspiration, and sends the blood inwards to the vital parts, where it tends to produce inflammatory disease. Few persons seem to be aware of these truths. We find young men heedlessly getting their feet wet, and sitting with them in that condition, thereby incurring the most deadly peril. Young women commit a similar folly, when they walk out in thin shoes in a wet or cold day. Exposure to wet, damp, or cold, is of comparatively little moment when the body, by a course of exercise or training, has been prepared to endure these conditions. Thus, a person brought up delicately, or much within doors, would be killed by that which would have little or no effect on a ploughman. It is therefore worthy of being suggested as a line of policy, that no one should accustom himself or herself to a pampered or too delicate mode of life. Every one should, if possible, go out daily, both in good and bad weather, with clothing corresponding to the nature of the weather, and in this way strengthen and harden the constitution to endure all ordinary and reasonable exposure. It is important, however, to note, that even the hardiest persons are never safe from the effects of wet clothes and other modes of exposure to a reduced temperature. No complaint is more common among out-of-door labourers, and also poor people in damp lodgings, than rheumatism. This is an affection produced solely by a violation of the natural law which demands that the body should not be chilled. Rheumatism is produced alike from exposure to a shower or to a draught of cold air when the body is warm, and from sitting with the feet on a cold stone or clay floor; the only difference, perhaps, being that the rheumatism

is in one case in the shoulders and in the other in the legs. Let us therefore impress on all the propriety of avoiding chills, the effects of which may be more fatal than a simple attack of rheumatism. When rheumatism has been contracted, the best remedy for its expulsion, if adopted in time, is friction of the part; if well rubbed before a fire with flour of mustard, so as to cause a counter-irritation on the surface, the internal complaint may be expelled.

ERRORS IN DRESS.

This is perhaps the most appropriate place in which to introduce some remarks upon errors in dress. The integuments which nature calls upon us to put on for the sake of warmth, are too often made the means of inflicting serious injury, either through ignorance or caprice. It is therefore necessary, in a treatise on the preservation of health, to advert in emphatic terms to this subject.

It is scarcely too much to say, that there is no part of the human frame, from the sole of the foot to the crown of the head, which has not been, and is not at this moment, mistreated by fashion. We laugh at the Chinese ladies, who have their feet constrained by iron moulds into mere bulbous appendages to the limbs; but we never reflect that, among ourselves, errors only inferior in degree are constantly committed. The foot naturally spreads out, fan-like, from the heel to the toes. But, instead of having our shoes formed in the same triangular shape, they are made in a lozenge form, truncated at the front, the toes being thus perverted from their radiating arrangement into one exactly the opposite; so that they become crushed under one another, and deprived of a great part of that muscular power by which they were designed to propel our bodies in walking. In the greater height usually given to the heels of shoes, another important deviation from nature is committed. When the heel is raised above the level of the ball of the foot, a complete derangement takes place in the muscles of locomotion; the power of the limb is impaired; and the whole body is thrown off its equipoise. It is impossible in such circumstances to exercise the body as it ought to be. The foot is also forced or plugged down into the narrow front of the shoe, where the toes become liable to the grievance of corns. Thus the free healthy play of the various parts of the body is further diminished. From the uneasiness and constraint experienced in the feet, sympathetic affections of a dangerous kind often assail the stomach and chest; as hemorrhage, apoplexy, and consumption. Low-heeled shoes, with a sufficiency of room for the toes, would completely prevent all such consequences.

An improved taste in the male sex has long since abolished the coarse and self-annoying absurdity of leathern small-clothes; but it is still too common to impede the circulation and the play of the muscles by tight apparel, especially in the regions of the stomach and neck. The immediate effect of these injudicious appliances is such inconvenience: the remote result is a diminution of the general strength and health. But all the errors of the male sex sink into insignificance, when compared with one to which the fair are liable. In the construction of the human chest, nature has provided ample room for several important viscera, the functions of which cannot be in any degree disturbed without a wrong being inflicted upon the whole system. Here reside the heart, the lungs, the liver, and the stomach. Fine ladies may affect to shut their mind's eye to the existence of such things; but the daintiest of their emotions depend upon the right state of those very viscera, without which they could no more think, speak, and act, than they could cast languishing looks without eyes, or melt our hearts by witching minstrelsy without a tongue and fingers. In the natural state, the external figure at this place tapers gently downwards. The waist of the Venus de Medici is of that form, and its perfect elegance was never challenged. But the women of the ordinary world have set up for themselves a different standard of beauty. A fine waist, in their estimation, is one which tapers rapidly below the arms, and is not above two-thirds of the natural girth. It must also be strictly round, although the waist of nature verges upon the oval. In order to reduce themselves to the desired shape and space, almost all the unmarried, and not a few of those who are otherwise, brace themselves in a greater or less degree with corsets, which no doubt produce the requisite roundness and slenderness, but at the expense of all the internal organs upon which health depends. The false ribs are pressed inwards; the respiratory and circulatory systems are crushed and thrust out of their proper place; the alimentary system is deranged; and even upon the exterior of the person, deformities of the most glaring kind, such as hooped shoulders and curved spines, are produced. Custom to a certain extent enables the victim to endure the inconvenience; there are even some who feel so little trouble from it, as to deny that any harm ensues from tight-lacing. But a violation so great cannot be otherwise than mischievous. We have seen a young lady's sash which measured exactly twenty-two inches, showing that the chest to which it was applied had been reduced to a diameter (allowing for clothes) of little more than seven inches. All who are aware of the internal organs at that part, know very well that it is impossible for them to exist in their natural condition within so small a space. Bruised, impeded, and disordered, they must of course be, and accordingly cannot fail to become a source of dreadful suffering to the wretched being who outrages them. Palpitations, flushings, dyspepsia, determination of blood to the head, and consumption, are among the evils which physicians enumerate as flowing from this sacrifice to vanity. Another of a moral kind is acknowledged to be of by no means unfrequent occurrence: in order to soothe the painful sensations produced by the constraint, spirituous liquors and cordials are resorted to, and thus habits of the most degrading nature are formed. Another evil still, respecting which a hint may be sufficient, is the unfitting of the system for the duties of a mother. How many domestic afflictions, which are submitted to in a spirit of resignation, as the unavoidable decrees of Providence; how many of the saddest scenes which this world ever presents—gentle and tender girls pining away under the eyes of heartless parents—beloved wives torn from the arms of husbands and children at the very moment when prolonged life was most needful—must be owing to a cause too trivial and unworthy to be mentioned in the same sentence with its so dire effects! No doubt it is well to submit meekly to such afflictions; but while they are ascribed in all humility to a Providence which is upon the whole only another term for Mercy and Justice, let us not be blind to the fact that they accrue through violations committed by ourselves upon laws established by Providence for our happiness, and might have been avoided by a different course of conduct.

The fashion of tight-lacing obviously owes its origin to a desire on the part of the ladies to attract admiration. It is of little importance to point out that they are quite wrong in their calculations as to the effect; but we would press upon the guilty parties, and all interested in their welfare, that tight-lacing is a practice which cannot be long persisted in without the most disastrous consequences. It is painful to reflect, that parents, so far from discouraging the practice, are so ignorant as often to force it upon their children. We have heard of a young lady whose mother stood over her every morning, with the engine of torture in her hand, and, notwithstanding many remonstrative tears, obliged her to submit to be laced so tightly as almost to stop the power of breathing

The result is, that the unfortunate victim is now severely afflicted with asthma, and has fallen into a state of low health As a general rule, it cannot be too strongly impressed upon those who have the care of young persons, that all clothing should sit lightly upon the figure, so as to allow of the full play of every part of the system.

INNOCENT ENJOYMENTS.

A sufficiency of innocent enjoyments has been set down as the sixth requisite towards the preservation of health. It may seem almost superfluous to treat this part of the subject, since the disposition to take amusement is one by no means generally wanting. A regard, however, for the completeness of our little treatise enforces us to make a few remarks on it; and we are not satisfied that there is not a considerable number of persons to whom an injunction to take innocent enjoyments is needful. There may be a general advantage in seeing the matter placed on something like a philosophical basis.

No physiological doctrine seems more entitled to faith and regard, than that a harmonious exercise, in moderation, of all parts of the system, including the organs of the mental faculties, is necessary for health. It is proved by the very craving which we experience, after a long task, or a long perseverance in some particular habits, for something which will engage a different set of faculties. There is nothing which will pleasingly engage our thoughts for any considerable length of time. Something inferior will invariably be preferred, if it only be new. Now, the duties by which men in general earn their subsistence, are in all cases of such a nature as only to call into exercise a part of their mental and bodily system. Something is required, at once to soothe and compensate us for the drudgery of our current labours, and to bring into exercise those parts of our muscular frame and intellect, which professional duty has left unoccupied. To begin with an humble illustration: how delightful to a tailor, after long exercising his fingers and arms alone at his business, to enter into some athletic sport upon the village green, by which his limbs also will be exercised! After a lawyer has fagged for a day at a brief, how delightful to be able, by the reading of a new novel or play, to call up another set of the intellectual powers! In these changes from grave to light occupation, there is at once repose given to the tasked faculty, and the gratification of employment given to others which have been pining for want of something to do. It so happens that, from the sentient nerves being mixed with those which direct the operations of all our organs, each organ has a sense of enjoyment in being rightly exercised. Even the stomach has, from this cause, a gratification when its functions are going on well, and this altogether independent of any pleasure we may have had in eating the meal upon which it is now employed. An organ left long unoccupied is thus somewhat like a child in a family which its parents have been overlooking. It craves to be noticed like the rest, and, when the desired notice at length comes, it experiences a high degree of satisfaction. In short, variation of occupation and pursuit, for the purpose of keeping all the parts of the system in harmonious exercise and in healthy tone, is one of the most important principles concerned in the preservation of health.

There are several powers of the mind which must have been designed for the express purpose of creating and receiving amusement, and the existence of which, therefore, shows that amusement has a place in the right economy of human life. The imitative arts in general, music, fiction, drollery of all kinds, spring directly from primitive faculties of the mind; and, when we see the pleasure they give in society, we cannot doubt that they are things naturally required by man, and in which it is quite legitimate for him to indulge within moderate bounds and in circumstances compatible with innocence. These things are doubtless designed to alleviate the burdens of life and beguile us of its cares. They furnish something like a different sphere of existence, into which we may enter and temporarily lose the sense of all that harasses us in the ordinary one. The *joculator*—under which name our ancestors associated the poet, tale-teller, and mimic, and which we may apply equally extensively to the poet, novelist, artist, and player—is therefore a most useful functionary in society. We say nothing on the present occasion of the refinement to be derived, in addition, from communion with the productions of the higher classes of such minds.

Amongst amusements, *reading* takes a most distinguished place, for there is none which may be more readily or more innocently indulged in, and fortunately, in our own country, it is one which may now be enjoyed by all. It is unquestionably the chief of in-door amusements; and few scenes are calculated to awaken more agreeable feelings in a well-constituted mind, than a family group assembled in their parlour, to hear some one of their number reading a pleasant book. Ever honoured be the great masters of fiction, who have allowed us, by these means, to pass from common life, for a time, into "the tale of Troy divine," the story of "the gentle lady married to the Moor," the tear-compelling fate of Ravenswood, and all the other numberless suppositions of things done, and persons who spoke and acted, which we feel to be more real than much of even the life that is passing around us!

Next to reading stands *music*, a means of enjoyment of which only a few comparatively, in our country, take advantage, but which might easily be made much more extensively available, and probably will be so in the course of a few years. Connected intimately with music is *dawing*, which is not only a cheerful amusement, but a positive and direct means of bodily exercise. A family musical or dancing scene, like a family reading scene, is a thing beautiful to look upon. There is a prejudice against both in some minds, on account of their being liable to abuse; but the abuses of both arise very much from their not being extensively or freely indulged in. Were music the general accomplishment which it might easily be made, it would not only be indulged in on all occasions with simplicity and innocence, but it would supplant coarser and more clandestine amusements. Dancing is the nightly amusement of the French peasantry, and it has never been pretended that these people are less virtuous than the corresponding class in our own country. *Theatrical representations* it might be more difficult to place on such a footing as to secure the unhesitating approbation of the good; but certainly, if this were done, they might prove highly serviceable in furnishing amusement.

In the class of amusements we must reckon meetings or promenades in ornamental grounds, excursions into the country, and little tours, all of which are highly commendable in those who are able to indulge in them. The entertainment of little parties of friends, and the going out to entertainments given by them in return, are other means of amusement common in society, and which may be moderately indulged in with much advantage. In short, whatever gives a pleasant variation to the monotony of life, without leading the mind away from duty or corrupting the manners, ought to be indulged in as freely as circumstances will permit. The mind returns from such diversions with renewed tone and power, and neither the time nor the expense is lost in the long run. It is the more necessary to impress these maxims, as many well-meaning persons, alarmed perhaps at the occasional abuses of such enjoyments, repudiate them nearly altogether, and thereby lower the tone of their health, both as respects the body and the mind. It is particularly distressing to see such persons exercising a control over the young, and denying to their unfortunate protegés an

element of life not much less pressingly necessary than the air they breathe.

Dr. Southwood Smith, in his excellent work "The Philosophy of Health," has pointed out that pleasure is the ordinary, and pain in all cases an extraordinary, result of the action of our organs. "There are," he says, "many cases in which pleasure is manifestly given for its own sake; but in no case is the excitement of pain gratuitous." Pain is always a punishment; and, when it reaches a certain extreme, it is destructive of what feels it. But "all such action of the organs as is productive of pleasure is conducive to the perpetuation of life. There is a close connection between happiness and longevity. Enjoyment is not only the end of life, but it is the only condition of life which is compatible with a protracted term of existence. The happier a human being is, the longer he lives; the more he suffers, the sooner he dies: to add to enjoyment is to lengthen life; to inflict pain is to shorten the duration of existence." It may fairly be presumed, then, that a certain amount of enjoyment in life is necessary for health, and that when the quantity actually secured is much below that point, unhealthy conditions must ensue. If, for example, poverty or embarrassed circumstances press so severely upon a cautious and conscientious man, as to leave him scarcely a moment's comfort from one year to another, he cannot fail to sink in health. If married to a female of bad temper, or who afflicts him by bad habits, and if, from these causes, he rarely enjoys a moment of happiness, so also must his health fail. In short, to be placed in any such circumstances as constitute a bar against nearly all enjoyments, must prove injurious, and tend to the shortening of life.

Enjoyments are of many kinds. Some are sensual, as the taking of agreeable food; others are intellectual, as agreeable music, reading, &c.; others are moral, as the exercise of philanthropy, the religious feelings, &c.; and some are sympathetic, and consist in the exercise of the affections and the reflection of that gratification which we have endeavoured to impart to others. We may consider as such all things over and above the plainest unrelished fare, and the supply of water, air, and a barely sufficient temperature. These are usually considered as strictly the *necessaries* of life, the others being the comforts or luxuries. The distinction is not quite correct. The first class are certainly immediately necessary to the support of life; that is to say, they are hourly, daily necessary. But more or less of what are called the comforts of life are also necessary, if we would preserve health. The only difference is, that the want of them would not tell in so short a time as the want of the so-called necessaries. If a human being be shut up in a cell, and allowed only a sufficiency of unrelished and unvaried food, with air and water, the want of all the enjoyments of life, sensual, intellectual, moral, and sympathetic, will in a certain time make him utterly miserable; the health of body and mind will give way; and if the experiment be sufficiently protracted, he will perish. The ignorance which prevails on this point has led to the trial of what is called the *silent system* in prisons, which is now about to be abandoned as utterly irreconcilable with humanity. It were well if more knowledge prevailed on the subject, for, from erroneous ideas of what is *necessary* for healthy life, many deprive themselves or others of things which, when we take the element of time into account, are as essential to health as the supply of the air we breathe. There is, in some enthusiastic minds, a spirit of asceticism and self-mortification which would give up all the enjoyments of life together. Such persons rarely fail to reduce their own health, if they do not also exercise some unhappy control to the same effect over their fellow-creatures. While self-denial for moral purposes is always admirable, and over-indulgence of every kind saps the vigour and fortitude of the human character, it should be ever kept in view that there is great danger in reducing the allowance of comforts and indulgences too low. Very rigid views of what is necessary for the support of life usually prevail, wherever the affluent have to dictate a style of living for the poor. The tendency there is to reduce allowances as nearly as possible to what may be called the *immediate necessaries*; for it does not seem just or right that paupers, adults or children, should enjoy any species of gratification. But these are short-sighted views. The health of these unfortunate persons requires something more, and this something would be granted by an enlightened humanity. We have a strong manifestation of this need in the eagerness with which paupers generally desire allowances of tea or tobacco, or indeed the least variation of their diet. The craving for these luxuries is not so much, what it is generally thought solely to be, the result of bad habits long indulged in, as it is the expression of a want in the personal economy—a want which, by one means or another, must be supplied, or injurious consequences will ensue.

EXEMPTION FROM HARASSING CARES.

It is little more than a repetition of doctrines already laid down, that, for health, a human being requires an exemption from acute distress of mind and harassing cares.

Mental distress and anxiety operate through the brain upon the condition of the whole body, and, when long protracted, effectually undermine the health. "It is impossible," says Dr. Smith, "to maintain the physical processes in a natural and vigorous condition, if the mind be in a state of suffering. Every one must have observed the altered appearance of persons who have sustained calamity. A misfortune, that struck to the heart, happened to a person a year ago: observe him some time afterwards—he is wasted, worn, the miserable shadow of himself; inquire about him at the distance of a few months—he is no more." It is Dr. Smith's opinion that the nearest cause of many suicides is not strictly a desire to escape from a state of suffering, but some disease, probably inflammation of the brain, brought on by distress of mind. "By a certain amount and intensity of misery, life may be suddenly destroyed; by a smaller amount and intensity, it may be slowly worn out and exhausted The state of the mind affects the physical condition; the continuance of life is wholly dependent on the physical condition; it follows that, in the degree in which the state of the mind is capable of affecting the physical condition, it is capable of influencing the duration of life."

Depression of mind, besides its immediate effect on the nervous system, deranges the respiration and mars the proper oxygenation and circulation of the blood. A diminished vitality is the consequence, often leading to pulmonary consumption. An excessive agitation and alarm of the selfish feelings, such as takes place in some minds on the approach of an epidemic, affects the whole system in such a way as—to use an expressive phrase of Dr. Combe—"places it on the brink of disease;" and hence the notoriously great liability of persons in this state of alarm and apprehension to fall victims to the malady when it comes. It has been remarked that an army in a high state of confidence and cheerfulness after a victory, has a much smaller proportion of sick than in the opposite circumstances, or even in its ordinary condition. The usual proportion of sick in a garrison quartered, during peace, in a healthy country, is five per cent.; during a campaign, when there is more anxiety of mind, it is ten; in the event of defeat, although the circumstances be otherwise not unfavourable, the proportion rises to a much higher amount. It is a very instructive fact, that in a large detachment of the French army cantoned in Bavaria immediately after the battle of Austerlitz, the proportion of sick was little more than *one* per cent.

GENERAL OBSERVATIONS.

The fundamental principle of all efforts to improve and preserve health has been thus stated:—"Man, as an organized being, is subject to organic laws, as much as the inanimate bodies which surround him are to laws mechanical and chemical; and we can as little escape the consequences of neglect or violation of those natural laws, which affect organic life through the air we breathe, the food we eat, and the exercise we take, as a stone projected from the hand, or a shot from the mouth of a cannon, can place itself beyond the bounds of gravitation." It may be added, that "all human science, all the arts of civilized man, consist of discoveries made by us of the laws impressed upon nature by the Author of the universe, and the applications of those laws to the conditions—which are laws also—in which man and the particular bodies and substances around him are placed; nor, it is manifest, should any science concern us more than that which relates to the conditions on which organic life is held by each individual."

The preceding sections are but explanations, such as we have been able to afford, of the conditions under which the organic frame of man exists, and the agencies, internal and external, which operate upon it, for the maintenance of health or the introduction of disease. It must be evident, where there is a conviction of the truth of the fundamental doctrine, that individuals and societies have their health very much at their own disposal; that a careful avoidance, on the one hand, of what is noxious, and a judicious attention to what is beneficial are what are chiefly necessary for the preservation of the human frame in health to old age; and that premature deaths, over and above those which result from unforseen casualties, instead of being, as supposed by the untutored mind, a mysterious and irreversible decree of Providence, are simply the natural effect of our own violation of laws which Providence has appointed for our welfare. It might still be objected that human nature is such, that the due obedience and observance of those natural ordinances are not to be expected; so that the vast quantity of disease, and the great number of premature deaths, which afflict our present state of being, are equally to be regarded as things immutable, and therefore to be tranquilly submitted to. But this view would be not less a mistaken one; for there is no fact more clearly ascertained, than that disease and premature deaths are not, and never have been, fixed at any given amount, but yield constantly to the power of any new conditions which man may be able to introduce. Regarding clear views on this subject as of great importance, we shall here enter a little into detail.

The object is, we apprehend, to show that sickness and mortality vary both in place and in time, according to physical and organic conditions.

Inquiries into these subjects were not made in ancient times; but, during the last two hundred years, such facts have been recorded as enable us to ascertain that, in that space of time, with regard to nearly the whole of Europe, there has been a gradual improvement in health and life, in proportion to improved conditions. In Sweden, for instance, between 1756 and 1763, the annual mortality was, for males, 1 in 33¼; for females, 1 in 35½; whereas, in the year 1800, it had diminished to 1 in 34½ for males, and 1 in 37½ for females. From mortuary tables preserved with considerable accuracy at Geneva, it appears that, at the time of the Reformation, one-half of the children born died within the sixth year; in the seventeenth century, not until the twelfth year; in the eighteenth century, not until the twenty-seventh year; consequently, in the space of about three centuries, the probability that a child born in Geneva would arrive at maturity, has increased fivefold. In London, in the year 1606, the annual deaths were 1 in 14½, or 7 per cent. of the population; and in plague years during that century it reached 25 in 100, or every fourth man, woman, and child! *In* 1838, *it was only* 1 *in* 35½. Knowing that, at the former period, the city was dense and ill-cleaned, and that the habits of the people were not then what they are now, we cannot doubt that this diminution of mortality to less than one-half, is owing to the improved conditions in which human beings now live in the metropolis. Between the years 1730 and 1750, 74 of every 100 children born in London, died before they were six years of age; but in more recent times, only 31 and a fraction out of every 100 die under the same age; that is to say, the deaths of children in London were then more than twice as numerous as they are now. About a century ago, the mortality of the children received into the London hospitals was of astonishing amount. Though the fact seems scarcely credible, we believe there is no good reason to doubt, that of the 2800 annually received, 2690, or *twenty-three in every twenty-four*, died before they were a year old. It was at length seen that this mortality was the effect of over-crowding, impure air, and imperfect aliment; and, after an act of parliament had been procured to compel the officers to send the infants to nurse in the country, only 450 out of 2800 died in the first year. It has been ascertained that, during the last century, about a third has been added to the average expectation of life; that is to say, an individual now has as good a chance of living forty years, as he had a hundred years ago of living thirty. To what can such a fact be owing but to the diminution of the causes of disease in the improved conditions of the people.

The facts ascertained with regard to differences of mortality in different places are equally striking. A remarkable instance of the effect of marshes upon health is cited by M. Villermé. Formerly the district of Vareggio in Tuscany was in this condition, and its few miserable inhabitants were every year visited by severe agues. In 1741, floodgates were erected to keep out the sea, the marsh was dried up, and ague appeared no more. Vareggio subsequently became a populous and healthy district. The Isle of Ely is a marshy district in the east of England, and it was ascertained that of 10,000 deaths which occurred in it between the years 1813 and 1830, no fewer than 4732 were of children under 10 years of age; the proportion of deaths of children under ten in all the other agricultural districts of England being only 3505, or as about 3 to 4 of the former number. Of 10,000 deaths between ten years and extreme old age, in the same period, there were, of persons between ten and forty, 3712 in the Isle of Ely, and only 3142 in drier districts. There are some remarkable discrepancies of mortality in different counties of England. While the proportion of annual deaths in every hundred persons under six years of age is, for the whole of England and Wales, about five and a third, the proportion in Suffolk is three and a half, in Warwick six, in Middlesex eight and a third. Suffolk is an agricultural county; Warwick contains Birmingham and some other large towns; and the metropolis is situated in Middlesex: can we resist concluding that the pure air and constant exercise which children obtain in the country are the immediate means of prolonging their lives; while the narrow accommodations, impure air, and limited exercise, to be had in large towns, have exactly the contrary effect? In the general population of England, 443 in 1000 die under ten years of age; but in Manchester and Salford the number is a third larger, or 602. Here, the miserable circumstances of many of the humbler classes in Manchester—above eighteen thousand of them, for one thing, living *in cellars*—must be considered as the immediate cause of the disproportioned mortality. When the general mortality of London is, as stated, 1 annually in 35¼, there are great differences with respect to different districts. In Camberwell, an open suburban district, it is 1 in 52; in

Hackney a similar district, 1 in 54; but in the huddled district of St. George's, Southwark, it is 1 in 30; and in the still more dense and miserable region of Whitechapel, so much as 1 in 26, or exactly double the mortality of Camberwell. A curious investigation has been made in London, to ascertain the effect of density of population upon health. In a large district, where the population is so dense that there is only 35 square yards for each person, the annual mortality is 3426; in another district of the same population, where each individual has an allowance of 119 square yards, the mortality sinks to 2786; in a third, where there are 180 square yards to each person, the mortality is only 2289, or under two-thirds of what it is in the closest of the three districts. It was also found that, in the three districts, the mortality from typus fever was, respectively, as we go from the roomiest to the closest, 131, 181, and 349. The proportion of sickness and mortality which the poor suffer in comparison with the rich, is thus placed in a striking point of view. Precisely similar results have been discovered in Paris. M. Villermé has there ascertained, that the deaths in some poor arrondissements are just double what they are in the rich. He states that, taking the whole of the French population, human life is protracted twelve and a half years among the wealthy beyond its duration among the poor; consequently, in the one class, a child, newly born, has a probability of living forty-two and a half years; in the other, only thirty years.

Taking the whole of the above facts into account, we must see that not only do health and longevity depend expressly on laws, the operation of which we can understand, but man has it in his power to modify to a great extent the circumstances in which he lives, with a view to the promotion of his organic well-being and preservation. We see that the draining of a marsh banishes the ague, that a change from city to country air diminishes mortality, and that the greater comforts possessed by the affluent secure them longer life than the poor. It may not immediately be in the power of every one to change his circumstances from the unhealthy to the healthy; but it is a great matter to know that the object is within human power, for then at least an encouragement is held out to induce each individual to make every possible effort to put himself, and to contribute to putting society, into more salubrious conditions.

The object may be said to depend partly upon individual and partly upon social efforts. Every person has some control over the quantity and quality of the food he eats, the condition of the air he breathes, and the exercise, repose, and recreation which are demanded by his muscular and nervous system, according to the principles laid down in this and similar treatises; as also some power to refrain from injurious excesses, and to avoid the various external agencies of a detrimental kind, which constantly beset him. Let him act as he ought to do in these respects, and he will reap an immediate reward in that pleasurable state of consciousness which attends a healthy condition. But some of the most important requisites for health depend on public measures. The amount of the necessaries and comforts of life to be obtained by the great mass of the operative classes in all countries, depends very much upon regulations which may have been made with regard to *production* and *exchange*, as also those which may have been made for instructing and morally elevating and sustaining the bulk of the people. It unfortunately happens, in most countries, that, while the bearing of certain acts upon individual happiness is fully seen and provided for, those which affect the condition of communities are imperfectly understood; so that measures destructively injurious to millions will be enforced and defended by those who would severely punish the slightest wrong inflicted by one man upon another.

Measures for improving general condition with respect to air and exercise, are perhaps more readily practicable: yet here also the bearing of active principles upon great masses is so dimly seen, that, not to speak of more positive difficulties, it is usually long before proper sanatory regulations are made.

Some facts elicited by recent parliamentary inquiry with regard to several of our principal cities, are of the most startling kind.

Dr. Arnott, when examined as to the prevalence of fever in Bethnal Green, Whitechapel, Wapping, and certain other districts in London, attributed them directly to the dirty and neglected state of these localities, instancing—"Houses, courts, and alleys without privies, without covered drains, and with only open surface gutters, so ill made that the fluid in many cases was stagnant; large open ditches containing stagnant liquid filth; houses dirty beyond description, as if never washed or swept, and extremely crowded with inhabitants; heaps of refuse and rubbish, vegetable and animal remains, at the bottom of close courts and in corners." [The amount of noxious matter which is hoarded or allowed to rest in London, is far beyond what most of its inhabitants have any conception of, as is the case with most other conditions chiefly or solely affecting the poor.] In Manchester, 19,300 persons, or one-twelfth of the whole working population, live beneath the level of the ground, with an insufficiency of both light and air. In that town, the dwellings of labourers are often built in close narrow courts, and back to back, so as to prevent ventilation; the drains are far from sufficient, and there is not in the town one free space in which the people can enjoy the slightest recreation. In Liverpool, 39,000 persons live in cellars, dark, damp, confined, ill-ventilated, and dirty. The class next above, to the number of 80,000, inhabit houses built around small courts, closely pent up, back to back, with only one entrance to each, and usually a receptacle for refuse in the centre; an arrangement which appears as if it had been expressly calculated to keep health low and mortality high. In Leeds, a similar style of building obtains, with a similar train of circumstances, "no effective drainage, inspection, or system of paving or cleansing." The greater part of this town was described in 1839 as "in a most filthy condition, demanding an immediate remedy." It was mentioned, that in a certain dirty yard, there was a house which for many years had been the seat of a disease of a very malignant character three years ago, the attention of the commissioners of police was directed to the extremely imperfect drainage of the surface-water; at that time a better escape for the refuse water was provided; and since that period, says the reporter, "I believe, *we have not had a single case of fever from that particular locality.*" Narrow alleys and close courts, with wet filth constantly exhaling within them, and containing a close huddled population of extremely poor persons, exist in Edinburgh, where, however, an exposure to high winds makes the evil less pestilential. In Glasgow, a comparatively level city, the same peculiarity exists to perhaps a greater extent than in any other British city. This, added to the miserably insufficient succour extended by law to the poor in Scotland, renders Glasgow one of the unhealthiest cities in Europe; the mortality of the year 1837 being 1 in 24½, and the number of fever cases for the five years before 1839 at an average of 11,118 per annum. Here, also, we have a most notable instance of the counteractive power of a single sanatory principle; for a house containing above five hundred poor inhabitants, having been ventilated by a draught from each room in 1832, fever, which had previously never been absent from that dwelling, was nearly banished, only four cases occurring in the ensuing eight years, though fever raged during that period in all the districts of the city occupied by the poorer classes.

COMMERCE—MONEY—BANKS.

COMMERCE.

Man has been defined by some naturalists as an *exchanging animal*—an animal who buys and sells, that being a thing performed by no other living creature, and therefore suitable as a distinction in character, though others, much more exalted, might readily be found. The practice of exchanging one commodity for another is doubtless coeval with the first herding of mankind together. No man, even in the rudest savage state, and who lives in the society of neighbours, can rest satisfied with such objects as he can procure or fashion by his own labour. He must depend on others for assistance, while he assists them in return. The cultivator of the ground would exchange some of its produce for an animal from the flocks of his neighbour; and both would be glad to give a portion of their wealth for the clothing or weapons made by a third party. Thus, *exchanging* becomes a matter of convenience between two parties, each of whom is anxious to obtain a share of the other's goods for a share of his own, and a mutual advantage is the result. Such desires and practices must have been displayed in the very earliest stages of society. No nation of African or Indian savages is ever found without a strong inclination to exchange the rude products of their country for the articles possessed by the traveller; an ox or sheep being perhaps eagerly offered by them for a single needle, a nail, or a small toy looking-glass.

As mankind advance in their social condition, the practice of exchanging increases; the desires and necessities become more urgent; each person finds it more profitable and agreeable to adopt and hold by one fixed employment, and to sell the produce of his labour for a variety of articles made by others, than to attempt to make every thing for himself; and, finally, for the sake of convenience, a class of persons are engaged to conduct the exchanges from one hand to another. In this improved condition, the production of articles of general consumption is called *manufacturing*; while that department of industry in which the exchanging is transacted is called *trade* or *commerce*. For still further convenience, the business of exchanging is committed to several orders of traders—the wholesale merchants, who in the first instance purchase large quantities of goods from the producers; the retail dealers, who have been supplied in smaller quantities from the merchants, and sell individual articles or minute portions to the public; and to these sometimes an intermediate dealer is added. In this manner the transfer from the workshop of the manufacturer to the house of the actual consumer is interrupted by several distinct processes of exchange, in which each seller obtains a certain profit at the expense of the person who has ultimately to buy and use the article. It is a principle of trade, that the fewer hands through which any article is made to pass, the better for the consumer, because the article can be brought with the least burden of profits, or at the lowest price, into general use. But this principle, sound as it is in the abstract, is counteracted by another which must on no account be lost sight of. This is the principle of *convenience*. A manufacturer engaged deeply in his own pursuits finds it more profitable and agreeable to sell his articles in large than small quantities. The maker of millions of yards of cloth has no time to spend in selling single yards. If he were compelled to sell by retail, he would have no time to conduct his affairs; he could manufacture only a small quantity, and, therefore, being limited in his amount of produce and sales, he must take larger profits. Thus, upon the whole, it is much better for all concerned to allow the manufacturer to pursue his own way in selling only very large quantities to wholesale merchants. To these traders the same rule may be applied. They seek out the seats of manufacture; and, purchasing a large variety of goods, they send them to the towns and places where they are required by the public, and there the articles can be had individually from a shop. It is evident that if any man wish to buy a handkerchief, he may procure it much more cheaply from any shop in which such things are sold at an advance upon the original cost, than if he were to travel perhaps hundreds of miles to the house of the manufacturer, and there make the purchase. The use of an intermediate class to conduct exchanges is thus very conspicuous; and any attempt to revert, generally, to the original practice of causing the maker to deal with the consumer, would be entirely incompatible with an enlarged system of trade between different countries, or even between different places in the same country. We say generally, because there are instances in which makers may, with advantage to themselves and the community, sell their produce in small quantities or single articles to the public, but these are exceptions to a common rule.

Convenience, it is evident, forms a guiding principle of trade, and requires the same consideration as the actual value of an article. This, however, has been recognised only in very recent times. At one period there were laws to prevent farmers from selling their grain in a large quantity or by the lump, without exposing it in an open market. Such laws were manifestly unjust. They interfered with the liberty of the former, who in his capacity of manufacturer had surely a right to sell his produce in whichever way he felt it to be most for his advantage. It would be the same kind of injustice, if the law were to prevent a manufacturer of handkerchiefs from selling them at his own workshop to wholesale dealers, and causing him to take them many miles to a certain street in a certain town, and there expose them for sale in small lots to the public. It is of the greatest importance in matters of trade and commerce *never to interfere in any shape to prevent men from dealing in whatever manner appears most beneficial and convenient to themselves, provided it be conformable with strict justice.* By being left to consult their own inclinations, the public, in the end, though probably in a way not easily recognisable by an unreflecting mind, reaps the advantage.

Commerce, by which we comprehend traffic carried on at home or with foreign countries, is of great antiquity, and, both in the earliest times and in our own day, has been one of the principal engines of civilization. Among the industrious nations which at a remote period of history were planted on the borders of the Mediterranean Sea, it became a means of spreading knowledge in the interior of Asia, and many parts of Africa and Europe. Unfortunately, the intelligence which was so disseminated was afterwards obliterated by the overruling powers of barbarous and warlike nations; but the efficacy of commerce in modern times is likely to be permanent wherever its influence is extended, seeing that the greatest manufacturing and mercantile people are at the same time the most powerful and most capable of offering protection to those who sustain a commercial intercourse with them. It is exceedingly pleasing thus to reflect on what commerce is capable of effecting, independent of the actual comfort which it produces, wherever it is fairly introduced. By its appeals to the selfishness, the vanity, and other passions, good and bad, of mankind, it appears to be the best of all forerunners to the efforts of the schoolmaster

and the missionary. Its influence in this respect has been remarkably exemplified in the boundless regions of Hindostan, which by the efforts of a company of merchants, have been laid open to the settlement of enlightened men from Europe, who, though by slow degrees, will ultimately spread the blessings of education, and the decencies of social life, among many millions of human beings. In the remote islands in the Pacific Ocean, the influence of commerce has been recently of marked utility. The introduction of articles of a fanciful nature, both for the ornamenting and covering of the person, has induced a desire of following European manners and customs; and as these commodities cannot be procured but by the exchange of native commodities, a spirit of industry has consequently been produced, which cannot fail to be of both moral and physical advantage to the natives. It is always thus with the intercourse which commerce necessarily involves. New tastes are created, and to be gratified, industry must be exerted. But to witness the extraordinary influence of commerce in producing civilized and refined habits, we need not look beyond our own country. Commerce, in this its chosen seat, has caused roads everywhere to be cut, canals to be opened, railways to be formed, expeditious modes of travelling by sea and land to be effected; all of which great accessories to our comfort have tended in the most wonderful manner to introduce not only useful commodities and personal luxuries, but highly cultivated sentiments, literature, and the arts, into districts which at no distant period lay in a comparatively primitive condition. The intercourse which commerce in this manner requires, is the grand lever which, it is apparent, must in the first place be employed to lift the load of ignorance from off the natives of Africa; and when this lever is properly insinuated, the way will soon be prepared for the introduction of those measures of melioration which philanthropists so anxiously design.

It is obvious that this scheme of mutual interchange among nations of the commodities which they respectively produce, is agreeable to every rational principle, and must have been designed by a wise Providence for the universal benefit of his creatures. In order that manufactures may be produced, and commerce brought in to disseminate them both at home and abroad where they are wanted, no species of legislative enactment is requisite either to encourage or direct. The law which governs production and consumption is a law of nature—it is the overruling principle of *self-interest*, by which only that quantity of manufactures is produced which can be advantageously disposed of, and only those commodities purchased and consumed which the wants of individuals require. And, curiously enough, this principle of self-interest, if allowed free scope, is uniformly and sufficiently competent to regulate both the production and consumption of commodities, to a degree more nice and satisfactory than could be attained by the best-devised statutes which the wisest legislators could enact. The grand principle, therefore, which can alone regulate commerce and manufactures, is found in the natural passion for gain; and the sole essential requisite for the successful advancement of mercantile and manufacturing industry and wealth among the people, is for the people to be let alone.

Evident as these principles must be to all who have any knowledge of social life, they have, either from ignorance or some other cause, been generally lost sight of by governments in all ages of the world, and plans have been contrived to regulate that which, if left alone, would have much better regulated itself. To such an extent have regulating and restrictive laws been carried in some countries, that they have nearly annihilated both manufactures and legitimate commerce, and reduced masses of the people to the condition of paupers, besides encouraging the pernicious and demoralizing pursuits of the smuggler. The restrictions and regulations which governments usually impose upon commerce, do not perhaps originate so much in the plea that manufacturers and merchants stand in the condition of children, and require to be taken care of lest they should hurt themselves, as from the unfortunate exigencies under which the governments happen to be placed. They have all less or more engaged in wars, which have been conducted at an enormous expense to their respective countries. In order to liquidate these expenses, all kinds of taxes are levied, directly and indirectly; but as the levying of these taxes breeds discontent, large bodies of military have usually to be kept up, to act as an armed national police. Thus, the people of these countries have for ages to go on paying not only the price of the wars, or the interest of the sums borrowed and laid out upon the wars, but as much more for the military force afterwards imposed upon them. What is more distressing, the people have probably to give a deal of money, in order that their respective governments may be the more able to secure the attachment of men of consequence to assist in allaying the general clamours for a redress of grievances. This is a very rough view of the matter, but it is enough to show the dreadful exigencies into which nations fall, by their engaging in wars or other expensive follies. In whatever manner, however, national exigencies originate, the plan pursued for relief consists chiefly in the imposition of duties on certain commodities much in demand, and at various stages of their manufacture, transmission, and sale. It is likewise customary to impose duties on goods imported from foreign countries, with the view of protecting the manufacturers of such articles in this country; but this only benefits a class, or a few persons, at the expense of the whole community, and, therefore, all such duties are in the main as detrimental to trade and the public welfare as those imposed for the liquidation of national debt and expenditure.* "There is (observes Mr. M'Culloch) no jugglery in commerce. Whether it be carried on between individuals of the same country, or of different countries, it is in all cases bottomed on a fair principle of reciprocity. Those who will not buy need not expect to sell, and conversely. It is impossible to export without making a corresponding importation. We get nothing from the foreigner gratuitously; and hence, when we prevent the importation of produce from abroad, we prevent, by the very same act, the exportation of an equal amount of British produce. All that the exclusion of foreign commodities ever effects, is the substitution of one sort of demand for another. It has been said, that 'when we drink beer and porter we consume the produce of English industry, whereas, when we drink port or claret we consume the produce of the industry of the Portuguese and French, to the obvious advantage of the latter, and the prejudice of our countrymen!' But how paradoxical soever the assertion may at first sight appear, there is not at bottom any real distinction between the two cases. What is it that induces foreigners to supply us with port and claret? The answer is obvious:—We either send directly to Portugal and France *an equivalent in British produce*, or we send such equivalent, in the first place, to South America for bullion, and then send that bullion to the Continent to pay for the wine. And hence it is as clear as the sun at noonday, that the Englishman who drinks only French wine, who eats only bread made of Polish wheat, and who wears only Saxon cloth, gives, by occasioning the exportation of a corresponding amount of British cotton, hardware, leather, or other produce, the same encouragement to the industry of his countrymen, that he would were he to consume nothing not immediately produced at home. A quantity of port-wine and a quantity of Birmingham goods are respectively of the same value

*See article POLITICAL ECONOMY.

so that, whether we directly consume the hardware, or having exchanged it for the wine, consume the latter, in so far as the employment of British labour is concerned, it is altogether indifferent."*

From these explanations, it will be observed that it is immaterial what is given in exchange for imported goods —whether money or native produce. At the same time, it must be understood that if money is given, there must exist some active industry in the country by which the money is realized. As a general question in commerce, it is of no consequence what is the nature of the industry by which the money is produced. It may consist in the raising of superabundant crops, or other raw produce for exportation, or of manufacturing raw and comparatively valueless materials into articles of value and demand, or of carrying goods from one country to another. Unless a country possess one or more of these branches of industry, it is without the means of paying for imported articles, and must retire from the field of general commerce. England is not of sufficiently large dimensions to export superabundant crops of grain, but it possesses in an extraordinary degree the means of manufacturing mineral and other substances into articles for exchange, and it derives no inconsiderable profit from the carrying of commodities. Its manufactured goods, therefore, pay for imports of foreign articles, including bullion or the raw material of money, and these again, in a manufactured state, are a fund for the payment of still further imports. Thus the wealth of our country has increased.

PRINCIPLES OF COMMERCE.

The practice of commerce is in a great measure dependent on mutual good faith, and the integrity of seller and buyer, and can in no case permanently flourish where these fundamental qualities are wanting. The first or great leading quality, therefore, in the character of a merchant, ought to be scrupulous honesty both in word and deed. The article which he proposes to dispose of must be exactly what he declares it to be, not inferior or in any respect unsound in its nature. If it possess any blemishes, these must be announced to the buyer before the bargain is concluded, and, if necessary, though at a considerable loss, an allowance made for them. The merchant is not less called on to be faithful in the fulfilment of all promises which he may make, whether with respect to goods or their payment; because those to whom the promises have been made may on that account have made similar promises to others, and, therefore, the breaking of a single promise may prove injurious in every link of a whole train of transactions. Perfect honesty or integrity is a fundamental principle of trade; and the next most important are, strict regularity in all proceedings, according to established usage, and also steady perseverance. The merchant must give regular attendance during the hours of business, be regular in executing all orders and answering all letters; regular in the keeping of his books, and in the reckoning of his stock and moneys; in short, he must be methodic and careful in all branches of his concerns, for without this species of attention, the best business is apt to become confused, and to be ultimately ruined. What is true of individuals is true when applied to a whole nation. No people have ever attained opulence and high mercantile consideration, who have not possessed a character for integrity and regularity in all their dealings.

Besides these indispensable qualities in the individual character of a merchant or tradesman, there is required a happy combination of enterprise and prudence with the utmost coolness—enterprise to embrace favourable opportunities of buying and selling, and prudence and coolness to restrain from engaging in over-hazardous and ruinous speculations. In all his transactions, the man of business is understood to proceed upon a cool inflexible principle of doing that which is most advantageous for himself, without fear or favour; because in commerce each party is supposed to be governed by motives of self-interest (always within the rules of honesty and propriety), and is under no obligation to deal from mere personal regard, or any kind of friendly consideration. In commerce there is, strictly speaking, no friendship. If there be friendship among the parties concerned, it is a thing aloof from business transactions—a matter of private arrangement—and is only to be regarded as such. On this account, even among the most intimate friends, there must be an exact mode of dealing, and the most accurate counting and reckoning.

The British, for several centuries, seem to have been endowed, above all other nations, with those qualities of mind which are suitable for the conducting of commerce on an enlarged and liberal scale. Their integrity, persevering industry, enterprise, prudence, and liberality of sentiment, have never been excelled. In patient industry they have been rivalled by the Dutch; but in point of enterprise and liberality, that people have fallen far short of them, and their trade has languished accordingly. The British are pre-eminently a commercial as well as a manufacturing people. Taking them generally, they possess a spirit of restless industry, which renders them actually unhappy, unless when busily engaged in some pursuit calculated to enrich them, or at least to produce for their families the means of a respectable subsistence. The Americans, who are but a branch of the same British stock, are equally, if not more, remarkable for this fervent spirit of industry; and, though only set up as a separate nation within a period of sixty years, and less distinguished for their integrity and prudence than the English, have already distanced many of those dignified European principalities and powers which first discovered and colonized their country. The French, the Germans, the Spaniards, the Portuguese, the Italians, and others, though each possessing a larger or smaller extent of manufactures and commerce, are obviously deficient, in a national sense, of the eager spirit of industry which is so characteristic of the people of Great Britain. Taken in the gross, they are too apt to addict themselves to amusement in preference to business. They delight in holidays, and will at any time leave their work to mingle in a dance or some kind of buffoonery, in which an Englishman would be ashamed to appear. Scarcely one of the continental nations, moreover, has yet settled down under a well-conducted government appointed by the people. There indeed seems to be little which is settled among them. Some of the principal are yet at that stage of social life which was common in England about the reign of Henry VII.; others are not farther advanced than a period considerably earlier; and all have yet a great deal to suffer and to learn before they attain that state of quietude and security to life and property, that condition of domestic comfort and national prosperity, which Great Britain, with all its faults, so amply enjoys.

COMMERCIAL TERMS AND TRANSACTIONS.

The following explanations of the principal terms used in commerce, will illustrate the mode of conducting business transactions.

Firm.—Every business, whether private or public, is conducted under a specified designation or title, called the name of the firm. This name may be that of a single individual to whom the business belongs, or of two or more individuals, or any title which it may be found advisable to adopt. Sometimes the name of a firm remains long after all who are indicated by it are dead

* Dictionary of Commerce.

in such a case, the business has passed into the hands of new proprietors, who, though legally responsible for its obligations, are not for some private reason inclined to change the old and well-known title of their firm. A particular firm or business-concern is sometimes personified in the term *house*—as, Such a house does a great deal of business, &c.

Company.—Two or more individuals engaged in one business constitute a company or copartnery, each individual being called a partner. Companies are of two kinds, private and public. A private company is organized by a private arrangement among the parties, each having certain duties to perform and a certain share in the concern. In companies of the private and common description, no individual can leave the concern at his own pleasure, for by doing so he might seriously injure or embarrass his partners. He can withdraw only after giving a reasonable warning, by which time is allowed to wind up the concern, or place it in a condition to pay him back the capital which he has risked, or the profits which are his due. No partner, however, can transfer his share to another person, by which a new member would be introduced into the firm without the consent of the partners.

The profits of partnerships are divided according to a specified agreement or deed of copartnery. Generally, in the case of partnerships of two or three persons, each receives the same share on the occasion of an annual division, but in other cases, a partner may not be entitled to more than a fourth or sixth part of what another receives. The amount of capital which a partner invests in the concern, the service he can be to the business, and other circumstances, regulate the amount of his share. When each of two persons sinks the same capital, but one takes the whole of the trouble, then he on whom the trouble falls, who is called the active partner, is entitled to receive a stated sum in the form of salary over and above his share of profits. Whatever be the share which individual partners have in a concern, the whole are equally liable for the debts incurred by the company, because the public give credit only on the faith that the company generally is responsible. He who draws the smallest fraction of profit, failing the others, may be compelled to pay the whole debts. On this account, every partner on leaving a company should be careful to advertise in the Gazette and newspapers that he no longer belongs to the firm of which he was a member; he is then responsible for no debts incurred subsequent to the announcement.

Public companies are very different; they consist of a large body of partners, or proprietors of shares, the aggregate amount of which forms a joint stock, and hence such associations are called *joint-stock companies*. They are public, from being constituted of all persons who choose to purchase shares, and these shares or rights of partnership are also publicly saleable at any time without the consent of the company. The value of a share in a joint-stock company is always the price which it will bring in the market; and this may be either greater or less, in any proportion, than the sum which its owner stands credited for in the stock of the company. Unless specially provided for in the fundamental deed of copartnery, every member of a joint-stock company is liable in his whole personal property or fortune for the debts of the concern. In some instances this liability is obviated by the provisions of an act of parliament, or parliamentary charter, establishing the company. Joint-stock companies are managed by directors appointed by the shareholders.

It is an axiom in commerce, that business is much better conducted by single individuals for their own behoof, than by companies of any kind; as respects joint-stock associations, they are only useful in very great concerns, requiring enormous capital, and involving serious risks of loss.

Capital.—What is now termed capital was in former times called *stock*. The capital of a merchant is strictly the amount of money which he embarks in his trade, or trades upon, that is, employs for buying goods, paying wages of servants, and liquidating all debts when due. When trading within the limits of his capital, business is done upon a secure footing; but if he proceeds beyond these, in any material degree, he is said to be *over-trading*, and is exposed to the chance of ruin or very serious embarrassment. Trading beyond the amount of available capital, is, nevertheless, a prevailing error, and causes innumerable bankruptcies. With a comparatively small capital, a tradesman may carry on a large business, by receiving payments shortly after making his outlays. By this means, there is a rapid turning over of money, and small profits upon the various transactions speedily mount up to a large revenue. For example, if a tradesman turn over his capital twelve times in the year, at each time receiving money for what he sells, he can afford to do business on a twelve times less profit than if he could turn over the same capital only once in a year. This leads us to a consideration of credit.

Credit.—Credit in business is of the nature of a loan, and is founded on a confidence in the integrity of the person credited, or the borrower. An individual wishes to buy an article from a tradesman, but he has not money to pay for it, and requires to have it on credit, giving either a special or implied promise to pay its value at a future time. This is getting credit; and it is clear that the seller is a lender to the buyer. In all such cases, the seller must be remunerated for making his loan. He cannot afford to sell on credit on the same favourable terms as for ready money; because, if he were to receive the money when he sold the article, he could lay it out to some advantage, or turn it over with other portions of its capital. By taking credit, the buyer deprives the seller of the opportunity of making this profit, and accordingly he must pay a higher price for the article, the price being increased in proportion to the length of credit. It very ordinarily happens that the seller himself has purchased the article on credit; but this only serves to increase its price to the consumer, and does not prevent the last seller from charging for the credit which he gives and the risk of ultimate payment which he runs. Credit for a short period is almost essential in all great transactions; but when going beyond fair and reasonable limits, it acts most perniciously on trade, by inducing heedless speculation, and causing an undue increase in the number of dealers with little or no capital. An excessive competition among these penniless adventurers is the consequence; each strives to undersell the other, with the hope of getting money to meet his obligations, and thus vast quantities of goods are sometimes thrown upon the market below the original cost, greatly to the injury of the manufacturer and the regular trader. What are called "gluts in the market" frequently ensue from causes of this nature.

Defoe, who wrote upwards of a century ago, makes the following observations on credit and over-trading, in his Complete English Tradesman:—"There are two things which may properly be called over-trading, and by both of which tradesmen are often overthrown:—1. Trading beyond their stock [or capital]; 2. Giving too large credit. A tradesman ought to consider and measure well the extent of his own strength: his stock of money and credit is properly his beginning; for credit is a stock as well as money. He that takes too much credit is really in as much danger as he that gives too much credit; and the danger lies particularly in this, if the tradesman over-buys himself, that is, buys faster than he can sell, buying upon credit the payments perhaps

become due too soon for him; the goods not being sold, he must answer the bills upon the strength of his proper stock—that is, pay for them out of his own cash; if that should not hold out, he is obliged to put off his bills after they are due, or suffer the impertinence of being dunned by the creditor, and perhaps by servants and apprentices, and that with the usual indecencies of such kind of people. This impairs his credit, and if he comes to deal with the same merchant or clothier, or other tradesman again, he is treated like one that is but an indifferent paymaster; and though they may give him credit as before, yet depending that if he bargains for six months, he will take eight or nine in the payment, they consider it in the price, and use him accordingly; and this impairs his gain, so that loss of credit is indeed loss of money, and this weakens him both ways.

"A tradesman, therefore, especially at his beginning, ought to be very wary of taking too much credit; he had much better slip the occasion of buying now and then a bargain to his advantage, for that is usually the temptation, than buying a greater quantity of goods than he can pay for, run into debt, and be insulted, and at last ruined. Merchants, and wholesale dealers, to put off their goods, are very apt to prompt young shopkeepers and young tradesmen to buy great quantities of goods, and take large credit at first; but it is a snare that many a young beginner has fallen into, and been ruined in the very bud; for if the young beginner does not find a vent for the quantity, he is undone; for at the time of payment the merchant expects his money, whether the goods are sold or not: and if he cannot pay he is gone at once. The tradesman that buys warily, always pays surely, and every young beginner ought to buy cautiously; if he has money to pay, he need never to fear goods to be had; the merchants' warehouses are always open, and he may supply himself upon all occasions, as he wants, and as his customers call." It certainly "is not possible in a country where there is such an infinite extent of trade as we see managed in this kingdom, that either on one hand or another it can be carried on without reciprocal credit both taken and given; but it is so nice an affair, that I am of opinion as many tradesmen break with giving too much credit as break with taking it. The danger, indeed, is mutual, and very great. Whatever, then, the young tradesman omits, let him guard against both giving and taking too much credit."

Orders.—An order is a request from one dealer to another to supply certain goods. An order, when in writing, should be plain, explicit, and contain no more words than are necessary to convey the sense in a simple, courteous manner. The same rule applies to all letters of business, which, by the practice of trade, are confined to their legitimate object. He that affects a rambling and bombastic style, and fills his letters with long harangues, compliments, and flourishes, should turn poet instead of tradesman, and set up for a wit, not a shopkeeper. A tradesman's letters should be plain, concise, and to the purpose; no quaint expressions, no bookphrases; and yet they must be full and sufficient to express what he means, so as not to be doubtful, much less unintelligible. We can by no means approve of studied abbreviations, or leaving out needful conjunctive terms and pronouns in trading letters; as, for example, "Have just received yours of the 11th," &c.; which ought to be expressed as follows—"I have just received your communication of the 11th instant," &c. The leaving out of pronouns and other words in a business letter, gives it a mean appearance.

Counting-house; in French *bureau*; in Dutch *kantoor*.—The counting-house is the office in which a merchant's literary correspondence, book-keeping, and other business is conducted. The English merchant's counting-house is a model of neatness and regularity. Its furniture consists chiefly of desks for the clerks, and the books of the establishment, which are secured at night in an iron or fire-proof safe. Almost every different business requires a different set of books, but the mode of keeping them is generally the same. The usual set of books comprises a day-book, in which sales or purchases on credit are individually entered as they occur; a leger, into which all these entries are engrossed in separate accounts; a journal or note-book, for entering miscellaneous transactions; a cash-book, in which every payment or receipt of money is regularly entered; a letter-book, into which all letters are copied before they are sent off; and a bill-book, for the entering of bills payable and receivable. In large concerns there are various other books, as foreign-leger, town-leger, country-leger, &c. The art of book-keeping is simple. It requires only a competent knowledge of arithmetic, and skill in penmanship, with a little training in the method of entering and posting accounts. The strictest care and accuracy are desirable. It is an understood rule, that no book should show a blot or erasure; a leaf, also, should never on any account be torn out, whatever blotch or error it contains. The reason for this scrupulous care is, that a merchant's books should be a clear and faithful mirror of his transactions, and an evidence of his integrity. In the case of misfortune in trade, or other circumstance, the books may be subjected to a rigid judicial examination, and the appearance of an erasure or torn-out leaf may lead to conjectures of an unpleasant nature and consequences. When an important error occurs in book-keeping, it is better to let it remain and write *error* below it, than to make a large erasure or to cut out the leaf.

From the books kept by a merchant, a condensed view of his affairs ought to be annually made up. This document contains an *inventory* or list of goods, money debts owing to the merchant, or other available property: also a contra list of all debts and other obligations due by the merchant. Both being balanced, the residue, whether for or against the merchant, is at once observable. Every man in trade, for at least his own satisfaction and government, should make up a *balance-sheet* of this nature annually.

Bill of Parcels.—An account or list of items of goods, given to their purchaser by the seller, or delivered along with the goods at the purchaser's house. Should a purchaser dispute the delivery of the goods, it is necessary to produce proof of the fact; when delivered to carriers, a receipt is usually given by subscribing a parcel book.

Invoice.—A bill or account of goods, which is forwarded separately, announcing the date of their despatch and the particular conveyance by which they are sent. If the seller fail to forward an invoice by post, and the goods be lost at sea while on their way, the purchaser is not answerable, for he is not supposed to know how or when the goods were sent, and therefore could not insure against their loss. The careful sending of invoices forms an important duty of a merchant's clerk.

Carriers.—Persons who undertake to convey goods from one place to another, whether by land or water, are carriers; and the carrying trade, as it is called, forms now a large and varied department of human industry. "Carriers are bound to receive and carry the goods of all persons, for a reasonable hire or reward; to take proper care of them in their passage; to deliver them safely, and in the same condition as they were received (excepting only such losses as may arise from *the act of God or the king's enemies*); or in default thereof, to make compensation to the owner for whatever loss or damage the goods may have received while in their custody, that might have been prevented. Hence a carrier is liable, though he be robbed of the goods, or they be taken from him by irresistible force. On the same prin

ciple, a carrier has been held accountable for goods accidentally consumed by fire while in his warehouse."* Violent storms, tempests, and lightning, are considered to be "the act of God," or such as no human precaution could have averted, and no fraudulent intention could have produced.

Bill of Lading.—A formal acknowledgment or receipt given by sailing masters for goods put on board their vessels, including a promise to deliver them safely as marked and addressed to their designed destination, always, however, excepting loss or injury by the act of God, the king's enemies, fire, or the dangers or accidents of the sea. This bill of lading is usually a printed form, filled up with writing, and concludes with the quaint and pious wish—"And so God send the good ship to her destined port in safety: Amen." A set of two bills of lading is furnished to the shipper of the goods, one of which he retains for his own satisfaction, and the other is forwarded by post, like an invoice, to the person to whom the goods are sent. When the ship arrives at its destined port, this document can be employed to cause the captain of the vessel to deliver the goods therein mentioned.

Debenture.—This is the name of a formal certificate employed to recover a certain amount of drawback of duties from the custom-house on goods exported. The exporter draws up and signs the certificate, the signature being attested by a magistrate; and being forwarded to the custom-house, it is compared with the return of the officer who has seen the goods packed and sealed. After a certain period has elapsed, the duties are paid to the exporter. The meaning of this transaction is, that on exporting goods, any king's duty that may have been imposed upon them is paid back to the exporter, so as to relieve the foreign or colonial receiver from the burden of using taxed commodities. It also acts as a bounty on exportation.

Customs—Excise.—The duties or taxes imposed upon goods entering or going out of the country are called *customs*, and those imposed upon goods at the period of their manufacture in the country, are called *excise duties*. Both form a prime element in the national revenue, and are levied by boards of customs and excise, each having an extensive ramification of subordinate functionaries, for the imposition and collection of the duties. A custom-house is established at every principal port. Nearly all customs and excise duties must be paid at the time the goods are passed through the hands of the officers of either department, and fall on the first instance on the merchant and manufacturer. They, however, enhance the price of the commodities, and are therefore ultimately paid by the consumer. For the accommodation of merchants, the custom-houses in the different chief ports possess large warehouses or depôts for goods, called *bonded warehouses*. Goods subject to duty may, on importation, be consigned to these depôts, where they are allowed to remain till the merchant finds it convenient to remove them and pay the accustomed duties. Until removed, therefore, the commodities in bond can hardly be said to be imported into the country, being in the condition of goods still lying in a foreign port.

Lloyd's.—Lloyd is not the designation of any individual or of any company: it is a name used in reference to a set of subscription rooms or coffee-house, in London. Formerly, the place of resort was in the Royal Exchange, but since the destruction of that building by fire, the place of meeting is in the neighbourhood of that locality. One of the rooms at Lloyd's is devoted to subscribers who follow the profession of marine insurers, technically called *underwriters*, from their writing under, or subscribing to, certain obligations in deeds presented for their acceptance. When a person wishes to insure a ship, or goods in a ship, against damage or loss at sea, he offers the risk to these underwriters, and they are at liberty to accept it for a specified premium. The policy or deed expressive of the insurance is usually signed by more than one underwriter, so as to divide the risk. Lloyd's is not only a centre point in the metropolis for all sea insurance business, but is the place to which every species of intelligence respecting shipping is forwarded from all parts of the world; and this information is exhibited publicly in one of the rooms, for the inspection of all. The intelligence is for the most part sent by appointed agents, one part of whose duty consists in investigating the cause of damage to vessels, and taking charge of wrecked property for behoof of the underwriters, whoever they may be. The lists made up and exhibited at Lloyd's furnish authentic information for the use of merchants and shippers of goods all over the united kingdom.

Vendue.—This is a colonial phrase, used instead of *public auction*. To sell goods at vendue is to dispose of them at auction. The place of sale is sometimes called "the Vendue."

Dutch Auction.—In common auction, the highest bidder by competition is the purchaser; but according to the process of sale called Dutch auction, there is a different mode of determining the successful bidder. According to this plan, the article is put up at a certain nominal price, which is gradually lowered, and the first who speaks and offers the sum mentioned by the auctioneer is at once knocked down as the purchaser. This is the fairest mode of auctioneering; it prevents competition, and the article brings its exact value—that which it is worth in the estimation of those present.

Official and declared Value.—All goods exported are entered in the custom-house books as of so much *official value*. The value is quite illusive as respects the real value of the articles. The official valuation is according to an estimate of the date 1694, without reference to the alteration of prices since that period. Knowing the fixed official price, we may be able to estimate the exact quantities, but this is a matter which few private individuals understand. The *declared value* is the price announced by the exporters of the goods, and amounts to nothing more than a rough estimate; it being necessary only to declare the value at something near the reality, for purposes of taxation, or making up reports of the export trade.

Insolvency, Bankruptcy.—When a person is not in circumstances to pay his debts in full, he is *insolvent*, which is nearly equivalent to being bankrupt; the term bankrupt, however, is more commonly applied to one who is legally announced or gazetted as being insolvent. The term bankrupt is derived from *bancus* a bench, and *ruptus* broken, in allusion to the benches formerly used by the money-dealers in Italy, which were broken in case of their failure to pay their debts. The law prescribes a certain form of procedure in the case of commercial insolvency, which has the effect of deliberately investigating the cause of the misfortune, and relieving the bankrupt from all obligations, on yielding up his entire property. Only persons in trade are entitled to the benefit of this bankrupt law, all others being excluded; so that, in the event of their insolvency, they must submit to the common laws respecting debtors, which are in some respects very rigorous. A bankrupt who has received a discharge or certificate from a competent authority, being released from all pecuniary claims, may again enter business for his own behoof without any fear of molestation; but a debtor who has merely taken the benefit of the Insolvent Act in England, or process of *Cessio Bonorum* in Scotland, though immediately relieved from prison and left at liberty to pursue any line of industry, the property he may accumulate is at all times liable to seizure by his former creditors.

* M'Culloch.

A commission of bankruptcy in Scotland is entitled a *sequestration*, meaning that the property of the bankrupt is officially sequestrated, or taken possession of, for behoof of creditors.

BRITISH COMMERCE.

British commerce is in two distinct branches—*inland*, or that which takes place within the country, and *export* and *import*, or that which pertains to foreign transactions. The inland trade conducted for home consumption is at least ten times the amount of the foreign trade. It is calculated that commodities are produced within the country annually to the value of *five hundred millions of pounds*, fully nine-tenths of which are sold from hand to hand, or accumulate as capital, while the remainder, or nearly one-tenth, is exported. All this is exclusive of the sale of imported foreign productions.

Comparatively small as is the foreign trade of the united kingdom, it employs a larger commercial marine than that of any other nation. In 1836, the united kingdom and its possessions in Europe owned 20,388 ships, with a burden of 2,[illegible]749 tons; the colonies at the same time owned 5[illegible]2 ships, with 442,897 tons; total 25,820 ships, with 2,[illegible]92,646 tons. All this is exclusive of ships of foreign proprietorship carrying on trade with the united kingdom.

Within a recent period, the manufactures and commerce of Scotland have wonderfully increased. The iron manufactures of Carron, and the cotton and silk manufactures of Glasgow and Paisley, are known all over the world. The sailcloth and coarse linen manufactures of Dundee, now one of the most flourishing ports in the empire, have greatly tended to the advancement of the Scottish export trade. The annual value of the Scottish manufactures was recently calculated to exceed £14,000,000. The tonnage of vessels on the Clyde is nearly as great as that of all Ireland, the tonnage of which, in 1828, only amounted to 97,379 tons—not one-third of the total tonnage of Scotland; the tonnage of Aberdeen is as great as that of Dublin and Belfast, the two principal Irish ports, put together. The Irish trade, however, is increasing, chiefly by means of steam navigation.

The most important commercial cities of England, besides London, are Liverpool, Bristol, and Hull; the most important manufacturing towns are Manchester, Birmingham, Leeds, Nottingham, Halifax, Rochdale, &c. In Scotland, the principal commercial places are Glasgow, Greenock, Leith, Dundee, and Aberdeen. The foreign trade of Glasgow and Greenock extends to the West Indies, the United States, the British American colonies, Brazil, and the whole continent of Europe. The foreign trade of Leith, Dundee, and Aberdeen, extends to the West Indies, America, the Mediterranean, and the Baltic. The greatest commercial cities of Ireland are Dublin, Cork, Wexford, Waterford, and Belfast. Nearly two-thirds of the traffic of Great Britain is carried on in London, and about one-sixth of the whole shipping of the empire belongs to that port. London is likewise the centre point for the negotiation of all the [illegible] commercial and pecuniary transactions in the united kingdom.

Both the export and import trade of the united kingdom have been steadily increasing for a number of years, in proportion as restrictions have become less harassing, as duties have been remitted, and as population has advanced. Not counting odd thousands, the following presents a view of this increase:—In 1800, the official value of the exports from Great Britain, of British manufactures and Irish produce, was twenty-two millions; in 1810, thirty millions; in 1821, thirty-seven millions; in 1828, fifty-one millions; and in 1830, fifty-five millions. This is not estimating the export of foreign and colonial produce, or exports from Ireland. The value of imports into Great Britain rose in a similar manner, from twenty-four millions in 1800, to forty-two millions in 1830.

Since this period, the foreign trade of the country has undergone some changes. A return to parliament published in March, 1840, shows the state of our foreign and domestic interests in the years 1838 and 1839. In the former year, the declared value of British and Irish produce and manufactures exported amounted to £43,344,631, and in 1839 to £45,281,254. There has been an increase in the exportation of cotton, linen, woollen, and silk goods, and woollen yarn; also in hardwares and cutlery, iron and steel, and other metals, and earthenware; and a falling off in coal, salt, cotton yarn, linen yarn, wool, and refined sugars. The following is an abstract of the annual accounts, showing the official value of goods exported in 1838 and 1839.

	1838.	1839.
Coals and culm,	£485,950	£543,156
Cotton manufactures,	16,715,857	17,694,303
Cotton yarn,	7,431,869	6,857,826
Earthenware,	651,344	768,496
Glass,	377,283	371,270
Hardwares, and cutlery,	1,498,327	1,819,000
Linen manufactures,	2,730,270	3,422,488
Linen yarn,	836,163	814,607
Metals, viz. iron and steel,	2,635,692	2,702,738
copper and brass,	1,221,732	1,293,977
lead,	154,126	595,640
tin, in bars, &c.,	101,846	112,620
tin plates,	436,577	345,442
Salt,	223,456	219,069
Silk manufactures,	777,280	865,768
Sugar refined,	553,247	213,738
Wool, sheep or lamb',	434,006	361,829
Woollen yarn,	384,535	401,188
Woollen manufactures,	5,795,069	6,278,[illegible]30
Total,	£43,344,631	£45,281,254

The gross amount of customs' duties inwards in 1838 was £22,966,214, and in 1839, £23,278,089. The gross amount of excise duties for the year ending October 1838 was £11,827,788, and for the year ending October 1839, it was £12,152,171; thus the custom and excise duties produce annually upwards of *thirty-four millions of pounds* to the national revenue.

MONEY.

Origin and Nature of Money.—In a rude state of society, exchanges are made by bartering one article for another, according to some kind of understood value. "But when the division of labour first began to take place (says Smith), this power of exchanging must frequently have been very much clogged and embarrassed in its operations. One man, we shall suppose, has more of a certain commodity than he himself has occasion for, while another has less. The former, consequently, would be glad to dispose of, and the latter to purchase, a part of this superfluity. But, if this latter should chance to have nothing that the former stands in need of, no exchange can be made between them. The butcher has more meat in his shop than he himself can consume, and the brewer and the baker would each of them be willing to purchase a part of it; but they have nothing to offer in exchange, except the different productions of their respective trades, and the butcher is already provided with all the bread and beer which he has immediate occasion for. No exchange can, in this case, be made between them. He cannot be their merchant, nor they his customers; and they are all of them thus mutually less serviceable to one another. In order to avoid the inconveniency of such situations, every prudent man, in

every period of society, after the first establishment of the division of labour, must naturally have endeavoured to manage his affairs in such a manner as to have at all times by him, besides the peculiar produce of his own industry, a certain quantity of some one commodity or other, such as he imagined few people would be likely to refuse in exchange for the produce of their industry.

"Many different commodities, it is probable, were successively both thought of and employed for this purpose. In the rude ages of society, cattle are said to have been the common instrument of commerce; and though they must have been a most inconvenient one, yet in old times we find things were frequently valued according to the number of cattle which had been given in exchange for them. The armour of Diomede, says Homer, cost only nine oxen; but that of Glaucus cost a hundred oxen. Salt is said to be the common instrument of commerce and exchanges in Abyssinia; a species of shells in some parts of the coast of India; dried cod at Newfoundland; tobacco in Virginia; sugar in some of our West India colonies; hides or dressed leather in some other countries; and there is at this day a village in Scotland where it is not uncommon, I am told, for a workman to carry nails, instead of money, to the baker's shop or the alehouse.

"In all countries, however, men seem at last to have been determined by irresistible reasons to give the preference, for this employment, to metals above every other commodity. Metals cannot only be kept with as little loss as any other commodity, scarce any thing being less perishable than they are, but they can likewise, without any loss, be divided into any number of parts, as by fusion those parts can easily be re-united again; a quality which no other equally durable commodities possess, and which, more than any other quality, renders them fit to be the instruments of commerce and circulation. The man who wanted to buy salt, for example, and had nothing but cattle to give in exchange for it, must have been obliged to buy salt to the value of a whole ox or a whole sheep at a time. He could seldom buy less than this, because what he was to give for it could seldom be divided without loss; and if he had a mind to buy more, he must, for the same reasons, have been obliged to buy double or triple the quantity, the value, to wit, of two or three oxen, or of two or three sheep. If, on the contrary, instead of sheep or oxen, he had metals to give in exchange for it, he could easily proportion the quantity of the metal to the precise quantity of the commodity which he had immediate occasion for.

"Different metals have been made use of by different nations for this purpose. Iron was the common instrument of commerce among the ancient Spartans; copper among the ancient Romans; and gold and silver among all rich and commercial nations.

"Those metals seem originally to have been made use of for this purpose in rude bars, without any stamp or coinage. Thus we are told by Pliny, upon the authority of Timæus, an ancient historian, that, till the time of Servius Tullius, the Romans had no coined money, but made use of unstamped bars of copper to purchase whatever they had occasion for. These rude bars, therefore, performed at this time the function of money.

"The use of metals in this rude state was attended with two very considerable inconveniences; first, with the trouble of weighing, and secondly, with that of assaying them. In the precious metals, where a small difference in the quantity makes a great difference in the value, even the business of weighing, with proper exactness, requires at least very accurate weights and scales. The weighing of gold, in particular, is an operation of some nicety. In the coarser metals, indeed, where a small error would be of little consequence, less accuracy would, no doubt, be necessary. Yet we should find it excessively troublesome, if, every time a poor man had occasion either to buy or sell a farthing's worth of goods, he was obliged to weigh the farthing. The operation of assaying is still more difficult, still more tedious, and, unless a part of the metal is fairly melted in the crucible, with proper dissolvents, any conclusion that can be drawn from it is extremely uncertain. Before the institution of coined money, however, unless they went through this tedious and difficult operation, people must always have been liable to the grossest frauds and impositions; and, instead of a pound weight of pure silver, or pure copper, might receive in exchange for their goods an adulterated composition of the coarsest and cheapest materials, which had, however, in their outward appearance, been made to resemble those metals. To prevent such abuses, to facilitate exchanges, and thereby to encourage all sorts of industry and commerce, it has been found necessary, in all countries that have made any considerable advances toward improvement, to affix a public stamp upon certain quantities of such particular metals as were in those countries commonly made use of to purchase goods. Hence the origin of *coined money*, and of those public offices called mints; institutions exactly of the same nature with those of the aulnagers and stampmasters of woollen and linen cloth. All of them are equally meant to ascertain, by means of a public stamp, the quantity and uniform goodness of those different commodities when brought to market."*

It will be understood from these explanations that money is only an article which can be conveniently used in exchanging. In itself, or as relates to its own intrinsic qualities, it is a thing but of small value. Gold and silver, or the precious metals, of which money is usually made, are chiefly brought from the mines of South America, and are commercially valued according to the cost of their production and their supply and demand, as is the case with every other object in trade. If an overabundance of any of these metals be easily obtained, and the demand be not increased, the value is immediately lowered; and if the supply is obtained with difficulty, while the demand remains steady or is increased, the value is heightened. It cannot be too strongly impressed on the mind of the reader, that money is but a metallic representative of something which has been given for it. To a misunderstanding regarding this apparently very simple circumstance, much human misery may be attributed. It has too often been the feeling of communities, that if they possessed gold they possessed riches, and not a mere article for facilitating commerce—an article which, from its uses in this respect, is itself a commodity. The most startling illustration of this fallacy is to be found in the history of Spain. Before the working of the gold mines in their American possessions, the Spaniards were a rich and prosperous commercial people; but when they began to find gold, they thought they had got at their hand that for which they formerly laboured, and that, like a poor industrious man who has unexpectedly succeeded to an estate, they need now work no longer. To prevent their riches from disappearing, the law prohibited the exportation of the precious metals, and thus effectually shut the door against the only way in which they could be made sources of wealth—exportation as an article of commerce. In that view, and in that alone, was there any advantage in the possession of gold; and even had it been employed in the most advantageous manner, it would not have been so profitable as many other means of employing capital and labour; for as already remarked, the peculiarity which makes gold so useful as a measure of value, is, that the labour expended in producing it bears so constant a ratio to the quantity realized, that but small profits are made from its production.

The manner in which the Spaniards became acquainted

* Smith's Wealth of Nations, book i. chap. 4.

with the treasures of South America tended to nourish the hallucination. They found a considerable quantity of gold in the possession of the natives, which they speedily seized. They found also native gold in the streams. Thus, by an accidental circumstance, such as that of finding a hidden treasure, they became possessed of money without working for it. They did not reflect that, if this lasted, gold would cease to be the representative of value which it was, and would be of no further service in commerce than as an extremely beautiful material for manufactures, which would fluctuate in value with the tide of fashion. When they could procure the mineral only by the result of hard labour, they still had the same preposterous feeling that they were possessed, not of the means of making wealth, but of wealth itself, and dearly did they pay the penalty. While starvation desolated the land, and the highest grandees could not command so much of the produce of ordinary commercial industry as a glass window, every wretched dwelling glittered with mountains of plate.

Gold, it is necessary to repeat, is simply a commodity—a commodity which we import: and if we can export it profitably, why not do so? If the country in question will take nothing from us but gold, then it is either worth our while to buy gold for the purpose of sending to it, or it is not. If it is not worth while, then the trade will not be carried on at all. If it is worth while, then the trade is on the whole a profitable one. If we import sugar from the Spanish settlement of Manilla, and export it to Germany, this is called "the carrying trade," and quite correctly; but it seems to be thought that if we import gold from South America, we must keep our hands upon it, otherwise we shall be ruined. It is commonly said that we can only establish a profitable trade when we pay in our own manufactures. Now, paying in gold is, after all, indirectly paying with our own manufactures, for (except the comparatively trifling quantity that may have been taken in war) there is not an ounce of bullion in the country that has not been obtained in exchange for some article produced either by our manufacturing or agricultural industry. Let him who doubts this position try if he can discover any other method by which gold can have found its way to this country.

Coined Money.—Gold and silver, as we have said, are chiefly brought from the mines of South America. They are generally imported in the form of bars, and in this rude state are commercially named *bullion*. The price of bullion in the market is liable to fluctuations, according to the cost of production, the supply, and the demand. However, this variation is never very great, and has little sensible effect on the coinage. It is customary to estimate the purity of gold by an imaginary standard of 24 carats.* If in a piece of gold weighing 24 carats there be 1-24th of alloy, then the piece is one below the standard. What is called jewellers' gold is seldom purer than 20 fine to 4 of alloy—the alloy being usually silver, but sometimes copper, which gives a deeper red tinge to the metal. Perfectly pure gold is never seen either in trinkets or coins, for it is too ductile, and for that and other reasons requires a certain quantity of alloy. Sovereigns, and other modern English gold coins, contain one-twelfth of alloy, but this twelfth is not reckoned as gold, in point of value. At present the gold coin of Great Britain is issued at very nearly its precise market value as bullion. A pound weight of gold, of 22 carats' fineness, produces coins to the amount of £46, 14s. 6d., which is about the price at which bullion sells for in the market. Thus the gold of our currency is coined free of expense. In coining silver, government is allowed, by the act of 56 Geo. III., a profit or seignorage of about six per cent.; the pound weight of silver, which should produce 62 shillings, being coined into 66 shillings. Our silver coins being therefore of a little less real value than the sums they represent, they are not liable to be melted down by silversmiths for the manufacture of articles in their trade.

Till the year 1816, on the occasion of a new coinage, the silver shilling was the standard of money, though, for convenience, the pound of twenty shillings was the principal sum named in commercial transactions. The act 56 Geo. III. rendered gold the principal standard, and made silver subsidiary to it; since which period, no more than forty shillings are a legal tender, that is to say, no one is bound to accept of more than forty shillings in silver in payment of any debt or demand. The legal tender, above forty shillings, is in sovereigns; but in point of fact an order on the Bank of England is considered equivalent.

The copper coinage, consisting of pennies, half-pence, and farthings, is issued from the mint at the rate of £224 per ton, being more than 100 per cent. above its market value; in other words, a penny piece is intrinsically worth no more than a halfpenny. Formerly, the pieces usually known as old pennies were larger; but, in consequence of a rise in the value of copper in 1806, it has since been thought advisable to adopt the rate above mentioned. Between 1815 and 1836, there was an issue of copper money to the value of £186,107, 4s.

The coined money of Great Britain is the most elegantly executed, and among the purest in the world. The greater part of the continental coinage is poorly executed and basely alloyed. In Holland, and most of the German states, the coins legally current as silver money are apparently one-third brass, and resemble the counterfeit shillings and sixpences of a former period in England. In France and Belgium, the new gold and silver coins are handsome, and so likewise are the large gold and silver pieces of Prussia. The coins and medals executed by direction of Napoleon in France are in a high style of art.

Money of the current and standard coinage is frequently signified by the term *sterling*, as "one pound sterling," &c. With respect to the origin of the word sterling, there are three opinions. The first is, that it is derived from Sterling Castle, and that Edward I. having penetrated so far into Scotland, caused a coin to be struck there, which he called Sterling. The second opinion derives it from the figure of a bird called starling, which appears about the cross in the ancient arms of England. The third most probably assigns its true origin, by deducing it from Esterling; for in the time of Henry III. it is called *Moneta Esterlingorum*, the money of the Esterlings or people of the East, who came hither to refine the silver of which it was made, and hence it was valued more than any other coin, on account of the purity of its substance. The denomination of the weights and their parts is of the Saxon or Esterling tongue, as pound, shilling, penny, and farthing, which are so called in their language to the present day. The term sterling is now disused in England in all ordinary transactions, but is still used in Scotland to distinguish sums from the ancient money of the country, as referred to in old deeds and notices of pecuniary transactions. The old Scots money, previous to the Union of 1707, was in pounds, shillings, and pence, but these were only a twelfth of the value of sterling money of the same denomination; thus, a pound Scots was only twenty pence sterling. The word sterling is also in use in the colonies, to distinguish the legal standard of Great Britain from the currency money in these places.

The following is a short explanation of the origin of the principal terms used in reference to coined money. The word *money* is from the temple of Juno *Moneta*, in which money was first coined by the ancients. *Pecuniary* is from *pecus*, cattle—flocks and herds of an-

* The carat is a small weight of universal use, containing four grains. It originated from the carat-bean, a small bean used by the Abyssinians for weighing gold. Diamonds are also weighed by it.

main being originally equivalent to money, or things constituting wealth. *Cash*, in commerce, signifies ready money, or actual coin paid on the instant, and is from the French word *caisse*, a coffer or chest in which money is kept. *Pound* never was a coin; the term was originally employed to signify a pound weight of silver, but afterwards it was applied to mean twenty shillings in tale, or by counting. *Guinea* took its name from the coast of Guinea in Africa, whence the gold for it was originally brought; at first, the piece was current at twenty shillings, afterwards it was equal to 21s. 6d., and finally settled at 21s. In the present day the guinea is not coined, and the term only remains to indicate 21s. Honorary fees and gifts are still usually reckoned in guineas, though paid in other money. *Shilling* and *penny* are both from Saxon words; the penny was first coined in silver. *Groat* was a name given to silver pieces equal to four pennies in value, coined by Edward III.; the word groats is a corruption of *grosses* or great pieces, and was given to distinguish this larger coinage from pennies or small coins. *Farthing* is a corruption of *fourthing*, or the fourth part of a penny.

A currency of coined gold is the most secure and permanent, and the pieces are received for their proper value in all countries. But notwithstanding these advantages, a metallic currency alone is quite unsuitable in highly commercial communities. There is no adequate importation of the precious metals, at the ordinary value, to supply material for a purely metallic currency; and if it were possible to provide a sufficient supply, the inconvenience and risk of loss to individuals from using coins only in all mercantile transactions, would be too great to be patiently borne. A heavy loss would also be incurred annually by government from tear and wear, which it would be impolitic to avert by imposing a proportionate seignorage. In these and other points of view, a currency of metal only would be exceedingly unsuitable to the existing condition of society and commerce in Britain. Something else requires to be employed as a medium of exchange and representative of the enormous sums which are daily transferred from one to another all over the country.

Paper Money.—The deficiencies of a metallic currency are compensated by the use of paper money. Paper money is in the form of small pieces of paper, each purporting to be an obligation or promise to pay a certain sum which is specified upon it. Whether passing by the name of a bank-note, a promissory-note, or bill of exchange, the principle on which it is issued is the same—an express obligation on the issuer to pay the specified sum in coined money on demand, or at a certain date which is mentioned. The notes of this kind issued by a bank pass from hand to hand, any holder having it in his power at any time to demand fulfilment of the obligation from the bank; but in the case of a bill of exchange, which is a promise by a private party, it is presentable for payment only at a specified period.

Bank-notes and bills together constitute the paper currency of the country, and are of prodigious use in carrying on commercial transactions. It is calculated that while the metallic currency seldom exceeds three millions, the paper currency, or amount of negotiable paper in circulation, is perhaps two hundred millions: of bank-notes alone, the circulation in the united kingdom may be reckoned to be sixty millions.

Bills of Exchange were first used for the purpose of settling pecuniary transactions between individuals at a distance from each other, and were therefore convenient expedients to avoid the risk of sending actual money to a creditor. This may be explained as follows:—If A, a merchant in London, have a debtor B and a creditor C, both in Paris, instead of sending money to C, and getting money sent to him by B, he may give C an order on B to pay the debt over at once to him. This is a bill of exchange in its simplest form. Suppose, however, that A has a creditor in Paris, but no debtor, while his neighbour E has a debtor, but no creditor: A may pay the money to E which the French debtor owes him, and obtain from him an order on his debtor to pay A's French creditor. This order he will be said to purchase. It will be an accommodation to him or to the other party, according to circumstances. In the complicated arrangements of modern commerce, the individual debtors and creditors are lost sight of. If a person has a sum to transmit to another country by such an order, the rate at which he will obtain it will depend on the pecuniary relations of the two places taken in the main. If there is more money payable at the moment by people in London to people in Paris, than there is payable by those in Paris to those in London, there will be a demand for orders on Paris, and a premium will be payable for the accommodation by those who want them. In this case, the *exchange* will be said to be against London. In Paris, on the other hand, there will be more people ready to give such drafts than there are in want of them, and those who dispose of them must do so at a discount. The rate of exchange is from this circumstance said to be in favour of Paris. The premium in the one case, and the discount in the other, will be measured by the balance due by London to Paris over what is due by Paris to London; and the principal sum to be met by the rate of exchange will be the expense of transmitting that balance in specie, unless the accounts can be adjusted by bringing transactions with some other community into the circle.

We may very this explanation of the principle of exchange as follows:—Great Britain, like every other country, is exposed to a drainage of its metallic currency, by the balance of trade falling against it. As long as our exports are equal to our imports they will balance each other; the bills drawn in England against foreign countries will be balanced by bills drawn in foreign countries against England. In this state of things, the exchange is said to be at *par*, or even. If our exports exceed our imports, then foreigners must send actual money for the overplus, because they have not occasion to remit bills for the amount. If our imports exceed our exports, we must, in the same manner, remit the overplus in actual money. Thus, a dearth and scarcity of corn in England will cause a drainage of the precious metals, because our imports of that article rise to a large amount, or much beyond the value of goods exported. The exchange is then said to be against England.

The multifarious transactions taking place between merchants in Britain and America, cause an incessant process of payment by the intervention of bills of exchange, many thousands of pounds being paid away daily in their accounts with each other without the aid of any metallic money, except a few coins for small odd sums.

Here is a common form of drawing a bill of exchange:—

£100. London, 5th August, 1840.

Three months after date, pay to me or my order the sum of one hundred pounds, value received.

To Mr. Thomas Styles, Merchant, John Nokes.
Cripplegate, London.

The bill being drawn in this form, Mr. Styles *accepts* it, by writing his name either below that of Mr. Nokes, or across the face of the writing. Mr. Nokes, who is called the *drawer*, now endorses the bill, by writing his name on the back of it, and thus the bill becomes *negotiable paper*. It may be paid away to a third party; and he endorsing it below Nokes' name, may pay it away to a fourth; and he endorsing it in the same manner may pay it away to a fifth; and so on. Thus the bill may pass from hand to hand, on each occasion liquidating a

debt of £100, till the day of payment by the original acceptor arrives, when it is duly presented by the last holder. Instead of running this course, the bill may at any period be *discounted* by a bill-broker or banker. The discounting of a bill consists in giving the money for it, less a certain sum for *interest*. Interest is a charge for the loan of money, and is ordinarily reckoned by *per cent.* Thus five per cent. (or centum) per annum, signifies a charge of £5 for every £100 for one year, which is equal to a shilling for each pound. Five per cent. is the highest legal interest chargeable in the united kingdom on all money lent in ordinary circumstances; but for discounting bills or promissory notes, a larger per centage may now be legally taken. When a bill for £100 for three months (or fourth part of a year) is discounted at five per cent. interest, a charge equal to the fourth part of £5 is made by the discounter, and this is his profit for the loan of the money for that period. Interest for a single day on any sum may be easily calculated by a rule in arithmetic; but merchants and bankers, for the sake of expedition and correctness, generally consult a set of printed interest tables.

According to a practice of old standing, bills are not presentable for payment till the third day after that which is specified for them to fall due. The three days allowed are called the *days of grace*. Thus, a bill drawn on the 5th of August, at three months, is not legally due till noon of the 8th of November. In some countries the period of grace is much longer than three days.

Bills of exchange are occasionally drawn in the form of promissory-notes; as, for example:—

£100. London, 5th August 1840.

Three months after date, I promise to pay to Mr. John Nokes, or order, the sum of one hundred pounds, value received. THOMAS STYLES.

When in this form, no signature is written across the front of the document—it is only endorsed by the creditor. Promissory-notes are in every respect liable to the same regulations as bills. Both promissory-notes and bills must be written on stamps of the proper price; if on stamps of an inferior value they are not negotiable, and cannot be protested. The protesting of a bill is simply the marking of a notary-public that it has not been duly paid on presentation; which marking, or *noting*, forms the warrant for the issuing of legal diligence by the competent authorities. If not protested on the day it has fallen due, this step cannot be taken afterwards, and the bill remains a mere evidence of the debt, to be produced in the course of a regular and perhaps tedious prosecution. Men in business are careful to present their bills for payment on the exact day they become due. When the acceptor of a bill fails to pay the amount, the holder can fall back for payment on any of the endorsers or the drawer.

Bills are sometimes drawn at *sight*, or so many days after sight; for example:—

£50. London, 5th August, 1840.

Ten days after sight, pay me or my order the sum of fifty pounds, value received.

To Mr. ISAAC WALTERS, Cheapside. JOHN JENKINS.

A bill of this kind is usually drawn by a person at a distance from his debtor, and on writing it out and endorsing it, he transmits it to an agent (or probably a creditor of his own) in the town in which the debtor resides. The agent having received it, hastens with it to the debtor to be *sighted*, which consists in the debtor, as for instance the above Mr. Walters, accepting it by signing his name and marking the day on which he has done so. The bill is now a negotiable instrument, and on the third day after the day specified, it is presentable for payment. This may be called a convenient way of getting ready money or prompt payment of any sum from a debtor. It is very common to draw foreign bills of exchange at so many days after sight. These bills are of precisely the same nature as inland or home bills of exchange; but, for the sake of security in transmission, they are drawn in sets of three. The following is a common form:—

£100. Montreal, 18th June, 1840.

Sixty days after sight, pay this my first bill of exchange (second and third of the same tenor being unpaid), for the sum of one hundred pounds sterling, value received. SAMUEL ROBERTSON.

To Messrs. BROWN and JONES, Merchants, Bristol.

This bill, being endorsed by Mr. Robertson, is transmitted to England (probably in liquidation of a debt of the same amount), and is presented to Messrs. Brown and Jones to be sighted, and is afterwards presented to them for payment accordingly. The agent or individual to whom it is sent, receives by the next packet the second bill of the same tenor. Should the first have been lost by shipwreck, this second is available, but otherwise it is of no use, and may be destroyed. The third bill of the same tenor is retained by the drawer till he learn whether the first or second have been received; if both have been lost, it is transmitted. Bills of this description are rarely sent by one actual drawer. They are usually paid away or sold on the spot to another party, who transmits them to a correspondent of his own, and he negotiates the payment.

Bills of exchange serve three useful purposes in commerce. 1. A bill puts a debt in a tangible form: for example, instead of leaving a debt of £100 to be paid at an indefinite period, so as to protract its settlement, let it be put in the shape of a promise to pay, and the creditor becomes satisfied that he now possesses the power to compel payment at a certain and not very distant period. 2. A bill is a negotiable instrument. If the parties be trustworthy, it may be discounted for cash; and thus, while the creditor will receive his money, less a trifle for discount, the debtor is left unmolested till the final day of payment. 3. A bill is a convenient representative of money, which may be sent from place to place in a letter, and if accidentally lost, its payment may be stopped and a new bill forwarded to its destination.

BANKS.

Origin of Banks.—The term *bank*, in reference to commerce, signifies a place of deposit of money, and is derived from the Italian word *banco*, a seat or bench, the first custodiers and dealers in money in Italy having been Jews, who sat on benches in the market-places of the principal towns. It is worthy of remark, that in the infancy of almost all modern civilized nations, the earliest money-dealers were Jews, and in the present day persons of that nation are the chief commercial negotiators in barbarous countries. Their acute intelligence, patient industry, and disregard of local attachments, have in all ages fitted the Jewish people for this course of life.

About the reign of Charles I., Jews and goldsmiths, to whom valuable property had been assigned for safe custody, began to exercise the profession of bankers in England; but till a much later period there were several eminent bankers in London who still kept goldsmiths' shops.

On the continent of Europe regular banking commenced much earlier than in this country. The Bank of Venice was established as early as 1171, the Bank of Amsterdam was began in 1609, and that of Hamburgh in 1619. Regular banking establishments were formed in England and Scotland shortly after the Revolution. The Bank of England began in 1694, and the Bank of

Scotland in 1695, since which period banks have been instituted in all the principal towns in the united kingdom.

Business of Banking.—A bank is a commercial institution, established and conducted by private individuals for their own behoof, or by joint companies. Like a merchant's counting-house, it consists of various officials—a manager, cashier, clerks, &c., including tellers, or persons for receiving and paying out the money. Banks are usually reckoned to be of two kinds—banks of *deposit* and banks of *issue*. By deposit it is meant that the bank takes charge of deposits of cash, which it is ready to restore on demand. Some banks of this nature allow interest on the sums received, and others do not do so; all, however, of necessity, make use of the money so deposited, by lending it out at a certain rate of interest, and thus compensate themselves for their trouble. The loans are most commonly in the form of discounts of bills, and occasionally advances on heritable property, or other securities. Banks of issue transact all the ordinary business of banks of deposit, and in addition issue notes of their own instead of actual cash or the notes of others. Almost all banks in this country are banks both of deposit and issue; they at least issue notes as far as the law allows them, which is to the extent of notes of £5 in value and upwards. The only banks permitted to issue below £5 are those in Scotland, for which a peculiar law exists.

Although banks are thus at liberty to issue notes to any extent, it is not to be supposed that they do so without a certain degree of restraint. The expense of manufacturing notes, notwithstanding that each requires a stamp, is a comparatively small check; the main restraint on over-issuing consists in the obligation to pay the sum which the note expresses, on demand. When, therefore, a banker discounts a bill for £100, and gives out one hundred notes of one pound each, he encounters the risk of having these notes returned upon him, and a demand made for them in cash within the compass of a day or two thereafter. This risk is increased by the practice among bankers of never issuing the notes of others. They are anxious enough to push forth on a safe principle their own paper, but when they receive deposits or payments in the paper of another bank, they use all convenient speed in demanding cash from that bank in exchange for its notes. The notes of any given bank being received purely on a principle of good faith or credit, it is of great importance that the bank should do nothing to incur the suspicion of being incapable of retiring its notes. When any suspicion of this nature arises, the public, who are ignorant probably of the true circumstances, rush to the bank for gold in exchange for its notes. This kind of panic is called a *run*. Bankers are always naturally anxious to issue their notes to as great an extent as is consistent with safety to the institution. The measure of this safety is the extent of capital at command to liquidate demands for cash. To accommodate the amount of this capital to the probable necessities of the case, is the point in banking for which the greatest skill is required, because if much capital is kept lying useless in the coffers of the bank, there is a loss of interest which may be ruinous, whereas, if too little is retained, a sudden run might utterly destroy the credit of the concern. When banking is managed with prudence, there is a certain amount of money kept at interest in the funds or government securities, upon which, if need be, an order is given. Thus a safety fund is established, whereon to fall back in case of emergency. A share of the subscribed and paid-in capital of the shareholders of the bank forms this safety fund, and it may be taken as a general rule, that where a bank is provided with no such security, but issues notes on the faith of the fund it may chance to have in hand, then the bank is trading on a principle alike dangerous to itself and the public. A banker who unites enterprise with prudence takes every available means to extend the circulation of his notes in as minute and distant channels as possible; for as long as a note is out, an interest is being received for the capital which it represents. In other words, when a pound note is out, it represents a sovereign which has been deposited or given for it, and which sovereign is employed in a fund in some manner of way at interest, for the advantage of the banker.

On considering the various operations connected with banking, it will be found, that, independently of the impulse and elasticity created by the facilities given to commerce, the direct and primary effect of them is the employment of waste money. A bank gathers, as it were, the money of a district into its hands, and, allowing each man to use as much of his own share as he requires at the time, keeps the remainder likewise in employment, which it would not have been had it remained in its owner's hands.

The rapidity with which all kinds of payments are made, and therefore the frequency with which money can be used, through the instrumentality of banks, form their most striking feature. In a bank office the same sum of money will have been made the means of paying its amount a dozen of times over in a day without being once uplifted. A, who is due B £100, gives a check for the sum, which will make it stand in his name instead of A's. B gives a similar check to C; C to D; and so on. "The transfer of lodgments," says Mr. Gilbert, "is extensively practised in our own times. If two persons, who have an account in the same bank, have business transactions with each other, the debtor will pay the creditor by a check upon the bank. The creditor will have this check placed to his credit. The amount of money in the bank remains the same; but a certain portion is transferred into a different name in the banker's books. The check given by the debtor is an authority from the debtor to the banker to make this transfer. Here the payment between the creditor and debtor is made without any employment of money. No money passes by one to the other: no money is paid out or received by the banker. Thus it is that banks of deposit economize the use of the circulating medium, and enable a large amount of transactions to be settled with a small amount of money. The money thus liberated is employed by the banker in making advances, by discount or otherwise, to his customers. Hence the principle of transfers gives additional efficacy to the deposit system, and increases the productive capital of the country. It matters not whether the two parties, who have dealings with each other, keep their accounts with the same banker or with different bankers, for as the banks exchange their checks with each other at the clearing-house, the effect, as regards the public, is the same."*

London, in which the government funds are managed, and where all the great pecuniary transactions of the empire may be said to centre, furnishes a remarkable instance of the economizing of money by the interchange of checks or drafts among bankers. Each banking-house in the metropolis sends daily the drafts it has received on other banking institutions to a place of common resort, called the clearing-house. Here a clerk from each bank attends and exchanges drafts. It is understood that the accounts balanced every day at this clearing-house amount to eight millions sterling, the settlement being effected by the intervention of only about £250,000 in notes and cash.

Bank of England.—This institution, which is the largest and most important banking establishment in the world, was projected by William Paterson, a Scotchman, and received its charter of incorporation July 27, 1694. It was constituted as a joint-stock association, with a

* History and Principles of Banking, pp. 123, 124.

capital of £1,200,000, which sum was lent at interest to the government of William and Mary, at the time in a state of embarrassment. At its very outset, therefore, the Bank of England was a mere engine of government; and in a lesser or greater degree it has enjoyed this character through all the stages of its subsequent history. According to its charter, the management is committed to a governor, lieutenant-governor, and twenty-four directors, elected by stockholders who have held £500 of stock for six months previous to the election. A director is required to hold £2000, a deputy-governor £3000, a governor £4000 of the capital stock. At first the charter of the bank was for only eleven years; but in consequence of the great services of the institution to government, its charter has been at various times renewed. The original stock of £1,200,000 has been augmented at different times, till, in 1816, it reached £14,553,000, upon which the stockholders drew dividends. The profits of the bank arise from traffic in bullion, discounting of bills, interest on mortgages, allowance for managing the public debt, &c.

The net profit of the bank in 1832, out of which interest was paid on the capital stock, was £1,189,627. The interest paid to stockholders has wavered from five to ten per cent. per annum, but has more generally been about eight per cent. The bank has, besides, at different times, made dividends under the name of *bonuses*. A bonus is a sum of money derived from the division of a fund, which had been suffered to accumulate or remain for use, in case of an emergency. The emergency being past, the fund is divided. The bonuses of the Bank of England have varied from ten to five per cent.

Originally, the business of the Bank of England was conducted at Grocers' Hall, in the Poultry; but about a century ago it was removed to a new edifice near the Royal Exchange, which may be described as the centre of the great business district of London. With numerous extensions, the bank structures cover an area of about eight acres of ground. The principal entrance is by Threadneedle Street, a thoroughfare immediately to the north of the Royal Exchange. Within the limits of the bank are conducted, on an extensive and perfect scale of art, the various processes of printing notes and other documents for the establishment; and in the fire-proof vaults beneath is the repository of bullion, or bars of gold and silver and coined money, constituting the substantial stock of capital for the time being. The number of clerks, porters, and other officials employed in the establishment, was lately about 900.

The Bank of England trades not only on its paid-up capital, but on the capital confided to it in the form of deposits, and usually called its liabilities. This is perfectly legitimate, and consistent with the true principles of banking, it being only necessary to take care that the institution always leaves itself a sufficient fund from which to satisfy all demands. The issue of notes by the bank is understood to be somewhat in accordance with the amount of its deposits; but this is necessarily dependent on various contingencies in public affairs. The leading feature in the character of the institution is the circumstance of its acting as the banking-house for the government. All the money drawn in the form of taxes or otherwise for the public service is consigned to the bank, while all drafts for the public service are likewise made from it. In carrying on this branch of its business, the bank allows the government to overdraw its account, that is, to take a loan of cash to a certain amount. The money so lent was some time ago upwards of £14,000,000, which parliament made a provision to reduce and finally pay off. The important services rendered to the government have in past times secured to the bank most valuable privileges, amounting almost to a monopoly of the business in money. In 1797, when the bank found itself unable to meet a run made upon it for gold for its notes, the government of that day summarily protected it from bankruptcy by issuing an order that Bank of England notes should be considered a legal tender; consequently, the holders of notes at the time were, by force of law, refused their value in cash. This extraordinary state of affairs, with various modifications, lasted till 1821, when cash payments were resumed. Meanwhile, the notes of the bank, from not being representatives of specie, were considerably depreciated in nominal value; so great was the depreciation at one time, that four pound notes would have been given in exchange for three guineas. It has been frequently represented as a serious hardship, that debts contracted during this prevalence of a depreciated currency, have had to be paid in a currency of full value; for by this means the creditor receives perhaps a third more money than the actual value of the original sum owing.

Joint-Stock Banks in England.—A parliamentary return was published early in 1840, relative to these establishments, from which it appeared that the number of joint-stocks in England, at 1st January, 1840, was 108, a considerable proportion of which had been instituted within the preceding ten years.

The number of partners in these banks varies from 50 to 1200, and may average about 300. There are half-a-dozen with less than fifty partners, the smallest number being seven. Fifty-eight of the banks have branches, and fifty have none. The branches, including the parent bank, are from two to sixty-seven in number. There are eight banks which have more than twenty branches. The whole number of parent banks and branches is 658.

There are besides about 550 *private banks* in England, that is, banks having not more than six partners. Adding these to the joint-stock banks and their branches, the whole number of banking establishments will be about 1200.

The issues of the joint-stock banks, when contrasted with the magnitude of the establishments, seem to us exceedingly small. According to the last return (August 2, 1839), the notes in circulation of all the joint-stock banks were in value £4,665,110. This, divided by the number of banks (108), gives an average circulation of only £43,200 for each; or, if we include the branches the average for each office or establishment is only £7000. Supposing the money to be employed in discounting at five per cent., the annual profit on £4,665,000 would be only £230,000, or no more than £350 to each establishment. It is evident that their profits must be chiefly derived from deposits, which they can employ at five per cent., while, we believe, they give only two.

The issues of the *private* banks, by the same return, were £7,610,700, which gives an average of about £14,000 for each establishment. It appears that the joint-stock banks, so far from superseding the private banks, have had but a very slight effect in narrowing their issues.

The chief advantage conferred on the Bank of England, and constituting its charter of monopoly, is the privilege of being the only bank in London, or within sixty-five miles of it, having more than six partners, which can issue notes payable to the bearer on demand. The bank has also the privilege of its notes being a legal tender by other banks for any sum above £5, so long as it pays its notes in cash on demand. This provision is a security to all other banks against the effects of sudden runs upon them for gold. It is ordained by act of parliament, that "upon one year's notice, given six months after the expiry of ten years from the 1st of August, 1834, and upon repayment by parliament of all sums that may be due from the public to the bank at the time of the expiration of such notice, the exclusive privilege of banking granted by this act shall cease and deter

mine at the expiration of such year's notice." Hence, in 1844–5, there will necessarily be a renewal or modification of the peculiar privileges of the Bank of England.

Stocks—Stock Exchange.—There are various kinds of stocks. Shares in a joint-stock company are called stock, and so are shares of debts due by government. It is the last-mentioned stock, which is variously termed *public securities*, or the *funds*, that requires to be explained, and in doing so we take the liberty of using the definition of a popular writer.*

"In every war in which this country has been engaged since the Revolution, the amount of the annual taxes has been found inadequate to defray the expenses of government. To supply the deficiency, our rulers have generally had recourse to loans—that is to say, they have borrowed money from such individuals as were able and willing to lend it, giving these individuals a security for the payment of a certain annual interest. To explain the nature of this transaction, I shall take a very simple case. Suppose, then, that £100 is the sum which government wishes to borrow, and that an individual offers to lend that sum at an interest of 5 per cent. On paying down the money, the lender receives a bill, bond, or acknowledgment, for the amount; by which acknowledgment he is entitled to draw yearly from the public revenue £5 of interest, but on the express condition that he is not to demand repayment of the principal, or sum lent, unless government is willing to repay it. The person who thus possesses the bill or acknowledgment is said to be a *holder of* £100 *of* 5 *per cent. stock*, and the money lent upon that bill constitutes a part of what is called the *national debt*, because it is in fact borrowed by the nation, and the interest is paid out of the taxes. It is obvious, however, that few persons would be disposed to lend money on the condition of never being allowed to demand repayment, even though they were quite certain of receiving annual interest, and of transmitting the right to that interest to their posterity. To remedy this inconvenience, therefore, the lender who wishes to employ the sum which he lent to government in any other way, though he cannot directly demand repayment, is at liberty to sell his bill to anybody who will purchase it, and for any sum that another may be willing to pay for it. In doing so, he merely sells to a second person the right which he himself possessed to the annual interest of £5, and that second person is of course at liberty to dispose of his right to another in the same way. This transaction, in general, is called a *transfer of stock*; and in the particular case which I have supposed, the one is said to sell, and the other to buy, £100 of 5 per cent. stock. If 5 per cent. be considered as a fair and equitable interest for money lent, it is obvious that such a bill as I have now been speaking of, or, in other words, that £100 of 5 per cent. stock, is just worth £100 sterling. It is possible, however, that in certain circumstances the holder of that bill may receive more, or be obliged to take less for it than £100. If two or three individuals, for example, have each a sum of money, which they are anxious to lay out at interest, but find it difficult to do so, a competition will naturally take place among them to become the purchaser of the bill in question, which will always secure to the holder £5 of yearly interest. The possessor of the bill will of course take advantage of this competition, and raise his price, say to £105. The purchaser, therefore, pays £105 for £100 of 5 per cent. stock, or he lays out his money at an interest of £5 for every £105, which is at the rate of something more than 4¾ per cent. If, on the other hand, however, the possessor of the bill or stock is anxious to dispose of it, while few are willing to buy it, he will be forced to offer it for less than £100, say £95. The purchaser, in this case, pays £95 for £100 of 5 per cent stock, or he lays out his money at an interest of £5 for every £95, which is at the rate of something more than 5¼ per cent. For simplicity of illustration, I have supposed that £100 is the sum borrowed by government, and that of course there is just one bill to be disposed of, or transferred by the lender. If it be supposed, however, as is really the fact, that the loans generally amount to several millions, the necessity which the lenders are under of selling their bills, or, in other words, transferring their stock, will be more apparent. The transaction between government and the lenders is precisely the same in the case of millions as in that of a hundred; and it is unnecessary, therefore, again to illustrate the general principle of that transaction. It is evident, however, that even the most opulent merchants, who are generally the lenders, cannot be supposed to have such a command of money as to be able to advance ten or twelve millions to government at once. When they contract for a loan, therefore—that is, when they agree to lend to government the sum required—they generally pay the money by instalments, or partial payments at certain intervals, say one million a month, till the whole is advanced. In the mean time, they sell or transfer the bills or securities which they receive from government to those who may have money to lay out at interest, and who of course will be disposed to purchase such bills, so that the sale of the bills of the first instalment may enable them to pay the second. In this way, government securities or bills become articles of commerce, and their price is regulated, like that of any other article, according to the supply and demand.

"It is easy to see how the price of stock is liable to fluctuation from accidental circumstances. I shall not attempt to enumerate these: but it may be worth while to point out how it is affected by peace and war, as these two conditions of the country are generally found to have the greatest influence in raising or depressing the value of stock. In the time of war, then, the price of stock is comparatively *low*, because, in such a state of things, it is likely that government will be under the necessity of borrowing; and as every loan produces new bills, the quantity of those to be disposed of, or, in other words, the supply of the market, will be increased. The price, therefore, will fall, for the same reason that the price of corn falls after a plentiful harvest. In time of peace, again, the price of stock is comparatively *high*, because, in such a state of things, the taxes are likely to be sufficient to defray the expenses of government without any loans, and consequently no new bills are to be disposed of, or the supply, though not positively diminished, ceases to be augmented. For the same reason, the price of stock in the time of war is materially affected by the nature of the intelligence that comes from the scene of action. If that intelligence be unfavourable, stock will fall, because there is a prospect either of protracted warfare, or of the necessity of more vigorous exertions on the part of government; in both which cases new loans may be necessary, and consequently a new supply of bills will be thrown into the money market. On the other hand, should the intelligence be favourable, the price of stock will rise, because the prospect of a successful termination of the war renders it probable that there will be no new loan, and consequently no new supply of stock.

"It is this variation in the price of stock that gives room for the nefarious practice of *stock-jobbing*. That practice consists in raising and circulating reports calculated to raise or depress the price of stock, according to the particular views of the individual. If he wishes, for example, to sell his stock or bills, he endeavours to propagate some report or other favourable to the issue of the war, and the establishment of peace, in order, if possible, to raise the price of stock; and, if he wishes to buy, he

* Blackwood's Magazine: 1816.

propagates reports of a contrary tendency. It is painful to think that this abominable system is sometimes carried on by men whose rank and station in society, to say nothing of the obligation of morality and religion, might be expected to place them far above any such disgraceful acts, but, in general, I believe it is confined to men of desperate fortune and little character, who subsist by a specie of gambling, to which the finance system of this country has opened a wide and extensive field. I allude to those men who make a practice of buying and selling stock, without actually possessing any, and whose transactions, therefore, are nothing more than wagers about the price of stock on a certain day. To explain the nature of the transaction by an example: I shall suppose that A. sells to B. a government bill of £100, or £100 of 5 per cent. stock, to be delivered on a certain future day, and that the price is fixed at £102. If, when the day arrives, the price of stock shall have fallen to £100, A. would be able to purchase the bill in question for £100, while, in consequence of his bargain, B. would be obliged to pay him £102 for it, so that A. would gain £2. If, however, stock had risen to £104, B. would still be obliged to give only £102, so that A. would lose £2; but instead of actually buying and selling the stock, the bargain is generally implemented by A. paying to B., or receiving from him, the £2, or whatever may be the sum of loss or gain. In such a case as this, it is obviously A.'s interest that the price of stock should fall, and as obviously B.'s interest that it should rise, between the day of the bargain and that of settling; and hence the temptation held out to both to circulate reports favourable to their own particular views. B., or the buyer, is usually denominated a Bull, as expressive of his desire to *toss up*; and A., or seller, a Bear, from his wish to trample upon or *tread down*. The law, of course, does not recognise a transaction which proceeds on a principle of gambling; but a sense of honour, or, what is perhaps nearer the truth, *self-interest*, generally secures the payment of the difference, as the person who refuses to pay his loss is exhibited in the Stock Exchange under the designation of a *lame duck*, a disgrace which is considered as the sentence of banishment from that scene of bustle and business."

In the preceding remarks, the loans to government have been supposed to be negotiated in bills bearing five per cent. interest; practically such is not the case. The stocks, from a variety of circumstances, are of different denominations, some having been created at one rate of interest or profit, and some at another. The principal stock is called the three per cent. consolidated fund—that is, several borrowings consolidated into one debt at three per cent. This stock is usually called, for shortness, three per cent. consols. Another stock is called three per cent. reduced annuities, or briefly, three per cent. red. an. The three per cent. consols embrace a debt of upwards of £300,000,000, or nearly one-half of all the money due by the nation; and in most instances it is a share of this debt which people purchase when they buy into the funds. In 1839, the debt, funded and unfunded, amounted to £763,803,563, the annual charge or interest upon which, to be raised by taxation, was £28,669,333. It was ascertained that this interest was payable to 279,751 persons, fully two-thirds of whom received under £50 each.

Banks in Scotland.—The earliest banking institution in North Britain was the Bank of Scotland, instituted by a charter of incorporation from the Scots parliament in 1695. The original capital was £1,200,000 Scots, or £100,000 sterling. The amount was raised by shares differing in extent, from £1000 Scots, or £83, 6s. 8d. sterling, to £20,000 Scots. In 1774, the amount of stock was extended to £200,000 sterling; and now it is a million and a half sterling. The shares are now £100 sterling each.

The establishment of the Bank of Scotland was of great service to the nation; the landholders borrowing notes and bringing the country into cultivation, and a spur being by that means given to various branches of manufactures. The Bank of Scotland continued to be the only bank in the country till the year 1727, when a new and similar establishment was constituted under the title of the Royal Bank of Scotland. These two establishments engrossed all the respectable banking business in the country till the year 1746, when a new association was formed, and incorporated by royal charter, with the title of the British Linen Company. The object of this association was at first to encourage the linen manufacture of Scotland, but gradually it fell into the course of common banking business, and now occupies a high station among these institutions. From £100,000, the capital of this bank has been raised to £500,000, where it has long remained stationary. By adroit management it carries on an immense deal of business and possesses as high credit as any bank in Scotland.

These are allowed to take precedence of others erected in the subsequent part of last, and in the present century, either in Edinburgh or in the provinces; and their shareholders enjoy the privilege of being responsible only for their individual stock.

All the banks, with few exceptions, are joint-stock associations, and are banks both of deposit and issue. Except the few private houses, all issue notes of one pound and upwards, which are payable on demand at the office whence they are issued. It was at one time ordained that Scottish bank notes should not be re-issued after they were three years old; but such a regulation is abrogated, and they are now sent out as long as they are in good condition. Almost all the modern notes are produced from plates of hardened steel, and of such peculiar and intricate devices, that forgery cannot be attempted with success, or remain long undetected.

No periodical returns of their issues are made by the Scottish banks. But on turning to the evidence given before the parliamentary committees of 1826, we find the usual value of the small notes in circulation estimated by Mr. Paul of the Commercial Bank, and Mr. Blair of the British Linen Company, at £1,800,000, which is increased by a third at particular seasons, and when trade is brisk. The committee estimate the paper money of all kinds in circulation in 1826 at £3,309,082. But in the year of great speculation, 1825, they estimate the highest amount of notes in circulation at £4,683,000, the lowest at £3,434,000.

The following is a return of the joint-stock banks existing in Scotland at 5th January, 1839, with the dates of their establishment:—

The Bank of Scotland, Edinburgh, 1695; the Royal Bank of Scotland, Edinburgh, 1727; the British Linen Company, Edinburgh, 1746; the Commercial Bank of Scotland, Edinburgh, 1810; the National Bank of Scotland, Edinburgh, 1825; the Aberdeen Bank, Aberdeen, 1825; the Ayr Bank, Ayr, 1825; the Dundee Banking Company, Dundee, 1825; the Dundee Union Bank, Dundee, 1825; the Dundee New Bank, Dundee, 1825; the Glasgow Bank Company, Glasgow, 1825; the Greenock Bank, Greenock, 1825; the Leith Bank, Leith, 1825; the Paisley Bank, Paisley, 1825; the Perth Banking Company, Perth, 1825; the Renfrewshire Banking Company, Greenock, 1825; the Paisley Union Bank, Paisley, 1809; the Aberdeen Town and County Bank, Aberdeen, 1825; the Arbroath Bank, Arbroath, 1825; the Dundee Commercial Bank, Dundee, 1825; the Glasgow Union Banking Company, Glasgow, 1830; the Ayrshire Banking Company, Ayr, 1831; the Western Bank of Scotland, Glasgow, 1832; the Central Bank of Scotland, Perth, 1834; the North of Scotland Banking Company, Aberdeen, 1836; the Clydesdale Banking Company, Glasgow, 1837; the Southern Bank of Scotland, Dum-

ries, 1837; the Eastern Bank of Scotland, Dundee, 1838; Edinburgh and Leith Bank, Edinburgh, 1838; being 29 in all.

The business done by the Scottish banking-houses is prodigiously increased by the institution of their branches in the provincial and country towns. From those banks already noticed, which are situated in Edinburgh, and from two or three of the chief provincial banks, there were altogether deputed, not long since, about one hundred and forty branches, and this number is undergoing a regular increase. The subsidiary establishments are to be found in every town of any note, from the borders to the most northern point of Scotland. They are conducted by resident wealthy or responsible merchants and others, who give securities for intermissions, and are subjected to a very rigorous supervision by inspectors, who are continually travelling about for this purpose.

The prudent and enterprising manner in which the business of banking is conducted in Scotland, has often been the subject of remark and commendation. Several reasons may be assigned for the remarkable stability of the Scotch banks. Each bank, before gaining credit with its neighbours, must show that it possesses a sufficient paid-up capital, with a reserve fund in London, on which orders for balances may be given. It is also the custom of the banks to exchange the notes of each other once or twice a week, by which means the notes are sent very speedily back to the issuers, and thus an over-issue on the part of any single establishment is prevented. There can only be an over-issue by all the banks in the country becoming equally reckless, a thing not likely to occur to any serious extent. A third cause of the stability of the institutions, is the liability of shareholders for the debts of the establishment. Excepting in the case of the three old-established banks above specified, all the shareholders in the various banks are liable not only for the amount of their own shares, but for the shares of all the others; and the whole of their property may be seized to make up deficiencies. Although many of the shareholders are certainly not men of opulence, a number are so; and as their fortunes are good for the paper issued, the public runs no risk of injury. To strengthen this liability of shareholders, by the law of Scotland all heritable property, lands and houses, may be seized in satisfaction for their debts. As this is not the case in England, where personal or movable property can alone be taken by creditors, it would not be possible to establish banks in the south part of the island on the principle of the Scottish banks, till the law touching heritable property be altered.

Other causes, not of a legal nature, conspire to render the system of Scottish banking perfect. By reason of the circumscribed limits of Scotland, and the character of the people, a ramification of intelligence is created and preserved throughout the whole of society, altogether unknown in England, whereby the character, the wealthiness, and the conduct of the partners or directors of each bank, are made fully known to the rest. All seek, and all find, a knowledge of the management of each other. All are mutually on the watch; and symptoms of over-issues or other improprieties are spread with an amazing celerity, and have their immediate effect.

In comparing Scottish banking institutions with those in England, and considering the different manner in which paper money has been guided by the two nations, the uniform security of the former appears almost miraculous. From the first issue of the bank-notes in 1704, till the year 1830, a single panic or general run did not occur in Scotland, although, during at least two-thirds of the intervening period, paper money had been used to the almost total exclusion of a gold currency. Partial and very temporary runs have assuredly been felt, from the effects of short-lived slander or mistaken notions, which have invariably been readily quashed; but in the course of a hundred and twenty-six years, there have only been two or three cases of banks failing to pay twenty shillings a pound (they paid 10*s.*), and four, in which, after a short suspension of payments, all demands were liquidated. Their failure or stoppage, with the exceptions we mention, did not put the public to any loss; but this was to the injury of the shareholders, many of whom were reduced from affluence to poverty.

The very common practice of making deposits of small sums in the banks, has further assisted in giving strength to the institutions. Each bank receives deposits of any sum above £10, for which a regular interest is given; and on this account the banks may be said to be the custodiers and traders upon all the spare capital of the country. Besides employing capital in discounting bills, lending money on heritable security, &c., the Scottish banks grant loans of fluctuating amount, called *cash accounts*. By a cash account is signified a process, whereby an individual, on entering into an arrangement with a bank, is entitled to draw out sums as required, to a stipulated amount, and by an implied condition to make deposits at his convenience towards the liquidation of the same.

Cash accounts are said to have originated from the following circumstance:—A shopkeeper in Edinburgh, in the year 1729, found himself at times in the possession of more than a sufficient supply of ready money to carry on his trade, the overplus of which he consigned to the care of the neighbouring bank. But on other occasions, by reason of the length of the credits given to his customers, his money became so scarce, that, after exhausting his bank deposits, he still felt himself in difficulties. Several dilemmas of this kind having occurred, he was prompted to make a proposal of a novel nature to the bank, to the effect that, if it would accommodate him in straits with small loans, he would always shortly afterwards make up such debits, and that the parties should come to a balancing of accounts at periodical intervals. It seems this proposal was acceded to. A cash credit, or liberty to draw to a certain extent, was instituted under securities; and thus originated a system which has been of immense benefit to bankers and traders, and is now followed over the whole of Scotland.

Cash credits are guaranteed by two sufficient securities, or the applicants give infeftment to heritable property in caution of the contingent debt, and when any such debt is liquidated, the deed is cancelled. The expense of expeding a cash credit varies according to the amount of the desired loan. One for £500 may be stated at about £15. The deed requires no renewal. At the end of every six, and in some cases twelve months, calculations are made of entries and debits; the interest for and against the bank—the one being a per cent. higher than the other—is added and balanced, and an account being then rendered, the balance, if in favour of the bank, is either paid up, or remains against the debtor at interest to his new account. In these cash credits the borrower is always at the mercy of the bank, which can call upon him at any time to balance his account, or, by his failing to do so, have recourse upon his securities.

Since 1729, cash credits have increased to an amazing extent. In 1826, it was computed that there were TEN THOUSAND in Scotland, varying in amount from £100 to £5000 each, but averaging from £200 to £500. Though originally designed for mercantile persons, they are now operated upon by farmers, manufacturers, house-builders, miners, lawyers, and all classes of traders and shopkeepers. From 1826, it is extremely probable that, instead of decreasing, they have increased a thousand or two more.

Banks are in the present day established in every civilized country. In the United States of North America they have been instituted to a great extent, and frequently on most unsound principles, their notes being

for very small sums, and these in few instances negotiable without a loss at a comparatively short distance from the place of issue; often, also, there has been an universal stoppage of cash payments, in consequence of over issues of paper money, a sure testimony that the country was trading beyond what its actual capital warranted.

Savings' Banks.— These are banks for receiving and taking charge of small sums, the savings of industry, and have been instituted for the benefit of workmen and others, who may be able to spare a shilling and upwards from their weekly earnings. The first savings' bank is understood to have been begun in Philadelphia in 1816, since which time they have been established in all parts of the United Kingdom, France, and other countries. Several acts of parliament were successively passed between 1817 and 1828, for the regulation of savings' banks in England; and in the year last mentioned, the whole of these were consolidated in one statute (9 Geo. IV. chap. 92). This act, together with another passed in 1833, conferring additional and important privileges on savings' banks (3 Will. IV. chap. 14), constitutes the existing law relative to these useful establishments: in 1835, the act was extended to Scotland. Savings' banks established according to the provisions of these acts are entitled National Security Savings' Banks, because the money deposited in them is paid into the Bank of England on account of government, whereby the nation becomes security for the amount of deposits—a security reckoned the best of all that could be given to the depositors. The interest given by government on the sums so deposited is £3, 16s. 0½d. per cent. per annum, whatever may be the fluctuations in the value of the public funds during the term of investment. This rate of interest being higher than what government could otherwise borrow money for, it happens that the public are really losing money annually by their generosity. The rate of interest payable to the depositors is £3, 8s. 5½d. per cent. per annum.

Deposits of from *one shilling* to *thirty pounds* may be received by these banks; but no individual depositor is allowed to lodge more than thirty pounds in one year, or than £150 in whole. Charitable and provident institutions may lodge funds to the amount of £100 in a single year, or £300 in all; and friendly societies are permitted to deposit the whole of their funds, whatever may be their amount. Compound interest is given on the sums lodged, the interest being added to the principal at the end of each year in some banks, and at the end of each half-year in others, and interest afterwards allowed on the whole. Any depositor may receive, on demand, the money lodged by him, if it do not amount to a considerable sum; and even in that case it will be returned on a few days', or at most two or three weeks' notice. Practically, payment is always made on demand. The wisest and most effectual provisions are made for ensuring the proper management of the affairs of the banks, so that those who intrust them with their money may place implicit reliance on its safety.

Each depositor is provided with a small book, in which his deposits are entered, and the amount of his interest marked. On the 20th of November, the interest is added in the bank books whether the depositor call or not. It is computed for the full term, and upon every fifth fraction of a pound. Depositors have thus the advantage of having their principal sum gradually increasing at 3½ per cent. compound interest. So successful has been the establishment of the savings' banks in England, that in November, 1835, there had been deposited in them, up till that period, the sum of sixteen millions and a half of pounds. The deposits now amount to about twenty two millions.

HISTORY AND NATURE OF LAWS.

THE ROMAN LAW, AND THE SYSTEMS DERIVED FROM IT.

Law may be defined as a system of regulations adopted in social communities for the general advantage, and on that account binding upon all the individuals constituting that community. Such regulations being absolutely essential to the existence of a social state, we may safely infer, that no sooner were any portion of mankind advanced into that state, than law began to exist. Its origin, being thus early, is necessarily obscure: we know extremely little of its history in any of the nations of antiquity besides Greece and Rome.

In Grecian history we find more than one well-known code of laws; but so limited and simple was their operation, and so little are they adapted to the wants of a complicated state of society, that they are to be looked upon rather as the municipal regulations for the temporary government of a small knot of men, than as systems from which any additional hints are to be obtained to aid modern jurisprudence. It does not appear to have been in Greece—the source, as it was, of philosophy, literature, and art—that useful laws, applicable to the business of life, had their origin. The Phœnicians, of whose history and institutions we unfortunately know so little, seem to have been among the first to establish a general system of mercantile law, which their extensive commerce distributed abroad. To Rhodes, which can scarcely be considered a province of Greece, we owe the earliest regulations applicable to shipping. The law of average, or that by which the loss occasioned by throwing goods overboard to relieve a ship in distress is laid proportionally on the whole property saved (a most important branch of the commercial code of modern nations), had its origin in that state, and is still called the Rhodian law.

There is the less importance in the inquiry into the laws of early nations, since all of ancient law which continues to have any force in civilized Europe, has come to us through one channel—namely, the Roman law. Most European nations, being, as it were, the remoulded wrecks of the Roman empire, have obtained the basis of their laws from that source. The Roman law is, therefore, by the common consent of Europe, denominated *The Civil Law*. In Europe, there was but one other system, at an early period, to combine with it. This was *The Feudal Law*, or that code of usage which had sprung up in European nations before they received the civil law. It is, after all, only in some countries that the feudal law exists: in other cases, the civil law has established a proportionate, and in some a preponderating influence

In Holland, and Germany, the original purity of the principles of the civil law have been preserved with such zealous care, that the writings of the lawyers of those countries are quoted as authorities on the law of Rome. In Spain, the system has been grafted on the feudal law, and on some peculiar customs derived from the Moors. In France, previously to the Revolution, the civil and the feudal law were united, as in most other nations of Europe: and in the Code Napoleon, which we shall hereafter have more particularly to notice, there are many regulations from the jurisprudence of Rome allowed to exist, or revived, while many of the feudal customs which were formerly so prominent are abolished. England distinguished herself from the other nations of Europe by rejecting the civil law as authority, but many of her institutions were derived from its spirit and practice. "With all its imperfections," says Sir William Jones, "it is a most valuable mine of judicial knowledge; it gives law at this hour to the greatest part of Europe, and, though few English lawyers will make such an acknowledgment, it is the true source of nearly all our English laws that are not of a feudal origin." In Scotland, the Roman law has always been a special subject of study; and though the number of native decisions, the extent of statute-law, and the necessary adaptation of the system to a state of society very different from that in which Justinian promulgated his laws, have rendered references to this source comparatively unfrequent, the civil law is still authority where the particular law of Scotland does not contradict it. It is a special object of study by the legal profession, and is the subject on which the members of the bar are first examined before they are admitted to practice. To complete the general outline of the influence of this system in modern Europe, it must be mentioned as the source of the canon law, which was created into a system by the Church of Rome, and still exists, more or less, either separately or incorporated with other systems, in all countries where the papal authority was acknowledged. The law of nations, or international code, has been, by the common assent of civilized nations, derived from the law of Rome.

Writers have divided the legislative sources from which the laws of Rome spring into five. Among the first of these is generally classed the people, and the laws sanctioned by them are technically divided into the *Lex* or *Populiscitum*, and the *Plebiscitum*, the former including the acts of the whole people, the latter those of the plebeians convened by their tribunes. It would appear that, in the earlier periods of the monarchy, the authority of all classes was in this description of legislation tolerably equal. Servius Tullius, however, the sixth king, introduced the well-known divisions into centuries and classes, by which ninety-eight votes were secured to the first class, while ninety-five only were allotted to the remaining five, of which the lowest and most numerous possessed only one. The tribunes, who were officers chosen for the ostensible purpose of protecting the people from the tyranny of the aristocracy, were, by the exclusive and important power they possessed, again the means of restoring popular election. They procured the assembling of the people by tribes, in which their votes were given individually, and without the necessity of a property qualification. All popular legislation, however, soon disappeared with the authority of the emperors. Augustus, except in one instance, found the popular assemblies profoundly obedient, and under his successor they ceased to exist; so that long before the Roman laws had become the grand system of jurisprudence which they constituted under the auspices of Justinian, the popular source of legislation had been dried up.

The decrees of the senate (*Senatus consulta*) are another source of the Roman law. The legislative power of this body seems to have grown out of its judicial, which was at first its proper province. By the original constitution, the people alone were understood to be the makers of the laws, and their authority seems to have been gradually engrossed by the senate, the interference of which, from having been confined to mere advice and paternal assistance in legislation, gradually extended itself to that of making laws. It was not till the days of Tiberius that these decrees were publicly promulgated as laws; but the senate had by that time lost its independent authority, and become merely an instrument in the hands of the emperor. The proceedings of the senate were generally suggested by some public officer, as a minister of the crown now introduces a bill into parliament, and a majority decided for passing or rejecting. In later times it became the practice for the emperor to propose a new law either by a message or letter laid before the senate, or by an oration delivered; and as there was no opposition intended or permitted, the legislative body became the mere registrars of the monarch's will.

Another source of the civil law is the constitutions and rescripts of the emperors. At what time they commenced the practice of making laws without the nominal concurrence either of the senate or the people, is not very distinctly known. A passage in the Pandects, the authenticity of which, long doubted, has been confirmed by late discoveries, states that the will of the emperor is law, and that by a particular act, the people had conferred upon him all their own power, which was thenceforth absolutely to remain in his hands—one of those transactions under the guise of which rulers are so fond of concealing their lust of power, by representing as a free gift that which no one can venture to refuse. Hadrian is believed to be the first emperor who exercised the authority of a supreme legislator. The imperial laws were issued in a variety of forms. Sometimes there was a new constitution springing from the monarch's own creative mind—on another occasion he would give his imperial judgment on some nice speculative question of law dutifully submitted to his wisdom. Many of the imperial laws, however, were the decisions of the monarch in particular cases, the spirit of which was piously preserved by the lawyers of the age, as the best criterion for a general rule of action. In modern times we associate with despotism a horror of innovation, and a desire to leave all institutions, whether expedient or hurtful, untouched. It was different in imperial Rome. The emperors were never tired of displaying the legislative produce of their own genius, or those which the prudent and courteous discoverers did not compete with them for the merit of suggesting. During four centuries from Hadrian to Justinian, the manufacturing of legislation was in almost constant operation. Diocletian alone enacted 1200 new laws—a number that would do no discredit to a moderately long reign of a British monarch.

Edicts of the prætors are another, and not the least important, source of Roman jurisprudence. Of these high magistrates there were different numbers at different times; but the supreme authority vested in two, one having jurisdiction over the city, the other over the provinces. The prætor held his office for a year; and, as a provision against his adapting his judgments to his own personal views, the Cornelian Law obliged him to issue a sort of proclamation at the commencement of his magistracy, imbodying the general principles to which he should adhere in his judgments; and thus, at the moment when he was least acquainted with the duties of his office, he had to fix the plan on which he was to execute them. The prætor was not originally vested with legislative power—it arose in the exercise of his judicial authority. He was merely the interpreter of the laws; but when they seemed to him to be hard or otherwise erroneous, he did not scruple to suspend or alter their execution. The prætorian law has been compared to the equity system in England—a distinct system of law, arising out of these

instances in which it was necessary to give relief from the strict interpretation of the common law. The common law had fixed a particular rule; a case would arise in which its application would be very oppressive; the common law judges, bound by their system, could give no relief; but the chancellor took upon him to modify the evil, and his decision was followed in like cases. The system of the prætors was somewhat similar, with this difference, that as they had no judges to compete with who pursued a system of strict interpretation, their equity had rather a tendency to modify the common law than to raise a rival structure. "The secret or probable wish of the dead," says Gibbon, when illustrating the prætorian system, "was suffered to prevail over the order of succession and the forms of testaments; and the claimant who was excluded in the character of heir, accepted with equal pleasure from an indulgent prætor the possession of the goods of his late kinsman or benefactor. In the redress of private wrongs, compensations and fines were substituted to the obsolete rigour of the Twelve Tables; time and space were annihilated by fanciful suppositions; and the plea of youth, or fraud, or violence, annulled the obligation or excused the performance of an inconvenient contract." With the expiry of his year of office, the edicts of the prætor cease to be imperative; but they were still looked up to as precedents; and when they became venerable by long use, they were considered as part of the fixed law of the land. By an enactment of the Emperor Hadrian, called the "Perpetual Edict," this doubtful and fluctuating branch of the law—at least as much of it as the emperor chose to sanction—received what might be called the royal assent, and was incorporated with the other portions of the civil law, as a distinct branch of the system.

In almost every nation which has passed gradually from barbarism to civilization, many laws will be found to have come into existence without the direct interference of any legislature, and from no better defined origin than a habit on the part of the people of submitting to certain rules, or obeying the commands of certain individuals; it is, indeed, generally in this manner that legislatures have originated. A considerable portion of the Roman law was of this kind; it arose in custom, was handed down by tradition and practice, and called consuetudinary law. It is a disputed question, how far it was necessary that some competent authority should certify that the principle actually was an established portion of the ancient customs of the nation, before it could be safely acted upon as law. It is a peculiarity of the civil, as distinguished from the English jurisprudence, that, according to the former, a law may be tacitly abrogated by long disuse. In England, no law, however long forgotten, ceases to exist till it be repealed by the legislature.

The last fountain of Roman jurisprudence which we shall notice, is the *Responia Prudentum*—literally, the answers of the wise men—the opinions of the sages of the law. It is difficult to conceive a state of society in which the opinions of legal writers, as to the interpretation of the law, will not have an influence. If a case occur in which the judge is uncertain as to the proper application of some enactment, where can he find a more suitable or safer guide than in the opinion of some far-seeing lawyer, who has anticipated the case without knowing the parties, and who, consequently, cannot have proceeded on a bias to one or the other—a defect of which the judge, if he be the first to interpret the law, will be at least suspected? Even in England, where interference with the doctrines of the common law is so jealously opposed, the early commentators are the only authority for its provisions: and there is no doubt that they gave the hue of their own opinions to the doctrines they laid down. In Rome, however, where the profession of the law, instead of being a trade, conferred a high rank in society the opinions of leading counsel had a much more extensive range. They not only interpreted, but they could create law, by suggesting how the decision should proceed in imaginary cases. At an early period, the relation of lawyer and client was that of patron and dependant. Patricians alone could act as lawyers, and the science was involved in riddles to which they only possessed the key. The poor client was dependent on the good will of his lordly patron for such protection from oppression, whether through the law or otherwise, as the influence of the latter might enable him to afford. When population and transactions increased, and the laws, instead of a mystery, became a serious study, which depended more on laborious application, than simple initiation, the profession was opened to plebeians. It became not an unusual case, at a still more advanced period, for the patron and lawyer to be separated; the former being chosen for his influence, the latter for his skill. The forms which regulated the intercourse between patron and client, however, still retained some relics of their origin; and it is a striking illustration of the influence which Roman jurisprudence has exercised over the human race, to find these still existing. To this day, it is against all etiquette to bargain with a barrister for his work. The law gives him no claim for remuneration, which it kindly views as unworthy of the dignity of his profession; and it is usual to pay him beforehand for his legal assistance. On the other hand, though he has been paid beforehand, he cannot be compelled to perform any duty in return, for he is presumed to assist the client from his own free good will. In most other professions, it is the custom for the person employed to feel under a sort of obligation to the employer who has preferred him to others. This principle is reversed at the bar; for the person employed is the patron, and the employer the client.

But to return to the legislation of the sages of the law During the commonwealth, whoever, by his superior sagacity or knowledge, could obtain deference for his opinions, might be said to be a manufacturer of laws. Under the earlier emperors, the privilege of promulgating authoritative opinions was confined to a limited number of lawyers, of equestrian rank, licensed by the government; but the profession was again thrown open to the public by Hadrian. The most brilliant era of legal wisdom commences within a short period of the decline of the republic, and terminates with the reign of Alexander Severus. Mucius Scævola, the tutor of Cicero, was one of its earliest ornaments; and it included the celebrated jurisconsults Paul, Ulpian, Papinian, Capito, and Labeo. The two last of these, who lived in the age of Augustus, were the founders of the two sects—the Proculians and Sabinians—into which the Roman lawyers were divided. The former advocated the doctrine that the laws should be amended at discretion, to meet circumstances as they occurred; the latter maintained the theory of their strict interpretation, be its inexpediency in the particular instance what it may. Capito, applying his doctrines to the inroads which the emperors were gradually making in the freedom of the republic, was a supporter of this species of innovation, and his followers were enrolled among the ready tools of despotism. Labeo sought to support the ancient freedom of the republic by an adherence to the letter of the old laws, and his sect became the champions of what may be termed constitutional freedom. The conflict is not unlike that which lately existed in Britain between Lord Mansfield and Lord Camden; the former supporting, to a certain degree, an equitable, the latter in all cases, a strict interpretation of the law.

Having now enumerated the principal sources of the Roman law, we may notice its remarkable epochs. The laws enacted during the reigns of the kings, although a curious subject of inquiry among antiquaries, exercised too little influence on the civil law, as handed down to

modern Europe, to be of much practical importance. During the administration of the decemvirs, the celebrated laws of the Twelve Tables were adopted. The traditionary history connected with this code is, that the Roman government, conscious of the want of a proper legal system, sent commissioners to Greece, who, after studying the laws of that comparatively civilized nation, produced the Twelve Tables for the acceptance of the Romans. The tradition, like many others connected with the Roman history of the period, has not sufficient historical evidence to support it against its natural improbability. These laws, of which specimens are professed to be preserved, are written in a language so different from that of the classical writers of Rome, that they were to Cicero an object of much the same curiosity as the old Scottish acts were to Bacon. Like the first laws of other rude states, they are simple and brief in their enactments. The bankruptcy system, which has so sadly shocked several benevolent scholars, that they have endeavoured to explain it as a merely symbolical provision, is peculiarly sharp and effective. It enacts that the insolvent debtor shall be cut in pieces, and that his body shall be distributed among his creditors. When law became a science openly studied, the Twelve Tables became the subject of many commentaries. It was not, however, till the Romans had been for some time degenerating, that those great collections of legislative wisdom which have come down to modern times were commenced. The first attempt to construct a code seems to have been the Perpetual Edict of Hadrian, already alluded to. Two private individuals, Gregorius and Hermogenes, appear to have collected the imperial constitutions into a system, or code, of which some fragments are still preserved. Nothing whatever is known of the biography of these compilers; it has not even been discovered in what reigns they respectively lived, though their labours received high commendation at the hands of Theodosius the Younger. Under this emperor, the celebrated Theodosian Code was promulgated, in the year 438. The compilation of this body of laws was committed to eight individuals, who were allowed considerable latitude in explaining and abridging, and even in supplying deficiencies. It contains the legislative acts of sixteen emperors, from the year 312 to 438. Fragments of this code have been rescued from oblivion inch by inch, by modern scholars, whose labours, it may safely be calculated, have amounted to some twenty or thirty times more than those of the original compilers. The celebrated Godfroy, of Geneva, spent thirty years in the task; and within the last twenty years, the discovery of some further fragments induced the celebrated Angelo Mai to study the Roman law for the purpose of editing them.

It is now our turn to notice those great collections of the legal wisdom of the Romans, to which the above may be considered only preparatory. In 529, ten commissioners, appointed by Justinian, prepared *The Code*, or *Codex*, as it is termed, from the collections previously made, and the intermediate enactments. Soon after its promulgation, the emperor issued several new constitutions, and the whole were consolidated and re-issued in 534. The great task was superintended by the celebrated Tribonian, whose eminent learning and discrimination, allied with untiring industry, but stained by the vices of corruption and partiality, have afforded a fruitful theme of praise and obloquy. This was by no means Tribonian's only labour. In the year 530, he was appointed the chief of a commission of sixteen, whose duty it was to cull the choice and useful passages from the authors of comments and opinions. The various authorities, which, we are told, would have made several camels' loads, were thus reduced within a compass which, if it do look somewhat formidable to the consulter, is still manageable. Such are the fifty books which constitute the celebrated "Pandects," or "Digest" of the Roman law; a work without which modern Europe would have known but little of the subject. Along with Theophilus and Dorotheus, the indefatigable commissioner was able to prepare, in conjunction with this great digest of the law, an abridgment or manual of its leading principles, which bears the well-known name of "The Institute." This condensed and elegant little work was sanctioned by the emperor in 533. It has become the subject of innumerable comments, and has afforded the model on which the legal writers of most modern nations have desired to prepare their treatises. Justinian continued, during the remainder of his life, to promulgate new laws; and these, collected together under the title of "*Novellæ*," or "Novels," form the remaining department of the "*corpus juris*," or body of the civil law.

With Justinian we reach the climax of the Roman law; and to trace its farther progress in the empire has been more a subject of curiosity to the antiquary than of importance to the lawyer. Some fragments by later commentators, chiefly in the Greek language, have been disentombed by zealous searchers. The Roman law was nominally respected by the northern conquerors of Rome. Alaric, King of the Visigoths, indeed, caused a compendium to be prepared for the use of his dominions, consisting chiefly of an abridgment of the codes of Gregorius, Hermogenes, and Theodosius. Towards the end of the ninth century, Basilius, Emperor of the East, issued a new code, intended to supersede the labours of Tribonian, termed the "*Basilica*."

In the dark ages, however much of the Roman law may have remained in practice, it had died away in literature, and was neither studied nor commented on. At the taking of Constantinople in the fifteenth century, only one copy of one of the Justinian labours, *the Novels*, seems to have been discovered. It was long believed, indeed, in the learned world, that from the period of the Basilica to the twelfth century, the very existence of the Roman law was among the things forgotten. The circumstance of its resuscitation were found in a traditional anecdote, that at the seige of Amalphi in 1137, some Pisan peasants discovered a complete copy of the Pandects among the plunder, the melodious language, comprehensive philosophy, and clear definitions of which, so charmed the readers of that barbarous age, that its contents were immediately devoured with avidity and propagated with zeal. In Florence, a manuscript is still preserved, said to be the identical book with which this anecdote is connected, taken at the siege of Pisa in 1406. The essence of the tradition has been disproved by late discoveries, which show that the civil law was known previously to the siege of Amalphi.

The real revival of the civil law is to be traced in the history of the universities. Of these, Paris, Bologna, and Leyden, took the lead in the department of jurisprudence. Contemporary with, or immediately after the siege of Amalphi, lectures were given on the Pandects in the University of Oxford, by a teacher of the name of Vicarius. For reasons which we shall have to state when we come to treat of the laws of England, the civil law, thus early commenced, never made much progress in England. Nor, although the civil law was so prominent a subject of professional study in Scotland, has that part of the empire done much to elucidate the science. Both England and Scotland, indeed, have produced writers on the civil law; but with one or two exceptions, the British jurists are not among those names which become familiar to the readers on the subject, from the frequent reference made to them by subsequent commentators. The earlier modern civilians followed three oracles, Bartolus, Baldus, and Accursius, whose works, it is believed, the most enthusiastic admirer of the study would not now peruse, and who probably retain their chief celebrity from having been targets for the wit

of Rabelais. In the seventeenth century, more elegant and philosophical commentators followed, and the subject was pursued with zeal to the middle of the following century. A prodigious number of civil law books issued from the press during that period; and we have heard it asserted, that a complete collection of all the books published on the civil and canon law would make a library of two hundred thousand volumes. The labours of Godefroy alone are sufficient to make a modern literary collector shudder; and there is perhaps no surer mode of comprehending what human patience and perseverance is capable of, than the contemplation of a civil law library. Holland has been profuse with great authorities: Grotius, Matthæus, Schulting, Noodt, Voet, and Huber, belonging to that country. Germany produced the philosophic jurist Puffendorf, and Heineccius, whose elementary works, as the clearest and most methodical of the commentaries, have been popular as class-books of civil law. Among modern investigators in this science, the Germans have taken the lead.

To give a general outline of the Roman law, would be to describe the common principles of the majority of the codes of civilized mankind. Although the progress of commerce and manufactures has introduced a quantity of transactions—such, for instance, as bills of exchange—which the Roman lawgivers could never have contemplated, yet their system is the foundation of all the commercial laws of Europe, a circumstance which has probably facilitated the uniformity so necessary in transactions which involve inhabitants of different countries. From the same source, Scotland and the greater part of continental Europe have derived a marriage law so different from the ceremonious system that prevails in England. Its leading principle is, that the consent of the parties alone is necessary to a valid marriage, and that when that is proved, nothing more is necessary; and that a child born between parties who are subsequently married, becomes legitimate by that act. The law of trusts and of the mutual rights and obligations of guardian and ward have found their way, more or less, into every modern system, and even into the statute-law of England. Prescription, or the principle that claims are limited by the lapse of time, has come down to us from the Romans. The law of testaments and the descent of movable property is mainly derived from the same quarter. It is in the case of the tenure and transmission of land, indeed, that the person versed in modern systems will find himself least at home in the Roman, from the effect which the feudal institutions of the various nations of Europe have produced on that branch of the law. The subjection in which children were placed to their parents is apt to create surprise, even when compared with the strict filial etiquette of our own ancestors. A revolting feature of the *corpus juris* is the portion of legislation devoted to the subject of slavery and the property in slaves.

The Roman law has already been mentioned as the source of the law of nations, or, as it is more justly called, the international law, in modern Europe. It was quite natural that a system voluntarily adopted among nations for regulating their mutual intercourse, should be founded, to as great an extent as might be expedient, on the system of the internal laws which the majority of the nations had chosen to adopt. But the law of nations is perpetually varying with circumstances, and it is impossible to draw that distinct view of its nature and provisions which may be given of the laws of any particular state. It has been argued, indeed, that the term "law" is improperly applied to the system. Wherever the term law is used, there is understood not only a regulation laid down, but a means of enforcing it in the hands of a superior power. The civil and criminal laws are enforced by the ordinary courts; the military law by courts martial; the law of the church, by the ecclesiastical courts, &c. But who, it is said, is to be the judge to enforce the law between nations? When two nations have a dispute, and their power is equal, it remains undecided; if the one is much superior in strength to the other, it has matters its own way. In the late war Great Britain maintained that she had a right to search all neutral vessels, for the purpose of ascertaining if they contained contraband goods or sheltered deserters. The smaller states were bound to submit; but America resisted, and the dispute occasioned a bloody war. So it probably will be again, when the same claim is urged. Instead of being a fixed law applicable to all, the weak will have to obey, and the strong will resist. For the enforcement of any rules that may be called the law of nations, then, it is clear, that there is no better sanction than this, that the powers which openly outrage them will call forth a degree of indignation on the part of the rest of the world which may prove dangerous. The partition of Poland, for instance, called forth the indignation of the rest of Europe; and it may be still a question whether the requisition was a prudent one to the nations concerned. It is not to be supposed, however, that there are no courts where the law of nations is enforced. Each country in Europe has generally a court where its own views on the subject are laid down. England has, for instance, the prize jurisdiction of the Court of Admiralty, which is thus called a civil law court. During the late war, when Napoleon by his Berlin decrees declared Great Britain and her colonies in a state of blockade, and Britain retaliated by the orders in council on the rest of Europe, a multitude of cases where the ships of neutral powers had been seized for breach of neutrality were adjudged. And here a circumstance occurred which could not take place probably in any other country, that the view taken of the law of nations by the judge was different from that taken by his government; for Lord Stowell declared that a blockade could not be held to exist by mere proclamation, but that there must be present on the spot an armament sufficient to enforce it.

One of the principal defects of the writings in the civil law, and one that renders the subject in a great measure unpopular at the present day, is the spirit of speculation with which they are imbued, and the extent to which they carry divisions and arrangements which are of no service in practice, and provide for wants purely hypothetical. The civilian in his study, shut out from the world and ignorant of its pursuits, set his brain at work to create the various exigencies of practical life to which the maxims of the institute were applicable, and to devise how they could be applied; but when his labours were brought to the light of day, it was found that the world in its practice and he in his thoughts had taken totally different routes, and that the one could not be the companion of the other. If a tailor make clothes with another man's cloth, to which of the two shall they belong? If an artist paint on another man's canvas, who shall be the proprietor of the picture? Such were among the subtleties discussed among the Roman jurists. In later days, when legislators have too much to do in keeping up with the practical demands of society to indulge in hypothetical law-making, such subjects would not be taken up until cases of difficulty actually occurred; and then, before deciding the abstract questions, it would probably be asked under what circumstances tailors are likely to make garments out of cloth which does not belong to them, or artists to paint on other people's canvas!

THE CANON LAW.

The Canon Law is, properly speaking, the ecclesiastical law of the Roman Catholic Church. In its more limited acceptation, it may be called the by-laws of the church as a separate corporation; but its field widened

with the influence of the hierarchy. It embraced many subjects of purely civil and municipal law, such as the distribution of property between married persons, succession, &c., by linking them with ecclesiastical matters; and thus the clerical tribunals came to rival, if not to excel in importance, those of the state. The canons of the Greek church, a portion of which were said to be the work of the apostles, added to and explained by general councils, were sanctioned by the Novels of Justinian, and have so been viewed as a portion of the body of civil law. A collection of canons was made in the year 520; and this work, with the papal decrees, and the privileges conceded to the church by Charlemagne, formed the chief subject-matter of the canon law down to the twelfth century. It was then that this law ceased to be the mere regulations of a peculiar body, and became a general system of jurisprudence. About the year 1114, a collection of the decrees of popes and cardinals was commenced by Ivo, Bishop of Chartres, and was revised and completed in 1149 by Gratian, a Benedictine monk. Another element in the system consisted of the Decretals which were rescripts or epistles by the pope, or by the pope and cardinals, deciding how the law of the church stood concerning disputed matters referred to them. These were first collected and edited in 1234 by Raimond de Renafort, chaplain to Gregory IX. This work was divided into five books, to which a sixth was added under the auspices of Boniface VIII. in 1298. These two great works, with some additions made to them by succeeding popes, formed what, in imitation of the collected works in the law of Rome, was called the *Corpus Juris Canonici*, or body of the Canon Law. Besides these general statutes, there were local canon laws passed by the clergy of various countries, at national or provincial assemblies, held under the auspices of papal legatees or archbishops. In the reign of Henry III. there were assemblies of the former kind; and under the respective archbishops of England, there were frequent provincial synods. In Scotland, two provincial synods, held at Perth in 1242 and 1269, passed some important laws regarding tithes.

The great aim of ecclesiastical legislation was to bring civil questions within its pale. Disputes as to tithe and the privileges of the clergy came very naturally to its hand. The priesthood were in a great measure intrusted with the administration of legacies, especially where they were destined to pious uses; and they thus acquired a jurisdiction in questions of succession, of which we see vestiges in this country, in the Court of Arches and the other ecclesiastical courts of England, and the commissary system in Scotland. Marriage being constituted a sacrament, the canon law not only took into its hands all questions regarding the union and separation of the parties, but adjudged in the criminal act out of which the latter circumstance might arise, and took under its cognisance questions as to dower. The church obtained a powerful hold over the proceedings of ordinary courts of law, by the introduction of the practice of witnesses and parties calling God to attest the truth of their statements—the origin of the present system of administering an oath. Over this ceremony, and all matters connected with the truth or falsehood of the statement it sanctioned, the clergy took a particular charge. Notaries, who in the days of ignorance were intrusted with the execution and registration of contracts—who, in fact, were the living registers of almost all transactions of importance, were necessarily taken from the only class who could write—the churchmen, and their appointment and removal naturally fell into ecclesiastical hands.

A great rivalry thus existed between the civil and the canon law; but it was a friendly rivalry. The clergy were the repositories of both systems, and they had to decide how much should be assigned to the one and how much to the other. The canon law borrowed largely from the civil, of which it is sometimes considered a mere branch; it was naturally, indeed, the object of the clergy not so much to change the law itself, as to take the administration of it into their own hands. To be *juris utriusque doctor*, or doctor of either law, civil and canon, was a common distinction. During Henry VIII.'s reign, lectures on the canon law were abolished in England, and with them the corresponding degree. Jealous as the English were of the encroachments of the civil law, they still more determinedly opposed that of the canon. What the powerful court of Rome had set its heart upon, however, could not be wholly resisted; but it was always a principle, that though the civil authorities of England might take laws from the ecclesiastical system, the canon law was never, in its own simple authority, to be obeyed within the realm.

THE FEUDAL LAW.

The feudal system and the Roman law may be said to have struggled for supremacy through nearly the whole of modern Europe. Of the influence of the latter we have already taken a cursory view. The former was an ingredient in the constitution of the continental and British monarchies. It was the source of those popular or aristocratic assemblies, which shared, more or less, according to circumstances, the government of the various states in which they existed; and it was thus the ostensible origin of the British parliament. Trial by jury has been traced to a similar source. The constitution of the German empire is essentially feudal, and the customs, or peculiar local laws of the various provinces of France, previously to the revolution, were models from which the system was studied. The English law, especially that of real or landed property, is full of feudal usages, though their operation has often been checked. In Scotland, the forms of the feudal system may be found existing in almost original purity, though, as we shall hereafter see, they have been adapted, perhaps as far as they are capable of being so, to the wants of civilized times.

An account of the rise and progress of the Roman law must, for obvious reasons, be far more satisfactory than any that can be given of the feudal system. The former was (at least the greater part of it) the construction of ingenious individuals, possessed of authority to enforce their mandates on their fellow-beings. The latter gradually rose out of circumstances, and the state of society. It was not devised by a powerful legislator, to be promulgated to a willing people; but it rose out of habits and events which took place in an age when there were no historians to record their progress. Hence, the origin of the feudal system has been a fruitful system of debate and theory; and in the absence of facts, it has often been necessary to resort to moral deductions. It has been maintained by some, that nothing can be more simple than the feudal system; that it was a mere arrangement by which military service was given in exchange for land, and that many half-civilized nations present instances of a similar contract. Ingenious speculators have found the resemblance of the system in particular stages of the history of Greece and Rome, in Turkey, Persia, Hindostan, and the Highlands of Scotland, among the aborigines of North America, and in the Loo-choo Islands. But, however important may be the investigation of such analogies between the practice of mankind under different circumstances, as a part of the history of the human mind, they throw but little light on the feudal system, the chief interest of which is to be found in the vastness of the field which it covered, and the influence which it has exercised for so many centuries over the legal institutions of Europe.

Since we can only say that this system existed, and cannot tell, as we have done in the case of the Roman law, the precise hands from which it came, it may be

better to commence with some account of its leading principles, reserving for after detail a history of its progress. The essential elements of the system were land, and military service given for the use of it, by the vassal who held it, to the superior of whom it was held. It would be wrong to speak of either of these two parties as the absolute proprietor of the lands; for, in the more perfect stage of the system, each had his own peculiar privileges, with which the other had no right to interfere, except where the law permitted him. The vassal was not, in the general case, the slave of the superior. The duties and services he had to perform were regulated by compact or custom. On the other hand, however, he was not the independent proprietor of the lands he held. He could not convey them to a purchaser, nor could he pledge or bequeath them, without obtaining the sanction of the superior to the person to be substituted to him. Land was thus completely removed from the operation of commerce; and in those countries where the feudal system continued to exist, it was only by fictions and connivances—by bribing the superior, or getting the courts of law to compel him to give his consent—that sales and pledges could be effected. The lands held in this manner were termed *fiefs*. When they became hereditary, as they did apparently by custom, arising from the tacit consent of the parties interested, the superior was still presumed to give an assent to the change from father to son; and before he acknowledged the latter as his vassal, he exacted from him a fine. When the successor was a minor, and thence unable to fulfil the military duties of the fief, the superior in some cases became his guardian, drawing the rents of the estate, and compelling him to marry whom he should point out, under a penalty, which, it would seem, ought to amount to the sum which the guardian, or superior, could receive by selling the alliance. The superior's claim upon the estate during the vassal's minority, became, like most other feudal exactions, fixed by usage, and seems in general to have amounted to one year's rent of the land. In some countries, females could not succeed. In others, where their right was acknowledged, the superior claimed the privilege of assigning husbands to them; and exacted a fine, sometimes for admitting the husband as a new vassal, sometimes as the price for permitting him to marry his ward. The feudal system, like every other, had its degrees of goodness and badness. Where we find the milder features of the feudal law, the right of the lord over his female vassals, or the wives and children of his followers, was a mere tax; but where the darker influences of the system were at work, it gave legality to a licentious despotism, which is frequently adduced as a disgusting memorial of the barbarism of feudality. Of illustrations of despotism, indeed, the feudal system is full. Independently of its own peculiarities, it would have been impossible for any legal system to have passed through the scenes of rapine, blood, and barbarism which characterized the middle ages of Europe, without being the instrument of many iniquities. At the outbreak of the French revolution, which at first was little more than an attack on the most offensive relics of feudalism in France, some of these horrors were dragged from their dingy retreat in parchment records and black-letter chronicles, to add to the frenzy of the times. Among other instances, was adduced that of a feudal lord, on his return from the chase in winter, disemboweling a vassal, that he might keep his feet warm in the reeking trunk during the evening revel.

The proper return of the vassal for his lands and the protection of his lord, was, as already stated, military service. Where this system was established as a fixed law, the quantity of service to be so given was regulated. A knight's fee imposed on the holder the duty of being forty days in the field for his superior, and the half or quarter of a knight's fee involved corresponding proportions of service. When fiefs came first into existence, it is probable that there was no other service worth possessing but the use of the strong arm. Conquered land was what the chief possessed, men to fight more battles was what he wanted; so that the one became the price of the other. It was not always the case, however, that land was valuable for nothing but as the reward of fighting, and it was gradually bestowed for other considerations; yet so closely connected had the relation of a military tenure become with land, that any other method of disposal was considered as irregular, and merely exceptional. Hence, when land was given without a price, and for the understood return of military service, it was said to be a proper feu; when any other consideration, such as a sum of money, was stipulated for, it was said to be improper. The former was always presumed to be the condition on which land was given, the latter required to be specially proved, and the unwillingness to admit it called for those legal subtleties which have made the commerce in land, to this day, so complicated. It behoved that there should be possessors of land who were not of necessity soldiers, and it was necessary to the monarch, or feudal superior, to employ people in various other capacities. All, however, took the impression and stamp, as it were, of fiefs. Salaries, taxes, honours, and dignities, even board and lodging, were feued out; the person who had engaged to bestow them acted the part of superior, and he who received them that of vassal. The church enjoyed lands which were not exempt from the ordinary feudal services. In the earlier ages, churchmen in many cases themselves assumed the spear and buckler. When it was considered inconsistent for churchmen to fight, it was held as by no means unsuitable for the church to employ soldiers. A clerical establishment would sometimes appoint a patron, or chivalrous assistant, in the person of a neighbouring baron, who would be called the "advocate" of the establishment—the use, by the way, to which that word, which now designates a class of peaceful lawyers, was first applied. It is not unfrequent to find in old tenures that a particular monastery is to supply so many archers and spearmen for so many days.

Borough communities were another class to whom military service seems inapplicable, but who, nevertheless, almost universally held by that tenure. They obtained certain privileges, and in return they had generally to keep watch and ward in their respective towns; a service in which their own safety might not be less interested than the ambition of their lord. As the privileges conceded to these communities were large and important, they did not, in general, escape taxation along with their military duties; and in later times these exactions became generally commuted for a money payment The privileges usually conceded to these commercial communities consisted of an exemption from the more vexatious of the feudal exactions, to be shortly noticed. These were generally conceded to them by the monarch, as a counterpoise to the growing power of the feudal aristocracy; and within these sanctuaries commerce and civilization created a power, by which both kings and nobility were effectually held in check.

Among those who were placed in the position of feudal vassals to the seignior, or lord, were his own domestic servants, whose power and influence would be, to a certain extent, measured by that of their master. To perform the menial duties of his household, a Roman emperor employed a slave, just as a senator or a proconsul might do. The barbarian conquerors, however, gave lands to those who performed these functions; and the person who performed for Charlemagne the office of butler, valet, huntsman, or groom, got for his services the commodity most readily at his master's hands—portions of conquered territory. The services were thus performed as the consideration for feudal benefices. The

menial servant of the monarch might have tenants and retainers under him; and thus the wages ennobled the functions. Hence we have had, in modern Europe, masters of the robes, grooms of the stole, masters of the buckhounds, masters of the horse, &c., held by the highest nobility of the realm. The *graf*, or land-steward of a district, was an important personage. Instead of attending to the letting of paddocks, and the rotation of crops, he was intrusted with the power of life and death over the inhabitants. The humble grieve, who has the management of a small landed estate in Scotland, and the shire-reeve, or sheriff, who performs high judicial functions in the same part of the empire, have divided, as it were, between them the original duties of the feudal officer from whom their names are derived. The same feudal origin may be as distinctly traced, on a larger scale, in the relation of master and servant in modern times. Servitude, however menial, when allied with feudal dependence, did not carry the same degradation as mere slavery; and in the opinion of some, the situation of the feudal attendant was higher than that of the menial servant of modern days, who freely gives his labour and attendance for a price. In Scotland, where feudal usages have lingered so long, it has been remarked, that the relation between master and servant is of a more confidential nature than it is found to be in other parts of the country. While the line drawn between their positions is as clear as it can well be in a free country, the situation of the servant has a more than ordinary share of respectability attached to it, because, instead of being the individual servant of an individual master, he and his race are looked upon, to a certain extent, as the retainers of the house which he serves. On this point, indeed, an adherence to feudal usages in situations to which they are not applicable, has been productive of one of the greatest evils of modern society—the extent to which servants are kept, not for use, but as an ornamental evidence of wealth. Our lineal aristocracy continue to follow, so far as the usages of the day permit, the practice of their ancestors; and the gentlemen of plush and shoulder-knots are the representatives of those who wore buff jerkins, and handled the pike. The rich merchant and manufacturer must not be without the usual insignia of wealth; and thus a race, whom idleness and constant association with each other must deprave, are kept up among a bustling and active community, as if we lived in the days when the majority must either serve or starve. It has been remarked, that in republics such as Holland, the wealth of rich individuals generally took the more ennobling direction of patronising the arts and literature.

In the earlier ages of the feudal system, when there was much land to distribute, the natural features and boundaries were sometimes little known to those who gave it away. The persons who received it were aggrandizing and ambitious, and not likely to yield to each other disputed portions. Above all, the conquerors were uneducated, and had little means of giving perpetuity to their bounty by written deeds. From all these circumstances, the investiture of the vassal became a very important and solemn affair. Investiture was divided into proper and improper. By the former, the superior went in person to the land, assembled all his other vassals upon it, and showed them the portion he had assigned to his new follower. The vassal, upon this, did homage, accepting the grant, and promising to perform the usual services in return. By the improper investiture, of the full practice of which in our day we shall give an instance, the superior gave authority to his bailiff, or some other person, to give investiture, which was done by the symbolical delivery of a portion of the property—some earth and a piece of stone generally—to the vassal, or some person authorized by him to accept the grant and perform his homage. Writing was probably in use before this latter usage was commenced, and the authority was generally a written one. The solemn investiture in presence of the co-vassals finally descended to a mummery between an attorney and his clerks. The necessity to have acts regarding the fiefs of a superior witnessed by his vassals, can be traced to a connection with two of the most important institutions of modern times. The great vassals of a king met together in public assembly to discuss what aids they might afford for their fiefs, how they were to defend them, &c., merged into a great council or legislature; and it is to such a body that the British Parliament at least partly owes its origin. At this moment, the Bishops of England sit in the House of Lords in virtue of the feudal baronies which they hold of the crown. Vassals of the lower grade were often summoned to attend at the hall of their lord as assessors, or assizers, to give, partly opinion, partly evidence, concerning some matter connected with the fief, or the conduct or rights of a fellow-vassal. With this institution, the system of trial by jury is intimately connected. A jury of perambulation, for the purpose of ascertaining boundaries—a sort of body lineally descended from the assemblage of co-vassals who were present at the investiture, and witnessed the extent of the gift—has been known in modern times.

It is probable, that if the feudal system had only established a relation between the monarch and his immediate vassals, the influence it would have exercised over the state of Europe would have been comparatively slight. The distribution of land as the reward of services is frequently exemplified in history; but that which chiefly distinguished the feudal system, is the numerous grades of dependence, and the manner in which all parts of society, from the emperor to the lowest serf, were bound together in one system of lord and vassal. In the first place, there were various grades of vassals holding of the monarch. The majority of the lower classes, however, generally found themselves under the protection of some intermediate chief. The duke, or count, who held immediately of the crown, sub-feued to a dependant, who, on his part, might dispose of a fragment in a similar manner. By such an alienation, however, the vassal dared not in any way interfere with his superior's rights; the latter, indeed, was not presumed to be conscious of the sub-infeudation, unless he had specially sanctioned it, and by doing so, he acknowledged the sub-vassal as his own immediate retainer. When a vassal, therefore, sub-feued without his superior's consent, he gave only a portion of the estate he himself possessed, his sub-vassal being liable to meet all the exactions that might fall upon him. So, if he rebelled against his lord, or withheld the feudal exactions, the superior could seize upon the fief without reference to the claims of the sub-vassal. The highest feudal noble was the Heretoch, who, from the Latin *dux*, a leader, received the designation of duke: this class was intrusted with the administration of large provinces. The graf, who had a smaller charge, was called *comes*, or count; and one class of graf, who was intrusted with the marches, was called the *mar-grave*, *march-graf*, or marquis. These nobles generally held lands of their sovereign, while they were authorized to represent his person over the districts to which they were assigned, administering justice in his name, levying his feudal exactions on his vassals, and receiving their homage. These powerful feudatories were held in check by Charlemagne; but under his successors, and the other European monarchs, it became their aim to be the independent sovereigns of the territories committed to their charge—an object in which they were more or less successful according to circumstances, some throwing off their master's yoke, while others made themselves intermediate superiors between the king and his vassals. The various states of Italy and Germany are illustrations of the working of these events. The feudatories of France

made a very near approach to independent sovereignties. They possessed within their own dominions the right of coining money, that of waging private war, exemption from all tributes, except the limited feudal duties by which they acknowledged the superiority of the crown, and finally, freedom from legislative and judicial control on the part of the sovereign and his courts. The vassal, too, in looking after his own concerns, sometimes conquered territories not inferior to those of his lord; and under such circumstances there was little chance of his being an obedient retainer. The Duke of Normandy, the vassal of the King of France, became monarch of England, and the Dukes of Burgundy were little less powerful.

From these high personages, vassalage went through many gradations till it reached abject slavery. There were the *vavassors* and *châtelains*, dependants on the higher nobility, but who themselves had large estates and fortified their houses. There were the burghers of free towns, whose privileges have been already mentioned. Of rank corresponding in the rural districts, were the *socage-holders*, and the class so well known in England by the designation *yeomen*. The lowest grade were the *villeins* or *serfs*, to whom was committed the task of tilling the lands which the soldier gained or protected. It was the characteristic of the other grades of feudality to impose duties upon the lord, corresponding to those of the vassal, but the villein had little power to exact performance of these regulations. There were grades, however, even among the serfs, though probably there were not instances in which one held of another as vassal and superior. The peculiarity of the class was, that they were astricted to the domain, and went with it when it changed hands. Some, however, had rights and privileges which they might maintain in the court of the manor of their lord. Some held small estates, which, however, they could not dispose of. The lowest class were as abject as the slaves of the Romans.

The different classes of feudal taxes have been mentioned above. There were others, however, of a more miscellaneous nature, which were chiefly encroachments on the purer spirit of feudality, dictated by despotism and cupidity. It was upon the vassals who approached nearest to the state of villeinage that these innovations naturally fell most heavily. They were designated "aids," and were demanded by the lord on any occasion which caused him outlay. If he had to make war with a neighbour, or to portion off a relation in marriage, or to ransom a son, he demanded an aid. Aids were profusely exacted by the knights who joined in the crusades. In England, the aids that might be exacted were restricted by *Magna Charta* to three; they were for the purpose of making the lord's eldest son a knight, for marrying his eldest daughter, and for redeeming his person from prison. By exactions in a different form, the more servile vassals were fleeced and kept in subjection. The superior, if he built a mill, astricted all his vassals to grind their grain at it, compelling them to pay a tax for the service they were forced to receive. He compelled them to assist in making roads and building bridges, and he exacted tolls of all below the degree of freeholders who crossed them—a system which placed impediments in the way of vassals escaping from place to place. He obtained tolls and duties, too, on the export and import of commodities; and if he found a clever artisan on his premises, he would keep him and his services for his own use.

The revival of literature was not favourable to pure feudalism. It brought with it the study of the civil and canon laws, and it was through the lights so acquired that the feudal customs were interpreted. The decline of the spirit of the feudal law is matter of history, and a view of it would lead to too long a digression. Not only its effects upon society, but its literal forms, still linger among us; even in republican America there is pride of birth, and a knowledge of the feudal system is sometimes requisite in ascertaining the title to property. Perhaps in no country has the letter of the feudal law been so curiously adjusted to the needs of modern society as in Scotland. As a general illustration of the system, we have drawn up from the notes of a professional friend the following outline of the manner in which land is conveyed and held in that part of Britain. All the land in Scotland is held of the crown, and the greater portion of it is possessed by vassals of the freeholders. Let us suppose one of these vassals selling a portion of his property, for a sum of money down, or an annual payment. There is only one side to the contract—that of the seller, for as he is going to act the part of a feudal lord giving away a benefice, it would be quite inconsistent for the buyer to come under any obligation to take the lands and pay for them. The seller, in a formal document, states, that he makes over the lands, and dictates what series of heirs they are to descend to, and how they are to be held. He then grants an authority to his bailiff to pass to the lands described, and invest the purchaser with them. The investiture is generally managed thus: A notary-public and four other persons repair to the grounds; one of these acts the part of the bailiff, or feudal officer of the seller, or superior; another that of the vassal's representative. The authority is read over, and then the bailiff, with all due solemnity, lifts a stone and a piece of earth, which he puts into the hands of the vassal's representative, who "takes instruments" in the hands of the notary by giving him a shilling, or protests that the ceremony is completed, calling on him (the notary) to attest it. The other two parties are the witnesses. This makes the buyer the vassal of the seller; but it is generally preferable to be in exactly the same position in which the seller was. To accomplish this, the consent of the seller's superior must be had, and according to feudal usage, it is thus signified. In virtue of an authority, or "procuratory," a representative of the seller goes to the superior, or his representative, and by the symbol of a "staff and baton," as the law-books say, but practically of a pen, the lands are delivered into the hands of the superior, who transfers them over to the purchaser by handing the pen to him or his agent. Then follows an investiture by the superior in the above form, which is conducted in virtue of a charter granted by him to his new vassal. To the superior this is not entirely a barren ceremony, for he receives a year's rent of the property to reconcile him to the change of vassals.

THE LAW OF ENGLAND.

England has already been mentioned as an exception to the general prevalence in Europe of the civil and canon laws; not that these systems were totally repulsed, but that they met with a countervailing resistance, which prevented them from obtaining the influence they possessed in other countries. This resistance may be found in the existence of a different, and, it may perhaps be said, hostile system, called the common law, and to the power of parliament to make laws or statutes. The three great elements of the jurisprudence of England are the common law, the law of equity, and the statute law. To these may be added, as codes limited to particular spheres, the admiralty law and the ecclesiastical law.

Speaking of the common law, Sir Matthew Hale, its historian, says: "This is that law by which proceedings and determinations in the king's ordinary courts of justice are directed and guided. This directs the course of descents of lands, and the kinds, the natures, and the extents and qualifications of estates; therein, also, the manner, forms, ceremonies, and solemnities of transferring estates from one to another; the rules of settling acquiring, and transferring of properties; the forms

solemnities, and obligations of contracts; the rules and directions for the exposition of wills, deeds, and acts of parliament; the process, proceedings, judgments, and executions of the king's ordinary courts of justice; the limits, bounds, and extent of courts, and their jurisdictions; the several kinds of temporal offences and punishments at common law, and the manner of the application of the several kinds of punishments; and infinite more particulars, which extend themselves as large as the many exigencies in the distribution of the king's ordinary justice require."

Common Law.—The origin of this system, one of the most interesting subjects of modern investigation, is involved in deep obscurity. Its progress, subsequently to the reign of Edward I., who has been called the English Justinian, is pretty accurately noticed; but when an unprofessional inquirer reads those portions of English law-books which attempt to carry the history to an earlier period, he cannot help feeling disappointed at the unsatisfactory result. The more marked features of the system were, doubtless, the customs of the Anglo-Saxons. A collection of the laws of England during the heptarchy, or laws of the Anglo-Saxons, was published by an eminent antiquary, at the commencement of the eighteenth century; but there is great reason to believe that they were written some centuries after the Conquest, while the fragments of Anglo-Saxon legislation which they contain refer chiefly to the arrangement of the military force, the clergy, and other matters of general or police regulation, which, in the present instance, are less interesting than a little insight into the laws relating to private rights would be. Alfred and Edgar have acquired much fame for having collected and emanced the laws of their predecessors, reformed them where they were impolitic, and completed them where deficient; but it would be difficult to determine their exact merits. Edward the Confessor enjoys a similar reputation. To him, indeed, history supplies us with good ground for referring equitable laws, for we find that when the people complained against the oppression of the Norman kings, they demanded "the good old laws of Edward the Confessor." It is probable, however, that the compliment did not apply to him so much in the capacity of a legislator as that of the last of the Saxon kings.

Whatever may have been the exact nature of the laws of the Anglo-Saxons, the Conquest effectually incorporated them with the feudal system, and the connection between vassal and superior became one of the most important features of the common law. It is not to be supposed, however, that this was the earliest visit of feudal institutions to Britain. The Saxons could not well escape the influence of a system which had deeply rooted itself among the kindred nations of the continent; and many feudal institutions are to be found existing under the Saxon kings. The increase of the spirit of feudalism under the sway of William the Conqueror was, however, so great, that many authors have attributed its origin in England to the era of the Conquest. It was then, indeed, that it became oppressive. The conqueror brought with him the system of his own province, for which he was a vassal to the King of France, and could not admit the possession of landed property in England, except as held from himself in the capacity of lord paramount. The greater nobles—chiefly the conqueror's companions in arms—naturally held the lands he liberally bestowed on them of him as superior, and they compelled all who lived upon their lands, or even in their neighbourhood, to acknowledge them as liege lords. The forcible increase of such a system as the feudal law, could not but be attended with acts of great oppression. These were added to by the selfish magnificence of the princes, who cleared large tracts of country of inhabitants, that they might enjoy the regal pleasures of the chase in undisturbed tranquillity. The Saxons had their own county courts, but the greater part of the causes were, after the Conquest, removed from them to be pleaded in the court of the monarch, which attended on his own person. Legal proceedings were conducted in the Norman dialect of the French, which was afterwards changed into Latin. The use of a tongue unknown to the people at large, continued down to the days of Oliver Cromwell, and at the restoration was restored, with other equally useful practices. It was abolished in as far as respects the proceedings of the courts of 1730.* If we knew nothing of the veneration with which the Saxons looked back upon "the good old laws of Edward the Confessor," the obstinacy with which they preserved their language would have led to the presumption that they had been equally tenacious of their ancient customs. The former outlived every attempt, moral, intellectual, or physical, by reprobation, sarcasms, or force, to extinguish it, and so, to a certain extent, did the latter. The judicial system, and the tenure of land, might both be altered; but to their original customs the people adhered so resolutely, that these were at length blended with the opinions and feelings of their Norman tyrants, and became to a certain extent the system of law which they administered. There was a further leaning on the part of the barons to the popular customs, from this circumstance, that the priests, whom they viewed as dangerous rivals, attempted to introduce the doctrines of the civil and canon laws. Hence it was, that at the parliament of Merton, in the thirteenth century, when an attempt was made to legalize the principles of the civil law with regard to marriage, and some other important points, the barons made that memorable declaration. "We will not change the laws of England"—words which, like every expression that becomes celebrated, have been used to very absurd purposes.

The charters that were so often granted by the earlier kings to the importunity of their subjects, were partially restrictions of the tyranny of the feudal law, and partially promises to adhere to the old Saxon customs—promises which would not have been so often exacted if they had not been continually broken. The most celebrated of these is that conceded by King John, called Magna Charta, or the Great Charter. Its privileges are, in a great measure, constitutional, and it has often been said that it was procured for the advantage of the aristocracy, and not of the people; but it is not without stipulations in favour of the latter, protecting them both from the crown and the nobility. It restricts the tyrannical forest laws, and the exactions by feudal lords from their vassals. The clause which has attracted chief interest, however, is that which says that no freeman shall be affected in his person or property, save by the legal judgment of his peers, or by the law of the land. Legal writers have found a stately tree of liberty growing out of the seed planted by this simple sentence. They see in it the origin of that judicial strictness which has kept the English judges so close to the rules laid down for them in the books and decisions of their predecessors. The judgment by peers is said to refer to jury trial, and it is urged that the whole clause strikes against arbitrary imprisonments, and involves the principles of the *habeas corpus*, by which every man, whose liberty is restricted, may demand to be brought before some competent court, that he may be either convicted or liberated. The great

* For many purposes connected with legal practice, Norman continued to be employed—law-books were written, and cases reported in it. The following specimen of a formal document of the end of the sixteenth century gives a grotesque picture of the manner in which languages were twisted to suit the convenience of those who used them:—

"Fuit resolve per le pluispart de les justices et le counsell del Roigne, cest terme à Sergeants Inne, in presentia comitis Sussex Justic. Forestar extra Trentram, que le building dun novel Meuse in le severall soyle on waste daseun home deins un Forest, est un purpresure et noyance al Forest et Game, et finable ou arrenable, pour le tolleration ou permission de ceo destroyer al arbiterment et discretion del justice, ou tenable et destrue al pleasure," &c.

charter has always been a favourite object of veneration, both with the aristocracy and the people, and Sir Edward Coke reckons thirty different occasions on which it was ratified.

Civil liberty may be defined as the permission of such an amount of free action as it is most conducive to the welfare of all that each individual should possess. This is one of the most important objects of the laws, and the circumstances which conduce to its existence are among the most interesting in legal history. In England, the progress of liberty has been in a great measure attributed to the division of interests in the country. The crown had an interest in checking the power of the great nobility. That the exercise of this power was essential to the liberty that has existed in England, is apparent in contemplating the state of France and Germany, where the aristocracy made themselves either quite or nearly independent of the crown, and revelled in the tyranny of their despotic will unchecked. A very important blow to the power of the aristocracy was accomplished by Edward I. in 1290, by the abolition of the system of sub-feuing. From that day, no vassal of the crown could grant lands to be held of himself, as he may to this day in Scotland—he could only put a new vassal in his own place, as an adherent of the crown. There is evidence that a similar law was passed in Scotland, but the crown was not strong enough to enforce a law that deprived the aristocracy of the dear privilege of being petty sovereigns. The disputes with the church were not without their service. The attempts of the ecclesiastics to urge the claims of their Roman and canon laws, caused the common lawyers to isolate themselves from the slavish doctrines of these systems, and to resist their encroachment with true professional hatred. It was in the universities, of course, that the clergy had their chief influence; and the students of the common law formed themselves into rival institutions, from which originated the Inns of Court. Then there was in the boroughs a separate interest, powerfully pointing towards freedom, and possessed of an influence not to be despised. The tendency of all these circumstances seems to have been, a gradual return to Saxon freedom, and a fixing of the common law in conformity with the long-cherished feelings of the English people.

That strong-minded and clear-headed man Edward I., whose ambition was so heavy a curse to his neighbours, took a great stride in the establishment of the common law. Of his reforms, as enumerated by Blackstone, we give the following specimens:—"He established, confirmed, and settled the Great Charter and Charter of Forests. He gave a mortal wound to the encroachments of the pope and his clergy, by limiting and establishing the grounds of ecclesiastical jurisdiction; and by obliging the ordinary, to whom all the goods of intestates at that time belonged, to discharge the debts of the deceased. He defined the limits of the several temporal courts of the highest jurisdiction—those of the King's Bench, Common Pleas, and Exchequer—so as they might not interfere with each other's proper business; to do which they must now have recourse to a fiction, very necessary and beneficial in the present enlarged state of property. He settled the boundaries of the inferior courts in counties, hundreds, and manors, confining them to causes of no great amount, according to their primitive institution, though of considerably greater than by the alteration of the value of money they are now permitted to determine. He secured the property of the subject, by abolishing all arbitrary taxes, and talliages levied without consent of the national council. He guarded the common justice of the kingdom from abuses, by giving up the royal prerogative of sending mandates to interfere in private causes. He instituted a speedier way for the recovery of debts, by granting execution, not only upon goods and chattels, but also upon lands, by writ of *elegit*, which was of signal benefit to a trading people, and upon the same commercial ideas, he also allowed the charging of lands in a statute merchant, to pay debts contracted in trade, contrary to all feudal principles." This last-mentioned reform refers to measures for enabling a creditor to get possession of his debtor's land in payment of his debt. How opposed such a remedy would be to feudal principles may easily be conceived, and the boldness with which Edward made his reforms will be felt when it is considered that what he had thus commenced was only completed in 1833. If the debt of a landed proprietor were not substantiated by some bond or other document, his land could not be applied in payment of it on his decease, and it was only in that year that landed property was made fully available for "simple contract debts." The statement that Edward imposed limits on ecclesiastical jurisdictions, refers to the authority which the clergy arrogated regarding wills—mentioned under the head of the canon law. Edward allowed them the charge of the deceased's effects, but compelled them to employ the money in paying his debts.

From the period when we discover any branch of the common law in existence, we find its observance rigorously enforced by the judges. Of course, they had very frequently, as society progressed, to apply it to the wants of an age very different from that in which it was invented; but, in doing so, instead of directly altering the law, which they always viewed as beyond their power, they accomplished the change by a manœuvre almost peculiar to the law of England, called "a fiction." A fiction may be defined to be the taking for granted that a thing has been done which has not been done, and acting accordingly. For instance, if a man had taken an article in loan or on hire, and refused to give it up to the owner, the legal remedy, by the common law, was a very complicated one. In the case, however, where a man had found another's property which he refused to restore, there was a very expeditious and distinct remedy. It occurred to lawyers, that the kind of process used in this latter case was the very thing that would be most suitable for the other; and therefore, when they brought an action against a person who thus wrongfully detained the goods of another, they stated that he had found them, and the judges, agreeing in the propriety of the form of action being applied to the purpose, would not allow the party to show that there was no finding in the case. Hence the well-known action of trover, from the French *trouver*, to find. Some curious illustrations of fictions of law will be given when we describe the method in which the courts acquired their jurisdiction.

Fictions were not, however, the only means by which the judges, while adhering apparently to the letter of the law, could adjust it to their own views of the wants of society. A far-seeing judge who looked forward to the probable rise of a new system of transactions, could, by a swaying of the principles of the law that might be quite imperceptible at the moment, adapt them to the new exigencies. It was thus that Lord Mansfield, without the aid of statute, created the law of insurance. There are frequently many underwriters, or insurers to a policy, and had the practice been as it was, each would have had to be prosecuted separately on the occasion of a loss; but Mansfield, by a very slight divergence from previous practice, brought all the claims in a policy into one action—an expedient without which the system as it at present stands could not have existed. This was accomplished by a rule of court known by the name of the consolidation rule, by which all the actions except one is stayed, on the various defendants becoming bound to abide by the issue of that action. In their covert efforts to change the laws, the judges did not spare even acts of parliament. They managed to hit a blow at the power of the aristocracy, by limiting the operation of the statute of entails. When the holder of the entailed

estate wished to sell it, he let the buyer bring an action against him, alleging that he had no title. He said he had bought the property from some one—usually the crier of the court—whose duty it was to support his title. The crier being called in, made default, and was nominally adjudged to give the holder under the entail an equivalent, with whom there was no effectual competitor, while the estate was adjudged to the purchaser.

The repositories of the common law are the treatises of eminent lawyers and the reports of decisions. Of the former, there are several of the thirteenth and fourteenth centuries—Glanvil, Bracton, Hengham, and the book called Fleta, the authorship of which is unknown. Lyttleton's treatise on Tenures, the work of a more matured system, was long the text-book in the practice of the feudal law. It was in the humble form of a comment on this work, that the great Chief-Justice Coke issued the vast treasury of legal learning so familiarly known as "Coke upon Lyttleton," a book which is in itself an almost inexhaustible subject of study to the lawyer. The next great name is Blackstone, a man who brought elegant accomplishments to bear on the austere drudgery of the law, and wrote a book, the clear perspicuity of which has made many men acquainted with the laws of their country who would have otherwise remained profoundly ignorant of them. The book has one great defect, that, professing to be not merely an exposition of the laws but an estimate of their worth, it bestows indiscriminate eulogy on all the vices of the system as well as its advantages. The reverential eye with which English lawyers look upon whatever is ancient in the common law, is singularly apparent in the majority of law-books. If any great authority, such as Coke or Blackstone, has treated of a particular subject, whoever afterwards writes upon it seems to be held bound to incorporate all that he has said, not only in spirit but in words. As the passages are not marked as quoted, the effect is a very peculiar one; for the reader, after perusing a few sentences in the easy flow of the nineteenth century, finds himself unexpectedly entangled in the quaint language of the reign of James I., without the slightest hint that he is going to get, not the statement of the author himself, but something taken from Coke or Spelman. Of the reports of cases there is now a vast collection. From the time of Edward I. to that of Henry VIII., they were annually collected by officers appointed for the purpose, and were called Year-books. They have latterly been published by private reporters. As they are all precedents for guidance in succeeding cases, and therefore the source to which the public look for the interpretation of the laws they must obey, it may be questioned whether they should not be officially recorded by persons responsible for the accuracy of their reports. This plan has, to a certain extent, been adopted in America.

Law of Equity.—The peculiar strictness with which the common law was administered, gave rise to the other great division of English jurisprudence—the law of equity. This was originally a system by which relief was given in cases where a strict interpretation of the common law would have produced injustice. It could look to the influence of accidents and frauds when common law could not. A deed, for instance, was lost. The common law courts could hear nothing about what might have been its contents. They could see nothing, know nothing, act on nothing, but the express words of the deed as set before them, and as that could not be found, the party must suffer. Here the court of equity came to his relief, by compelling a "discovery" of the contents of the document. When a trustee was put in possession, common law could not look at him in any other light but as holding for his own behoof; but equity compelled him to do his duty to his employers. Where an obligation was to pay, common law could comprehend its nature and exact performance, but if it was to perform any other act, the assistance of equity was generally necessary. Again, the courts of law might give a remedy for a mischief after it had been perpetrated, but they could not interfere to prevent it. This necessary branch of legal administration came likewise within the jurisdiction of the judge in equity, who, on cause shown, could issue his "injunction."

The origin of this system is as obscure as that of the common law, though it is evidently of a more modern date, having been introduced as a remedy to the evils of the latter. The earlier law-books do not mention it, and it was probably long in operation as a sort of exception to the ordinary course of law, before lawyers would acknowledge it as a system. Its most plausible origin is simply this—that when a person suffered a manifest injury, which the ordinary courts could not remedy, he applied for redress to the sovereign in person. The king's conscience-keeper, or chaplain, became the referee on these occasions, and what he did he sealed, by way of testimony of the royal authority, with the king's seal. Hence the origin of the lord chancellor with his great seal, whose office, in this form, has been traced, or imagined to be, [illegible] far back as the days of Edward the Confessor. [illegible]nes, the chancellors were ecclesiastics, and they were in the habit of adjusting their equity, [illegible] in which they administered it, to the civil law, [illegible]sioned great feuds with the common law [illegible] at the commencement of the seventeenth [illegible]d so fierce, that in a case where a remedy was sought in equity from the proceedings of the Court of King's Bench, the lawyers who conducted the proceeding, and a master in Chancery, were indicted for an offence. With the assistance of King James, whose legal notions were derived from the civilians, the courts of equity triumphed. The great Sir Edward Coke was then at the head of the King's Bench—a man who, notwithstanding his harsh and tyrannical acts, must still be admired for the bravery with which he supported the strict administration of the law, however high might be the personage who wished to evade it. Whatever may have been the origin of equity, it became at last a fixed system of law. It is a popular mistake that a judge in equity gives his decision according to what is called "the general principles of equity and justice," without reference to strict rules. He is bound down by precedents and rules, and there are many acts of parliament which regulate his proceedings; so that, in reality, equity is but a department of the general system of law.

Statute Law.—We have now to speak of the third branch of the law—statutes, or acts of parliament. The constitution of the legislature by which they are passed does not belong to the present subject; it need only be observed, that to be law, every word of an act requires to have the consent of the three branches of the legislature—the sovereign, the lords, and the commons. In very early times, acts of parliament seem to have been petitions by the parliament acceded to by the sovereign. The parliament was convened to supply the king with money, and while it kept him in suspense, it sometimes prepared a petition against grievances, to which a needy monarch found it prudent to accede. It became a practice for the judges, at the end of a session of parliament, to convert the substance of the "petitions," or "bills," which had been acceded to by the king, into acts. This practice was fraught with manifest danger, the judges having the power, when parliament had ceased to sit, of altering the intended provisions. To remedy this, the plan now followed was adopted, of making the bill contain the exact words which it was intended should constitute the act. Singularly enough, the bill is still in the form of a petition, and when it is made an act, all the alteration that takes place is, that the words "May it therefore please your Majesty," are taken out. A bill may be in-

troduced either in the House of Commons or in the House of Lords. It is a rule, that all bills affecting personal station—such as bills of attainder for treason, bills for naturalizing foreigners, &c.—shall make their first appearance in the House of Lords. The commons possess the more substantial privilege of originating all bills of supply, or for the levying and appropriation of taxes. The privilege is jealously guarded, and it is usual, should the House of Lords amend such a measure, for the House of Commons to refuse to take it into consideration again, and to authorize their speaker to throw it over the table. About seventy years ago, in the case of a bill for the protection of game, the House of Lords thought fit to raise the penalties higher than those sanctioned by the lower house, and as the money went to the exchequer, the commons considered this an infringement of their privileges, and acted accordingly. All measures involving taxation originate in what is called "a committee of supply," in which the house is presumed to be sitting, not to debate great questions, but simply to transact pecuniary business. In the case of the introduction of any ordinary bill, amending the law, into the House of Commons, the first stage is, to obtain leave from the house to "bring it in." In the House of Lords, a member may move a bill without previously obtaining leave. On a bill being brought in, the next step is the first reading. A member moves that it be read a first time. If there be a party in the house bitterly opposed to the principle of the measure, it may be opposed in this stage, and a debate and division will of course ensue. If the objections be merely to the details, they are reserved for a future opportunity. On its passing this ordeal, the bill is ordered to be printed. The next ordeal is the second reading, after which the bill is referred to a committee of the whole house, to be examined. In this committee, as in a committee of supply, the body is the same in every respect as that which constitutes the House of Commons, but the members are considered as having assembled, not to debate general questions, but to enter on a business-like examination of the various clauses of the measure. When the committee have examined all the clauses, the next formality is, that they report to the house, and that their report be received. It is then moved that the bill be read a third time. This stage is, in disputed measures, generally the last trial of party strength. If the third reading is carried, there is still another motion, to the effect "that the bill do pass," and this motion is seldom opposed. On the bill passing one house, it is conveyed to the other, where it has to pass through the same succession of readings. When amendments are made on a bill after it has passed through one of the houses, in that to which it is then sent, it must be re-transmitted to the house where it first passed. That house may accede to the amendments, and so let the bill pass; or it may reject the whole measure in consequence of them; or it may, adhering to its first opinions, hold a conference with the other house, with a view to a settlement of differences. When a bill has passed both houses, its next step is the royal assent, which may be given either by the sovereign personally, or by commission.

A bill that has received the royal assent becomes a law, the operation of which commences from the moment when the consent is adhibited, unless another point of time be stated in the act. All the statutes of a session are ranked in order, according to the date at which they have received the royal assent; and the whole set are distinguished from others by the year of the reign in which they have been passed. Technically, the whole legislation of the session is called one act, and each statute, or act, according to the common acceptation of the term, is called a chapter of it. The privilege of printing the statutes in their original state, without note or comment, is reserved to the king's or queen's printers. In the printed edition of the statutes, each chapter is divided into sections. This arrangement has been adopted by the printers for convenience of reference, but in the original copy of the act there is no such division—the whole is a continuous manuscript without break. Nor is the division into chapters even authoritative. The consequence is, that when a new act is passed, making alteration on some part of a previous one, instead of specifying the chapter and section that is altered, it describes the act vaguely, as an act passed in such a session, for such a purpose. Thus, in 1839, an act was passed to alter a section of the Patents Act, passed in 1837. For any ordinary purpose, this would have been called an act to amend the seventh section of the act 5 and 6 William IV. chapter 83; this would have led to the exact point at once: but as there are no such things as chapters and sections known in law, the legislature could only give a roundabout description, thus—"An act to amend an act of the fifth and sixth years of the reign of his late Majesty William IV., intituled an act to amend the law touching letters-patent for inventions." Sometimes, there is a series of acts, the latter ones amending those that have preceded them, so that the titles are involved in almost inextricable confusion. Even where the acts are divided into sections, as they are by the printers, it is found very difficult for lawyers to unravel their meaning, and to unprofessional people they are often a sealed book. A section generally consists of but one sentence, and as it has often to give a long narrative of things that must be done, independently of circumstances, and others that must be done in particular cases, and others that may be done but are not imperative, and others that must not be done, &c., the comprehension of the full meaning of the sentence requires a strong mental effort. Among the statutes, there are individual sentences which, if printed in the form of an ordinary novel, would fill a hundred pages.

There are some acts which are passed every session in the same terms, such as the Mutiny Act, the indemnity for neglecting to take the oaths, &c. Independently of these, the statutes now passed in a single year generally fill a quarto volume of about 500 pages, very closely printed. Besides these acts, which generally either apply to the whole empire, or to some one of the great national divisions of it, there are annually passed several folio volumes of statutes, called "Public Local Acts," consisting of the police acts of the various towns, and acts for the construction and management of harbours turnpike roads, bridges, gas-works, water-works, railways, &c. It is by virtue of legislative authority only that monopolies can be constituted in such cases, and that individuals can be compelled to sell their property for the use of public works. Hence, this is a separate branch of the statute law, comprising several hundred volumes.

The necessity of consolidating together the various statutes on different subjects, has from time to time been felt and expressed by the first legal statesmen of Britain. Lord Bacon, in whose days the statute law did not occupy a twentieth part of its present bulk, spoke with alarm of its overgrown size, and recommended that the whole ought to be abridged before it should become unmanageable. Already something has been done. The revenue acts, which occupy a large portion of the statute-book, were partially consolidated in 1826. About 400 acts relating to the customs, and similar matters, the prevention of smuggling, registration of vessels, &c., were repealed, and the new regulations on the various heads were consolidated in eight acts. To these acts, each subsequent session has generally made some addition; but to prevent confusion from this source, a very simple remedy has been devised. When there have been several additions made to an act, a new one is framed, embodying the whole contents of the old act, as altered by the subsequent ones, and then all previous legislation on

the subject is repealed. Thus, in 1833, all the custom-house acts were a second time consolidated; that is to say, the acts of 1826, with the additions and alterations made to them by later acts, were imbodied together in a set of new acts, so that no one, in consulting the custom-house laws, can have to go farther back than 1833. Measures are no doubt in preparation to extend this principle to other departments. At this moment, there are upwards of 120 stamp-acts in operation, one of them as old as the reign of William III. The existence of these confused masses of legislation effectually prevents people from being able to act up to the laws, however willing they may be, and their protection is frequently in other people being equally ignorant of the laws that are broken. Invidious investigations into antiquated laws are thus occasionally the means of subjecting individuals to great hardships, by bringing punishment upon them which no foresight could have averted. Hence the trade of what are called common informers, whose vindication of the law has too often the effect of merely heaping calamities on individuals, instead of producing a uniform observance of the laws. The pursuit is a very unpopular one; but when laws are in every respect just and good, it is difficult to see how the enforcement of them can be other than an advantage; and it would appear to an unprejudiced stranger to be a somewhat contradictory practice, first to make laws, and then teach society to hate and punish those who put them in force. As society advances in intelligence, the necessity for the reform of the whole system of law, and its simplification into one comprehensive code, will become more apparent, while the mode of administering the law in courts will also be seen to require revision. Every thing at present indicates that we are approaching the point when these important steps must be taken.

English Courts.—We have now to notice the various courts of law in England. The House of Lords must be mentioned as a general court of appeal from the whole kingdom. There is only one set of superior judicatures from which a reference may not come before it in some form or other—the criminal courts of Scotland. The origin of parliament is connected with the great council of the feudal kings, which gave them advice both in legislative and judicial matters. When parliament was separated into two houses, the judicial business adhered in general to the upper, and, probably at the instigation of the bishops, the Lords adopted the power of administering oaths, which was not possessed by the Commons—a circumstance which more distinctly marked their judicial character. To bring causes which have passed through the hands of learned judges under the direct cognisance of a body consisting of clergymen, soldiers, and young men of fashion, would be too preposterous to be practically adopted; and though the appeal is nominally taken to the House of Lords, it is heard and decided on by one of the eminent lawyers, of whom there are always several in the house, and generally by the Lord Chancellor. Independently of their powers as judges of appeal, the Peers act as a criminal court in all cases where a peer of the realm is tried for a capital crime. They are formed into a temporary tribunal for the occasion, presided over by a judge called the lord high steward. This official is properly the judge, the peers acting as a jury, and giving their verdict on the question of guilt. The directly feudal origin of this relic of ancient practice will be at once recognised.

The principal courts of first resort are naturally divided into courts of common law and courts of equity. The former are three in number; the King's or Queen's Bench, the Common Pleas, and the Exchequer. Each has a chief, and four assistant judges, called puisne or junior judges. These courts date their origin to the Conquest. On feudal principles, the Norman kings called all the principal causes which had, under the Saxons, proceeded before the county courts, to be decided in their own hall, or court, by their own great council, which was presided over by an officer called the justiciar. This court, called the *Aula Regis*, or King's Court, at first followed the king's person, a great inconvenience, removed by Magna Charta, which fixed it permanently in Westminster. Under Edward I., the system was adopted of sending deputations from the court twice a year, to try cases in various parts of the country. Under the same monarch, the jurisdiction of the court was split into three parts. To the justiciar, afterwards called chief-justice, were assigned the pleas of the crown, as they were termed, involving all offences; and being the highest judicial officer in point of rank, his court was appointed to have cognisance over the two others. The matters connected with the exchequer, viz., the regulation of the royal domains, the collection of duties and other taxes, were committed to judges called barons, presided over by a chief-baron. All questions about the possession of land, and other litigations between one citizen and another regarding matters of property, were called "common pleas," and were committed to certain justices, presided over by a chief justice.

The King's or Queen's Bench is thus the chief criminal court, and the Exchequer is the principal tribunal for revenue matters; but these courts are by no means restricted to the departments to which they are so assigned—they possess, concurrently with the common pleas, a jurisdiction in all ordinary questions of common law. The manner in which they obtained this power is one of the most extraordinary circumstances in the history of the laws of any country. The instruments made use of were, as has been hinted, the fictions, described as a peculiarity of the English law. To get at the real motives which were at work, it is necessary to recollect, that formerly not only the judges, but all the officials connected with the several courts, were paid by fees, the amount of which depended on the extent of business transacted. They were thus like so many tradesmen keeping shops for the sale of justice, each anxious to keep a large supply of whatever was most wanted, and to serve the public on the most tempting terms. In this manner, the courts of law undersold the courts of equity by not demanding any sanction, such as an oath, for the truth of what litigants declared in their pleadings. An arduous run for business was carried on between the three common law courts, the accounts of which, as given in the legal histories and law-books, are infinitely grotesque. The extent to which a court could carry its jurisdiction by these means, depended less upon reason than upon the muscular power of those officers of the court who enforced its decrees. The Exchequer, when it attempted to levy taxes, was told occasionally that the person charged with them could not pay, by reason that his debtors had not paid what they owed him; while he hinted, that if the Exchequer wished his money, they had better assist him in recovering it. On this, it became the practice of the Exchequer to assist those who were in debt to the crown to get payment of the money due to them. It occurred to some ingenious lawyers, employed to recover debts, that if they stated to the Court of Exchequer that certain clients were debtors of the crown, and could not pay by reason of their own debtors not satisfying their demands, the court would make very little inquiry into the truth of the statement, but would adjudicate in the case, and levy the money forthwith. The court made so little inquiry as to the truth of the case, that it would not allow the statement to be contradicted, however inaccurate it might be; and down to the year 1832, when one brought an action in the Court of Exchequer, it was a matter of form that he should say he was a debtor to the king, and that he could not pay his debt, unless an obligation, incurred in his favour by the defendant, were fulfilled. The jurisdiction of the

King's Bench was limited to cases that were either purely criminal, or had some connection with offences. When any one, however, happened to be in the prison of the King's Bench for an offence, there was no means of getting at him but through that court; and so the plan was devised, of stating that a man was in the King's Bench prison when he was not. "And in process of time," says Blackstone, "it [the Court of King's Bench] began, by a fiction, to hold plea of all personal actions whatsoever, and has continued to do so for ages; it being surmised, that the defendant is arrested for a supposed trespass, which he never has, in reality, committed; and, being thus in custody of the marshal of the court, the plaintiff is at liberty to proceed against him for any other personal injury, which surmise of being in the marshal's custody the defendant is not at liberty to dispute." These fictions were not abolished until the year 1832, when, by act of parliament, a uniform process was established in the three common law courts. An appeal lies from the decision of any one of these courts to the judges of the other two, who, when met to decide on such appeals, constitute a court called the Exchequer Chamber. Fourteen of the fifteen judges who form these common law courts hold the assizes in the various county towns —in some of them twice, and in others thrice a year. Here they act both as civil and criminal judges. Offences committed in London and its vicinity are tried by a tribunal lately created, called the Central Criminal Court.

The origin of the authority of equity tribunals has been already considered. The principal establishment of this description in England is that of the Chancery. It has in it three distinct courts, and three judges—the chancellor, the vice-chancellor, and the master of the rolls. Formerly, all proceedings in bankruptcy centered with the lord chancellor, but the increasing importance of this class of business rendered it necessary to appropriate a separate court to the purpose. This was accomplished in 1832 by Lord Brougham's act. The term Bankruptcy is in England confined entirely to persons engaged in commerce; and the jurisdiction of the court is so limited. Previous to its formation, however, it had been found expedient to create a court for the relief of insolvent debtors who might not be engaged in trade, on their giving up their property to their creditors. By Sir John Campbell's act for restricting imprisonment for debt, the practice of relieving insolvent debtors was improved, nearly on the model of the Scottish system of *cessio*, and a bankruptcy code was applied to debtors who might not be tradesmen. The utility and importance of the Insolvent Debtors' Court were thus materially enlarged. Another court was lately brought into existence, called the Judicial Committee of the Privy-Council. It consists almost entirely of the judges of the other courts. Its principal jurisdiction is in appeals from the colonial courts, and the Court of Admiralty. This Court of Admiralty has jurisdiction in maritime contracts, and crimes committed on the high seas. Having to deal with matters in which the inhabitants of this and of other countries are jointly interested, it professes to follow, not the special law of England, but the general commercial law of modern Europe, founded on the Roman law. In time of war, the court receives a commission to adjudicate regarding prizes taken from enemies, or from neutrals committing breaches of neutrality. Besides all the tribunals already mentioned, there are ecclesiastical courts in the two archiepiscopal provinces of Canterbury and York. In the former, there are the Court of Arches, the Prerogative or Testamentary Court, and the Court of Peculiars; in the latter, the Prerogative Court and the Chancery Court. There are also many inferior ecclesiastical courts. The chief jurisdiction exercised by these tribunals, besides questions of ecclesiastical discipline, is in matters relating to succession to movable goods. If we were to complete the list of English tribunals, it would be necessary to include the justices of peace, who, besides many special powers in revenue and other matters conferred by act of parliament, sit, at the general and quarter-sessions, as judges in minor offences. Then there are various courts, of greater or less jurisdiction, connected with cities and boroughs; and, in some places, establishments called courts of requests, for adjudicating in cases of petty debts.

After having detailed the legal system of England, it is unnecessary to describe that of Ireland, which is almost in all respects a model of it. The bankruptcy system of England was lately ingrafted on that part of the empire, and the principles of the improved Insolvent Debtors' Act were extended to it in August, 1840. The chief distinction in the nature of the courts of law, consists in this, that in Ireland a considerable amount of the judicial business is transacted at courts of general session, held quarterly by the justices of the peace, who act under the advice of professional lawyers, called assistant barristers.

LAW OF SCOTLAND.

From what has been already said, it will be gathered that the law of Scotland was chiefly composed of the feudal system and the Roman law. The former was in practice according to the form in which it had adapted itself to the particular customs of the country, the latter was taken from the doctrines of the civilians. The origin and progress of feudalism in Scotland are very obscure. The chroniclers attribute the foundation of the system to Malcolm II., in the eleventh century, but with little probability. It is more likely that, with the resort of foreigners, Saxon and Norman, to the court of the Scottish king, subsequently to the conquest of England, the system was imperceptibly and gradually introduced. The monarchs, who were ambitious of presiding over a distinguished court, gave particular encouragement to the Normans, to whom they granted large fiefs or lordships; and it was natural that they should return the same homage to which they were accustomed in the country of their origin. The whole of the Lowlands, indeed, and a great part of the Highlands, became nearly as thickly adorned with Norman aristocratic names as the broad plains of England; and it was this alien aristocracy that submitted with so much indifference to the claims and encroachments of Edward I. There appear to have been many points on which the earlier laws of the two divisions of the island were identical. In England, however, as we have already seen, the feudal system received many checks, while in Scotland it was allowed to grow rank; and the deference paid to the civil law in the north served to widen the distinction. The alliance and continued intercourse with France, moreover, naturally drew the legal practice in the direction of the example set by that country.

There is little information to be derived concerning the practice of the law in Scotland, previous to the sixteenth century. Edward I. probably destroyed some vestiges, through which its history might have been traced; but he seems to have been charged by some antiquaries with the destruction of more than ever existed. He did more, probably, by fabrication than by destruction to poison the sources of Scottish jurisprudence. The earliest alleged collection of the laws, commonly called the *Regiam Majestatem*, bears so near a resemblance to the English work of Glanvil, noticed above, that it is naturally supposed to have been a digest, not of what the laws were, but of what the conqueror wished them to be. The earliest Scottish legal writer, whose works are quoted, is Balfour, who prepared, about the latter end of the sixteenth century, a compendium, chiefly derived from the Regiam Majestatem, the acts of parliament, and the decisions of the court. In the reign of James VI.

a commission to make inquiry into the laws, of which the celebrated Sir John Skene—whom Sir James Melville chose as his legal adviser on his embassy to Denmark, because he was "a stout man like a Dutchman" —was a member. They collected and published many acts of parliament, the Regiam Majestatem, and other consuetudinary laws, such as the customs of the royal burghs; and Sir John Skene wrote a curious work on the meaning of technical legal expressions. But the first really scientific writer on the law of Scotland was Sir Thomas Craig, whose book on the feudal law was published in 1655. It is a work of great learning and thought, in which the reader is somewhat surprised to find that, though the work professes to be a Scottish law-book, it should derive so much of its learning from the practice of continental nations. The next great authority is Lord Stair, the equivocal statesman of the reign of James VII., whose Institute, on the model of that of Justinian, is remarkable for the breadth of its legal principles, and the acuteness with which they are practically applied. Soon after the middle of the eighteenth century, a second Institute was prepared by Mr. Erskine, professor of Scottish law, more suited to the knowledge of the age than that of Stair, but more dry and formal. Sir Walter Scott has justly denominated Erskine's Institute the Scottish "Coke upon Lyttleton." There were formerly few opportunities of acquiring a legal education in Scotland, and it was the practice for the youth studying the Scottish law to repair to one of the continental universities, among which Leyden and Paris were preferred. On the occasion of the appointment to a chair of law in Aberdeen, in the seventeenth century, Spalding the Chronicler says, it was "strange to see ane man admitted to teach the lawes, who was never out of the countrie studieing and learning the lawes;" thus expressing his astonishment that any man could be presumed to become acquainted with a system of law on the spot where it is administered. The civil law is still professedly studied in Scotland, but its ancient influence has sunk beneath the progress of commerce, and the increase of statutory regulations, which compel the lawyer to spend much of his time with acts of parliament and reports of decisions.

Scotland has a considerable quantity of early statute law, but not nearly so much as England. Down to the time of the Revolution, the general principles only of the acts had the assent of the assembled parliament—the details were all prepared by a committee called the Lords of the Articles. The older acts are remarkable for their Spartan brevity—a dozen of them could be put into the title of an act of the reign of George III.; and a modern malt or glass duties' act would occupy half the Scottish statute-book down to the reign of Charles II. It was a practice derived from the civil law, that acts of parliament became repealed by disuse, or contrary practice. Since the union with England, the parliament of the united kingdom has legislated for Scotland, and to the acts so passed the above doctrine does not apply. The description of the passing of an act given above, applies to acts relating to Scotland as well as to those which apply to England. It has been felt as a defect in Scotland, that in many cases acts applicable to the whole kingdom are drawn by English lawyers, who do not apply their provisions to meet the peculiarities of Scottish practice.

The earliest superior tribunals in Scotland were either the parliament, as the king's great council, or a committee of it, acting with the delegated powers of the whole body. There was likewise, as in England, a king's justiciar, whose authority was vast, and not very well defined, especially in criminal matters. Committees of parliament were, in the fifteenth and the beginning of the sixteenth century, sometimes formed into regular courts of justice, in which, however, a certain degree of fluctuation could not be avoided. In 1532, the present Court of Session was constituted, on the model, it is believed, of the parliament of Paris. The chancellor, whose principal duties disappeared at the Union, was chairman of this body. It consisted of fifteen judges, including a president, who was chairman in absence of the chancellor. In 1830, the number of judges was reduced to thirteen; and about the same time, the authority of some other tribunals, the chief of which were the Courts of Admiralty and Exchequer, was transferred to the Court of Session. It consists of two divisions which are separate tribunals. Some of the judges also act as individual judges in courts of their own, in which capacity they are termed "lords ordinary." An ordinary case, on coming into court, is discussed before a lord ordinary, from whose decision there is a reference to one of the divisions of the "Inner House," as it is termed, where the remaining judges sit collectively. From them there is an appeal to the House of Lords. There is no such conventional distinctions as that between law and equity known in Scotland, and hence English lawyers, who are apt to measure all other systems by their own, absurdly enough speak of the Court of Session as a court "both of law and equity." Besides the usual adjudication of litigated cases, there are two very useful descriptions of action peculiar to this court. The one is called an action of "declarator," which a person who is puzzled about any difficulty, and is afraid of committing an illegal act, may bring, to have the law as to the point declared, and his course of action made plain; another is called a "multiplepoinding," which may be raised by a man having money in his hands which more than one person is claiming, that he may know to whom he can legally pay it. Trial by jury was not, until very lately, added to the jurisdiction of this court. It is limited to certain descriptions of cases, and is far from popular.

The principal criminal court is the Court of Justiciary, consisting of seven of the judges of the Court of Session, who sit in Edinburgh, and commission some of their number to hold circuits in the country. Almost all offences in Scotland are prosecuted by a public prosecutor; there is no grand jury, and the ordinary jury, consisting of fifteen, give their verdict by a majority. The criminal law is partly statute, partly founded on long usage. There are many offences which, by this latter portion of the law, are punishable with death, if the prosecutor do not restrict the extent of punishment to be awarded, which he now does in almost every case except murder. The sheriffs, or local judges of counties, have important judicial powers, both civil and criminal. The former extends to every description of dispute regarding property, except what refers to land. The powers of these judges have lately received extensive additions, especially in matters of insolvency and bankruptcy. They do not employ a jury except in criminal cases, in which their power of inflicting punishment does not exceed imprisonment. They hold small debt courts, where questions of debt to the amount of £8, 6s. 8d. are summarily decided. The magistrates of royal burghs enjoy powers somewhat analogous to those of sheriffs. The authority of the justices of peace in Scotland is not so extensive as it is in England.

There has latterly been some indications of the assimilation of the legal usages of Scotland to those of England, and it is highly desirable that an end should speedily be put to all existing diversities.

THE FRENCH CODES.

The ancient laws of France were a mixture of the civil, feudal, and canon law. Partly they were the doctrines of the authorities on the civil law, and partly they were the ordinances issued by the various monarchs. By

far the greatest portion, however, in bulk, consisted of the peculiar feudal customs of the various provinces. In these the feudal system was sometimes retained in so high a state of purity, that the collections of provincial customs are esteemed excellent authorities on the subject. But it was not merely in each province that there was a local custom. The power of the crown, or any other paramount legislature, was so feeble, that wherever an assembly of men were held together by one common tie, as where they were co-vassals of one lord, or members of the same civic community, they had in some measure a code of laws of their own. The royal codes, which existed on a large scale, are estimated at about 300, but of the number of inferior local customs it would be impossible to make an estimate. Voltaire observes, that a man travelling through his country has to change laws as often as he has to change horses, and that the most learned barrister in one village will be a complete ignoramus a few miles off. The seignorial courts were divided into three grades, according to the extent of the penal authority exercised by them. The principal courts of law were the parliaments of the respective provinces. Seats in them were generally held by purchase, or were in the hereditary succession of great families, who thus constituted a species of professional nobility. The decrees of these bodies were often baffled or reversed by the royal authority, exercised in the well-known form of *lettres de cachet*. These alterations of the decisions of the courts, however, were performed not as a judicial revision, but by the simple authority of the king; and thus the parliaments being subject to no judicial control or responsibility, adhered but slightly to fixed rules of law, and often acted according to their own will and discretion. The jury, even so much of it as may have existed under the old feudal form, had entirely disappeared, and proceedings were conducted in secret. Criminal investigations, instead of terminating in a conclusive trial, as in England, were protracted through a liagering succession of written pleadings and secret investigations, from which the accused could never calculate on being free. The torture was extensively employed; but in the general case, only where there was as much circumstantial evidence as would justify a conviction in this country.
