The copy filmed here has been reproduced thanks to the generosity of:

Library of Congress Photoduplication Service

The images appearing here are the best quality possible considering the condition and legibility of the original copy and in keeping with the filming contract specifications.

Original copies in printed paper covers are filmed beginning with the front cover and ending on the last page with a printed or illustrated impression, or the back cover when appropriate. All other original copies are filmed beginning on the first page with a printed or illustrated impression, and ending on the last page with a printed or illustrated impression.

The last recorded frame on each microfiche shall contain the symbol → (meaning "CONTINUED"), or the symbol ▼ (meaning "END"), whichever applies.

Maps. plates, charts, etc., may be filmed at different reduction ratios. Those too large to be entirely included in one exposure are filmed beginning in the upper left hand corner, left to right and top to bottom, as many frames as required. The following diagrams illustrate the method:

L'exemplaire filmé fut reproduit grâce à la générosité de.

Library of Congress
Photoduplication Service

Les images suivantes ont été reproduites avec le plus grand soin, compte terru de la condition et de la netteté de l'exemplaire filmé, et en conformité avec les conditions du contrat de filmage.

Les exemplaires originaux dont la couverture en papier est imprimée sont filmés en commençant par le premier plat et en terminant soit par la dernière page qui comporte une empreinte d'impression ou d'illustration, soit par le second plat, selon le cas. Tous les autres exemplaires originaux sont filmés en commençant par la première page qui comporte une empreinte d'impression ou d'illustration et en terminant par la dernière page qui comporte une telle empreinte.

Un des symboles suivants apparaîtra sur la dernière image de chaque microfiche, selon le cas: le symbole → signifie "A SUIVRE", le symbole ♥ signifie "FIN".

Les cartes, planches, tableaux, etc., peuvent être filmés à des taux de réduction différents. Lorsque le document est trop grand pour être reproduit en un seul cliché, il est filmé à partir de l'angle supérieur gauche, de gauche à droite, et de haut en bas, en prenant le nombre d'images nécessaire. Les diagrammes suivants illustrent la méthode.

VOYAGES AND TRAVELS.

TRAVELS

IN THE

TWO SICILIES, AND SOME PARTS OF THE APENNINES.

TRANSLATED FROM THE ORIGINAL ITALIAN OF THE

ABBE LAZZARO SPALLANZANI,

Professor-Royal of Natural History in the University of Pavia, and Superintendant of the Imperial Museum in that city; Fellow of the Royal Society of London; and Member of the Academies of Prussia, Stockholm, Cottingen, Turin, Padua, &c. &c.*

ADVERTISEMENT BY THE TRANSLATOR.

THE name and established reputation of the abbe Spallanzani must certainly be a sufficient recommendation of any work he gives to the public, especially of one like the present, on which the appears to have bestowed a more than ordinary degree of labour and attention. The variety of objects, highly interesting to the naturalist and the philosopher, on which treats may be seen in the following introduction, which contains, in part, a summer of the treats.

course, have been principally studied. The reader, faithful transcript of the original (if the expression admitted of no doubt, the In the translation it is presumed, has may be allowed) in translator thought h to depart from the phraseology of his author, to licence which the different idioms of language give his idea with g will frequently rend where any shadow of ambiguity appeared (and lence, such ambiguities of expression will occain every work, espe adhered to the literal expression of his text, sionally be found) that the reader may his judgment in the same manner as from the original.

* T he parts least interesting to the general reader are omitted.

VOL. V.

B

As the abbe has continually employed the terms of what is called the new nomenclature of chemistry, it has been thought proper, for the benefit of readers not familiar with this science, to add, in a parenthesis, the more usual names of chemical substances; as for instance, to subjoin to muriate of alumine the common term of alum; and to muriate of soda that of sea-salt. The abbe has likewise used the term caloric, on all occasions, instead of heat or warmth. In this the translator has not judged it advisable to follow him, except when he has employed it in the proper chemical sense of the matter of heat.

The plates are faithful copies of those in the original, but more carefully and elegantly finished. Some may, perhaps, object to the disproportionate size of the human figures represented in plates II, III, and V. This objection the author has foreseen, and, at the end of vol. IV, apologizes, by remarking, that "the painter canceived he might be permitted this licence, as, had he attempted to observe the rules of proportion, these figures would have been scarcely discernible."*

The work in the original is dedicated to count Wilzeck, imperial plenipotentiary of the general administration of Austrian Lombardy; but as this dedication only contains the eulogiums of which such compositions usually consist, it has been omitted.

INTRODUCTION.

THE zeal with which I have always been animated to contribute as much as might be in my power, to the improvement of the Public Imperial Musuer of Natural History in the University of Pavia, by enriching it with the new and important productions I procured in the various journeys and voyages I undertook both in Italy and other countries, incited me to travel, during the summer and autumn vacations, into the Two Sicilies. Though this Museum abounded in other kinds of natural productions, it was extremely deficient in volcanic matters, which merely consist it of a few trivial scorize of Vesuvius, and some extremely common lavas of the sate: mountain, that, having been cut into tablets and polished, had lost their distinguising characteristics, and consequently could little contribute to the instruction of your and the advancement of knowledge.

As I knew that no countries in Europe could furnish a more amplication of volcanic products than the Phlegrean Fields, Mount E a, and Eolian, or Lipari Isles; I resolved to visit them, and employed several months full researches. To make a proper choice, however, of the substances suitable to the design I had in view, it was necessary to examine on the spot the arious qualities of the bodies composing those volcanized regions. This I performed with the same diligence and care I have usually exerted in the examination of other natural objects. Still more to enable myself to make this selection, and correct my judge in the with respect to these subjects, I had read, and then re-perused, whatever had been ritten by travellers and the most eminent naturalists relative to volcanos, and was sincer grateful to them for the instruction I derived from their works. In the course of this inquiry, however, I discovered what I had often experienced before, with respect to othe subjects, in which I had been preceded by other naturalists, that, not with standing the element and interesting accounts they had given us of the countries which have suffered the a ion of fire, it was

^{*} These plates are omitted as a disgrace to the state of the arta in the eight enth century. The view of the crater of Etna is that of a well!

still possible to add to them by my researches, and throw new light on volcanic knowledge. This I say not to arrogate to myself any merit, and still less to detract from that of others. The powers of the human mind are so limited, that it never can entirely exhaust the subject it investigates. Other naturalists who shall hereafter diligently explore the countries through which I travelled, it is not to be doubted, may improve this part of natural history with still new discoveries. In like manner, though others have written of the Phlegrean Fields, Etna, and the Eolian Isles, the observations I have made

appear to me to merit publication.

The method in which I prosecuted my researches in these Travels was the following: I have endeavoured to study volcanic countries as mountains should be studied. The lithologist who would acquire an accurate knowledge of the latter, attentively considers their structure of rock, the whole of their huge masses, the position and direction of the various parts or strata which compose them, and the intertexture and relations of those strata. I have adopted the same mode of inquiry in the course of these travels. Fire in conjunction with elastic gases has formed whole mountains and islands; but all of them have not been produced in the same manner, nor are they composed of the same substance. Here we find large masses of tufa; there of scoriæ and lavas; in another part, pumices, enamels, and glasses; and in another, a mixture of all these substances. It was therefore necessary to examine them on the spot, and observe, both when they were separate and intermingled, their relations, directions, mixtures, &c. without once losing sight of the peculiar composition of these volcanic mountains, every

part and recess of which it was requisite I should explore.

In these inquiries I particularly directed my notice to two objects: the central summit of the islands and mountains, and their shores. The former is usually the first sensible effect of the subterranean conflagrations, the part which first emerges from the waves, which often preserves the crater entire, and sometimes burning, but more frequently only its recognizable traces. The shores of volcanic islands and mountains bathed by the sea, were also peculiarly entitled to attention, nor do I know that any volcanist who has hitherto travelled has made them one of the objects of his inquiry. We know how much it conduces to an accurate knowledge of the structure of mountains, to cross, or go round them in the beds of torrents which have corroded their foundations, and laid bare a part of their sides; thus revealing, if I may use the expression, their internal organization, which without this aid would have been sought in vain from external appearances. The sca, by incessantly beating with its furious waves the skirts of the islands, has caused fractures and ravages incomparably greater than those occasioned by rivers. By coasting, therefore, these shores in a boat, landing where they appear to invite particular attention, and examining their open sides, and rocks half fallen down and falling, we may observe a variety of important facts conducive to the improvement of that kind of science. I shall not here enlarge on the advantages to be derived from coasting volcanic islands; in the course of this work they will be proved by facts. When the war and the same of the sam

The researches I made in volcanic countries, though necessary, and highly instructive were not, however, sufficient to complete my design. As lithologists are not satisfied with knowing the structure, stratification, and other general qualities of mountains, but endeavour likewise to discover the nature of their component parts, I resolved not to depart from the same method of inquiry. It is true that some volcanic productions are so altered by the fire, that it is difficult to ascertain the nature of the earths from which they have been produced, unless we call in aid the processes of chemistry. Such are enamels, glasses, and frequently pumices. But lavas, which, in the greater

part of the places where I made my observations, are abundant beyond all belief, are seldom so changed by the fire as not to retain the evident characters of their primitive rocks.

I began, then, by considering the external appearance and qualities of the places I ex-

amined, as far, at least, as circumstances would permit.

Whoever has undertaken to travel among mountains, in order to make researches relative to the fossil kingdom, is not ignorant to what changes the surfaces of stony substances, even the most solid and hard, are subject, from the action of the elements during a long series of years and ages. Hence, if he would form an accurate judgment of the stones he examines, he will not fix his attention on those found on the surface of the earth, but rather on those buried at some depth, and will frequently forcibly creak and detach them from the internal masses of which they are a continuation. Still greater changes take place in some parts of the mountains which throw out fire, from the action of sulphureous acid vapours, besides that of the atmosphere and of time; and very frequently the volcanic product, which on the surface seems to be of one kind, and at some depth, of another, is in fact the same, but more or less changed in the first instance by the action of the atmosphere, or that of sulphureous vapours.

To render my researches more accurate and certain, it was necessary that I should not content myself with a single inspection of the volcanic substances, on the spot where I gathered them. I therefore, when I returned to Pavia, re-examined them with the greatest care, in the retirement of my study; not only with the naked eye, but with the aid of the lens, before I began to characterise and describe them lithologically. The reader will find some of the descriptions rather diffuse; and, perhaps, I may be charged with having been too minute. But it appeared to me that I could not be more concise; as a detailed description of such products can alone enable us to discover to what kind of rocks they appertain, and what is the particular characteristic of the volcanic countries in which they are found. Those who, when treating of volcanos, have been sparing of such descriptions, have left us imperfect works, though in other respects they may be very valuable. All who are versed in these subjects, are acquainted with the account of the famous eruption of Ema in 1669, and the memoirs relative to different remarkable conflagrations of Vesuvius by Scrao, Della Torre, Sir William Hamilton, and Bottis. With respect to what regards the currents of lava which those two volcanos at those times poured forth, the symptoms and phenomena that accompanied them, and the other circumstances deserving notice which preceded and followed them, their histories certainly merit great commendation. They will be highly valuable in the estimation of every lover of volcanic science; and I have frequently, in the course of this work, derived such assistance from them as demands my grateful acknowledgment. But from these relations, what idea can we in general form of the nature of the products ejected, and the currents they have formed? When do they describe with sufficient accuracy a single substance? After having read these relations of the violent eruptions which have burst from the sides of Vesuvius and Etna, we femain profoundly ignorant, to what primitive rocks they appertain. I mean not by these remarks to injure the reputation these writers have justly acquired. Their deficiency in lithological studies, not cultivated at that time as in the present, is a sufficient excuse; I intend only to shew the necessity there is for circumstantial description, which, in fact, form the basis of all solid science.

It is necessary that I should here mention, with respect to the descriptions I have given of the different products of the various volcanic places I visited, that, though I have treated diffusely, and in detail, of those of the Phlegrean Fields, situated to the

I have hough I d to the west of Naples, and of others of the Eolian or Lipari Isles; I have only spoken incidentally of the productions of Vesuvius and Etna, though both these volcanos have furnished me with a great number of specimens for the Museum at Pavia; not only because that to have examined these two mountains minutely, would have required years instead of a few months; but because a description of these has already been executed with great ability by the Chevalier Gioeni, in his Lithologia Vesuviana, and by M. Dolomieu, in his "Descriptive Catalogue of the Products of Etna."

The opportunity afforded me by having these volcanic substances continually under my inspection at Pavia, induced me to make new experiments on them. It is certain, that the greater part of them contain iron. Yet the proof of this by experiment was not superfluous, as the greater or less quantity of the martial principle might thus be discovered. I therefore used, according to circumstances, the magnetic needle, or magnetized knife. I applied the former to the products reduced to powder, and the latter to those in fragments; taking care that they should always be, as far as I was able to effect it, of the same configuration and volume. I then observed the different distances at which they attracted the magnetic needle, without noticing the pieces which exerted no such power, though I do not mean by that to deny that they contained iron.*

I was attentive at the same time to an inquiry of much greater importance. Vesuvius, Etna, the Eolian Isles, and Ischia, are large mountains formed of rocks which have undergone liquefaction, and sometimes a true vitrification; such has been the violence of the subterranean conflagrations. What fire can we produce equivalent to these effects? I have discovered that the fire of the glass-furnace will completely fuse again the vitrifications, enamels, pumices, scoriæ, and lavas of these and other volcanic countries. The same will, in like manner, vitrify rocks congenerous to those from which these mountains have originated by the means of subterranean conflagrations. A less intense fire, on the contrary, produces no such effect on any of these substances.

As I wished to attain to the most rigorous accuracy in this experiment, I was not satisfied with discovering that the fire of the glass furnace was capable of effecting these fusions; I determined, if possible, to ascertain the precise degree of heat necessary to produce them, for which purpose nothing could be better adapted than the pyrometer of Wedgwood. This instrument, it is well known, is composed of two parts: the thermometric pieces and the gage. The forner are small cylinders of very fine clay. The latter, which is six inches long, is formed by two pieces of the same earth, the internal sides of which are straight and smooth; but so disposed as to be more distant from each other at one extremity than the other, thus forming a converging space divided into two hundred and forty parts. The greater aperture of this gage is the beginning of the scale, and denotes the heat which produces a beginning of redness in iron. If, therefore, one of the clay cylinders shall have been exposed to a greater heat, it will be contracted, and sink lower between the converging sides; and, the sides being graduated, the degree at which it stops will be the measure of its contraction, and consequently of the degree of heat it has undergone; the cylinders, as the inventor has observed, representing the mercury, and the converging sides the scale of the thermometer.

To ascertain, therefore, the degree of heat in the glass furnace necessary for the fusion of these volcanic productions, and the rocks whence they derive their origin, I made use of this pyrometer in the following manner. I placed in the furnace, near the substances I intended to fuse, one or more of the clay cylinders above-mentioned, in a case of

As the iron is sometimes in the state of oxyde (calx) I employed the usual methods to revive it in the productions I examined.

the same clay, and let them remain there the whole time necessary for the fusion of those substances. I then measured their contraction by the gage; and found that the heat of the glass furnace was 87½ degrees of this pyrometer; a heat, according to the observation of the inventor, but 2½ degrees less than that of welding iron, which latter heat corresponds to 12,777° of Fahrenheit's thermometer.* In fact, filings of iron (in which the surface of the metal is greatly enlarged) being continued four-and-twenty hours in the glass furnace of Pavia, of which I always made use in these experiments, conglutinated into a solid though friable body, and shewed an evident beginning fusion. Whence I conclude that a greater heat is usually kept up in these furnaces than is necessary for the fusion of glass.

Though the blowing pipe did not in general greatly conduce to the success of my experiments, I sometimes found it useful. In some cases I likewise had recourse to the

assistance of fire excited by oxygenous gas (dephlogisticated air.)

There is scarcely any natural product, volcanic or not volcanic, of which I have treated in this work, that I did not try in the fire, in one or other of the manners I have described, and frequently more than once. These experiments in the dry way I often accompanied with others in the humid, with respect to the productions of volcanic

fire. The manner in which I proceeded was as follows:

When the external appearance of these products perfectly agreed with that of earths not volcanic before known, and analised by able chemists; I thought I might determine the genus of the volcanic production without analysing it in the humid way; and when I made experiments on a few pieces, I found I was not deceived. But when the external appearance appeared to me new, and not to agree with that of the earths already known, I then had recourse to an examination by the humid method, by which I elucidated the genus, and frequently the species, of these substances. Before, therefore, I proceeded to describe any pieces I had collected, I was certain, or thought myself so, that I had obtained a sufficient knowledge of them. And when I could not arrive at this knowledge, but remained uncertain to what genus they appertained, I have never failed to express myself doubtfully. In these researches, equally laborious, delicate, and necessary, I have employed much of my time, not without considerable expense. In my volcanic travels I have been obliged to take upon myself the parts both of naturalist and chemist. The natural history of fossils is so closely connected with modern chemistry, and the rapid and prodigious progress of the one so exactly keeps pace with that of the other, that we cannot separate them without great injury to both. But as the chemist in his laboratory can reason but imperfectly concerning the mountains, the component earth of which he analyses; so the observations of the lithological traveller must always be defective when not conjoined (at least when it may be necessary) with chemical investigations. What is true of fossils not volcanic, must likewise be so, in a ccrtain degree, and with necessary allowances, of volcanic fossils. Here, in fine, neither observation alone, nor experience alone, are sufficient; but both must join to conduct the investigator of nature, or he cannot be successful in his researches.

Where my experimental inquiries have been short, I have incorporated them with my narrative; as they are relative to the productions I met with in the different places I visited. But more than once I have found it convenient to act otherwise; and the sub-

jects treated, appear to me to justify the method I have adopted.

What is the activity, in general, of volcanic fires, has been a question long agitated, and which is certainly of difficult solution. In this dispute, writers have gone into opposite extremes; some asserting that these fires are extremely active, and others that they

^{*} Journal de Rozier, tom. xxx.

are very feeble, while all endeavour to support their opinions by facts. Having treated on volcanos so much at length in this work, I could not avoid considering this question. I have weighed the arguments on both sides without prejudice; I have made various experiments; and declared in favour of the opinion which appeared to me to have the

strongest support from reason and from facts.

The nature of elastic gases by which the liquefied matters of volcanos are penetrated and agitated, was another subject well deserving attentive consideration. The vacuities, inflations, and tumors, which such matters frequently retain in a state of congelation, can only be ascribed to the elasticity of these gases while they were in a state of liquidity. Our common fire will reproduce in them these gases equally with the volcanic. In fact, many lavas, pumices, glasses, enamels, and scoriæ, though by pulverisation they may be deprived of these vacuities, which are more or less large, and usually orbicular, recover them by refusion in the furnace; and in many of these bodies the gaseous bubbles are so abundant, that by their great inflation, while in actual fusion, they force them to flow over the edges of the crucible. These observations led the way to inquiries relative to the qualities of these gases, by liquefying in chemical furnaces volcanic substances reduced to powder, and placed in matrasses fitted to a chemical mercurial apparatus. By a great number of experiments of this kind I discovered the true nature of these gaseous substances, of which our knowledge was before very vague and uncertain.

This discovery naturally led to the inquiry what part the elastic gases take in the eruptions of volcanos; and this inquiry to a discussion of the causes of those cruptions.

The chemical processes I employed to ascertain the characters of the gases of volcanic productions likewise discovered to me a new fact, which was, that several of these productions contain muriatic acid. This discovery again produced new inquiries.*

Lastly, I must not omit the researches relative to the origin prismatic or basaltiform lavas. It is an opinion almost universal, that lavas take this regular figure in the sea, by the sudden condensation and congelation they suffered when they flowed into it in a fluid state. I could not have met with examples of this kind more proper to enable me to form a judgment on the subject than those which presented themselves to my view while coasting the shores of Italy, a great part of Etna, and the whole of the Lipari Islands.

These different discussions relative to the efficacy of subterraneous conflagrations, the gases of volcanic productions, the causes of the eruptions of volcanos, and the muriatic acid contained in various of their products; with the inquiries concerning the origin of basaltiform lavas; to treat them at length, as they required, would have too much broken the thread of the narrative of my travels. I have therefore placed them in such a manner as not to interfere with my accounts of the Phlegrean Fields, Etna, and the Eolian Isles.

In the volcanized countries in which I travelled, there are four craters still burning, Vesuvius, Etna, Stromboli, and Vulcano. To all these four, from an ardent desire of obtaining knowledge, I wished to make a near approach. By Vesuvius this wish was not gratified; but Etna was more condescending, though incomparably more formidable; and a similar good fortune attended me at Stromboli and Vulcano. The clear and distinct view I had of these three craters was equally pleasing and instructive. The crater of Etna I delineated myself; the views of Vulcano and Stromboli are the work of a draughtsman I took with me for that purpose, and who likewise furnished me with

^{*} In these chemical experiments I was greatly assisted by the Signors Nocetti, father and son; the former operator in the public school of chemistry in Pavia, and the latter repeater in the same. They are both well versed in chemical science, and are entitled to my grateful acknowledgments.

drawings of some other volcanic mountains described in this work. I shall only add, that all these designs have been retouched and greatly improved by Sig. Francesco

Lanfranchi, an eminent painter in the university of Pavia.

The origin of the Lipari islands, which are the productions of fire, was certainly the principal motive of my visiting them; yet in many other respects they are certainly very interesting. The character, manners, and customs of the inhabitants; their population, agriculture, and commerce, are objects well deserving inquiry, and have the greater claim to the attention of an Italian, from their being so little known in Italy.

I have also made some observations on the animals in those islands, as for instance, on a kind of birds which with us are birds of passage, but there (in part at least) stationary; I mean swallows. Some years ago I made observations on the natural qualities of several species of swallows (the hirundo rustica, urbica, riparia, apus, melba, Linn.)

and to these I now add those I made in the Lipari islands.

The environs of Messina, where, after I had finished my volcanic travels, I remained more than a month, afforded me much instruction, from the variety of natural objects they presented. Though four years and a half had elapsed since that unfortunate city had been laid in ruins by earthquakes, the melancholy scene was still fresh in every one's memory. A great part of the public and private edifices were still in the same ruinous condition to which they were reduced by that calamitous event. Numbers of the inhabitants still continued to lodge in the half-destroyed houses, and others in huts and sheds; while they all appeared oppressed and overwhelmed with fears from which they had not yet recovered. The impressions made on me by what I saw of the effects of this calamity were such that I could not refrain from giving a brief account of the melancholy situation in which I found Messina, and of the destruction occasioned by the dreadful earthquake in 1783.

Scylla and Charybdis, the former distant twelve miles from Messina, and the latter about a hundred paces within the famous Strait, were two objects to which I first turned my attention. That part of the sea being then calm, at least as calm as the Strait of Messina can be, I was enabled to take a near view of them both, and even to pass over Charybdis in a boat. I also made inquiries of the Messinese sailors, who are employed the greater part of the year in that Strait, and consequently have an opportunity of forming a just and precise idea of these two celebrated places; and from what they told me, and the observations I made myself, I am convinced that Charybdis is not a real whirl-

pool, as has been hitherto believed.

In the Strait of Messina I found other instructive natural curiosities furnished by the fisheries for the sword-fish (Xiphias gladius, Linn.) the ravenous shark (Squalus carcha-

rias) and for coral (Isis nobilis.)

Being at Messina at the time of the annual passage of the sword-fish through the Strait, I was present at the fishery, which appeared to merit some description, from the singular form of the vessels employed in it; the method of striking and taking the fish; and the qualities and periodical migrations of the animal. I have likewise made some observations on some fish of the genus of the squalus, particularly the shark, sometimes

so dangerous to fishermen in that sea.

Coral, for which the Messinese mariners fish the whole year, by tearing it with nets suitable to the purpose from the rocks at the bottom of their Strait, has been long an ambiguous production, and made to pass through all the three kingdoms of nature; some considering it as a fossil, others as a vegetable; until at length it has been proved to appertain to the class of animals, though it has the appearance of a plant; and is therefore now properly classed among the zoophyta. The excellent observations of

Peyssonel and Vitalianio Donati are well known; nor ought Marsigli to be denied the praise he merits, though a zealous maintainer that coral is a plant. Notwithstanding, however, these great discoveries, much was wanting to a complete history of this noble zoophyte, to which, I flatter myself, I have in some small degree contributed by the ob-

servations I made on it at the time of the fishery, at which I was present.

On this occasion, while the fishermen were throwing the net for the coral, I employed myself in researches for marine animalcula. I carefully examined every piece of a stalk, leaf, or other fragment of a marine plant, or any thing else which hung to the net, having learned from experience that these substances sometimes contain wonders in the class of animated beings; for, as Pliny has wisely remarked, nature is greatest in her least productions. When the fishermen, therefore, turned up their nets to free them from the weeds which were mixed with the coral, I put these weeds into glass vessels, filled with sea water, to observe the animals adhering to them, and select those which appeared to present any remarkable novelty. Several of these were not wanting; of the genera of the ascidize and the escharæ. I likewise discovered some small polypi, in which I could distinctly see the circulation of the fluids; which has not, to my knowledge, been before observed in these minute animals. The description I have given of them is accompanied with the necessary figures.

The surface likewise of the Strait of Messina was equally favourable to my researches with the bottom. In other parts of the Mediterranean, the Adriatic, the Archipelago, and the Strait of Constantinople, I had examined several species of those molusca which are commonly called medusæ. I had admired the simplicity of their organization, and especially that property by which certain species of them, of the weight of twenty pounds or more, dissolve almost entirely into a liquor, nothing remaining of them but some thin and dry pellicles, which are only a few grains in weight. I had never, however, met with any of that phosphorescent kind which Læssingius tells us he saw in the ocean between Spain and America. The mention he has thus made of them, without adding any further observations, can only serve to excite the curiosity of the reader; nor do I know that any other author has described this rare animal. In the Strait of Messina I had the pleasure to find abundance of these phosphorescent molusca, and the stay I made in that city afforded me an opportunity to examine their organization, their mo-

tion, and the beautiful light they emit in the dark.

I concluded my researches relative to the natural objects in the vicinity of Messina, by examining the shore, hills, and mountains, which on the side opposite the sea look toward that city. I could discover no sign of volcanization; but I observed, first, immense masses of testaceous and other animals petrified, the species of which were perfectly distinguishable. Secondly, granite, which probably is a continuation of that of Melazzo, distant from Messina thirty miles to the north; and with respect to which I endeavoured to ascertain whether it formed strata, as some suppose, or only great masses, as is the opinion of others; as also whether it contained within it petrified marine bodies, as has been conjectured. Thirdly, sand stone, which, it appears to me probable, forms, in a great measure, the bottom of the Strait of Messina, extending to the point Pelero, and being reproduced by a petrifying principle. We shall see that by means of this principle, human skeletons, and other extraneous bodies, are sometimes found included in it; and that, in consequence of the same, at the part near Peloro, where the Strait is narrowest, it is probable that Sicily, losing the name of an island, will one day be again joined to Italy.

Having made the circuit of the Phlegrean Fields, the Eolian Isles, and Etna, the principal objects of my travels, I returned to Pavia, going by sea from Naples, with-

out the least thought of making any new observations. But the lake of Orbitello, celebrated for the immense quantities of large cels (Murena anguilla Linn.) it produces, became a new incentive to my curiosity; and a dead calm detaining the vessel in which I had taken my passage several days at Porto Ercole, a few miles distant from Orbitello; as I could easily obtain as many cels as I chose, I examined them with great attention, to discover, if possible, the manner in which they propagate their species, since, notwithstanding the numerous experiments that have been made both by ancient and modern naturalists to elucidate this question, it is not yet known with certainty whether they are viviparous or oviparous. To the experiments I now made, when I returned into Lombardy, I added many others in the following years, made in every season.

With this view expressly I repaired to the lakes of Comacchio, which, with that abovementioned, abound more with this fish than any in Europe. I here assiduously studied the various qualities of the animal, in order to illustrate its history, which is in many respects deficient and obscure.

The last place at which I landed before my arrival at Genoa, was the island of Elba, where I was obliged to remain five days in consequence of another calm. I profited by this delay to visit the ancient and celebrated iron mines, where I procured for the Imperial Museum at Pavia some noble specimens of that metal crystallized, and augmented the copious collection I carried with me with some sulphures of iron (pyrites.)

I returned to the university about the end of the year 1788, having employed six months in my travels in the two Sicilies; with which, though they were at my own expence, like the greater part of my other travels, I am well satisfied, since I have been able to contribute something to that noble public institution the Museum at Pavia; but my satisfaction will be still greater, if the work I now present to the public be approved by its readers.

Thus I employed the summer and autumn vacations of that year. Some time before, but especially in the vacations of 1789 and 1790, I made researches among the mountains of Modena and Reggio, with respect to objects which, as they have a relation to volcanos, may have a place in this work.

The fires of Barigazzo, which burn on the Apennines of Modena, have been long known. These consist of groups of feeble flames collected in a narrow space, which rise above the earth, are almost always visible, and, if by chance they become extinct, may be rekindled by bringing a small flame to the spot where they were. The accounts of them, however, are so few, and so defective, that at most they can only serve to compare the present state of these flames with what it once was. The light afforded by modern physics enables us to affirm, without farther examination, that the cause of this feeble fire must be hydrogenous gas (or inflammable gas.) I made a journey to Barigazzo purposely to ascertain this, and found it to be the fact. In that vicinity there are six other similar fires, at present only known to the Alpine peasants, all originating from the same principle.

But in the present accurate state of our knowledge relative to aeriform gases, it is too little to say and prove that the cause of these various flames is hydrogenous gas. The following are the principal inquiries which I think it necessary for me, as a naturalist, to make with respect to these fires, and such objects as may have a relation to them.

First, to examine the structure and composition of those mountains; and here I shall incidentally have occasion to speak of Cimone, not far distant from Barigazzo, and the highest mountain of our Apennines.

Secondly, carefully to remark the qualities of each of these fires, and the phenomena accompanying them.

.

in the second

to the state of the or to

Thirdly, to compare these fires nourished by natural hydrogenous gas, with those produced by hydrogenous gas procured by art.

Fourthly, to make a rigorous analysis of the hydrogenous gas of the fires of Barigaz. 20 and the other neighbouring places, by means of the chemical mercurial apparatus; and to carry to those Alpine heights vessels to contain the different aeriform fluids, and instruments necessary for these analyses.

Fifthly, to make the same analysis of the earths from which these fires arise. And here I must observe by the way, that having made at Barigazzo an excavation of some depth and size, in order to obtain the earth pure; the fires multiplied so much, and became so powerful, that, after I had left the place, the hollow was employed as a furnace for lime, and lime-stone as perfectly burnt in it as in furnaces prepared for the purpose.

Sixthly, to examine what may be the matters generative of this inexhaustible supply of hydrogenous gas, which has been so long continually developed; it being certain, from authentic documents, that these fires have burned for a century and a half.

In the hills of Modena and Reggio we find certain places which the people of the country call Salse, and which are a kind of volcanos in miniature, having the form externally of the truncated cone, and internally of the inverted funnel. They sometimes throw up into the air earthy matters; which at other times overflow, and, pouring down their sides, form small currents. After the manner of burning mountains, they frequently open with several mouths, and like them rage, thunder, and cause slight earthquakes around them. But in the true volcanos the primary agent is fire; in these salse the generative principle is entirely different.

Some of them have hitherto remained wholly unknown to naturalists; of others authors have written, but have described the phenomena with little accuracy and frequent exaggeration; not to mention that, at the time when they wrote, the nature of the agent

from which these phenomena derive their origin was not discovered.

These salse have claimed my attention equally with the fires above mentioned; and I have applied myself to study them with equal assiduity, and with the same chemical analysis; and as they both, after the manner of volcanos, undergo changes which appear sometimes to have relation to those of the atmosphere, I have judged it necessary frequently to visit them, and in different seasons to observe the various phenomena, and with more certainty discover the secret causes to which they owe their origin.

The Travels I now present to the public, and of which I have here given the summary, will be speedily followed by another work containing an account of my voyages to

Constantinople, in the Mediterranean, and in the Adriatic.

TRAVELS, &c.

CHAPTER I.

A VISIT TO VESUVIUS DURING THE TIME OF AN ERUPTION.

Little notice taken by the Neapolitans of the smaller eruptions of this volcano....Phenomena observed by the author on his arrival at Naples His approach near to the crater prevented by showers of ignited stones, and acid-sulphureous fumes.... Extraordinary phenomenon relative to these showers.... Explication of that phenomenon.... Remarks on the congelation of a torrent of lava....Observations on a stream of lava flowing within a cevern....Projected experiment for measuring the quantity of heat in the flowing lava.... Other observations on t' . lava issuing from a subterraneous cavity Remarkable cataract formed by it in its passage Length, breadth, and termination of this torrent.... Phenomena of this eruption of Vesuvius compared with those of preceding ones.... Erroneous opinion of some naturalists, that the lava is not fluid, but of the consistence of paste.... Composition of this lava.... Observations on a lava of Vesuvius which flowed in 1785....Proofs that the shoerls and feltspars found in the lava existed previously in the primordial rocks.

WHEN I arrived at Naples, on the 24th of July 1788, though Vesuvius was not in a state of inactivity, its conflagration was not sufficient to excite the curiosity of the Neapolitans; who, from having it continually before their eyes, are seldom inclined to visit it, but during its great and destructive eruptions. At that time, during the day, it without intermission sent forth smoke, which rising formed a white cloud round the summit, and, being driven by the north-east wind, extended in a long stream to the island of Capri. By night repeated eruptions of fire were visible, though no subterraneous explosions were to be heard at Naples; and a tract of ground to the south of the crater assumed a dusky red colour, which, by the experienced in volcanic phenomena, was said to be preparatory to the flowing of the lava. I should immediately have repaired to the place, had not my friends at Naples assured me, from the practical knowledge they had of their burning mountain, that that eruption, which at my arrival was but inconsiderable, would after some time become much more extensive. It was in fact my wish to see Vesuvius, if not raging with its most tremendous fury, at least in a more than ordinary commotion.

I, in consequence, returned from Sicily to Naples in the beginning of November, when a stream of lava, issuing from an aperture in the side of the mountain, covered a considerable extent of ground, and began to be visible before day-light, from beyond Capri, under the appearance of a streak of a reddish colour. On the 4th of the same month I began my journey to the volcano, and passed the night at the Hermitage del Salvatore, two miles from the summit of the mountain. Before I retired to rest, I passed several hours in making observations with the greatest attention; nor could the opportunity have been more favourable, as there was no moon, and the sky was perfectly free

from clouds.

I had therefore a clear view of the eruption of the mountain, which had the appearance of a red flame, that enlarged as it rose, continued a few seconds, and then disappeared. The ejections succeeded each other at unequal intervals of time; but no in-

termission continued longer than five minutes.

I rose four hours before day, and continued my journey towards the burning crater, from which, as I have before said, flames arose at intervals, which on a nearer approach appeared larger and more vivid; and every ejection was followed by a detonation, more or less loud, according to the quantity of burning matter ejected: a circumstance I did not notice before, on account of the distance, but which became more perceptible to the ear in proportion as I approached the mouth of the volcano; and I observed, when I had arrived within half a mile of it, in a direct line, that the ejections preceded their accompanying explosions only by an instant, which is agreeable to the laws of the propagation of light and sound. At this distance not only flames were visible to the eye, but a shower of ignited stones, which, in the stronger ejections, were thrown to a prodigious height, and thence fell on the declivities of the mountain, emitting a great quantity of vivid sparks, and bounding and rolling till they came within a short distance of the place where I stood. These stones, when I afterwards examined them, I found to be only particles of the lava, which had become solid in the air, and taken a globose form. These showers of lava appeared an invincible obstacle to my nearer approach to the volcanic furnace. I did not, however, lose all hope, being encouraged by the following observation. The showers of heated stones, I remarked, did not fall vertically, but all inclined a little to the west. I therefore removed to the east side of Vesuvius, where I could approach nearer to the burning mouth: but a wind suddenly springing up from the west, compelled me to remove, with no little regret, to a greater distance, as the smoke from the mouth of the crater, which before rose in a perpendicular column, was now drifted by the wind to the side on which I stood; so that I soon found myself enveloped in a cloud of smoke abounding with sulphureous vapours, and was obliged hastily to retire down the side of the mountain. Yet though I was thus disappointed of the pleasure of approaching nearer to the edge of the crater, and observing the cruptions more nearly and accurately, many instructive objects were not wanting. But before I proceed to any remarks on these, I must notice a curious and unexpected

I have already spoken of the detonations which accompanied the showers of lava. It is now necessary to add, that these did not constantly accompany every eruption. When I had taken my station in the lower part of the mountain, I found the detonations more sensible, and resembling the noise produced by a large mine when it explodes; but suddenly, to my great surprise, they ceased, though the ejections of fiery matter continued both frequent and copious. I counted eighteen eruptions which were not accompanied by the smallest noise. The nineteenth, though not larger than the former, was followed by its detonation, as were eleven more, though others which succeeded were silent. This irregularity I observed so repeatedly, that the detonations appeared to me rather accidental than necessarily connected with the explosions. In this opinion I am supported by the authority of my ingenious friend, the abbe Fortis who afterwards told me, at Naples, that he had frequently observed the same inconstancy in the eruptions of Vesuvius.

This peculiar phenomenon, which has not, to my knowledge, been remarked by any one of the numerous authors who have written on Vesuvius, does not appear, at first view, to be easily explicable from the physical cause of the explosions. As it must be allowed that the fire alone is not sufficient to produce it, we must liave recourse to an elastic fluid, which disengages itself from the lava, impelling at the same time a part of it into the air; which effect can scarcely happen without a detonation. But on more

mature reflection it appeared to me most probable that this takes place only within certain limits. When the elastic fluid bursts suddenly against the lava, it is to be expected that it will produce a considerable report; but when it acts slowly it will occasion little or none, though the ejection may be very strong. Thus, if the atmospheric air be confined between two pellets of tow in a tube, and one of them be forced suddenly towards the other, the latter will be projected to some distance, with a considerable sound, but none, or very little, will be heard if the pellet be gradually pressed towards the other. In like manner the air contained in an air gun produces scarcely any report on its discharge, on account of the interposition of the valve delaying its action on the ball.

In what I have said, however, I do not mean to assert that these volcanic eruptions were entirely unaccompanied with any explosive sound. It is highly probable they were not; but that I could not hear the feebler detonations on account of the distance.

It has been already said, that the liquid lava had opened itself a way, not immediately from the summit of the crater, but? Im one side of the mountain. The following are the observations made on this subject. Towards the south-east, at the distance of about half a mile from the crater, on a declivity, there arose sixty or more small columns of smoke, one of which was about nine feet in diameter, and came from a not very deep cavern. The ground from which these streams of smoke issued was tinged with yellow, from the muriate of ammoniae, and so hot, that even at some distance, I could bear my feet on it only for a few seconds. It is sufficiently manifest that the smoke and heat proceeded from the same cause; that is to say, from the subterrancous conflagration which communicated with that part, and caused the smoke to burst forth through

the fissures in the ground. At the distance of a few paces from this spot, the aperture was visible through which, six months before, the lava disgorged itself, as I was assured by my guide; but it no longer flowed at the time of my arrival, its current having acquired the hardness of stone. About fifty paces lower, however, in the same direction, that is towards the south, the lava was still running within a kind of pit, but without rising above its borders; and at a place still lower, about two miles from the principal crater of Vesuvius, the lava issued from the subterranean cavern, forming in the open air a long current. But before I proceed to describe the latter, it will be proper to notice the highly curious phenomena observable in the lava moving within the above-mentioned cavity or pit. This pit was of a shape approaching to an oval, about twenty-three feet in circuit. The sides, or banks, were nearly perpendicular, about four feet and a half in height; and it was excavated in the hardened lava of the last eruption. The burning lava moved within this cavern, of which it covered the whole bottom, in the direction of from north to south. From it arose a cloud of smoke, which reflecting the light from the red hot lava, produced in the air a red brightness, that during the night might be seen at a considerable distance. But as this smoke was strongly impregnated with acid-sulphureous vapours, I found it a great obstacle to my making any observations on the liquid lava, when, from the calmness of the air, it ascended perpendicularly. But, from time to time, a slight breeze arose which carried the stream towards one side; and I then removed to the opposite, where I was no longer incommoded in my experiments by the vapour. During these favourable intervals, I could stoop down towards the pit, in which I observed the appearances which I here faithfully relate.

At the distance between the lower extremities of my body and the lava was only five feet, the heat it sent forth was very vehement, but not absolutely intolerable, though it forced me to remove from it a little, from time to time.

I observed then that the lava flowed, as I have before said, along this cavity, from the north to the south, and then disappeared under the excavated hardened lava. Its surface exhibited the redness of burning coal, but without the smallest appearance of flame. I know nothing to which it can be more properly compared then melted brass in a furnace. This superficies was in some places covered with a white froth; and from time to time bubbles arose in it, which burst a moment after with a sensible noise. Sometimes, likewise, the lava rose in small jets or spouts, which, in an instant after, subsided, and

the surface again became smooth and even.

The nearness of my approach to this melted matter, which I observed, first, during the darkness of the night, and afterwards by the light of day, removed every shade of doubt or uncertainty respecting the remarks I made. It likewise furnished me with an opportunity to make some experiments which I otherwise could not have made. I was desirous to let fall some heavy body into the flowing lava; but my situation would only permit me to use, for this purpose, pieces of lava which lay round the cavern, as I could find no substance of any other kind. When I threw these pieces into the lava, they occasioned that dull kind of sound which would have been produced by striking soft earth or thick mud; and at the same time formed in the lava an incavation, in which they were buried about one third part of their bulk, and in this situation were carried away by the current. The same happened when I, at other times, used larger pieces, and threw them forcibly into the lava; the only difference was that then they sunk in

deeper.

From this experiment I ascertained the velocity of the lava, as it is certain that must have been the same with that of the stone carried by it. In about half a minute, the pieces of solid lava were carried ten feet and a half. The motion of the current was therefore very slow; which was not surprising, as the declivity was very little. We shall see presently, that the pieces of lava with which I made my experiment, were probably of the same kind with the lava which was flowing; on which account I, at first, expected that they would have sunk entirely within it, since it is well known that all bodies which pass from a fluid to a solid state become more compact; but a moment's reflection convinced me that the fact could happen no otherwise than it did. The pieces of lava which I threw into the current were full of pores and cavities, which in the liquid lava could not have place, or at least could not be so numerous; these pieces, therefore, must be lighter than the liquid lava. Another reason, which I consider as still more decisive, is derived from the tenacious liquidity of the flowing lava, which must prevent the entire immersion of the solid lava, though the latter should be specifically heavier. Thus I have observed that a solid globe of glass, though thrown with some force into a liquid mass of the same matter, will not remain entirely submerged, but float with a part above the surface.

I would willingly have made another experiment, which I should have considered as of much greater importance; but I had not with me the instruments necessary to undertake it; because I had not the least expectation that I should have been able to approach so near to the flowing lava as would have given me an opportunity to have

used them.

The experiment I mean was to have ascertained the degree of absolute heat of the flowing lava, and might have been very conveniently made at this place. As therefore circumstances did not permit me to make a second visit to Vesuvius, and as these cavities which receive into them the flowing lava are frequently met with in volcanic eruptions, it may not be improper here to detail the nature and mode of the experiments I would have made, had I been furnished with the necessary means, in hope that some

and it withrth to t lava, siderus val lava, me to

en rey the pit, in

ly five ugh it similar opportunity may induce some one of the few naturalists of Naples who are desirous to enlarge the knowledge we have of their volcano, to carry them into effect.

First, therefore, I would have let fall on the lava within that cavity two kinds of substances, inflammable and fusible, contriving some means to keep them fixed in the bame place; punctually noticing the time required for the inflaming of the former and the fusion of the latter. I would then have exposed the same substances to our common fires, until the same effects had been produced, observing the difference of time between the production of the effect by the volcanic fire and the common. I should thus have obtained a term of comparison of great utility in the inquiry proposed. But a method more precise and certain, would be to make use of the pyrometer of Mr. Wedgwood;* which should be used in the following manner; to ascertain the absolute heat of the superficies of the lava, one or more of the cylinders of clay should be let down upon it, inclosed in the box of the same earth adapted to them, fastened to an iron chain that it may not be carried away by the current, and the experiment prevented. This being taken up, after having been suffered to remain there some hours, the shortening of the cylinders would show the quantity of absolute heat they had suffered, and, consequently, that of the lava on which they had rested.

But with this experiment alone I should not have been entirely satisfied. By the assistance of this same pyrometer, I would have endeavoured to discover the internal absolute heat of the lava, by immerging within it some of the cylinders I have before mentioned, inclosed in a thick hollow globe of iron, fastened to a chain of the same metal. The infusibility of iron in our common furnaces inclines me to believe that it would resist the heat of the liquid lava; but should it not, its melting would supply the place of

a pyrometer, and sufficiently prove the violence of the heat.

I am aware that these experiments would not ascertain, with precision, the heat of other torrents of lava, which must necessarily depend on the greater or less depth of the ignited matter, its distance from the principal seat of the conflagration, and the different qualities of the lava. But they must have been of considerable importance, and

I can never sufficiently regret not having had it in my power to make them.

It may, perhaps, be doubted whether the globe of iron I have mentioned could be made to penetrate through the tenacious superficies of the lava: but there seems little reason for this doubt, when we consider that the pieces of porous lava, which are far lighter than this metal, penetrated it to one third of their bulk. And though it should not be able to divide that part of the superficies which, by being in contact with the air, has less liquidity; that might be separated by other means, and the globe immediately plunged into the more fluid part of the lava.

I do not deny but that these and other similar experiments are difficult, offensive, and, in some degree even dangerous; but what experiment can be undertaken perfectly free from inconvenience, and all fear of danger, on mountains which vomit forth fire? I would certainly advise the philosopher who wishes always to make his observations en-

tirely at his ease, and without risk, never to visit volcanos.

But it is time to continue my narrative of the phenomena I observed in this eruption of Vesuvius. Though the lava issued at its origin from only a narrow aperture, the stream of it became considerably enlarged as it descended the declivity of the mountain, and formed other smaller torrents: but at about the space of a mile from the mouth whence it issued, its superficies had acquired the solidity of stone. I endeavoured to pass over this, notwithstanding the difficulty of walking on it, as it was en-

^{*} See the Introduction.

tirely composed of small disjoined scorize, on which the foot could not rest with firmness, and so hot that I was obliged to change my shoes, those I had being worn out, and half-burnt.

Besides two other pits, similar to that I have described, and some burning orifices in which, when I looked into them, I could perceive the liquid lava resembling melted glass in a furnace when it burns with the utmost violence; I observed, likewise, the traces of the course which the lava had taken or resumed. Here the channels through which it had flowed remained, but empty; there some residue of it was to be seen; and others were full of it. One had the form of a cylindric tube, and another that of a parallelopiped. But the direction of all these channels through which the lava had flowed was towards the south. It did not require much attention to perceive, that under the solid lava on which I walked the fluid was still running; the low but distinct sound it occa-

sioned in its passage was clearly perceptible to the ear.

A sufficient illustration of what I mean may be given from what frequently happens, in winter to many slow streams, in the northern parts of Italy. In these, when the winter is severe, the superficies of the water at first adheres to the banks, and afterwards congeals in the middle, forming a crust of ice which increases in thickness, from night to night, while the water, which is still fluid, if there is sufficient depth, continues to run under it; though the thickness of the ice increases, till after some days it is sufficiently strong to bear men to walk on it, or even greater weights. If any person should then go upon it, and apply his ear close to it, he would hear the sound of the water running under, as I have several times experienced in the vicinity of Pavis. This sound appears to me to be precisely the same with that occasioned by the Vesuvian lava flowing under the solid lava, and proceeds doubtless from the same cause; I mean the obstacles the fluids meet with and strike against in their passage; as the cause of congelation is likewise the same in both, that is, the privation or rather the diminution of their absolute heat,

Pursuing my way to the south, along the declivity of the mountain, I arrived at the part where the lava run above the ground. Where the stream was broadest, it was twenty-two feet in breadth, and eighteen where narrowest. The length of this torrent was two miles, or nearly so. This stream of lava when compared with others which have flowed from Vesuvius, and extended to the distance of five or six miles, with a proportionate breadth, must certainly suffer in the comparison; but considered in itself, and especially by a person unaccustomed to such scenes, it cannot but astonish and most powerfully affect the mind. When I travelled in Switzerland, the impression made upon me by the Glaciers was, I confess, great; to see in the midst of summer immense mountains of ice and snow, placed on enormous rocks, and to find myself shake with cold, wrapped up in my pelisse on their frozen cliffs, while in the plain below nature appeared languid with the extreme heat. But much more forcibly was I affected at the sight of this torrent of lava, which resembled a river of fire. It issued from an aperture excavated in the congealed lava, and took its course towards the south. For thirty or forty paces from its source, it had a red colour, but less ardent than that of the lava which flowed within the cavern I have mentioned above. Through this whole space its surface was filled with tumours which momentarily arose and disappeared. I was able to approach it to within the distance of ten feet; but the heat I felt was extremely great, and almost insupportable, when the air, put in motion, crossed the lava, and blew upon me. When I threw into the torrent pieces of the hardened lava, they left a very slight hollow trace. The sound they produced was like that of one stone striking against another; and they swam following the motion of the stream. The torrent at VOL. V.

first descended down an inclined plane which made an angle of about 45 degrees with the horizon, flowing at the rate of eighteen feet in a minute; but at about the distance of thirty or forty paces from its source, its superficies, cleared from the tumours I have before mentioned, shewed only large flakes of the substance of the lava, of an extremely dull red, which, clashing together, produced a confused sound, and were borne along

by the current under them.

Observing these phenomena with attention, I perceived the cause of this diversity of appearance. The lava, when it issued from the subterranean caverns, began, from the impression of the cold air, to lose its fluidity, so that it yielded less to the stroke of solid bodies. The loss of the principle, however was not such as to prevent the superficies from flowing. But at length it diminished by the increasing induration; and then, the superficial part of the lava, by the unequal adhesion of its parts, was separated into flakes, which would have remained motionless had they not been borne away by the subjacent matter, which still remained fluid, on account of its not being exposed to the immediate action of the air, in the same manner as water carries on its surface floating flakes of ice.

Proceeding further, I perceived that the stream was covered, not only with these flakes, but with a great quantity of scoriæ; and the whole mass of these floating matters was carried away by the fluid lava, with unequal velocity, which was small where the declivity was slight, but considerable when it was great. In one place, for ten or twelve feet, the descent was so steep that it differed but little from a perpendicular. The lava must therefore be expected there to form a cataract. This it in fact did, and no sight could be more curious. When it arrived at the brow of this descent, it fell headlong, forming a large liquid sheet of a pale red, which dashed with a loud noise on the ground below, where the torrent continued its course.

It appeared to me that it might be expected that, where the channel was narrow, the velocity of the torrent must be increased, and where it was capacious diminished; but I observed that, in proportion as it removed from its source, its progressive motion became slower; and the reason for this is extremely obvious; since the current of melted matter being continually exposed to the cold air, must continually lose some

portion of its heat, and consequently, of its fluidity.

At length the lava, after having continued its course about two miles, along the declivity of the mountain, stopped, and formed a kind of small lake, but solid, at least on the superficies. Here the fiery redness disappeared; but about two hundred feet higher it was still visible, and more apparent still nearer to its source. From the whole of this lake strong sulphureous fumes arose, which were likewise to be observed at the sides where the lava had ceased to flow, but still retained a considerable degree of heat.

After having written these observations on the lava ejected by Vesuvius, as it appeared from its source to its termination, which I made in company with Dr. Comi Abruzzese, a young student of great promise in medical and physical science, I had an opportunity to read the accounts of former cruptions, as they have been given by men of great abilities, who had observed them on the spot, I mean Dr. Serao, Father Della Torre, M. Delue, and Sir William Hamilton. I perceive that in the principal facts, the phenomena I have observed agree with their observations, and that the differences are but few. Thus the torrents of lava which they have described were accompanied with great fumes, and covered with pieces of lava and scories. In like manner the liquid lava received but small impressions from the stroke of solid bodies, and sometimes none. Scrao informs us, that the lava of 1737, when struck on the surface

with long pointed staves, was found to be so hard that it resounded. According to the observation of Father Della Torre, the thick lava of the eruption of 1754, when raised with long poles, split into pieces. M. Delue shewed me, some years since, in his private cabinet of natural history, at Geneva, a piece of Vesuvian lava, of the eruption of 1758, marked with a slight impression, which he made on it, on the spot, while it retained its softness. If this naturalist should ever chance to come to Pavia I could shew him, in return, in the public Imperial Museum, among the collection of volcanic productions which I have made, a cylinder of lava, eighteen inches long, and five and a half thick, which, in one part, has been bent to an angle, while it was half liquid, by the hands of the guide who accompanied me when I visited the eruption I have above described. In the eruption of 1766, likewise, though the lava flowed with surprising velocity, we are told by Sir William Hamilton, that it received but a very slight impression from some large stones that he threw into it. Father Della Torre has also remarked another phenomenon which I observed, and have described, relative to the effervescence

and tumours of the fluid lava.

But my meeting with the subterranean cavity in which the lava flowed, was a fortunate and singular circumstance, which is not, that I know of, mentioned by any one else, because prebably it was not seen; since all the descriptions of eruptions which we have, relate solely to currents of lava running over the surface of the ground, exposed to the free action of the air; from the effect of which the lava must soon cool and harden; as appears from the very slight impression made by stones thrown into it, according to all the accounts I have cited, and my own observations. But the narrowness cithis cavern, and in some measure its depth, prevented this action of the air; whence I was enabled to observe the lava in a state in which it cannot be seen above the ground, still retaining a great part of its fluidity, as appeared from its from time to time spouting into the air, and from the impressions made on it by the pieces of lava thrown into it. It cannot, therefore, be doubted but it had a much greater degree of fluidity when it boiled up in the Vesuvian furnace; as it must then have been penetrated with a greater quantity of absolute heat, by the action of which its parts must have been more disjoined and separated, and therefore have possessed a greater degree of fluidity and mobility. But I shall adduce still stronger reasons to prove the great fluidity of the lava, when it foams and boils up in its craters, when I come to speak of the volcano of Stromboli. I dwell the longer on this subject, because I know some have denied that the lava is ever fluid, asserting, that it has only the consistence of paste moistened with a good deal of water, and descends down any declivity in consequence of its gravity.

To complete the observations I have made on this eruption, nothing appears to remain but to speak of the quality of the ejected lava. On this I made different experiments, all of which, some extrinsic or accidental circumstances excepted, furnished the same results. The base of the lava is of horn-stone rock, of a dark-gray colour, of moderate hardness, dry to the touch, where it has been fresh broken somewhat earthy, and gives some sparks with the steel. This lava put the magnetic needle in motion at the distance

of three lines and a half, or somewhat more than a quarter of an inch.

It is well known to volcanic naturalists, that many of the lavas of Vesuvius contain colourless garnets. In that of which I treat, they were found very numerous, though very small. When broken, they appeared glassy; and sometimes a kind of side or face was visible, though without its being possible to determine the quality of the crystallization, not so much from their smallness as from their being too intimately incorporated with their tenacious matrix. With the garnets were united a number of shoerls, of the colour and lustre of asphaltum, vitreous crystallized in faces, the largest of which was

D 2

nearly five lines. Those which were found in the running lava had received no injury from the fire; but those in the globes ejected from the crater in that cruption, were in a state of beginning fusion.

The fire of the furnace changed this lava into a kind of enamel, full of bubbles, of the colour of pitch, shining, which gave sparks with steel, and adhered strongly to the sides of the crucible.* The shoerls melted, but the garnets did not; they only became

whitish, but without entirely losing their vitreous appearance.

After having made my observations on the phenomena exhibited by the stream of lava then running, I proceeded to examine the vestiges of others which had flowed some time before; one of which, in November 1785, had issued at about one third of a mile from its crater, on the side of Monte Somma. As I do not know that any notice has yet been taken of it by others, I shall relate the observations I made as I passed over the remains of it, and likewise the information given me concerning it by my guide, and some persons who cultivate the study of Natural History, who had observed it on the spot at the time of its cruption.

Although at its source it was but narrow (as generally happens to these streams of lava) it afterwards became considerably enlarged, and did not form small, disjoined, and rugged pieces like the others I have described; but large masses, many feet in breadth and depth, and separated by numerous fissures. Its superficies presented an appearance not a little curious. It was rugged and irregular, from an immense number of small cylindric bodies resembling twisted cords, and which are only the lava itself reduced into striated and contorted fibres, when near the end of its course, and ready to congcal. In its qualities it did not appear to me to differ from the other Vesuvian lava I had already examined, either in its base or the garnets and shoerls which it contained.

The greater part of this lava lies in a valley under Massa, and on one side of Salvatore. Before it arrived there, it must have fallen from a high rock, and consequently formed a cataract, which, when seen by night, I was told, exhibited a most wonderful spectacle to the eyes of beholders. But though its fall through the air must have been very considerable, and it must in consequence have lost much of its heat, when it reached the ground it continued still to flow for a considerable space. On the side of Massa, I observed that it had approached within ten or twelve feet of some oaks which grew on the side of a precipice. Some of them appeared entirely withered; others preserved their verdure only on that side of the trunk and branches which was opposite to that next the lava. In its passage it did such damage to a small church called Madonna della Vetrana, that it has ever since remained deserted. The fiery torrent took it in front, and broke down the wall, which indeed required no great force, as it was built with soft stones of tufa brought from the neighbouring mountains of Massa, and much like that of Naples. Thence it penetrated into the church, and having destroyed the door on the opposite side, and beat down a part of the wall, continued its course, through the church, within which it was observed to flow with greater velocity than the rest of the surrounding lava, from being confined by the walls on the sides. With this lava the floor of the edifice still continues covered, and the contiguous sacristy partly filled; while large pieces of the broken wall, which the torrent had carried away, lie at more than eighty feet distance from the church, in the middle of the hardened lava. Some linden trees

^{*}To avoid repetitions, I shall here mention, that, when I use the word furnace without any other addition, I always mean the furnace of a glass-house; and that by the term enamel, I understand, with the generality of our chemists, a substance produced by heat, resembling glass, but without its transparency. It may also be proper to add, that, as often as an entire fusion of the lava took place in the crucibles, it adhered strongly to the sides.

are likewise to be seen surrounded by the same, the trunks of which are blackened and burnt. The lava, as I was assured, continued to flow fifteen months; and when I visited the place, which was ten months after it had ceased to flow, it was still warm, and emitted thin fumes.

On one side of Vesuvius, about a mile below Salvatore, is a spacious cavern, which widens as we descend into it, called the Fossa Grande. I took this way to return to Naples, and gained from it considerable and useful information. It is well known what doubts have been entertained relative to the shoerls and feltspars which are usually found, either conjointly or separately, in the lavas; I mean whether they have been formed within them, either while they were fluid, or at the time of their congelation; or whether they existed in the original rock before the fire changed it into lava. Bergman has stated the arguments on each side, but has left the controversy undecided. It is true, that, when that chemist wrote on volcanic productions, the opinion was, with good reason, most prevalent, which supposes that the shoerls and feltspars existed originally in the primordial rocks. This hypothesis has received considerable support from the pieces of rock anciently thrown out of Vesuvius, which are to be found on the surface of the ground; or by searching and digging in the tufaceous matters of the Fossa Grande.

But it is necessary to proceed to particulars. One species of these rocks is of a margaceous nature, the carbonate of lime however prevailing. As this did not appear to be at all calcined, but unchanged, and similar to stones of the same kind which are not volcanic, it afforded a convincing proof that these rocks have received no sensible injury from the fire; but if we break some of these, we shall find in them numbers of feltspars, which, in their crystallization, and other exterior characters, extremely resemble many of those we meet with in some lavas of Vesuvius, and other neighbouring volcanic places. Still more numerous also are the shoerls of a shining black; some of the shape of needles, and others of prisms, and varying in their size; some being so small as to be scarcely visible, and others of the length of seven lines, or above half an inch, and broad in proportion. These pieces of rock do not form veins, strata, or great masses, but are distributed in different places in scattered fragments.

Here likewise we find various pieces of granite, not in the least injured by the fire; the quartz of which, besides mica, is accompanied by feltspars and shoerls, which in no

respect differ from the volcanic shoerls and feltspars.

I might have considerably extended these remarks on the species of rock thrown out by the Vesuvian fires without receiving injury or change; but I think that what I have said will be sufficient to shew, that, in order to account for the presence of feltspars and shoerls in lava, and their various crystallizations, it is not necessary to suppose them formed within it, either when it was fluid, or at the time of its congelation; since we meet with similar vitreous bodies in the substances from which it derives its origin.

CHAPTER II.

THE GROTTO OF POSILIPO....SOLFATARA....THE PISCIARELLI.

The city of Naples founded on volcanic substances.... Different opinions relative to the origin of volcanic tufas.... Those of Posilipo appear to have been formed by thick eruptions.... Lavas on the road to Solfatara described.... Specular iron found in one of these.... Solfatara is not an isolated mountain, as has been supposed by some.... Sulphures of iron (or pyrites) lavas of Solfatara, and the Pisciarelli.... Observations on the decomposition of lava, and the shoerls and feltspars which are found within it; as also on the sulphureous-acid fumes which incessantly exhale from this volcano... Conjecture that Solfatara has arisen out of the sea... Method lately employed to extract, more abundantly than formerly, alum and sal ammoniac from this volcano... Critical disquisition relative to a curious phenomenon in the vicinity of Solfatara, from which M. Ferber conjectures that the level of the sea has there sunk nine feet.

DURING my stay at Naples, I determined to visit the other principal Phlegrean fields, as well as Vesuvius, and I had the good fortune to meet with, and have for a companion, the abbe Breislak, formerly professor of philosophy at Rome, and of mathematics in the Nazarine College; and now director of Solfatara, near Pozzuolo.

The beautiful city of Naples is entirely founded on volcanic substances. Among these the tufa predominates, which has also contributed not a little to the materials of many buildings. To the north and west it is accumulated in large heaps, and forms spacious hills. A philosophical stranger, on his arrival in this country, when he views these immense masses of a substance which must excite in his mind the idea of fire, cannot but feel astonishment, and inquire with a kind of serious thoughtfulness, what has been their origin. It is known that on this subject naturalists are divided. Some conjecture that the volcanic tufa was generated within the sea when it bathed the foot of the burning mountains; others suppose that the cinders ejected by the fire have, in a long course of years, been hardened into this species of stone by the filtration of rain water; lastly, others incline to think that the tuf derives its origin from the slimy and fluid substances thrown out by the volcanos in some of their eruptions.

The diversity of volcanic tufas has perhaps been the cause of these different opinions, each of which may possibly be true with respect to different kinds of tufa. Those, however, which are found in the vicinity of Naples are probably the produce of thick cruptions, as we may conclude from the curious discovery of Sir William Hamilton, who, in digging up in the tufa which had covered Herculaneum, the head of an ancient statue, observed that the perfect impression of the head was visible in the tufa, which cannot be supposed to have happened but by its having enveloped the statue in a liquid or moist state.

To the observation of Sir William let me be permitted to add one of my own, which I made in the grotto of Posilipo. It is well known that this grotto has been excavated within the tufa, and serves as a public road from Naples to Pozzuolo. This tufa, which is of a clear gray, has for its base an earth in part argillaceous, of a slight hardness, which contains vitreous flakes, pieces of feltspars and fragments of yellowish pumicestone, which by the changes it has undergone has become extremely friable, and almost reducible to powder. This tufa has been in some measure analysed by the excavation made in it by art, which furnishes a proof of the nature of its origin. For if any person,

in the summer time, enters the grotto about the rising of the sun, since at other times of the day there is not sufficient light, the solar rays, shining on the entrance which looks towards Naples, will sufficiently illuminate the roof and sides to shew layers or lakes, similar to those which may be observed on the steep sides of mountains, or in perpendicular sections of the earth, in low places, where sediments of various kinds of slime have been formed by the inundations of the rivers. It seems, however, impossible to doubt that this accumulation of tufa, through the midst of which the Romans opened that long and spacious grotto, has been produced by the thick eruptions which have frequently issued from volcanos, and which, heaping up one upon another, have hardened in time into this tufaceous stone; since both Vesuvius and Etna furnish sufficient examples of such cruptions. And as in many other tufas in the vicinity I have observed a similar constructure, I cannot suppose their origin to have been different.

Coming out of this subterraneous passage, and proceeding towards Solfatara, I observed, on the right hand side of the road, a ridge of lava, nearly parallel with it, which had every appearance of having been thrown out of the volcano when burning, both because it was extremely near to it, and had its highest part in that direction. Its thickness exceeded five-and-thirty feet, and it was situated between two layers of tufa, one above and the other below. It formed a high rock, perpendicular to one side of the road. A number of labourers were continually employed in separating pieces of this lava with pick-axes, or other instruments proper for such work. It is compact, heavy, somewhat vitreous, gives sparks with steel, and appeared to me to have for its base the petrosilex. Incorporated with it are found shoerls and feltspars. The former are shining, of a dark violet colour, in shape rectangular needles, vitreous, in length from the sixth of a line to two lines: it besides contains a considerable quantity of others which have no regular form. But the feltspars are more conspicuous than the shoerls, both from their larger size and greater number. They are in general of a flat rhomboidal form, and consist of an aggregate of small white lamellæ, duly transparent, brilliant, marked with longitudinal streaks parallel to each other, closely adhering together, but easily separated by the hammer, giving sparks with steel more readily than the lava; and, in the full light of day, exhibiting that changing colour which usually accompanies this stone. The largest are ten lines long and six broad, and the smallest exceed one line. The shoerls are also found in the lava, in the same manner, and are so fixed in it, that they occupy nearly the half of it. It is impossible to extricute them entire. They are distributed within it without any order, and frequently cross and intersect each other at right angles.

In some situations of this lava, which are more than others exposed to the inclemency of the air and seasons, the feltspars are visible on the superficies, by a mixture of emerald and purple, probably occasioned by the action of the atmosphere, as from the same cause

some volcanic vitrifications acquire externally their peculiar colour.

This lava has not equal solidity throughout, being in some places porous, or rather cavernous; and, in some of its varieties, it was remarkable, that it abounded with specular iron. This was found in very thin leaves, for the most part, closely connected together. These are extremely friable; and the finger being passed over them, they adhere to it like particles of mica. But their small size, which in the largest is scarcely a line, renders it necessary to make use of a lens to examine them properly; by the aid of which we shall find that they are of very different shapes, have the lustre of burnished steel, and that many of them appear to be aggregate of small thin scales, closely united.

This iron acts on the magnetic needle, at the distance of two lines. Like many other irons exposed to the air, it has acquired polarity; attracting the needle on one side, and repelling it on the other.

nions, Those, thick nilton, ncient which liquid

which avated which dness, micealmost avation person, When we extract these thin scales of iron from the lava, and examine them with the lens, there frequently appear, intermingled with them, various fragments of microscopic transparent prisms, which I at first thought to be shoerls of feltspars, but which afterwards I rather conceived to be zeolites, as they exhibited the appearance of radii diverging from their centre; but their extreme minuteness rendered it impossible accurately to ascertain their species.

Proceeding along the road to Solfatara, we find on the left hand a natural ridge of rock, formed of a very light lava, the base of which is horn-stone, of the colour of blue baked brick, of a coarse earthy grain, which attaches slightly to the tongue, and gives an argillaceous seent on wetting it, or even merely moistening it with the breath.*

It is very probable that this lava has been decomposed, and that the decomposition has penetrated to the feltspars with which it abounds, as they are become very friable,

though they in general still retain their natural brilliancy.

Having made these cursory observations, I proceeded to Solfatara: nor did I satisfy myself with one visit only, but repeated it several days; being extremely desirous carefully to examine, and gain every information relative to a place so celebrated.

From reading the notes of M. Dietrich to M. Ferber's Travels in Italy, I had been induced to imagine that Solfatara was a mountain isolated on every side; † but the truth is, it is connected with the other neighbouring mountains, with which it forms an un-

interrupted chain of considerable extent.

It would be that of little utility for me to describe at length the form, extent, and circuit of this Phlegrean field; the various qualities of the hot vapours which exhale from it; or the hollow noise which is heard on striking the ground in various parts of it; not that these circumstances were not carefully examined by me; or that I think them unworthy of my narrative; but because it appears to me unnecessary to enlarge on them, as they have been already repeatedly described by a great number of travellers. It will, in my opinion, be more agreeable to the naturalist to proceed to a minute examination of the principal productions of this yet unextinguished volcano, as they have hitherto been, for the most part, either unobserved, or passed over in silence.

In the obscurity and uncertainty in which we find ourselves, relative to the causes productive of subterraneous conflagrations, the spontaneous inflammation of sulphures of iron (or pyrites) has been considered as one of the most probable. The well-known experiment of Lemery, by which a similar conflagration is produced by mixing filings of iron with powdered sulphur properly moistened, has given great support to this opinion. But sulphures of iron, in volcanic countries, are less frequent than has been supposed. This has been clearly proved by the accurate observations of mineralogists who have written on them. And though Sir William Hamilton expressly affirms that both Etna and Vesuvius abound with them,‡ it is now well known that he mistook the shoerls for sulphures of iron (or pyrites) from want of mineralogical knewledge. In fact, Signior Dolomieu, in his Catologo Ragionato de' Prodotti dell' Etna, mentions only one single piece of lava as containing sulphur of iron: and the Chevalier Gioeni, in his Litologia Vesuviana, has never noticed any such production. In Vulcano and Stromboli, two islands which are in a state of actual conflagration, I could trace no vestiges of such

†" La Solfatare represente encore aujourd' hui une montagne assez elevee et isolee de tous cotes."

Lettres sur la Mineralogie, &c. d'Italie, &c.

^{*} In many lavas the scent of clay is perceived, on moistening them with the breath, or by other means: whenever, therefore, I may hereafter mention the argillaceous scent of lava I always understand it to have been subjected to this humectation, though I omit to mention it, to avoid prolixity.

[‡] Both these mountains abound with pyrites. Campi Phlegræi.

sulphures, as will be remarked in the proper place. As the same kind of substance, therefore, is found diffused in several parts of Solfatara, I think it well deserves that we should carefully consider it, and the bodies with which it is found united.

I. The stones which I here undertake to describe are principally found in the interior sides of Solfatara. The first I shall mention exhibits, both externally and internally, a number of shining particles, which, when examined by the lens, appear to be small aggregates of sulphur of iron, some crystallized in cubes, others in globes, and others in irregular figures. When the flame of the blow-pipe is applied to them, they begin to

lose their yellow colour, which quickly, in consequence of their destruction, entirely disappears; when an odour slightly sulphureous is emitted.

This substance is a lava, the base of which is horn-stone; in part decomposed, light, friable, granulous, and of a cincreous colour.

II. The small sulphures of iron in this second lava are less numerous, but in their qualities very analogous to that already described; except that they are less decom-

posed, and less friable.

oli, ch III. The appearances exhibited by this lava are two. The external part is extremely white, and so decomposed, that the slightest blow reduces it to powder; we likewise find in it some of the external characters of ordinary clay. It tenaciously adheres to the inside of the lip; is soft to the touch, and becomes still more so when slightly moistened. It absorbs water greedily, and with a kind of hissing noise; but is not reducible to a lubricious paste, as clay is. But the internal part of this lava, besides being of a gray colour, is three-fourths heavier, and in its compactness and its grain, approaches to that species of calcareous earth, called calcareus æquabilis, though in fact it only resembles it in appearance, not being reduced to calx by fire, nor dissolved by acids. In this lava the sulphure of iron is not found in cubes, or globes, but in thin lamellæ; and is dispersed throughout its whole substance, especially in certain parts, where the colour of the stone inclines to black, and has a greater consistency. No sign of this mineral appears in the white decompounded lava, probably because it was destroyed gradually, in proportion as the decomposition took place.

IV. This lava is much heavier than the three preceding; which, no doubt, arises from the greater abundance of sulphure of iron that it contains. The shining particles of this mineral are principally to be seen in the vacuities (of which, however, it has not many.) They are polyhedrous, but the number of their faces is not constant. When exposed to the fire it loses its brassy colour, burns with a thin blue flame, and emits a strong smell of sulphur. The lava which contains it, and which is of a livid gray colour, is, in some situations, so soft that it may be scratched with the nail, but in others much harder, and some of it will give sparks with steel. In this lava, the base of which appeared to me to be horn-stone, we find crystallized feltspars, but decomposed, though

less so than the lava in which they are inclosed.

V. Around the extensive plain of Solfatara, we observe in several places a circular ridge of steep rocks, which once formed the upper sides of this enormous crater. The rain-water, descending this declivity, over the decomposed lava, carries down with it the more minute parts to the lower grounds, where various concretions are produced, especially those stalactites which are commonly called oolithes, or pisolithes. But of these stalactites we shall speak hereafter. Here we shall only notice, that this water in its descent carries down with it small pieces of decomposed lava, and that in some places many of these pieces are found united, and bound together by a crust of sulphure of iron. It is black where it is exposed to the immediate action of the air, but in the fractures of a shining appearance, though the colour inclines more to a lead colour than to Vol. V.

yellow. Its structure is scaly. The sulphures of iron which have before been mentioned give fire with steel; but this does not, from want of sufficient hardness. In abounds with sulphur; since, being exposed to the flame of the blow-pipe, it visibly melts, and, the activity of the fire being increased, a blue flame arises, which continues till the crust is consumed, nothing remaining but a very small quantity of a white pulverous earth, which is no other than a portion of decomposed lava, that had been united with this sulphur.

With this sulphur, the presence of which is extremely manifest from its strong smell is also united arsenic; as sufficiently appears from the white fumes which arise from the combustion of the sulphure of iron, and which emit a very sensible odour of garlic.

These are the volcanic matters which, at Solfatara, abound more or less with sulphures of iron. But whence is their origin? It is well known they are formed by the combination of sulphur with iron. With the former this volcano abounds, whence it obtained the name of Solfatara; and as the latter is almost always found mixed with volcanic productions, which commonly derive from it their varying colours, we have thus the two proximate principles of sulphure of iron. But is their commendation effected by the dry, or, as is more probable, by the humid way? I find it difficult to conceive how it can take place by the first method, on account of the speedy dissipation of the sulphur sublimed by fire, which must prevent its uniting with the iron to form these sulphures. It appears to me more probable that they have been formed by the action of water, which having penetrated the lava, the sulphur, dissolving in the fluid, has combined with the iron. But as such solutions of sulphur in water seldom take place, as Bergman has observed, we rarely find sulphures of iron in volcanized countries, notwithstanding the existence of these two minerals.

But let us continue the description of the productions of this celebrated place, the greater part of which are decomposed lavas; though this decomposition, notwithstanding it has been noticed by several writers, has not, to my knowledge, been examined by any one with requisite care and attention.

VI. This lava is coloured on the upper part with a covering of yellow oxyde of iron, under which is a white decomposed stratum, to which corresponds another lower one of a cinereous colour, where the lava is much less changed. These two strata form a very strong contrast. The white may be cut with a knife, in some places more easily and in some less; adheres to the tongue, does not give sparks with steel, feels soft to the wet finger passed over it, has considerable lightness, and being struck with a hammer gives a dull sound, like earth moderately hardened. On the contrary, the cinereous stratum sounds, when struck with a hammer, like a hard stone, of which it also has the weight; is rough to the touch, scarcely at all adheres to the tongue, gives fire with steel, and cannot be cut with the knife. The white stratum in some places is an inch thick, and in others more, but there are likewise places where it is only a few lines in thickness.

reparation is sudden and abrupt.

The feltspars in this lava (for of these it is full) are prisms, the largest of which are ten lines in length, and the smallest the sixth of a line. In the cinereous stratum, notwithstanding a beginning decomposition may be perceived, the feltspars are unimpaired. On the contrary, in the more decomposed stratum, I mean the white, their decomposition is very apparent; they have all lost their transparency, though many of them still retain their splendour. Others have acquired a resemblance to a sulphate of lime that has remained some time in the fire; to which they might likewise be compared in softness, had they a little less consistence. Some of them are infixed in that part of the

lava, the colour of which is between the cinercous and white, and here we find them less changed than in the stratum which is entirely white. Others have one part of them in the white, and the other in the cinereous stratum; in which case we find the part fixed in the latter stratum to have suffered nothing, but that in the former considerably. In short, from the inspection of this lava it is manifest, that, in proportion as the nature of it is changed, the feltspars it contains undergo a change, except when the principle producing the alteration is unable to affect them. Besides these feltspars, we find, incorporated with the lava, a number of very small and almost invisible black shoerls, which are not distinguishable where the lava is white; less, perhaps, because they do not exist, than because they have lost their colour in consequence of the decomposition.

This lava, which is of a margaceous base, does not liquify in the furnace, when its decomposition is considerable, but other parts of it, which have been less decomposed,

are reduced to a kind of frit.

VII. Solfatara, perhaps, does not afford a lava more compact, hard, heavy, or of finer grain than this. Its composition is siliceous, its colour gray, it gives sparks strongly with steel, and, at the distance of two lines, attracts the magnetic needle. Its base is of the petrosilex, and it contains within it different feltspars and shoerls; but some of the latter have been melted by the fire, as appears from the bubbles or speckles occasioned by the liquefaction. This lava is covered with a very white crust, nearly an inch thick, produced by the decomposition it has undergone. The effects of the furnace on this lava are nearly the same with those on the lava No. VI.

VIII. This lava is entirely decomposed. On the surface, and for some depth, it is white, and almost pulverous; but in the internal part the white colour changes into a reddish blue, and acquires a degree of hardness, though not too great to be cut with a knise. The feltspars, in which it abounds, have suffered different degrees of decomposition. Some of them, besides being calcined, attach strongly to the tongue. Others, when viewed with a common lens, appear full of filaments, but when examined with a deeper magnifier, these filaments appear to be no other than extremely thin, striated, and

very friable laminæ. This production is infusible in the furnace.

IX. The feltspars in this lava occupy more than one third of its mass. They are in shape flat prisms, and, except having somewhat less hardness, retain all the qualities which characterise the species of stone to which they belong. There are also a number of shoerls, which, from their extreme minuteness, appear like points, but are easily distinguishable, by their black colour from the lava, which is whitish, and has greater consistence than that of No. VIII. It is likewise heavier; to which the quantity of feltspars but little changed, which it contains, undoubtedly contributes.

X. The shoerls which make so great a part of the other kinds of lava, are found so strongly adherent to them, that we usually can only separate them in fragments. The present lava, in this respect, offers an exception which may be considered as recommendatory of it. It has acquired so great a degree of softness by its decomposition, that the numerous shoerls it contains may be detached from it entire. They are hexagonal prisms, truncated perpendicular to their axes, the faces of which are slightly striated

lengthwise, and their colour is a yellowish black.

In this lava, the base of which appeared to me of horn-stone, another more remarkable peculiarity presents itself. On breaking it, the fractures discover a number of small caverns, jewelled, if I may employ the term, with a multitude of extremely minute shoerls, of different colours, some green, some yellow, others of a dark chesnut, but all similar, being hexagonal prisms, with rhomboidal faces, and each terminating in a dihedrous pyramid. Their angles are regular, their faces shining, and in part trans-

hick,

nposin still e that n softof the parent. They sometimes form geodes in the body of the lava. To examine them a lens is necessary, and a good magnifier, clearly to perceive other shoerls still more minute. These are infixed in the small cavities I before mentioned, and, though they are extended to a considerable length in front of the others before described, are so minute and numerous, that a single cavity will contain a hundred of them. Every one of both these kinds of shoerls has one extremity fixed in the lava, and the other in the air, and all together appear like a wood in miniature. I was, at first, in doubt whether I should consider them as shoerls or volcanic glass, as more than one instance has been known of such glass reduced to a capillary minuteness within lava. But the latter appeared to me improbable, because, after all the observations that have hitherto been made, we are not yet certain that any volcanic glass has been found crystallized; for, with respect to the pretended crystallization of some glasses in Iceland, we have not facts which demonstrate it incontrovertibly. On the other hand, the minute corpuscles I have described, if not all, at least those which from their larger size are more discernible by the eye, have a prismatic figure, and analogy must induce us to conclude the same of the rest.

I incline to believe these infinitesimal crystallizations produced, after the cooling of the lava, within the cavity in which they are found, from extremely subtle shoerlaceous sediments, by the filtration of water. But we shall have occasion to speak of similar adventitious crystallizations within the substance of lava, in another part of this work.

XI. The oolithes, mentioned in No. V, lie in certain small channels of Solfatara, through which the water runs when it rains. They are either round, or somewhat flattened; rather more than half an inch in diameter, white as snow, extremely light, easily crumbled, and convertible into an almost impalpable powder. They adhere strongly to the tongue, and are composed of a number of thin scales. The formation, therefore, of this volcanic stalactites does not differ from that of the other species.

It would be superfluous to speak here of the sulphate of lime, adhering to some kinds of lava, or of the sulphate of iron, and the oxyde of red sulphurate arsenic, as these productions of Solfatara have already been sufficiently examined and described by others, and I have no particular observations concering them which merit to be mentioned.

XII. It is not uncommon to find at Solfatara pumices of various species; and it is more probable that they have been thrown out of this volcano than from any of the others. We do not find them in great masses, as in other places, but in detached pieces and fragments. I shall only remark one particular relative to them, as it appears to me that in every other respect they perfectly resemble those already known. We now know that pumice is only a glass which wants but little of being perfect; and seems to require only a degree more of heat to become such. The transition from glass less perfect to perfect, may be perceived in some of these pumices in a very evident manner. In some places their texture is fibrous, and the fibres are vitreous; but without that degree of transparency, which are inseparable from volcanic glasses. But following them with the eye, we perceive them consolidate, here and there, into masses of various sizes, which resemble a shining and smooth varnish, but are in fact perfect glass, as will sufficiently appear, if they be detached from the pumice, and examined separately. These are sufficiently hard to give sparks with steel, a property observable in every volcanic glass.

Having now described the principal productions of the interior part of Solfatara, I shall proceed to make a few observations on some which are found in its exterior; in that part which is next to the Pisciarelli, so called from the warm bubbling water, which issues, with some noise, from the bottom of a little hill contiguous to this volcano, and which has been long celebrated for its medicinal virtues. I collected here speci-

mens of five kinds of lava; but, as in their general qualities they are analogous to those already described, I shall only mention them in a cursory manner.

d. it is XIII. The first specimen is a simple or homogeneous lava, in which, notwithstanding the most careful examination, I could not discover either shoerls, feltspars, or any extraneous body. In other respects, like those before mentioned, it is decomposed, adheres to the tongue, is friable, but without crumbling under the finger; its whiteness extends through its whole mass, and wherever it is broken has the taste of sulphate of alumine (or alum.)

XIV. The second specimen, through acarly the half of it, exhibits a similar decomposition, and is of a white colour; but the other half, which is of a lead colour, has suffered little, gives sparks strongly with steel, and moves the magnetic needle at two lines distance. This lava has for its base the petrosilex. Both that part of it which is slightly decomposed, and the other which is more so, contain rhomboidal feltspars, of which the largest are about an inch in length. Their alteration is scarcely visible where the lava is least changed; and where it is more they exfoliate with some facility, but retain a considerable degree of their natural hardness and splendour.

XV. The third specimen is a lava of a dark gray colour, siliceous where fractured, very compact, and which gives sparks with steel. It is of a petrosiliceous base, and contains abundance of feltspars and shoerls. But to shew these, it is necessary to divest it of a thick, whitish, and half-pulverous crust, produced by its decomposition. In this crust the shoerls and feltspars retain some consistence, but have lost, in a great degree,

XVI. The fourth specimen contains within it a nucleus of a deep red colour, of the hardness and appearance of the carbonates of lime (calcareous earth) of a fine grain, but which is not dissolved or affected by acids, nor yields sparks with steel. It attracts the magnetic needle at the distance of one line. It contains a number of fissures, through which has penetrated, together with water, a quartzous matter, which has consolidated into a semi-transparent, and somewhat rough covering. In this lava, which is but little decomposed, are found, dispersed, a number of small masses of sulphure of iron.

XVII. Small shoerls, and large crystallized feltspars, occupy the substance of this last lava, which is somewhat porous, but sufficiently hard to give sparks with steel.

It is covered with a whitish yellow crust, which flakes off with a knife, and a reddish tineture has penetrated to its internal part, which is of a blackish ground.

In these lavas of Pisciarelli, the decomposition has, likewise, been much more con-

siderable, than in the feltspars and shoerls which they contain within them.

I do not pretend to be certain that I have enumerated all the species of lava to be found at Solfatara: it is possible there may be others unobserved by me. I am persuaded, however, that I have described the principal; and such as enable me to deduce from their qualities the following conclusions.

I. Almost all the species of lava, hitherto described, are more or less decomposed, and this decomposition is usually accompanied with a proportionable degree of whiteness.

This observation has been made by several authors; and first by Sir William Hamilton, and M. Ferber, who have endeavoured to account for the fact by a very plausible reason, which is, that the sulphureous acid vapours which issue from Solfatara, and must have been produced in an infinitely greater quantity when the conflagration was at its height, penetrating the lava by degrees, have insensibly softened it, and given it a white colour. And, in fact, similar changes are observed to take place in a piece of black lava, exposed for a sufficient time to the fumes of burning sulphur. But it does not

hence follow that this lava will be changed into an argillaceous substance, as the above mentioned Swedish philosopher would have us believe; since, from a chemical analysis, it appears that an earth of that kind, combined with other principles, pre-existed in it, and has only been rendered manifest by the diminution of aggregation produced by the before-mentioned vapours.

It is likewise not strictly true that the walls, or inclosing sides, of Solfatara are every where white and decomposed, as we might infer from the description of M. Ferber.

Those which look toward the south, indeed are so, but not those which are situated in another direction, and especially those which front the north, which are of a blackish colour, and little, or not at all, decomposed. The abbe Breislak, director of Solfatara, who accompanied me when I made my observations, suggested a very probable reason for this diversity of appearance in the different sides, observing that the sulphureous acid is less powerful to effect the decomposition of lava, and requires longer time, when the lava has considerable humidity; which humidity must be much less on the southern side, where the heat of the sun is greatest. In fact, he exposed a piece of solid lava, to a very humid sulphureous exhalation, at Solfatara, during two months, without producing in it

the least decomposition. II. The observations I have made convince me that the alterations here described always take place in the upper part of the lava; and that, in proportion as we penetrate downwards into it, they become gradually less, and, at a certain depth, entirely cease. This, at first view, does not appear to accord with the effect of sulphureous vapours, which, rising from the bottom of Solfatara, and passing through the lava, might be expected to cause a greater change in the lower parts than the higher, from their having there greater heat, and consequently being more active. But we must consider that this may indeed be the nature of their action, where the lava is spongy, or at least very porous, but not where it is compact, and almost impenetrable to such vapours, as is that of Solfatara. And, in fact, we find that the sulphureous fumes which arise there do not issue from the body of the lava, but always from fissures or apertures in it, or the subjacent tufa. These impediments, therefore, prevent them from acting except on the surface, when issuing forth they are driven over it by the wind, and penetrating the lava, in a long course of time, produce the changes in question. We meet with few decomposed layas, within which we do not find fragments of sulphur adherent, condensed there by the acids above mentioned, and which are of the same kind with that produced in such abundance in Solfatara.

But what productive cause shall we assign for those sulphureous vapours, the slow destroyers of the lava, which continually issue from a number of fissures in Solfatara, in the form of hot white fumes? I can conceive no principle to which they can with greater probability be ascribed than those sulphurs of iron (pyrites) which abound at the bottom of the volcano, and decomposing, in consequence of a mixture with the subterraneous waters, slowly inflame, and produce those hot sulphureous vapours, which evidently prove that the subterraneous conflagration is not entirely extinguished. The noisy effervescence, likewise, which in more than one place is heard under the plain of Solfatara, seems to give a certain indication of the decomposition of these sulphurs.

The streams of vapour which arise from Solfatara, according to Father* Della Torre, in the night appear like flame. No person can be more competent to ascertain the truth of this fact than the abbe Breislak, who resides near the place, and who, when I questioned him on the subject, assured me that he had never observed any such appearance.

It is, however, not impossible but that, at the time he observed them, they might have

undergone some change.

The vapours which arise from the ground of the Pisciarelli are very few, and almost insensible, though formerly they must have been numerous and strong, as may be inferred from the great decomposition and whiteness of the lavas found there. I have already mentioned the noise with which the springs that bear this name burst from the earth. They resemble a boiling caldron. The reasons assigned for this phenomenon, by different authors, are various, but, hitherto, all conjectural. On applying the car to the place where the spring issues, we may perceive that the bubbling noise does not proceed from any great depth, but from a small distance from the surface of the earth. Were the ground here to be dug into, we might, perhaps, be able to discover this secret, the knowledge of which might prove advantageous to volcanic researches. My want of time, and other causes, did not permit me to make the experiment myself when I was at Naples; but I entertain a hope that what I have said may induce some of the lovers of natural knowledge in that city to engage in that undertaking, which I incline to think will not be found useless.

III. We have seen that almost all the lavas of Solfatara contain within them shoerly and feltspars. But it has been proved that the changes occasioned in both the latter, by the action of sulphureous acids, are considerably less than those which take place in the lavas their matrices; which difference must arise from the nature of these two stones, which is less liable to extrinsic injuries. We find them, in fact, firmly resist the power of the humid elements. To the south of Vesuvius, and at a little distance from Salvatore, I have found several pieces of very acient lava, porous, and half-consumed by

time, which, however, preserved unaltered their black crystallised shoerls.

It has been observed that the houses of Pompeii, long since overwhelmed by Vesuvius, and now in part dug into and cleared, are found to have been built of lava. I have ascertained this fact on the spot. They are of a reddish colour, very dry to the touch, and some of them will crumble under the finger, evident proofs of the change they have undergone; but no such alteration has taken place in the shoerls they contain; they still retain the hardness and glassy splendour which is appropriate to that stone.

We likewise know that the feltspars are indestructible by the air, as appears in the

porphyries of which they are a part.

IV. I have already remaked that the lavas of Solfatara usually have for their basis the petrosilex and the horn-stone. I shall add that I have also met with the granite in them, though not in a large mass, but in small detached pieces, which induced me to doubt whether they properly belong to this volcano; and as they likewise appeared to me untouched by the fire, I rather inclined to believe them adventitious. This granite consists

of two substances, quartz and shoerl.

But another production must not be forgotten, which forms large heaps on one side of the internal crater of this volcano. This is an ash-coloured tufa, of a middling consistence, in strata of various thickness, with the superficies of each stratum covered with a black crust, in which may be discovered manifest vestiges of plants. The abbe Breislak, who first observed this tufa, after having shewn it me on the spot, gave me some of these impressions of plants to examine, conjecturing them to be some species of the alga marina, or sea-weed. While I was at Naples, I had not sufficient time to make an accurate examination of them; but this I afterwards made at Pavia, from several specimens of the same tufa. Some parts exhibited only the impressions of plants, but in others I found real leaves. They are striated, with striæ running lengthwise, and when touched with the point of a needle, easily break, and appear converted into a

carbonaceous substance. At first I doubted whether they were plants of the alga; but on examining them again, carefully with a lens, and comparing the leaves found in

the tufa with those of the natural alga, I was fully convinced they were.

This observation appeared, both to me and the abbe Breislak, to be of considerable importance; since we may conclude from it, that part of Solfatara which is formed by this tufa, has once made a part of the bottom of the sea, and been thrown up by the action of submarine fires. Nor is it improbable that the rest of it has had the same origin, and that all the substances of this volcano have issued from the waters of the sea. Such we know to have been the origin of many other mountains, either now actu-

ally burning, or which have ceased to burn.

It is well known that for a long time alum and sal-ammoniac have been extracted from this half extinguished volcano. The method employed for each was as follows. In the process for the alum, certain square places were cleared out in the plain of Solfatara, in which it effloresced, and the efflorescences were swept together, and from them, by methods well known, the salt was collected purified. The sal-ammoniac was obtained by placing a number of pieces of tile round the apertures from which that salt issued, in the form of a subtle vapour, upon which the vapour was condensed. A description of these two methods is to be found in almost all the authors who have written on Solfatara; some of whom, with reason, censure them as imperfect, and consequently not likely to produce the profit which might be obtained.

But we may now hope that both these manufactures may become objects of importance under the direction of the abbe Breislak, and the liberal patronage of Baron Don Giuseppe Brentano, who has taken this celebrated Phlegrean field at a constant rent. The able, proceeding on the principle that the quantity of alum procured from Solfatara must be proportionate to the area of the space on which it effloresces, instead of the narrow squares formerly appropriated to this purpose, and called gardens, has greatly extended the spaces allotted: and that the preparation of this salt may not be prevented by the rain-water draining into the bottom from the steep sides of the volcano, he has surrounded them with small ditches, with deep wells at intervals which receive the water, and where it is soon absorbed by the spongy earth. In the lower part of these sides he

has likewise opened a number of cavities equally proper to furnish alum.

The same principle appears to have guided the abbe in his attempts to increase the quantity produced of sal-ammoniac, by making use of long and capacious tubes of earth, open at both extremities, and baked in the furnace. These receive at their lower ends the vapours abounding with this salt, which attaches itself to their inner sides, and forms there a crust that in time increases to a considerable thickness. I have seen with pleasure at Naples the effects of these two methods; and it is expected they will be still more productive, when some alterations suggested by persons well acquainted with this business have been made.

Formerly sulphur was extracted from the crater of this volcano; but the small quantity of it; and the low price of the commodity, have caused this labour to be abandoned.

Descending from Solfatara, a little above the level of the sea, and near to Pozzuolo, we meet with the ruins of a temple, supposed to have been dedicated to Serapis, and in modern times freed from a slimy cruption under which it was buried. This edifice may at once gratify the admirer of the imitative arts by its architecture, and the curiosity of the naturalist. Among the parts which still remain entire, are three beautiful columns of that species of white Greeian marble, usually called cipollino. They are erect, but at the height of about nine feet from the ground, each column begins to appear worn; and this wearing extending round the column, forms a horizontal band or fillet, which is rough and unequal, about two feet in breadth, while the remainder of the column is smooth and polished. This band is in every part bored by the marine animalcule called mytilus lithophagus by Linnæus, and in some of the perforations the shells are still to be

found, either entire or in fragments.

But besides this species, which is well known to Conchiologists, I have discovered another, which I had before found, in a living state, in some subaqueous marbles in the lake of Venice, an accurate description of which I shall reserve for another work. Several of the shells of this mytilus, which is smaller than the other, are to be found in the perforations of this part of the column. In fact, on examining with attention besides the holes made by the two species of mytili already mentioned, I found many others, extremely small ones, which all who are acquainted with the different species of marine animalcula, will know to be the work of other lithophagous worms. I must likewise add that I have found among them some scrpules, and particularly the contortuplicata, and the triquetra of Linnæus. These are the marine animalcula which have eaten into the three columns near the middle of the shaft, producing that circle of inequalities and roughness, except which there is no vestige of these animals.

On the plain of the Temple are found several other fragments of columns, some of the same cipollino marble with the former, and others of African marble; which fragments have likewise bands or fillets of inequalities and roughness similar to those before described, above and below which the marble is perfectly smooth, and still retains the

polish it originally received from the hand of the artist.

On the same plain we see scattered several columns of granite which appeared to me to be oriental; the component parts of which are black mica with large flakes, which is very abundant, a large proportion of feltspar and quartz. But these columns have not been touched by the corroding werms; nor was it to be expected that they should, as

it appears, from a variety of instances, that they only attack calcareous stone.

M. Ferber, in his letters before cited, mentions this appearance in the columns; but he only notices the mytilus lithophagus, which he calls the pholas or dactylus. But the cavities in which these pholades have lodged being nine feet high above the present level of the sea, he infers that the sea has sunk nine feet, supporting this inference by the observation "that the pholades always reside in rocks level with the surface of the water,

and never are found near the bottom."

122 170 La 10

But this is an assumption contrary to fact, as I shall easily prove. The pholades in these columns, which, according to Linnaus and other systematic naturalists, belong to the genus of the mytili, I have very frequently found in the Gulf of Spezia at Genoa, and in its environs, within the port itself of that city, in several places in the sea of Istria, and other parts of the Adriatic, and likewise in the Mediterranean. But in all these places I have found them in subaqueous rocks, never or scarcely ever level with the surface of the water; and frequently I have procured them to be fished up from the bottom of the sea at the depth of ten or twelve feet, by the means of long and stout forceps, which drew up large pieces of the rock in which they were contained in a living state. I have also in my possession several of these pholades, or more properly speaking mytili, infixed within the hard shells of very large oysters fished up in my presence from the depth of one hundred and forty-two feet. But in these columns we find not only the remains of mytili, but of serpules and of other very small lithophagous worms which are found in the sea at every depth. As therefore the supposition of Ferber, that the pholades or mytili always reside at the surface of the water only is contrary to fact, his deduction that the level of the sea has sunk nine feet since the time of the corroding of VOL. V.

these columns, must likewise evidently be erroneous. All that we can with certainty affirm is, that the circle or fillet which has been the habitation of these marine worms, has been covered by the sea for a long series of years; as may be inferred from the remains of these animals found in the cells they have sunk, which shew that they had attained their perfect size, to complete which they require nearly half a century, as I could prove by incontestible facts, did I not fear it would lead me too far from my subject.

It may perhaps be objected, that it must appear extraordinary that these columns which are now in an erect position, should have been so long washed by the sea-water in that circle only, while the part of the shaft below it remained untouched. Yet might they not, before they were employed in the fabric of which they made a part, have been buried in the sea in such a manner that this circle alone, which is now rich with marine spoils, might be accessible to the water?* But though this hypothesis should not appear satisfactory, and I have no other to offer, I shall content myself with stating the facts of which I have knowledge, without feeling any great solicitude that I am not able to explain them.

CHAPTER III.

THE GROTTA DEL CANE.

Errors of Ferber relative to this celebrated grotto....Experiments of the Author and abbe Breislak, relative to the mortiferous vapour....Description of the grotto....Conjecture that the vapour was anciently more extensive... Its mean height....Its heat greater than that of the atmosphere.... Consists of carbonic-acid gas, mixed with atmospheric air and azotic gas....This carbonic acid, according to the abbe Breislak, is the produce of the carbure of iron contained in volcanic substances, and combined with oxygene....The mephitic vapour exhibits no signs of magnetism or electricity....Phenomena which accompanied the burning of several substances placed within the vapour....Remarks of the author on the experiments of the abbe Breislak, and his conjectures on the origin of this carbonic acid.

HAVING visited Solfatara and the surrounding rocks, continuing my journey to the west, I soon arrived at the Grotta del Cane. There is no person conversant with literature who does not know that this name has been given to a small cavern between Naples and Pozzuolo, because if a dog be brought into it, and his nose held to the ground, he soon begins to breathe with difficulty, and loses all sense, and even life if he be not speedily removed into the open and purer air. This grotto, though so celebrated both in ancient and modern times, in fact shares its fame with several other places which are endowed with the same deleterious quality; as it is only one of the almost innumerable pestiferous vapours in different parts of the world, especially in volcanic countries, which are quickly fatal both to brute animals and man, though they do not offer to the eye the slightest indication of their presence. They have been mentioned by a numerous list of writers, whom I might cite, were I disposed to make an unseasonable parade of my reading. It is to be remarked that the greater part of these vapours are only temporary, whereas that of the Grotta del Cane is perpetual, and seems to have produced its deadly effects in the time of Pliny. A man standing erect suffers nothing from it, as the mephitic vapour rises only to a small height from the ground: I therefore entered it without danger; but notwithstanding the most attentive observation I could make, I could not perceive the smallest visible exhalation.

^{*} They may have originally belonged to an edifice in a durant country, overwhelmed by the sea.

d by the sea.

It therefore appeared to me that M. Feroer must have been mistaken, when he says, "the killing damps rise from the ground about a palm above the floor, move along it as a white smoke, and spread through the door in the open air."* But as it has already been observed nat the smoke of a torch extinguished in the vapour sinks downwards, assumes a whitish colour, and goes out at the bottom of the door; it appears probable that this occasioned his mistake, especially as he mentions the experiment of the extinguished torch in the same place.

As little can I agree with him that the mischievous effects of this vapour are the consequence of the air being deprived of its elasticity;† since it has been demonstrated that they are to be attributed to the carbonic-acid gas; as was first proved by is learned countryman, M. Adolphus Murray. As we know likewise, that a canute seing extinguished in this gas, the fumes which proceed from it mix more readily with the gas than with the atmospheric air; we perceive why the smoke of a torch that ceases to burn in the Grotta del Cane sinks where the pestiferous vapour is strongest, and passing along the ground, goes out at the lower part of the door.

The person who is the keeper or guide at the grotto, and who shews to strangers the experiment of the dog for a gratuity, when the animal is panting and half dad, takes him into the open air, and afterwards throws him into the neighbouring lake of Agnano; insinuating that this short immersion into the water is necessary completely to restore him. M. Ferber relates this fact, and shews that he believed all that was told him concerning it. The truth however is, that the plunging the dog into the lake is a mere trick to render the experiment more specious, and obtain money from the credulous, as the atmospheric air alone is sufficient to restore the animal to life.

The experiments made by M. Murray, to ascertain the nature of this mephitic vapour, have discovered to us what was before unknown, and we owe to him every grateful acknowledgment. They have not however explained every thing we could wish to learn relative to this cavern. Whoever is versed in the knowledge of nature, and acquainted in any degree with the difficult art of making experiments, must be convinced what a number of these might be made in it, which would greatly tend to throw new light on physiology and physics. I conceived a strong desire to attempt several, and communicated my intention to the abbe Breislak, who accompanied me to the Grotta del Cane. We agreed to divide them between us, that I should apply myself to the physiological, or those which had for their object living beings, and he bestowed his attention on the physical. As I was on the point of setting out for Sicily, I resolved to carry this plan into execution on my return to Naples. But Mount Etna and the Lipari isles detained me a long time; and when I returned I had scarcely time to visit Vesuvius, being obliged to repair almost immediately to Padua, to begin my public lectures in Natural History. My friend the abbe, however, who resides constantly near Solfatara, in consequence of his superintendance of the works there, proceeded after my departure to fulfil the task I had assigned him, and communicated to me the result of his experiments in a letter, which with his consent I here publish, as I am convinced that it will be highly gratifying to my readers.

"RESPECTABLE FRIEND,

Naples, Nov. 20, 1790.

"WHEN you visited this city two years ago, to make observations on the Phlegrean fields, you did me the honour to propose to me to assist you in making a regular series

of experiments on the celebrated mephitic vapour of the Grotta del Cane. remember that we agreed to divide between us the objects to be examined. You proposed to inquire in what manner the exhalation acts on the animal occonomy, so as first to suspend its functions, and at last totally destroy them, unless the means of restoration are speedily applied. This problem, though considered by many, has never been investigated with that precision and accuracy which it deserves, nor have experiments been sufficiently multiplied and diversified to establish a general rule. From you I expected that it would have received new light, accustomed as you are to develope the most complicated arcana of nature. In the experiments to be made, you reserved to yourself the physiological, leaving to me the physico-chemical. Your journey into Sicily, and your hasty return to Padua to exercise the duties of your professorship, rendered it impossible at that time for you to execute your part of the plan. I have not dared to treat a subject reserved for you, but I hope that some other, to me fortunate, combination of circumstances may once more bring you back to Naples, and afford you an opportunity to prosecute these inquiries, together with others analogous to them. In the mean time in some excursions which I have made to the lake Agnano, I have examined with the utmost attention, this little grotto; and have made several experiments, by the detail of which I doubt not but you will be gratified. The subject it is true, has been repeatedly examined by many naturalists, both natives of Italy and foreigners; but their success has

not been sufficient to preclude every new experiment.

"The mephitic vapour, as you well know, occupies the floor of a small grotto near the lake Agnano, a place highly interesting to naturalists from the phenomena its environs present, and the hills within which it is included. This grotto is situated on the southeast side of the lake, at a little distance from it. Its length is about twelve feet, and its breadth from four to five. It appears to have been originally a small excavation, made for the purpose of obtaining puzzolana. In the sides of the grotto, among the earthy volcanic matters are found pieces of lava of the same kind with those we meet with scattered near the lake. I examined some of them, and found them a compact lava, of a deep gray colour, interspersed with small hexadreous prisms of mica. They are of an earthy grain, a micaceous consistence, and have a sensible effect on the magnet. Particles of feltspar are rarely found in them, and we meet with no specimens which contain shoerls. I am persuaded that were new excavations made in the vicinity of the grotto, at a level with its floor, or a little lower, the same mephitic vapour would be found, and it would certainly be curious to ascertain the limits of its extent. It would likewise be extremely advantageous for physical observations were the grotto somewhat enlarged, and its floor reduced to a level horizontal plain, by lowering it two or three feet, and surrounding it by a low wall, with steps at the entrance. In its present state, it is extremely inconvenient for experiments, and the inclination of the ground towards the deer causes a great part of the vapour, from the effect of its specific gravity, to make its way out close to the ground. When I consider the narrow limits of this place, and the small quantity of the vapour which has rendered it so celebrated, I have no doubt but it must have undergone considerable changes; for it does not appear probable to me that Pliny meant only the present confined vapour, when (lib. ii. cap. 93.) enumerating many places from which a deadly air exhaled, he mentions the territory of Pozzuolo. The internal fermentations by which it is caused are certainly much diminished in the vicinity of the lake Agnano. The water near its banks is no longer seen to bubble up, from the disengagement of a gas, as we learn that it formerly did, from accounts of no very great antiquity, I have attentively examined the borders of the lake when its waters were at the highest, and after heavy rains, but I never could discover a single bubble of air. A

fair. A

number of aquatic insects which sport on the surface, may at first view occasion some deception; but a little observation will detect the error. If we do not suppose those authors who have described the ebullition of the water near the banks of the lake Agnano to have been deceived, we must at least confess that this phenomenon has now ceased. The quantity of the hepatic vapours which rise in the contiguous stoves, called the stoves of St. Germano, must likewise be greatly diminished from what it anciently was: for adjoining to the present stoves, we still find the remains of a spacious ancient fabric, with tubes of terra cotta inserted in the walls, which by their direction shew for what purpose they were intended. It appears certain that this was a building in which by the means of pipes properly disposed, the vapours of the place were introduced into different rooms, for the use of patients, who were accommodated there in a much better manner than they are in the modern stoves of St. Germano, which wretched places nothing could induce them to endure but the hope of being restored to health. To these ruins, however, the vapours no longer extend; so that if this edifice still remained, it could not be employed for the purpose for which it was intended. The veins of pyrites which have produced the more ancient conflagrations of the Phlegrean fields, between Naples and Cuma, and which in some places are entirely consumed, approach their total extinction. But let us proceed to the experiments made, and frequently repeated within

the grotto.

"I. The first had for its object to determine the height of the mephitis at the centre of the grotto, that is, at the intersection of the line of its greatest length with that of its greatest breadth. This height varies according to the different dispositions and temperatures of the atmosphere, the diversity of winds, and the accidental variations that take place in the internal fermentations by which the vapour is produced; it may however be

estimated at a mean, at eight Paris inches.

11

V 1 1

"II. The entrance into the mephitis is accompanied with a slight sensation of heat, in the feet and lower part of the legs. When, in the year 1786, I visited the large me-phitic vapours of Latera, in the dutchy of Castro, I likewise observed that they produced the sensation of heat in the part of the body which was encompassed by the mephitic atmosphere. Yet on taking out of the vapour several substances which had remained in it a long time, as stones, leaves, carcasses of animals, &c. I found that these were of the same temperature with the atmospheric air; but as I had broken my thermometer on the road, and was unable to procure another in any of the places through which I passed, I could not ascertain the temperature of the mephitis. I felt in my body a slight degree of heat, which I could not perceive in the substances I took out of the mephitic vapour; and endeavouring to compare one thing with another, I concluded that the temperature of the mephitis was the same with that of the atmospheric air, which I attempted to explain to myself on the principles laid down by Dr. Crawford. But a number of other experiments made in the Grotta del Cane, convinced me that this exhalation has a distinct degree of heat different from that of the atmosphere. In these experiments, which I repeated many times, the the mometer suspended at the aperture of the grotto, three feet above the surface of the mephitis, stood at between 13 and 14 of Reaumur's scale (62 and 64 of Fahr.) and placing the ball on the ground, so that it was immersed in the mephitic vapour, the mercury arose to between 21 and 22 of Reaumur (80 and 82 of Fahr.) Nor ought it to excite surprise, that the substances taken out of the mephitis did not exhibit this diversity of temperature, both because the difference is small, and on account of the quantity of humidity with which they are always loaded, and which produces on their surface a continual evaporation. I frequently repeated this experiment, making use of different thermometers, because I knew that the celebrated M. Adolphus Murray when

he made his experiments in the Grotta del Cane, had not observed the vapour to pro-

duce any effect on the mercury in the thermometer.

"III. I repeated, for my own satisfaction, the usual experiments made by many naturalists, with the tincture of turnsole, lime-water, the crystallizations of alkalis, the absorption of water, and the acidulous taste communicated to it, which prove beyond all doubt the existence of fixed air, or carbonic acid, in the exhalation of which we treat. But is it composed of fixed air alone? This I wished to ascertain. When exposed in a cudiometer to nitrous gas, an absorption took place, to about the 100 of the quantity. In a phial filled with this air, and continued with the mouth immersed in water for fifteen days, the water slowly rose until it occupied 100 it it may therefore be concluded, that the relative quantities of the different gases which compose the mephitic air of the Grotta del Cane are as follows: 100 of ital air, or oxygenous gas, 100 of fixed air, or carbonic acid, and 100 of phlogisticated in azotic gas; or perhaps it is a mixture of carbonic acid and atmospheric air, with:

all quantity of azotic gas, more than is contained in the atmospheric air.

"The vicinity of the grotto to the stoves of Agnano, the warm vapours of which contain a considerable quantity of hydrogenous sulphurated gas, induced me to suspect that some portion of the latter might be found mixed with the gas of the mephitis; but I was not able to discover in it the smallest quantity. I made use of the sugar of lead, or acetite of lead, which, as you well know, is extremely sensible to the slightest impression of hepatic gas, leaving it immersed in the mephitis for the space of half an hour.

"It is certainly a curious problem to investigate the origin of this fixed air. You are acquainted with the different opinions of naturalists, some of whom consider it as an atmospheric air changed into fixed by the action of the electric matter of the lava; while others suppose it produced by a slow and successive decomposition of the calcareous earth, effected either by a subterraneous fire, or by an acid. But the fact is, that in the Grotta del Cane there is not a single vein of lava, and that the atmosphere of that vicinity exhibits no particular signs of electricity. The hypothesis founded on the decomposition of the calcareous earth, is likewise subject to great difficulties. Our excellent common friend, the Commendatory de Dolomieu, in his valuable notes to the dissertations of Bergman on the products of volcanos, is of opinion that the fixed air of volcanic places is produced by the re-action of the sulphur on the calcareous earth, with which it forms a liver of earthy sulphur. I am rather inclined to believe that the fixed air of volcanized countries is not developed ready formed from any substance, but is the produce of the plumbago contained in the iron, with which all volcanic substances abound combined with the base of vital air afforded by the internal decompositions of the pyrites. I am not induced to embrace this system by its novelty. The experiments of Messrs. Lavoisier, Berthollet, Mongez, Landriani, and many other excellent chemists, compared with local observations, have proved, beyond a doubt, the existence of plumbago in iron. It is certain that all volcanic substances abound in iron, and the hepatic vapours which rise in the stoves of St. Germano, in the vicinity of the Grotta del Cane, prove the internal decomposition of the pyrites, which still takes place here: a decomposition which, by giving birth to the mephitic acid, furnishes likewise the base of

"IV. Among the notices which the celebrated Bergman wished to receive, relative to the Grotta del Cane, he desired a detail of the phenomena of magnetism and electricity. With respect to the former, I have observed no new appearance. The magnetic needle, placed on the ground, and consequently immersed in the mephitis, rested in the direction of its meridian; and, at the approach of a magnetized bar, exhibited the usual-

effects of attraction and repulsion, according as either pole was presented. With regard to the latter article, it is not possible to make electrical experiments within the mephitis; not because that kind of air is a conductor of the electric fluid, as M. Murray imagined, but because the humidity that constantly accompanies it disperses the electric matter, whin not being collected in a conductor, cannot be rendered sensible. I several times attempted to fire inflammable gas, in the mephitic vapour, with electric sparks, by means of the conductor of the electrophorous; but, notwithstanding my utmost endeavours to animate the electricity, I never could obtain a single spark; as the isolator became a conductor the moment it entered into the mephitis, on account of the humi-

dity which adhered to its surface.

nt aic it it ic e, ic e, ic e, ic e, ic W. One of the principal objects of the researches of academies and naturalists at present is the theory of the combustion of bodies. My first experiment was directed to ascertain whether those spontaneous inflammations which result from the mixture of concentrated acids with essential oils could be obtained. I placed on the ground, in the grotto, a small vessel, in such a situation that the mephitis rose six inches above the edges of the vessel. I made use of oil of turpentine, and the vitriolic and nitrous acids, and the same inflammation followed, accompanied with a lively flame, as would have taken place in the open atmospheric air. The dense smoke which always accompanies these inflammations, attracted by the humidity of the mephitis, presented its undulations to the eye, and formed a very pleasing object. As I had put a considerable quantity of acid in the vessel, I repeatedly poured in a little of the oil, and the flame appeared in the mouth of the vessel fifteen times successively. This oxygenous principle contained in the acids, and with which the nitrous acid principally abounds, undoubtedly contributed to the production and duration of this flame, though enveloped in an atmosphere

inimical to inflammation.

"In the district of Latera, which I have mentioned above, I observed that in a mephitis of hydrogenous sulphurated gas, or hepatic gas, a slow combustion of phosphorus took place, with the same resplendence as in the atmospheric air. As I had not with me a sufficient quantity of phosphorus, I could not proceed farther with this experiment, nor vary it as might have been necessary. In the mephitis of Agnano, the first experiment I made was with common phosphoric matches, of which I broke five, holding them close to the ground, and consequently immersed in the mephitis. They all produced a short and transient flame, which became extinguished the moment it was communicated to the wick of a candle. The second experiment I made was the following: I placed on the ground, in the grotto, a long table, in such a manner that one end of it was without the mephitis; while the other, and four-fifths of its whole length, were immersed in it. Along this table I laid a train of gunpowder, beginning from the end without the mephitis; and at the other, which was immersed within it, the depth of seven inches, I placed, adjoining to the gunpowder, a cylinder of phosphorus, eight lines in length. The gunpowder without the mephitis being fired, the combustion was soon communicated to the other extremity of the train, and to the phosphorus, which took fire with decrepitation, burnt rapidly, with a bright flame, slightly coloured with yellow and green, and left on the wood a black mark, as of charcoal. The combustion lasted nearly two minutes, till the whole phosphoric matter was consumed.

"I then proceeded to another experiment. I placed some gunpowder on the ground in the grotto; and having lighted a cylinder of phosphorus without the mephitis, I immerged it within it while burning, carried it the distance of ten feet, and threw it on the gunpowder, which immediately took fire. No alteration was perceptible in the flame, or manner of burning, of the lighted phosphorus, either at the moment of its entrance

into the mephitis, or during its continuance in it.

"I afterwards lighted another cylinder of phosphorus, and conveyed it immediately into the mephitis, supporting it with a small piece of wood; and this likewise burnt

briskly, until it was entirely consumed.

"It may perhaps be suspected that, in the experiments with gunpowder, the oxygenous gas contained in the nitre co-operated to the combustion of the phosphorus; but it is certain that, independent of the nitre, this curious substance, though it burnt in mephitic air, presented the same appearances as in the atmospheric air. I am aware that, among the experiments of M. Lavoisier, there is one on the combustion of phosphorus produced by means of a burning mirror, under a glass bell, the mouth of which was immersed in mercury. That excellent naturalist observed that the phosphorus began to burn, but that in a few moments the air of the receiver being no longer proper to nourish the combustion, it became extinguished. Is it not probable that the extinction of the phosphorus did not proceed from the infection of the air, but that the vapours of the phosphorus, matter remaining confined in the receiver, and condensing around the phosphorus, suffocated its flame? The mephitic gas of the Grotta del Cane is certainly unfit for the respiration of animals, and the inflammation of common combustible substances; but phosphorus, nevertheless, burns in it, and emits, as usual, luminous sparks.

"I must not conclude without noticing the production of the phosphoric acid from the slow combustion of phosphorus in the mephitis. Perhaps this may present particular modifications, dependent on the carbonic acid, to which it must necessarily unite itself in this situation. But I have not yet been able to prosecute this experiment, the temperature of the place not being such as is requisite to make use of the apparatus suited to the method of M. Sage. I shall therefore defer the investigation of this subject until the winter, when I purpose to resume it, if I can procure free access to the grotto, for

some little time, by satisfying the avidity of its rapacious guardian.

I remain, with sentiments of the utmost friendship and esteem, Your devoted servant and friend,

SCIPIO BREISLAE."

The observations and experiments communicated in the above letter, undoubtedly enlarge very considerably the sphere of our knowledge relative to this mephitic place; and I sincerely congratulate the author on the success of his researches. But the same sincerity induces me to mention an observation which occurred to me while reading his letter, and which I am convinced his friendship will permit me to make public. The method he used to obtain the mortiferous gas on which he made the experiments here related, was, I doubt not, the same with that employed to ascertain the salubrity of the atmospheric air; that is, by taking a phial filled with water, inverting and plunging it into the mephitis, then letting the water gradually out, and carefully closing the phial. Had any other method been used, I doubt not but it would have been mentioned. But by this the mephitis could not be obtained pure, such as it immediately issues from the floor of the grotto, but must be more or less mixed with atmospheric air. For the carbonic acid gas being heavier than the atmospheric air, it must consequently form a stratum in the lower parts of the grotto, where it will in general remain, though there will be some mixture of the two fluids; especially when the door is opened, and the internal ambient air put in motion. Hence the mixture of the three gases, the carbonic acid, the azotic, and the oxygenous obtained by the abbe Breislak. I had, however, suggested to him, that the best method to obtain this emanation pure would be to dig a small trench in the ground of the grotto, and to fill it with water; when a number of bubbles

would no doubt rise from the bottom to the surface, which would probably only consist of the carbonic acid gas suspended in the body of the water. The contents of these bubbles might be collected by methods well known, and we should thus procure the genuine mephitis, without any mixture of atmospheric air. For greater accuracy in the experiment, mercury might be placed under the water; as it seems probable that the

tufaceous soil would not be sufficiently dense to retain it.

We have seen the opinion of this learned naturalist, relative to the origin of the carbonic acid in this grotto. It is evident that in this, as in many other questions of a similar kind, we can only amuse ourselves with conjecture, and perhaps we may never be able to proceed further than conjecture, relative to an operation which nature has veiled in profound obscurity, and withdrawn from the observation of our senses. But since certainty is not attainable, I must ingenuously declare, that among the different hypotheses that have been framed to account for this abstruse phenomenon, I prefer that which supposes that the mephitis of the Grotta del Cane is separated, by the means of fire, from carbonates of lime (or calcareous earths) and that, passing through different volcanic substances, it has penetrated to that place. It is highly probable that the volcanos of the Neapolitan territory, and also those of the ecclesiastical state, are superincumbent on strata of such carbonates, continued and connected with those of the Apennines. In my way from Lombardy to Naples, when I arrived in the neighbourhood of Loretto, the road began to lead between mountains, which continued to Fuligno, a distance of nearly seventy miles. These mountains, almost all with horizontal strata, are composed of these carbonates. The road from Fuligno to Spoleto and Terni presents a chain of mountains of the same kind, and nearly with the same stratifications. These mountains extended to within a little distance of Civita Castellana, where I found sufficient testimonies of extinct volcanos, in the puzzolano and lavas, which I met with at every step. Some of these lavas are of a base of shoerl in the mass, and others of a hornstone base: they all resemble the Vesuvian with respect to the white garnets they contain. The volcanic bodies, and various kinds of tufa and puzzolana, continued to present themselves quite to the gates of Rome. From this city, continuing my journey to Naples by the way of Veletri, I continually met with volcanized matters; but at Terracina the mountains next the sea again appeared to be formed of calcareous earth, as did those of Sessa. But whatever may be the character of the more elevated parts, the bottoms, through which the high road passes, consists of tufa, which exhibits the true signs of volcanization not only in the pieces of lava, and the great number of pumices it contains, but from being in a great degree a mixture of small fragments of lava and scoria.

It is to be remarked, and it is worthy of attentive consideration, that when we leave the road, and ascend the steep eminences on its sides, we frequently find beneath the tufa calcareous stone, especially in places where the former has been corroded by rain water. The remainder of the Apennines from Sessa to Naples are formed of the same calcareous stone; though in lower situations the volcanic tufa is scarcely ever inter-

rupted.

In Chap. VI, I shall speak of a volcano which I observed near Caserta, a small city about sixteen miles from Naples. I shall then shew that the volcanic matters are there

every where surrounded by calcareous stone.

The Fossa Grande, which descends laterally from Mount Vesuvius, and which I have mentioned in Chap. I, is bordered on the sides by two high rocks. That which is on the left, the side toward Naples, owes its origin to an aggregate of lava; while that on the right is composed of pumice stone and tufa; which not being firmly connected, vol. v.

frequently fall by their own weight, especially when loosened by rains, and in their fall bring down with them various substances, of which some are calcareous spars, mixed with pieces of the common calcarcous earth, which, as I have already mentioned, I met with in my journey to Naples. These substances seldom exhibit any traces of injury by the fire: their angles likewise are not blunt or ragged, but sharp. It is, however, indubitable that they are pieces rent from great masses of calcareous stone, before the vehemence of the fire had time to change them. These observations I made on my return from Vesuvius to Naples.

The author of the Campi Phlegræi, speaking incidentally of the Fosse Grande, gives the figure of a piece of calcareous breccia found there; and observes that similar pieces are frequently found in the excavations made by the rains in the sides of Vesuvius and Monte Somma. The Lithologia Gioeniana, which treats on the productions of this volcano, mentions similar calcareous stones to have been thrown up from its mouths in

former times.

The island of Capri, near Naples, it is to be observed, is likewise composed of calcareous earth.

From all these observations, it appears to admit of no doubt that the Neapolitan territory, which we see volcanized, rests on calcareous strata. This was likewise the opi-

nion of Ferber and Sir William Hamilton.

If then we suppose the subterraneous fire to act gradually on the calcareous stone, compelling it to divest itself by degrees of its acid, while it becomes covered with earthy aggregations easily permeable to this acid, now becomes gaseous, the gas will issue above it, and form a current mingling with the atmospheric air. This probably will explain the nature of the emanation in the Grotta del Cane. The abbe Breislak has shewn that the heat of this emanation is greater than that of the atmosphere; which affords us reason to suppose that a remainder of volcanic fire exists under the grotto. The great humidity of the vapour is likewise extremely favourable to this hypothesis, since we know that calcareous stone, by the action of fire, is not only deprived of its acid, but of the water which it contained. It may be objected that on this supposition the mephitis must diminish; but it should be considered that its extent is very confined, while the quantity of the subjacent calcareous matter is immense; and it is likewise well known what a prodigious quantity of this acid is combined with such stones.

This hypothesis will likewise explain the temporary mcphites which arise only in consequence of particular eruptions, as frequently happens in the environs of Vesuvius. The deleterious exhalations will continue till the subterraneous fires have decomposed

the calcareous stones; but they cease when the conflagrations are extinguished.

CHAPTER IV.

BAKES OF AGNANO AND AVERNO....MONTE NUOVO....PROMONTORY AND CA-VERN OF MISENO....ROCK OF BURNT STONES....PROCIDA.

The lake of Agnano once a spacious volcanic crater....Tenches and frogs found in this lake....
The absurd report that monstrous animals are produced there, detected by Vallisneri....The lake of Averno presents the mouth of another ancient volcano....It is false that birds cannot approach this lake....No deleterious exhalation emitted by it....Volcanic substances of Monte Nuovo....I.avas found there of the nature of pumice and enamel....Soda grows in a little cavern of its crater....Peculiarity of amphibious animals observed here....The cavern of Miseno abounds in sulphate of alumine (alum) and pumice....Well of water full of gaseous bubbles....Volcanic crater still discernible on the promontory of Miseno....Pumices found there, containing feltspars....Lava, pumices, and enamels of the same nature, found on the Rock of Burnt Stones, and at Procida....Great friability of this enamel, not common to volcanic enamels, and its probable cause.

THOUGH the Phlegrean fields are numerous, I in this work propose to describe, or at least to give a sketch of them all; since, though they are all volcanic, the objects

they present are few, and little different from each other.

I believe no one doubts that the cavity filled with water, and usually denominated the lake of Agnano, has been the mouth of a volcano. It certainly has internally the resemblance of one, since it is shaped like an inverted funnel, the usual figure of volcanic craters. It must have been a very large one, since it is nearly two miles in circuit. Numerous flocks of ducks swim on its surface, and its waters contain great quantities of tenches and frogs, which were once celebrated for a pretended monstrous formation, until the cause of this absurd error was detected by Villisneri. It may not perhaps be uninstructive should I, by way of an amusing digression, relate the story of this pleasant mistake to the reader.

It is well known that frogs, before they arrive at the perfect form of their species, have that of a kind of worms, usually called tadpoles, the bodies of which are of an orbicular shape, and have tails. We know likewise that these tadpoles become frogs by degrees, the hinder legs being first produced, and afterwards the fore legs, while they retain the tail for a considerable time. This gives them a strange appearance, as the tail appears like the lower half of a fish, while the round body and legs resemble the frog. Hence persons unacquainted with the productions of nature have supposed them to be monstrous animals, half fish and half frogs. A credulous Neapolitan brought one of these monsters, which he said was a native of the lake Agnano, to Villisneri, at Milan, that he might view it and admire. It did not, however, require the knowledge of so great a naturalist immediately to perceive the absurd error. The tadpole, which to him was an object of laughter, not of admiration, was of an extraordinary size, whence he concluded that the frogs of the lake Agnano were extremely large. They are not, however, larger than the comm on size, nor did I find the tadpoles bigger, though, as it was the end of July, they had arrived at their full growth, and many, having cast their tails, had become perfect frogs. That which was shewn to Vallisneri was possibly brought from some other country, perhaps America, where the frogs grow to an extremely large size.

The sides and bottom of this lake are of tufa, interspersed in some places with fragments of lava and pumice-stone; though we do not find, at least so far as the eye can reach, any veins or strata of lava: whence I infer the cruption to have been entirely, or

in a great degree, thick and slimy.

The same ideas which naturally occur to the observer at sight of the lake Agnano, will be suggested likewise by that of Averno, as there can be no doubt but this likewise was the crater of an ancient volcano. The Greeks called it Aornus; because no birds were found near it, probably on account of some pestilential vapour which then exhaled, and deprived them of life. The author of the Campi Phlegræi asserts that it is very rarely that any water-fowl are to be seen on this lake, and that when they come they remain there but a very short time. The truth however is, that whenever I was there, I saw great numbers of teal swimming on the surface, and the peasants assured me that the lake abounded with water-fowl in the winter. Nor do I know any cause which can, at present, drive them from a place where they may find plenty of food; as neither the environs, nor the lake itself, afford any indications of noxious exhalations.

These two places lie to the west of Naples, near Pozzuolo, in the vicinity of which is Monte Nuovo, so called because it was produced by subterranean fires in 1538. It is not very high, and seen from the port of Pozzuolo, appears to be an obtuse cone; but, on reaching the top, we discover that this cone is only the exterior part of a crater, the upper edges of which form a circle of about one hundred and fifty feet in

diameter.

Like other volcanic craters, the internal sides of this grow narrow towards the bottom, and both that which I call the bottom, and the external part of Monte Nuovo, consist of a friable tufa, in many places, covered with plants. The sea bathes the sides of this volcano, which, if they are dug into a little, as well within the water as without, are found very warm. The same warmth is likewise perceived at the bottom of the crater. From such excavations, likewise, arise thin warm vapours. In fact, in the internal parts

of Monte Nuovo we find all the last remains of volcanic conflagration.

In the external sides of the mountain many pieces of lava are found, which deserve notice from their singular quality. They are a substance of a middle character between lava and pumice-stone, on which account I shall call them pumice-lavas. They have the lightness and friability of a compact pumice-stone. When broken by the teeth, by which a good judgment may be formed of some stones, they appear real pumice-stone. They are dry and rough to the touch, as is usual with such kinds of volcanic productions. Their structure is not fibrous, contrary to what we observe in common pumice-stone, but granulous, and very similar to that of various kinds of lava, as is likewise the internal appearance. This production is of importance, as presenting a middle substance between lava and pumice-stone. The base of these stones is a horn-stone, mixed with a few feltspar scales: they scarcely adhere to the tongue, and emit a slight argillaceous odour. In the furnace they produce a compact enamel, of a dark gray colour, transparent at the angles, and which gives a few sparks with steel.

Towards the internal bottom of the crater we find, projecting from the tufa, the same kind of lava, penetrated with feltspars, but more compact and heavy, and interspersed with beautiful and shining veins of black enamel of various thickness. I am in doubt whether this species of vitrification was the consequence of a greater degree of heat to which the lava had been there exposed, or whether, from the difference of its quality in those places, it had undergone a more perfect fusion, and become enamel, while in

others it had remained in the state of lava.

On the side of this bottom we find, within the tufa, a small cavity, I know not whether formed by nature or art, that abounds with saline efflorescences, which I at first imagined to be muriate of ammoniac (sal ammoniac) or sulphate of alumine (alum) but their urinous acrid taste, the green colour which they gave to syrup of violets, and other qualities that are proper to soda, and which I omit for the sake of brevity, leave no doubt that they are formed from that salt. Besides these efflorescences, the small hollows, corners, and bottom of this cavity are more or less covered with the dust of this soda.

I cannot take leave of this volcano without mentioning an observation, which has some analogy to what has been before noticed of lake Agnano, as it relates to the same species of animals. On the tufaceous sides of the erater, both internal and external, as often as I approached them, I saw a great number of frogs leaping about. They were nearly half an inch long, and a quarter in breadth. They had the complete form of the frog, were of a dark yellow colour, and their fore feet were divided into four toes, and their hinder into five, though they have not the shape of the hand, which constitutes an essential difference between these frogs and the others of these countries. But how are these amphibious animals produced? Among all the different species of European frogs (and under this genus I, with Linnæus, likewise include toads) I know none which do not begin their existence in water, and continue to live in it some time, until they throw off the mask of the tadpole, and assume the shape of frogs. But Monte Nuovo is not only entirely without moisture, but, as I learned from the peasants who reside in the neighbourhood, even when heavy rains fall, the bottom of the crater (which is the only place where rain-water can be collected and retained) imbibes all the water immediately; as, in fact, it must, since it consists of a light spongy tufa full of cracks and fissures.

The only water near, is that of the lake Agnano, about half a mile distant; from which these animals might be supposed to have derived their origin, were it not that the frogs of that lake are of a totally different species. I must therefore confess, that the presence of these creatures here was to me an enigma, which, perhaps, I might have been able to have solved, not without some advantage to natural knowledge, had I been able to have

made a longer stay in this volcanic country.

Before we reach the promontory of Miseno we arrive at the harbour, which is a very secure basin, as it is surrounded on every side by eminences. This was the port for the Roman fleet in the Mediterranean. The eminences are of tufa; and, on one side, a little above the level of the sea, we find a spacious cavity, the work of art, called the Cavern of Miseno, in which the muriate of alumine continually effloresces. This salt is either unknown to or neglected by the inhabitants; though it might be extracted with great advantage, especially were the cavern enlarged (which it might easily be, as the tufa is extremely soft) since the saline efflorescences would certainly increase in proportion to the enlargement of the superficies.

At the bottom of the cavern there is a well of water bubbling up, with sometimes more, sometimes fewer, gaseous bubbles, which rise from the bottom. The water is nearly of the same temperature with the atmosphere, and the gas, from the scent, appears to be sulphurated hydrogenous; but I had not convenient opportunity exactly to ascertain its quality. The sides and roof of the cavern are scattered over with common pumices, containing various feltspars, some calcined and consequently deprived of their native lustre, without, however, having lost their natural crystallization, which is

rhomboidal.

Beyond the port of Miseno is the promontory of the same name, which forms a tufaceous mountain of no despicable height; from the top of which some admirable prospects present themselves. This, likewise, certainly owes its origin to a volcano, as its crater is still very discernible, though in a great measure destroyed, on the south side, by the waves of the sea.

Having proceeded to some distance from this promontory, I met with several lavas immersed in the tufa, both of the compact and porous species, but common to other volcanos, and all detached. Mixed with these were various pieces of pumice, in like manner detached, in which feltspars were, I will not say scattered, but thickly sown. In a square inch of this pumice I counted fourteen on the exterior surface, and forty-seven within. They are crystallized with various faces, are somewhat less hard than quartz, and have that changeable brilliancy which is inseparable from feltspars. The fire does not appear to have been able to injure them, though it has changed their base into pumice, which is in fact a real vitrification.

In front of Procida, and at a little distance from it a small low rock projects into the sea, formerly only known to fishermen, and called the Rock of Burnt Stones, because it is in fact a mixture of pumices, enamels, and lavas. The first naturalist who noticed it was the abbe Breislak, who conducted me to it with a particular kind of pleasure, as a place appertaining to himself. A stay of two hours, which I made on it, was well rewarded by the objects it presented. Its elevation above the surface of the water is only a few feet, and consequently in tempestuous weather, it must be covered by the waves. On making the circuit of it in a boat, and examining it, we find that only the projecting points rise above the water, and that the body of the rock is below the surface. Hence it appears probable, that it was once much larger, but has been in a great degree destroyed by the violence of the waves.

The stones of which this rock is composed are principally of two qualities. The first, a lava of a horn-stone base, light, of a dark gray colour, an earthy grain, unequal, and which gives scarcely any sparks with steel. The second is a lava, with a base of shoerls in the mass, which has undergone various changes and modifications, according to the different heats to which it has been exposed. In many fragments, therefore, we only find it a simple lava, while in others, it has become pumice, and in others enamel. In one part they appear of a witish colour, fibrous, light, and extremely friable; but, as their levity and friability diminish, they become more compact, and the fibres less discernible; the colour grows darker, and a glassy lustre begins to appear. A little farther, their fibrous quality is entirely lost; their compactness, weight, hardness, and lustre increase, and the unequivocal characters of a perfect enamel are seen. This latter is black, gives sparks with steel, and in its appearance resembles the aspaltum. Its black colour is interrupted by feltspars, which are likewise common to the first lava with the horn-stone base. They are extremely brilliant, somewhat fibrous, crystallized in hexaedrous prisms, and several of them five lines in length.

It frequently happens, that the volcanic productions which exist in one place are found likewise in another: that is, that in different situations the earthy matters and the activity of the fire have been the same; a concurrence which may easily take place in various parts of the globe; and which is exemplified in the similarity of a corner of the island of Procida to the Rock of Burnt Stones. The island is situated to the west of the rock, and is about six leagues in circuit. The shore, being an accumulated mass of tufa, abounds with shrubs and plants. This tufa on the side next Ischia, having been much corroded by the sea, affords a distinct view of its structure, which is in strata;

whence we may infer that it has been the production of successive fluid dispositions. To the north-west of the island is a rock, on which we find pumices, pumiceous lava, and enamels, both pumiceous and pure, accompanied with feltspars, and the other concomitants with which they are found on the Rock of Burnt Stones; on which account it would be only loss of time to recapitulate their description. I met with only one new stone, which was a common granite, in which were distinctly discoverable its three constituent parts: the feltspar in shining needles; a lightly livid, and slightly calcined quartz; and a black mica, which did not shine. It could not therefore be doubted, that it had been exposed to the action of the fire. But as I found this granite loose on the shore, detached from the volcanic products I have before mentioned, I shall notice it no farther.

From the lavas of the horn-stone base, found on this rock, we obtain in the furnace a very compact and hard enamel, which affords sparks with steel; and from the lavas the base of which is shoerl in the mass, as also from the pumice and the enamel, which originate from the same stone, is produced a scorified enamel, so ebullient, that a great part of it boiled over the edges of the crucible, though it was only half full. This violent

fusion, however, produced no sensible change in the feltspars.

I shall conclude this chapter with an observation relative to the enamels of the Rock of Burnt Stones, and Procida. They are extremely friable; a slight stroke with a hammer will break them into pieces; whereas the enamels of most other volcanos, as we shall see in their respective places, possess considerable hardness, and a much greater than that of common glass. I imagine this defect may be caused by the sea-water which is mixed with them, and raised from the sea by the action of fire and aeri-form fluids. Thus we know that those liquid vitreous substances which are congealed and consolidated in water, are much more friable than when hardened in the air. I am confirmed in this opinion by observing, that a number of cracks and fissures are to be found in these enamels, an appearance we likewise observe in glass which has been dropped into water while in a state of fusion. It is to be remarked that these enamels, while they were fluid have received within them several extraneous bodies; as pieces of tufa and lava, sands and earths of various kinds, which are found within them more or less calcined.

It is probable from the small distance between Procida and the Rock of Burnt Stones, that they once were joined, and have been separated, in the course of a long series of

years, by the action of the sea.

CHAPTER V.

ISCHIA.

The Castle of Ischia founded on a rock of lava and tufa....Singular species of swallows, which make their nests at its top, and on the higher eminences of the island ... Lava of the Arso described....Its pumices originate from the horn-stone....The opinion of some volcanic naturalists, that the lava of the Arso, which flowed in 1302, still smokes, ill founded ... Lavas and pumices scattered between the city of Ischia and the Arso Conical mountain, called the Rotara, composed of lavas and pumices, is the only one in the island which contains enamels....The high mountain of St. Nicola, probably, at first, rose out of the sea.... Volcanic substances of that mountain....Some of those substances yield sulphate of alumine (alum).... Excursion round the shore of Ischia....Volcanic productions found there....Ferruginous sand abundant on that island....Is found to be all crystallized....Inquiries concerning its origin....No prismatic configuration in the lavas which fall into the sea.... The assertion of some modern writers, that the lavas of the shores of Ischia are a nidus for the pholades, greatly to be doubted....The Stoves of Ischia, the only probable indication of a remaining internal conflagration....Considerable diminution of this island....Difference between the volcanic materials of Ischia and those of the other Phlegrean Fields....Singular property of the feltspars of the Ischian havas, which melt in a glass furnace, whereas those of other lavas are almost always infusible by its heat.

THE volcanic substances of which this island, eighteen miles in circuit, is internally composed, prove, beyond the possibility of doubt, that it owes its origin to fire. The obscure epochs of the cruptions of these substances have been fixed, by conjecture, by M. Niccola Andria, the learned professor royal in the university of Naples, in his interesting work, entitled, Delle Acque Termali,* in which, before he treats of the warm springs of Ischia, he gives a detail of the natural history of the country, in which he displays equal learning and ingenuity. To this work I refer the curious reader, who will find it extremely instructive.

I shall, however, according to the plan I originally proposed to myself, proceed to describe the principal productions of this island which owe their origin to fire, adding such remarks as the subject may seem to render necessary. I shall begin therefore at the castle of the city of Ischia, which is built on a rock surrounded by the sea, and a little more than a quarter of a mile in circuit. Lava and tufa are the two component substances of this rock. The former is different in its appearance, according to the different places in which it is found; but its qualities appeared to me to be substantially the same. Its base is hornstone: it is compact, of a moderate hardness, an earthy appearance; of a black colour externally, but grayish within. Its dead lurid hue is diversified by a few sparkling rhomboidal feltspars.

The furnace produced from it a very compact enamel, of a mixed colour, between that of honey and dark blue, without any alteration in the feltspars.

The tufa has no quality by which it is distinguished from the common.

On examining the direction of the tufa and the lava, it was found to continue the same in the neighbouring mountain, which is separated from the rock by a narrow channel of the sea: whence it is obvious to infer, that several currents have descended from

^{*} On the waters of hot baths,

the mountain and plunged into the water, thus forming the rock, which has been divided from the island by the action of the waves.

A number of black and white swallows* make their nests in different parts of this castle, and in the clefts of the rock. The steep and lofty rocks of the island, likewise,

afford a secure retreat to these birds of passage.

nded from

Leaving the castle and the city of Ischia, and proceeding about a mile to the west, we meet with a torrent of lava, called the Arso (or Burnt Ground) which is the most recent of any in the island, since it flowed in 1302, and is described by Villani, in his History of Florence. It extended about half a mile in breadth, and about a mile and a half in length, and would have flowed farther, had it not met the sea, in which it was buried. The course of the torrrent appears interrupted by eminences and descents, and, at some distance, presents to the eye the resemblance of an immense number of large heaps of mulberries confusedly thrown together. It has no visible crater, if by that term we understand, as is usual, a mouth more or less enlarged towards the edges, and contracted at the bottom; for the lava issued from a narrow cleft at the foot of Mount Tripeta. Though it is little less than five centuries since this lava flowed, a gloomy sterility reigns upon it; it does not produce a single blade of grass, and only affords, in some places, a few arid and useless plants of the lichen, or liverwort. On the surface, and for a little depth, it is light and spongy, and easily crumbles; but deeper, it becomes dense and harder. The same is observable in many lavas, and is the natural effect of the laws of gravity: the lighter parts of a liquid mass rising to the surface, and the heavier sinking to the bottom.

This lava is of the hom-stone base, and has an earthy ground. Its colour is different in different places, and varies from that of iron to a reddish black. The feltspars incorporated in it are extremely numerous, and, when attentively examined, in some specimens, may induce us to conclude that the fire which produced this torrent must have been extremely violent; since we find the feltspars more or less melted, though generally, those included in lavas appear not to have undergone the least alteration. When we take the lava of the Arso from some depth, in the middle of the current, we find this fusion of the feltspars extremely apparent. Some appear transformed into little globes, or cylinders; others have been only melted on one side, on which they have lost their crystallized form, though they have preserved it entire in other parts. In some cavities of the lava, where the fusion of the feltspars has been more considerable, we meet with singular appearances, which well deserve notice. Sometimes the melted feltspar hangs, as it were, in the air, attached only by some radiating threads of the lava itself, in the centre of which it hangs; while another, melting in the side of a cavity, takes the shape of a transparent concave veil. Even those that have not undergone fusion exhibit decisive signs of a strong calcination. They are extremely friable, and their shining changeable colour is in many places turned to a dead white. In consequence of this calcination, the crystals are often no longer found entire, but scattered here in small fragments in the body of the lava. Those in the lava on the sides of the current are less injured, and their crystallization is in quadrangular faces.

As the volcanic fire had reduced many of the feltspars in this lava to a state of fusion, I determined to try what effect I could produce on them in the furnace; but though I

kept them there two days, I could only obtain a simple calcination.

M. Dolomieu, speaking of the island of Ischia, tells us that the eruption of the Arso, though we know it continued two years, never produced any pumice, but only black

^{*} Hirundo melba. Lin.

scoriæ.* It is true I could only find scoriaceous lava on the surface, and solid lava in the internal parts, through the whole length of the course of the torrent, except at the aperture whence it had flowed; where, amidst a great quantity of fragments of lava, I found several pieces of pumice so completely characterised, that there was no danger of confounding them with the light and porose scoriæ, which have been frequently by persons of insufficient discernment, taken for pumices. These besides being dry and rough to the touch, were fibrous, with long fibres, vitreous, extremely light, shining, and brittle; whereas the texture of the scoriæ and scoriaceous lava of the Arso is granulous, or so confused that no shadow of a fibre appears; nor have they much friability. In other respects, these pumices of the Arso agree in substance with the scoriæ and lava of the same place; the feltspars in them are alike, and equally affected by the fire. This observation proves therefore, that the horn-stone, by a violent fire may be changed into a true pumice, though this transmutation rarely happens.

The above-mentioned French naturalist likewise asserts, that the lava of the Arso still smokes in many places; and that the white fumes which rise from it are very visible in

the morning when much dew has fallen.

This assertion, though it must appear somewhat extraordinary, would certainly merit belief, had M. Dolomieu himself been an eye-witness to the fact; which had he been, he certainly would have told us. As however he only expresses himself in general terms, it is probable he relied on the information of others. The abbe Breislak and myself made our observations on the Arso, at the most proper time for discovering these fumes. We repaired thither at sun-rise, and passed there the greatest part of a morning in which there was no want of dew; but our eyes sought this wonderful appearance in vain. Nor could we learn that it had been seen by any other persons; those at least of the inhabitants of the vicinity whom we interrogated on the subject, and they were not few, nor people likely to deceive us, all declared that they had never seen either smoke, vapour, or mist, arise from the Arso. However notwithstanding this, I will not take upon me absolutely to deny the fact. I will only say, that I find it difficult to overcome my doubts; nor am I convinced by the instances adduced by M. Dolomieu, of some lavas of Etna which have not yet ceased to smoke, though they were ejected in 1762; since the time elapsed in the latter case is only twenty-six years, but in the other four hundred and eighty-six.

On my return to the city of Ischia, I met with three lavas rising from the earth like huge rocks. The base of all the three was the horn-stone, but they were distinguished

from each other by certain exterior characters.

One of them was of a cinereous colour, of a coarse grain, but compact, dry, and rough to the touch. In its external appearance it was not unlike to come sand-stones.

The second was of a ground entirely earthy: its compactness, weight, and hardness were however greater than those of the first lava.

The third, in its recent fractures, was half vitreous; gave sparks with steel, but languidly and was more fixed, heavy, and hard than the two others

guidly; and was more fixed, heavy, and hard than the two others.

All these three lavas had an argillaceous scent, and contained numerous feltspars so brilliant and perfect that they appeared to have entirely eluded the violence of the fire.

A number of detached pumices accompanied these lavas, which they resembled in their general qualities; they contained feltspars and shoerls, but both reduced to a beginning state of fusion.

^{*} Catalogue Raisonnee des Produits de l'Etna.

But no part of the island so abounds with pumices as the Rotaro, a mountain situated between Casamicciola and the city of Ischia. This mountain is of a conical shape, and composed of tufa, pumices, and enamels. It appears to have been produced by a thick and slimy eruption, and is divided into several strata, particularly distinguishable in the road called Via del Rotaro. Between these strata there is an immense quantity of pumices, differing in their size, colours, and density; but similar in their texture, which in all is fibrous. They contain various feltspars, which manifest a beginning fusion. They do not form continued currents, as we observe in many of the pumices of Lipari, but are found in detached pieces; yet so disposed, that in many places they form beds or strata. It appears extremely probable, that the volcano, after an eruption of tufa, threw up a shower of pumices, which falling on the tufa produced a bed of stratum, upon which another eructation formed another tufaccous stratum, that was again covered with another shower of pumices; and thus by alternate ejections of tufaceous and pumiceous matters, a great part of the conical mountain was formed. The extent of the pumices, in the direction of the Via del Rotaro, is more than a mile; and they principally abound in the more elevated places, where those most proper for the purposes for which these stones are used in Italy, may be collected in great abundance.

Intermixed with the pumices and tufa, we find many pieces of enamel, the thickness of which is from an inch to a foot and a half, and even two feet. These were probably thrown out at the time when the above-mentioned mountain was formed. They are of a black colour, and yield to the strokes of a hammer much more than the enamels of the Rock of Burnt Stones and Procida. Like them, they abound in feltspars, and present the usual rhomboidal figure. The Rotaro is the only place in Ischia which affords

enamels.

It seems as if it might be considered as an invariable rule, that among the mountains of different elevation which have riven birth to volcanic islands, that which rises above the rest, and is commonly placed in the centre, was first produced by the fire; and that those which surround it, and by their junction and extent form the body of the island, are the work of succeeding eruptions, which have issued either from the crater of the primitive mountain, or from the lateral and lower craters, whence have been ejected that aggregate of subaltern and successively lower mountains, by which the most elevated, which occupies the centre is surrounded. In this manner we perceive several of the Eolian isles to have been formed. Such also has been the origin of Ischia; where the mountain of St. Niccola, which in earlier times was called Epopeo, and which is in the centre of the island, and higher than the rest, was no doubt the first that towered above the waves. The constituent substances of this mountain are of various kinds. I have considered, with some attention, those on the side of Lacco, which are stones that in the same manner as those of Solfatara, have undergone a decomposition probably to be attributed to sulphureous acids, if from the resemblance of effects we may argue a similarity of cause. The rocks near the sea on the coast of Fasano are less decomposed; nor is it difficult to discover their nature, which is granitous; the mica, feltspar, and quartz, being clearly discernible, with some greenish particles of steatites. The quartz and feltspars, though somewhat calcined, are tolerably hard; and the mica which is black, has not lost its native splendour. This rock, which does not appear to have suffered fusion, is whitish, and changed in such a manner that it will not resist a blow of the ham-

Proceeding towards the summit of the Epopeo, we meet with decomposed lavas, partly of the horn-stone base, and partly of that of the petro-silex, in which however the argilla occupies no small part. The lavas of this latter quality, in part not affected

by the sulphureous acids, are of a black huc, of considerable compactness, give sparks freely with steel, and in their fractures, and sometimes externally, present a siliceous appearance. Their odour is sensibly argillaceous. These petrosiliceous lavas are not simple, but contain within them some small flakes of feltspar and mice.

In the furnace they melt into a substance of the colour and lustre of pitch, in which

however the white feltspars appear, or rather are conspicuous.

These lavas are found to be variously decomposed by the acids, in the same manner as is observable in those of Solfatara. In some places they are covered with a thin whitish crust, light, soft to the touch, which attaches to the tongue, and is extremely friable. In others this crust is some inches deep, and in others it extends through the whole thickness of the lava. Sometimes we find it so softened that it has become pulverous; and there is a great quantity of white dust on the brow of the mountain. We may therefore conclude that the sulphureous acids have there been very abundant, and of long duration; though now there is no perceivable sign of any such exhalations.

We know that formerly in Ischia the sulphate of alumine (alum) was extracted for commercial purposes; and according to M. Andria, who has been before cited, the manufacture of this salt was principally carried on at Catrico, a place situated above Lacco, on the higher eminences of the Epopeo. He informs us however, that he was not able, after the most careful and minute research, to discover any remaining vestige of sulphate

of alumine. I will candidly state what I myself observed.

I collected a number of specimens of the different lavas of Catrico and the environs. They are generally compact, very white, and homogeneous to the eye; but they differ from each other by the following exterior characters. Some are moderately heavy and hard; in their recent fractures, and frequently without, they are smooth; and in the centre of some we find a small nucleus of blackish lava, but little decomposed. Others are very light, may be scratched by the nail, are rough and somewhat pulverous in their factures, and scarcely ever contain within them any residue not decomposed. In short, the former lavas have undergone less change by the sulphureous acids than the latter. When I first examined on the spot the fragments of these two lavas, I could not perceive by the taste any symptom of the sulphate of alumine; but when I had conveyed my specimens to Pavia, together with other volcanic substances, and placed them in my cabinet, on large tables, after some months I observed the following appearances:

In the lavas of Catrico and its vicinity, which had been less affected by the acids, I could discover no trace of alum; but in the other lavas of the same situation, which had been more changed by the said acids, I perceived the sweetish and astringent taste of that salt; and could discover a whitish thin coat of the same, which entirely in-

crusted them.

At the end of six months the thickness of this coat was a quarter of a line; after which, I did not perceive it to encrease in thickness. I made new fractures in these lavas, and continually discovered new coats of the sulphate of alumine; and at the time I now write, which is twenty-seven months since I brought the specimens of lava from Ischia, they still retain a thin saline crust. I have also satisfactorily ascertained the true nature of this sulphate of alumine, by the ordinary chemical proofs.

As to the second species of lava, it never at any time exhibited any sign of the presence of this sulphate; nor have I been able to obtain it by calcination, and a method similar to that which is employed in the territory of Civita Vecchia for extracting alum

from such argillaceous stones.

These observations however sufficiently prove, that this valuable salt might still be obtained at Ischia; nor should it excite surprise that, when on the spot I could not discover it by the taste; since the humidity of the night, the dew, and still more the rains, had dissipated it as fast as it effloresced. As the species of decomposed lava in which I discovered it, is found in very large quantities on the Epopeo, this branch of commerce, which has been so long neglected in Ischia, might doubtless be revived with very great advantage.

Besides the places I have mentioned, I examined this island in many others, without discovering any novelty worthy of remark; but I could not entirely satisfy myself with such excursions. When I first formed the design of attentively examining Ischia and the Eolian isles, I resolved not only to make my researches in their interior parts, but to coast their shores in a boat, landing at such places as appeared the most suitable to my inquiries. In this manner I met with many volcanic bodies, which I should have sought in vain within the island; either because they do not exist there, or because they are rendered inaccessible by the rocks and precipices with which they are surrounded, or which they themselves form. The coasts of the volcanic isles are also clothed with lavas, which run out into the sea, and which in some places, by tracing them upwards, discover the crater or mouth from which they have issued. Lastly, by coasting the shores of the islands, we may be enabled to determine whether the prismatic lavis owe their origin to the sea; many writers of repute having asserted that the regularity of their form arises from the sudden congelation that takes place on their precipitating into the sea-water, which causes them to take the shape of regular prismatic columns; a configuration which they affirm is only found in places adjoining to the sea.

For these reasons I determined, after having examined the higher parts of the island, to proceed to consider the lower; and took my departure from Lacco by water, coasting the island on the left. The first mountain which presented itself was the Vico, partly formed of tufa, and partly of two currents of lava, which descend into the sea. The colour of the first, which is of a horn-stone base, is between the gray and iron colour: it is of an unequal grain, earthy, and moderately hard; and abounds in feltspars, some in thin plates, others in prisms, and both conspicuous for their brilliancy.

The other lava, which is of the same base, and contains similar feltspars, is less compact, more earthy, and consequently less hard: its colour is partly cinereous, and partly gray. These two lavas, in their descent, have raised themselves into little mounts, and are of a considerable thickness.

Farther on is Monte Zaro, formed towards the sca by a river of lava extending a mile in length, and nearly two in breadth. It appears to have been generated by several successive eruptions, which have consolidated one after the other. The base of this lava is horn-stone, and it contains mica and feltspars. It is various in its colour, being in some parts of the current of a more or less reddish blue, in others cinereous, and in others white. The mica, which is black, and especially conspicuous in the white pieces, though it has not undergone fusion, has lost its lustre, and acquired a much greater degree of friability than it naturally has. The same has not happened to the feltspars, which are as well preserved as if they had never been exposed to the fire. They give sparks plentifully with steel, have a beauteous changeable lustre, are of a vitreous semi-transparent whiteness, and being broken, are detached with difficulty. This species of lava so abounds with them, that they occupy the full half of its volume. The greater part are prisms.

Another lava makes a part of the same current of Monte Zaro. This, though it is likewise of a horn-stone base, differs from the former by being one-third less heavy, and

of an earthy appearance; whereas that of the other is somewhat vitreous. Its colour in the more internal parts is reddish; but in the external an ochreous yellow. On the surface especially it is manifestly decomposed; for it is become so soft that it may be scraped with a knife. But the cause which has produced this superficial decomposition in the lava has not injured the feltspars, which are extremely perfect, and in this lava may be easily extracted to examine their figure, which is hexagonal with rhomboidal faces. Some of them are half an inch in length, though others are not more than a line.

The bottom of Monte Zaro, which is washed by the sea, is covered with a vitreous sand; which viewed with a lens, appears to consist of a number of particles of feltspars, which by liquefaction have had their angles blunted, and been reduced to a roundish figure. They belong to the feltspars of the last mentioned lava.

From the termination of Monte Zaro to the beginning of Monte Imperatore is a long and ample tract, almost entirely tufaceous, scattered over with rapillo, as the Neapolitans

call it; or as a naturalist would say, with fragments of pumice.

The side of Monte Imperatore which over-hangs the sea, derives its origin from a very singular species of lava. I have already spoken of the abundance of feltspars in the lava of Monte Zara; but in this they are found so prodigiously numerous, that at first view they appear to constitute the entire substance. It is necessary to break it, and consider the pieces attentively, to perceive that it has a base, which is of a yellowish earthy horn-stone, easily friable, to very small quantities of which the feltspars are feebly attached. Their crystallization is in rhomboidal faces of various sizes, from a line to three quarters of an inch. To this little earthy base are likewise attached various small scales of black hexædrous mica.

The same Monte Imperatore presents us on the side of the sea with large quantities of another lava; which, excepting a very few particles of yellow mica, and some still fewer microscopic feltspars, may be considered as simple. This likewise has for its base the horn-stone. The lava appears to have issued from the mouth of the volcano at different times, as we find currents which have flowed over currents, intermixed in a

strange and confused manner.

Leaving the Monte Imperatore, we next arrive at the Calle di Panza; a place on the shore from which rises a very high and large rock of lava, interrupted by some protuberances, that attract the eye at a distance and invite observation, which they certainly merit, as they consist of beautiful groups of numerous rough rhomboidal feltspars, some two inches in length. They are of a yellowish white, transparent in a slight degree, of a vitreous appearance, a changing aspect, a foliating texture, and manifest their hardness by the quantity of sparks they give with steel. Many hundreds of them grouped together, form roundish masses of half a foot, a foot, and two feet in thickness, which at their lower extremity are set in the lava. Though, as has been said, they are very hard; yet by the means of certain fissures they contain, they may easily be divided into small pieces, either of the parallelopipedon or rhomboidal form. Whence it appears that they have been injured by some external agent, but which seems to have had no relation to sulphureous acid vapours, as we do not perceive the smallest indication of these, either in the feltspars or in the lava which contains them. This agent however, whatever it may have been, has produced a considerable effect on the lava, which is corroded in every part; and it is in consequence of its being so deeply corroded, that the groups of feltspars have been left uncovered, so that they may easily with an iron point be extracted entire.

This fact appeared to me the more deserving of remark, as in all my former volcanic researches I had never met with any similar: nor indeed have I since; the feltspars of other lavas being never grouped, or forming a kind of tumours, but scattered and distributed within them in equal quantities. But in what manner are we to consider these tumours? Are they extraneous bodies that have been by accident included within the lava while it was in a fluid state? 'This is possible; but it appears to me much more natural to suppose that they appertained to the stony substance which has been changed into lava by the violence of the fire. I would therefore thus explain this phenomenon. Since as we have already observed, the feltspars (and the same may be afirmed of the shoerls) are not the produce or consequence of the fire, as they are found to exist in many of the primordial rocks; it appears most probable that they were formed within those rocks when they were in a state of fluidity, or at least sufficiently approaching it.

I mean to say, that then the integrant particles of the feltspars by their powerful affinity, united in crystallized masses. Where they were at a certain distance from each other they united, forming complete crystals; but where they were thickly clustered, their tunnultuary union produced groups of crystals, the greater part of which were of irregular forms. The same may be observed in salts, stones, and especially in quartzose and sparry crystals. Thus, with respect to the feltspars in this lava: they are contained in every part of it; and where there is any space interposed between them, their crystallization is perfect; but very imperfect in their groups I have described, and probably

from the cause suggested above.

This lava, like the preceding, has for its base the horn-stone; and the external appearance of its current resembles that of a stream which precipitating from a height, has been suddenly congealed and hardened by cold. It abounds therefore in inequalities, elevations, and descents; and on observing its principal track, which passes by the Calle di Panza, we are led to expect that the aperture whence it flowed lies higher in the direction of that place where it is in fact found.

A strong wind rising from the south, though it did not prevent me from coasting the island, hindered me from landing, as there was danger of being dashed on some rock by the violence of the waves. I could therefore only observe at a distance a variety of lavas, and a great quantity of tufa, which being continually beaten and diminished by the waves, form precipices and cliffs hanging over the sea.

I however continued my researches by removing to the northern side of the island, where I was sheltered from the wind; but I did not find that the volcanic productions to be met with here presented any novelty. They were almost all of the horn-stone

base, and filled as usual with crystallized feltspars.

I did not fail to collect and examine the sand of the other parts of the island where I landed, as well that of the shore near Monte Zaro. I found it as I expected, to be of the same nature with the volcanic productions at the foot of which it was found. The greater portion of the sand consisted however of small fragments of feltspars; that being the stone which most abounds in these lavas, and which best resists the vicissitudes of the seasons, and every extrinsic injury.

I must not omit to mention the ferruginous sand which we meet with in many parts of the island, and which is especially abundant on the sea-shore. It not only moves the magnetic needle, but is strongly attracted by the load stone. This sand is well known in Naples and other places; but one of its qualities which I discovered with the assistance of a lens; has not to my knowledge been hitherto observed. At the first view I imagined with the generality of naturalists, that it must consist of very minute particles of iron, of entirely irregular shape, like those of lapidarious sands. Such in fact, they appeared to

the naked eye; but, by the aid of a good lens, I discovered with pleasing surprise, that every grain was the fragment of a crystal, or a complete specular crystal of iron. Of the latter there were not more than three or four among every hundred grains. These small material crystals are formed of two quadrangular pyramids united at the base, and every side of the pyramid is a rectangular or isocles triangle. But in general we meet with only the fragment of a crystal, and perceive that the part wanting has been destroyed by the action of the waves of the sea on the ferruginous sand; many of the grains exhibiting their angles blunted, and having assumed a globose figure.

This sand is not confined to Ischia; it is likewise found in considerable quantities on the shore of Pozzuolo. But what is its origin? It is certain that this iron could not thus have crystallized without having a base, or point of support; and in the volcanized countries, no substance presents itself more proper for such a base than the lava, on and within which it has assumed this configuration: but it must be allowed that this lava has been destroyed by length of time, since, among the innumerable specimens I have observed in these countries, I have not found one which exhibited similar martial crystals.

While making the circuit of this island, I continually had in my recollection the opinion of those naturalists who, as I have mentioned above, maintain that the formation of prismatic lavas owes its origin to the sudden immersion of the flowing lava into the water. I could not have wished a better opportunity to form a judgment on this hypothesis, than I here found; where a multitude of currents of lava, in different directions, appear to have rushed into the sea, in which they are still visible to a considerable depth. But I did not meet with one that had assumed any such regular form, or any other resembling it; either among the lavas above the water, those which touch its surface in their descent, or those immersed within it, as far at least as the eye could discern.

From the observations I made while coasting this little island, I was likewise strongly induced to doubt of a fact expressly asserted by M. Andria, in these words; "The lavas, in some places near the sea shore, are found full of holes made by the pholades; at least I am of opinion they are to be attributed to those animals, though I could not find in them any fragments of their shells."

He then immediately proceeds to reason on this fact: "It is manifest that the pholades were directed by instinct to make their lodgements here; but they could not do this

till after a long time, when the lava was become fixed and solid."

I shall not venture expressly to contradict this assertion, as I was not able to examine the whole shore of Ischia; and, even if I had examined it, I should still have distrusted my researches; since I could not have been certain that I had explored the precise places of which he speaks, as they are not distinctly described. I shall only candidly say, that I greatly fear there is some mistake, since I never met with any lavas, or other volcanic substances, which had been made the habitation of the pholas, whether by that name he understands the mytilus lithophagus or the pholas dactylus of Linnæus. In my researches relative to marine animals, I have given particular attention to those which pierce and inhabit subaqueous stones. I have examined, with the utmost care, the volcanic substances of Etna, which are bathed by the sea, those of the Eolian isles, and some of those of Vesuvius. Nothing is more frequent than to find on these, various kinds of testaceous animals, as oysters, serpules, lepades, and various others of the same species; but I never found them pierced by pholades, or any other animals which corrode fossil substances. I have found these animals in places not volcanic, though not in all, as I have observed that they never make their lodgements but in calcareous stones, of which kind the Ischian lavas, and in general, other lavas, are notI therefore incline to suspect that some other cavities, resembling those which are the work of the pholades, have deceived M. Andria. I could at least wish that he would ascertain the fact by repeating his observations on the spot, as, should it be established, it would, in my opinion, be the only example of the kind ever discovered in volcanized stones.

I employed three days in examining this island; and, during my researches, carefully observed whether I could discern any smoke or vapour arising from the ground, whence it might be concluded that the volcanic conflagrations were not entirely extinguished; but I could not discover the least appearance of the kind, nor had any been observed by the oldest inhabitants of the vicinity, of whom I made the most careful inquiries. The stoves of Ischia may, however, induce us to be of a contrary opinion. It is well known that these stoves are filled with warm aqueous vapours, which continually issue from cracks and fissures in the lava, and which, though they have some of the noxious qualities common to volcanic exhalations, are extremely beneficial in many disorders. These certainly can only be produced by a heat which, whatever may be the cause of it, raises the subterraneous water in vapour.

This island, when it was first produced by conflagrations in ancient, and, to us, unknown times, must have been of much greater extent than it is at present. The southern side, exposed to a sea which beats against it without any interposing obstacle, and formed in many places of tufa, one of the least hard of volcanic substances, must have been considerably worn away and diminished; and this diminution must continually increase. Time, which changes and destroys every thing, has likewise produced a great alteration in the interior parts of the island. From the summit of Epopeo, we discover a number of conical eminences; but their internal craters no longer exist, nor do we find in Ischia incontestible traces of a single one, since those depths and ample cavities, those resemblances of theatres and amphitheatres, which we observe around us, may be

equally the effect of fire or water.

Of

I shall conclude these observations by an important reflection on the volcanic materials of Ischia. These are different from those of the other Phlegrean fields. Except the mountain Vesuvius, the extensive plain on which the city of Naples stands, the surrounding hills to the north, the north-west, and the west, the craters of the lakes Agnano and Averno, many parts of Solfatara, Monte Nuovo, the promontory of Miseno, Procida, &c. they are the result of tufaceous substances. These are, in fact, not wanting in Ischia; but the predominant part of its composition is various kinds of rock, and principally the horn-stone. The eruption of the Arso, likewise, which is the last conflagration of which we have any knowledge, is composed of the same stone. The substances, therefore, which have furnished aliment to the different conflagrations of Ischia, have had their centre in those argillaceous rocks, which by the above-mentioned eruption in 1302 shewed that they were not then exhausted.

These rocks, as we have seen, abound in crystallized feltspars, which in the furnace exhibit a quality we rarely meet with in the feltspars of other lavas subjected to the same degree of heat. I mean their fusibility. If we except those of the Arso, which do not yield to the fire, all the feltspars of these lavas may be perfectly liquefied. The lava, in which the feltspars are contained, acquires a clear colour, and becomes slightly transparent; while in other parts it presents an opaque and imperfect enamel. If the quantity of the feltspars included is more than double that of the lava, the product which results is a true glass, but somewhat less transparent than factitious glass; but when the feltspars are solitary, and not at all injured by the lava, like those of the Calle di

Panza, the glass is perfect and extremely transparent. It has no colour, is very compact, and gives sparks strongly with steel. To bring it to this perfection, it requires a fire of about two days. At the end of the first day, the feltspar is only reduced to a paste, similar to porcelain; the pieces then conglutinate together; many exhibit a semi-vitrification, and the surface within the crucible is not horizontal and even, but has risings and cavities, according as the pieces have been put in: by continuing the fire, how-

ever it becomes level and smooth.

The prosecution of these experiments induced me to attempt to fuse, with the same degree of heat, two other felispars which are not from volcanic countries; the one being from Mount St. Gothard, and the other from Baveno. Father Pini has the honour of their discovery. The first is in mass, of a shining white, foliated, and very hard, I kept it in the furnace during eight-and-forty hours, but it had only contracted a slight superficial vitreous appearance. When placed within two crucibles joined by their tops, with charcoal entirely surrounding them, in a furnace, the fire of which was violently excited by the bellows for two hours, the angles of this feltspar became blunted, and the pieces attached together, contracting a smooth surface, and a milky whiteness, but without any sensible fusion taking place in the internal parts.

The other feltspar, from Baveno, is crystallized in tetrahedrous prisms, opaque, less hard than the former, and of a reddish yellow colour. After continuing forty-out hours in the furnace, a slight conglutination took place in the pieces, which had acquired

a snowy whiteness.

On comparing these two feltspars and others contained in innumerable lavas, with those of the Ischian lavas, we may conclude that it is very rarely that the fusion of these

stones can be obtained by the utmost heat of a glass furnace.

From these observations on the lavas of Ischia we likewise learn another truth. Mineralogists have said that shoerls are more easily fusible than feltspars; because they have observed that the degree of heat in which the former fuse is insufficient to fuse the latter. But I have experienced that this assertion is not always true; and it will be seen in the course of this work, that the shoerls of some lavas will resist the same degree of heat in which the feltspars of Ischia are completely fused. The cause of this may be, either that the silex sometimes is less abundant in the feltspars than in the shoerls, or that their component principles are proportioned in such a manner, that the fusion of some is facilitated more than that of others, or because they contain more iron, it being well known that this metal promotes the fusion of stones.

A STATE OF THE STA

CHAPTER VI.

THE VALLEY OF METELONA, NEAR CASERTA.

The tusa found in this valley, composed of fragments of pumice surrounded by calcareous earths....

Pieces of enamel mixed with it....This tusa different from other volcanic tusas....Probability
that it communicates with the volcanos of Naples and its environs, and perhaps also with those
of the Agro Romano and Tuscany....Means proposed to ascertain whether the Bay of Naples
be the remains of an ancient volcanic crater, and to what distance within the sea the roots of
Mount Vesuvius and those of Ischia extend.

AN excursion from Naples to Caserta, and thence to the neighbouring aqueducts, furnished me with an opportunity for new volcanic observations. Some miles before we arrive at the small city of Caserta, ennobled by the superb royal palace, which may be said to consist of four grand palaces united in one by the hand of a master, we meet with calcarcous earth, which continues to the aqueducts, distant six miles from that city, and which are a prodigy of art. They consist of a large and magnificent bridge, of the astonishing length of two miles, and of a proportionate breadth. Within this bridge runs a wide canal, brought from a mountain at the distance of twenty-six miles, which, passing through subterranean conduits, skirts the side of the hill, and descends to Caserta, near the Royal Gardens. As the neighbouring mountains abound in calcareous stone, I was not surprised to find the pavement of the bridge formed of that stone; but it somewhat excited my attention when I perceived that the remainder of the edifice was ecustructed with volcanic tufa, in which are mixed some pieces of enamel. Sir William Hamilton has told us, that in the environs of Caserta, below a stratum of vegetable earth four or five feet in thickness, we meet with cinders, pumices, and fragments of lava; and that, on digging near the foundations of the above-mentioned aqueducts, volcanic earths are discovered. I therefore first conjectured that the tufa had been procured from these subterranean places; an opinion in which I was confirmed by observing that the whole country round was calcareous, not excepting the highest mountains, which were, nearly all, of the same contexture and colour with the chains of hills between Naples and Loretto. One of the inhabitants of this part of the country, however, assured me that this tufa was dug from a plain, about a mile distant to the north, called the Valley of Metelona, of which I was convinced, on repairing to the spot. This tufa, in several places, lies in heaps on each side of the public road, principally near the Taverna, where we find the excavations, not within but above the ground, which have in part supplied materials for these aqueducts. This tufa is extremely porous, and being immersed in water attracts it forcibly, and with a slightly hissing sound, as is the case with other bibacious bodies. Like tufas in general, it has a moderate weight and consistence, is rough to the touch, and inclines to a yellow colour. But on a more minute examination, it discovers its original, and is found to be composed of a mixture of small fragments of pumice, and any piece of it detached from the mass will be found to contain fragments of that stone. It appears as if composed of small threads extended lengthwise, which viewed with the lens are found to be slender filaments, extremely friable, and generally parallel to each other. It contains many cavities, within which the pumice appears changed into vitreous balls; we likewise find little globes of pumice, which have an external vitreous coat, but which, within, have preserved their fibrous nature;

7 2

comires a l to a semins ris-

how-

same being our of I kept uperfitops, blently

nd the

s, but

e, less -cight qu. ed

, with

Mie they ise the vill be ne deof this

fusion

on, it

. . 10.

lastly, in some parts of this tufa are contained pieces of solid enamel, extremely friable,

shining, and in their fractures resembling asphaltum.

The tufa now described is of a singular quality; at least in my travels through the Two Sicilies, I have not found any resembling it. The others are usually of an argillaceous base; this, as has been said, is a composition of fragments of pumice. Hence we may easily conceive that the results produced by the furnace must be different. The tufa of Metelona afforded a true enamel, but the others remained infusible.

The edges of the tufa, or rather of the broken and half pulverized pumices, are surrounded with calcareous stone. There is, however, no doubt that these punices, besides having deep roots, extend likewise laterally among the stone to a great distance. These volcanic matters have probably an immediate communication with the volcanos of Naples and its environs, as also with those of the Agro Romano, and perhaps also with those of Tuscany, so as to form a soil entirely volcanized, of immense extent.

Some have conjectured, and perhaps not without reason, that the great basin of the sea, called the bay of Naples, in front of Capri, is the remains of an ancient volcanic crater. It would contribute to the advancement of natural knowledge, were the bottom to be explored, at various distances from the shore, by the means of such instruments as are employed to fish up coral, and sometimes pieces of the rock on which it grows. Should we by such means discover a cavity similar to an inverted funnel, or draw up substances from the bottom, which should be known to owe their origin to fire, this

conjecture would become a well-founded opinion.

A portion of the roots of Mount Vesuvius are bathed by the sea. Who can say how far these roots may extend under the water? The same may be remarked of Ischia, which, perhaps, as some have conjectured, was anciently joined to Procida: it were to be wished that we could obtain facts that might ascertain the truth of such conjectures. It is well known how far Sir William Hamilton has extended the limits of the volcanization of the Phlegrean fields, by land; and there is no doubt but they might be still more enlarged by sea. The experiments necessary for this are certainly difficult, but not impossible. The industry of two Italians of merit, the Count Ferdinando Marsigli, and Vitaliano Donati, has made us acquainted with the nature of the bottom of some parts of the Mediterranean and the Adriatic. In the course of this work I shall state what I have observed relative to the bottom of the famous strait of Messina, and that in which the channels that separate the Eolian isles terminate. It is greatly to be wished, for the advancement of volcanic knowledge, that the bottom of the sea near Naples, and the adjacent places, might be explored by similar experiments.

CHAPTER VII.

JOURNEY TO MOUNT ETNA.

Comparison between Vesuvius and Etna....The lavas of the latter volcano begin to appear, from the sea, at the distance of thirty-seven miles from Messina....Different epochs of the flowing of these lavas....Modern Catania almost entirely built of lava; as was the ancient city, which was destroyed by an earthquake in 1693....Remarks on the observations of Mr. Brydone, relative to Etna....Uncertainty of the opinion of Count Borch, that the age of the lava may be calculated by the quantity of vegetable earth produced by time....Fruitless attempts to render cultivable the eruption of 1669....The thinness of the crust of vegetable earth, the cause of the fertility of the lower region of Etna....Monte Rosso....Eructation of its lavas....Abundance of shoerls on this mountain....Chemical analysis of these shoerls....Feltspars not always more difficult to fuse than shoerls....View from Monte Rosso of the whole current, which in 1669 flowed into the sca....Calamities suffered at different times by St. Niccolo dell Arena from the eruptions of Etna....Lavas of the middle region.....Its great celebrity for luxuriant vegetation, and the loftiness of its trees....Great antiquity of these two regions....Grotta delle Capre....Nature of the lavas of that grotto.

THOUGH Vesuvius, considered in itself, may be justly called a grand volcano, and though, from the destruction and calamities it has at various times occasioned, it has continually been an object of consternation and terror to the inhabitants of the neighbouring country; yet when it is compared with Etna it must lose much of its celebrity, and appear so diminished, that if the expression may be allowed, it may be called a volcano for a cabinet. Vesuvius does not, perhaps, rise higher than a mile above the level of the sea; and the whole circuit of its base, including Ottajano and Somma, is not more than thirty miles; while Mount Etna covers a space of one hundred and eighty, and in its height above the sea considerably exceeds two miles. From the sides of Etna other lesser mountains rise, which are as it were its offspring, and more than one of which equals Vesuvius in size. The most extensive lavas of the latter mountain do not exceed seven miles in length; while those of Etna are fifteen or twenty, and some even thirty miles in extent. The borders of the crater of Mount Etna are never less than a mile in circuit, and according to the changes to which they are subject, sometimes two or three miles; it is even reported, that in the dreadful eruption of 1669 they were enlarged to six.* But the circumference of the Vesuvian crater is never more than half a mile, even when widest distended, in its most destructive conflagrations.† Lastly, the earthquakes occasioned by the two volcanos, their eruptions, showers of ignited stones, and the destruction and desolation they occasion, are all likewise proportionable to their respective dimensions. We cannot therefore wonder that visits to Vesuvius should be considered as undertakings of little consequence, and never be made public, except lavas should have been flowing at the time; while a journey to Etna is considered as no tri-

* Borelli, Hist. Incend. Ætnæ, an. 1669.

[†] I know not how M. Sage was led into so strange an error as to assert that the crater of Vesuvius is more than three miles in diameter (Elem. de Min. tom. 1.) Were this true, the circumference of the Vesuvian crater must be nearly ten miles, an extent which perhaps the crater of no volcano in the world ever had.

vial enterprise, both from the difficulty of the way and the distance; as from Catania, whence it is usul to set out, it is thirty miles to the summit of Etna. On such a journey, likewise, we have to pass through three different climates; whereas to go from Naples to Vesuvius should be rather called an excursion than a journey. We find also little difference between the temperature of the air at the bottom of this latter mountain, and that of its summit. Notwithstanding these difficulties, however, the gigantic majesty of the Sicilian volcano, its sublime elevation, and the extensive, varied, and grand prospects its summit presents, have induced the curious, in every age, to ascend and examine it; and not a few have transmitted to posterity the observations they have made

These examples would alone have strongly excited me to make the same journey, and similar researches; but I had also a still more powerful incentive in the undertaking in which I had engaged to travel through the Two Sicilies, in order to make observations on the volcanos, among which Etna must principally claim my attention, as being the largest and most stupendous of all that are, at present, in a state of conflagration on the surface of the globe. I was, likewise, induced to believe that, notwithstanding so many journeys to this mountain have already appeared, I might still publish mine; and that for several reasons. First, because I flatter myself that I shall be able to state some observations which will be, in part at least, new to the reader; secondly, because I shall thus have an opportunity to examine many things related by the travellers who have preceded me, which do not always appear to bear the stamp of truth; and lastly, because my remarks may furnish subjects for useful discussion.

I took my departure from Messina for Catania, a distance of sixty miles by sea, in a small vescel, coasting close upon the land all the way, to examine the shore. On the first of September I landed at the distance of fifteen miles from Messina, on a part of the shore which forms there a headland, where mariners are accustomed sometimes to make a short stay. The shore here was entirely of calcareous earth, except some pieces of scattered detached lava. The latter production excited in me some doubts whether the explosions of Etna had ever reached to so great a distance; but the mariners who were with me assured me, that these pieces of lava had been brought from the shore of Catania by vessels who had taken them in as ballast, and left them here when they had no farther occasion for them, in consequence of having taken in other lading. Of the truth of this account I was afterwards satisfied, as I found this lava perfectly similar to that in the neighbourhood of Catania.

The real eruptions of this volcano begin first to appear, in the form of rocks of different elevations, which overhang the sea, at the distance of thirty-seven miles from Messina, on the way to Catania; and at the same distance Etna is faintly seen to smoke, and majestically raises its head above the other mountains of Sicily. We had a clear view of it, the sky being free from clouds; and I began to entertain a hope that I should be able to visit its highest summit, since it was not, as it frequently is, covered with snow.

Before we arrived at Catania, I landed at several places, to examine the shore, which is entirely formed of lava. I was particularly attentive to its course and changeable structure. The greater part of the lavas proceed in a right line from the body of Mount Etna, with various inclinations to the level of the sea; and many of them, having been broken by the violent shocks of the waves, exhibit their various stratification, and shew the difference pochs in which they have flowed, by the difference of their strata, and the coatings of vegetable earth more or less thick interspersed between those strata.

All these lavas, at least those which I examined, are similar with respect to their base, as they all derive their origin from the horn-stone, and all contain within them feltspar

crystals.

I employed two days in this coasting voyage from Messina to Catania. The materials of which the latter city is built are such as might be expected in a volcanized country where stones of any other than a volcanic nature are not to be found but at a considerable distance. The edifices, both public and private, and even the walls of the city, are principally of lava; which has furnished materials not only for the modern Catania, but also for that more ancient city, which was entirely destroyed by an earthquake in the year 1693; at least its ruins when dug up have all been found to consist of lava. We learn likewise from observations anterior to that fatal period, that lava has been met with under its foundations on the occasion of digging for wells; * nor is it possible for us to say to what depth the roots of the Etnean eruptions extend. If we only take a view of the surface of the territory of Catania, we every where meet with immense accumulations of lava, among which the most conspicuous are the remains of that torrent which poured from one of the sides of Etna in 1669, inundated, with widespreading ruin, a space of fourteen miles in length, and nearly four in breadth rose over the walls of Catania, burying under it a part of the city and at length precipitated itself into the sea.

It would be a superfluous labour were I to proceed to give a long and minute description of this torrent of lava, which has been already so amply described by Mr. Brydone,† count Borch,‡ Sir William Hamilton,∮ and Riedesel;∥ though I cannot say that the relations of four travellers, who repeat the same things after each other, were much wanted; since our illustrious countryman, the Italian Alphonsus Borelli, who was present at the time when this dreadful torrent of fire burst forth, wrote a work expressly to describe it.¶ It appears to me preferable to present the reader with the view, with

* Borelli ubi sup. § Campi Phlegræi. † Tour through Sicily. || Travels in Sicily.

‡ Lettres sur la Sicile.

Mr. Brydone is the only one of these travellers who mentions Borelli. He cites four observations from him; but perverts them, to give them more an air of the marvellous.

from him; but perverts them, to give them more an air of the marvellous.

He says, first, that according to the testimony of Borelli, "after the most violent struggles and shaking

He says, first, that according to the testimony of Borelli, "after the most violent struggles and shaking of the whole island, when the lava at last burst through, it sprang up into the air to the height of sixty names."

Mr. Brydone I hope will pardon me, when I tell him that Borelli, here, certainly, only speaks of some local shocks, and tremblings of certain places in the vicinity of the volcano, and by no means of a shaking felt over the whole island. As for the lava springing up into the air to the height of sixty palms, there is not a word about it in the whole book.

Mr. Brydonz, likewise, makes Borelli say, that "for many weeks the sun did not appear, and the

day seemed to be changed into night."

But all we find in Borelli's account, relative to this darkness, is, that "on the 8th of March, an hour before sun-set, the air, in the suburb of Pidaria, and some other neighbouring places, became somewhat thick and dark, with a darkness similar to that which is caused by some partial eclipses of the sun."

The two other passages, which I omit for the sake of brevity, are perverted.

Mr. Brydone, indeed, through his whole journey to Etna has sufficiently shewn his attachment to the marvellous, and, where that has failed him, has had recourse to the aid of his playful fancy to furnish him with extravagant, though ingenious, inventions of the ridiculous kind. The story of the veil of St. Agatha is an example; which veil, according to him, the people of Catania consider as an infallible remedy against volcanos, but which at the time of a great cruption "seemed to have lost its virtue; the torrent bursting over the walls, and sweeping away the image of every saint that was placed there to oppose it." But would it not have been more commendable to have furnished his readers with real information, instead of filling so many pages with these trivial and insipid pleasantries? In fact, after having read his five letters on Etna, what idea do they enable us to form of the nature of this mountain?

some improvement which this celebrated physician of Naples caused to be taken on the spot at the time, and which in the most natural manner represents this river of fire, such as it appeared at its beginning, during its progress, and at its end; it will likewise render much more intelligible several particulars of which I propose hereafter to treat.

Having mentioned these travellers, I shall make some observations on what has been said by count Borch relative to the changes that have taken place in the lava of 1669, and those of some other eruptions preceding and posterior to that time. These changes consist in the vegetable earth which begins to appear on them, generated in part from the decomposition of the lava, and in part from the destruction of the plants, which, after a certain time, are produced upon it. From the quantity of this earth he deduces a rule to judge of the age of the lava; which he endeavours to prove by examples of different Etnean lavas, of various epochs, which are covered with more or less of this earth in proportion as they are more or less ancient. Thus, a lava produced by an eruption in 1157, when he examined it in December 1776, had a coating of earth twelve inches thick; another which had flowed in 1329, had one of eight inches; on that of 1669, was found more than one inch; while the most recent, that of 1766, was entirely destitute of such earth. Whence he concludes, that from the antiquity of the lavas, ascertained by the quantity of earth with which they are covered, may be deduced the antiquity of the world.

As this argument is certainly somewhat specious, and has been employed by others, it merits to be discussed. We undoubtedly know from repeated observations, that lavas, after a series of years, are invested with a stratum of earth proper for vegetation; and the fact has already been proved in this work: nor can it be denied that this earth is originally produced by the decomposition of the lavas, and that of the plants which have taken root upon it. The same may be observed in mountains not volcanized, the stones of which (at least very frequently) being long exposed to the action of the air and seasons, are resolved into an earth proper for the growth of vegetables. It would not, therefore, admit of a doubt that the more ancient lavas must afford a greater quantity of earth than those of more recent date, were every exterior circumstance equal; were they all of the same consistence and qualities, and all equally affected by the fire. But how greatly they differ in these respects we have already seen, and shall see still more in the progress of this work. Such differences, therefore, must render the argument of count Borch extremely inconclusive; since a lava of an earlier age may have much less earth than one of later date; a circumstance which the chevalier Gioeni told me he

had frequently observed in several of the lavas of Etna.

Among the lavas adduced by count Borch, in favour of his hypothesis, is that which flowed in 1329, which when he examined it, that is four hundred and forty-seven years after its eruption, was covered with eight inches of earth. Yet the lava of the Arso, in Ischia, which rushed into the sea in 1302, when I saw it in 1788, still preserved in every part its hardness and sterility.†

It appears, likewise, extraordinary, that this writer should not have noticed the remains of another current of lava near Catania, which has been employed for two thousand

I do not mean, by what I have said, indiscriminately to condemn the whole work of Mr. Brydone. His Tour frequently contains facts and observations well deserving attention. It is elegantly written, and the author was well acquainted with the secret of exciting our curiosity, and rendering his narrative interesting; though frequently, with that kind of interest which seems more suitable to romance than to authentic history.

† Chap. V.

years as materials for buildings, and which retains such hardness, that where the labour of the cultivator has not been exerted it still continues entirely sterile.

With respect to the lava of 1669, I cannot conceive how the count could attribute to it an inch or more of earth, since it is entirely destitute of it. Were this the fact, the surface of the lava must at least, in some few places, exhibit some blades of grass, or small plants, as a stratum of earth an inch thick would be sufficient to nourish them; but we find it, on the contrary, destitute of every vegetable, except a few lichens, which we know will take root and grow on the hardest bodies, and such as entirely resist all effect of the air, as quartzes, and even on the smooth and slippery surface of vitreous substances. The count, very possibly, examined this lava in low hollow places, into which the rain-water had drained, and brought down with it some particles of earth, that

might have formed a thin stratum.*

Before I travelled into Sicily, I had read the eulogium bestowed on the prince of Biscaris, by count Borch, among other reasons, because he had exerted himself in attempts to change the face of the lava of 1669, and transform the ungrateful soil into a fruitful garden. When I arrived in the island, I admired the effect of human art. In many places the hardest lava had been opened by the force of mines; while in others it had been broken into extremely minute fragments, into which, when collected in certain receptacles, several kinds of useful plants had been inserted: but, unfortunately, they always perished, though they were repeatedly planted. Some few I found living, as here and there a pomegranate or an almond tree; but these were extremely weak and languid, though the broken lava among which they had taken root was mixed with vegetable earth. A species of the Indian fig† alone throve and flourished; but it is well known that this shrub delights in lavas, and that it will take root, grow to a considerable height, and bear fruit plentifully, on the most sterile. In the course of this work I shall have occasion to treat more at length on this subject. At present there only remains a large pond which has been dug in the lava of a considerable depth, and communicating with the water of the sea, in which are preserved different kinds of fish.

After having, for a considerable time, examined the environs of Catania, assisted by the chevalier Gioeni, to whom I owe the most lively and sincere gratitude for numerous favours, I set out for Mount Etna, on the morning of the 3d of September, accompanied, among others, by Carmelo Pugliesi, and Dominico Mazzagaglia, two guides extremely well acquainted with the roads. I performed the greater part of the journey on foot, only riding when I found myself fatigued. I think it scarcely necessary to mention, what has been so often repeated by travellers, and therefore must be so well known, that the lower region of Mount Etna, which extends through twelve miles of the ascent towards the summit, is incredibly abundant in pastures and fruit trees of every kind.‡

It is well known that this fertility is to be ascribed to the lava, which, softened by length of time, has produced a most fertile soil, thus compensating past calamity by pre-

† Cactus opuntia. Linn.

VOL. V.

^{*}With respect to the uncertainty and fallacy of any calculations deduced from the greater or less quantity of vegetable earth which may cover lavas, the reader may consult the work of M. Dolomicu above cited.

[†] The fertility of this region has been celebrated by the greater part of those authors who have written concerning Etna; among which the most distinguished are Strabo, and Fazello, but shove all Peter Bembo, who, after having visited the mountain, composed an ingenious dialogue on the subject. It may excite some surprise, that, after so many descriptions of this region, and after Borelli, above a century before, had thought such a description superfluous, Mr. Brydone should imagine it worth while once more to recount the prodigies of this fertile soil.

SPALLANZANI'S TRAVELS

rept fruitfulness. To this, however, the industry of man and arts of agriculture have not a little contributed; as well as the corruption and decomposition of vegetables, which have so great a share in the fructification of the earth. These lavas, however, in some places, still manifest their native wildness, rising above the useful soil, in craggy points and tumours, or discovering their naked sides on the banks of rapid torrents. On some declivities, where the earth has but little depth, we find trees, the roots of which not having been able to penetrate the unyielding lava, have turned aside, and extended horizontally along the surface of the soil. Whence it evidently appears that the fertility of the inferior region depends entirely on a crust of earth, more or less thick, without which the same barrenness must take place, which, it cannot be doubted, once prevailed.

At ten in the morning, I arrived at the village of Nicolosi (Plate I,) near Monte Rosso, which formerly was a plain, when in 1669, a new vortex opened, and disgorged a dreadful torrent of lava, which poured headlong down until it reached the sea, where it formed a kind of promontory (Y). It would have been a great omission not to have visited this mountain, though it lies a little out of the direct road to Etna. Besides the memorable cruption which has been mentioned more than once, other objects relative to it, which I had here an opportunity of examining on the spot, attracted my attention. Among these was that quantity of black sand which was thrown out in that eruption from the new volcanic mouth, which still remains, and covers an extensive plain beyond Nicolosi, where once verdant trees flourished; some of which still preserve remains of life, and raise their leafy branches above the changing sand. This sand, which covers a circuit of two miles round Monte Rosso, when it was first ejected from the vortex, extended over a space of fifteen miles; and covered the ground to such a height, that the vines and shrubs were entirely buried. Some of the finer particles of it were carried by the southerly wind even to Calabria, where they fell thick in many places, as we are informed by Borelli.

As I approached the Mountain, I found the depth of the sand greater, and it became a considerable impediment in my way, as my leg frequently sank into it up to the knee. It is well known that this mountain is forked, being so formed by the eruption, at which time it was called by the country people, Monte della Ruina (the Mountain of Ruin) and afterwards Monte Rosso (the Red Mountain) probably because some parts of it appeared of that colour. Borelli tells us, that its circumference at the base does not exceed two miles, and that its perpendicular height is not more than one hundred and fifty paces; while Sir William Hamilton estimates its height at a mile, and its circuit at least at three. From the observations I have been able to make, I must prefer the estimate of the Italian mathematician to that of Sir William.

The accurate accounts of the same Borelli inform us, that the gulf whence this eruption issued opened on the 11th of March, 1669, about the time of the setting of the sun; that the lava burst forth that same night; and that, on the 13th of the same month, a shower of scoriæ and sand began to be cast into the air, which continued three months, and formed Monte Rosso. From among a hundred or more mountains which rear their heads on the sides of Mount Etna, this is the only one with the history of the formation of which we are acquainted.*

^{*} Sir William Hamilton, in his journey to Etna, speaking of this eruption, cites an account of it by the earl of Winchelsea, who was present at the time, but which is more marvellous than true. He did not approach the place, but only beheld the eruption from the towers of Catania. He tells us, that the fire divided one mountain into two; and that it was composed, as were the stones and ashes vomited out (besides other principles) of mercury, lead, bronze, and every other kind of metal, which alone would be sufficient to deprive this account of all credit.

On examining this bifurcated mountain at the top, on the sides, and at the bottom, especially in those places where the rain-waters had produced furrows and deep excavations, I found it composed of different scoriæ and sand, that is to say, lava that had undergone various modifications, and from that same lava which has formed the immense current, as sufficiently appears from the identity of their principles. The base of this lava is the horn-stone: it is of a gray colour, dry in its fractures, rough to the touch, of a grain moderately fine, gives sparks with steel, and sounds when struck. It serves as a matrix to a great number of felt-spathouse and shoerlaceous crystallizations.* If from this lava we turn our eyes to scoriæ, of which Monte Rosso is principally composed, we observe the same kind of base, containing, in like manner, shoerls and feltspars; except only that the scoriæ have more lightness and friability, from their greater number of pores, which gives them the resemblance of certain spunges; besides that they have a kind of vitreous appearance, and that the pieces on the surface are scabrous; differences which arise from the scoriæ having been more changed than the lavas by the activity of the fire, and that of the elastic gases.

When the volcano threw up a deluge of scoriæ, a great number of them must clash, be broken, and reduced to powder; thus producing showers of sand: whence the sand that covers the environs of Monte Rosso, which, from the examinations I have made I find to consist only of triturated scoriæ. The lava of Monte Rosso, the scoriæ, and the

sand consist, therefore, of the same component parts.

M. Dolomieu having found, at Monte Rosso, great numbers of detached shoerls, of the same kind with those which enter into the lava of that current; that is to say, black, lamellated, flat, of a hexædrous prismatic form, and, for the most part, terminated by a dihedrous pyramid, he thought, with apparent reason, that they at first entered into the body of the lava; he therefore endeavoured to explain in what manner they were separated from it: having recourse to the sulphur, which, according to him, had scorified the lava, but had not been able to produce the same effect on the shoerls, from the small quantity of iron they contain, which, consequently, remained free and detached.

It is incredible how great a number of these loose shoerls are to be met with about Monte Rosso, and particularly on its top. When I was there, the sun shining clear, I saw them, in several places, sparkling on the ground, and I had only slightly to move the scoriæ and sand, to bring them to light by hundreds. They were exactly such as they are described by the French naturalist. I formed a design to ascertain the truth of the theory by which he has endeavoured to explain the separation of the shoerls from the lava, and when I returned to Pavia I made several experiments for that purpose. As his hypothesis was that it proceeded from the shoerls containing a less quantity of iron than the lava, it was to be expected that the magnetic needle would be less affected by the former than the latter. From the experiments I made both with the lava, or more properly speaking, its base, and with the detached shoerls, I perceived that the needle was attracted by the former at the distance of one-fourth, one-third, and even one-half of a line, while the attractive force of the detached shoerls acted on it at the distance of one-fourth of a line, one-third of a line, and a whole line; one shoerl even gave manifest signs of attraction at the distance of a line and a half. It is scarcely necessary to remark, that in such experiments every accessary circumstance ought to be equal; that is, the pieces of lava ought to be equal in size, and of the same configuration with the

^{*} I have given a brief description of this lava, as, in the present case, it seemed necessary; but, in future, I do not propose to describe the lavas and other productions of Etna; both because a month would not have been sufficient to have made a proper examination of them all, much less the short time I was able to employ in this journey, and because M. Dolomieu has already undertaken to give this description.

detached shoerls. These experiments prevented my adopting the theory in question, since they shewed that the martial principle was much more abundant in the shoerls than in their base; contrary to the hypothesis of M. Dolomicu. Reflecting, however, on the phenomenon of the isolated shoerls, another mode of explanation occurred to

me, which I shall here submit to the judgment of the learned reader.

Experience has shewn that the volcanic fire which melted the lava was incapable of melting the shoerls, as they are found within it as completely crystallized, with angles as acute, and of the same lustre, as those which are detached among the sand and scoriæ. As they are therefore so refractory to the fire, and are, besides, of a different specific gravity from the lava, it may reasonably be supposed that, when the latter was melted, and in the eruption of 1669, forced by elastic vapours to a prodigious height, where it was separated into small particles, numbers of shoerls were detached from it, and fell, isolated, partly within the crater, and partly around it. As these showers of fiery lava continued three months, the number of shoerls which thus fell detached must have been

very considerable, as we, in fact, find them at present.

The results produced by the furnace on these shoerls when detached, are very different from those they exhibit when incorporated with the lava. In the former case they are infusible, though they should remain there several days. When minutely triturated, indeed, their particles will conglutinate together, but without forming a compact and vitreous body. The fusion, on the contrary, is perfect in those which are enveloped in the body of the lava. Monte Rosso, quite to the sea, abounds in such shoerls. A few hours in the furnace are sufficient to change them into a shining, compact, and extremely hard enamel. Some lineament of the feltspars contained in the lava always remains; but it is impossible to discover any traces of the shoerls, they having formed, with their base, which has passed into the state of enamel, a similar and homogeneous body. The base of this lava, which, as we have said, is of horn-stone, has therefore acted as a flux on the shoerls.

This experiment throws light on another subject of some importance, already mentioned in Chap. V, which treats of Ischia; where speaking of the fusion obtained in the furnace of some feltspars, though detached, of some of the lavas of that island, I observed that it is not always true that the feltspars are more difficult to fuse than shoerls, as is generally imagined. I then alluded to what is here detailed, though this is not the

only place where that truth will be proved.

4 . 4 4 4

1214,

I shall make another remark or two on these shoerls. They do not belong, exclusively,

to this lava of Monte Rosso, but are found in many others of Mount Etna.

I do not know that any attempt has been hitherto made to analyse them chemically. I therefore undertook to ascertain their component principles by the process with asbestine earth invented by Bergman. From one hundred docimastic pounds of these shoerls I obtained the following result:

S	ilex													1	Pounds. 34.5	
	ime		•		-	•		-	•	•	•	-		•	18.7	
	ron Llum	•		•	•		•	-	-	•	•		•	•	7.6 12.4	
	Aagnesia		•		•	•	•	-	•	•	•	4		, ·	11.0	
1, 1			,							,	11/2		Sum	,	85.2*	

It must be remarked, that besides the almost irreparable loss in manipulation, and that of the water pre-existing in the shoerls, the lime is here deprived of the acid with which it was before combined.

Monte Rosso (the Red Mountain) as we have already said, has received this name from some parts of it being tinged with that colour, though there are others which are white, and others yellow. All these parts of it are found to be more or less decomposed, and, in general, they are only scorize. It seems indubitable that these colours

are produced by iron, changed or modified by acids.

Some of these scoriæ, which have not been affected by the action of the acids, exhibit a remarkable phenomenon. They are covered with a thin coat of pellucid glass, and seem as if a sheet of water had flowed over them and been suddenly frozen. This appearance, which in the neighbourhood of any other volcano would not merit a moment's regard, is remarkable at Etna, because we there meet with no vitrifications; M. Dolomieu, whose industry and accuracy are so great in all his researches, having found only one piece, and that of uncertain origin.

This vitreous integument has very probably been occasioned by a more energetic

action of the fire.

After I had staid some time at Monte Rosso, equally to my instruction and amusement, and had viewed with admiration the trunk and branches of that extensive river of lava, which issuing from the root of the mountain, and inundating an immense tract of country, had rushed into the sea, I took my way towards the monastery of St. Niccolo dell' Arena, a pleasing resting-place for travellers who visit Etna, where I arrived about noon on the 3d of September. This very ancient edifice, founded on the lava, was the habitation of a number of Benedictine monks, who about two hundred years ago, in consequence of the devastation occasioned by the lava, were obliged to abandon it, and retire to Catania. The injuries it has at different times suffered are recorded in various inscriptions still remaining, which commemorate ruinous earthquakes, torrents of lava, and showers of sand and ashes, by which it has been damaged and almost destroyed; with the dates of the different repairs. The environs of this place would still be entirely covered with the black sand thrown up by Monte Rosso in 1669, were it not that this sand becomes more easily changed into vegetable earth than the lava; and, for many years, has been planted with more than one extensive vineyard. After taking a slight refreshment in this hospitable place, I continued my journey towards the summit of Etna, proceeding over ancient lavas, which were still every where unproductive of any kind of vegetable.

About three miles above San Niccolo dell' Arcna, the lower region of Etna ends, and the middle begins, which extends for ten miles, or nearly that distance, in a direct line, up the mountain. It is, with great propriety, called selvosa, or the woody region; since it abounds with aged caks, beeches, firs, and pines. The soil of this region is a vegetable earth, generated by the decomposition of the lavas, and similar to that in the lower region; which lavas may not only every where be found on digging a little depth into the ground, but display themselves uncovered in many places, as we have already remarked of the lavas of the other region. The middle region is celebrated for its luxuriant vegetation and its lofty trees; but it appeared to me scarcely to deserve this celebrity. The trees (at least in the places where I noticed them) and especially the oaks, which form the greatest part of this woody zone, are low, and as I may say stinted in their growth; and would lose much when compared with those of other countries. The beeches, which grow only on the upper extremity of the zone, would appear mere pigmies, if placed beside those which rear their lofty heads on the Apennines and the Alps. This, I am of opinion, is to be attributed to the little depth of the earth proper for vegetation. The woods and verdure of these two regions, the inferior and the middle, are recorded by the greater part of the writers of antiquity; so that the commencement of this vegetation appears to be lost in the obscurity of time. How much more ancient then, must have been the date of the flowing of those lavas to the slow decompo-

sition of which the vegetation owes its origin!

Before the day closed, I reached the celebrated Grotto delle Capre, but it only afforded us a wretched couch of leaves and straw. It is, however, the only place where the traveller can rest who wishes early in the morning to reach the top of Etna, which is eight miles distant. It is one of those caverns which we frequently meet with in the middle of the lavas of that immense mountain; and a little higher begins the last and sublime region. Here I stopped to pass the night; but, before I endeavoured to compose myself to sleep, I found it very agreeable to warm myself by a fire made with some branches cut from the neighbouring trees; as, at this height, Reaumur's thermometer stood at 8½ degrees above the freezing point (51° of Fahrenheit;) while in the morning of the same day, at Catania, it had been at 23° (72 of Fahrenheit.) Casting my eye around the grotto, I perceived the names of several travellers; some of them names of eminence, with the dates when they had been here, cut on the trunks of several of the oaks; but I must confess that I felt some little indignation on remarking that among all these

there was not one Italian name. I shall conclude this chapter with some remarks relative to an object that has not, to my knowledge, been attended to by any other traveller. We have been told that the grotto is called La Grotta delle Capre (the grotto of the goats) because goats are used to be shut in it, in rainy weather; that it is hollowed in the lava in the shape of a furnace; that it is surrounded with ancient and venerable oaks; that leaves, there, compose the beds of travellers; but no one has yet described the qualities of the lava of which it is formed. Without pretending perfectly to supply this omission, I shall say that the lava here is of a horn-stone base; that it is of an earthy texture; and that, though it abounds with pores and vacuities, it has considerable hardness, it contains some shoerls, and likewise two kinds of feltspars; some of a flat figure, which are extremely brilliant in the fractures; the others of an irregular shape, with little lustre, and which manifest a degree of calcination, though without any indication of fusion. A few other thin small stones are interspersed in them, which from their hardness and green colour I incline to think are chrysolites; as it is known that these noble stones are found in many of the lavas of Etna.

This lava in the furnace is transformed into an enamel full of bubbles; and as it then changes to a blacker colour, the white feltspars become more conspicuous. The magnetic needle is acted upon by it at the distance of a line and a half. The other lavas of the vicinity do not differ from that of the Grotta delle Capre, or rather they are a continuation of the same, even where they are covered by a stratum of earth and a multitude of trees. It is therefore evident, that this grotto has been formed from time immemorial; and that it is not the work of the rain-water, but has been produced by the action of the elastic gases of the lavas when they were fluid, which have generated in them this hollow place, as they have elsewhere many others, of which we may have occasion hereafter to treat.

CHAPTER VIII.

CONTINUATION OF THE JOURNEY TO ETNA.

Upper region of Etna, destitute of vegetables....Its lavas....View of the rising sun from those heights....Lavas which issued from the principal crater of Etna in the months of July and October 1787....Difficulty of crossing those lavas to arrive at the summit of Etna....After burning eleven months and more, some places not yet extinguished....Other difficulties....Arrival at the top of Etna....Clear view of the great crater, circumference of the great crater, with other particulars....Etna a bifurcated mountain....Another smaller crater....Obstacles usually met with in a journey to Mount Etna. Comparison of what the author observed within the crater of Mount Etna, with the observations before made by M. Reidesel, Sir William Hamilton, Brydone, and Borch....Physical causes of the changes in volcanic craters....Ancient accounts of these changes.... Large masses have sometimes fallen from the top of Etna into the crater....No sensible diminution of the height of this mountain in the times of which we have any account....Various phenomena observable in the smoke which at different times has exhaled from the Etnean furnace.... No inconvenience experienced by the author from the thinness of the air on the top of Etna.... The effect of this different on different individuals....Extensive and admirable prospect from the summit of Etna.

THREE hours before day I, with my companions, left the Grotta delle Capre, which had afforded us a welcome asylum, though our bed was not of the softest, at it consisted only of a few oak leaves scattered over the floor of lava. I continued my journey towards the summit of Etna; and the clearness of the sky induced me to hope that it would continue the same during the approaching day, that I might enjoy the extensive and sublime prospect from the top of this lofty mountain, which is usually involved in clouds. I soon left the middle region, and entered the upper one, which is entirely destitute of vegetation, except a few bushes very thinly scattered. The light of several torches which were carried before us enabled me to observe the nature of the ground over which we passed, and to ascertain, from such experiments as I was able to make, that our road lay over lavas either perfectly the same with, or analogous to, those in which the Grotta delle Capre is hollowed.

We had arrived at within about four miles of the borders of the great crater, when the dawn of day began to disperse the darkness of night. Faint gleams of a whitish light were succeeded by the ruddy hues of aurora; and soon after the sun rose above the horizon, turbid at first and dimmed by mists, but his rays insensibly became more clear and resplendent. These gradations of the rising day are no where to be viewed with such precision and delight, as from the lofty height we had reached, which was not far from the most elevated point of Etna. Here likewise I began to perceive the effects of the eruption of Etna which took place in July 1787, and which has been so accurately described by the chevalier Gioeni.* These were visible in a coating of black scoriæ, at first thin, but which became gradually thicker as I approached the summit of the mountain, till it composed a stratum of several palms in thickness. Over these scoriæ I was obliged to proceed, not without considerable difficulty and fatigue, as my leg at every step sank deep into it. The figure of these scoriæ, the smallest of which are about a line or somewhat less in diameter, is very irregular. Externally they have

^{*}His account of this eruption was printed at Catania in 1787. There is likewise a French translation at the end of the Catalogue Raisonne of M. Dolomieu.

the appearance of scorize of iron; and when broken, are found full of small cavities, which are almost all spherical, or nearly of that figure. They are therefore light and friable; two qualities which are almost always inseparable from scorie. This great number of eavities is an evident proof of the quantity and vigorous action of the elastic fluids, which in this eruption, imprisoned in the liquid matter within the crater, dilated it on every side, seeking to extricate themselves; and forced it in scoriaceous particles, to various heights and distances, according to the respective weights of those particles. The most attentive eye cannot discover in them the smallest shoerl; either because these stones have been perfectly fused, and with the lava passed into one homogenous consistence, or because they never existed in it. Some linear feltspars are however found, which by their splendour, semi-transparency, and solidity, shew that they have suffered no injury from the fire. When these scorize are pulverised, they become extremely black; but retain the dryness and scabrous contexture which they had when entire. They abound in iron, and in consequence the dust produced by pulverising them copiously adheres to the point of a magnetized knife; and a small piece of these scorize will put the magnetic needle in motion at the distance of two lines.

In the midst of this immense quantity of scoriæ, I in several places met with some substances of a spherical figure, which, like the lava, were at first small, but increased in size as I approached the summit of the mountain. These were originally particles of lava ejected from the crater in the cruption before mentioned, which assumed a spherical figure when they were congealed by the coldness of the air. On examining them, I found them in their qualities perfectly to resemble the scoriæ, and to possess the same

magnetism.

Only two miles and a half remained of our journey, when the great laboratory of nature, inclosed within the abysses of Etna, began its astonishing operations. Two white columns of smoke arose from its summit; one, which was the smallest, towards the north-east side of the mountain, and the other towards the north-west. A light wind blowing from the east, they both made a curve towards the west, gradually dilating, until they disappeared in the wide expanse of air. Several streams of smoke, which arose lower down towards the west, followed the two columns. These appearances could not but tend to inspire me with new ardour to prosecute my journey, that I might discover and admire the secrets of this stupendous volcano. The sun likewise shining in all his splendour, seemed to promise that this day should crown my wishes. But experience taught me that the two miles and a half I had yet to go presented many more obstacles than I could have imagined, and that nothing but the resolution I had formed to complete my design at every hazard could have enabled me to surmount them.

Having proceeded about an hundred paces further, I met with a torrent of lava, which I was obliged to cross to arrive at the smoking summit. My guides informed me that this lava had issued from the mountain in October 1787; and as the account of the chevalier Gioeni, which I have above cited, only mentions the eruption of the month of July of the same year, I shall here give a brief description of it, as it does not seem hi-

therto to have been described.

This very recent lava extends three miles in length; its breadth is various, in some places being about a quarter of a mile, in others one-third, and in others still more. Its height, or rather depth, is different in different parts; the greatest being, as far as I was able to observe, about eighteen feet, and the least six. Its course is down the west side of the mountain; and, like the other lava which flowed in the July of 1787, it issued immediately from the great crater of Etna. The whole number of the eruptions

of this mountain of which we have any record, before and after the Christian æra, is, thirty-one; and ten only, as we are informed by Giocni, including that of which he has given an account, have issued immediately from the highest crater. That which I observed may be the eleventh, unless it should rather be considered as the same with that described by the Sicilian naturalist, since the interval between August and October is a very short intermission of rest for a volcano. The cause of the rarity of the eruptions which issue immediately from the crater, compared with those which disgorge from the sides, seems easily to be assigned. The centre of this volcano is probably at a great depth, and perhaps on a level with the sea. It is therefore much more easy for the matter liquefied by the fire, put in effervescence by the clastic fluids, and impelled on every side from the centre to the circumference, to force its way through one of the sides of the mountain where it finds least resistance, and there form a current, than to be thrown up, notwithstanding the resistance of gravity, from the bottom of so great a height as the highest crater of Etna. It is evident, therefore, that the effervescence in the eruptions of the months of July and October 1787 was extremely violent. The torrent of the month of October is every where covered with scorize, which resemble those ejected in the month of July in their black colour, but differ from them in the great adhesion they have to the lava, in their exterior vitreous appearance, their greater weight, and their hardness, which is so great that they give sparks with steel almost as plentifully as flints. These differences, however, are to be attributed only to accidental combinations of the same substance; the constituent principles of the scorize of this lava not being different from those of the detached scorize mentioned above. Both likewise contain the same feltspar lamellæ.

This new current was however extremely difficult, and even dangerous, in the passage. In some places the scoriæ projected in prominent angles and points, and in others sunk in hollows, or steep declivities; in some, from their fragility and smoothness, they resemble thin plates of ice, and in others they presented vertical and sharp projections. In addition to these difficulties, my guides informed me I should have to pass three places where the lava was still red-hot, though it was now eleven months since it had ceased to flow. These obstacles, however, could not overcome my resolution to surmount them, and I then experienced, as I have frequently done at other times, how much may be effected, in difficulties and dangers like these, by mere physical courage, by the assistance of which we may proceed along the edge of a precipice in safety; while the adventurer who suffers himself to be surprised by a panic fear will be induced cowardly to desist from the enterprise he might have completed. In several places, it is true, the scoriæ broke under my feet; and in others I slipped, and had nearly fallen into cavities from which I should have been with difficulty extricated. One of the three places pointed out by the guides had likewise, from its extreme heat, proved highly disagreeable; yet at length I surmounted all these obstacles and reached the opposite side, not without making several cursory observations on the places whence those heats originated. Two large clefts, or apertures, in different places appeared in the lava, which there, notwithstanding the clearness of the day, had an obscure redness; and on applying the end of the staff which I used as a support in this difficult journey to one of these, it presently smoked, and immediately after took fire. It was therefore indubitable that this heap of ejected lava still contained within it the active remains of fire, which were more manifest there than in other places, because those matters were there collected in greater quantities.

I had yet to encounter other obstacles. I had to pass that tract which may properly be called the cone of Etna, and which, in a right line, is about a mile or somewhat more

in length. This was extremely steep, and not less rugged, from the accumulated scorize which had been heaped upon it in the last eruption, the pieces of which were neither connected together, nor attached to the ground; so that frequently, when I stepped upon one of them, before I could advance my other foot, it gave way, and forcing other pieces before it down the steep declivity, carried me with it, compelling me to take many steps backwards instead of one forwards. To add to this inconvenience, the larger pieces of scoriæ above that on which I had stepped, being deprived of the support of those contiguous to them, came rolling down upon me, not without danger of violently bruising my feet, or breaking my legs. After several ineffectual attempts to proceed, I found the only method to avoid this inconvenience, and continue my journey, was to step only on those larger pieces of scoriæ which on account of their weight, remained firm; but the length of the way was thus more than doubled, by the circuitous windings it was necessary to make to find such pieces of scoriæ as from their large size were capable of affording a stable support. I employed three hours in passing, or rather dragging myself to the top of the mountain, partly from being unable to proceed in a right line, and partly from the steepness of the declivity, which obliged me to climb with my hands and feet, sweating and breathless, and under the necessity of stopping at intervals to rest, and recover my strength. How much did I then envy the good fortune of those who had visited Etna before the eruption of 1787, when, as my guides assured me, the journey was far less difficult and laborious!

I was not more than a hundred and fifty paces distant from the vertex of the cone, and already beheld close to me, in all their majesty, the two columns of smoke. Anxious to reach the borders of the stupendous gulf, I summoned the little strength I had remaining to make a last effort, when an unioreseen obstacle for a moment cruelly retarded the completion of my ardent wishes. The volcanic craters, which are still burning more or less, are usually surrounded with hot sulphureous acid steams, which issue from their sides, and rise in the air. From these the summit of Etna is not exempt; but the largest of them rose to the west, and I was on the south-east side. Here likewise four or five streams of smoke arose from a part somewhat lower, and through these it was necessary to pass; since on one side was a dreadful precipice, and on the other so steep a declivity, that I and my companion, from weakness and fatigue, were unable to ascend it; and it was with the utmost difficulty that our two guides made their way up it, notwithstanding they were so much accustomed to such laborious expeditions. We continued our journey, therefore, through the midst of the vapours; but though we ran as fast as the ground and our strength would permit, the sulphureous steams with which they were loaded were extremely offensive and prejudicial to respiration, and affected me in particular so much, that for some moments I was deprived of sense; and found by experience how dangerous an undertaking it is to visit volcanic

regions infested by such vapours,

Having passed this place, and recovered by degrees my former presence of mind, in less than an hour I arrived at the utmost summit of Etna, and began to discover the edges of the crater; when our guides, who had preceded me at some distance, turned back, and hastening towards me, exclaimed in a kind of transport, that I never could have arrived at a more proper time to discover and observe the internal part of this stupendous volcano. The reader will easily conceive, without my attempting to describe it, how great a pleasure I felt at finding my labours and fatigue at length crowned with such complete success. This pleasure was exalted to a kind of rapture when I had completely reached the spot, and perceived that I might without danger contemplate this amazing spectacle. I sat down near the edge of the crater, and remained there two

hours, to recover my strength after the fatigues I had undergone in my journey. I viewed with astonishment the configuration of the borders, the internal sides, the form of its immense cavern, its bottom, an aperture which appeared in it, the melted matter which boiled within, and the smoke which ascended from it. The whole of this stupendous scene was distinctly displayed before me; and I shall now proceed to give some description of it, though it will only be possible to present the reader with a very feeble image, as the sight alone can enable him to form ideas at all adequate to objects so grand

and astonishing.

The upper edges of the crater, to judge by the eye, are about a mile and a half in circuit, and form an oval, the longest diameter of which extends from east to west. As they are in several placer broken, and crumbled away in large fragments, they appear as it were indented, and these indentations are a kind of enormous steps, formed of projecting lavas and scorie. The internal sides of the cavern, or crater, are inclined in different angles in different places. To the west their declivity is slight: they are more steep to the north; still more so to the east; and to the south-east, on which side I was, they are almost perpendicular. Notwithstanding this irregularity, however, they form a kind of funnel, large at the top, and narrow at the bottom, as we usually observe in other craters. The sides appear irregularly rugged, and abound with concretions of an orange colour, which at first I took for sulphur, but afterwards found to be the muriate of ammoniac, having been able to gather some pieces of it from the edges of the gulf. The bottom is nearly a horizontal plane, about two-thirds of a mile in circumference. It appears striped with yellow, probably from the above-mentioned salt. In this plane, from the place where I stood, a circular aperture was visible, apparently about five poles in diameter, from which issued the larger column of smoke, which I had seen before I arrived at the summit of Etna. I shall not mention several streams of smoke, which arose like thin clouds from the same bottom, and different places in the sides. The principal column, which at its origin might be about twenty feet in diameter, ascended rapidly in a perpendicular direction while it was within the crater; but when it had risen above the edges, inclined towards the west, from the action of a light wind, and when it had risen higher, dilated into an extended but thin volume. This smoke was white, and being impelled to the side opposite that on which I was, did not prevent my seeing within the aperture; in which I can affirm, I very distinctly perceived a liquid ignited matter, which continually undulated, boiled, and rose and fell, without spreading over the bottom. This certainly was the melted lava which had arisen to that aperture from the bottom of the Etnean gulf.

The favourable circumstance of having this aperture immediately under my view induced me to throw into it some large stones, by rolling them down the steep declivity below me. These stones, which were only large pieces of lava that I had detached from the edges of the crater, bounding down the side, in a few moments fell on the bottom, and those which entered into the aperture, and struck the liquid lava, produced a sound similar to that they would have occasioned had they fallen into a thick tenacious paste. Every stone I thus threw struck against and loosened others in its passage, which fell with it, and in like manner struck and detached others in their way, whence the sounds produced were considerably multiplied. The stones which fell on the bottom-rebounded, even when they were very large, and returned a sound different from that I have before described. The bottom cannot therefore be considered as only a thin crust; since, were it not thick and solid, it must have been broken by stones so

heavy falling from so great a height,

This description will perhaps be better understood by an inspection of Plate II,* which exhibits the summit of Mount Etna surrounded with large pieces and masses of lava. A A A represents one edge of the lava of 17%, which issued from the upper crater. B B the circumference of the crater, with its dift C C, through which the internal part is discernible. D the flat bottom of the crater. E the aperture in the bottom, from which the larger column of smoke F F crose; which aperture, though it was on one side of the bottom, is, for the greater perspicuity, represented in the middle. G G that part of the edge of the crater from which its internal part is most distinctly visible, and where the design of it might most conveniently be taken. H H the smaller column of smoke to the north-east.

To satisfy one emotion of curiosity, is frequently to excite another. I had at first approached this volcano with a kind of superstitions awe. The histories of every age, the relations of travellers, the universal voice of Europe, had all contributed to inspire those who should adventure to visit it with dread: but as at this time it seemed to have laid aside its terrors, and was in a state of perfect calmness and tranquillity, I was encouraged to become more familiar, and to endeavour to pry into more of its secrets. I have already observed that the side of the crater to the west is of a more gentle declivity than the others; and I therefore conceived that this might serve me as a ladder to deseend to the bottom, where I might have added to the observations I had already made, other novel and important facts. But the persons whom I had brought with me as guides would not consent that I should expose myself to such danger. They could not, however, prevent me from making at my ease the observations I have here published, and walking leisurely about the summit of the mountain, notwithstanding the dangerous consequences with which they threatened me; telling me that, should the wind change, the column of smoke must be turned towards us, and might deprive us of life by its pestilential fumes; that besides, we were not certain that the lava at the bottom, which now appeared so calm and still, would long remain in the same state; but that it was possible, from circumstances difficult to foresee, that it might be thrown up on a sudden, and punish our imprudent curiosity by burying us beneath the fiery ruin; in support of which suggestion they produced several instances of sudden and most unexpected eruptions.

We have seen above that there were two columns of smoke arising from Etna. It is to be remarked that, besides that point of Mount Etna on which I stood, there is another to the north, a quarter of a mile higher, and which renders the summits of Etna properly bifurcated. Within the first prominence is sunk the crater I have described; and on the side of the other is the second, from which ascends a lesser column of smoke. 'The second crater is smaller by about the one half than that I have already described'; and the one is separated from the other only by a partition of scoriæ and accumulated lava, which lies in the direction of from east to west. I made my observations on this second crater from a small distance; but it was impossible to advance to it, on account of the numerous and thick streams of smoke by which it was surrounded. ever, was no great disappointment, after having seen and examined the principal crater, which is that whence several currents of lava had issued in 1787. I ought certainly to consider myself as extremely fortunate, in being able to gratify my curiosity with so near and distinct a view of the objects I have described; as the guides assured me that, among all the times when they had conducted strangers to the summit of Etna, this was the only one in which they had a clear and undisturbed view of the internal parts of that immense gulf. After my return to Catania, the chevalier Gioeni likewise declared

Jumil of Chial.

I himmit of Chial.

to me that in all his different excursions to that mountain, he had never had a good fortune similar to mine; and that a month before my arrival he had made a journey to Etna with the chevalier Dangios, furnished with the necessary instruments to ascertain accurately the height of the mountain; but when they had arrived at the foot of the cone, where they had proposed to begin their operations, they were obliged to return back from the obstacles they met with, which, to say the truth, are commonly neither few nor small.

Etna rises to a prodigious height above the level of the sea, and its summit is usually covered with snows and ice, and obscured with clouds, except when the latter are low and range along the sides. The winds likewise frequently blow with such violence that persons can scarcely keep their feet, not to mention the acute cold which benumbs the limbs. But the most formidable impediments to the progress of the adventurers who attempt this perilous journey, are the streams of sulphureous vapour which rise on the sides, and the thick clouds of sulphureous smoke which burst forth from the mouth of the volcano, even when not in a state of agitation. It seems as if nature had placed these noxious fumes as a guard to Etna, and other fiery mountains, to prevent the approach of curiosity, and secure her mysterious and wondrous labours from discovery. I should, however, justly incur the reproach of being ungrateful, were I not to acknowledge the generous partiality she appeared to manifest towards me. At the time I made my visit the sky was clear, the mountain free from snows, the temperature of the atmosphere not incommodious, the thermometer standing at seven degrees above the freezing point (48° of Fahrenheit) and the wind favouring my design, by driving the smoke of the crater from me, which otherwise would alone have been sufficient to have frustrated all my attempts. The streams of smoke I met with in my way were indeed somewhat troublesome, but they might have been much more so; though, had our guides conducted us by another road, as on my return to Catania I found they might have done, we should have escaped this inconvenience.

It here will not be improper to compare these observations on the crater of Etna with those of baron Riedesel, Sir William Hamilton, Mr. Brydone, and count Borch; as such a comparison will shew the great changes which have taken place in this volcano within the space of twenty years; that is, from the time when it was visited by baron Riedesel in 1767, to that of my journey in 1789. At the time when that traveller made his observations, the crater was enlarged towards the east, with an aperture which now no longer exists. He has not given the measure of its circuit, nor has he mentioned the interior aspect of the crater; probably because he had not seen it, having been, as I imagine, prevented by the quantity of smoke which he tells us continually as-

cended from it.

It is worthy of notice, however, that at that time there was not at the bottom of the crater the hard flat surface I have described; since the stones thrown into it did not return the smallest sound. Within the gulf itself was heard a noise similar to that of the waves of the sea when agitated by a tempest, which noise probably proceeded from the lava within the bowels of the mountain, liquefied and in motion. We may hence conceive how easily a volcano may begin to rage on a sudden, though before apparently in a state of complete tranquillity; for if we suppose a superabundant quantity of elastic substances to have been suddenly developed in the liquid lava of Etna, either at the time when baron Rièdesel visited the crater, or when I observed it in a state of slight commotion within the gulf, it must immediately have swelled in every part, beating violently against the sides of the caverns in which it was imprisoned, thundered among the deep cavities, and bursting forth through the sides, have poured out a river of fire; or should

its violence have been there resisted, it would have rushed up within the crater, until it overflowed its brink, and deluged the sides of the mountains with its torrents.

Sir William Hamilton, on the 26th of October, 1769, arrived at the summit of Etna with great difficulty, on account of the snows he met with in his way, the severity of the atmosphere, the sulphureous vapours, and the violence of the wind. He was unable to view distinctly the lower parts of the crater, being prevented by the great quantity of smoke which is and from it; though when this smoke was sometimes driven away by the wind, he concern that the crater was shaped like a funnel, diminishing until it ended in a point, and that this funnel was incrusted over with salt and sulphur. The crater was two miles and a half in circumference.

From the time therefore of the journey of baron Riedesel to that of Sir William Hamilton, the crater must have undergone great changes in its structure; since if the stones that were thrown into it gave no indications to the ear that they struck against any solid body, it is manifest that there must then have been an abyss as well as a funnel; and as the funnel terminated in a point when it was observed by Sir William Hamilton, it is evident that the flat bottom I have described, and which was about two-thirds of a mile in circuit, did not then exist.

The internal sides of the crater, Sir William tells us, were covered with a crust of salt and sulphur; but he does not specify the nature of the former; and though the presence of the latter is not improbable, he might have been led into a mistake by the yellow colour, and have taken the muriate of ammoniac (sal ammoniac) for sulphur, as I did before I examined it. Sir William has not told us that he made any examination at all; and it is probable that he judged only from the appearance it presented to his eye.

He observes, lastly, that the crater was two miles and a half in circumference; an estimate which may be made to agree with mine by neglecting the partition which separates the greater crater from the less, and considering them both as one. The sum of the two circumferences, according to the estimate I have given, would not then greatly differ from the measure of Sir William Hamilton. Nothing likewise can be more probable, than that among the various changes that have happened to Etna, this partition, by which the great crater is divided into two parts, has been produced.

Omitting the observations of Mr. Brydone, that "the tremendous gulf of Etna, so celebrated in all ages, has been looked upon as the terror both of this and another life; that it inspires such awe and horror, that it is not surprising that it has been considered as the place of the damned:" and other similar philosophical reflections which he has employed; and confining ourselves to what he actually saw on the 29th of May, 1770, we learn from him that "the crater was then a circle of about three miles and a half in circumference; that it went shelving down on each side, and formed a regular hollow, like a vast amphitheatre; and that a great mouth opened near the centre."*

From the time of the journey of Sir William Hamilton therefore, to that of the visit of Brydone, that is to say within the short space of a year, various changes had happened to this volcano, by the enlargement of its crater, and a spacious aperture formed in its bottom.

Count Borch appears to have wished to exceed the three other travellers in brevity, relative to this subject; since he only tells us that he arrived at the mountain on the 16th of December 1776, and that the crater of Etna is formed like a funnel. He adds,

^{*} Brydone's Tour through Sicily and Malta, vol. i. p. 195, 196.

however, what is worthy of notice, that the summit of Etna is bifurcated, as I observed it to be; a circumstance not noticed by others, Sir William Hamilton even affirming that the summit of the mountain is single; whence we may conclude that one of these summits has been produced since the time of the journey of Brydone, in 1770.

On comparing the above-cited observations, made within the space of twenty-one years we may perceive how many changes have taken place in Etna during that interval; and as within that time the mountain has suffered only two violent convulsions, in the cruptions of 1781 and 1787, it is evident that even in the state of apparent inaction, it still

internally exerts its force.

To these observations, it may likewise not be without utility to add those of M. D'Orville. He ascended Etna in 1727, and remarked two craters; one larger than the other. The latter he only mentions, but the former he describes at some length. Its circumference was perhaps somewhat more than four miles. From it issued clouds of smoke and reddish flames. These however did not prevent his approaching to the edge of the gulf; though to prevent the danger of falling into it, he and his companions fastened themselves to a rope held by three men. On looking into the crater, they were unable to discern the bottom, on account of the flames and smoke: they only observed that a conical hill formed of lava, rose in the middle of the crater, the top of which they estimated to be sixty feet below them; and they were able to see perhaps about sixty lower; where they conjectured the circuit of this hill might be from six hundred to

eight hundred feet.*

We have here a remarkable circumstance relative to Etna, as it appeared in the time of M. D'Orville, and not observed by any one of the four travellers above cited; I mean the conical hill within the crater. Every observation therefore, tends to confirm the inconstancy of the internal configuration and dimensions of this volcano. It is an extinguished forge, which in proportion to the violeties of the fire, to the nature of the fossil matters on which it acts, and of the elastic fluids which tige and set it in motion, produces, destroys, and re-produces various forms. The usual hind natural figure of the summit of a volcanic mountain is that of an inverted contave cone within, and one solid and erect without; and such a configuration, in completes which are no longer in a state of conflagration, is one of the most certain indication of the existence of an ancient volcano. This cone, however, is hable to very great charges; according to the greater or less fury of the volcano, and the quantity and quality if the matters ejected. Its internal part, from more than one cause, is exposed to continue the property of the continue to the greater of the greater o The prodigious cavities of the mountain make it almost uppear suspended in the air. It may easily therefore give way, and fall in; especially in the virtual inputse of new matters which endeavour to force a passage through the upper part i iii consequence of which the inverted cone may, according to circumstatives present the appearance of an aperture, or whirlpool, or a gulf. Should the liquid lave mass through the aperture, and continue there some time, its superficies by the contact of the cold air losing its heat gradually, would congeal and form a crust fit solid plane; and should the fluid lava beneath, afterwards act forcibly on this crust, it might burst it, or make a passage where it found least resistance; in which case the incited lava would occupy that aperture. Should then the crust, instead of ascending in a single body, be forced up in small fragments, these cooled in the air, would fall down in immense quantities within the crater, and from the effect of the laws of gravity, must accumulate in the figure of a cone. These theoretical conjectures, if they do not perfectly explain, may at least enable us to con-

^{*} Jacobi Philippi D'Orville Sicula.

ceive the nature of the causes which have produced the difference of appearance observed at different times in the crater of Etna.

It is much to be regretted that we have no history of Etna; which, did we possess it, must greatly contribute to elucidate the theory of volcanos, and the causes of the various changes which have taken place at different times, in the summit of this mountain. That such changes have happened, is evident from the few but valuable notices concerning Etna, which we find in ancient authors. Of these I shall briefly state two or three which appear to be of most importance.

I shall first produce the authority of Strabo, though he was not himself an ocular witness, but relied on the information of others, who had visited Etna, and from whom he received the account, "That the summit was a level plain of about twenty stadia in circumference, surrounded by a brow or ridge, of the height of a wall; and that in the middle of the plain arose a smoky hill, the smoke of which ascended in a direct line, to

the height of two hundred feet."*

If we consider this description as accurate, the crater of Etna was at that time surrounded by a brow or ridge, which I should explain as the sides or edges; and in the lower part, was separated by a mount rising in the middle.† The same geographer relates, that two men having ventured to descend upon the plain, were obliged immediately to return, from the violence of the heat.‡

Solinus tells us that there were two craters from which the vapours issued.

Cardinal Bembo likewise found two craters on the summit, the one higher than the other, and about as far distant as a stone might be thrown from a sling. The extreme violence of the wind, and the exhaling fumes, prevented him from approaching the upper crater. The lower he found to be formed like an immense pit, and surrounded with a plain of no great extent, which was so hot that he could not bear his hand on it. From

its mouth, as from a chimney, continually issued a column of smoke.

Of the other crater which he could not observe himself, he received a description at Catania from a monk, who, he assures us, was a man deserving credit, and well acquainted with such subjects. He informed him that this crater was situated on the highest part of the summit of Etna; that it was about three miles in circumference; formed like a funnel; and that it had in the middle a spacious cavity. He asserted that he had made the circuit of it, along a kind of narrow ridge; that from time to time, it threw out stones and burning matters to a considerable height, roaring and shaking the ground; but that in the intervals when it was undisturbed, he had observed it without danger or difficulty.

In the time of Fazello, however, who visited Etna after cardnial Bembo, there were no longer two craters, but only one; the circumference of which, as he informs us, was four miles. It had the usual form of the funnel, emitted fire and thick smoke, but at intervals was calm, and might be approached; at which times a subterraneous noise was heard, and a sound like that of the boiling of an immense caldron on a vast fire.

†This observation agrees with that of D'Orville mentioned above. I find likewise that similar mounts have sometimes been thrown up within the crater of Vesuvius. De Bottis Istoria di varj incendi del Vesuvio.

ap. xi.

These few citations appear to me sufficient to shew what changes have taken place in the summit of Etna, relative to number, the form, and the size of its craters, according to the different effects of its conflagrations at different times. But there is likewise another alteration which should not be passed unnoticed, described by two writers who themselves observed it, Pazelio and Borelii; I mean the falling in and absorption of the extreme summit of Etna within its crater. The former of the above-mentioned authors relates, that in his time there arose in the mouth of the crater, a little hill, isolated on every side, which formed the vertex of the mountain; and which in a terrible cruption fell into, and was buried in the gulf, thus enlarging the crater, and diminishing the height of the mountain. This hill itself had been produced by a former cruption in 1444.†

In like manner Borelli informs us that in the conflagration of 1669, the summit of Etna, which rose like a tower to a great height above the part which is level, was swal-

lowed up in the deep gulf.‡

I have already said, that when I visited Etna, its summit was divided into two points, or little mountains, one of which rose a quarter of a mile above the other. I should not be surprised were I to hear that in some new and fierce eruption, the highest of these had fallen in, and the two craters become one of much larger dimensions. We know that the summit of Vesuvius has sometimes fallen down in the same manner; nor does it appear difficult to assign the cause. It seems to admit of no doubt that the highest parts of Etna, and other mountains which vomit fire from their summits, have their foundations on the sides of the crater, which extend to an immense depth. In any violent earthquake therefore, or impetuous shock of the lava endeavouring to force a passage, it may easily be imagined that those foundations must be torn up and broken

away, and the summit of the volcano fall and be lost in the gulf.

These dilapidations have not however, from time immemorial, produced any sensible diminution of the height of the summit of Etna; since the losses occasioned by some eruptions are repared by others which follow. This may be inferred from a phenomenon usually inseparable from the summit of Etna, though by rare accident, not observable at the time of my journey; I mean the ice and snow with which it is covered. Had any considerable decrease of the height of the mountain taken place, in consequence of the summit repeatedly falling in, in former ages, the ice and snow would not certainly in a climate so mild, have continued to envelope the top of the mountain as they now do, even during the greatest heats of summer. But this continual residence of the snow and ice on Etna has been celebrated by all antiquity; for near observation was not necessary to ascertain this phenomenon, since it is distinctly apparent at the distance of a hundred miles. Adscendit ea regio (says Fazello, speaking of the upper region of Etna) passuum millia sere xii.; quæ per hyemem tota nivibus obsita extremisque frigoribus riget: per æstatem quoque nulla sui parte nec canitic nec gelu caret: quod equidem admiratione dignum est; cun vertex incendia prope sempiterna jugi flammarum eructatione inter nives ipsas pariat, enutriat, ac continuet. "This region extends nearly twelve miles; and even in summer, is almost perpetually covered with snow, and extremely cold; which is the more wonderful as the summit continually produces, nourishes, and pours forth flames amid the ice and snow with which it is enveloped."

* Fazel. Sic.

† Ubi sup.

1 Ubi sup.

VOL. V.

Solinus and Silius Italicus give the same description. The former says—Mirum est quod in illa ferventis nature pervicacia mixtas ignibus (Ætna) nives profert: et licet vastis exundet incendiis, aprica canite perpetuo brumalem detinet faciem.* "Etna, in a wonderful manner, exhibits snows mixed with fires; and retains every appearance of the severest winter amid her vast conflagrations."

Silius Italicus has the following lines:

"Summo cana jugo cohibit (mirabile dictu)
Vicinam flammis glaciem, æternoque rigore
Ardentes horrent scopuli; stat vertice celsi
Collis hyems, calidaque nivem tegit atra favilla."†

"Where burning Etna, towering, threats the skies, 'Mid flames and ice the lofty rocks arise; The fire amid eternal winter glows, And the warm ashes hide the hoary snows."

And since I have quoted a poet, I will cite two others; Claudian and Pindar; as it is sufficiently evident that poetry here must express truth and not fiction.

"Sed quamvis nimio fervens exuberet æstu, Scit nivibus servare fidem: pariterque favillis Durescit glacies, tanti secura vaporis, Arcano defensa gelu, fumoque fideli Lambit contiguas innoxia fiamma pruinas."‡

"Amid the fires accumulates the snow, And frost remains where burning ashes glow; O'er ice eternal sweep th' inactive flames, And winter, spite of fire, the region claims."

Thus the Latin poet; but the Greek has given us a picture of Etna much more highly coloured, representing it not only as the eternal abode of snows, but as the column of heaven to express its astonishing height.

"Kim d'ugmin Nigotor Afra materis Xistog oftia mibra."

The mighty prop of heaven."

It is to be remarked that Pindar lived five hundred years before the Christian ara. I now return from this digression, which though not indeed very short, appears to me perfectly appropriate to the subject; and proceed to resume my narrative. I shall first speak briefly of a phenomenon relative to the smoke which arises from the crater of Etna, and which was seen differently by Mr. Brydone, count Borch, and myself. Mr. Brydone tells us that "from many places of the crater issue volumes of sulphureous smoke, which being much heavier than the circumambient air, instead of rising in it, as smoke generally does, immediately on its getting out of the crater, rolls down the side of the mountain like a torrent, till coming to that part of the atmosphere of the same specific gravity with itself, it shoots off horizontally, and forms a large track in the air according to the direction of the wind."

On the contrary, the smoke when seen by count Borch, at the intervals when the air was calm, arose, perpendicularly, to a great height, and afterwards fell, like white fleeces, on the top of the mountain. I shall not presume to doubt these two facts, though I observed neither of them. The two columns of smoke which I saw, though bent somewhat from the perpendicular by the wind, ascended with the usual promptitude of ordinary smoke (a certain proof that it was considerably lighter than the ambient air) and, when at a great height, became extremely rarefied and dispersed. This difference in the appearance of the smoke as observed by the two authors before mentioned and myself, may arise not only from the gravity of the air on Etna being different at different times, but also from the diversity of the smoke, which may be sometimes lighter and sometimes heavier than the air that surrounds it; differing in its nature according to the quality of the substances from which it is produced. Such a variation in its specific gravity must induce us to conclude that the bodies which burn within the crater are specifically different.

The effects of the air at the summit of Etna, as experienced by myself and some of the travellers I have before cited, were likewise different. Sir William Hamilton tells us, that the thinness of that fluid occasioned a difficulty of respiration; and count Borch appears to have experienced a still greater inconvenience of that kind, since he says—"The rarity of the air on this mountain is extremely sensible, and almost renders that fluid unfit for respiration." On the contrary, baron Riedesel felt no such effect, as far, at least, as we can judge from his own words. "I did not perceive, as several travellers have asserted, that the air here is so thin and rarefied as to prevent, or at least greatly incommode, respiration." Mr. Brydone has said nothing on the subject, and his silence may induce us to conclude that he experienced no difficulty.

I, my servant, and the two guides, suffered no inconvenience from the air. The exertions we had made, indeed, in climbing up the craggy steep declivities which surround the crater, produced a shortness of breathing; but when we had reached the summit, and recovered from our weariness by rest, we felt no kind of inconvenience, either while sitting, or when, incited by curiosity, we went round and examined different parts of the edges of the crater. The same is affirmed by Borelli: Æque bene respiratio in cacumine Ætnæ absolvitur, ac in locis subjectis campestribus. "Respiration is perform-

ed with the same ease on the top of Etna, as in the country below."

Several writers have treated of the difficulty of respiration experienced by those who travel over high mountains, and other inconveniences to which they are exposed; but none, in my opinion, more judiciously than M. Saussure, in his Travels among the Alps. The observations he has made appear to me to explain the cause of these different accounts, relative to the effect of the air on the top of Etna. When the height above the level of the sea was two thousand four hundred and fifty poles, or nearly such, which he found to be that of Mont Blanc, every individual felt more or less inconvenience from the rarefaction of the air, as happened to himself and nineteen persons who accompanied him, when in August 1787, he ascended that mountain. But when the elevation was much less, as for example, nineteen hundred poles, some of these persons felt no difficulty, among whom was this naturalist; though he confesses that he began to experience inconvenience as he ascended higher. We have not indeed any certain observations relative to the exact height of Etna, as is sufficiently proved by the different estimates given by different naturalists. Signor Dangios, however, astronomer at Malta, in the year 1787, measured the height of this mountain by a geometrical method, and the public anxiously expects the results, which will satisfactorily solve this important problem. In the mean time, from comparing the measures hitherto assigned,

the elevation of Etna above the level of the sea is probably somewhat less than nineteen hundred poles. Hence we understand why respiration, in many persons, is not incommoded, while the contrary happens to others, according to the different strength and

habit of body of different individuals.

After having, for two hours, indulged my eyes with a view of the interior of the crater, that is, in the contemplation of a spectacle which in its kind, and in the present age, is without a parallel in the world; I turned them to another scene, which is likewise unequalled for the multiplicity, the beauty and the variety of the objects it presents. In fact, there is, perhaps, no elevated region on the whole globe which offers, at one view, so ample an extent of sea and land as the summit of Etna. The first of the sublime objects which it presents is the immense mass of its own colossal body. When in the country below it, near Catania, we raise our eyes to this sovereign of the mountains, we certainly survey it with admiration, as it rises majestically, and lifts its lofty head above the clouds; and with a kind of geometric glance we estimate its height from the base to the summit: but we only see it in profile. Very different is the appearance it presents, viewed from its towering top, when the whole of its enormous bulk is subjected to the eye. The first part, and that nearest the observer, is the Upper Region, which, from the quantity of snows and ice beneath which it is buried during the greater part of the year, may be called the frigid zone, but which, at that time, was divested of this covering, and only exhibited rough and craggy cliffs, here piled on each other, and there separate, and rising perpendicularly; fearful to view and impossible to ascend. Towards the middle of this zone, an assemblage of fugitive clouds, irradiated by the sun, and all in motion, increased the wild variety of the scene. Lower down, appeared the Middle Region, which, from the mildness of its climate, may merit the name of the temperate zone. Its numerous woods, interrupted in various places, seem, like a torn garment, to discover the nudity of the mountain. Here arise a multitude of other mountains, which in any other situation would appear of a gigantic size, but are but pigmies compared to Etna. These have all originated from fiery eruptions. Lastly the eye contemplates, with admiration, the Lower Region, which, from its violent heat, may claim the appellation of the torrid zone; the most extensive of the three, adorned with elegant villas and castles, verdant hills, and flowery fields, and terminated by the extensive coast, where to the south, stands the beautiful city of Catania, to which the waves of the neighbouring sea serve as a mirror.

But not only do we discover, from this astonishing elevation, the entire massy body of Mount Etna; but the whole of the island of Sicily, with all its noble cities, lofty hills, extensive plains, and meandering rivers. In the indistinct distance we perceive Malta; but have a clear view of the environs of Messina, and the greater part of Calabria; while Lipari, the fuming Vulcano, the blazing Stromboli, and the other Eolian isles, appear immediately under our feet, and seem as if, on stooping down, we might touch

them with the finger.

Another object no less superb and majestic, was the far-stretching surface of the subjacent sea which surrounded me, and led my eye to an immense distance, till it seemed

gradually to mingle with the heavens.

Seated in the midst of this theatre of the wonders of Nature, I felt an indescribable pleasure from the multiplicity and beauty of the objects I surveyed; and a kind of internal satisfaction and exultation of heart. The sun was advancing to the meridian, unobscured by the smallest cloud, and Reaumur's thermometer stood at the tenth degree above the freezing point. I was therefore in that temperature which is most friendly to man; and the refined air I breathed, as if it had been entirely vital, communicated a

vigour and agility to my limbs, and an activity and life to my ideas, which appeared to be of a celestial nature.

Not without regret, I, at length, recollected it was time to return, and relinquish this enchanting scene; since I had determined to pass the ensuing night at San Niccolo dell' Arena, to avoid the hard bed and inconveniences of the Grotto delle Capre. I had resolved, likewise, to return to Catania by another way, in order to examine objects which might render my journey of greater utility. The road I took, the objects which presented themselves, and the observations I made on them, I shall relate in the following chapter.

CHAPTER IX.

RETURN FROM MOUNT ETNA TO CATANIA.

Manner in which the author descended with ease and security from the summit of Etna....Materials of which the Torre del Filosofo is composed....Confirmation that the lava which flowed in October 1787, is still internally penetrated by the fire....The observation that the secondary mountains on the sides of Etna are of volcanic origin, not novel but ancient....Probability that Monte Losso was the result of a partial eruption which had no communication with the crater of Etna....Another eruption from the sides of Etna which had no connection with that crater... Great want of water experienced by the peasants who inhabit Etna, from a long dry season.... Affecting incident arising from this circumstance....A scarcity of springs common in volcanized countries....The Scogli de' Ciclopi, or Rocks of Cyclops...Some of them, but not all, of a prismatic conformation....Zeolites found on these rocks....Vitrification of those zeolites in the furnace....Pumices not found on Mount Etna, as has been affirmed by count Borch, and others.... Animals observed by the author in the Middle and Upper Regions of Etna....Two museums in Catania already known to strangers, and a third lately established, valuable for its contents.... Natural History little cultivated at Catania, with respect to that part which relates to the mineral kingdom; but more relatively to the animal.

THE ascent up the steep and craggy cone of Etna, though not more than a mile in a direct line, cost me, as I have already said, three hours of laborious and fatiguing exertion. It seems scarcely necessary to say that the descent employed me less time, but the difference greatly exceeded my expectation. I found that to effect this descent nothing more was required, but to fix my feet firmly on some large piece of scoriæ and balance my body, since that piece, from almost the smallest impulse I could give it, would slide swiftly down the descent, and convey me to a considerable distance, till stopped by the accumulation of the lesser pieces of scoriæ which it drove before it; when I had only to select another large piece, on which I again glided down as before; only taking care, with the staff I held in my hand, to turn aside the pieces of scoriæ which followed me in my descent, that they might not strike against and wound my legs. In this manner, in a few minutes, I arrived at the bottom of that declivity.

A little below the summit of Etna, are the ruins of a very ancient fabric, called La Torre del Filosofo, the Tower of the Philosopher; it having been pretended, and believed by many, that it was built by Empedocles, that he might fix his habitation in a place convenient for observing the conflagrations of Etna. Others imagine it to have been an ancient temple of some deity; while others have conjectured that it was a watch-tower, built by the Normans to observe the motions of their enemies, and give notice of them, by some signal, to the different bodies of troops scattered over the island.

It is very apparent that these, and other opinions which I omit for the sake of brevity, are very inconclusive with respect to the real use and design of this ruined edifice, which could but little attract the notice of history. I did not visit it in my journey to Etna, having been conducted another way by my guides. Nor should I have regretted not having seen it, had I not reflected, that the great antiquity of the fabric might justly excite a curiosity to examine the materials, and ascertain whether they were lateritious or volcanic. This induced me, after I had returned to Italy, to write to the abbate Francesco Ferrara, at Catania, a person well versed in the science of nature, requesting him to send me, to Pavia, some specimens of the materials of which the Torre del Filosofo was composed. He very politely complied with my request, and I found on examination, that these materials were of the following kind: they consist, first, of a cement of lime, which, by length of time, has become carbonate of lime; in which cement were incorporated great numbers of pieces of black cellular scoriæ of lava; but so changed by the effect of time, that many of them were become externally pulverulent, and internally extremely friable. The shoerls they contained had likewise lost, at the superficies of the scoriæ, their natural lineaments, and all their lustre, and were become so soft that they might every where be cut with the point of a penknife. This cement was, in the second place, united to two kinds of lava, which exhaled an argillaceous odour in their fractures, and had for their base the horn-stone. One of these was very compact, extremely hard, of a ferruginous colour, a fine grain, with numerous feltspar points scattered in it. The other was a gray colour, of rather a fine texture, and contained an incredible quantity of feltspars; so that when viewed with a lens, by the clear light of the sun, it appeared extremely brilliant. The materials, therefore, of this edifice, whatever was its original destination, were, in part taken from the place, with the addition of a cement of lime, to give the building the necessary solidity.*

I afterwards, again crossed the lava which flowed in October 1787, and, as I returned by a different way, I found myself near another part of it, where it still remained extremely hot; which tended to confirm me in my opinion that the internal and central

part of this lava still contains a very active and strong fire.

Having reached the middle region, I ascended some of those mountains which I had observed from the summit of Etna, and which, from their conical figure, and the cavity at their top, clearly shew that they are the productions of fire. \(\tau\) I was, in fact,

*I have read, in the works of some travellers, that fragments of brick and marble are found in the Torre del Filosofo; but the abbate Ferrara has assured me that such fragments no longer exist.

† I had at first believed that the observation that these mountains are truly volcanic was of late date, referring it to Sir William Hamilton, who has described their conical form, and the crater, or incavation at their summit; but I find it to be very old, since it is mentioned by Borelli, and, before him, by Favello. The following are the words of the former: "Extant nedum in summittate Ætaæ, sed etiam in ejus dorso, campestres voragines, quæ habent fere omnes peculiarem monticulam adinstar verrueæ in animalis cute exporrectæ; suntque predicti colles valde acclives, habentque figuram coni acutanguli plano parallelo basi dissecti; et in summitate cujuslibet eorum sinuosa cavitas reperitur, a qua olim flammæ, arenæ, et glaræ exierunt." "Extinct vortices (or craters) are found not only on the summit of Etna, but also on the sides. They have almost all of them their peculiar hills, projecting like a wart on the skin of an animal; which hills are extremely steep, and have the figure of a rectangular cone dissected parallel to its base. At the top of each is a sinuous cavity, from which formerly issued flames, sand, and lava."

We know that by glarea he means lava; in fact, at Catania, it is still called sciara.

Fazello had before observed and described these volcanic hills. His words are: "Plurimos præterea nemorosos et editos offendimus colles, quorum cacumina voragines, licet filvescentes, exhibebant. Eos veterem esse materiam ex visceribus montis olim proditam, prostremi profluvii hiatus, qui similem fere formam, enatasque recens habet arbores, arguebat." "We likewise find several lofty hills, the tops of which, though overgrown with wood, exhibit the appearance of craters. The mouth

convinced that they bear unequivocal marks of the effects of that destructive agent in an accumulation of lavas, scoriæ, and volcanic sand.

Another inquiry relative to these mountains here naturally suggests itself. Is their origin derived from the melted matter contained within the immense abyss of Etna, which, unable to reach the crater, from the extensive height, has burst forth through its sides, and thus formed these mountains? or, as is perhaps more probable, have they been produced by particular conflagrations and eruptions which have no communication with the immense furnace within the crater? I know that the generality of volcanists embrace the former opinion, and reject the latter with contempt; and I find, that, whenever the lesser mountains are produced on the sides of the principal volcano, by the means of eruptions, they usually have recourse to this hypothesis for the explication of the cause. Thus, since the eruptions of lava which have issued from the crater of Vesuvius are much more numerous than those of Etna, they endeavour to account for the difference, by alleging that, in consequence of the small height of the former volcano, the lava can more easily reach the crater; whereas, in the latter it is compelled to force a passage through the side, from being unable to rise to so prodigious an elevation.

I readily admit, that this frequently happens; but instances may certainly be cited which afford strong reasons to believe that the production of the lateral mountain arises from partial eruptions, which have no communication with the principal crater. Of this Monte Rosso is an example. In the morning of the 11th of March 1669, a vast cleft opened not far from the place in which, afterwards, Monte Rosso arose, and extended for the space of ten miles, in the direction of the grand crater of Etna. On the night following, in the place where this mountain now stands, another large cleft opened, from which were immediately ejected immense clouds of snoke, and showers of melted stones, preceded by a tremendous noise and violent concussions of the cartin.

On the night of the 12th a river of lava poured down; and the next day a prodigious quantity of sand and stones was thrown out. Yet during all these subterranean thunders, convulsions of the earth, streams of lava, and showers of stones, the upper crater of Etna ws perfectly undisturbed, and only, from time to time, emitted some light smoke which had before issued, and is usually in its greatest state of tranquillity.* I know not whether I am mistaken in considering this as a probable proof that there is no communication between the highest mouth of Etna, and the new one which has opened in the side some miles distant from it. I have observed likewise, with Borelli, that the

of the last eruption, which is n arly of the same form, and already bears trees, renders it probable that they are composed of the matter anciently ejected from the bowels of the mountain."

The same observation is likewise repeated by D'Orville, who, in 1727, visited Etna. "Colles hi non solum circum magnum creterom (£tnæ) verum ctiam inde per circuitum viginti mille passuum et ultra in toto monte dispersi sunt: Onnes hos colles aliquando igneam materiam e summo vertice ejecisse, omnia suadent; et in multis hujus rei adeo aperta extant vestigia, ut nemo dubitare possit. Quin ipse in culmine collis illius, quem metæ similem diximus, positos in verticibus nonnullorum crateres depressos, et plane undique lapidum exustorum congerie circundatos animadverti." "These hills are not only found adjoining to the great crater but are dispersed in a circuit of twenty miles and more, and, indeed, throughout the whole mountain. Every appearance proves that all these hills have once ejected a fiery matter from their summits; and in many the traces of this are so evident, that it is impossible to entertain a doubt. The remains of craters are apparent, and they are frequently surrounded with accumulations of burnt stones."

Thus we find the description given by the English naturalist of this lesser volcanic mountain, had been preceded by that of a Sicilian, an Italian, and a Dutch writer, all eye-witnesses of what they described.

*Borelli, ubi sup.

highest crater, having remained silent and at rest until the twenty-fifth day, afterwaw; began to rage with the same symptoms of smoke, thunders, earthquakes, and ejected sand and stones; and in fine, by the ruin of its summit, precipitated and buried in its gulf. It seems extremely probable, that this change has been effected by the breaking away of the stony mass which separated the old and new gulfs, in consequence of which the fire and effervescent matters forced their passage, and discharged themselves from another opening at the summit of the mountain.

We must not omit to notice another fact related by the same writer, which, though it does not respect the formation of any mountain on the sides of Etna, independent of a communication with its highest crater, may authorise us to conclude, that some lateral gulf may open and disgorge fiery torrents without any such communication. Such an eruption happened in 1636, when the ground nine miles from the summit of Etna, opened in two places, and poured out two torrents of lava without any appearance of fire or smoke at the summit of the mountain. It is very probable that we should have accounts of other similar eruptions, and other mountains formed on the sides of Etna, had the ancients studied and recorded the conflagrations of that mountain, in the manner the moderns have begun to observe and describe them.

Whatever may be the matters which cause and continue volcanos, it is only necessary that they should exist and take fire in a place that has no communication with the central volcano, to produce partial eruptions and mountains, which may very naturally be supposed to happen.

After having slept at San Niccolo dell Arena the night preceding the 5th of September, I set out early the next morning, taking my way by the Rocks of the Cyclops, celebrated for the basaltiform lavas of which they consist. In this part of my journey I continually passed over lavas, and through several villages built upon them.

A short time before I reached the rocks I was in search of, a scene presented itself, which, though foreign to my subject, the sentiment of humanity and compassion we feel on witnessing the misfortunes of our fellow-creatures will not permit me to pass in silence.

Mount Etna has at all times been very deficient in springs; but when I was there the scarcity of water was extreme, not a drop of rain having fallen for nine months; and the rain-water which the peasants of these places had collected in cisterns being exhausted, they were obliged to go in search of it to those parts of the mountain where a scanty spring might still be found. Though in my journey up Etna I had sufficient reason to notice this scarcity of water, by being made to pay for it much dearer than for wine at Catania, I was much more convinced of it when, on my way, I saw a number of women and girls carrying barrels as beasts of burden, to fill with water at a spring on one side of the road. But the scene which made the greatest impression on me, I met with on my return, in the vicinity of Jaci; where I saw more than one hundred poor mountaineers of both sexes, who had come thither to quench their thirst at a stream of water which issued from the midst of the lava. It strongly excited my pity to see these wretched peasants, all bare-footed, exposed to a burning sun, for the heat was then very great in those low parts of the mountain; and labouring and sweating under the load of large earthen vessels, which they had brought on their shoulders and heads, a distance of more than ten miles, to carry home water. When they came within sight of the spring, they exerted all the strength they retained, hastened their weary steps, and, when they reached it, began to drink with extreme eagerness, without for a long time taking away their lips. How much was my commiseration increased, when they informed me they were obliged to perform this laborious journey every day, that is, to

erwaw; ejected d in its reaking which es from

though bendent it some ication amit of appearshould ides of , in the

Etna: from the Case.

Corner, from the Casis.

employ the whole day in it; travelling from the time of sun-rise till noon to reach the spring, and from noon to the dusk of the evening to regain their habitations, and carry refreshment to their parched families! While I was listening to their sad story, in chanced that one of them, a boy about thirteen years of age, in setting down the vessel he carried on his shoulder, let it slip, I know not how, out of his hand, and it broke by the fall. Words can scarcely describe the consternation, grief, and anguish, with which he appeared transfixed at the accident, while with bitter tears and in broken exclamations he lamented his misfortune, and expressed his fears of the consequences he apprehended to himself, from his being thus disabled from carrying home to his thirsty parents the expected supply. As little is it possible to describe the joy, delight, and lively sentiment of gratitude which he expressed, on my giving him a small piece of money that he might buy, in a neighbouring village, another vessel to replace that which was broken, and complete with the useal success his laborious journey.

Etna is not alone scantily supplied with springs. I have observed a similar scarcity of them in the Eolian or Lipari islands, as we shall see in another part of this work; and if I am not mistaken, the same want of them will be found in other volcanic countries; the cause of which appears to me evident. The rains which descend on mountains of this kind, either fall on bibacious tufas or scoriaceous matters, in which they sink deep without again appearing on the surface in the lower places, because they meet with no argillaceous or stony strata to detain them; whereas such strata are frequent in mountains not volcanic, and produce numerous dropping springs, fountains, and sources

of rivers, as we find in the Alps and Apennines.

When again the rains fall on the solid and compact lavas, they do not sink into them, but run down their declivities, forming indeed rivers and torrents, in the rainy season, but never true springs. In several parts of Etna, and especially near the Grotta delle Capre, I have seen large furrows hollowed in the lavas, by the continued action of the rain-water.

Two hours after noon I arrived at the Rocks of the Cyclops; which are likewise termed islands, because surrounded by the sea, though they are scarcely a stone's throw from the shore on which the village of Trezza stands. It is possible that they might once make a part of the sides of Etna, and have been separated from them by the sea; or they may have been thrown up out of the water by partial cruptions. I examined them, first making the circuit of them in a boat, and then ascending them to observe their parts.

It is immediately apparent that some of these rocks consist externally only of prismatic columns, which fall perpendicularly into the sea, in some places of the length of one foot, in others two, and in others more; but it is certain that other parts of these rocks have not the least prismatic appearance, and are only full of very irregular fissures, which have divided them into irregular pieces, as we frequently see in common lavas.

The Rocks of the Cyclops present another object which has not escaped the acute examination of M. Dolomieu; I mean the numerous and various zeolites of great beauty which are found on their surface, and even in the middle of their substance, where there are small pores and cavities. That naturalist thinks, with great reason, that these noble stones, after the congelation of the lavas derived their origin from the waters which filtrated through them, and held in solution the particles proper for the production of zeolites. It would be a useless labour were I to attempt their description after it has been so well given by M. Dolomieu; I shall, therefore, only mention what I observed in them when I examined them in the furnace.

If we take small pieces of lave, detached from the rocks to which the zeolites adhere, leave them for some time in the fire, and observe them after they have cooled, the fol-

lowing are the results:

The zeolites, though the lava, their matrix, has not undergone a complete fusion, are vitrified, and have flowed over the surface of the lava, forming a leaf of glass; but the greater part become globules, which, from their lucid milky whiteness, resemble pearls. When examined with the lens, these globules are found to be full of cracks, probably caused by the sudden removal of the lavas from the furnace into the cold air. This glass is semi-transparent and hard. If we break the pieces of lava exposed to the fire and examine the fractures, we shall find that only a semi-vitrification has taken place in the zeolites they contain. Some of these zeolitic lavas, are of a homogeneous substance, but others include small shoerls. The magnet attracts the powder of them, and some have polarity, attracting one end of the magnetic needle, and repelling the other.

I have but a few observations more to make, relative to Etna. Count Borch, not perfectly satisfied with the received division of the mountain into three regions, the lower, the middle, and the higher, has added a fourth, which he calls the region of snow; and each of the four regions he again subdivides into several districts. I shall not dispute with him these minute districtions, which, whether they tend more to clearness or confusion may be difficult to determine. I shall only make some brief remarks on his district of scoriæ, in the second region, of which he says: "The district of scoriæ contains a surface of two miles entirely covered with pumices, ashes, and scoriæ."

Without noticing the scoriæ and ashes, I know not what he understood by pumices. The truth is, that Etna affords none, as Dolomicu, who so minutely examined the mountain, has expressly asserted; and, as I took nearly the same road with Borch, I must have met with them had they been so plentiful as he describes. The chevalier Gioeni, likewise, in his account of the products of the cruption of 1787, describing one which, in its configuration resembles the porous pumices of Lapari, remarks that this is the first time that Etna has ejected such a kind of stone.*

In my journey to Etna, and on my return, at the same time that I examined volcanic objects I did not neglect to observe whether the two more elevated regions of the mountain were inhabited by animals. A little beyond Monte Rosso, I bought five patridges (Tetrao rufus Lin.) of a sportsman, who had shot them at the upper extremity of the middle region. These I had roasted at San Niccolo dell' Arena, and they furnished me with two good meals. In crossing the same region I met with several birds of the titmouse species (Parus major; Parus cœruleus Lin.) a kite (Falco milvus) three jays (Corvus glandularius) two thrushes (Turdus viscivorus) and several ravens and crows (Corvus corax; Corvus corone:) half way up the higher region I saw no other animals, except some lion-ants (Myrmeleon formicarum Linn.) which made their pit-falls in the dust of the lavas. There were several of them in a dusty corner of the Grotta delle Capre. As they live by ensnaring other small animals, and especially ants in the slip-

Borch is not the only person who has fallen into this error. Sir William Hamilton, when he visited Etna, found there no punices; but he was told by the Canon Recupero of Catania that the mountain produced them: the Canon, however, it is well known, was unacquainted with the first principles of lithology. Baron Riedesel, who in this part of science, was perhaps not superior to the Canon, says that pumice is among the number of stones ejected by Etna; and joins with it the sand-stone; a production which, according to those best acquainted with the mineralogy of volcanos, is as much a stranger to Etna as the pumice. One of these writers may, probably, have induced M. Sage to assert that "Etna throws out a great quantity of pumices." This gross error was probably occasioned by the resemblance which to persons little acquainted with such substances, scoriz and cellular lavas appear to have to pumices.

n, when he nia that the e first printo the Cat the sand-canos, is as ed M. Sage hably occae and cellu-

pery pits they form; it may be necessary to observe, that these are not wanting there, though I did not see them.

The city of Catania, during my stay there, amply afforded me the means of amuse ment and instruction. The two muscums, the one belonging to the prince di Biscari, and the other to the Benedictine Fathers, besides the various objects they contain relative to the arts and antiquities, are also furnished with a collection of natural productions, and will be found to correspond to the great expectations that may have been formed of them from the advantageous descriptions of Riedesel, Brydone, and Borch. That of the prince is distinguished by some rare specimens which might adorn the richest and most extensive collections. But in that city a third museum, hitherto little known, because it is new, is beginning to flourish. It may be said it is yet in its infancy; but the infant may become a giant. The possessor and founder of it is the chevalier Gioeni. His first intention was to collect the most curious and interesting productions of the Sicilian sea; and he has succeeded admirably. We here find dry preparations of the fishes most remarkable for their form or the rarity of their species. Among the numerous families of zoophyta, the aleyonia, the antipathes, the cellulariæ, the escharæ, the pennatulæ, the sertulariæ, the milleporæ, and the isides (coral) are not wanting; but the madrepore and the gorgone are the most conspicuous for their beauty and rarity. It is equally well furnished with specimens of the principal crustaceous animals of that sea, but the numerous and chosen collection of those of the testaceous kind is the principal ornament of the museum. With respect to these, we find a practice adopted we meet with in no other cabinet. As there are some extremely minute shells, in size not exceeding a grain of sand, which it is impossible to view distinctly with the naked eye, they are as it were lost in the greater part of other museums; but here they are placed, methodically distributed, at the bottom of small tubes, at the other end of which is a lens; by the aid of which the eye is enabled to discover the beauty of the colours, the peculiarity of the involutions, the infinite variety of the forms, the windings of the apertures, the eavities, prominences, points, threads, &c. In fine, these points of organized matter, by this means, equally with the larger crustaceous animals, afford pleasure to the eyes of the curious, and useful instruction to the learned, for characterising

The chevalier Gioeni, in consequence of his researches relative to these aquatic animals, has distinguished himself by the discovery of a new genus of multivalve conchylia, which he has already made known; but he will do himself much more honour by

the publication of a work on the subject on which he is now employed.

He has not confined himself to marine productions, but has extended his diligence to terrestrial; and the neighbouring volcano has added to his collection. We here find specimens of all the Ethean products; and amid the multitude of various lavas he has collected, he has discovered a new species, which he has denominated fibrous. The method he has adopted of placing the different lavas with the stones and primitive rocks, from which they derive their origin, is highly instructive.

Equally conducive to the advancement of knowledge is the numerous series of testaceous fossils, which he has collected with great labour to the north-east of Etna, in a situation more than three hundred poles above the level of the sea. These extremely resemble the natural which are now found in the neighbouring waters. But as the time when the sea reached to that height is certainly anterior to the annals of history, of what great antiquity must the volcano be which existed before that epocha!

The productions of this part of Sicily are accompanied with those of the rest of the island. We find a noble collection of marbles and jaspers, with various minerals, and

crystallized sulphurs.

Though this museum deserves great commendation for the multiplicity and choice of the objects collected within a few years, it perhaps deserves still greater praise for the accurate and judicious manner in which every part of it is systematised; a regulation extremely necessary in every collection, and which it is to be wished might be introduced into the two other museums before mentioned.

I have been somewhat more diffuse in my description of this collection, because it merited to be known to foreigners who, should they chance to visit Catania, may by its means procure information of various productions of Sicily and the neighbouring sea,

which they might elsewhere seek in vain.

The chevalier Gioeni is professor of natural history in the university of his country, which can likewise boast of other men of genius, principally in polite literature. The natural sciences, especially those which have relation to the fossil kingdom, are not the most cultivated; less I believe from indisposition towards them, than from want of encouragement. It is not the same with respect to the other two kingdoms. While I was at Catania, I had the honour to receive visits from several persons of learning; and I found that more than one of them had read with advantage the works of Bonnet, Buffon, and Duhamel. Among them may be distinguished the Abbate Don Francesco Ferrara, who afforded me the opportunity of examining the materials of the Torre del Filosofo. The taste for these extensive branches of natural history must become greater, and spread more extensively, from the laudable example set by Signior Ferrara, who has lately published in Sicily, The Contemplation of Nature of the philosopher of Geneva (Bonnet:) to which he has added, besides my notes and those of others, a great number of his own, replete with learning and good sense, which must render such a work still more valuable.

THE LIPARI ISLANDS.

INTRODUCTION.

The volcanization of these islands known to the ancients, and studied by several of the moderns.... A wide field for observation, nevertheless, left for others.... Felicuda and Alicuda, two of these islands, first examined by the author.

THE Lipari islands are situated in the Mediterranean, between Sicily and Italy, and are called the Eolian isles, from Æolus their reputed king, but more generally the Lipari islands, from the name of the principal and largest. Though they were anciently known to be volcanic, and therefore are called vulcanian, it is only in modern times that their volcanization has been considered as an interesting object of the researches of the philosopher, who labours to promote the knowledge of nature. M. de Luc, Sir William Hamilton, and the Commendator Dolomicu, in this respect, particularly deserve notice.

The former of these naturalists, in the year 1757, visited Volcano, one of these islands, and made a number of observations; especially with respect to the principal circumstances relative to its extensive crater.

The same island, as well as that of Stromboli, exercised the curiosity of Sir William Hamilton; though he only saw it at a distance, as he was returning from Messina to Naples, in the year 1768. The accounts of these two writers will be related and examined in their respective places.

But much more complete and interesting, relative to volcanic inquiries, is the information we received from the Commendator Dolomieu, in his work entitled "A Voyage to the Lipari islands."* The field, however, in which he laboured is so extensive and productive, that there is still room for new and abundant harvests. These islands are ten in number, and he remained there only eight days, circumstances perhaps not permitting him a longer stay. Some of them, it is true, are very small; yet others would require many weeks to examine them minutely. Among the latter is the island of Lipari, which is nineteen and a half Italian miles in circuit.

These considerations, therefore, far from causing me to abandon my design of visiting and examining these countries, rather increased my desire to carry my plan into execution; and the work of M. Dolomieu itself gave the last impulse to my determination. With a candour worthy of himself, he thus concludes his observations: "In the description I have given of the Eolian isles, I do not pretend that I have been able to point out every thing interesting which they contain, or entirely exhausted the subject; I rather hope that I shall excite other travellers, who have more time at their disposal, to examine them with attention; in which case, I can assure them, they will be rewarded with a much more abundant harvest than that I have reaped."

I shall conclude with adding that two of these islands, Felicuda and Alicuda, were not visited by this naturalist; and it was no small gratification to me to recollect that I was the first who had examined them. Wherever I have been preceded by M. Dolomieu, I shall not fail to notice it to the reader; and, while I relate my own observations, shall be careful to do justice to his discoveries.

^{*} Viaggio alle Isole di Lipari.

CHAPTER X.

STROMBOLI.

The fires of this volcano visible by night at the distance of a hundred miles....Their apparent intermissions....Intermissions in the smoke seen by day....Shoals of dolphins met with near this island....Appearances observed in the smoke of the volcano, when seen at a small distance.... Explosions of the volcano.... The alterations in the volcano symptoms of the changes of the atmosphere, according to the opinion of the people of Stromboli....Signs of good and bad weather deduced from these alterations.... Observations on these prognostics, made by the author during a stay of five-and-thirty days....Phenomena of the volcano observed at the distance of two miles from the crater....Quality of the ashes ejected at that time....Quality and origin of the sand which occupies a considerable part of the island....Internal constructure of the island....Conjectures that the crater of this volcano was anciently at the summit of Stromboli.... The island formed of a single, but bifurcated mountain....Incontrovertible testimonies that for more than a century the crater of this volcano has been situated towards the middle of the mountain.... Error of Sir William Hamilton in placing this crater at the summit.... The opinion, generally admitted, of the intermissions of the conflagration of Stromboli, probably not well founded The eruptions at that time much weaker than they frequently are.... The declivity of the mountain to the west the only place where the ejected matter falls into the sea.... Absurd reason assigned by the inhabitants of the Eolian isles why that part of the sea into which the ejected matter falls is never filled with volcanic substances.... Explanation of the author.... Description of the road up the mountain towards the crater....Height of Stromboli....Hot acid-sulphureous fumes near the summit, which have an internal communication with the volcano....Remains of an ancient crater at the summit of Stromboli.... Appearance of the ejections seen from above.... Their perpendicular height....Conclusive proofs that the volcano of Stromboli is not intermittent, as some travellers have asserted....the cavity of the crater of this volcano probably not very deep....Streams of smoke which issue from three several parts of the volcano.... The author succeeds in an attempt to approach nearer to the crater....Phenomena which he observed in consequence of this nearer approach.... Form and structure of the crater Liquid lava within it Qualities of that lava...The eruptions of Stromboli little, or not at all, intermittent....Observations made by night within the crater itself.... An unexpected and terrible phenomenon.... Its explanation.

THE island of Stromboli is distant from Sicily fifty miles, and is the first of the Eolian isles to the north-east. It was called \$\frac{\text{\$\tex{

I sailed from Naples for Sicily on the 24th of August 1788; and the next night, having proceeded to a considerable distance beyond the straits of Capri, I began to discover the fires of Stromboli, though at the distance of at least a hundred miles. I observed a sudden blaze, which feebly struck my eyes, and after two or three seconds disappeared. After ten or twelve minutes the flame again became visible, and again disappeared. I observed this phenomenon for several hours, and it only differed in its

longer or shorter duration, and the intervals between its appearances. The mariners with whom I sailed testified considerable joy at the sight of this fire, as they assured me that, were it not for the light it afforded in dark and stormy nights, they should frequently be in danger of being shipwreeked at sea, or running on shore on the neighbouring coast of Calabria.

When they arrived, and we had approached much nearer the volcanic island, the light of the sun prevented the flame from being visible; but a smoke appeared, which had nearly the same alternations with the fire before observed. As I was now, however, on my way to Messina, with intention to ascend and examine Mount Etna, I soon lost sight of the volcano, which I proposed afterwards to visit, on my return from Sicily, when I

should take up my residence for a short time in Lipari.

This design I carried into execution on the 1st of October, taking the advantage of a felucea which was returning to Stromboli. We sailed early in the morning, a strong south-west wind blowing, and some clouds floating in the atmosphere which appeared to threaten a tempest. The sea was rough; but the wind being in our favour, the master of the felucea, who was at the same time our pilot, encouraged us against the fear of any accident, only telling us, in a jocular manner, that we should have a little dancing. All the sails were set, and we flew rather than sailed over the surface of the sea. Though the wind continually increased, and the sea ran higher, so that we were sometimes hanging on the pinnacle of a wave, and again plunged to the bottom of a yawning gulf, we had nothing to fear, as the gale was exactly in our stern; and in less than three hours we arrived at Stromboli, which is thirty Italian miles from Lipari, and anchored on the north-east side of the island, where the body of the mountain breaking the force of the wind rendered the sea somewhat more calm.

During a great part of this voyage we were accompanied by a number of fish, which appeared to attend us as an escort. These were dolphins, which surrounded the ship, playing their gambols, and springing sometimes from the stern to the prow, and back again; then suddenly plunging under the waves, and as suddenly re-appearing, holding up their snouts, and throwing up the water to the height of several feet from the spiracles which they have in the head. On this occasion I observed what I had never noticed before in any of the smaller fish of the cetaceous kind in other seas, I mean the incredible swiftness with which they swim and turn in the water. They would frequently dark from the stern to the stem of the ship, and, though they had to encounter the resistance

of the agitated waves, fly with the rapidity of an arrow.

But I return to observations of another kind, and such as are relative to the principal

object of this work.

As we advanced towards Stromboli, which was continually before me, I observed that its summit was covered with a very thick smoke, which extended to the brow of the mountain. I landed at nine in the morning, and eager to gain information relative to the volcano, without delay began to ascend the mountain, till I arrived at the extreme edge of the smoke, which I wished to examine with attention. This smoke, to all appearance perfectly resembled the clouds. In the lower part it was black and dark, and white and shining in the upper; from the former being penetrated with but little of the solar light, and the latter with a greater quantity. It was so thick that the sun could not be seen through it. The upper part of it separated into a number of globes, and various irregular and unusual forms, which, according to the motion of the air, ascended, descended, or took a circular course, becoming whiter and more irradiated by the sun the higher they arose; all which appearances are observable in the clouds, especially in the time of summer. This smoke, when it had reached a great height, became so thin

as to be longer discensible by the eye. The sulphureous acid it contained was extremely manifest, and so inconvenient to respiration, that I was obliged to return to the plain, not being able at that time to attempt a nearer approach to the volcano, from

which dull and hollow explosions were almost continually heard.

The remainder of the day I employed in interrogating the people of the island relative to their volcano, it appearing to me that no persons could give me more information than those who continually had the mountain before their eyes. The following were the accounts I received from them. When the north or north-west winds blow, the smoke is little in quantity and white, and the explosions of the volcano very moderate; whereas the latter are louder and more frequent, and the former much more extensive and black, or at least dark, when the south-west, south-east, or south winds prevail; and should any one of these three winds blow with violence, the smoke will sometimes spread itself over the whole island, and darken it like heavy clouds in rainy weather. Should this cloud of smoke thus extend itself when the vines of Stromboli are in leaf, if it remains only a few hours, it will not injure them; but should it continue a whole day, or longer, the grapes will not ripen, or at least the vintage will be less productive. The smoke constantly has the odour of burning sulphur, and consequently is very disagreeable and noxious.

This thick and copious smoke, which is commonly accompanied with more violent and frequent eruptions, not only is emitted while the south, south-cast, and south-west winds blow, but precedes these winds several days. The people of the country are therefore enabled to foretel the winds which will be propitious or adverse to mariners. They told me that not unfrequently vessels which had anchored at Stromboli during the winter, and proposed to sail because the sea appeared calm and the weather favourable, had been induced to remain longer by the observance of these prognostics, which they had not found deceitful. The knowledge of these indications is not, however, the fruit of the modern observations of these islanders: it is extremely ancient,* and has been transmitted from the most remote ages to the present, from generation to generation, and will probably be delivered down in like manner to the latest posterity. Æolus, who is said to have reigned in these islands, is styled in fable the king of the Winds, probably, as some writers have conjectured, because, from the changes in the smoke

and eruptions of the volcano, he was able to predict what winds would blow.

I shall here (if I may be allowed a short digression not unsuitable to my subject) relate the observations which I made relative to the connection between the phenomena of the

the observations which I made relative to the connection between the phenomena of the atmosphere and those of the volcano, during the five-and-thirty days which I remained in the Eolian isles; the smoke of Stromboli by day, and the flames by night, being

clearly visible in those islands and the adjacent sea.

Twice within that time on the 13th of September and the 1st of October, the Libeccio, or south-west wind, blew strong. The first time no sensible change was observable in the volcano of Stromboli, though according to the assertion of the people of the island, the smoke should have collected thicker round the mountain, and the explosions have become louder. The second time, the appearances approached nearer to those they describe.

The Scilocco, or south-east wind, blew three times; on the 21st and 26th of September, and the 7th of October. This wind, if we believe the mariners of Stromboli, has a similar effect on their volcano with the south-west; and in fact, on two of the above-

^{*} Those who wish to know the productions of the ancients, relative to the changes in the air and the sea, deduced from the smoke and fires of Stromboli, may consult the Sicilia Antiqua of Philip Cluverius.

mentioned days, while this wind blew, the eruptions were stronger, and the cloud of smoke more extensive; but the third time these effects were not observable.

On the contrary, the north wind, which blew on the 11th and 12th of October, and which, according to these islanders, leaves the volcano at rest, was preceded and accompanied by explosions which were heard in the other islands, and by a large cloud of smoke which covered the half of Stromboli, and rose with a white edge, like that we sometimes observe in tempestuous clouds.

I must add, that sometimes, though not a breath of wind blew, the cruptions were

very copious, and the smoke was extremely thick.

These observations render me not much inclined to receive implicitly all that the people of Stromboli so positively assert relative to their volcano; and the less, since the mariners of the other Eolian isles are of a different opinion. When I was at Felicuda, where the cruptions of Stromboli may be very clearly seen by night, those cruptions were very strong, and almost continual, and every one was followed by an explosion, which might be very distinctly heard in that island. I turned to one of the mariners of Felicuda, who stood near me, and asked him what he thought of the prognostics of that volcano. He returned me the following brief sententious answer: Stromboli non fa marinaro. Stromboli will not make a scannar. To determine, however, with certainty, whether there are any direct and immediate relations between the changes of the atmosphere and those of Stromboli, and what those relations are, would require a series of observations for several years, made on the spot by some intelligent and unprejudiced naturalist, and these we certainly have not.

I shall now proceed to relate what I observed relative to the volcano on the night of the 1st of October. My residence was in a cottage on the north side of the island, about half a mile from the sea, and two miles from the volcano; but so situated that the cloud of smoke round the mountain searcely permitted me to see the top of the fiery ejections. I employed more hours of the night in making my observations, than I permitted my-self for repose; and the following is a brief summary of the principal appearances I

noticed.

The south-east wind blew strong. The sky, which was clear, the moon not shining, exhibited the appearance of a beautiful aurora borealis over that part of the mountain where the volcano is situated, and which from time to time became more red and brilliant, when the ignited stones were thrown to a greater height from the top of the mountain. The fiery showers were then more copious, and the explosions which followed them louder, the strongest resembling those of a large mine which does not succeed properly, from some eleft or vent. Every explosion, however, slightly shook the house in which I was, and the degree of the shock was proportionate to the loudness of the sound. I do not believe that these shocks were of the nature of the earthquake; they were certainly to be ascribed to the sudden action of the fiery ejections on the air, which struck the small house in which I was, in the same manner as the discharge of a cannon will shake the windows of the neighbouring houses, and sometimes the houses themselves. A proof of this is, that the fiery showers always were seen a few seconds before the shock was felt; whereas the house was so near the volcano, that had it been a real carthquake, no interval of time would have been perceptible.

Before the morning rose the fiery light over the volcano increased so much, at three different times, that it illuminated the whole island, and a part of the sea. This light was each time but of short duration, and the showers of ignited stones were, while it

lasted, more copious than before.

VOL. V.

On the morning of the second of the same month the south-east wind blew stronger than ever, and the sea was greatly agitated. The smoke of Stromboli formed a kind of cap round the top of the mountain, which descended much lover than on the preceding day. The phenomena were the same; but the convulsions of the volcano were more violent. The explosions were very frequent, but always with a hollow sound; and the ejected ashes reached the scattered dwellings of the people of the island. In the morning the ground appeared very plentifully sprinkled with these ushes, as they are called by the natives; but on examination I found that they were not properly ashes, but very finely triumsted scorize, consisting of very small grains, of no determined form, dry, and rough to the touch, and which crumble into produce under the finger. They are not very far flown a vitocous nature, in colour between a gray and a red, semi-transparent, and so light, that some will float on the water. Their levity proceeds from the great quantity of vesicles or power which they contain, and which causes them, when viewed with the leak, to bear some resemblance to the sea production of unknown origin called favage (favageire)

The islanders assured me that these comptions were very inconsiderable, compared with others which had formerly taken place, during which the ashes had, in a few hours, formed a covering over the ground and the houses of several inches thick; and the stones abrown out were scattered over the whole island, to the great damage of the vineyards and woods which were near the volcano, to which the flames communicated.*

As the day advanced, the hope I had entertained that I should be able immediately to visit the volcanic fives of Stromboli greatly diminished; since I must have had to pass a large tract of the mountain entirely covered with smoke, which had extended itself so widely through the air, that it darkened the whole island. I deterred, therefore, my intended journey till the next day, should that prove more favourable, and employed myself in examining the principal productions of the place.

Wherever I placed my first I found the whole share, to the east and north-east, composed of a black volcanic sand. This sand is an aggregate of fragments of shoerls, as has been remarked by M. Dolomicu; but when we view it with the lens, we discover, besides the shoerls, which are entirely opaque, and are attracted by the magnet, a number of small transparent and vincous bodies, of a yellowish green tineture, and which are insensible to the magnet. I was doubtful whether these were likewise fragments of shoetls, but of a different species, or whether they were volcanic chrysolites; their expresses minutely as a permitting me to ascertain their nature by any satisfactory expensions.

This sand extends into die sea, to the distance of more than a mile from the shore; as appeared from its adhering to the sunken plummet, when it had been previously covered with talken a probabily it reaches to a still greater distance.

The sea cash penetrates through this sand; for if any part of the shore be dug into allithe depth sea water is found, but rendered somewhat more fresh by having left a part of its salts in the sand; as happens to the same water when it issues, drop by drop, through a long turbe filled with sand, through which it is filtred. The fishermen of Strombolli, when they are in want of fresh water, frequently dig wells on the shore, and drink the water these afford.

These showers of sand and puliverused seems seem to be inseparable from volcanic eruptions, and to be common in perspection as the latter are violent. Of this we have an example in the eruption of Etma in 1777, when the sand was covered as far as Malta. How great a space was covered by the sand-quarted from Etma in the comprises of 1869, has been already noticed. There is likewise no eruption of Westivians which is an accompanied by similar showers of sand and ashes.

This sand, as has been already said, occupies that part of the island which fronte the east, and the north east, extending on the one side to the sea, into which it stretches, and on the other to the summit of the mountain. It owes deorigin partly to the immediate ejections of it by the volcano, and partly to the pieces of score evens by thrown out by the same, which being, as has been said, extremely feedle, and preatly abounding in shortly, easily decompose and become pulverised in this sandy matter. In fact, nothing is intere trainly than to find in it fragments of this scoriaceous lava, of various sizes. This said is found principally near the volcano, where both it add the event cous lavas from which it is found fall in the greatest quantities. But as, from its finences, it is easily movemble, it is carried by the wind to the value and lower grounds quite to the sea.

This, however, is only the thin upper conting of those parts of Strambeli which it envers, is under it lies the firm texture of the island. I mean the solid laws, which are visible in several steep descents, that have been stripped of the sand either by the action

of the min water, or that of the winds,

On the same day I made the circuit of a great part of the lose of the island, which is about nine tails in circumference, and found the same solid constructure, a small truet

of tufa to the north side excepted, which descends to the sea,

In this exercision I carefully examined the course and direction of the lavas, and sees convinced that they all had flowed from the steepest summit of the mountain, under different angles of inclination, passing one over mother, and thus forming a succession of crusts of strata, like, in some measure, the coatings of which an onion consists. In several places where the lava has entered the sea, these crusts may be seen lying one over the other, some of them broken or separated by the shock of the waves.

These facts strongly induced me to suspect that the crater of Stromboli had anciently been situated on the summit of the mountain, and that the layer which had principally

contributed to the production of the island had flowed from that center.

On the sides of Etna and Vesuvins mountains of an inferior order arise, which likewise owe their origin to fire: Stromboli, on the contrary, is entirely a single mountain, except that its top is divided into two summits. Hence it appears that there have been none of those cruptions in its sides, which generate lesser mountains or bills, of a conical form.

But this crater, which I conjecture, and shall hereafter prove actually to have existed, has long since given place to that which at present burns. Among the various inquiries which I made of the inhabitants of Stromboli, I interrogated them with respect to the precise situation in former times, as far as they had heard or could remember; of that burning gulf which throws out fire and red-hot stones; and they all agreed in assuring me that they had never known it in any other place but that in which it now is, that is to say, about half way up the mountain.

I lodged with a priest who was now approaching the decline of life, who not only confirmed this account, but adduced the authority of his lather, who had died at the age of eighty, and who had told him that he had heard, from persons older than himself, that

in their time the situation of the burning furnace was the same as at present.

About a mile from the mouth of the volcano lives a peasant, who from his cottage can distinctly see every burning cruption; and though he frequently feels no little alarm, when the fragments of lava are thrown quite to his doors, and the fire reaches his little vineyard, yet, from long habit, and love for the place of his birth, he still continues to reside there. When I asked this man what was the situation of the burning cavern in former times, he returned me the same answer I had received before; alleging, in confirmation of its truth, the testimony of his ancestors who had resided on the same spot. And as to the

ruptions, ruption by the o erupshowers of ejected matter, all of whom I enquired unanimously assured me that they had always seen them such as they at present appear, except that they might be sometimes stronger and sometimes weaker.

All these testimonics appear sufficiently to prove that the volcano of Stromboli has burned for more than a century where it now burns, without any sensible change hav-

ing taken place in its situation.

I shall here make a few remarks on the account which Sir William Hamilton has given

us of Stromboli, agreeable to my promise in the introduction to this volume.

He tells us, that on his return from Messina to Naples he met with a calm while among the Lipari islands, which lasted three days. "Hence," says he, "I had an opportunity clearly to ascertain that all these islands have been formed by eruptions. That which is called Volcano, is in the same state in which Solfatara now is. Stromboli is a volcano which has preserved its vigour entire, and consequently a form more pyramidal than the rest of the islands. We frequently saw bursting stones thrown from its crater, and lava issuing from the sides of the mountain, flow down into the sea."

This description is accompanied by a plate, which is the thirty-seventh plate of the Campi Phlegræi, and represents the mountains of Stromboli. In it the crater is represented at the summit, throwing out flames and ignited stones; and on the sides are seen streams of liquid lava descending into the sea. That the observations of this respectable naturalist on volcanos merit the most attentive consideration, the work I have cited furnishes numerous and incontestable proofs: that impartiality, however, which ought to be inseparable from philosophy, compels me to declare that what he has said of this mountain is not exactly consonant to fact. From the time of his observations to that of mine, only twenty years have clapsed. If, therefore, the crater of Stromboli had thenbeen at the summit of the mountain, and had it thrown out thence its showers of fiery matter, the inhabitants of the island would surely have remembered the fact when I was there: but when I told them that, twenty years before, the burning gulf of their mountain was not situated half way up its side, but at the top, they all positively asserted that this must be a mistake.

The same they affirmed of the assertion that lava had issued from the sides of the mountain, and flowed down into the sea; when, to hear their answer, I told them that this had been observed at the same time. Indeed, it seems very extraordinary that I should never have met with any traces of these currents of lava, though I so carefully examined the island.

I am of opinion that Sir William fell into these errors from not having landed at Stromboli, but only viewed it at sea at a distance, where he might easily be deceived by some illusion of sight. In fact, had he landed, it is not to be doubted but he would have mentioned it. That he made his observations at some distance from the island is sufficiently indicated by these words: "Stromboli is a volcano which has preserved a form more pyramidal than the rest of the islands." When Stromboli is seen at a distance it certainly appears of this pyramidal, or more properly conical form, much more than when seen near; for then it appears bifurcated, nearly similar to Monte Rosso, on one of the sides of Mount Etna.

The distance has likewise rendered him inaccurate relative to the island of Volcano. Had he landed there and examined the place, he would not have compared it to Solfatara. We shall see in chap. XIV, of this work, the difference of the states of the two volcanos.

The figure, more or less conical, of the Eolian isles, as seen from the sea, while Sir William sailed among them, the smoke which he saw rise from some, and the fiery erup-

nile Sir y crup-

tions of others, suggested to him, I imagine, the idea that "they have all been formed by eruptions," as he has not adduced a single local fact in support of that opinion.

On the 2d of October I made the observations I have already related, at the foot and the lower part of the sides of Stromboli. The following night the volcano exhibited phenomena similar to those of the preceding, and the next day (the 3d) proved favourable to my wishes to approach nearer to the burning crater. It now smoked but little, and only a few explosions, and those scarcely audible, were heard. The sky was free from clouds, and the sea calm.

The crater may be approached by two several ways; either by taking a boat, and observing it from the sea; or by land, passing the top of the mountain, and proceeding as near as possible to the edges of the crater. I resolved to observe it, first from the water, taking advantage of the calm which then prevailed, as I well knew how frequently that

sea is violently agitated by tempestuous winds.

After having coasted the island the distance of three miles and a half towards the north, I arrived opposite the place where the showers of ignited matter fall into the sea. The side of the mountain is here a steep declivity, almost perpendicular, about half a mile broad at the bottom, and a full mile long, terminating above in a point, and forming an isosceeles triangle, the base of which is washed by the sea. The apex of the triangle is at the brink of the crater. Before I reached the steep declivity, I observed a great cloud of dust extending along it, of which I could not assign the origin; but on a nearer approach I discovered the secret. It was evidently produced by pieces of lava, of various sizes, which rolled down, and in their descent raised the fine sand with which this declivity is covered.

While I was intently observing this object, the mountain suddenly made an explosion. A quantity of pieces of lava, of a dark-red colour, enveloped in smoke, were ejected from the top of the precipice, and thrown high into the air. A part of them fell again upon the declivity, and rolled headlong down, the smaller preceded by the greater, which after a few long bounds dashed into the sea, and on entering the waves, gave that sharp hissing sound which, in a lesser degree, is produced by a bar of red-hot iron which a smith plunges in the water. The lesser fragments of lava followed, but from their lightness and the hindrance of the sand, rolled slowly down the declivity, which was then obscured by a small cloud of dust; and striking against each other produced nearly the same sound as is occasioned by large hailstones falling on the roofs of houses. In a few moments after another explosion followed; but this was a small one, without any sensible noise, and the few pieces of lava that were thrown up rose to but a small height, and fell back into the crater. Two minutes after a third eruption took place, with a much louder explosion than the first, and a far more copious ejection of lava. The eruptions which I afterwards observed, and which were innumerable in the space of three hours that I continued there, exhibited the same appearances.

These observations caused me to doubt of the truth of an opinion to which I had inclined before my arrival in the island. I mean the periodical intermissions which travellers ascribe to the eruptions of Stromboli, and which I supposed I had observed in the night in my voyage from Naples to Sicily. When from the bottom of this precipice I had the volcano and its fiery hall before my eyes, I do not indeed mean to affirm that it continually raged and thundered equally; but the intermissions between its ejections were so short that they rarely exceeded three minutes, though by the accounts of these travellers they are considerably longer. Yet was I willing still to suspend my judgment, until I should have had a nearer view of the crater on the mountain itself.

The following night I returned to the same place, persuaded that I should see new objects to excite my admiration; and in fact, the scene I beheld appeared to me as delightful and astonishing, as it was noble and majestic. The volcano raged with more violent eruptions, and rapidly hurled to a great height thousands of red-hot stones, forming diverging rays in the air. Those which fell upon the precipice, and rolled down it, produced a hail of streaming fire, which illuminated and embellished the steep descent, and diffused itself around through a considerable space.

But, independent of these ignited stones, I remarked a vivid light in the air, which hovered over the volcano, and was not diminished when that was at rest. It was not properly flame, but real light reverberated by the atmosphere, impregnated by extraneous particles, and especially by the ascending smoke. Besides varying in its intensity, it appeared constantly in motion, ascended, descended, dilated, and contracted, but constantly continued fixed to one place, that is, over the mouth of the volcano, and clearly shewed that it was caused by the conflagration within the crater.

The detonations in the greater eruptions resembled the distant roar of thunder; in the more moderate the explosion of a mine; and in the least they were searcely audible. Every detonation was some seconds later than the ejection. This likewise was observable by day.

I remained that night two hours on the water at this place, and the cruptions were so frequent, and with such short intermissions, that they might be said to be continual.

During both these visits thick showers of sand and fine scorize fell into the sea, and falling on my hat, which was of oil-cloth, made a noise like a small hail.

The five sailors who had the care of the boat in which I was, and some other natives of Stromboli who were with me, and whose occupation frequently brought them to that part of the sea, told me that the volcano might now be considered as very quiet; assuring me that in its greater fits of fury red-hot stones were frequently thrown to the distance of a mile from the shore, and that consequently at such times it was impossible to remain with a boat so near the mountain as we then were. Their assertion appeared to me sufficiently proved by a comparison of the size of the fragments thrown out in the explosions I now witnessed, with that of those which had been ejected in several former cruptions. The first (many of which had been stopped at the bottom of the precipice by other pieces of lava, and were scoriaceous lavas, approaching to a globose form) were not more than three feet in diameter; but many of the fragments thrown out at other times, of similar quality to them, and which lay in large heaps on the shore, were some four some five feet in diameter, and others even still larger.

Travellers have generally asserted that the volcano of Stromboli has for a long time discharged its fury into the sea, without causing either alarm or injury to the inhabitants of the island. The eruptions, however, fall equally on every side around the volcano; though at this place they only fall into the sea, and in that sense their assertion is well founded.

But the people of Stromboli, and indeed almost all the inhabitants of the Eolian islands, entertain an opinion, equally amusing and paradoxical, by which they explain why that part of the sea which is contiguous to the precipice is never filled up notwithstanding the immense quantities of stones which have been contually falling into it from time immemorial; where, instead of a peninsula having been formed by those stones, as might naturally have been expected, the sea is generally said to have no bottom. To explain this apparent paradox, these good folks affirm, with the most entire conviction that what they say is true, that the stones of the volcano which fall into the sea are attracted again by the mountain through secret passages; so that there is a constant circulation from the volcano to the sea, and the sea to the volcano.

culation -

I did not attempt to controvert their favourite hypothesis, which would have been to no advantage, and to no avail; but I caused that part of the sea to be sounded, and found it a hundred and twenty-four feet deep, which, though it is not a great depth in the Mediterranean, is certainly, in this place, somewhat surprising; as it was rather to be expected that the continual discharge of stones into it should have produced a little

hill, which would at last have emerged above the waves.

Thinking this an object deserving some inquiry, I determined to make my observa-tions on the spot, and I flatted myself I have discovered the true explanation of the diffi-The stones which have formerly been thrown into the sea by Stromboli, and those which that volcano still continues to eject, are of the same kind; that is, as I have already said, scoriaccous lava. These, from their being porous and little cohering in their internal structure, easily crumble, and are converted into sand, as is seen on the east and north-east parts of the islands; and this separation of parts is produced by the simple action of the elements of air and water, and the rolling of the pieces over each other in their descent. A similar trituration is effected at the place where the lavas fall into the sea. The steep descent I have so frequently mentioned is covered with this pulverised lava quite to the sea-shore. A part, therefore, of the scorize is already reduced to powder before it touches the water; and the remainder, which falls into the sea in whole pieces, must soon undergo the same trituration, from the action of the waves which beat so violently in various directions.

I must here repeat that the sea which surrounds the islands of Lipari, and especially that part of it which washes Stromboli, is subject to very frequent and very violent storms. The two times that I observed the volcano from the sea, near the precipice, though it was what the sailors called a perfect calm, our boat was so tossed that it was necessary to make use of the oars to prevent its being carried from the place. This agitation of the water, likewise, extends here to a considerable depth, as is sufficiently proved by several observations. The inhabitants of Stromboli, besides nets, make use of wheels, or a kind of wicker traps, to catch fish. Into these they put stones, and sink them to the bottom, leaving a sort of floating buoy to point out where they lie; but to prevent their being carried away by the waves, in a storm, it is necessary that they should be sunk to the depth of a hundred and forty feet; otherwise they would be dashed against the rocks under the water, and lost. As the depth, therefore, of that part of the sea into which the scoriæ fall is less than this, that is, only a hundred and twenty-four feet, they must, by the shocks of the tempestuous waves, no doubt, be soon broken, reduced to sand, and carried away by the violence of the current. It is not, therefore, so extraordinary, as it may at first view appear, that this part of the sea should be scarcely ever filled by the secrimeous lava which is continually falling into it.

I have said, scarcely ever, because I was told, by some of the people of Stromboli, that about forty-four years ago the volcano threw out such an immense quantity of scoriæ, that it caused a dry place, to use their expression, in the sca. A kind of hill rose above the waters, which remained from March to the following July, when it gradually diminished, by the action of the waves, and at last disappeared. The hill was formed precisely in that place where, according to the popular report, the sea has no bottom. This fart not only is agreeable to the hypothesis I have offered, but is a strong confir-

mation of this truth.

The observations I had been able to make on the volcano from the sea appeared to me interesting and instructive; but I flattered myself, that more of its secrets would be revealed to me, if I made a nearer visit to it, over the mountain itself. The way thither lay on the east side of the island, it being impossible to approach it from the sea, both from the incessant showers of heated stones, and the insuperable precipices on both sides of the steep and almost perpendicular declivity. I began this journey on the 4th of October, and was much encouraged by the state of the volcano; to hope I should succeed according to my wishes, as scarcely a shade of smoke covered the highest points of the island. To arrive there it was necessary to make a journey of a mile and a half, reckoning from the sea-shore. The first mile is not disagreeable, but the remainder of the way, though not dangerous, is very difficult; both from the extreme steepness of the ascent, from the impediment of the sand, in which the leg sinks almost up to the knee at every step, and from the loose and moveable scoriæ, which render the summit of the mountain extremely rugged and slippery.

Having reached this summit, I found myself on one of the two points which render Stromboli bifurcated, though, when viewed at a distance it appears conical. This summit is situated to the north-east; the other, which is somewhat higher, inclines to the south-west. As nearly as I could estimate it, the altitude of the latter above the sea was about a mile.

To pass from one summit to the other, we go over an extensive plain, which appeared to me to deserve the most attentive examination. We first observe white funies, which arise from five apertures, not very distant from each other. These fumes have a strong sulphureous odour, and, gliding along the ground, are insufferable from their extreme heat. The five apertures appear sprinkled over with small crystals of sulphur, and muriate of ammoniac (sal ammoniac.) The ground here is a mixture of sand and scoriæ; and the sand, as well below as on the surface, is moist, which may arise from two causes, either from the subterraneous waters being raised in vapour by the volcanic fire, as water constantly accompanies burning volcanos; or from the union of the acid of sulphur with the humidity of the atmosphere.

The ground in the vicinity of these fumes is very hot; and wherever a hole is made with a stick, a new stream of smoke arises, which is not fugitive but durable. If you stamp with the foot, a feeble kind of echoing sound is heard, which I do not imagine to be occasioned by any subjacent gulf or abyss, but only from the very loose contexture of the ground, which is only composed of sand and very porous scoriæ; in the same manner as in several parts of the Apennines, where the ground is light and loose, I have heard the same kind of sound on stamping with the foot. I am, therefore, of opinion, that this hot fuming ground has a communication with the volcano, by narrow winding cavities which afford a passage to the vapours.

Proceeding to the west, over the plain which extends between the two summits, another object arrests still more the attention of the observer. The summits themselves have no crater, nor any vestiges of one; but these vestiges are sufficiently evident on the sides of the plain; which here sinks into a cavity, which may be about three hundred feet in length, from east to west, above two hundred in breadth, and one hundred and sixty in depth. The bottom is covered with sand and scoriæ, not of a very ancient date, but the produce of the ejections of the present volcano. The internal sides of the cavity, however, are not of these materials; they are formed of stratas of lava which bear the most evident marks of the highest antiquity. I am, therefore, of opinion that this was the first and largest volcano of Stromboli, which formed the contexture of the island by its lavas, and which, in a great degree, had been filled up and destroyed by the earthy depositions of the rain-waters, the matter ejected into it by the present volcano, and, perhaps, by the falling in of its own sides. This opinion is confirmed by the direction of the lavas, all of which appear to have descended from the centre of the summit; and this direction, when I examined the lower parts of the

both sides the 4th of should suchest points and a half, emainder of oness of the the knee at

hich render This sumlines to the ove the sea

ch appeared ames, which ave a strong eir extreme ar, and muand scoriæ; two causes, fire, as wad of sulphur

ole is made ole. If you not imagine ose contexriæ; in the at and loose, therefore, of by narrow

ummits, anstheinselves evident on three hundred very ancient I sides of the lava which opinion that ontexture of a destroyed the present ion is coned from the parts of the

island, induced me to conjecture that the principal volcano had formerly existed on the summit.

These remains of an ancient crater lie between two points of the mountain which were probably formed when the lava gushed forth, in the same manner as the volcano of Monte Rosso formed two distinct hills. The bottom of this higher and more ancient crater of Stromboli, in two places, emits fumes, which do not differ in their quality from those that have been mentioned above.

From these two summits the ejections of the present crater are distinctly observable, as it is not distant more than half a mile to the north; and we there evidently perceive that it lies about half way up the mountain, the edges obscurely projecting, and forming a cliff. Here I was better able than on the sea to estimate, by the eye, the height to which the ejected matter ascends; and can affirm that, in the more violent eruptions, it rises to the height of half a mile, or even higher, as many of the ignited stones were thrown above the highest summit of the mountain. They did not, however, reach me, but fell, partly on the precipice which descends to the sea, and partly into and around the crater. The ejections, indeed, which I call the most violent, were certainly very moderate, compared with those which the two natives of Stromboli who served me as guides, assured me they had witnessed, at other times, from that summit, when, as they said, we should not have been safe at the distance and height at which we were; and the numerous scoriæ around us, the produce of former eruptions, fully confirmed the truth of what they asserted. They likewise descreed attention when they affirmed that, at those times, the stones were thrown to more than a mile in height.

From the summit of Stromboli I descended about a quarter of a mile down the mountain towards the volcano, and took my station on an eminence where I had a much more distinct view of the crater, and every eruption; and was more than ever convinced that the intermissions which have been so frequently and positively ascribed to it do not exist. The explosions succeeded each other with such rapidity, that there was rarely the integral of three or four minutes between any two. They, however, differed greatly in their strength, which has probably occasioned the mistake of travellers relative to the intermissions of Strombol. The highest ejections, as I have already said, did not rise less than half a mile in height; while the lowest did not reach the height of fifty feet, and the matter fell back into the crater. Between the greatest and the least there were ejections without number; and the intensity of the sound corresponded to the quality of the ejection. At a considerable distance from the volcano the moderate and smaller eruptions, with their accompanying detonations, were not perceptible, but the greater only; which not being so frequent, may easily induce us to form the false opinion that this burning mountain has considerable intervals of repose. But when we approach nearer, we distinctly perceive the difference of the ejections, and the error of such a supposition. Nor can the fact I observed be considered as accidental, since the two guides I took with me, who are accustomed to conduct strangers to this place, as well as other natives of Stromboli, who frequently pass that way to cut wood, all agreed that the cruptions of this volcano are continual though they are sometimes stronger and sometimes weaker.

At a distance, there was a very perceptible interval between the appearance of the eruption and the detonation; but here, the difference of time between them was scarcely any. The fragments of lava, as they flew, produced a hissing sound; and many of them acquired in the air a globose figure, an evident proof of their fluidity; but before they came to the ground they were hardened, retaining the same figure, while they bounded down the cliffs and precipice. From the little eminence on which I stood I could in part

VOL. V.

discover the internal sides of the crater, though I could not see far into it; but appearances seemed to indicate that it could not be very deep; for, attentively observing the fragments of lava that fell again immediately into the crater, I remarked that almost as soon as they had entered it I heard the sound produced by their collision against the substance on which they fell. This sound resembled that which would be caused should water, or rather some denser fluid, be struck with a number of staves or poles. But of this phenomenon, and others more deserving notice, I shall treat presently more at length, when I come to speak of other secrets of the volcano which were disclosed by a nearer approach.

Here it is proper to notice the fumes which exhale from this mountain, as they have an immediate relation to the volcano. Though when I observed them from the sea they appeared to me of little importance, when I saw them from the summit and body of the mountain they exhibited a thick cloud, several miles in length, exhaling a strong smell of sulphur, which, however, was not incommodious to me, as they were raised several poles above the surface of the ground. This cloud entirely obscured the sun, was black in the middle, but whitish at the edges, and more or less clear according to the different inclinations, refrangencies, and reflections of the light. It appeared to me that this immense mass of smoke extended more than a mile in height. Though it continually issued in a considerable quantity, its volume did not increase, since as much was dissipated in the upper regions of the air, as rose from the earth. It derived its origin from a threefold source. First as often as the crater threw up stones, a cloud of gray smoke immediately arose, which was thick in proportion as the ejection was violent and copious. Secondly, to the west of the crater, and at a little distance from it, are some obscure apertures, through which arise, like white clouds, not less than a hundred and fifty streams of smoke, which, though they are distinct at first, mingle as they rise, and form one cloud.

Lastly, to the east of the crater, there is a large and deep cavern from which ascends a column of dark and very thick smoke, about twelve feet in diameter, which at that time, from the stillness of the air, arose perpendicularly, moving in large circles through a considerable space, and afterwards insensibly rarefying as it removed to a distance. This cavern while I was there threw out no stones, nor had it ever been known to do so, as my guides assured me, though it had always emitted a prodigious quantity of smoke. The causes, therefore, of this smoky cloud were these three, of which the first and third are continual, and the second acts as often as the crater ejects its hurning matter: nor can there be any doubt that they are all three connected with the volcanic gulf which makes its greatest discharge from the mouth of the crater, and a much smaller from each of the sides.

Not satisfied with the observations I had already made, my curiosity impelled me to attempt further discoveries. From the pointed rock on which I stood, I could only see the edges of the inside of the crater. I considered, therefore, whether it might not be possible to obtain a sight of the lower parts likewise; and, looking round me, I perceived a small cavern, hollowed in the rock, very near the gulf of the volcano, into which the rock above prevented the entrance of any burning stones, should they be thrown so far. It was likewise so clevated, that from it the crater was open to my view. I therefore hastened to take my station in this cavity, taking advantage of one of the very short intervals between the eruptions. To my great satisfaction, my expectations were completely fulfilled; I could here look down into the very bowels of the volcano, and Truth and Nature, stood, as it were, unveiled before me. The following is the description of the objects which presented themselves to my wondering eyes.

appearing the most as nst the should But of nore at

The edges of the crater, which is of a circular form, and not more than three hundred and forty feet in circumference, are composed of a confused mixture of lavas, scoriæ, and sand. The internal sides contract as they descend, and assume the shape of a truncated inverted cone. These sides, from the cast to the south, have only a gentle declivity, but in the other parts, they are very steep. In many places, they appeared in crusted over with yellow substances, which I imagine to be the muriate of ammoniac

(sal ammoniac) or sulphur.

The crater, to a certain height, is filled with a liquid red-hot matter, resembling melted brass, and which is the fluid lava. This lava appeared to be agitated by two distinct motions; the one intestine, whirling, and tumultuous; and the other, that by which it is impelled upwards. This motion in particular merited to be examined with attention. The liquid matter is raised, sometimes with more and sometimes with less rapidity within the crater, and when it has reached the distance of twenty-five or thirty feet, from the upper edge, a sound is heard not unlike a very short clap of thunder; while at the same momenta portion of the lava, separated into a thousand pieces, is thrown up, with indescribable swiftness, accompanied with a copious eruption of smoke, ashes, and sand. A few moments before the report, the superfices of the lava is inflated, and covered with large bubbles; some of which are several feet in diameter, which bubbles presently burst, and, at the same instant, the detonation and fiery shower take place. After the explosion, the lava within the crater sinks, but soon again rises as before, and new tumours appear, which again burst and produce new explosions. When the lava sinks, it produces little or no sound; but when it rises, and especially when it begins to be inflated with bubbles, it is accompanied with a sound, similar, in proportion to the difference of magnitude, to that of a liquor boiling vehemently in a caldron.

I remained in this cavity, which so conveniently sheltered me from danger, an hour and a quarter; during which time, besides the observations I have already stated, I was

enabled to make the following:

Every ejection, however small, was not only accompanied by an explosion, but was proportionate to it in its intensity. Hence, as the stones which are only thrown to the height of ten or twenty yards above the crater, are not visible to the eye at a distance, so neither is the detonation, by which such ejections are accompanied, sensible to the ear.

In the smaller and moderate ejections, the stones fell back into the crater, and at their collision with the fluid lava produced, as I have already said, a sound similar to that of water struck by a number of staves; but in the greater ejections, a considerable quantity of them always fell without the mouth; though that lying low, and surrounded with heights, the greater part of them rolled again into it. Here, however, we must except that side of the crater which lies immediately over the precipice before described, since there every stone which fell without the crater bounded down the declivity, and descended to the sea. When I viewed this precipice from the water, it appeared to me to terminate in a point; but here I distinctly perceived, that, where it reached the volcano, it was more than sixty feet in breadth.

The redness of the larger ignited stones (which were only pieces of scoriaceous lava) was visible in the air, notwithstanding the light of the sun. Many of them clashed against each other and were broken, which happened only when they were at a certain height; for, when they were nearer to the volcan, they frequently adhered, on touching each other, in consequence of the fluidity they retained. The lava of the crater, when it rose or fell, emitted but little smoke; but a great quantity when it exploded.

The smoke issued from its fissures, but almost immediately disappeared after the explosion. It might be compared to the smoke produced by the firing of gunpowder, and which appears and disappears with the flash. This smoke appeared to me extraneous to the lava; at least, the fragments of the latter neither smoke as they fly in the air, nor after they have reached the ground.

In consequence of the alternate rising and sinking of the lava, according as it is inflated or makes its discharge, the depth of the crater cannot be considered as constant. When the lava is at its height, it may be about five and twenty or thirty feet deep, and when it has subsided, about forty or fifty: the greatest rising of the lava may, therefore, be estimated at about twenty feet.

If we attentively examine the edges of the crater, we can discover no signs that the lava has ever overflowed the brink, much less that it has poured a torrent down the steep side of the mountain.

Though the ejections of the larger and heavier stones have short intermissions, those of the lesser and lighter have scarcely any. Did not the eye perceive how these showers of stones originate, it would be supposed that they fell from the sky: the noise of the more violent eruptions resembling that of thunder, and the darkness occasioned by the mounting cloud of smoke, present the image of a tempest.

Such were the phenomena of the volcano of Stromboli, which I observed with the utmost convenience from the station I have described. Though it is impossible perfectly to pourtray such astonishing scenes by any drawing; the representation I have given in the plate of a part of Stromboli, may enable the reader to form a more adequate idea of the principal objects.

In this plate AAA represents the vast column of smoke which, to the east of the mountain, issues from a deep and spacious cavern, moving directly upward. BBB, the numerous streams of smoke arising on the opposite side, above which I am myself represented, standing in the cavity of the rock which I have described, and looking down on the showers of fiery matter ejected from the mouth of the crater, which has an opening in front to afford a view of the internal parts of the crater and the fiery ejections. A part of the latter are represented as falling at the top of the precipice which joins to the edge of the volcane, down which they bound, and precipitate into the sea.

To the appearances already described, which I observed by day, I shall add others that presented themselves by night; the cavity in the rock, which I have before mentioned, affording me the convenience to make my observations, likewise at that time, in perfect security.

The surface of the burning lava within the crater never emitted any sensible flame, not even when the bubbles upon it burst with an explosion; but it shone with a glowing vivid light, and resembled, in its appearance, melted glass in a furnace. From this surface the light diffused itself around, and shot upwards, but with irregularity, sometimes rising and sometimes falling, according, as it appeared to me, the lava itself rose or sunk.

This light in the air became more vivid at every ejection of ignited stones; and was likewise increased in intensity by the quantity of sparks that accompanied each ejection which were produced, in part, from the breaking of a number of the stones, in their clashing against each other.

Such was the appearance of the volcano during the night; but while I was observing it in my secure recess, and contemplating the astonishing spectacle, an unexpected phenomenon excited in me much more alarm than pleasure. The eruptions of the volcano suddenly ceased, the boiling lava sank lower than usual, without again rising, and

lost its vivid glowing redness; while at the same time the numerous streams of smoke, to the west of the volcano, which before rose in silence, began to issue with a loud hissing sound, and the apertures from which they exhaled to shine with a bright colour of fire. I know nothing to which the sound produced by the issuing of these fumes can be more properly compared than the blowing of large bellows into a furnace by which metals are melted; such as I have seen at Zalatna in Transylvania, and Schemnitz, and Kremnitz, in Hungary; except that these volcanic bellows roared a hundred times louder, and almost deafened the ear.

The unexpected change within the crater, and my nearness to those fumes, which, as they abounded with highly noxious sulphureous vapours, I feared might have mischievous effects, alarmed me so much, that I was on the point of abandoning a place which appeared so dangerous, and seeking safety in flight; had not the guides encouraged me to stay, assuring me, from their repeated experience, that my fears were groundless. "The burning matter which boils within the cavern," said one of them, "always contains a great quantity of air. This air has at present left the fire, and passed through subterraneous passages to those apertures from which the smoke issues, and which we call respiri (vent-holes) because there the air from the fire finds vent. But there is nothing to fear: the noise of these vent-holes will soon cease, and the crater boil and throw out burning matter as before."

My companion gave me this account in such a manner as shewed he had himself no idea of danger, and the event happened precisely as he foretold. In a very short time the fumes and the volcano returned to their former state. My two guides afterwards assured me that this appearance very rarely happened, and when it did was never of long duration. From this discourse, and other conversation which I had with them afterwards, I perceived that these two natives of Stromboli were better acquainted than any other person with the secrets of their volcano, and the explanation they had given me of

the phenomenon I had witnessed, appeared to me extremely judicious.

I think it cannot be doubted that the bubbles which arise in the liquid lava, and burst with an explosion, are generated by an elastic fluid there collected and confined, which being dilated by the strong action of the fire, and incapable easily to disengage itself from the tenacious lava, violently bursts it, and rushes above the crater, producing at the same time a detonation. Hence originate the showers of ejected matter, which are more or less copious, and rise to a greater or less height, in proportion to the greater or less quantity and strength of this fluid; which escaping, at every explosion, from the upper parts of the lava, these sink, and again rise when they have received a fresh supply. Supposing, then, the source of the fluid confined, from time to time, within the liquid lava, to be inexhaustible, we shall easily perceive that the eruptions must be incessant. If from the extreme tenacity of the lava, its want of sufficient fluidity, or any other unknown cause, it should be unable to burst it, and open itself a passage within the crater, it will make its way through the subterraneous channels to those apertures from which the fumes ascend, through which it will issue, with considerable noise, till the obstacle it met with in the lava be removed. In such a case the lava will sink without again rising during this interval, and will lose its fiery redness from being no longer urged by the energy of the elastic fluid; while, from the contrary reason, the apertures from which the fumes issue will acquire a glowing redness, because the fluid escapes through them

Such were the ideas which floated in my mind, when, the night being considerably advanced, I returned home, with my imagination strongly impressed with the objects I had seen. These ideas I afterwards, in a cooler moment, recalled to a rigorous exa-

mination, inquiring, especially, what might be the nature of volcanic gases, not only of such as are imprisoned in the liquid lavas of Stromboli, but of those which are inseparable from other burning volcanos; as likewise in what manner they act, to produce the ejections; objects which appear to me to be at once new and highly interesting. These inquiries produced a number of observations and connected experiments, which it will be more proper to present the reader in another part of the work than in this place; both because they regard volcanos in general, and because to detail and explain them would lead me too far from my present subject, which is to speak of the objects I observed in this volcanic country. As I have, therefore, given some account of the nature and conformation of Stromboli, and the most remarkable phenomena of its volcano, I shall proceed to describe, in the following chapter, the different substances of which this island is composed.

CHAPTER XI.

STROMBOLI, CONTINUED.

The component substances of this island are scoriæ, lavas, tufas, pumices, and specular iron.... Three kinds of scoria.... The first kind has some degree of vitrification.... Stromboli produces no true vitrifications or enamels.... The name of pumice not suitable to this kind of scorie.... Its ejection, and the figure which it sometimes takes in the air....Second kind of scoriæ, for which Stromboli is remarkable....Its decomposition where the acid sulphureous vapours prevail....The substances thrown out of Stromboli more acted on by the fire, than those ejected by other volcanos....The activity of the fires of Stromboli has long remained the same....False opinion of some, that volcanic glasses derive their origin from re-melted lavas....Third kind of scoriæ.... All these three kinds of scoriæ originally porphyry with a horn-stone base.... Enumeration of the different lavas of Stromboli....Its tufas and pumices....Specular iron....Dangerous situation in which the latter is found.... Its crystallization, beauty, and variety Flakes of sulphate of lime (selenite or gypsum) incrust some of these crystallizations, which consist of very thin leaves of iron fastened on each other.... Hardness, and, at the same time, fragility of this iron.... Changes produced in it, when exposed to the fire of the furnace, and that excited by oxygenous gas (dephlogisticated air)... Decomposed lava the matrix of this specular iron.... Cause of this decomposition....Comparison between this specular iron discovered by the author, and that noticed by others in volcanic matters....This specular iron produced in the dry way....Rareness of it in volcanic countries....Sulphureous acids produce no change in the iron of Stromboli....Its antiquityThe island of Stromboli formed by rocks of porphyry, melted by subterraneous conflagrations, and thrown up by the sea Different porphyries of countries not volcanic exposed to the fire of the furnace, to compare the changes caused in them by that with those produced by the volcanic fire... The epoch of the first conflagrations of Stromboli anterior to all history.... Few notices left of them by the ancients....Strabo's accounts of Stromboli and Volcano....The eruptions of the latter mountain must have been more frequent and stronger, in the time of that geographer, than at present....Wind which, according to Diodorus Siculus, blew from these two aslands....Mistake of Cluverius, that in his time the crater of Stromboli was at the summit of the mountain....The most ancient epoch of the conflagration of Stromboli, known to us from history, anterior to the Christian era by about 290 years.... Inquiries relative to the matters which have so long maintained this conflagration.

THE substances of which this island is formed, at least so far as I have been able to discover, are scoriæ, lavas, pumices, and specular iron: as likewise the sand of which I

only of insepauce the These it will would rved in ad conall prosland is

r iron.... roduces iæ....Its which 1....The her volnion of oriæ.... n of the ation in of lime aves of hanges gas (decompoiced by

ble to

have sufficiently spoken in the preceding chapter. Of the scorae there are three kinds: the first is extremely light, of a dark gray colour, and on it the violence of the fire has taken most effect. Some small pieces are coated over with a true varnish of glass; the others in general consist of semi-transparent vitreous threads, some of which are as fine as the threads of a spider's web. We may, therefore, conclude that the matter was in a state of semi-vitrification, when its parts were separated by the elastic fluids, and rendered extremely porous; but that some of it, instead of separating, lengthened into threads, which hardened on its contact with the air. We perceive likewise, that only a degree more of heat was necessary to render the vitrification complete.

Of the various bodies ejected by the volcano of Stromboli, this kind of scoria appears to be that on which it has acted with most effect. It has not, however, been changed into a true glass, if we except some pieces of very inconsiderable size. The conflagration of Stromboli has never, therefore, arrived at this degree of violence, as I could not find throughout the whole island either vitrifications or enamels. The natives themselves indeed sufficiently satisfied me of their non-existence, as those of the neighbouring island of Lipari are well known to the inhabitants of all the Eolian isles, under the common

name of ferizzi.

But may not the scoria here described as in a great degree filamentous, be considered as a species of pumice? I certainly do not perceive in it the distinguishing characteristics, for the fibrous quality alone is not sufficient. I conclude, therefore, that when any stone, in consequence of the action of volcanic fires, passes into the state of pumice, certain determinate conditions are required, either in it, or in the degree of heat to which it is exposed, or perhaps in both, which are not yet sufficiently known to volcanic naturalists, notwithstanding the attention they have bestowed on the subject. Of this the present scoria may furnish an example. The stone which was its base, by the action of fire, had been dissolved into lava within the crater; and this lava by the action of elastic fluids, and probably by that likewise of sulphur, has become a filamentous substance, and as its filaments are vitreous, appears to shew an immediate disposition to change into pumice; but it was not formed by nature to become that substance, as appears by the small pieces which have assumed the thin vitreous coating. Were the fires of Stromboli more violent and powerful, the stones which are melted and thrown out would pass from the state of scoria to that of perfect glass, without first acquiring the nature of pumice.

The scoriæ of this kind are never thrown by the volcano in large pieces to any great

distance, from the great ease with which they break and pulverise.

It is worthy of remark, that not a few pieces of these scoriæ incline to a cylindrical figure, and that their filaments are parallel to the axis of the cylinder. Both these effects, in my opinion, may be attributed to the projectile impetus received from the elastic fluids when forced from the lava in the crater; those pieces not having had time to take a globular form, both from their sudden cooling and coagulation in the air, and from the smallness of their size.

I shall now proceed to speak of the second kind of scoria, I mean that for which Stromboli is celebrated, and of which its ejections principally consist. This species in its external appearance has no essential difference from the former; but its specific gravity is nearly three times as great, it is not at all fibrous, and only exhibits the slightest signs of a beginning vitrification. In other respects, like the greater part of scoriæ, it is not only rough, scattered over with tumours and irregular figures, and every where scorified; but it is full of vacuities of round, oblong, and other forms. The largest of these are about half an inch in length, and the smallest almost invisible. They extend

through every part of the scoria quite to the innermost substance, even in the largest pieces; and in the centre of some they are found more numerous and large. Hence it appears that a universal effervescence of the elastic fluids must have prevailed in the substance of these scoriæ while they were in a fluid state. The internal surface of each of these cavities is, as it were, coated with a dull dark-red varnish, while the rest of the scoriæ is black. To discover the visible characteristics of this scoria, it must be examined with a lens in the recent fractures: we then perceive that the grain is not very fine, without brilliancy, and of a uniform texture. Its hardness is moderate, its fracture irregular, it gives some sparks with steel, emits a weak earthy odour, and attracts the magnetic needle at the distance of half a line. These exterior marks afford ground to believe that this scoria has for its base the horn-stone; and its component principles confirm the supposition beyond contradiction.

This base however, is not homogeneous, since it contains feltspars and shoerls. On examining it with attention, we perceive that it is interspersed with a great number of small white spots, which form a remarkable contrast with the black ground on which they appear. By having recourse to the aid of the lens, we discover that these spots are scales of feltspar. As they are quite flat, wherever they are viewed in the fracture, they appear about the thickness of a line, but longer when seen on a flat surface.

The number of the shoerls contained in this scoria is very considerably less than that of the feltspars, but they are much larger. They are of a black colour, and in figure prisms, the length of many of which is five lines, and the breadth two. It is, however, very difficult to extract entire prisms from the scoria, on account of the tenacity with which they adhere to it.

They may be obtained much more easily in certain low bottoms near the crater, where they may be found separated from the scoria, the small fragments of which are there accumulated in great quantities. Detached shoerls may there be found little altered by the atmosphere and elements; many of them indeed fractured and mutilated, but some few entire, and still preserving their prismatic figure, which is octohedrous, and terminated by two pyramids.* They will scarcely cut glass, and consequently cannot be very hard. Their appearance is vitreous, and they seem as uninjured as when they were in the rock, their primitive matrix.

Besides the feltspars and shoerls, these scorize contain various other small stones, which I at first doubted whether I should consider as another species of shoerls, or as what have been called volcanic crysolites. They have the transparency of glass, and are of beautiful colours. Some are of a fine grass green, others of a deeper emerald green, and others of a mixture of green and yellow. Some of these qualities, which are common to crysolites, and to certain species of shoerls, caused me to doubt, when I first examined them, whether I should class them with the former or the latter. But besides that I could not discover that they had any regular figure, the ease with which they were fused with the blow-pipe, determined me rather to consider them as shoerls.

From the observations that have already been made, it seems clear that these two species of scoriæ are of the nature of porphyry, as they are composed of a horn-stone in which feltspars and shoerls are incorporated.

^{*} The original has "two dihedrous pyramids" (due piramidi diedre). But (as the German translator has rightly remarked) who has ever seen a pyramid with only two sides? I have, therefore, with him, omitted the word, which must have been inserted by some mistake. T.

[†] It appears to be proved by the most recent discoveries of chemical analysis, that the base of the greater part of porphyries is shoerl in the mass, or horn-stone, or trapp; though it cannot be denied that this base is likewise frequently siliceous. Many of the lavas, therefore, of the Phlegrean Fields, which I have described in the first volume, may be referred to this kind of stone.

But before I dismiss this second kind of scoria, I must make one more observation on it. Some pieces of this scoria lay near the apertures, from which the streams of smoke I have already mentioned arose to the west of the volcano. I collected some of these, which had almost stopped up one of the orifices through which the fumes issued, and which consequently was strongly acted on by them. These pieces had undergone changes similar to those of the lavas of Solfatara. They had lost their black colour, were covered with light-yellowish crust, and were become so soft that they might be cut with a knife. The shoerls, however, in the part where this alteration had taken place, had undergone no change. But the sulphureous acid which had acted on this scoria, besides having in part decomposed it, had likewise produced in its cavities small aggregates of sulphate of alumine (alum) and sulphate of lime (gypsum.) This observation I have had an opportunity of making, not on volcanic products long since decomposed, which decomposition there is every reason to believe must have been effected by the means of sulphureous acids; but, instructed by nature herself, on a product actually undergoing decomposition, and thus presenting an incontestable proof of the power of these acids to decompose such substances.

I have denominated the principal matters ejected by Stromboli, and on which I have hitherto treated, scoriæ; though, according to the judicious and just remark of M. Dolomicu, these differ from lavas only in having undergone greater alteration within the volcano, having been more inflated, and acquired a surface more rugged, and of a more irregular form; and such precisely is the appearance of the stones thrown out by Stromboli. I am aware, however, that the difference of these circumstances is not intrinsic and essential; and that, therefore, what I have termed scoria may be likewise called lava, only more changed in the volcano, since it is in substance the same matter melted by the fire, and differently modified by the elastic gases. I think, notwithstanding, that I have expressed myself with sufficient propriety, when, in the last chapter, I said that the lava swelled, sunk, burst, and was thrown up into the air, though I have afterwards called the congealed pieces of it scoriæ, since they possess the characteristics of that substance.

With respect to the matters that ferment and boil up in the crater of Stromboli, I shall here make a remark which may deserve consideration. This volcano, besides the singularity of having been in a continual state of eruption from time immemorial, has also this other, that the substances it ejects are more repeatedly acted on by the fires of its crater than in other volcanos. The latter being situated at the summit of steep mountains, having once thrown out their ignited stones beyond the edges of the fiery gulf, never receive them again, as they pour headlong down their sides. But the crater of Stromboli is situated half-way up the mountain, and surrounded, except only on the side which faces the north, by steep precipices; so that, besides the scoriæ which are thrown up perpendicularly, and fall again immediately into it, great quantities which are thrown beyond its edges roll down the declivities, and return again into it. When we consider, therefore, how many ages this recurrence of burning matters into the volcano has continued, we might expect that from the continued action of the fire they must approach very near to a vitreous nature, or rather be changed into perfect glass; yet this is by no means the fact. I caused a quantity of scoriæ to be dug up from the depth of eight feet, at no great distance from the mouth of the crater, and found it exactly resemble that on the surface, though it must have been ejected so long a time before. It is likewise to be remarked that the shoerls in the recent scoriæ are as entire, and as completely crystallized, as those in the most ancient.

These observations are a certain, and, in my opinion, elegant proof that the activity of the fire has never been, in former ages, either greater or less than it is at present.

VOL. V.

O

Not less, since then the fusion of the matters in the crater would not have taken place, and consequently there would have been no eruptions; nor greater (at least not in any considerable degree) otherwise the scoriae would have been completely vitrified, and the shoerls fused, as we find them by our common fires when intense.

Hence likewise appears what little foundation there is for the opinion of some naturalists, who have supposed that volcanic glasses owe their origin to the refusion of lavas; since, as we have seen, no true glass has ever been thrown out by Stromboli, notwithstanding the multiplied refusions of the ejected scoriæ, or scoriaccous lavas, if any should

choose to call them by that name.*

But it is time to consider the third species of scoria. This properly belongs to the ancient volcano, and is found, on removing the sand, at a small depth, on the east side of the island, a little above the foot of the mountain. It is disposed in strata forming one body with the subjacent lavas, which at some distant period flowed from the summit of Stromboli into the sea. The inhabitants make great use of this scoria to build their houses, as it is very firm and very light, which lightness arises from the small quantity of matter it contains in proportion to its bulk, and its great porousness. As the partitions which separate the cells or pores are very thin, it is difficult properly to examine this scoria, which bears the marks of the highest antiquity. After as attentive an examination as I could bestow, I discovered in it black shoerls and white feltspars. The body of its substance does not differ, that I could perceive, from that of the other two kinds.

Having thus described the three kinds of scoriæ of Stromboli, though I do not mean to say that other inquirers may not discover more species, I shall next proceed to enumerate and describe the lavas, which, for the sake of order, I shall divide into porous

and solid, beginning with the former.

I. This lava forms an ascent of some hundred paces, to the west of the island. The eye does not hesitate a moment to recognise it as a product not at all differing in substance from the second species of scoria. It has the same ground, consistence, and colour; and contains the same feltspars and shoerls, both of which are in like manner unmutilated, and have the same crystallization. It likewise gives sparks, in the same manner, with steel. But the size and number of its cavities or pores is less, the solid parts are more smooth, nor have they in their grain that irregularity which appears to be inseparable from scoriæ. We might therefore suppose that it is the produce of the present volcano; nor should I object to that supposition, were the course of the lava on that side; but I find it is directed towards the summit of the mountain, where there is every reason to believe the greater volcano aciently was situated. I am therefore of opinion that this was its source.

II. This lava is less porous. The grain has somewhat of a siliceous appearance. It is smooth to the touch, and gives sparks plentifully with steel. It contains but few felt-spar seales, but immunerable shoerls. It lies on the south side of the mountain, in large

single stones

III. The difference between this lava and that of No. II, is but small, and consists in its greater porosity, and a feeble argillaceous odour. This lava is found scattered over the island. The petrosilex is the base of both these lavas.

This reasoning may at first view appear plausible, but is sufficiently refuted by the easy vitrification of these scories in the furnace, as we shall see presently.

^{*} With respect to the matters ejected by Stromboli which scorify and do not vitrify, it may perhaps be said that this does not happen, because they have not caloric enough to become glass, but from the quality of these matters, which, originating from the horn-stone, only produce scorification, and that from the quantity of iron they contain.

ed over

perhaps from the and that vitrificaI shall now speak of the solid lavas, which I so term, not because they are without pores, but because their pores are so minute that they escape the eye.

I. This lava, notwithstanding its solidity, is friable, and gives sparks feebly with steel. It abounds in feltspars, and still more in shoerls. It is of a dark-gray colour; its base

is horn-stone, and consequently it emits an earthy odour.

II. This second species of solid lava is still more friable than the former, and it has a considerable argillaceous odour. It contains no shoerls, but so abounds in feltspars that they occupy more than one-third of its mass, and are easily distinguished, as they are of a shining whiteness on a brown ground. Their lamellæ are distributed equally through its whole contexture. I collected both this lava, and that of No. I, from several currents of it on the south-east side of Stromboli.

III. I am in doubt whether I ought to call this stone a lava, as it is a perphyry of a beautiful dark-red colour, which changes to a black as soon as it is exposed to the activity of the furnace. The place, likewise, in which I found it, contributes to increase my doubts. This was a hill of tufa forming a large inclined stratum, on the south-east side of the island, within which it is found in large masses. I was led, therefore, to conjecture, that both this porphyry and the tufa might have been thrown out by the volcano without having been exposed to the violence of the fire. I am still, however, madde to form any determinate conclusion, since I am in possession of several other specimens of porphyry, which bear indubitable marks of having been fused, though they still retain a beautiful red colour, as will be seen when I come to treat of the island of Lipari. However this may be, this stone has for its base the petrosilex, is spotted with white feltspars, and takes a fine and brilliant polish.

IV. This lava which is found in a long-continued current, on the south-west side of Stromboli, contains, as usual, scattered feltspars. It is of a black colour, of the horn-stone base, and emits a strong earthy odour. It is accompanied with various greenish and black shoerls. A number of eurling veins and waves appear in it, which probably were produced when it flowed from the mountain. Though it is solid, it has in it several small cavities, all of which are long ellipses, all placed in the direction of the current from which they containly desire their feature.

from which they certainly derive their figure.

These are the scorize and lavas found at Stromboli, omitting a few varieties, which

would only swell the work, without adding to its utility.

According to the division I have made, after the lavas, I should proceed to speak of the tufas, as I have already given the reader to understand they are not wanting in some parts of the island. But I think I fully describe these, when I say that they are an argillaceous earth, pulverisable, extremely bibacious, of a gray colour, containing fragments of feltspar and shoerl, and which, in the furnace, hardens without melting. Such, at least, are the characters of the tufas which I observed at Stromboli.

I now proceed to the fourth kind of the volcanic productions of this island, the pumices. These are found on the east side of the mountain, at about one-third of its height, on the sides of some pathways which cross several vineyards, and in the furrows made by the descent of the waters. They are not found in masses, and still less in currents, but in small pieces, which are not numerous, and it is easy to perceive that they have been brought above ground by the labours of men, or by the action of the rains; and, following the traces they afford, we find them buried under the sand, at the depth of several feet. Here they are but thinly scattered, and are in the same state as when thrown out of the volcano. I cannot pretend to ascertain from what crater they originated, whether the ancient, the present, or some other, the remembrance and traces of which are lost; as nothing affords any light to direct my researches relative to this obseure

question. I found them in no other part of the island. As they do not differ from the more common and known species, it would be superfluous to give a long description of them. I shall only say that their base is petrosiliceous, with a mixture, as usual, of feltspars.

Stromboli has, therefore, at some other period thrown out pumices, though it does not eject them at present. A similar change, though on a larger scale, we find likewise

take place in Vesuvius.

The different kinds of scoriæ and lavas being exposed to the fire of the furnace in separate crucibles, the base, whether of petrosilex or horn-stone, changes into a shining, ebullient, but hard glass, with a fusion of the shoerls, but not of the felt pars. From the pumice was obtained a glass, lighter from the multitude of its pores, of a gray colour,

and dully transparent.

It now remains to speak of the iron, the fifth and last of the volcanic productions which I found on this island. 'This is specular. I am not ignorant that this species of metal has been likewise observed in other volcanos; but it gave me pleasure that I was the first who had discovered it in the Lipari islands; and this pleasure was considerably increased, when I perceived that the crystallizations of this iron were much larger than those which had been observed by others; and, consequently, much better adapted to shew and explain their formation. It is found on the southern side of the island, at the distance of somewhat more than a mile from the inhabited part, in a rock of lava, which descends almost perpendicularly into the sea, from the height of about a hundred and fifty paces. Some natives of Stromboli having shewn me a small specimen of this iron, without knowing what it was, as one of the rarities of their country, I was very desirous to obtain some others, but such as might shew the iron still adhering to the matrix, as these were detached pieces, found on the beach under the rock. But to procure new pieces of this production, neither entreaties nor any common offers of reward availed; and, to say the truth, so great was the labour and danger of obtaining them, that they never could be sufficiently paid for. To get at these stones, as they call them, it was necessary to go by a very dangerous way, scarcely passable by the wild goat, much less by men, and therefore called very properly il malo passo, the bad or dangerous road. But, to reach the precise spot where the iron is found, still greater danger must be encountered, as the rock, besides its extreme steepness, is partly fallen down, and the rest on the point of falling; and it is very difficult to find firm footing on it, without slipping, and falling headlong into the sea. The desire of gain, however, added to the habit in which these peasants are of passing cliffs and fearful precipices, induced two of them to undertake this enterprise, which they successfully executed, bringing back with them some very beautiful pieces of this iron which they had separated from the lava with a pick-axe. From them I learned, that the rock has clefts in many places, and that within those clefts the iron is found.

This metal is crystallized in laminæ, vertical to the mother rock, in which they are so firmly infixed, that they must be broken to obtain them detached. The two faces of every lamina or plate are parallel to each other, or nearly so. In general, the plates, at a first view, appear oval; but, when examined with more attention, they are found to be polygons. The figure of these polygons is extremely diversified. Sometimes they are triangles, terminating, in the upper part, in an obtuse angle; and sometimes in a right, or acute angle, though this but rarely. Some of those plates have six, seven, eight, and sometimes more, sides; nor is there less variety in the length of the sides, or the measure of the contained angles. The sides are frequently cut by plates, which are triangular, quadrangular, rhomboidal, or of other polygonal figures. Nature, therefore, in the

formation of this metal, appears not to have prescribed to herself any single form of crystallization; or, at least, if she has, it is not easy to discover the simple primitive figure from which has arisen so great a variety.

The plates or faces have such a brilliancy and polish, that if the finest steel be not inferior, it certainly is not superior to them in beauty. They reflect the light equally with the most perfect mirrors. The largest exceed four inches in length, and three and a half in breadth; but there are innumerable others which are smaller; and only one inch, or the half, the third, or the quarter, of an inch, until they become so minute as to be only visible by the microscope; but they are always crystallized in one of the figures already mentioned. A single lamina is never seen, but they are always in groups, which groups are sometimes twenty or more inches in circuit. The number of them,

therefore, is very great.

ngular, in the I must not here omit to mention a peculiar circumstance, which usually attends these crystallizations. The circumference of these thick metallic groups is formed of laminar so minute, that a strong lens is necessary to discern them; but they become gradually larger as they approach the centre, where they are largest of all. There are also places in these groups where Nature seems rather to have sketched than completed her work. We find there groups or small masses of iron which present only the first principle of crystallization. In others we do not find even this sketch but only a crust attached to the matrix. There are also places in which a number of small tumours arise, that viewed with the naked eye appear to be without form, but when examined with the lens, are discovered to consist of a multitude of small laminæ irregularly conglutinated. In the same manner, some crusts are formed, in some places three lines in thickness, which, both internally and on the superficies, are found to be composed of an aggregate of laminæ thrown irregularly on each other.

In reference to some observations I shall hereafter have to make, I must mention that some of these aggregates of laminæ are either entirely covered with a coating of sulphate of lime, so that it must be taken off to get at them, or at least only the upper part of them rises above it. This coating is of a very white colour, and so strongly attached to the

iron, that it appears like wax that has been poured over it and hardened.

The colour of these laminæ, in general, greatly resembles that of the finest and most brilliant steel; except some which have a violent tineture. They are as resplendent in the fractures as on the faces. Notwithstanding their great hardness, they are nearly as

brittle as glass.

On carefully examining these laminæ, a phenomenon presented itself, which increased my attention. This was some scales parallel to each other, which arose from the faces of these crystals, and induced me to suspect that their composition might be the result of a number of small leaves united and conglutinated together. An inspection of the larger laminæ convinced me that this conjecture was well founded; for, on breaking them crosswise, I frequently found in the fractures very small leaves. There are also some which very evidently shew them, and in great numbers, on their faces. A leaf, for example, may occupy a sixth part of the face and their end. Further on, under that, another appears, which extends another sixth, and then terminates like the former. Still farther, under the second leaf, appears a third, which extends only a small space: and in like manner others: so that the lamina will be the less, the smaller the number of the leaves or which it is composed. I shall here avail himself of a comparison, which, though not very scientific, will aptly explain what I mean. When a number of leaves of paper are, first, rolled up, and afterwards spread out on a flat surface, it will happen, on their unrolling, that each will separate a little from the next, so that

they may all be numbered; and it will be evident that the first, which is above all the rest, renders the heap larger, and that the leaves being successively taken away, the heap will be diminished, until it will at length only consist of the single last leaf.

The laminæ, however, are not all composed in this manner. In some the component scales are conglutinated in such a manner that they do not appear, and the fracture presents a continual surface. Yet there are but few laminæ so smooth on both their faces as not to shew the presence of some leaf. More than once I have found on one lamina others attached which shewed they were of later formation.

These facts, when compared, must remove every doubt with respect to the nature of the formation of these noble crystals, as it is manifest they are composed of a greater or less number of small plates, which, placed upon, and adhering to, each other, form the larger laminæ.

Among all the volcanic productions which I met with and collected in my travels, there is not one which gives sparks so plentifully with steel, or influences the magnetic needle at so great a distance, as this of which I now treat.

Almost every lamina, part, or fragment of this production possesses polarity, attracting the magnetic needle at one end, and repelling it at the other; which attraction and repulsion are equal in force. The same powers of attracting and repelling are equally found in the crusts of iron apparently not crystallized, and in their parts.

Notwithstanding, however, its power to move the magnetic needle, it is scarcely at all acted on by the magnet, at least, not unless it be reduced to very small particles. When approached to the Leyden phial, it freely conducts the electric shock.

The furnace has no other effect on it than to deprive the laminæ of their brilliancy, and diminish, in a small degree, its magnetic virtue, which is not destroyed even by the fusion of the laminæ; to obtain which the blowing pipe is not sufficient; but oxygenous gas (dephiogisticated air) must be applied for about two minutes, as one will not be long enough. The little ball into which a small lamina of specular iron is converted, loses on its surface all brilliancy, and acquires the colour of lead exposed to the air. Internally, however, it still retains some resplendence; but the friability of its parts is increased, and it gives but few sparks with steel. The same change takes place in this metal which is so frequently observable in other bodies after having been in a state of fusion: it is interspersed with small air-bubbles, and rendered, in a manner, spongy.

Such are the principal properties of the specular iron which I discovered at Stromboli. But it is of importance to know, of what nature is its matrix. This is a lava which does not essentially differ from those lavas of this volcanic country which are of the horn-stone base, except that it has undergone great changes. It is so friable, that it may be scratched with the nail. Instead of being black, or dark brown, it is of a cinereous, and, in some places, of a reddish colour. It is extremely porous, and therefore light; and its grain rough and dry, not unlike that of some sand-stones. Its odour is argillaceous, and it adheres strongly to the tongue, like a burnt bone. When immersed in water, it imbibes it with a hissing noise, and saturates itself with it.

Besides that it gives no sparks whatever with steel, this lava has not the smallest effect on the magnetic needle, except when some small particle of specular iron still remains within it; for though the latter principally covers the external surface of the lava, a number of microscopic laminæ glitter, here and there, in its internal pores.

The small feltspar crystals in this changed lava are entire, but their natural brilliancy is diminished, and they are cracked. It is necessary to look with attention to distinguish them from the substance of the lava, as their colour is the same; but they are much more easily discernible when the lava has been exposed to the furnace, since they

brilliancy to distinat they are since they have then acquired a greater degree of whiteness, and are seen through a thin blackish crust of enamely-into which the surface of the lava is changed. This, however, in a few seconds, is entirely freed from the oxygenous gas, and a homogeneous but ebullient enamel produced.

The great analogy between the alteration undergone by this lava and the changes produced in sany others by the action of sulphureous acids, sufficiently shews that it proceeds from the same cause. This is likewise evidently confirmed, by the thin crusts of sulphate of lime with which it is coated, and which have been generated by the sulphureous acids, combined with the small portion of lime contained within the hornstone.

It will here not be improper to give a concise account of some observations of a similar kind with those I have made, that by comparing we may be enabled to deduce such

conclusions as may elucidate the subject.

The first author, who, to my knowledge, has spoken of crystallized iron adhering to volcanic matters, is M. Faujas in his Mineralogie des Vulcains. He tells us that he found at Volvic, in Auvergne,* a homogeneous and heavy lava, from the surface and fissures of which projected a great number of small thin plates of iron, which had the lustre of the finest polished steel. Though he does not give their size, there is reason to believe they must have been almost microscopic; since he says a lens of considerable magnifying power was necessary to discover that some of these plates were eigments of hexagonal prisms, and that others consisted of two hexagonal pyramids joined at the base. They were attracted by the magnet. The lava to which they adhered, according to him, was basaltic, but greatly altered, having become white, cracked, friable and softened.

M. De Larbre, physician at Riom, examined with great care, both the iron of Volvic above-mentioned, and that I the Puy de Dome and Mont d'Or in the same province.† The crystals of the latter iron are sections of octahedrons similar to those of alum, and sometimes perfect octahedrons. It is at Mont d'Or that the crystallizations, or plates, of specular iron are most beautiful and distinct. The largest are about an inch and a half in breadth, somewhat more in length, and about a line and a half, or at most two lines in thickness. The faces of the plates, when viewed with the lens, discover streaks and diminutions which prove the accumulation of a number of small

laminæ

The specular iron of the three above-mentioned places in Auvergne possesses a magnetic quality, and many pieces of it attract the magnetic needle on one side, and repel it on the other.

M. De Larbre remarks that the specular crystallized irons of Mont d'Or, the Puy de Dome, and Volvic, have the same matrix, that is, a cellular and pumiceous lava;

and that this lava has been more or less changed by the action of acids.

Lastly, a third specimen of the crystals of specular iron has been described by the commendator Dolomieu, which was found by him on some solid lavas, at Jaci Reale, and on different scoriæ, which had been changed and softened by acid sulphureous vapours, in the crater of Monte Rosso. Those found at the former place were thin shining plates, of a regular hexagonal figure, hard, slightly attracted by the magnet, and the largest not exceeding a line and a half. Those of Monte Rosso consisted only of small, thin, irregular scales.

* Now the department of Velay. T.

[†] See his Dissertation in the Journal de Physique par l'Abbe Rozier, l'an. 1786.

When I compare these observations on specular iron with my own, I find that they greatly resemble them. The iron described by these authors is, like mine, crystallized; but the crystallization is different, and the laminæ of the iron of Stromboli are larger than those of that of Auvergne and Etna. The beautiful lustre, like that of steel, and the magnetic virtue, are the same in both. The formation of the crystals of Auvergne is observed to arise from the apposition of small scales, as I observed in mine, only that, in the latter, it is more distinctly seen. Lastly, the lavas in which this specular iron is

found excepting those of Jaci Reale, have all undergone a change.

This identity in the effects naturally induces to conclude an identity of cause. The three naturalists above cited are of opinion, that the formation of these martial crystals is to be ascribed to the volcanic fire; by the action of which the metal was separated from the lava of which it made a part, and sublimed; and that afterwards, falling on the surface, and into the clefts, it there attached and collected, taking a regular form. This explanation is, certainly, not only the most natural, but is confirmed by facts; since iron, in crucibles, using certain precautions, crystallizes in a similar manner, as has been observed by MM. Grignon, Faujas and Buffon. I am therefore of the some opinion relative to the specular iron of Stromboli, that is, that the vehement heat of the fire deprived the lavas of this metal, by subliming it, which afterwards attached to their surface, producing laminated crystals, more or less large, and more or less numerous, with those varieties which usually accompany crystallizations. In fact, while almost all the other lavas of Stromboli move the magnetic needle, those which have crystallization of iron on their surface, have not the least effect on it; no doubt because they are in a great measure deprived of that metal. But as, in general, the fire has acted on the other lavas, in the same manner as on those which exhibit the specular iron, and as, besides, the specimens of the latter are not numerous in volcanized countries (since, excepting the places above-mentioned, and some of the Phlegrean-fields,* I know none where this crystallized iron is found) it seems not to be doubted out some other circumstance, besides the fire, must concur to its formation; which perhaps may be the union of the iron with the muriate of ammoniac, as it is well known that by such a union that metal is sublimed and passes into the nature of specular iron.

We have seen that the specular iron of Stromboli is, in many places, covered with sulphate of lime; and since this sulphate derives its formation from the action of the sulphureous acids, they must have acted likewise on the metal, the crystallization of which is anterior in its origin to this neutral salt, which closely invests and covers it. But though these acids are sufficiently powerful to attack and decompose the most solid and hard lavas, they have not been able to make any impression on the specular crystals, which have likewise resisted all the shocks of other destructive causes, among which the aeriform fluids floating in the atmosphere are no small part, and still retain that brilliant lustre which they received at first, notwithstanding the antiquity of their production, which is probably the same with that of Stromboli itself, of which the annals of time afford no memory. For, in fact, these crystallizations being found adhering to a rock formed of strata of lava, which serves as a foundation to almost the whole superstructure of the mountain, we cannot recur to any times known to history, but must go back to that most remote period in which the island was formed by subterrancous con-

flagrations.

We have now finished the description of the volcanic products of Stromboli; I mean the sand, scoriæ, lavas, tusas, pumices, and specular iron. Omitting this metal, the pu-

mices, and the tufa, three productions which occupy only a small corner of Stromboli, this island may be said to be formed, as far at least as externally appears, of scoriæ and lavas; and since these scoriæ and lavas have been shewn to derive their origin from porphyry rocks, partly with the horn-stone base, and partly with that of the petrosilex, it must be concluded, that the material origin and increase of Stromboli is to be attributed to porphyry, which, melted by subterranean conflagrations, and rarified by clastic gaseous substances, arose from the bottom of the sea, and, extending itself on the sides, in lavas and scoriæ, has formed an island of its present size. These porphyry rocks likewise still furnish mater for the present eruptions.

Before I conclude this chapter, I must not omit two inquiries which I consider as of no little importance. In my researches relative to volcanos, I have proposed as a rule, to subject the volcanized bodies to the action of the furnace, in order to compare the activity and manner of action of the subterranean fires with that of our common fire; and I have found this practice, and expect still to find it, not a little instructive. But with respect to the Eolian isles, which I have studied with the greatest attention, I have

judged it proper to make other experiments of the following kind.

Having ascertained, by various observations, the different kinds of primitive rocks, which by their fusion have contributed to the formation of each of these islands; I resolved to subject to the furnace, rocks of a similar nature, but brought from countries not volcanic, remarking in what manner they are affected by our common fire, and thus make a comparison of another kind, which must be of equal utility with the former.

To this inquiry, which has perhaps been first made by myself, I shall add another, relative to the accounts left us by the ancients concerning the conflagrations of Stromboli, which I shall state and consider. I shall proceed in the same manner with respect to the other islands, as an examination of these accounts will enable us to compare the present state of these countries produced by subterraneous conflagrations with that of former times.

With respect to the first object of research, as the principal materials of Stromboli derive their origin from rocks of porphyry, I shall briefly relate the results of experiments made on different kinds of this stone, in its natural state, exposed in the usual manner to the furnace; and I request my courteous readers to endure the fatigue of

reading these experiments, since I endured the fatigue of making them.

I. This porphyry is Egyptian. Its colour is a dark red, i's base compact; and its recent fractures fine and earthy. It gives sparks plentifully with steel, and breaks into irregular pieces. The base includes a few black, shining, linear and opaque, shoerls; with abundance of feltspars of two kinds; the one quadrangular, of a pale red colour, and almost opaque; the other likewise quadrangular, but transparent and brilliant. It is well known that this porphyry takes a fine polish, which renders it very beautiful to the eye.

After remaining twenty-four hours in the furnace, it is perfectly fused; when it is changed into a black enamel, minutely spotted with ash-gray points, which are feltspars. These, therefore, continue entire. This enamel abounds in pores, gives fire with steel,

but less than the porphyry, has a lively lustre, and is transparent in the angles.

If this stone remains in the furnace eight-and-forty hours successively, it becomes a compact enamel, uniformly black, from the complete fusion of the feltspars, which then form with the base one homogeneous whole.

It has been the opinion of many celebrated naturalists, that the base of the Egyptian porphyry is a jasper; but the easy fusion of it in the glass-furnace convinces me of the contrary; and I find one of the most eminent of our modern lithologists agrees with me vol. v.

in that conclusion. To obtain, however, as much certainty as possible, on this point, which I considered as important, I exposed some jaspers to the heat of the same furnace but no fusion took place. The following are the results of my experiments on five different kinds of jasper, which I exposed, in small fragments, to the fire of the furnace,

during forty-eight hours.

The first jasper was of the yellow colour of honey, interrupted with red streaks, with a grain rather siliceous than earthy, and received a beautiful polish, though with little lustre. This became lighter, extremely friable, of a colour approaching that of iren, the red streaks having acquired that of scaling-wax. No fusion followed, except in some parts, which, being higher than the rest in the crucible, had been more exposed to the violence of the fire, and were covered with a very thin vitreous coating.

The second jasper was of the yellow colour of wax, of a fine grain, and siliceous, gave sparks plentifully with steel, and took a very beautiful polish. This only underwent a considerable degree of calciument, by which it became light, friable, full of

cracks, and of a blackish-brown.

The same colour, and the same calculation, without any sign of fusion, was observable likewise in a third jasper, of a blood-red colour, of an appearance between the siliceous and the argillaceous, and less hard than the second kind.

A fourth and fifth species equally resisted fusion. One of these was of a dark-red, and the other of a mixed colour. Both were of a grain rather siliceous, gave sparks with steel, and, like the other three, were entirely opaque.

These five kinds of jasper were brought, some from Lower Hungary, and some from

Germany; and all the five, as has been seen were infusible in the glass furnace.

The experiments I have here described perfectly agree with those of M. D'Arcet, who found the same infusibility in four kinds of jasper, notwithstanding they were reduced to powder, and exposed to the action of the most violent fire employed in the manufacture of porcelaine. M. Mongez found this stone equally infusible with the blowing-pipe.

These facts, therefore, convince me that the base of the porphyry cannot be a jasper; for, had it been, it would not have melted; I must add, likewise, that I obtained the

same easy fusion from two other kinds of oriental porphyry.

Dolomieu and Delametherie, who both agree that the base of the Egyptian porphyry is not jasper, differ, nevertheless, as to what this base is, the former maintaining it is petrosilex, and the latter that it is horn-stone. The chemical analysis, however, adduced by M. Delametheric of a red porphyry, similar to mine, which shews its base to be horn-stone, induces me to prefer his opinion to that of the other French naturalist. I have not yet had leisure to examine chemically the Egyptian porphyries which I exposed to the action of the fire; but of this operation, which I certainly shall not omit, I shall give an account hereafter, when, in another part of this work, I shall have occasion to say more of volcanic porphyrics. At present, let us return to our subject.

II. This porphyry, which has the petrosilex for its base, is of a blueish red, of a grain moderately fine, angular in its fractures, of middling hardness, and heavy. It contains very brilliant quadrangular scales of feltspar, and a few small leaves of black mica.

In the furnace this stone produced a compact enamel which gave sparks plentifully with steel, very even in its fractures, transparent at the angles, and of a dark cinereous colour, with some black spots, which were half-fused mica. The feltspars remained entire, but calcined. This enamel, on the surface where the heat had acted with most violence, was invested with a very thin vitreous coating, which was semi-transparent, and of a topaz colour.

III. In this porphyry, the feltspars, which were in round scales, but little brilliant, and of a yellowish colour, are included in a petrosiliceous ground, of a reddish brown, of a scaly fracture, and which contains points of steatites.

To melt it entirely, it requires a continuance of thirty six hours in the furnace, when a dully transparent, hard, compact glass is produced, of the colour of the common chalcedony, in which the feltspars are preserved entire, though changed to a milky

whiteness.

IV. The petrosilex, which is the base of the present porphyry, and which, both in its substance and grain, approaches very near to the common flint, is semi-transparent, of an olive green; its feltspars are quadrangular, and of a changing aspect.

It is infusible in the furnace, except on the surface, which is changed into a transpa-

rent and compact glass, without the fusion of its feltspars.

V. The feltspars in this porphyry are very brilliant and sparkling; they are found in a petrosiliceous ground, of a pale rose red, scaly, opaque, and of moderate hardness.

In the furnace the feltspars lose, by calcination, the beauty of their changing colours, and their compactness from the number of cracks they contract: the petrosiliceous base is likewise transmuted into a dully transparent glass, of the colour of soot.

VI. This porphyry is extremely compact, hard, and heavy. Its base is a clear red petrosilex, of an equal grain, smooth, and containing small quadrangular scales of bril-

liant feltspars.

A continuance in the furnace of not less than forty-eight hours is necessary for this porphyry to acquire an imperfect vitrification. It is then transparent at the angles, of a black colour, and has lost its natural hardness: the feltspars it contains, however, show

no signs of fusion.

Besides the six porphyries already described, the base of which is petrosilex, I made experiments, in the same fire, on some specimens of pure petrosilex, of which I shall not give a particular account, to avoid superfluous prolixity. I shall only say, in general, that I found them refractory, that they abounded in silex, and that they formed, as it were, the point of transition of the petrosilex into the silex. On the contrary, all the rest are more or less fusible.

I likewise made similar experiments on some natural porphyries, with the horn-stone

base; many of these having likewise suffered the fires of Stromboli.

VII. The base of this porphyry is not sufficiently hard to give sparks with steel. It is of a dark gray, earthy, unequal in its fractures, soft to the touch, yielding a sensible argillaceous odour, and containing, besides some grains of a crystal and pellucid quartz, a great number of white feltspars, which being easily cut with a penknife, shew how great a change they have undergone from the influence of the seasons and the atmosphere.

The furnace changed this porphyry into a black scoria of little consistence, and its

feltspars assumed a vitreous appearance, though without any sensible fusion.

VIII. This stone, at first sight, would rather be taken for a granite than a porphyry, as we find in it quartz, mica, and feltspar, did we not observe that the three latter substances are united in a common cement or paste, which is a horn-stone, rather soft, of a cincreous colour, and an argillaceous odour.

The three substances remain entire in the furnace; but the ground in which they are

included is changed into a hard, black, and shining enamel.

IX. The base of this porphyry is a horn-stone of rather a fine grain, sufficiently hard to give sparks with steel, of a greenish colour, and emits a strong earthy odour. Some of its feltspars form rather large irregular masses of a brick red colour; and others small quadrangular crystals of a light yellow colour.

This stone is changed by the furnace into a black enamel, moderately inflated, and hard. Its feltspars, however, remain entire, only with the change of their red colour into a white.

X. The horn-stone of the present porphyry is laminated, of a smooth surface, easily cut with the knife, and of a reddish-green colour. Its feltspars are rhomboidal; and some are four lines and a half in length and three in thickness.

In the furnace they remain unaltered; but the ground of the porphyry is changed into

a black and hard scoria, full of little bubbles.

I shall omit the description of many other porphyries, the base of which was in like manner horn-stone, and on which I made the same experiments, since the results were essentially the same with those already stated. I shall only mention that these different species of porphyry, some of which had the petrosilex, and others the horn-stone for their base, were brought from those parts of Hungary and Germany, where, according to the observations of scientific travellers, no traces whatever of volcanization are discoverable.

If we now compare the effects of the volcanic fires and our common fire on these various kinds of porphyries, we shall find that the principal difference is, that the furnace vitrifies them, destroying their original structure, whereas the fires of Stromboli seldom change their natural lineaments. In both cases we find the feltspars, for the most part, remain infusible; but what appears of most importance to the present object of our research is, that the stones with a petrosiliceous base, as well as those with that of horn-stone, may be fused in a strong heat (such as that of the glass furnace) and without its being necessary to have recourse to the most vehement that can be procured.

From these experiments we learn, therefore, in what manner the subterranean fire of Stromboli, even though we should not consider it as extraordinarily active, may have been able to melt, and may still continue to liquefy, the rocks of porphyry which have existed, and still exist, in the abysses of that mountain. The facility, likewise, with which its lavas may be re-melted in a glass furnace, is a strong confirmation of the hypo-

chesis.

With respect to the time when this volcano began to exert its activity, and to melt these rocks, we are profoundly ignorant, this being an epocha anterior to all history. We must be contented with the imperfect accounts the ancients have left us of the conflagrations of Stromboli, which did not but forth in their time, but ages before. Of these accounts I shall proceed to give a concise view, this being the second inquiry it was proposed to make, and it will necessarily be brief, as the notices left us on this subject by the ancients are extremely few.

Eustatius, Solinus, and Pliny, inform us that the flames of Stromboli are less powerful than those of the other islands of Lipari, but that they exceed them in clearness and splendour. These writers, however, were only the copiers of Strabo, or perhaps some abridgment of him, in which he is copied incorrectly. We shall therefore have recourse to that celebrated Grecian geographer himself; who, after having mentioned Lipari and Vulcano, and informed us that Stromboli likewise burns, tells us that the last island compared to the others, is inferior to them in the violent eruption of its flames, but that it exceeds them in their brightness.**

It is evident, that by "the others," Strabo means Vulcano, which was the only one of the Eolian isles, besides Stromboli, in a state of conflagration in his time. When I compare Stromboli with Vulcano, I perceive that, even now, there is this difference

[&]quot; 'Fri di (Στρογιύλη) και αυτη διάπυρος, βία μέν φλυγός λοιπομένη, τω δί φίγβοι πλουσευτώσα. Lib. vi.

between the two islands, that the flames of the former are much more resplendent and lively than those of the latter, as will appear when we come to treat of Vulcano; but I cannot say that those of Stromboli are less violent, as the contrary is certainly the fact. We must, however, conclude, that in those ages, the cruptions of Vulcano were very strong and frequent, which agrees with the testimony of Diodorus, and that of Agathocles as cited by the Scholiast on Apollonius; the former of whom asserts, that, in his time, Vulcano and Stromboli vomited great quantities of sand and burning stones,* and the latter, that these two islands threw out fire, both by day and night.†

There is another circumstance mentioned by the Sicilian historian which deserves notice. This is, that a wind issues from both these islands with a great noise. This, in some measure, agrees with the observations I made at Stromboli; and is still more applicable to the other island, as will be seen when I come to give an account of Vul-

Philip Cluverius, in his Sicilia Antiqua, speaking of Stromboli, tells us that its crater is situated at the summit of a mountain, from which it pours forth, both by day and by night, with a horrible noise, bright flames, and great quantities of pumice.‡ In one of the plates prefixed to his work, this island is represented with the smoke rising from the

summit of the mountain.

Nearly one hundred and seventy-three years have now elapsed since this author travelled in Sicily. Ought we then to conclude, that, at that time, the mouth of the volcano was situated at the summit of the mountain? Had the learned antiquary himself visited the island, I could not have objected to his evidence. But he not only does not say this, but the contrary may be inferred from his own words. Immediately after the passage I have already cited, he adds, "sed perpetui ejus ignes eminus navigantibus, nocte tantum, conspiciuntur. Fumum corum candidissimum ex Italiæ pariter ac Siciliæ littoribus conspexi." It is therefore evident that he saw this volcano only from a distance, and that, consequently, his assertion, that the fiery crater was situated at the summit, is not to be depended on. What he has said of the pumices then thrown out by it, he may have taken on the credit of some of the natives who gave him that information, and who confounded the scoriaceous lavas with pumices; or it may in fact be true, since under the scoriæ and lavas of Stromboli, scattered pumices are found, as I have observed above.

From the authorities above adduced it appears, therefore, that the most ancient accounts of the conflagrations of Stromboli, transmitted to us by history, are prior to the Christian era by about two hundred and ninety years, the date of the reign of Agathocles the celebrated tyrant of Syracuse. This volcano burned likewise in the times of Augustus and Tiberius, when Diodorus and Strabo flourished. But after this latter period, a long series of ages succeeds, during which, from want of documents, we are ignorant of the state of Stromboli, and it is not until the seventeenth century that we again know, with certainty, that it ejected fire; though it is not improbable that it continued to burn likewise during the times in which we find no mention of it in history: on which supposition, its uninterrupted conflagration, for so great a length of time, must indeed appear astonishing. Yet, though it should have ceased for several ages, we know, from

^{* &#}x27;Εν δι τη Στρογίολη, και τη Ιερο, μιχρι τα του, οκ των χασματών εκπιπθοι πιομαθος μοροθος, και βρομος εξαιτιος. εκφοσαται δι και αμμος, και λιθων διαπορών πληθος, καθαποριείε ορών και περι την Αιτναν γινομείτε. Lib. v.

‡ Strongule hodieque liquidissimam flammam, et pumices magna copia, ex vertice, ubi craterem habet, noctes atque dies, cum fremitu horrendo, cructat.

various public testimonies, that its continued eruptions cannot have lasted less than two hundred years.

Here our curiosity may naturally be excited by the question, What are the substances which, without diminution, have nourished, during such a number of years, and still continue to feed these fires? I do not perceive that there is any reason to suppose them different from those which furnish fuel to the intermitting volcanos, except that their source appears to be inexhaustible. It is believed, with much reason, that sulphur produces and continues volcanos; and wherever these mountains burn, we have indisputable proofs of its presence. Still more effectually to explain these conflagrations, petroleum has likewise been called in aid; and, in fact, it has sometimes been found to issue in the neighbourhood of a volcano, of which Vesuvius is an example.* The clouds of thick black smoke, which frequently rise into the air from the mouths of volcanos, and the unctuosity and sootiness, which are said to be found in the recent scoriæ, seem likewise to be evident indications of some bituminous sublimate.

That Stromboli contains within its deep gulfs and recesses an immense mine of burning sulphur, we can entertain little doubt, when we consider the streams of smoke, of extraordinary whiteness (a colour which constantly accompanies sulphurcous fumes) that rise on the west side of the island, and the smell of sulphur, not only perceptible from them, but from the large cloud of smoke which overhangs the summit of the mountain. The small pieces of that mineral produced near the apertures whence those fumes arise, are likewise another proof. But of the presence of petroleum, and its effects, I have never perceived the least sign. Besides that no vein of it is found in the island, nor any ever seen swimming on the sea which surrounds Stromboli, as I was assured by the general testimony of the inhabitants, the smell of this bitumen is no where sensible, though naturally it is very acute. I have frequently visited the sources of petroleum, at Monte Zibio, in the territory of Modena, and I could always perceive the smell of their penetrating vapours, at the distance of several hundred paces before I reached them. I therefore conclude, that these vapours must have been much more sensible at Stromboli, as they would have been much more active, had petroleum actually burned within its gulf. I have likewise examined, with the greatest attention, the scoriæ thrown out by the volcano, and while they were very hot; but I never could perceive that they emitted, either from their surface, or within their pores and cavities, the least smell of that bituminous substance, or that they any where exhibited any unctuous humidity. As I knew that the smoke which exhales from burning petroleum is of a blackish hue, I suspected that the thick and dark column of smoke, which arose to the cast of the volcano, might be a sign of its presence; but, on a nearer appreach, I perceived that its darkness proceeded from aqueous vapours which were mixed with it, and which, by my continuing a short time in it, rendered my clothes damp and wet.

Shall we then affirm that the fires of Stromboli receive no kind of aliment from this bitumen? Notwithstanding the observations I have stated, I would not venture confidently to deduce such a conclusion; since it is possible that the petroleum may burn under the mountain, at so great a depth, that its vapours may not reach to the top, but may be dispersed and consumed by the fire, and the immense mass of liquefied matter,

which probably extends from the crater to the lowest roots of the island.

But though we should not admit the existence of this oil within the deep recesses of the mountain, I do not perceive but the sulphur alone may be sufficient for the nourish-

^{*} Serao, Istoria dell' Incendio del Vesuvio, del 1737. Bottis, Istoria di varj Incendi del Monte Vesuvio.

ment of the volcano, when its flame is animated by oxygenous gas, the presence of which, in volcanic abysses, seems undeniable, from the substances they contain proper to generate it, when acted on by the fire. The long duration, without intermission, therefore, of these conflagrations, may be very sufficiently explained by the immense quantities of sulphur, or, to speak more properly, sulphures of iron which we must necessarily suppose contained in the bowels of the mountain; a supposition rendered the more probable by the prodigious subterranean accumulations of this mineral which have been discovered in various parts of the globe.

CHAPTER XII.

BASILUZZO, BOTTERO, LISCA-BIANCA, DATTOLO, PANARIA, SALINE.

Basiluzzo, in part, formed of granitous lavas....Its sterility....Uninhabited....Bottero and Lisca-Bianca, two rocks, in many places decomposed by acid vapours...Sulphurated hydrogenous gas (hepatic gas) issues from the sea near these rocks, which still probably, cover the remains of fire.... Dattolo formed of lavas in a great measure decomposed....Panaria formed of granitous lavas.... This island fertile and inhabited....Probability that this group of rocks and small islands are the remains of a vast ancient volcano....Saline formed by an accumulation of currents of lavas.... Course of these currents to the south of the island....Their various stratification and nature.... Some remains of craters on the summit of this island....Result of experiments in which natural granites were exposed to the furnace, to compare then with those which, by the action of subterranean fires, have contributed to the formation of Basiluzzo and Panaria....An extremely strong fire required for their fusion....A fire equally strong required for the re-fusion of these granitous lavas....Consequence which appears naturally to follow from the great violence of the volcanic fires required to produce the granitous lavas of these two islands.

THOUGH this chapter will contain an account of several islands, it will be very short; since several of them are rather rocks than islands, and they have all been so carefully examined by the commendator Dolomieu that little remains for me to add to his observations. The first five are situated between Lipari and Stromboli, and it is manifest to occular inspection that they are the work of fire.

Basiluzzo is about two miles in circumference, and is raised some poles above the surface of the sea. On the south side is a narrow bay, which I entered on the morning of the 7th of October, on my return from Stromboli to Lipari. I went on shore, and, by a winding path, soon reached the summit, which is a plain of no great extent, and the only place capable of cultivation, though it produces only a little corn and pulse. This scanty vegetation is nourished by a thin crust of decomposed lava, under which we soon discover the solid lava, which, in many situations, is granitous, the quartz, feltspar, and mica, being very apparent in it; as has been before observed by the excellent French naturalist above-mentioned; and on making the circuit of the island we find that almost all the remainder of it is composed of similar lavas.

Two little cottages which belong to the proprietors of this ungrateful soil are the only buildings here. Near them are some ancient ruins, amongst which I found a piece of red porphyry, spotted with reddish feltspars. I at first imagined it a volcanic product, but soon changed my opinion; since I could not find any specimen of the same stone on the whole island, and because I was convinced, on a more careful examination, that the fragment in question was an ancient Egyptian porphyry, which had been polished by art, and had never been exposed to the action of the fire. I was therefore

induced to believe, from the circumstances of the place in which I found it, that it had either made a part of the materials of some of those ruined edifices, or, which seemed more probable, that it had been brought thither by the people who had once inhabited them.

Rabbits are the only animals found in Basiluzzo; but these had nearly reduced to despair the few inhabitants of the island, by the mischief they did to their corn, till they at last brought against them an enemy capable of following them through their subter-

ranean holes, I mean the cat.

From Basiluzzo I proceeded to Bottero and Lisca-Bianca, two rocks abounding in crusts of sulphate of alumine (alum) and for the most part formed of lavas whitened, and so decomposed that they are easily reducible to powder. This decomposition has manifestly been the effect of acid vapours, though of these there is at present no sign; except that near these two rocks we meet with a strong smell of sulphurated hydrogenous gas, and following it where it is most powerful, are led to a shallow part of the sea where a great number of air bubbles rise with rapidity, and as soon as they reach the surface burst. This gas it is which produces the smell.

The sea could not have been more favourable for the collecting this aeriform fluid; since when I sailed from Lipari to Stromboli it was stormy and ran high, but on my return was perfectly calm. I secured, therefore, a sufficient quantity of it in some flasks, which I had taken with me in my journey through the two Sicilies, in order to make some experiments on it when I should arrive at Lipari, the result of which I shall

here, as it seems the proper place, lay before the reader.

This gas, when a lighted candle was applied to it, rose in flame, but with scarcely any detonation. It took fire slowly, and the flame was of a reddish blue. It was therefore a sulphurated hydrogenous gas, as more evidently appeared from its having deposited some particles of sulphur in the vessel in which it was fired. The little depth of the sea at the place from which this gas issued, and its perfect calmness, enabled me to make another experiment, by letting down, by means of a small cord, precisely on the place from which this gas rose, one of those thermometers, which, in consequence of being included within several wrappers, slowly receive, and lose as slowly, the temperature to which they may be exposed. After having left one of these immersed under the water for three quarters of an hour, I found, on drawing it up, that the mercury had risen to 28 (96½ of Fahrenheit) though in the atmosphere above the surface it only stood at 20½ (69 of Fahrenheit.) A hot exhalation therefore arose from that part of the bottom together with the sulphurated hydrogenous gas; an observation which renders it probable that a latent fire still remains there. The depth of the water was eleven feet; and it was evident that the bottom was a continuation of the rock Bottero.

Scarcely a mile from Lisca-Bianca and Bottero, towards the west, a third rock rises above the water, named Dattolo, the formation of which is likewise to be ascribed to lavas, in a great degree decomposed like the former, and some of which have an iron-red colour. M. Dolomicu says, that a spring of boiling water gushes out at the foot of it; but all my endeavours to discover this spring were fruitless. The sailors who managed the boat in which I was, and who were natives of Stromboli, and, from making the passage from their island to Lipari, several times in a week, must be acquainted with every part of that sea, and all the rocks it contains, assured me that they had never seen nor heard of any such spring. I shall not, however, venture to deny its existence, but am rather willing to believe, that neither they nor I discovered it from want of attention. Supposing its reality, it certainly is a proof that the conflagration under these rocks is not

entirely exhausted.

ck rises ribed to an ironfoot of the mamaking ed with ver seen ace, but tention, as is not Proceeding still from Stromboli towards Lipari we next arrive at Panaria, which is not a rock but an island, in circuit more than eight miles, though it is but little raised above the sea. The rock of which it is constructed is here, likewise, volcanic granite; but as it is in many places superficially decomposed, and in others mixed with substances very easily decomposable, a rich soil is afforded in various parts of the island, on which olives, and other fruit-trees, cultivated by many families resident here, luxuriantly flourish.

We must therefore ascribe the origin of this group of rocks and islands to submarine conflagrations. But are we to conclude that each of them owes its formation to a particular volcano, or that these rocks and small islands are no other than the remains of a very ancient larger island, in a great degree destroyed by the powerful action of the waves of the sea? M. Dolomieu is of the latter opinion, in support of which he adduces many plausible arguments, conjecturing that this island was the ancient Euonimos, the seventh of the Eolian isles, which, according to Strabo, lay on the left in sailing from Lipari to Sicily, which is exactly the situation of the small islands I have described. I shall not repeat the reasons by which he supports this conjecture, but refer such of my readers as may be desirous of examining them to the author's own work.

Late in the night of the same day I returned to Lipari, where I had my residence, and whence, from time to time, I made excursions to the other neighbouring islands. As the sea was perfectly calm during the whole of that day, we could make no use of our sails but were obliged to perform the whole passage by the assistance of our oars. So great a calm in that sea, which is usually tempestuous, is extremely rare; and, indeed, during my whole continuance among these islands, I did not witness such another day.

In the morning I embarked for Saline, which is so near to Lipari, that by the aid of a light easterly wind, I arrived there in less than an hour. This island derives its name of Saline (or the salt pits) from the muriate of soda (sea salt) which is dug on one part of the shore. It was anciently called Didyme, or the twin, from its appearing at a distance bifurcated, though on a nearer approach it is found to be trifurcated, as its summit terminates in three points. Among all the Eolian islands, this, after Lipari, is the largest, since it is more than fifteen miles in circuit. From the examination which I made of its shores, and the parts of a moderate elevation, I ascertained that its structure was an accumulation of currents of lavas. Of these M. Dolomicu has examined and described several: I principally fixed my attention on those which descend from the south side of the island to the sea. It is evident that they have flowed from the summit of the mountain, and fallen almost perpendicularly into the sea, after a course of a mile or more. But it is, at the same time, equally evident that these currents have flowed at different periods. In many places they are found with deep fissures, though it is difficult to say, whether these have ar sen from the lavas suddenly congealing, and thence contracting and opening in many places, or whether they have been produced by the action of the rain waters or by some other cause. However this may be, these fractures are a kind of anatomic dissections of the lava, which show that the upper coat of it lies upon another, and that upon a third, below which are many others. It is also to be remarked that these strata are commonly specifically different from each other. We must therefore conclude, that as many currents of lava have flowed from the highest part of the mountain, to the south, as there are distinct strata; and it is probable, that were we able to penetrate to the most internal part of the island, we should find the whole, or almost the whole of it, of a similar formation.

This certainly is the structure of almost all volcanic mountains. Their beginning is but small, and proportionate to the quantity of the first eruption; but as the succeeding vol. v.

eruptions increase in number and extent, they augment in size and solidity, till in time they acquire considerable dimension. In this manner, in fact, appears to have been produced the immense bulk of Etna, Vesuvius, the islands of Lipari, and many other burning mountains. I do not, however, deny that there are some which are the offspring of a single cruption, as Monte Nuovo, near Pozzuolo, and Monte Rosso, on the side of Etna.

It appears to me superfluous to particularise the different qualities of the lavas, since as has been observed by M. Dolomieu, they are common to other volcanos. I shall only remark, in general, that I did not find one which can properly be called simple, as they all abound, more or less, with feltspars and shoerls, and have for their base the petrosilex, and the horn-stone.

No traces, at present, remain of those volcanic fires which have produced Saline, except the currents of lava, and some vestiges of ancient craters on the summits of the mountain.

When treating of Stromboli, we found that the natural rocks, which by their fusion, gave birth to the island, were a species of porphyry, having for their basis either the petrosilex or the horn-stone. We have now seen that the rocks to which Saline owes its origin are of the same kind. But the formation of Basiluzzo and Panaria has been different; the rocks which have there been converted into lava by the action of the fire being granitous; and it seems probable that the spacious volcano, which it has been conjectured, once arose in the sea between Stromboli and Lipari, and of which, at present, only some small remains exist in Basiluzzo, Dattolo, and Panaria, derived its origin from the same stone.

In pursuance of the plan I have prescribed to myself of subjecting to our common fire some natural rocks similar to those from which the Eolian isles have been formed, I shall here describe the effects produced by the furnace on different specimens of granite; and I must add, likewise, that the difficulty with which, it is well known, granites are fused in our common fires, was to me a considerable inducement to make these experiments.

The furnaces which are worked at Pavia, at a certain season of the year, only fuse common glass, that is, such as is blown into small vessels, and is but little transparent, of a yellowish or greenish colour, and usually full of bubbles; but at another season they will melt fine crystal glass, manufactured for the same purposes, and which is white, transparent, and much purer. The greater part of the volcanic productions mentioned in this work, as also the analogous natural stones, have melted in the furnace in which common glass is made; but the specimens of granite have proved more refractory, and in the same degree of heat have only been rendered friable from the enfecbled affinity of their aggregate parts; or, at the utmost, a few of them only have been found covered with a thin vitreous varnish. I was therefore obliged to have recourse to the furnace in which the crystal glass is elaborated, when the heat was nearly 87\(\frac{1}{3}\) degrees of Wedgwood's pyrometer, or, according to the observations of Mr. Wedgwood, only 2\(\frac{1}{3}\) degrees less than the welding heat of iron. The following are the results afforded by several species of granite, after having been continued in this heat during forty-

1. Granite of Mount Baveno, in the Milanese. This granite, which forms a great part of the materials of the principal public and private edifices in Milan, Pavia, and other towns in Austrian Lombardy, has for its constituent principles, quartz, mica, and feltspar. There are two varieties of it; one, in which the feltspar is white, and the other, in which it is of a more or less deep flesh colour.

The fire changed the mica, and produced a beginning fusion in both the varieties of

feltspar, which abounded with microscopic bubbles, without however acting as a flux to

the quartz, which, calcining, acquired a whiteness, without, however, losing its vitreous

nature, and the degree of transparency it possessed. The sharp angles and projections,

if they are feltspathose, become blunted and round; and the fragments, if there are

more than one, adhere in consequence of the slight fusion of the feltspar, but they never incorporate into one mass within the crucible; on the contrary, they become ex-

II. Mount Baveno likewise produces a granite which may be considered as a different species from that now described, and which is equally used in buildings. It is schistous, and easily separates into large flakes. The mica, which is of a shining black, instead of being dispersed within it in separates scales, extends in broad leaves, placed one over the other; and the quartz and feltspar are frequently distributed in flakes.

This granite loses its solidity in the fire, without fusion; but the mica and feltspar

shew evident signs that they have been softened.

III. Granites of the Italian Apennines. Though a considerable part of the Alps which surround Italy abound with these rocks of the first formation, they are very rare in the Apennines, which are principally formed of calcareous stone, sand, sand stones, and steatites. In the various excursions which I have made to different parts of them, I have rarely found this stone, and never but in very small quantities and detached pieces, without being able to discover whence they came. In the spring of the year 1790, I collected some of these scattered pieces in the river Stafora, at the foot of a hill, a few miles from the town of Voghera. They were of three species: the following are the distinguishing properties of the first.

Its constituent principles are four: the quartz, of the colour of water, scattered in small but numerous pieces; the black raica, in few and extremely minute flakes; the feltspar, rather abundant, and of the colour of honey; and very small shoerls, included

within the feltspar.

The pieces, except they adhered together, retained, when they came out of the fire, the same figure they had before, though the feltspars were a little, and the shoerls en-

tirely fused.

The second of these granites, with respect to its component principles, is similar to the common, consisting of mica, feltspar, and quartz; but it is one of the hardest and most beautiful that I have seen, and takes a very elegant polish.

In the fire the quartz becomes almost pulverulent, the feltspar assumes a slightly enamelled surface, and the fusion of the black mica covers the pieces with a thin coating

which has an unctuous appearance.

The third granite has for its component principles semi-transparent quartz in small

and rare grains, and feltspar in large and numerous particles.

In the furnace the quartz becomes friable, but in the feltspar we only perceive signs that it is softened.

IV. In chap. XI, I have mentioned an Egyptian porphyry which was exposed to the fire. I shall now add that this stone, from porphyritic that it was, became in many places granitous. In consequence, therefore, of torcible separation, or insensible alteration, the mass of porphyry may be lost, and succeeded by the granite, composed of shoerls, abundant feltspars, and argillaceous particles.

In the furnace, this granite imperfectly fuses into an ebullient scoriaceous enamel.

V. This granite, as it contains sulphure of iron, and red sulphurated oxyde of mercury (cinnabar) merits a particular description. It forms a mountain in the district of Feltre, in the Venetian territory; to the east of which lies the Valle Alta, to the west

the Acqua Pezza, to the south the Bosco delle Monache, and to the north Vallone. Some years past, this rock was dug into, and perhaps is still; not to employ it in building, but to extract the mercury with which it is impregnated, and of which it furnishes fifteen parts out of a hundred. This interesting information I received from Signor Francesco Antonio Tavelli, student of natural history, under whose directions these excavations were undertaken, in the year 1786. He furnished me with several fine specimens of this rock, which I immediately perceived to be grante. Its component parts are quartz, in crystallized grains; feltspar, in lamellar, semi-transparent, whitish sca. s; and steatites. The latter does not form a paste, or common cement, which conglutinates the quartz and feltspar but is distributed in such a manner, that these three constituent parts adhere together solely by the force of attraction. The steatites is soft and schistons, and of a dark green colour. This is the only part of the granite to which the sulphur has penetrated; to free it from which, it is necessary to break it into small pieces. The sulphur, therefore, has sometimes mineralized the mercury and sometimes the iron. Some parts, however, of seven or ten lines, and frequently even an inch and a half, or two inches, in thickness, are of a lively red, though the steatites has lost its peculiar texture; and these parts, as they abound most with mercury, are the heaviest. The rest, on the contrary, are lighter, as they contain a less quantity of this metal; and hence, likewise, their colour is of deeper or paler red. In the midst however of this diversity of tints, the feltspar and quartz seem to have been impenetrable by the sulphur, and, in the reddest places, still preserve their natural colours and respective degrees of transparency. But in other parts of the steatites, the sulphur has mineralized the iron, producing sulphure of iron. This is of a brassy yellow, and sufficiently soft to decompose in the air, efflorescing, and emitting sulphate of iron (vitriol of iron.) About four years ago, I received from Signor Tavelli at Venice some pieces containing this sulphate, which I put into a box; and a few months after found them to be broken, and covered with a yellowish efflorescence. When touched with the point of the tongue they occasioned a strong astringent taste, from the presence of this sulphate (vitriol) which, in fact, is likewise procured from that rock.

When this granite came out of the furnace, the steatites and the feltspar were blend-

ed into one porous scoriæ, but the quartous grain remained unfused.

VI. The experiments on Numbers IV, and V, are, however, less to the purpose, since, if we should compare, by the means of our common fires, the granites which are found fused at Basiluzzo and Panaria, the constituent parts of which are feltspar, mica, and quartz, and the natural granites; the latter must necessarily be found to consist of the same principles. I have already, as has been seen, made the proof with several, nor did I neglect to do the same with five other species, which I do not describe that I may not tire the reader. I shall only say, in general, that the quartz was always infusible; the mica, in two instances, melted; and the feltspar, every time, gave signs of a beginning liquefaction; which occasioned the pieces in the crucible to adhere together, but without forming a consolidated whole, as the effect of complete fusions.

VII. As. M. Dolomicu has remarked that the Eolian isles have a part of their base of granite, I endeavoured to discover from what places it might derive its origin; and, after several laborious researches among the mountains of Sicily, concluded that it proceeded from rocks of the same species, extending to the mountains of Capo di Melazzo, which are in part formed of granite and have likewise their direction towards this

island.

In my passage from Lipari to Messina (a distance of about sixty miles) I made some stay purposely at this cape, which lies about the midway, judging it to be of importance to examine the nature of the place; and I, in fact, found there granite.

Vallone. in buildfurnishes n Signor ons these eral fine oniponent , whitish hich conthree cons soft and which the nto small ometimes inch and as lost its e heaviest. netal; and of this disulphur, legrees of the iron, to decombout four

nade some

Mica, sometimes black, and sometimes of a silver colour; blucish, and sometimes milk-white quartz; and reddish or whitish feltspar, are the three component parts of this granite, sometimes distributed nearly equally, and sometimes in very unequal portions. Sometimes, though rarely, the mica is hexagonal; and the feltspar shews a beginning crystallization.

This granite is not found in strata, but large masses, which form a considerable part of Cape Melazzo and its environs, and in many places extend quite to the sea. Here, likewise, we discover, under the water, the ruins of a very ancient edifice, built of this

stone.

As, therefore, it appeared extremely probable that this granite was the same with that of which Panaria and others of the Lipari islands are composed, it was more particularly requisite that the same experiment should be made on it in the furnace, which had been made on the other species; and since the proportions of its three elementary parts varied in it, I took five varieties, and placed small pieces of each in separate crucibles.

The result was, that the mica became more fragile, the feltspar exhibited some signs of fusion, and the quartz lost its transparency and became full of flaws. The pieces,

however, all retained their original form.

VIII. In Panaria, and some parts of Basiluzzo, are found pieces of granite, in which the fire appears not to have caused the least alteration; and yet there is every reason to believe that they have been thrown out of the mouths of volcanos, though they are still in the natural state in which they are found in the bowels of the earth. This granite in its three constituent principles, and the qualities of each of them, extremely resembles that of Melazzo. It likewise resembles it in its resistance to the fire, as only some traces of fusion in the feltspars are observable.

IX. Lastly, I made some experiments on certain specimens of granitous lavas, which have formed currents at Panaria and Basiluzzo; but the result was not more successful than with the other granites: they entirely resisted the fire, except that the feltspar was in some places thinly covered with a kind of enamel varnish. This was one of the very

few lavas which was not fusible in the glass furnace.

These facts sufficiently prove that these granites, such at least as are composed of quartz, feltspar, and mica, are infusible in a heat of 87 degrees of the pyrometer of Wedgwood, though continued in it for forty-eight hours; a heat which, as has been said, is only 2½ degrees below that in which iron begins to fuse, which is at 90 degrees of the same pyrometer. I determined, therefore, to expose these stones to that degree of heat, or even a greater, having recourse to a wind-furnace in which iron is completely melted. In this, in less than an hour, a fusion took place which was perfect or little less in the feltspars, and beginning and sometimes complete in the mica; but the quartz shewed no signs of liquefaction. When, therefore, the quantity of the feltspar was greater than that of the two other component parts, the pieces in the crucible formed one single mass, with a smooth surface, either uneven, concave, or convex, in the same manner as in the fusion of lavas. The mass, however, was not homogeneous. The feltspar, whatever was its colour, became of a milky whiteness, extremely smooth and shining, and considerably harder. It is remarkable that the mica which, in some granites, was of a silver whiteness, and in others of a gold colour, is changed in consequence of its fusion to a deep black.*

[&]quot;I shall here add a remark, which I had intended to make in the introduction to this work, but which will not be improperly placed here. As in these fusions I make use of crucibles of clay, it may be objected to me, that I am not certain whether the substances on which I made my experiments were fusible in themselves, or in consequence of their combination with the clay of the crucible. But

These experiments when compared and considered must lead us to conclude that the fusion of granites requires a very violent heat; and with these experiments likewise agree those made on stones of the same kind by MM. D'Arcet, Gerhard, and Saussure. I have said in general, since I do not deny that, in a less intense fire, the fusion of the feltspar may be obtained, in some species of granite, which may draw after it that of the quartz.* Though in the almost endless varieties which I fused and have described in this work, the feltspars in general were refractory; yet they sometimes easily melted in the furnace used at Pavia for the manufacture of common glass, the heat of which, as has been said, is much less than that employed in making crystal glass. This has been proved in the feltspars of the lavas of Ischia, which, whether mechanically united to other substances, or single, completely fuse. † The facility with which some few feltspars melt, and the refractoriness of others I have found to proceed from the different quantity of silex they contain combined with other earths, which is small in the former, and very abundant in the latter. If therefore a granite which has for its base the feltspar contain but a small portion of silex, there is no doubt but its fusion may be obtained with a moderate heat. It is, however, certain, from the experiments above adduced, that completely to fuse the feltspar in the granite of Cape Melazzo, and in the detached pieces of a similar kind found at Panaria and Basiluzzo, as also that which constitutes the basis of the lavas of these two islands, not to mention other species which have been enumerated, a very strong heat is necessary, and equal to that required to melt iron.

It hence appears to be sufficiently proved that the volcanic fires which have produced Basiluzzo, Panaria, and the other neighbouring islands, must have been extremely violent; the importance of which deduction will more distinctly appear when we come to

consider the question relative to the activity of volcanic fires in general.

I answer, in the first place, that this combination rarely happened; and that when it did, it was too conspicuous not to be perceived, as the crucible was more or less corroded. Secondly, that I did not form my judgment of the fusibility of the substances I examined, from the parts of them in contact with the crucible or at a little distance from its sides; but from those near the middle, where, from the distance, this combination could not have place, as the circular mouth of the crucibles I used was two inches in diameter. When, therefore, I speak of the fusion of any product, I consider myself as perfectly certain that the clay of the crucible had no part in it.

* Morveau, in a letter to the Comte de Busson, writes, that two pieces of different kinds of granite, being placed separately in the crucible, in less than two hours melted into a homogeneous glass (Busson Miner. t. i. in. 12.) but he neither specifies the constituent parts of the two granites, nor the de-

gree of heat necessary to fuse them.

CHAPTER XIII.

VULCANO.

Different parts of this island distinctly visible from the summit of the Monte della Guardia, in Lipari....Shore of the island entirely formed of volcanic productions. Vulcanello, a small island, once separated from Vulcano, but long since united to it by an eruption.... Iwo singular lavas of Vulcanello....Its crater....Surrounded by sulphureous fumes and hot exhalations.... Lumps of sulphur found in the earth through which these fumes pass....Grotto celebrated for a medicinal water which it contains, and other peculiarities....Summit of the mountain scattered over with vitreous lavas, pumices, and glasses. The transition of the pumice into glass distinctly observable....Hot sulphureous exhalations on the side of the mountain which has the figure of a truncated cone....The stones found there, whitened and decomposed....Other similar fumes higher up the mountain....Subterranean noise heard there; with a shaking of the earth when struck with the foot....Sulphur formerly extracted at Vulcano by the Liparese, and purified on these heights....This profitable labour now abandoned, and why....New sulphur re-produced where it had been dug up.... The larger crater of Vulcano situated at the summit of the truncated cone.... Descent of the author into the crater.... Its interior described.... Subterranean noise heard at the bottom of the crater....Wind which blows at the bottom generated by sulphurated hydrogenous gas.... Extreme heat of the bottom.... A kind of hill in the middle of it exhaling a quantity of vapours, and incrusted with various minerals....Reverberated sound produced in it by the falling of a stone....Gulf immediately under it in which a strong fire burns....Blueish sulphureous flames seen by night rising from this bottom.... A cavern of considerable size hollowed in the sides of the crater, which descends to the bottom.... Objects most deserving notice in this cavern....Glasses and pumices of this volcanic bottom decomposed by sulphureous acids....Prismacic or basaltiform lavas, which the ever their origin from fire, discovered within it.... Erroneous opinion of M. Sage that the decomposition of the lavas, and other volcanic productions, is to be ascribed to the muriatic acid....Demonstrative proof that these decompositions are the effect of sulphureous acid vapours.... Incidental notice of another error of that chemist, relative to the Grotta del Cane, near the lake Agnano.

AS from the top of a lofty tower which overlooks a spacious and noble city, we command a perfect view of the latter, its circuit and extent, its lofty and sumptuous palaces, and its numerous edifices; in like manner, from the summit of the Monte della Guarda, one of the highest mountains in the island of Lipari, we contemplate with astonishment the circumference, the massy body, and the various distinct parts of the neighbouring Vulcano.

To this mountain I, therefore, repaired, expressly to take a comprehensive view of the island previous to my visiting it; in which, besides the course and inclination of its rocks and cliffs, its craters are clearly perceivable, and it may be distinctly seen that the form of the larger is that of a truncated cone. The white fumes which ascend from it are likewise very visible by day, while by night the atmosphere above the crater assumes an obscure redness. Here too, we may most distinctly perceive the junction of Vulcano to Vulcanello; which latter, as is well known, was anciently an island separated from Vulcano by a narrow arm of the sea, that has since been filled up with earth by a violent eruption. The new land which has joined the islands may be very clearly seen, and appears to be formed of a sterile sand. The two small havens at its extremities, one of which is called the castern, and the other the western, are likewise distinctly visible.

Such was the anticipated pleasure afforded one by this mountain, which was afterwards still more increased, and accompanied with still greater instruction when I coasted the island in a boat. Its shore is about eleven miles in circuit, and every where presents to the eye the traces of fire, in the remains of streams of lava, enamels, vitrifications,

puzzolanas, and pumices.

Vulcanello has long made a part of Vulcano, but is still perfectly distinguishable from it by the interposed land. It has the form of a scalene triangle, two sides of which sink abruptly into the sea, and merit examination more than any other parts of the shore. They consist of many strata of lava, several feet high, and piled one above the other. When they flowed, they must certainly have extended farther into the water; but they have been broken, gradually, by the violence of the waves; and their fractures now form a kind of wall of a great height, which descends perpendicularly into the sea. As the water here is shallow, the bottom may be seen scattered overwith large pieces of these lavas; and the wall, on a near approach, presents to the eye a number of currents of lava, which have flowed at different times, and differ in their colour, component parts, and consistence.

The appearance of these currents of lava, which have flowed one over the other, reminded me of what I had observed several years ago, in the glaciers of Switzerland; where some parts of the snowy coating being broken, the different strata of snow, which had fallen at different times, are distinctly discernible by the difference of the

colour.

As the greater part of these lavas differ very little from those of other volcanos, I shall not give a description of any of them except two only, which appear to me not to be common.

The first lies buried in the midst of the others, and would, therefore, only become visible by cutting them away, did not the superincumbent lavas, which are in several places broken, discover it in those fractures. In its superficial parts it is a true enamel, very black and shining, entirely opaque, which easily crumbles, and in which are incorporated many shoerlaceous and feltspathose scales. This enamel contains tumors marked with stripes and large threads, which appear every where in it, but always run in the same direction, which is that of the course of the lava, or from the mountain to the sea. The substance of these stripes and threads is likewise enamel. Their presence and direction sufficiently indicate that the enamel when it flowed and entered the sea was rather of a soft consistence than fluid.

I at first imagined that, as the other contiguous lavas were each of one substance through the whole of their depth, it must be the same with this enamel, as far as it formed a distinct current, as we shall see in the enamels of Lipari; but, on breaking some of the larger pieces, I found that this was not the fact. The enamel is only the superficial part, or crust, of a lava many feet deep, which crust, where it is thinnest, is scarcely more than a line in depth, but where thickest frequently more than two inches. It cannot, however, in any manner be considered as a later product, or as having flowed after the lava and attached itself on it; this crust of enamel is certainly a true continuation of the lava itself, as I have, in my opinion, satisfactorily ascertained by repeated and careful examinations. The enamel, therefore, after having formed this crust of greater or less thickness, suddenly lost its distinctive characters, and changed into a lava of a reddish gray colour, dry, rough to the touch, earthy, emitting an argillaceous odour, and having for its base the horn-stone, without losing its scales of shoerls and feltspars. We must hence conclude that the current was more affected by the fire on its surface than in its internal parts; for I know no other mode of explaining this phenomenon.

aftercoasted resents ations,

ishable des of oarts of above to the did their cularly dover the eye in their

I shall of to be

several enamel, e incormarked in the the seaand diwas ra-

bstance ar as it reaking only the nest, is inches. Howed ontinua-epeated crust of to a lava odour, eltspars. surface

non.

From this enamel and lava, when exposed to the furnace, results a similar enamel; that is to say, one of a dark gray colour, very hard and compact; with a fusion of the

shoerls, and a semi-fusion of the feltspars.

Another product with a horn-stone base, of a very singular quality, and which I do not remember to have seen any where else in my volcanic travels, is found on one of the sides of Vulcanello that descend perpendicularly into the sea, and, having been broken in different places by the violence of the waves, present upon the shore, and within the water, a large heap of fragments of a globular form. At the first view it might be taken for a tufa. It is rather light than heavy, may be crumbled to powder between the finger and thumb, imbibes water, with which it is in a few moments saturated, with a kind of hissing sound, and emits an argillaceous odour. We know that similar properties are usually found in volcanic tufas: but these have an earthy grain, whereas the present substance rather inclines to the vitreous. Besides, when the shoerls it contains, which are innumerable, are examined, they are found to be distributed equally as they usually are in lavas—a distribution never met with in tufas, in which the shoerls that are sometimes found in them are scattered confusedly and at random. Hence as they are extraneous bodies, they are easily detached from the tufaceous mass; but this is not the case with the product in question, which, consequently, we must consider as a true lava.

But to what are we to attribute its softness? Pernaps it has been considerably clanged on the surface by sulphureous-acid vapours, by length of time, or some other unknown cause. Such, at least, was the first idea which presented itself to my mind, but which I found inadequate, both because in that place no sulphureous fumes exhale, nor are there any indications that any ever have exhaled; and, because, having procured this lava to be dug up from the depth of five feet, I found it, there, extremely soft as well as at the surface. I am rather of opinion that this lava is the result of the combined effect of fire and water; as examples are not wanting, in volcanized countries, of similar combinations. I mean that the lava, while flowing, was met and penetrated by a stream of water, that had gushed from some aperture of the volcano, by which it was suddenly cooled, and lost that coherence which is usually the property of lavas. I found this opinion on several observations. I perceive that the lava has a number of cracks and fissures, such as are usual in stony substances which, while in a state of fusion, have come into contact with water. I observe that the shoerls, which in other lavas have the hardness of glass, are in this so friable that they may be scratched with the nail; and as such appearances are not usually the effects of volcanic fire alone, I know not to what to ascribe them but to the action of water; since vitreous substances in a state of fusion are affected in precisely the same manner by contact with that fluid.

The ebullient though hard enamel, which is the result of this lava in the furnace, is of a fine deep black; the shoer are melted; and it is worthy remark that in it we discover some small flakes of white feltspar which before were not discernible in the lava

on account of its cinereous colour.

The two lavas I have described, as likewise others of which I have omitted the description on account of their being common, and which together form the two sides of Vulcanello, appear by their direction all to have proceeded from the crater, which is about two hundred paces distant from the sea; and which still retains its natural figure of an inverted tunnel, except that the bottom is covered to some height by earth which has been carried down by the rains from the internal sides. These sides are formed of pulverised clay and sand, and are marked with deep furrows caused by the descent of

the rain water. The circumference of the bottom of the crater, judging by the eye, cannot at the utmost be more than seventy, but that of the top is about the sixth of a mile. Its depth is scarcely eighty feet. The crater on the outside is surrounded with rocks of lava, probably the consequences of an eruption. It is evident that, as more earth is continually falling into it, it must at last be filled up; and as the external sides of it are ill-formed, there is no doubt but that one day every trace of it must be lost. We hence perceive how many volcanised countries may appear, and in fact do appear, to be destitute of craters; these not having been able to resist the injuries of time.

Here was it that I began to perceive the indications of the subterranean burning furnace; for round the crater of Vulcanello many streams of a white smoke arise; and it is only necessary to strike the ground with the foot to produce more. They are very hot, as are likewise the apertures through which they issue, and which, in the night, from time to time, emit a feeble flame. The ground, which fumes at the surface, within, contains crusts of sulphur, which are most abundant in the places where the fumes exhale most copiously. But we shall soon have occasion to treat more at length of the

sulphur of this island.

From Vulcanello I proceeded to a grotto which has obtained some celebrity on account of a mineral water it contains, and is at the distance of about a mile from the western haven. To reach this water it is necessary to descend into the grotto, the entrance of which is so narrow, that you are forced to stoop very much, and almost creep on the hands and knees. It is a moderately large cavern, incrusted round with sulphate of alumine (alum) muriate of ammoniac (sal ammoniac) and sulphur. These minerals are found to be very warm, as likewise is the atmospheric air in this place, on account of the heat of which, the strong sulphureous smell, and the difficulty of respiration, it is impossible to remain long in the grotto, which you are obliged to leave from time to time to breathe fresh air. At the bottom is a small pool of very warm water, which is esteemed by the Liparese to be efficacious in many disorders. The abbate Gactano Trovatini, a learned physician of Lipari, has published an analysis of this water.* I shall not therefore enter into a minute account of it, which would be superfluous, but shall only remark that, besides the sulphureous odour it emits, it contains abundantly the muriate of ammoniac (sal ammoniac) and still more of the muriate of soda (sea-salt;) which latter salt I imagine it derives from a communication with a neighbouring sea, with which it appeared to me on a level. Though its temperature is not higher than 80 degrees, it continually appears to boil, from the great number of airbubbles that rise from the bottom to the surface, which they entirely cover. This water, in fact, so much abounds with this aeriform fluid (which I found to be carbonic acid gas) that when shaken in the slightest manner a prodigious quantity of bubbles arise. I likewise observed, relative to the same object, that if a stone be let fall into this water, as it sinks, a vast quantity of these bubbles will ascend, and will continue to rush to the surface several minutes after it has reached the bottom. The continual emission of so much carbonic acid, which doubtless concurs to render the air in the cavern unfit for respiration, produces within the grotto a confused noise, which may be heard likewise without.

M. Dolomieu, in his account of this subterraneous place, observes that a considerable quantity of smoke issued from it. This, when I was there, I could not perceive; either because it had opened to itself another passage, or that the cause by which it was produced has ceased: changes not unfrequent in volcanic countries.

ooli 1786.

To this place the ascent of the island is gradual; but the remainder of the way which leads to the highest crater of Vulcano is extremely rugged and difficult; as it lies over a long mile of continued heaps of lavas, vitrifications, and pumices. The fatigue, however, is alleviated by the pleasure which the instructive examination of these productions affords. Some of the vitrifications found among the lavas clearly manifest, that they were originally pumices, which, by a more intense heat, have passed into the nature of complete glass. The breaking of some of them proves this beyond the possibility of a doubt. We then find one part a common pumice; I mean resembling threads of silk, light, extremely friable, floating on water, and of a very white colour. Another part we find to be vitreous, of a different texture, less filamentous, less light, less white, and less friable. Still farther begin to appear long veins or threads of glass, which continually increase in thickness; and at last in another part of the piece, multiply and consolidate into a mass completely glass. This glass is semi-transparent, of a colour between gray and black, and so hard as to give sparks with steel.

It is worthy of remark that some of the black shoerls, and white feltspars, incorporated

in the pumice, are preserved entire in this glass.

The furnace melts neither of these; though it completely fuses the glass, which is

charged into an extremely porous enamel.

Mixed with these curious combinations of glass and pumice are found true glasses, and true pumices, as also a variety of lavas, which having lost in a considerable degree, the texture of their primitive rocks, have acquired a vitreous appearance. They are extremely compact, give sparks with steel, are of a blackish or dark blue colour, and are not wanting in feltspars and shoerls. Some of them will move the magnetic needle at the distance of three quarters of a line. One of them has become a volcanic breecia, as it contains within it fragments of other lavas which it enveloped while in a state of fusion. These fragments are of a coarse grain, and a spongy texture, and when minutely examined are found to derive their origin from the horn-stone, while that of the including lava is from the petrosilex. The same difference continues even in the furnace; the fragments becoming scoriaceous, and the lava a semi-transparent glass.

These glasses, pumices, and lavas, do not form currents, but are found in large masses; and it is probable that they were thrown out of the mouth of the volcano in the same

state in which we now see them.

As we proceed up this difficult ascent, we perceive, near the top of the truncated cone, five or six streams of smoke, approaching which we find that each of them issues from an aperture incrusted round with small crystals of sulphur. If a stick be thrust into them, and drawn out again soon after, it will appear black, and smoke. The earth is here extremely hot, every stone is decomposed, and of a white colour; and if new apertures are made with a staff (which may easily be done from the great softness of the ground) new fumes will immediately issue similar to the other; that is to say, white, very offensive from their sulphureous smell, and extremely hot.

Above these fumes there is a plain, of no great extent, which one is, at first, afraid to venture on, from the subterranean noise heard there, and from the shaking of the ground when struck with the foot. Here we find other sulphureous fumes, besides ammoniacal vapours, which, attaching to the decomposed lavas, generate thin crusts of

that salt.

On this plain it was, that, formerly, stood the furnaces in which the sulphur of Vulcano was purified. But this useful labour has been long since abandoned, and even prohibited, from the supposition that the vapours arising from the purgation of the sulphur were prejudicial to the plantations of vines in Lipari. A lew years ago, indeed, it

then exist.

was again resumed, by the special permission of his Sicilian majesty; but was soon again given up, not because any fear was then entertained that the vines would be injured, which the more judicious of the natives of Lipari are now convinced is a vulgar error, since they sustain no damage from the smoke of the crater of Vulcano itself, though that is beyond all comparison more in quantity than that produced by the purification of the sulphur: nor was it abandoned because the quantity of sulphur obtained was too little to repay the trouble and expence, as the vein is very rich and even inexhaustible; for wherever the ground about the craters of Vulcano and Vulcanello is but slightly turned, fine clods of sulphur are found; which are larger and more numerous the deeper the earth is dug into. My own observations have in this particular sufficiently confirmed the testimony of the people of Lipari: as I was convinced, in my different visits to the island, that in the very places from which the sulphur had been extracted, after a short time it is re-produced.

The real cause why the inhabitants of Lipari no longer continued this work was, that the ground, which on the surface is more or less warm, grows hotter the deeper it is dug into, and, at the depth of five or six feet becomes so hot as to be almost insupportable; to which is to be added the offensive stench of the sulphureous fumes that issue in great abundance from these excavations. If this mineral was once extracted here to great advantage, as we are assured by history, it seems certain that these difficulties could not

Continuing my journey towards the south from these forsaken furnaces, and having mounted a short but steep ascent, a second, but a much more spacious plain opened before me, which was every where sandy, except that a few erratic lavas were thinly scattered over it. Beyond it rose a considerable eminence, which when I had ascended, the noblest spectacle Vulcano can offer presented itself to my view, I mean its crater. Except that of Etna, I know none more capacious and majestic. It exceeds a mile in circuit, the mouth is oval, and its greatest diameter is from the south-east to the west. This mountain externally has the form of a direct cone, and its crater that of a cone inverted. The height of the internal sides from the bottom to the top is more than a quarter of a mile. From the top, the bottom may be seen, which is flat, and from many places in it exhale streams of smoke, that rise above the crater and emit a sulphureous odour which may be perceived at a considerable distance.

After having made the circuit of the upper circumference of the crater, I became desirous to enter it, and descend to the bottom, to examine the internal parts; the southern side, which is not very steep, appearing to invite to such an examination. I was not willing however to undertake such an adventure alone, but wished for some one to accompany me, who might serve me as a guide, and, I may likewise add, who might keep up my courage. But my wishes were vain. The four sailors who had worked the boat which brought me to the island, and had gone with me to the edges of the crater, when they found I entertained thoughts of going down into it, positively refused to follow me, alleging the evident danger to which I should be exposed, and adducing the example of I know not what traveller, who a few years ago, having descended into this deep gulf, paid for his temerity by never coming out again. All my entreaties, therefore, and all offers of reward were fruitless; and I was obliged to return to Lipari without having been able to gratify my wish. These sailors were natives of Lipari, nor could I find any of their countrymen who would hazard accompanying me in making this experiment. So great is the dread they are inspired with by this volcano, proceeding probably from the fame of its ancient terrors, and also from some recent eruption, of which we shall hereafter have occasion to speak.

s soon A resolute Calabrian, who had been banished to Lipari for some crime committed at be in-Naples, was the only one who, with the permission of the Marchese Chiavelli, the govulgar vernor of that city, and the promise of a large reward, could be induced to go down itself, with me into the crater. We descended on the 13th of September 1788. I have already purisaid that the sides towards the south-east are not very steep, and on this side we theretained fore safely reached the bottom, where I proceeded to make such observations as I inexthought of most importance. I here perceived, more distinctly than I could above, is but that the crater was a hollow cone reversed, but truncated by the bottom on which I nerous stood. The sides, except in that part where we descended, are every where inaccessisuffible. As they are covered with sand, they are marked with deep furrows which are the ny difeffect of rains. en ex-

The bottom on which we stood, may be about somewhat more than a third of a mile in circumference. It is covered with sand, like the sides, and in form an oval. I soon perceived that it could not be walked over without danger, and that it was necessary to use the greatest circumspection in examining it. I have already mentioned the subterranean noise heard on approaching the crater of Vulcano. Here it may be said to be a hundred times louder. Under this bottom we seem to hear a river running, or rather a conflict of agitated waves which meet, and impetuously clash together. The ground, likewise, in some places cleaves in cracks, fissures, and apertures, from which hissing sounds issue resembling those produced by the bellows of a furnace. I therefore thought there was every reason to conclude, that these sounds are occasioned by an elastic gas which issues through those fissures; and was afterwards perfectly convinced of the truth of this supposition by the following facts; if the hand be approached to any of these clefts or apertures, a strong impression is felt of an extremely subtle invisible fluid; and if a lighted candle be applied to them it will, it is true, be frequently extinguished by the impetus of the fluid, but sometimes it will set fire to the fluid itself, producing a flame of a blueish red colour which lasts for several minutes. The fetid odour which is then perceived convinced me that it is a sulphurated hydro-

genous gas.

The ground at the bottom was so hot that it burned my feet; and I should not long have been able to endure its heat, had I not from time to time got on some large pieces of lava which were not so hot. From the extreme heat, and the strong stench of sulphur emitted by every part of the bottom, so as to render respiration somewhat difficult. I could scarcely go round it, and it was quite impossible to cross it near the middle; at least it would have been very dangerous to have attempted it. About the middle of this bottom arose a circular eminence of about forty-five feet in diameter, from every part of which a dense vapour sublimes, and the surface is covered with crusts of sulphate of iron (vitriol of iron) sulphate of alumine (alum) muriate of ammoniac (sal ammoniac) and sulphur; as I found by collecting and examining some fragments of these crusts at the edges of the eminence. Its heat is insufferable, and on pressing the edge with my feet I perceived it shake very sensibly, as if I had trod on a floor of boards which yielded and sprung up again under me. On letting fall a large piece of lava from the height of my body, a subterraneous echoing sound was heard, which continued some seconds; and this happened on whatever part of the bottom the piece of lava was let fall, but the sound was loudest near the eminence in the middle. These circumstances sufficiently proved that, while on this bottom, I walked over a gulf from which I was only separated by a flooring of volcanic matters of inconsiderable thickness, and that in this gulf the fires of the volcano still continued active, of which the subterraneous noise, the fumes, vapours, and extreme heat were evident indications.

Another proof, in confirmation of this, is furnished by an observation I made at other times by night, for I was not contented with a single visit. This is, that, when it was dark, several blueish flames might be seen to rise from the bottom, to the height of half a foot, a foot, and sometimes higher. It is to be remarked, that those which ascended from the eminence before mentioned were more numerous and rose higher; and that besides those which issued spontaneously, it was in my power to produce new ones, by making small excavations in the ground. The strong disgusting sulphureous odour which all these flames emitted convinced me, that they were the effect of the sulphur itself, which still continued slowly to burn below, in a state of

But the object most curious and most interesting to a naturalist is a grotto, on the west side of this hottom, which, from the variety of things it contains, merits to be described at some length. It is an excavation in the sides of the crater a hundred and ten feet in height, two hundred and fifty in breadth, and ends at the bottom in a pit thirty feet in circumference. From this pit continually arises a column of whitish smoke, which alone equals in quantity, or perhaps exceeds, all the fumes that arise from the bottom of the crater. Its strong and suffocating sulphureous stench, and its extreme heat prevent any near approach. A part of this smoke, meeting with no obstacle, ascends in a direct line, and rises above the mouth of the crater; but another part of it, soon after it has issued from the bottom, is obstructed by some stones which jet out from the sides of the grotto; and attaching to the lower surface of these, the su phur which had been sublimed with the smoke falls down again, and collecting in several places, forms stalactites of sulphur; some in the shape of inverted cones, and others cylindrical. The largest are three feet in length and two inches thick. On striking several of them with a stick, I found that this sulphur is extremely pure. Sometimes it is of a flesh colour, but more frequently of a fine yellow, brilliant on the surface, and semi-transparent where the stalactites are thinner; which properties also give value to the other sulphur that is dug round the crater of Vulcano, and exists likewise at its bottom; as I observed that in the fissures from which the sulphureous fumes issue, it is found consolidated in fragments of various sizes. The stalactical alone, however, has the cylindrical or conical form, which is produced by the fusion of its parts, and their descent by gravity; whereas that which is generated under ground is usually found in amorphous masses, and sometimes in strangely irregular configurations.

It seems scarcely necessary that I should mention the manner in which sulphur must be continually formed in this island; since it is well known that this mineral is not entirely consumed in conflagration, but that a great part of it is sublimed, unchanged in its substance, which again deposits itself, sometimes crystallized, and sometimes amorphous, on any bodies with which it may meet. As it is therefore perpetually burning in the subterraneous furnace of Vulcano, it continually produces those numerous white fumes which arise from various places, and those lumps, cylinders and cones of sulphur which I have before mentioned. The sulphur which is so frequently found in other

burning mountains is generated in the same manner.

From the pit within the cavern, whence the cloud of smoke continually issued, a louder noise was heard, than at any other part of the bottom; and on throwing stones into it I could not perceive that they struck against any obstacle, as they gave no sound, but a kind of hissing one occasioned by the resistance of the air in their fall. It appears probable, that this cavern has an immediate communication with the subjacent furnace

of the volcano.

a loustones sound, ppears irnace From one of the sides of the cavern, at the height of eight feet from the bottom on which I stood, issues a small spring of mineral water, which leaves on the different lavas depositions which well merit to be examined. If we suppose this water to proceed from the sea, it can only be by evaporation, as the level of the sea is very much lower than the place whence it issues. It may possibly derive its origin from rains, which penetrating to the interior parts of the mountain, and accumulating in some cavity, have found a free outlet, depositing in different places the heterogeneous substances with which they became impregnated in their passage.

Where this water flows, we find, in the first place, hanging stalactites of sulphate of alumine, some of which are of the thickness of ten inches, and a foot and a half in length. On breaking them, they are found to be a congeries, of barks or rinds, similar to the

coats of onions, as stalactites in fact usually are.

Secondly, these stalactics are not always composed entirely of sulphate of alumine, but are mixed with muriate of ammoniac.

Thirdly, the sulphate of alumine, in some places instead of being stalactical, is crystallized in beautiful stellated groups consisting of very fine silver silky threads.

Fourthly, between the stones where this water issues, we frequently find stalactites

of sulphate of iron.

Lastly, on the ground where this water falls, we find a number of hollows filled with a kind of thick pulpy matter, which is no other than a confused mixture of all these salts, which, from the partial evaporation of the water, begin to assume a body and consistence.

The sides of the crater of Vulcano, and the oval plain which forms its bottom, are covered with sand, as has been already observed. This sand, however, cannot properly be so called, since it is a mixture of fragments and small particles of pumices, lavas and glass; among which are found, principally where the sulphureous fumes are strongest, entire and large pieces of vitrifications, pumices, and lavas, which well de-

serve the careful and accurate examination of the observing naturalist.

We will begin with the former of these substances. At the bottom of the crater of Vulcano we find a glass which is of a lead colour, and not unlike another kind found in ascending the cone of Vulcano. Many pieces which lie without the fumes are preserved unchanged; but many of those within them exhibit different degrees of alteration. The first and slightest degree is a thin cinereous coating, which invests the glass, and is less hard than the internal part. The sulphureous acids, therefore, have only acted on the surface of these pieces. In others they have penetrated deeper, as appears by the greater thickness of this tender and half pulverous coating. Some are so changed, that nothing remains of the glass but a small central nucleus; while others have entirely lost even this nucleus, and the whole piece, from being of a lead-colour, hard, semi-transparent, and smooth, is become of an ash-colour, soft, opaque, and yielding to the touch. In these, therefore, the glass has undergone a complete decomposition.

It had been discovered, long before I wrote on the subject of volcanos, that sulphurcous acids would decompose lavas; but I believe I am the first who has observed a simi-

lar decomposition in volcanic glass.

In the same place we find pieces of various sizes, of a more perfect, harder, and extremely black glass; which, likewise, where the sulphureous acids abound, has under-

gone the same changes.

A number of particles of sulphur are frequently attached to the surface of both these glasses, and some are also found within their substance, where small fissures have opened to them an entrance.

We will now say a word of the pumices. They do not differ from those we meet with on the declivity which leads to the summit of the mountain, and which we observed with an intense heat, changed into glass. Yet these likewise suffered more or less alteration from the above-mentioned acids. In some their fibrous texture was reduced to a kind of pulverulent earth, which scarcely retained a single original filament. In others this texture was preserved, yet they might be easily reduced to powder by the finger.

It now remains to treat briefly of certain prismatic or basaltiform lavas likewise found in this volcanic bottom. In the first place, where the sulphureous acids are strongest, we find scattered pieces, superficially decomposed, which seem to have been broken off from larger columns. They have a pentagonal prismatic figure, with unequal sides and angles; and the larger pieces are about nine inches in length by eight in thickness. Their base is a petrosilex, which from its having suffered fusion, is of a very singular

kind.

In the course of this work I have frequently had occasion to speak of lavas with a petrosiliceous base, and shall certainly have occasion to speak of them again. They are all too strongly characterised for their base to be confounded with other stones. They, however, carry in them the marks of fire, in a certain fibrous appearance which they have, and which originates from a diminution of the affinity of aggregation when in a state of fluidity. The petrosilex of which I now speak, on the contrary, exhibits no signs of injury from the fire, though it is certain that it has suffered fusion. It is of that kind which is somewhat scaly; has a grain and hardness little different from that of silex; is transparent at the edges, of a shelly fracture, and of a livid ash colour. When pulverised it becomes white. The pieces, when struck together, sound like flint. This stone contains a few irregular shoerls, of a black colour, and but little lustre.

After a continuance of forty-eight hours in a furnace of sufficient heat to liquefy the fine crystal glass, this prismatic lava with difficulty melts. To obtain a complete fusion, it is necessary to have recourse to a stronger heat; with which view I used a wind-furnace. After thirteen minutes, its volume increased almost threefold, from the diminished force of aggregation, and then the lava acquired a snowy whiteness. Continuing the same fire, its dimensions contracted, and it at length produced a white

chamel, moderately hard, and interspersed with microscopic bubbles.

The first time I ventured to explore the bottom of the crater of Vulcano, I only found some fragments of this prismatic lava: but when I repeated my visits, and had divested myself of the fear I at first felt, and more carefully examined this dreary bottom, I was enabled to complete my discovery by ascertaining the origin of these prismatic, or, as some may choose to call them, these basaltiform lavas. For, raising any eyes to that part of the sides of the crater which was over my head, and facing the northeast, I perceived a large stratum of lava, almost perpendicular, divided lengthwise into complete prisms, some of which were continued with the lava and made one body with it; while others were in a great measure detached from it, so that, striking them with a long and heavy pole, I beat three of them down. I then clearly perceived that the pieces I mentioned above were fragments of entire prisms, since the external characters of both were precisely the same.

Each of these prisms, exceeded a foot in length; but, as far as could be judged by the eye, other prisms adhering to the mass, which I could not reach, were of much larger dimensions. The lava which contained them stretched to the ground, but did not appear of great extent, as its upper parts and sides were covered with a thick

sand.

ed by much it did thick The production of these basaltiform lavas, which, from their situation, and their forming a whole with the lava, no one can doubt derive their origin from fire, may, I conceive, be thus explained. In former times an effervescence took place in the melted lava in the crater, which, after having swelled, and perhaps overflowed its edges, slowly sunk into the cavity of the crater, from the diminution of the fire, and the impellent elastic substances, while a portion of the lava attaching itself to the internal sides, and hastily cooled by the atmospheric air, contracted, and divided into regular parts, such as are the forms of the hexagon prisms above-mentioned. Their perfect preservation and freshness are a clear proof that they are not of very ancient date.

I shall conclude this chapter with a few observations relative to the decompositions which I remarked in various productions both within and around the crater of Vulcano. These decompositions, I have said, were produced by sulphureous acid exhalations. I have asserted the same of some decomposed lavas in the vicinity of the volcano of Stromboli, as also of a great number of those of which Solfatara is principally formed.* And in general, when the question is of lavas, the alteration of which consists in being softened and rendered mild and saponaceous like argilla, and in a whitening of the parts, I perceive that the greater number of volcanists agree with me in sentiment. I find, however, that M. Sage is, of a different opinion, maintaining that such decompositions are generally to be ascribed to the action of muriatic acid, which is the cause of the greater part of the alterations that take place in the products of volcanic eruptions. He attempts to demonstrate this by the experiment of a black lava which, in his laboratory, became white and equally decomposed with those found in some volcanos, by keeping it in digestion in concentrated muriatic acid. Other similar experiments likewise confirm him in this opinion.†

That the muriatic acid is capable of producing decompositions in various volcanic productions analogous to those we frequently observe in the materials of burning mountains, I am the more easily persuaded, since, having repeated the experiment of the French chemist, I have found it accurate. I placed in two vessels, filled with concentrated muriatic acid, some fragments of two different lavas, the one from Etna, the other from Vesuvius, both of a colour approaching black, of the horn-stone base, and containing a number of black shoerls. Having closely stepped the vessels, I left them for a month; at the end of which time the lavas were become of a yellowish einercous colour, and, having washed away the muriatic acid with which they were impregnated with distilled water, they lost the yellowish tincture, and became entirely of the cinereous colour. Some of them had likewise become in some degree friable, though before they were hard. The decomposition had in fact penetrated more or less to their internal parts, though the shoerls remained unaltered both in texture and colour.

This author however admits, in another place, that the sulphuric acid is likewise capable of producing the same effect, which I also experimentally ascertained on the two lavas above mentioned. It is in like manner known that the sulphuric acid possesses

^{*} See chap. II. and chap. XI. † Elemens de Mineralogie.

Notwithstanding that, at the end of a month, the muriatic and sulphuric acids had been equally efficacious in producing alteration in the two lavas, yet, after a longer time, the muriatic appeared to be more powerful than the sulphuric. At the end of seven months and a half, on examining the lavas which had remained in the same situation in the two acids, I found that the muriatic acid had decomposed them more than the sulphuric. Besides that they had acquired a whiteness almost equal to that of snow, they had become very light, and extremely friable and spongy, from the corrosion of the acids. The shoerls remained black, but had lost their vitreous appearance. Both these lavas, likewise, contained a number of feltspars, which suffered less than the shoerls, as they always retained their natural changing

an equal strength when the sulphur is caused to burn very slowly. It remains therefore to determine which of these two acids, the muriatic or the sulphuric, is the real cause of the decomposition and whitening which is frequently observed in products of volcanos, at least of those which I have most attentively examined, Stromboli and Vulcano. And though I shall, in another part of the present work, produce direct proofs, that some lavas, enamels, and volcanic glasses, sometimes give reception to the muriatic acid, yet certainly the decompositions in question are not to be attributed to this acid, but to the sulphurcous. The odour of these acids is too different for them to be confounded; and both at Stromboli and Vulcano, in the places where these decomposed products are found, enveloped in white fumes, I very sensibly perceived the aerid, pungent, and suffocating fetor of the sulphur, as also the sharp taste, if a particle of the fumes by accident entered my mouth. I likewise particularly remarked at Vulcano, that where the sulphureous fumes were most dense, and left crusts of sulphur attached to the bodies they touched, these bodies, whether lavas, pumices, or glasses, suffered greater alteration than others; and in some of them, the decomposition had penetrated to the depth of two feet.

An experiment which I shall now relate offers a new and indisputable proof of what I have here asserted. At Vulcano, I left a piece of extremely black lava, which had for its base shoerl in the mass, and was one of the firmest and hardest I could find, in an aperture from which issued a great quantity of very hot fumes; and after it had continued there two-and-thirty days, I observed that, in its upper part, it remained untouched; its black colour only having become somewhat lighter; but on the sides, and still more on the lower part, where the impression made by the sulphurcous fumes had been greater and more active, it was become white, with a sensible softening of the solid parts near the surface.

Had M. Sage, instead of deciding, while shut up in his laboratory, that the muriatic acid is the cause of the alterations which take place in volcanic countries, himself visited those countries, he would have thought differently; and had he in the course of such a journey entered the Grotta del Cane near Pozzuolo, the expression would never have escaped him, that this perpetual mephitis is produced by the volatile marine acid.*

lustre. But the sulphuric acid only produced in these lavas a cinercous colour, a less degree of friability and lightness than was caused by the other acid; and the black shoerls did not lose any of their glassy brilliancy. This acid was concentrated equally with the muriatic. Instead of the colour and limpidness of water, it was become turbid and dark. The muriatic had acquired a beautiful golden yellow. I must add, that, having poured some fresh sulphuric acid on the old, the decomposition and whitening of the lavas, after some time, was not inferior to that produced by the muriatic acid. I found a remarkable difference between the alteration observable in lavas in the vicinity of volcanos, and that which is effected by the sulphuric and muriatic acids, since the volcanic alterations are sometimes accompanied by an unctuous smoothness, I never observed in the two lavas exposed to the action of the above-mentioned acids, which, on the contrary, had become rough and scabrous.

CHAPTER XIV.

VULCANO, CONTINUED.

Among the few naturalists who have made a voyage to the Eolian isles, M. de Luc the only one who has entered the crater of Vulcano....Summary of the observations made by him there, in 1757, compared with those of the author Similarities and differences between the local circumstances of the crater at that time and those of the present crater.... Observations made by the commendator Dolomieu from the summit of the crater in 1781 Remarkable changes which have, since that time, taken place in the crater....Commotion of Vulcano in 1786....No eruption of lava from the crater has happened within the memory of any of the natives of Lipari now living....The phænomena of this volcano habitually observed by them Visits made to this crater by Father Bartoli, in 1646, and professor d'Orville in 1727.... Interior conflagration through the whole of the crater at the first period Not one but two craters at the second Hill which at that time rose from the bottom of one of the two craters.... Vulcano then in its greatest agitation....Some obscure memory still retained by some aged natives of Lipari of a double crater at the summit of Vulcano....Sterility of this island on the side next Lipari, though there is no want of vegetation on the opposite side....Porphyritic lavas in this part of the island, but greatly decomposed....Small crater on the side of Vulcano described for the first time.... The fumes of Vulcano observed by some of the Liparese as signs of good or bad weather, in the same manner as the inhabitants of Stromboli consult their burning mountain.... Observations published by a native of Lipari, on the diversity of the fumes, and internal commotions of Vulcano, betokening, according to him, what winds will blow.... Observations of the author not agreeable to those of the Liparese....The fires of Vulcano more powerful at that time than now, if the accounts given by that writer may be relied on....Ancient accounts of the conflagrations of Vulcano....Number and size of its craters....Its different eructations....This burning mountain, in a certain degree, comparable to Vesuvius and Etna Prognostics of the winds which may be expected to blow from the symptoms of the volcano very ancient; and perhaps deserve equal credit with the

AMONG the very few naturalists who have made a voyage to the island of Lipari, M. W. de Luc is the only one, to my knowledge, who has entered the crater of Vul-This he did on the 30th of March, 1757, as appears from an account of the observations he made there, published in the second volume of the travels of M. de Luc, a summary of which account I shall here present to the reader, as we shall thus be enabled to compare the local circumstances which existed at that time, with those observed by me in one of the most superb and spacious gulfs at this day to be found among burning mountains.

He relates that he reached the bottom of the crater, by a narrow passage, which afforded him entrance, but with great risk of being suffocated by the dense sulphureous fumes that enveloped him; in consequence of which danger he was obliged to enter alone, the guide who had conducted him to the summit of the crater, and who was a native of Lipari, having refused to follow him. He found the bottom very rugged and uneven, of an oval form, with several apertures, from which issued sulphureous vapours, and from some a strong wind. The sound of his feet as he walked on it was very sen-

The longest diameter of the oval appeared to him to be about eight or nine hundred paces, and the shorter between five and six hundred. The height of the sides of the crater he imagined might be about one hundred and fifty, or, towards the east and the south, two hundred feet. At the bottom they were nearly perpendicular, and were

composed entirely of volcanic materials.

A column of smoke, of fifteen or eighteen feet in diameter, issued from a cavern which above lost itself in one of the highest sides of the crater, and below ended in a kind of tunnel, or rather abyss, of about sixty paces in circuit; and the sumes on issuing out of that abyss roared like the vapour of boiling water, when it escapes from a vessel not closely covered. Several pieces of scorize being thrown into it were no longer heard

when they had passed beyond the tunnel.

Another object likewise strongly attracted the attention of M. de Luc: this was an aperture, five or six inches in diameter, which terminated in a small tunnel about two feet and a half deep, from which the air rushed with as much violence as from the bellows of a forge. He threw into it great pieces of lava, which enlarging the opening, caused the wind to issue with less rorce, but the small pieces that were detached from the aperture were driven outwards by it. The fragments of lava which fell within, produced the same effect as the scoriæ thrown into the tunnel of the cavern. As these observations convinced him of the extreme thinness of the floor or shell on which he stood, he thought it advisable to quit this perilous gulf, and direct his researches to objects less dangerous.

He then remarked that the sulphureous vapours of the volcano had here a communication with the sea, which was in many places of a yellow colour, and in others emitted fumes; and that in the places where the fumes rose its heat was intolerable; so that the fish that happened to approach that shore soon died, and the beach, where a few inches above the level of the sea warm veins of water burst out, was scattered over

with dead fish.

Such is the substance of the observations of M. de Luc, made about thirty-one years before mine. On comparing the one with the other, it will appear, that if the internal parts of the crater of Vulcano have suffered some changes since that time, they are still essentially the same. At present (at least, at the time when I was there, I might have said at present) the sides of the crater are in most parts nearly perpendicular, the circumference of the bottom is an oval, from a number of fissures and apertures sulphureous fumes issue, and from others streams of wind with a hissing sound. The bottom likewise shews evidently that it is a dangerous and a false bottom, by shaking and sounding when walked over. The cavern excavated in the sides of the crater, and described by the above-cited traveller, also still exists, and from it a cloud of sulphureous fumes continues to exhale; and had not M. de Luc been fearful of prosecuting his researches, it is more than probable that he would have found it abounding with sulphur and various salts, as it is at present.

The differences, therefore, between the state of the crater at the time it was entered by M. de Luc and at present are reduced to these; first, that the narrow passage by which he reached the bottom now no longer exists; but that, on the other hand, the sides on the south-east are become less steep, and afford a way to descend into that gulf: secondly, that the height of the crater is now much greater than it was then, as I found it to exceed a quarter of a mile, whereas when M. de Luc was there it was not more than two hundred feet: lastly, that the furnace below the bottom burns much more violently at present, as may be inferred from the intense and almost intolerable heat I felt when I was there, which circumstance, had it existed when M. de Luc made his

observations, he certainly would not have failed to have mentioned.

I do not mean to say by this that the subterranean conflagration of the island is now more active or energetic; since it appears that the extreme heat, though not then felt within the crater, manifested itself without, and even in the sea itself, which as has been observed, smoked in several places near the shore, and was so hot that the fish all died : circumstances which did not exist when I visited the island.

M. Dolomieu, who was there seven years before me, could not go down into the crater, because the narrow passage by which M. de Luc entered no longer existed, and the sides were too steep to admit of any descent. The volcanic mouth, however, was then in the same situation, was large, of an o al form, and emitted, in a great number of

places, sulphureous acid and suffocating fumes.

Yet within this short interval, very considerable changes have taken place. The depth of the crater, as far as my judgment could be formed by the eye, was then about a mile, the larger diameter of its mouth was half a mile, and that of its bottom about fifty paces. Whence it appears that the bottom, since that time, must have been greatly raised, and likewise have become narrower, while the mouth has been considerably enlarged. From the edge of the crater, he threw into it large stones, which, when they reached the bottom, he perceived sank in some fluid, that could not be aqueous, since it must have been soon evaporated by the excessive heat, but which he judged to be melted sulphur; as he in fact saw that substance trickle down the sides against which it had sublimed. With a good telescope he could discover at the bottom two small pools, which he supposed to be full of the same combustible matter. He likewise observed that the sulphureous fumes which in the day time appeared white, were by night resplendent but placid flames that rose above the mountain, and diffused their light to some distance.

When I made my observations at the bottom of the crater, though the sulphur flowed in many parts of the cavern, as I have already said, yet it did not stagnate in small pools or pits at the bottom; nor did the sulphureous flames arise by night more than some

feet from the bottom.

The changes which have taken place in the internal parts of this volcano, since it was visited by the French naturalist, have probably originated from some later eruption; since it is to that cause that changes of any moment in volcanic craters are usually to be attributed. And in fact, according to the unanimous testimony of the inhabitants of Lipari, it suffered a very violent commotion in the month of March 1786. After subterraneous thunders and roarings, which were heard over all the islands, and which in Vulcano were accompanied with frequent concussions and violent shocks, the crater threw out a prodigious quantity of sand mixed with immense volumes of smoke and fire. This eruption continued fifteen days; and so great was the quantity of sand ejected, that the circumjacent places were entirely covered with it to a considerable height; and, at a small distance from the crater, to the east, there is still an eminence, of a conical form, half a mile in circumference, consisting wholly of this pulverised substance, and, as I was assured, entirely produced at this time. The aperture that must then have been made in the bottom of the crater to discharge such a quantity of matter, and the accumulations of that matter in various places, must necessarily have caused great changes around and within the crater; one of which, without doubt, is the declivity produced in the southern sides, in consequence of which it is now possible to descend to the bottom of the gulf; for we find that this long descent is entirely composed of sand.

No lava flowed in this eruption, at least not over the edges of the crater. With respect to the lava of a vitreous nature which is found on the surface on the northern side of the mountain, and of which we have already spoken, M. Dolomieu observed that it existed

when he was there, and he tells us that it was thrown out in large masses in an eruption in the year 1775: an assertion of the truth of which he should have produced unquestionable documents; for, according to the accounts I received from the natives of Lipari, no cruption of lava has happened in the memory of any persons now living in the island, nor do they seem to have any tradition of any. Clouds more or less frequent or thick, sometimes black and sometimes of a white colour, and emitting a stench of sulphur; subterraneous thunders and concussions, which often shake the whole mountain; flames which rise to a greater or less height from the bottom and sides of the volcanic gulf; the possibility of entering this gulf at one time, and the impossibility of such entrance at another; ejections at different times of ignited stones, pieces of vitreous substances, sand, and ashes; these are phenomena with which the people of Lipari have been long acquainted.

I must here add the observations of two other men of science, relative to the crater of Vulcano, Father Bartoli and M. d'Orville. The former visited the island in 1646, and relates that it contained a deep gulf, entirely in a state of conflagration within, and in a small degree to be compared to Etna; and that from its mouth a copious smoke conti-

nually exhaled.*

When M. d'Orville visited Vulcano, in 1727, it had two distinct craters, each of which was at the summit of an eminence. From the first crater, which was situated to the south, and which was about a mile and a half in circuit, besides flame and smoke, ignited stones were ejected; and its roaring was not less than that of the loudest thunder. From the bottom of this gulf rose a small hill, about two hundred feet lower than the top of the crater, and from this hill, which was entirely covered with sulphur and dirty corroded stones, fiery vapours exhaled in every part. M. d'Orville had, however, scarcely reached the edge of this burning furnace when he was obliged precipitately to retire.

The second crater lay towards the north part of the island. Its conflagrations were more frequent and ardent; and its ejections of stones mixed with ashes and an extremely black smoke were almost continual. M. d'Orville further relates that the noise of this volcanic island was heard many miles; and was so loud at Lipari that he could not sleep

the whole night that he remained there.†

If we consider for a moment these two accounts, we shall perceive from the first, that when Father Bartoli visited Vulcano, the conflagration in its crater was much more vigorous than when I was there; and from the second, that in the time of d'Orville it was in a state of complete eruption. But the most remarkable circumstances are the double burning crater, and the bifurcation of the mountain of Vulcano; whereas at present there is but one crater, and the summit of the mountain is single, which summit contains the crater, resembling in figure a truncated cone. The hill which rose to a certain height from the bottom of one of the two craters still exists, though it is not peculiar to this volcanic mouth, since the same kind of hill has at times been observed in Etna,‡ and likewise in Vesuvius.§

When I was at Lipari, as I had read d'Orville's account, I made inquiries of some of the oldest people in the island relative to this double burning crater, and I found some few of them who retained an imperfect recollection of it. But from that time to this there has been only one crater, and I am not certain whether the present be that which the above-cited author describes as on the south side of the island, or that which he men-

tions as on the north.

The side of the island which looks towards Lipari is entirely barren, and does not produce any kind of vegetable; but this is not the case with the other sides that front the south and the west, and which are partly covered with holms and oaks, besides quantities of broom and other shrubs. It is obvious to suppose that those parts of the island which afford so much nourishment for plants have been more subject to decompositions than that which remains barren. The substances of which they are composed are lavas become soft to a certain depth, and affording reception and nutriment to plants. This decomposition is not to be attributed to sulphureous acids; for it is not distinguished by a white or any other colour; but originates from the humid elements, and other causes in the atmosphere. I caused several of these lavas to be broken away with hammers and pick-axes, quite to the internal part, to which the causes producing change could not penetrate; and there I found them retain all their usual solidity and freshness. In general they are porphyritic, with a petrosiliceous base, and contain feltspathose crystallizations. They descend from the summit of the mountain, on the southern side, with a steep fall till they reach the sea. Mixed with the lavas are found large pieces of glass and enamel, which I shall not here describe, as they do not differ from those of Lipari, of which I shall speak in their place.

Such are the observations I made in four different visits to this island, to which I shall add another relative to a smaller crater, different from that of Vulcanello, and which has not, to my knowledge, been noticed by any other traveller. It lies about half way up the mountain, to the east of the way I took to reach the summit. Its form could not more distinctly characterize it as a real crater, since it is precisely that of a tunnel, wide above and narrowing below. Its mouth is about three hundred feet in circuit, and its bottom about eighty. A full quarter of this bottom is filled up with earth carried by the rain down the sides, which are in consequence marked with long furrows. Hence it appears that in process of time this crater will be entirely filled up with earth, like

that of Vulcanello, and no trace of it remain.

In the same manner as many of the sailors of Stromboli, before they put to sea, are accustomed to consult the fumes and eruptions of their burning mountain; the mariners of Lipari believe the changes of the winds and weather may be foretold by observing Vulcano. Instructed, they say, by long experience, they are able to predict, twenty-four hours before any change, whether the weather will be fair or tempestuous, and from what point the wind will blow. In a work entitled Tracts by Sicilian Authors,* printed at Palermo in 1761, there is a "physico-mathematical discourse on the manner in which the variations of the winds may be foretold, twenty-four hours before they happen; by the different qualities and effects of the fumes of Vulcano, by Sig. Don Salvadore Paparcuri of Messina."† In this essay we find an extract from a number of observations made on Vulcano between the years 1730 and 1740, and communicated to the author by Don Ignazio Rossi, a native of Lipari. This extract I shall here present to my readers.

"The change of weather and winds is presignified by Mount Vulcano twenty-four hours before it takes place, by a louder than usual noise, resembling distant thunder; and if we carefully observe the smoke which then issues in a greater quantity than usual, we may likewise discover what kind of wind will succeed, which may be predicted from the greater or less density of the smoke, and its more or less dark colour, which is occasioned

* Opuscoli di Autori Siciliani.

[†] Discorso Fisico-matematico sopra la variazione de' venti pronosticata ventiquattre ore prima dalle varie e diverse qualita ed effetti de' fumi di Vulcano, del Sig. Don Salvadore Paparcuri, Messinese.

by the quality and quantity of the dust that rises in the smoke, and renders it sometimes of an rsh-gray colour, sometimes perfectly white, sometimes of a colour approaching to

black, and sometimes entirely black.

"The following are the observations I have made on this subject. When the wind is about to change to the sirocco or south-east, or the east-south-east, or south-south-east, the smoke rises so dense and black, in so great a quantity and to such a height, and afterwards dissipates in so black a dust as to strike the beholder with a kind of awe; and at the same time so loud a roaring is heard, frequently accompanied with a shaking of the earth, as to inspire with dread even those long accustomed to these roarings and shocks. But when the wind is on the point of changing to the north-north-east or north-northwest, the smoke rises more slowly, is less dense, and entirely white; and when it is dissipated, the dust which falls is extremely white. No such loud noise is then heard, nor any shock felt; at least I observed none, nor can the oldest inhabitant of this island remember to have felt any. When it is about to change to the east or east-north-east, an explosion is heard in the body of the mountain, which soon after throws out a little smoke of a gray colour, of which colour are likewise the ashes that fall when the cloud is dispersed. The mountain in the mean time explodes and roars so violently at intervals, that we frequently dread the shock of an earthquake. Lastly, previous to a change of the wind to the west, the west-south-west, or west-north-west, vast volumes of smoke arise, of a dark ash-gray, approaching the colour of lead, and so thick that when they disperse they occasion a continued shower of ashes."

On these observations of the Liparese meteorologist, Signor Paparcuri proceeds to phi-

losophise, whether pertinently or not I shall not inquire.

. I should think myself justly to incur the imputation of rashness, should I venture absolutely to deny these facts, without having sufficient reasons so to do; especially as they are so precise, so circumstantial, and said to have been observed upon the spot. It besides does not appear credible that the abbate Rossi would have published these observations, had they been merely the fabrications of his invention, in a place where he was liable to be disgraced by the contradiction of all his countrymen. I must however say, with philosophic candour, that during my stay of several weeks at Lipari, where I continually had Vulcano before my eyes, the principal winds mentioned in this extract blew, and particularly the south-east, the west, and the south-west; but I never observed, either before they began, or while they continued to blow, any shaking of the earth, or roaring, lofty columns of smoke, or showers of ashes. Once only, when a violent southwest wind was on the decline, the column of smoke which issued from the cavern of Vulcano increased prodigiously, and, from the resistance of the agitated atmospheric air, made some spiry windings; but when it had risen some poles above the upper edge of the crater, it began to grow thinner, and soon after entirely vanished. Though the wind ceased to blow, this prodigious cloud of smoke still continued to rise for several hours. I must add, that I once remarked the smoke of Vulcano to be extremely thin, and little in quantity, when a strong west wind blew; and that twice, when the air was perfectly calin, I observed the smoke extremely copious and rising to a great height. To conclude, after carefully noticing day by day every change that took place in the phenomena exhibited by Vulcano, during my stay in its vicinity, I could perceive none which afforded support to these famous prognostics. I likewise inquired of the sailors of Lipari, and frequently brought them to confess that the fact did not accord with their assertions. But, besides that they did not agree among themselves, they endeavoured to evade conviction by all those excuses and pretexts which I have observed sea-faring people never to want, to support their particular prejudices relative to the signs of good or bad weather;

l'o connomena hich af-Lipari, ertions.

de connever to reather; in consequence of which they sometimes become the victims of their own credulity by suffering shipwreck.

I am not, however, so positive as to deny the whole of these observations. To know with certainty whether any direct relations exist between the various symptoms of Vulcano and the changes of the atmosphere, it would be necessary to reside for some years in that island, a place truly wild and desolate; and he who, like Empedocles at Etna, should go to erect his dwelling there, in order to observe the changes of the mountain, would have no other companions than the rabbits which make their burrows on the southern side of the island.

Disregarding, however, at present the pretended relations, observed by Signor Rossi, between Vulcano and the winds; if the accounts of the eruptions which then from time to time issued from its crater may be relied on, we must own that at that period the convulsions of this mountain were much more violent and frequent than they are at present: a fact which accords with the observations of M. d'Orville and Father Bartoli.

Before I conclude my remarks on Vulcano, two things remain for me to notice, agreeably to the plan I have followed relatively to the other Eolian isles. First, to specify the results obtained by our common fires in those kinds of rock which, liquefied by subterranean conflagrations, have given birth to the island; and, secondly, to mention the notices left us by the ancient writers relative to Vulcano. The former object of inquiry has been sufficiently discussed, while treating of Stromboli, where we have detailed the changes undergone in the furnace by porphyritic rocks; since, as has been already shewn, rocks of a similar kind have furnished the materials of which Vulcano is composed. We have therefore only to treat of the latter of these subjects.

We are indebted to Thucydides for the first account we have of this island. He relates in his history, that in his time Vulcano threw out a considerable flame by night, and

smoke by day.*

Aristotle, in his Treatise concerning Meteors, describes an ancient cruption of Vulcano, a part of which swelled and rose, with great noise, into a hill; which bursting, a violent wind issued forth together with fire, and so great a quantity of ashes as entirely to cover the neighbouring city of Lipari, and extend to several of the towns of Italy.

This eruption was still visible in his time.+

The interesting observations of Polybius relative to the number, size, and figure of the craters of Vulcano, are likewise particularly deserving our notice. In his time there were three; two tolerably well preserved, and one in part fallen in. The mouth of the larger, which was round, was about five stadi, or five-eighths of an Italian mile, in circuit. This crater towards the bottom grew gradually less, till at last it was only fifty feet in diameter; this part was one stadium above the level of the sea. The form of the other two craters was the same.

Such is the account of Polybius, as quoted by Strabo, who himself tells us of three openings or craters at Vulcano, from which flames issued, and ignited matters were

thrown out, that filled up a part of the sea of considerable extent.

VOL. V.

From the two latter passages we learn, therefore, that anciently there were in Vulcano three burning mouths, or more properly craters, and that one of them was very large. Are we to conclude that this larger crater was the same that at present exists, and which since that time may have increased its dimensions? This may possibly be the truth; and it may perhaps be equally so, that of the three craters mentioned by Polybius and Strabo, two still remained in the time of d'Orville, who found a double burning crater at Volcano, though at present there is only one; the other two no longer appearing, either because they have fallen in, or been filled with earth by the rains, or possibly have been covered by subsequent ejections.

From the text of Strabo it may be inferred, that in his time Vulcano ejected lava, since the burning matter thrown out filled up a part of the sea of considerable extent.

Callias, in his Life of Agithocles, 'Tyrant of Syracuse, relates that on a lofty eminence of Vulcano there were two craters, one of which was three stadi in circumference, casting a great light to a vast distance; and that from his mouth burning stones, of a prodigious size, were thrown out with so great a noise that it might be heard to the distance of five hundred stadia.*

If, therefore, we believe the testimony of Diodorus and Fazello, who, as natives of Sicily, have the best claim to our attention, we have already seen, when treating of Stromboli, that the former asserts that both that island and Vulcano threw out sands and burning stones; and we learn from the latter, that Vulcano was in a continual state of conflagration; and that from its gulf, which lay in the middle of the island, a cloud of thick smoke continually issued, while through the fissures of the stones, and narrow apertures, a pale flame arose in the midst of the dark cloud.†

Cluverius likewise affirms, that from the neighbouring shore of Sicily he had himself

observed by night a similar fire amid the dark smoke. 1,

And here it is proper, with Cluverius, to correct a mistake of Fazello, who, relying on the authority of some superficial writer, has been induced to believe that the island of Vulcano emerged from the sea in the year of Rome 550, without reflecting that, two hundred years before that period, it is mentioned by Thucydides, and that Aristotle, about a century after him, had described one of its eruptions. The mistake has been occasioned by the origin of Vulcanello, which about this time arose out of the water. Pliny has remarked that when this island was thrown up, a great number of fish were found dead, and caused the death of those who ate of them.

The same Fazello relates, that Vulcano was separated from Vulcanello by a narrow channel of the sea, in which ships might lie with safety; and that this strait was open

in his time; but afterwards filled up by new eruptions of Vulcano.)

The brief statement of facts recorded by history, when compared with the observations of Bartoli, d'Orville, De Luc, Dolomieu, and myself, clearly proves that this island

is a volcano, which may be compared to Vesuvius or Etna, with respect to the changes in its craters, the variety of its eruptions, and its longer or shorter intervals of repose; except that, from the want of aliment for its fires, its ejections are less frequent and less conjous.

From the authorities above adduced, we perceive that the fires of this mountain are very ancient, since they burned in the age when Thucydides flourished, or 475 years before the Christian æra. This island was then called Hiera (**in**) or the sacred isle, as being sacred to Vulcan; for the inhabitants of the neighbouring islands, as Thucydides informs us, perceiving it continually to flame by night, and smoke by day, believed it was the residence and forge of that god.* It is however extremely probable that these volcanic conflagrations are much more ancient than this period; as is the island where they are produced, which no doubt derived its origin from fire, though its formation is concealed amid the darkness of the most remote ages.

The accounts here given of the present state of Vulcano, clearly shew the mistake of Sir William Hamilton, who compares it to Solfatara near Naples; a mistake occasioned

by his not having visited the island.

We have spoken above of the opinion of many of the natives of Lipari, that it is possible to forctel with certainty what winds will blow, from the different appearances of the smoke of Vulcano. I find that the ancients likewise boasted the knowledge of the same prognostics. They inform us that before a south wind blew, the island of Vulcano was enveloped in a dark cloud, so that Sicily could not be seen; and that when a north wind was to be expected, a pure flame rose high above the crater, and the roarings were more violent; while a kind of I know not what middle symptoms preceded the zephyr or west wind. The various sounds of the explosions likewise, and the different places where the eruptions began, the flames, and the smoke, were all prognostics of the wind which should blow after the third day. Such is the account of Polybius, who has been copied by all the writers who have succeeded him.†

These prognostics, however, which the Creek historian probably received from the mariners, accord but little with those of Signor Rossi above cited, and still less with the phenomena observable in Vulcano at present; either because such indicatory signs can no longer take place, now that the volcano is in a comparative state of tranquillity; or because these boasted predictions originated more in exaggeration and credulity than the

faithful testimony of the senses.

CHAPTER XV.

LIPARI.

PART THE FIRST.

OBSERVATIONS MADE ROUND THE SHORES OF THE ISLAND.

Unavoidable delays in making the circuit of the island....The city of Lipari and its harbour.... Immense rock of lava and glass on which the castle of Lipari is founded....Reasons for believing that the internal part of this rock is a true glass....Other proofs of the ancient existence of fire in that place, derived from the pumices of the same rock.... Our common fire acts on volcanic glasses differently from the subterranean fires.... Other observations made within the harbour....Porphyritic lava of a beautiful red found in its vicinity.... author leaves the harbour, and makes the circuit of the island, proceeding towards the north.... The enormous breaches made by the sea in the shores of the Eolian islands extremely favourable to the discovery of volcanic products....Another red porphyritic lava.... Extraordinary course of another lava.... The Campo Bianco (White Field) so called from the white pumices of which it is an entire mountain....Their different species described in detail....Analysis of these and other kinds of pumices in the humid way....Discussion of the different opinions relative to this kind of volcanic products....The Monte della Castagna composed of vitrifications and enamels....Properties of theseCapillary vitrifications....Others which may be considered as in a state of transition from pumice to glass.... Not probable that the glass passes into pumice, as some have believed Resemblance and difference of these two substances.... Enumeration of some other kinds of glasses, one of which greatly resembles what is called the Iceland agate, or gallinaceous stone of Peru.... Glassy lavas of the Monte della Castagna....This mountain and Campo Bianco, with their environs, form a vitrified mass eight miles in circuit....This vitrification more extensive in ancient times.... No characteristic sign of the existence of the ancient volcanos on the sides of this mountain....Indubitable proofs, however, that some of the above-mentioned vitreous substances have flowed, and others been thrown up, from volcanic gulfs....Feltspars and petrosilex commonly the base of these vitrifications ... Question, whether the vitreous parts, incorporated with or continued through the different lavas, owe their origin to a more vehement action of the fire, or to their being more easily vitrifiable....Singular phenomenon relative to this subject....Universal sterility of this extensive vitrified tract....Uncertainty of the rule which estimates the dates of lavas from their being more or less converted into vegetable earth.... Multiplicity of lavas decomposed by sulphureous acids, and variously coloured by the oxyde of iron, found beyond the Monte della Castagna....Decompositions of other lavas, occasioned by the same acids, and other enamels and pumices found on the shores of the island ... Extremely minute shoerls, and beautiful quartzose crystals, and chalcedonies, originating from filtration, in some decomposed lavasTwo large rocks in the narrow channel which divides Lipari from Vulcano....This channel in ancient times must have been narrower than at present.... Conjecture that it once did not exist, and, consequently, that these two islands formed but one ... Figure of the Monte della Guardia seen from the sea....Its rocks of lavas, pumices, and vitrifications.....Prodigious quantity of vitreous eruptions which compose this mountain.

THIS island, from its extent, the city which renders it illustrious, the number of its inhabitants, its commerce and agriculture, claims pre-eminence above all the others by

which it is surrounded, and which from it derive the name of the Lipari islands. Nor is it less important in the estimation of the naturalist, from the quantity, variety and unusual beauty of the volcanic products it contains. M. Dolomicu, during the four days he remained here, gathered as ample a harvest as within so short a time could be expected from the most discerning and indefatigable lithologist; but it is easy to conceive that he must still leave much to be discovered in an island nineteen miles in circuit. During the eighteen days that I remained there, I may say that the sickle was never out of my hand; yet I will freely confess that I left behind me many a handful, which I would willingly have gathered, had this volcanic island been less distant from my home.

For the sake of order in my account of the observations I made in this island, I shall first state those which occurred to me in making its circuit, and examining its shores; and next, those I made in its interior, and in ascending its mountains. My remarks will

thus, naturally, be divided into two parts.

PART THE FIRST.

OBSERVATIONS MADE ROUND THE SHORES OF LIPARI.

IN making this circuit, that I might perform it completely, I employed more time than I had imagined it could require. Besides the time necessary for remaining with the boat at a little distance from the shore to observe the different courses taken by the volcanic matters, in their way to the sea, when liquefied by the power of the fire; besides that consumed in landing to examine these matters more nearly, and breaking them to pieces with suitable instruments, that I might collect and preserve them; lastly, besides the time requisite to ascend or rather to climb up, steep rocks, cliffs, and precipices, which rose from the waves, at the termination of the course of the eruptions; I was not a little delayed by the obstacles which continually opposed the execution of my design. How often, when I attempted to prosecute my intended circuit while the sea was calm and smooth as the most placid lake, have I been obliged to desist, and return with my boat, by a wind suddenly rising, either contrary, or blowing in upon the land, so as to expose me to the danger of being driven upon the shore, and shipwrecked on the rocks! Frequently, though the sea was sufficiently calm for a considerable distance, yet, where the coast broke off, or sunk in, I found it running high, from the remains of a storm that had not long ceased, or, as it is termed, an old sea, which my boat was unable to encounter without great danger. Every one who is acquainted with the sea that surrounds the Eolian isles, knows how liable it is to sudden tempests.

The city of Lipari extends along the shore in the form of an amphitheatre. Behind it rise a chain of mountains; and in front is its harbour, formed by the hollowing in of the sea, which here divides the shore. I omit to mention another very small harbour to the south, only fit for the reception of such vessels as may be drawn up on shore.

I began my researches in the harbour itself, under the eastle of the city, which is erected on an immense rock of lava, that rises perpendicularly from the water, and is entirely destitute of all vegetation except a few stalks of the Indian fig,* which grow in its fissures.

This lava has for its base feltspar, is of a fine and compact grain, of a scaly fracture, dry to the touch, and gives sparks, like flint, with steel. It is of a cinereous colour, in many places approaching to that of lead. It is full of an immense quantity of small extraneous bodies, which would be with difficulty distinguished from the substance of the

believence of volcae hararbour, eaches very of The moun-

ic pro-

f these

desemes, one eru.... eir enincient of this stances c comd with he fire,

lava on account of their resemblance in colour, were they not little globes. This lava is joined to large masses of glass, which form a whole with it, without any divisions of separations in the middle. It therefore is the same lava, which in some places retains its nature, and in others is transmuted to glass. This glass in some parts contains the small extraneous bodies before mentioned, but in others it is pure glass. In general it is extremely compact, of a dull black colour, and fractures rather in irregular pieces than in waving streaks, as is usual with glass. It has besides a kind of unctuosity to the touch, and even apparent to the eye, which is not observable in any other of the most perfect volcanic glasses. Like the lava it gives sparks with steel; but the lava is entirely opaque, whereas the glass in the angles and thinner edges, has a considerable degree of transparency. It only appears opaque where it contains the minute globes, which are particles of the lava. Though the lava in the fractures has not the lustre of the glass of which it is a continuation, yet when cut and polished, it is not in the least inferior to it in that respect. I possess several pieces, cut and polished, which are half glass and half lava, and of which the different colours form an excellent contrast.

An observation which I made relative to this kind of glass appears to me too impor-

tant to be omitted.

If we take a piece of this glass, six or seven feet in length, and four or five thick, and attentively examine it, we shall discover that it is marked with small gray veins parallel to each other, which give it the appearance of being divided into strata or flakes; and if the point of a large pick-axe be struck by a powerful arm into one of these veins, and used as a lever, the whole mass will split into two parts, from one end to the other, following the course of the vein; and with equal facility, by proceeding in the same manner, may new divisions of the glass be obtained in the other veins, till the whole piece is divided into a number of plates proportionate to the number of veins: but if we attempt to divide them in any other part but the vein, they only break into small irregular fragments.

When we examine the face of one of the plates thus divided, we perceive that every vein consists of a thin leaf of earthy and scoriaceous particles, which prevents the vitreous strata from perfectly uniting. The direction of these veins, which intersect the glass transversely, is generally from above to below; and it appears evident to me, that the plates or sections of glass interposed between the veins have been produced by as many different flowings of the fluid matter. The formation of the earthy veins I conceive to have been as follows: the first stream, that is to say the lowest of all, containing lighter and less fusible particles than the remainder of the liquefied vitreous matter, these floated on the top; and the glassy current, cooling, produced, or rather left on the surface, a first pulverous coating, which prevented the perfect union of the second current that succeeded the first; and this second, containing similar subtile matters, prevented in like manner the full adhesion of the third, and so of the rest. Thus have successive flowings of the liquid matter produced the masses of glass we now see, exhibiting those apparent veins, in which they may be so easily split. But as we shall have occasion to speak of other glasses, in another place, we shall then have an opportunity to resume the subject of this peculiar texture.

Such were the observations I made on that rock, and some fragments which had fallen down from it on the shore; since, though it is composed of hard lava and glass, yet from the numerous fissures in it, caused by congelation, it has sustained many losses. In fact there is danger that it may become so entirely ruinous as to occasion its fall, to-

gether with that of the castle it supports.

ich had d glass, y losses. fall, tøI cannot dismiss this subject without mentioning certain circumstances which induce me to believe that the inside of this rock is one prodigious mass of glass. The waves of the sea, by incessantly beating against it, have corroded it in several places, but especially towards the middle, where they have formed a spacious cavern; which, as the lower part of it is covered with water, I entered in my boat, and found that the sides were real and solid glass.

In other places, against which the sea has dashed, and more or less broken the rock, the same vitreous substance is apparent. If we ascend from the shore to the castle, in more than one place near the road, which lies over lava, we find volcanic glass. In the small square, near the house of the commandant, we find it rising above the ground in large pieces resembling steps. Great masses of it likewise project from the ground within the city, in two places of which, having caused the earth to be dug into, I found

the same glass.

All these facts and observations appear to me sufficiently to support my opinion, which as I have said, is, that the inside of this vast rock is entirely of glass. We perceive therefore that though on making the circuit of the other parts of the island, we should not be able satisfactorily to ascertain its nature, these facts alone would be more than sufficient to prove it volcanic; and an intelligent, though indolent traveller, who on arriving at Lipari should only take the trouble to go over the city, would perceive, in a few hours, what in many other countries, once subjected to the action of fire, he would not be able to discover in a much greater number of days.

But the indubitable testimonies of the ancient existence of fire in this place do not conclude here. The vitreous substances are frequently accompanied by pumices which are, in fact, only an imperfect glass. If we view the steep masses of glass and lava, which rise perpendicularly from the sca, like a wall; we perceive that they are interspersed with different strata of pumice, from which, by the aid of a pole tipped with iron, small pieces may be broken off. On the shore, however, we do not find it in any

great quantities.

This pumice is of two kinds, the one heavy and compact, the other light and porous, and both of a cinereous colour. The compactness of the former species, however, is not so great, but it may be broken into small pieces, and crumbled into powder between the fingers. It is dry and rough to the touch, is filamentous in many places, and crackles between the teeth; qualities appertaining to common pumices. Its structure is not every where filamentous, but in some places so fixed that its fibrous texture cannot be discerned. By the aid of the lens we perceive that it is of a vitreous nature, and discovers an infinity of lucid points, which we might take for very minute feltspars, did not a careful examination with a good magnifier shew them to be real particles of glass. It cannot be denied, that this pumice is of the same nature with the lava of the rock, since we see, in many places, the lava gradually lose its solidity and fineness of grain, and assume the characters of this species of pumice.

The other kind is rather scaly than filamentous, and its scales have a degree more of vitrification than the other; the confluence, likewise, of some of these scales has produced, in several places, small lumps of a black glass. It is, however, extremely light in consequence of the pores and vacuities with which it abounds. This pumice is usually a continuation of the other, and, in my opinion, derives its origin from the greater

degree of heat which it has sustained.

After having examined, and attentively considered on the spot, this mixture of lava, glass, and pumice, which forms the body of the rock, it appears evident to me that there have been several currents that have flowed down the sides, and, perhaps, from the sum-

nit, of the contiguous mountain della Guardia, into the sea, since the direction of their descent is found on that side, and even the filaments of the pumices point towards that mountain.

If we except those minute globules, which appear to me to be portions of lava, this lava, glass and pumice, exhibit neither feltspars, shoerls, nor any other extraneous body; either because these have been melted by the fire, or, perhaps, because they never existed in them. But in what manner this fire must have acted in fusing those masses of feltspar of which the rock that supports the eastle of Lipari is formed, so that this stone should now have remained a simple lava, and now have passed into the state of glass or pumice, shall be considered in another place; at present I shall proceed to state other facts analogous to the same subject.

The lava and glass of the rock, when exposed to the furnace in separate crucibles, fused into a light gray glass, the globules which before appeared in them melting at the same time. This glass is incredibly porous. Though the crucible in which these substances were fused was only filled to one quarter part of its contents, they swelled so much when in a state of liquefaction, that they rose several lines above the edges of the crucible, and flowed over, down its sides.

The two kinds of pumice, though both derive their origin from the same feltspar, which is the base both of the lava and the glass, afford different results in the same fire; since their volume instead of augmenting is diminished, only retaining its former colour.

The tumefaction or inflation of this glass may, perhaps, excite some surprise; since it implies a prodigious quantity of gaseous bubbles contained within it; whereas nothing of the kind is observable in it, when it is acted on by the fire. But we shall see hereafter that this is an appearance common to almost all glasses and compact volcanic enamels, and which I shall consider when I come to speak of the nature of the gaseous substances that frequently turnefy more or less different volcanic products: at present my object is only to state and compare facts. I shall only say that I have never met with any thing similar in the re-fusion, not only of common factitious glass, but even of that which is sometimes produced in the furnaces for baking bricks and tiles. A few years ago a large piece of glass was put into my hands which was said to be volcanic, but of which I entertained doubts, since, though in its great weight and hardness it resembled the volcanic glasses, it differed from them in certain spots and blueish streaks, and in a kind of little stars which seem. I to indicate a principle of crystallization in this glass; neither of which appearances I ever observed in the glasses of volcanos; and on a careful examination, to discover with certainty its origin, I found that this glass had been brought from a tile-kiln. When re-melted in a glass furnace it retained its former solidity and compactness, without exhibiting the smallest pore or bubble; and instead of swelling in the crucible, and assuming a convex superficies, it sunk, and acquired a concave one. I have observed the same in two other similar glasses.

The haven of Lipari forms a curve in the shore, which to the south begins at the foot of the Monte Capiscello, and ends to the north-east at the bottom of the Monte della Rosa. After having therefore examined that part of the shore which is contiguous to the harbour, lying under the eastle, and on the right side of Monte Capiscello, I made the circuit of the remainder of that curve to the base of Monte della Rosa. The objects which here attracted my notice were first a tufa above a lava, which the industry of the inhabitants had converted into a soil suitable to small vineyards; and next a mass of crags and precipices, partly fallen into the sea, and partly threatening to fall, among which, besides scoriæ of an iron colour, we meet with beautiful volcanic breccias of a lava of a petrosiliceous base, and containing small particles of glass and pumice.

egins at the the Monte contiguous ello, I made The obindustry of ext a mass of fall, among preccias of a nice.

I cannot think of this place without shuddering at the dreadful danger to which I should have been exposed had I visited it two days later. I was there on the 21st of September, and examined the breccias which had fallen down on the shore, and those, much more numerous, and more deserving attention, which remained still attached to the rugged declivity that descends into the sea. On the 23d in the afternoon, almost the whole of this declivity fell down with a dreadful crash. I was at that time taking my afternoons nap in the house which had been politely appointed for my reception by the consul of Lipari, and is situated on the shore of the harbour. The noise immediately waked me, and at first I could not tell whether it was a violent clap of thunder, an earthquake, or the roaring of the waves in a tempest. I ran to the window, and perceived that it came from the declivity I have described, but could discern nothing but an immense cloud of dust by which it was covered. The noise lasted, perhaps, five minutes; and when the cloud of dust had somewhat dispersed, I perceived it was occasioned by a prodigious quantity of stones that had fallen down into the sea, and that a great number continued still falling.

Two sensations, on this occasion, most powerfully affected my mind; the one of shuddering and horror on reflecting that my destruction must have been inevitable had I postponed my visit to this place two days and a half, and the other of satisfaction and

joy at my fortunate escape.

The fall of so great a quantity of stones, produced a large longitudinal furrow in the declivity, and a small indentation in the sea. The next day I procured several of these stones, and found that they were pieces of lava, partly of the horn-stone base, and partly of that of feltspar. The latter had a fine grain, and some transparency when in thin pieces; the former were of a coarser grain, and opaque. When I went in the boat to examine the part of the mountain where these stones had fallen, I perceived that it was formed of loose volcanic stones, which were very liable to fall from the steepness of the declivity, and I judged them to be fragments of lava, detached by length of time, from a more elevated rock, and afterwards accumulated below, at a little distance from the sea.

Having arrived at the foot of the Monte della Rosa, where, as I have said, the harbour of Lipari ends, I perceived on the shore a stone, which, from its singularity, drew my attention. It forms a rock that in part rises above the sea, and in part is concealed by the water. There are also several detached pieces of it which have been made round by the action of the waves. I, at first, took it for a jasper. Its ground was of a bloodred colour; it gave sparks strongly with steel, was of a rather fine grain, and had almost the hardness of quartz. When I first saw it, it reminded me of the jasper I had observed and collected at Schemnitz in Lower Hungary, under the hill Calvario, and of which some specimens are preserved in the Imperial Museum, it appearing to me that these two stones were extremely similar; but on a more attentive examination, I perceived that this stone was not simple like the jasper, but of a compound formation, containing in it reddish scales of feltspar, and shoerls, which gave it the character of that kind of porphyry which has for its base a hard horn-stone. But is this porphyry in a natural state, or in that of lava? Lavas of a red, and a bright red, colour, I confess, I had never before seen, nor do I know that they have been observed by any other naturalist; and I therefore doubt whether the detached red porphyry I found at Stromboli had ever suffered the action of the fire. It is true that many lavas near the stoves of Lipari and elsewhere have this colour, as we shall see in the following chapter; but this arises from the decomposition they have suffered by the force of sulphureous acids, and the action of iron: and I shall there shew that the red colour (and the same may be VOL. V.

said of the white, green, and other colours) has only penetrated as far as the action of these acids, and, consequently, the decomposition, has extended; but where the lava remains untouched by them, it still retains its natural colour, that is, either a gray or the colour of lead or iron, but without any mixture of red. We lo not, however, discover any traces of decomposition in the production of which I no peak. After the most careful examination, I cannot exclude it from the number of tage and real lavas; though, on the other hand, I am unable to affirm that its reduces is an effect of calcination, as is the case in other lavas, since of this it does not exhibit the slightest indication. We must here, therefore, have recourse to one of those limitations which experience has obliged us to admit in many other rules of philosophy, which were at first thought to be absolutely general, but afterwards found to be subject to more than one exception. The reasons of fact on which I found my assertion, that this porphyritic rock has passed into the state of lava, are two: the great number of minute cells it contains in many parts of it, and the direction of those cells. Where local circumstances are insufficient to determine, the compact lavas rarely leave the inquirer in doubt whether they derive their origin from fire, as the fire has not so changed them as to destroy the characters of the stone from which they were produced. But it is not the same with the cellular, since it is known that their configuration can only be the effect of acriform fluids, put in motion by the action of the fire. This cellular conformation is found in the present stone. The cells in many large pieces are so numerous, as to occupy nearly one half of the volume of the stone. The largest are about five lines, and the smallest a quarter of a line; but between these two extremes there are an infinity of intermediary sizes. It is worthy of remark, that these cells are not only superficial, but extend into the internal part of the mass, as is seen in fractures two or three feet in depth, which may serve to obviate the objection that even stones not of volcanic origin are sometimes cellular, since it is known that their cells of minute cavities are merely superficial, and originate from the corrosion of some of their external parts, by the filtration of the rain-water. This proof is supported by another still stronger, taken from the direction of the cells, which is the same in all, as well in the pieces detached from the rock, and deprived of their sharp edges by the waves, as in the rock itself. This direction is every where found to be from the Monte della Rosa to the sea, as they form ellipses more or less acute, the greater diameters of which are invariably in that position, and this greater diameter is frequently twice or three times the length of the less. This stone, therefore, is not only a true porphyritic lava, but it is evident that it once flowed from the mountain above-mentioned to the sea, and in its motion the naturally circular figure of its pores or cells was changed into an oval. - I have almost always observed the same appearance, on a smaller scale, in re-melted lavas, and glasses. As long as the matter in fusion remains within the crucible, the bubbles are orbicular, but become elliptical in that part of it which overflowing the edges runs down the side of the crucible; and the greater diameter of these ellipses is generally in the direction of that side.

All the pieces of this kind of lava are not, however, of a blood-red colour; some of them are of a duller red, though the component principles of both are essentially the same.

This lava, when fused in the furnace, doubled its volume, and its upper part assumed a vitreous convexity, which was smooth, shining, semi-transparent, and of a greenish tincture; but internally it was a very black vitreous seoria, extremely porous, and sufficiently hard to give sparks with steel.

With these observations on this uncommon species of lava, I shall conclude the account of my tour round the harbour of Lipari, which may extend about two miles.

miles.

According to my proposed plan, I was now to proceed to make the circuit of the island, which I did, taking my departure immediately from the foot of Monte della Rosa, and proceeding towards the north.

At the distance of somewhat more than three hundred feet a lofty rock rises from the sea of a horrid and dreadful aspect, formed of large plates of stone, feebly supported by projecting points, and appearing to hang in the air, and threatening to fall, as many have already, the fragments of which are seen on the shore. I must candidly confess, that, after the fall of the rock I have already mentioned, I approached this with no small dread. My ardour to make some new discoveries, however, triumphed; and, as I was afterwards frequently obliged to risk myself in similar situations, in order to examine accurately the shores of the island, I gradually acquired an habitual courage, and became almost incapable of any idea of danger. I hope I may be pardoned this little digression.

The Eolian isles, especially Lipari, Felicuda, and Alicuda, are, at their basis, more or less corroded by the sea, which, there, is so frequently in a state of violent agitation. The lower excavations cause the parts above them to give way, and, in a series of years, great masses fall into the sea. To this the nature of the lava, which is full of cracks and fissures, considerably contributes; not to mention the influence of the humidity of the atmosphere, and other destructive elements. Large heaps of these fragments, in consequence, accumulate on the shore, where they are dispersed by the waves, and make room

for others, and thus a gradual diminution of the island takes place.

These corrosions of the water, these fissares, and fragments of the stones and rocks are, however, peculiarly interesting to the inquiring naturalist, who, though he may make important discoveries while traversing the summits and sides of volcame regions, can never penetrate beyond the surface. The internal effects of the fire, the substances more or less modified by it, and sometimes prodigiously changed, even to the entire annihilation of the character of the original stone, and many other combinations produced in the subterranean recesses, by this ever active element, can only be known by incavations and fractures which exceed the strength of man to effect, but which, to a certain degree at least, are in many places produced by the sea. Of this we have already mentioned some instances, observed in making the circuit of the shores of the other islands, and shall adduce others in those which yet remain to be described; we have also a very remarkable example before us, in the half-destroyed rock of which we are now speaking.

Above, it is covered with a thick coating of earth, which prevents its true character from being visible; but on the shore it may be very distinctly seen, and appears to be formed of a lava, in thick strata, taking an oblique direction to the sea. This lava is likewise porphyritic, of a petrosiliceous base, containing crystallized feltspars, and, like the other rock I have before mentioned, of a red, but rather a dull red colour. It is not in the least porous, but extremely compact and solid, and is consequently extremely heavy, and rather of a siliceous than earthy grain. It lies on the shore in large pieces; the solidity and beauty of which, when well polished, would render it a no less splendid

ornament in buildings than the porphyrics which are not volcanic.

The degree of heat which fuses the other porphyritic lava is only sufficient to soften the present, and make it take the shape of the inside of the crucible and adhere strongly to its sides. It then assumes a black colour, and loses it's compactness, becomes filled with small round bubbles. In a more intense heat, it melts into an enamel, in like manner black and filled with bubbles: the feltspars, however, remain untouched, as in the enamel produced from the other porphyritic lava.

Continuing my tour beyond the harbour and the porphyritic rock, I found the sea form a kind of bay within the land, round which a few cottages are built, affording shelter to a small number of inhabitants who live by the profits of a vineyard that but ill repays their labour. The name of this place is Canneto; and above it is a current of lava, of an argillaceous base, similar to that of the Arso in Ischia.* This lava is not continued without interruption, but, like that of Ischia, broken, uneven, and here and there raised into a kind of little hills. Its external appearance is, on a larger scale, that of a field ploughed, with several furrows in an irregular direction, having great hillocks and deep intervals between them. I have observed this appearance in several other lavas beside the present and that of the Arso; and the cause of such a conformation may, it appears to me, be the following: It frequently happens that the lavas, when they flow, meet with impediments in their way which obstruct their course. When, therefore, such an obstacle occurs the stream must stop, or its motion become slower; but this not taking place in the parts behind, they continue to flow and increase the quantity of the lava which swells in that place, and, in consequence of its contact with the cold air, soon loses its fluidity, and is congealed into stone. The liquid lava, in the mean time, takes its course another way, if the obstacle is insurmountable; and if it meets with others, new stoppages or retardations are the consequence, producing other tumours; and thus the lava in many places becomes full of hillocks. It may likewise be, that the lavas flowing over places abounding with cavities, of which there are many in volcanic mountains, may partly sink into them, and thence afterwards rise somewhat above the former level, and thus produce the small elevations which are here observable.

I had now continued my tour, in the boat, till I approached Campo Bianco (the White Field) distant three miles from the haven of Lipari, and so called because it is a lofty and extensive mountain composed entirely of white pumices. When seen at a distance, it excites the idea that it is covered with snow from the summit to the foot. Almost all the pumices that are employed for various purposes in Europe are brought from this immense mine, and Italian, French, and other vessels continually repair hither to take in targoes of this commodity: the captain of the ship which had brought me to Lipari, had sailed from Marseilles to carry back a freight of this merchandize. I was not, however, actuated merely by those motives of curiosity that might induce any traveller to visit this remarkable mountain; I proposed to examine it with the eye of a philosopher and a naturalist.

The pumice-stone, with respect to its origin, though universally admitted to be the product of fire, is one of those bodies which have divided the opinions of chemists and naturalists both ancient and modern. It may, in fact, be affirmed that it has given rise to as many hypotheses and extravagant suppositions, as the question formerly so much agitated, relative to the nature of the yellow and gray amber. Without noticing the more absurd of these, I shall only mention that Pott, Bergman, and Demeste imagined that pumices were amianthuses decomposed by the fire; Wallerius, that they were coal or schistus calcined; Sage, that they were scorified marles; and, lastly, the commendator Dolomieu, that they were grantes rendered tumefled and fibrous by the action of the fire and aeriform substances.

The most effectual method to investigate the truth in so obscure a question, appeared to me to make the most accurate and minute observations on the spot; to collect and attentively examine the pumices most suitable to this purpose, and to make further ex-

Campo Bianco is a mountain that rises almost perpendicularly from the sea, and which, seen at a distance, appears to be about a quarter of a mile in height, and above half a mile in breadth. No plants grow on it, except a few which bear no fruit, and likewise grow on the tops of the Alps. Its sides are streaked with a great number of furrows, that grow deeper and wider as they approach the bottom, and have been formed by the rains, which easily corrode and excavate a substance so soft and yielding as pumice. The sea at the foot of it has likewise occasioned great devastations, by means of which we discovered a large vein of horizontal lava on which the last waves die away when the sea becomes calm. The formation of this lava was, therefore, prior to the vast

accumulation of pumices which rest upon it.

On attentively viewing this prodigious mass of pumice, we soon perceive that it is not one solid whole, and forming only one solid single piece; but that it is an aggregation of numerous beds or strata of pumices, successively placed on each other; which beds are distinguishable by their colour, and in many places project from the mountain. They are almost all disposed horizontally, and their position is not dissimilar to the stratifications so frequently met with in calcareous mountains. Each bed of pumice does not form a distinct whole, which might lead us to suppose that they had flowed at different intervals, and every current produced a bed or stratum; but it consists of an aggregate of balls of pumice united together, but without adhesion. It is hence evident that the pumices were thrown out by the volcano in a state of fusion, and took a globose form in the air, which they preserved at the time of their sudden congelation. We find many such cruptions of pumices in the Phlegrean Fields; as, for example, that which overwhelmed and buried the unfortunate town of Pompeii. The excavations which have been made to exhibit to view some parts of that city, manifestly shew, that repeated ejections of small pumices in immense quantities from Vesuvius, have covered it with vast accumulations of that substance, disposed in different beds or strata.

A great quantity of these Liparese pumices, of a globular form, are first met with on the shore near Campo Bianco; but as I doubted whether the action of the waves might not concur to produce the roundness of their figure, I rather chose to make my observations on those that actually formed the beds, which I did, by climbing up one of the sides where the ascent, though difficult, was not impracticable. Here I found pumices approaching, some more some less, to the globular form, and of different sizes, some not being larger than nuts, and others a foot or more in diameter, with innumerable sizes between these extremes. Though the ground colour of them all is white, in some ich clines to yellow, and in others to gray. They swim in water, do not give spark with steel, nor cause the least motion in the magnetic needle. Their fracture is dry and rough to the touch, their angles and thinner parts are slightly transparent; and their texture in all of them when viewed through the lens, appears vitreous; but this texture has diversities which it will be proper to specify.

Some of these pumices are so compact that the smallest pore is not visible to the eyes nor do they exhibit the least trace of a filamentous nature. When viewed through a lens with a strong light, they appear an irregular accumulation of small flakes of ice, their compactness, however, does not prevent their swimming on the water.

Others are full of pores, and vacuities of a larger size, usually of a round figure; and their texture is formed by filaments and streaks, in general parallel to each other, of a shining silver whiteness; and which, at first view, might seem to be silken, did they not present to the touch the usual roughness of the pumice.

These varieties are not only observable in different globes of pumice, but frequently in the same: it is therefore indubitable that these differences are not intrinsical and essential to the nature of pumices, but accidental, and arising from the action of aeriform fluids, which, dilating them in many places, when they were in a state of fusion, have produced that multitude of pores, and those filaments and subtile streaks that denote a separation of the parts; whereas the other pumices which have not been acted on by these gases, have preserved that compactness which results from the force of aggregation.

The fractures of the compact pumices are, in some places, shaded with a blackish, but at the same time shining tinge; which, when carefully examined, is found to be caused by a greater, though still a very slight degree of vitrification of the pumice itself; either because the fire has there acted with somewhat more force, or because the parts

were there more easily vitrifiable.

The pumices hitherto described form one of the species which the Liparese sell to

foreign traders.

None of these, so far as can be discerned by the eye, or even with the assistance of the lens, contain any extraneous bodies; but were we too hastily to conclude that they really do not, we should commit an error, as their vitrification by artificial means will prove. When kept in the furnace during an hour they become only more friable and of a reddish yellow colour; but when continued in the same heat for a longer time, they condense into a vitreous and semi-transparent mass, within which appear a number of small white feltspar crystals that were not visible in the pumice, because they were of the same colour. These stones, however, are not seen in every pumice thus fused; either because it did not contain them, or because they have melted into one homogeneous mass with the pumice. This is one of the many important cases in which we are able, by the means of common fire, to discover the composition of volcanic products which had at first been supposed to be simple.

But to render complete my inquiries relative to the pumices of Campo Bianco, it was necessary that I should not confine my researches merely to the part of the mountain I have mentioned, but extend them to all the principal places where they might be found. This I did, accompanied by two natives of Lipari, whose assistance was particularly useful to me, as they lived by digging pumice, and were well acquainted with every part of the mountain, and the different kinds of pumices it contained. It is impossible to describe the difficulties I met with in these excursions. We frequently passed along the edges of the deep ditches made by the rain-water, at the hazard, in case of a false step, of falling into them, and not easily getting out again; or the still greater danger of precipitating into the sea. The dazzling whiteness of the pumice, equal to that of snow, increased my fears; for I made my excursions in the day-time, when the sun shone, and was strongly reflected by these stones. Every one knows that snow, besides dazzling the sight, is accompanied with the inconvenience, when it is deep and has lately fallen, that the person who walks on it sinks into it to a greater or less depth: and the same inconvenience is experienced from the pumice, which in many parts of Campo Bianco is reduced to a powder several feet deep, and, when the wind blows on it, sinks in on one side, and is heaped up on the other. All these difficulties and obstacles I however surmounted, animated by that ardour which inspires the phitosophical traveller, and enables him to brave the greatest dangers, and such as can only be known and appreciated by those who have engaged in similar undertakings. I can affirm, therefore, with great satisfaction, that with the assistance and guidance of the two Liperese, there was no corner of the mountain that I did not visit; and when I reached the summe, and saw that it

w that it

joined another mountain, the foot of which was in the sea, and which was, in like manner, composed of pumice, I extended my researches to that likewise, and examined the different species of pumice it afforded, or rather which compose a very considerable part of it. I shall proceed to describe them severally, with as much brevity as possible.

I shall first mention those which constitute a branch of commerce at Lipari, and are applied to various purposes. One of these has already been sufficiently described: I shall only add, that it is found in considerable quantities in Campo Bianco, but solely in detached pieces, and not forming currents or veins; whence it is evident that it has

been ejected from the volcano, and has not flowed in the manner of lava.

The second species is cut by the labourers in parallelopipeds, about twenty-two inches long, and cight broad. This pumice is of a dark dirty colour, contains no extraneous bodies, gives a few sparks with steel, and is so light that some pieces of it will float on the water. It is formed by agglomeration of pumiceous bubbles, which are as it were, conglutinated together, and incline more or less to an oblong figure. To detail their various sizes would be useless prolixity. I shall only say, that from the very minute, and, if I may so term them, infinitesimal, they increase in size till some of them exceed an inch in diameter, though the latter are less numerous than the former. They are all extremely friable as their sides are very thin, and always semi-vitreous. The glass of many of them is white, and has some transparency, but in others is dull, and almost

entirely opaque.

As I do not know that this species of pumice has ever been described before though it certainly well deserves attention, I would wish my description to be as clear and explicit as possible. It has been already said that many lavas, and other volcanic productions, on re-fusion, become cellular. To apply this to the pumice in question would be an error. A lava, which has undergone this change by the action of elastic gases, continues to form one whole, though interrupted by these multiplied pores. The pumice of which I now speak is principally formed by an accumulation of small vitreous vesicles, which attach themselves to each other while they are yet soft from the action of the fire; and which, from their globose figure, not adhering except in a few points, have left many vacuities very visible in the fracture of the pieces. The labourers who dig these pumices, after they have shaped them into parallelopipeds, take them on their backs and carry them down to the shore, where they pile them up in large heaps, to be ready for sale when opportunity shall offer. We are not to imagine, however, that this species of pumice is to be found in every part of the mountain: the workmen, to find what they call the vein of it, are obliged to make great excavations, and frequently without success, which, as they told me, in this case, as in fishing for coral, often depends on chance. When they have found the vein they dig it, following its direction; in which laborious employment a number of men are occupied for whole weeks, the vein being sometimes a hundred and fifty, two hundred, or even three hundred feet long, and large in proportion. These veins are called Faraglioni. I have examined them, and satisfied myself, that the accounts I received were true. Pumice dust, and large heaps of the first species of pumice, with some scattered vitrifications, usually cover these veins, which, when viewed with the attentive eye of the naturalist, give reason to believe that they are long tracts of pumice, which once flowed in a liquid state, Their bubbles, frequently lengthened in the direction of the vein, seem likewise to prove the same.

M. Dolomieu, who first suggested that many pumices have flowed in currents like lavas, observed that at Campo Bianco the lighter pumices lie above the heavier; in the same manner as in the common currents of lava the porous lavas occupy the highest

place. I have certainly observed this disposition; but sometimes it proves fallacious: for if the excavation be continued below the vein which forms the second species of pumice, we frequently again find masses of extremely light and pulverulent pumice.

The first action of the fire of the furnace thickens the sides of the vitreous vesicles, of the second species, and diminishes the internal pores. A longer continued heat entirely annihilates the pores, and changes the pumice into a fixed, obscure, homogeneous, and

hard glass, which gives sparks plentifully with steel.

The third species is likewise an object of traffic with the natives of the island, who dig it in the same s where they find the second; and in like manner, shape it into pahis is likewise an aggregate of bubbles, but differing from those of rallelopipedo the former in several respects. Those, as we have seen, are conglutinated together in some points, while they are separated in others, so that we can frequently detach them without breaking; while these, on the contrary, are so incorporated by different solid points, that if we attempt the separation of one, we break the others that are contiguous. Here the elastic gases, investing the pumaceous substance in several points, have expanded it in every part into tumours and cavities, nearly as we see in raised and baked paste. It is worthy remark, that frequently when we break one vesicle, we meet with another within it, and concentrical. There is likewise another difference between these two pumices. The vesicles of the second species are all more or less vitrified; but many of the third show no signs of vitrification, are extremely friable, and of a pale red colour.

This pumice, though destitute of any fibrous texture, is specifically lighter than water. To obtain it, large pieces of white pumice, of the first species, in which it is enveloped, must be removed; and it commonly lies in long tracts, in the direction of which its vesicles are sometimes lengthened, which may induce us to suspect that this likewise, when

it was liquid, formed small currents. It contains no extraneous bodies.

In the furnace it condenses into an obscure mass of glass, almost opaque, but little po-

rous, and sufficiently hard to give sparks with steel.

These are the three kinds of pumice which the people of Lipari dig for sale. The first is employed in polishing different substances, and the other two are used in the construction of arched vaults, and on the corners of buildings. There are, however, other species which deserve the attention of the naturalist, and which I shall here proceed to describe.

On Campo Bianco, and in its environs, we find a fourth species of pumice, of a filamentous and extremely black texture. It is rough to the touch, scarcely at all porous, so heavy as to sink in water, and gives sparks moderately with steel. This pumice likewise contains no extraneous substances. Though when viewed in the mass it appears entirely opaque; its filaments when detached, and examined by a strong light, appear to be transparent, and only dark from their black colour. The second and third species are vesicular; but in this there are not any vesicles. The threads or filaments of which this fourth species is composed have all one direction, which is that of the current. It is here necessary to observe, that though this black pumice is found scattered on the sides of Campo Bianco, in a rock which descends almost perpendicularly into the sea, it forms an entire vein almost horizontal, which enlarges from the breadth of seven feet to twelve, and is above sixty feet in length. If we here examine the structure of this pumice, we shall find that, besides being filamentous, as we have before described it, its filaments preserve a parallelism among themselves, and the direction of them all is from the mountain to the sea; there can therefore be no doubt but this vein may be considered as a true current of pumice.

I was at first inclined to believe that the black colour of this pumice proceeded from fron, but afterwards suspected that it was rather the effect of a bituminous substance, from the strong scent of bitumen which it emitted on rubbing two pieces of it together; and my suspicion was afterwards confirmed by its losing its black, and acquiring a white colour, by remaining a short time in the furnace; on a longer continuance it became a

vitreous paste.

But among the different productions of this nature, there is none which more merits attention than that of which I now proceed to speak, and from which originate no small part of the pumices of Campo Bianco. This is a lava, with a feltspar base, which is found over the whole mountain and its environs, rising in rocks and crags of an enormous size. It is of a gray colour, of an appearance between siliceous and vitreous, with a consistence or grain less fine than that of quartz, having a small degree of transparency in the angles, and sufficient hardness to give sparks with steel. On attentively examining this lava, we may distinctly perceive in it the gradual transition of the lava into pumice. In many pieces of it we find the external appearances above described. In others the lava begins to soften, and become friable and rough to the touch, but without losing its siliceous-vitreous appearance. In many other we discover the commencement of the pumiceous character. Some small cavities in this lava exhibit minute grous of fibres, of a silvery whiteness, light, extremely triable, but only discernible by the lens. These crackle between the teeth, and rub to powder under the finger; but at the same time, shew they have a rough grain, and, in a word, prove, by the most indubitable marks, that they are real pumice. On breaking other pieces, the groups or clusters of fibres are found more fixed and large, so as to occupy a great part of the lava, which becomes lighter even where there are none of these clusters, since its texture becomes thinner, though not at all porous; and here the nail only is sufficient to scratch and break them, and the eye accustomed to pumices recognizes the characteristic marks of that substance, though they are not an apparent as in the filamentous aggregates. Lastly, it is not uncommon to find mashed if lave, which on one side retain the characters of feltspar, and on the other are changed infit the first species of pumice entirely resembling it in colour, lightness, structure, and its other exterior characters. In this pumice we likewise perceive many crystallized Julispars, such as we find them in the generative lava, and seemingly not at all happened by the fire.

We thus clearly discover the origin of the first the first species of pumice. I must

here remark likewise, that these imasses of lava, even where they do not appear pumiceous, if they are triturated and pulverised; printing a powder resembling in every respect, the whiteness of its colour and excepted, that while the property programming in every respect, the whiteness of its colour and excepted, that while the property programming in every respect, the whiteness of its colour and excepted, that while the property programming in every resembling in and lies deep in the mountains, and which is product. The furnace reduces this pumice to a kind of the first testabling that obtained

from the first species.

All these circumstances concur to prove the plentily of this pumice derived from the feltspar, with that first described. I shall only his type, that if the greater part of this kind of pumice has not formed currents, but been thrown out at different times in detached pieces from the volcanie fulfface, as has been before remarked, another portion has actually flowed; that, for instance, which in many parts of Campo Bianco is united to the feltspathose lava.

This lava, however, merits to be considered in another point of view. Hitherto we have only noticed it as the original base of pumice, but we shall likewise find it productive of glass. To be convinced of this, we have only to examine some other pieces from the same mountain; some of which, without losing the appearance of the feltspar, begin

VOL. V.

to assume the veins of glass, and are at the same time filled with innumerable small bubbles, that are likewise vitreous. But this glass differs from that of the pumices by being more perfect, and more transparent. In other pieces the bubbles are larger, and the small vitreous veins more numerous. On breaking a large mass, or following the large veins, we find in some parts groups of feltspathose lava, in others pieces of vesicular glass, and in others solid glass.

But whence has it happened that the same rock in some places has been changed into pumice, and in others has become glass? since, though the grater part of pumices are vitreous, their glass is far from being so perfect as that in question; which likewise differs from the pumices in this, that though it forms vesicular masses, these masses have

a hardness that can never be compared with the usual friability of pumices.

The origin of this difference, it appears to me, may be explained as follows: a certain degree of heat has produced a semi-vitrification in the feltspar, which has changed it into pumice. Such a degree of heat therefore was only sufficient for the production of this stone; but a stronger, or perhaps a longer continued heat, has produced a complete fusion, that is, a perfect glass, sometimes abounding in bubbles, from the abundance of the gaseous substances with which it is penetrated.

Seven varieties of these cellular glasses, which are all of a cinereous colour, having been exposed for several hours to the furnace, on their re-fusion, were reduced in volume, and the new glass was consequently deprived of that multitude of pores it before

contained.

But to return to the pumices: we have now ascertained that there are four species, of which Campo Bianco and its environs are principally composed.

It may perhaps be objected, that the second and third species which I have described,

do not properly belong to the class of pumices, as they are both vesicular; whereas one of the characters of the pumice is the filamentous texture.

I admit without hesitation, that many pumices used by artists to polish different substances have this character; but others, employed for the same purposes, and perhaps in equal quantities, and which no person has ever doubted to be pumices, have no sensible trace of filaments. Of this every one may convince himself by an inspection of the pumices usually sold. Besides, even those that are filamentous do not constantly retain that character; of which the first species furnishes numerous examples. Of this, large masses are found on the shore, cut by the natives into pieces for sale; among which I have observed that, though many pieces have the filamentous texture, there are many others which have it not, either externally or internally. The same I observed in many of the scattered pieces with which the mountain abounds. If, therefore, the filamentous texture be not a character essential to the pumice, I did not see why the stones of the second and third species should not be considered as true pumices, since they bear all the other marks by which the pumice is characterized. It may be added, that at Lipari, and in commerce, they are denominated pumices, and names adopted by the arts ought not to be changed without absolute necessity.

From these observations, made at Campo Bianco, we begin to obtain some light relative to the origin of pumices, since we have seen that those of the first and fifth species have the feltspar for their base. The same has likewise been shown of the others contained in the rock on which the eastle of Lipari is built. We still, however, remain in uncertainty with respect to the second, third, and fourth species, from their being always found in the state of complete pumice, and never met with in those strata or masses of lava, which, by shewing the first principles of these pumices, might enable us to discover the stone from which they have originated. To attain this discovery, it was therefore

necessary to analyse these three species by the humid method; and though the base of I bubthe first and fifth species, as also of that from the rock of the castle of Liparl, was suffibeing ciently evident; I yet, for the greater certainty, resolved to subject these likewise to the nd the same analysis; and, while employed on this operation, determined at the same time to make similar experiments on some pumices of other countries; that, for instance, which is found in small quantities in the Arso in the island of Ischia, and two other kinds from the island of Santorine in the Archipelago, a country certainly volcanic. Both the latter species are white, and float in water; but the texture of the one is compact and equable, and that of the other full of pores, and extremely filamentous.

The following are the results I obtained:

		FIRST	SPECIES	OF CA	MFO BI	ANCO.

From these results it appears that the component principles of the first and fifth species of pumices of Campo Bianco, as also that of the rock of the Castle of Lipari, perfectly resemble those obtained by the analysis of various feltspars made by different che-

mists; among others, by Mayer, Fabroni, Heyer, Westrumb, and Morell.

The same agreement would be found in the second, third, and fourth species, were it not that they contain a greater quantity of silex, and less of alumine; which, however, does not appear to be a sufficient reason for excluding the feltspar from these three pumices; both because I know no other stone hitherto discovered, and chemically analysed, to which these component principles can be more properly referred than to the feltspar; and because, the species of that stone being extremely numerous, it cannot excite surprise if some should differ a little from others, in the quantities of their constituent parts, which is the case in every kind of stone.

With respect to the pumice of the Arso in Ischia, it appears evident from its component principles, that its base is a horn-stone, from which the current of lava likewise de-

rives its origin.

Lastly, with regard to the two species of pumices from the volcanic isle of Santorine, it appears, from the analyses adduced, that their base has been an asbestus, or at least some stone analogous to the asbestus: of this we shall be convinced, if we compare these two analyses with those made by Bergman of different kinds of the asbestus.**

If we now proceed to consider the various opinions relative to the origin of pumices, and examine them by the facts now stated, we shall certainly find that the hypothesis of the Swedish chemist, as also of Pott and Demeste, that pumices originate from the asbestus, is not without foundation; it is only erroneous in supposing that they are produced from that exclusively; since it has been shewn, that the base of the pumices of Campo Bianco, and the rock of the Castle of Lipari is a feltspar, and that of the pumices

of the Acso is a horn-stone.

I foresee that some will with difficulty be persuaded, that the pumices of any volcanoes have for their base either the asbestus or the amianthus, since these two magnesian stones are rare, and only found in small quantities. But this is a mistake; for we know, from the information of naturalists and travellers, that they are both found in many countries; as in the islands of the Archipelago, in Asia, in Persia, and Tartary, not to mention Savoy, Switzerland, and Italy. It is likewise certain that the asbestus is found in some countries in such abundance that whole rocks are entirely composed of it, as in Siberia. I have some large pieces of asbestus, with parallel fibres, of a greenish gray, and difficult to separate, which were brought to me a few years ago by one of my pupils from Chiavenna, in the country of the Grisons, and taken by himself from Mount Uschione, near his native place, which is full of this species of stone.

When we speak of pumices with an asbestine or amianthine base, it is always to be understood that the volcanic fire which has produced them has been excessively powerful; since we know, from the experiments of D'Arcet, Saussure, and Ehrmann, how obstinately these stones resist the fire of the furnace when raised to an excessive degree of heat. The asbestus of Chiavenna, the Genoese territory, Savoy, Corsica, and other countries of Europe, after I had kept them a long time in a glass furnace, still continued

refractory, having only lost their yielding consistence, and their flexibility.

From the great affinity between some serpentines and the asbestus, I cannot hesitate to believe, that should the furnace of a volcano be situated among the former, they would

likewise be converted into pumice.

I cannot, however, by any means, subscribe to the opinion of Wallerius, that primices are coal or schistus calcined; nor to that of M. Sage, that they are margaceous scoriæ; for, with respect to the former, we have seen that pumices are not in a state of calcination, but of vitrification; and with regard to the latter, inspection alone is sufficient to show the essential difference between pumices and scoriæ.

It now remains to say a word of the opinion of M. Dolomicu, who supposes pumices to originate from granite. This naturalist having examined with the greatest attention the pumices found in the places which I afterwards visited, especially those that had undergone the least alteration from the fire, since these are most likely to preserve some

characters of their primitive base, made the following observations:

First, he found in some a residue of ordinary granite, that is, quartz, mica, and felt-spar; and remarked that these three substances, which, according to him, serve interchangeably as a flux one to the other, had acquired, by the action of the fire, a species of virification of a middle nature between that of enamel and that of porcelaine, and which might be compared to that of a fritt, somewhat inflated.

Secondly, he observed, that they gradually assume the fibrous and porous texture, and the other qualities of pumice; whence he concluded that the granite and granitous schistus are the primitive substances, which, by the action of the volcanic fire, pass into the

state of pumice.

On my first arrival at the mountain of pumices, I was, as may be supposed, desirous to ascertain the truth of this discovery; and not being successful the first time, I returned

again another day; and this second visit proving as little satisfactory as the former, I made two others, but with the same ill success. I examined with the greatest care every corner of Campo Bianco, and every other part of Lipari where pumices are to be found; and as it was only necessary to have eyes to discover immediately these granitous rocks, changed more or less into pumices by the action of the fire, had they existed; I shall say, with the freedom of a philosopher, that I was frequently tempted to believe that none were any longer to be found here, because they had all been carried away by the French naturalist.

I do not, however, mean absolutely to deny the truth of this discovery (and indeed how can it be doubted, when M. Dolomicu asserts that he has sent to several men of learning specimens of these granites, which have gradually passed into the state of pumice.) It is consequently proved that pumices, besides having for their base the horn-stone, the asbestus, and the feltspar, likewise originate from the common granite. We may likewise add the petrosilex, since the pumices formerly ejected from Stromboli derive their origin from that stone;* and if naturalists were to examine the pumices of other countries, and to their local observations join chemical analysis, it would perhaps not be difficult to find pumices which originate from other kinds of stone.

As to the pumices with a granitous base, it is obvious to remark that the subterraneous fire which produced them must have been extremely violent, since such must be that of our furnaces to reduce the granite composed of feltspar, mica, and quartz, to a homogeneous consistence, similar to that of perfect pumices. Sufficient proofs of this assertion may be found in chap. XII.

Proceeding from Campo Bianco by sea, and coasting the base of the mountain, we find the side lying on the left, and which is in like manner composed entirely of pumices, full of furrows and channels that take their direction to the sea. Other lesser mountains, which are white, because they are likewise formed of pumices, join the principal one, Campo Bianco. Beyond these rises a mountain of another kind, called the Monte della Castagna, which, in the part of it descending to the sea, is about a mile in extent, and in its circumference exceeds four miles. But who would believe that this mountain is entirely composed of enamels and glasses? Before I had read the excellent work of the chevalier Dolomieu, I knew that Lipari abounds in vitrifications, and the reading of this book confirmed me still more in the idea; but I was entirely ignorant that they were accumulated in such immense quantities in one place as to form an entire mountain; and I feel some pleasure in being the first person who has announced to the world so extraordinary a circumstance. I shall proceed, therefore, to consider these products; first, as they appear on the spot, and afterwards divide them into their species and principal varieties.

I know not to what a tract of these vitrified substances can be more properly compared, than to a large river, which, breaking into a thousand streams, dashes from height to height down a steep precipice, and, suddenly congealed by excessive cold, freezes, breaking every where into clefts and fissures, so that the precipice appears covered with a rough wavy ice, divided into large flakes. Such is the appearance of some of these vitrifications on the back of the Monte della Castagna; but seen from the snore they have a different aspect. In the places where the waves of the sea have produced deep excavations, we perceive that under this vitreous stratum, divided into flakes or plates, there are other strata, and beneath them others, all equally vitreous, but differing in colour, consistence, and direction. Beneath these there may likewise possibly be others.

concealed from the eye by those above them. The thickness of these strata is different; that of the uppermost in some places is not more than a foot and a half, but in others twelve feet. As it is higher than the others, it has not suffered so much from the dashing of the waves, except in its lowest parts. The higher have flowed over the rock, taking from it their configuration. These vitreous bodies, having in them numerous fissures and clefts, are easily broken by the beating of the waves, and detached pieces of them are therefore found in great quantities on the shore and under the water, but more or less rounded by the dashing of the sea, and entirely resembling those smooth irregular stones which form the beds of the rivers.

I shall now proceed to describe the different qualities of the vitrified substances that compose the Monte della Castagna; in which description it will be impossible to be very brief, on account of the numerous varieties of those substances, and the distinct atten-

tion which each justly claims.

I. And since the nature and quality of pumices was the last subject that engaged our attention, I shall begin with a substance which may be considered as the point of transition of these bodies into glass. Not that it is not a true glass; but it is so light, that, like many pumices, it will swim in water, and possesses that fragility which always ac companies pumices. Hence it easily shivers when struck against steel, and rarely emits sparks. It has besides, in more than one part, small pores, interrupted by vitreous threads, which is observable in many of these kind of stones. The vitrification is more advanced than in the pumices. The glass is of a whitish-gray, transparent, in part scaly, and in part involuted and contorted, from the number of pores which interrupt the direction of the structure. It is found in detached pieces on the sides of the mountain; and some float in the sea, the sport of the waves.

II. This second glass resembles the former in more than one quality; but it is somewhat more heavy, and what I should call reticulated, as it contains small eyes, or spots, which give it be appearance of a net. It is found in strata above strata, and the face of every stratum is covered with an earthy and half-pulverous coating, in consequence of

which coating it easily splits.

III. Capillary glass, or glass reduced by fusion to the fineness of a hair, is so rare in volcanized countries, that only four specimens of it are known to those who have most diligently examined the productions of subterranean fires. The first of these was produced by an eruption in the Isle of Bourbon in 1766, the second by Vesuvius in 1779, the third by Vulcano in 1774, and discovered by the chevalier Dolomicu; and the fourth noticed by M. Faujas, who in the cavity of a basaltic lava, brought by Besson from the volcanic caves of St. Sebastian at Rome, observed a great number of capillary filaments from three to four lines in length, of a transparent and vitreous substance.

The Monte della Castagna at Lipari furnishes a great quantity of this capillary glass, which I shall consider as the third species of the substances that now claim our attention. Several of these glasses, which have a very thin texture, and are consequently very light, if they are examined internally, usually abound with cracks, sometimes extending from one end to the other of the pieces; and when struck in the direction of these they are easily split. In these vacuities, the glass is extremely small and thin; in many places as fine as a hair, and forms minute entangled filaments, resembling the finest wool, or thin threads tending all the same way. Some of the latter are so fine, that only breathing on them will put them in motion, and break them. They are transparent, and have a lustre like silver. Many of them are two inches long; and besides those which are visible to the naked eye, there are others in great numbers which are only discoverable by the lens. The nature of their formation does not appear to me duficult to explain,

as it probably is to be attributed to the viscosity of the glass when in a liquid state, and the distension which took place from the enlargement of the apertures by congelation.

These thick groups of vitreous threads, when viewed by the less experienced observer, might lead him to believe that they are a species of extremely fine pumice; but a moment's attentive observation will be sufficient to discover the difference, which, as

it is essential, I shall here state.

One of the sensible characters of pumices, at least of the greater part, is their being vitreous; but their vitrification is always in some degree less than that of the true volcanic glass. The filaments, however, of which I have just spoken, are entirely vitreous. In fact, they have the transparency of glass, and are smooth to the touch like that; whereas those of pumices are almost opaque, and rough to the touch. The latter may be safely pressed with the finger; but the former, though thicker, enter the skin, and draw blood, as may be expected from the points and sharp edges of glass. It is true, many pumices have their original base the same with the volcanic glasses; but the action of the fire has not been the same on both, but on the glass has either been stronger or

longer continued.

Though this seems so clear in itself as to need no proof, I shall yet produce one which is extremely obvious on the comparison of some light filamentous pumices of Campo Bianco and the present glass. Both these bodies contain crystallized feltspars of the same species, which in the punciees appear to have suffered no injury from the fire, as they retain their changeable lustre, their laminated structure, their natural transparency and hardness. On the contrary, in the glass in which we find these capillary filaments, though they have not undergone fusion, they are so changed that they have lost all the characters above mentioned; and when touched with the finger, fall into small pieces, the larger only retaining a kind of central point of the original nature of the stone. I have in my possession one of these feltspars, which presents a curious appearance. It is placed within one of these apertures, but without touching the sides, and is, as it were, sustained in the air by a crown of capillary threads of glass that are attached to it at one extremity, and at the other fastened to the sides of the aperture. The feltspar must no doubt have been originally confined in the glass when it was fluid; but this drawing back at the time of its congelation formed the cavity, and left the feltspar as it were isolated, and communicating only with that part of the capillary down, which is a part of the glass itself reduced to threads by the retiring of the sides of the cavity. This feltspar, which is four lines in length, and three in breadth, is changed equally with the rest by the fire.

From the facts now adduced, it is evident that the fire which produced these pumices was less powerful in its effects than that from which the glass derives its origin; it is not,

therefore, surprising that the latter should be more perfect than the former.

I have entered into these minute details relative to pumices and glasses, because it appears to me that the modifications and gradations visible in the operations of nature deserve the most careful attention of the philosopher, as, otherwise by considering things too generally, we should meur the danger of confounding objects very different in themselves; as for instance, not to wander from our subject, since pumices, enamels, and glasses are virified substances, we might confound them together, and even not distinguish them from lavas; and, in fact, there have not been wanting eminent writers who have characterized these also as true vitrifications.

This remark leads me to make a few strictures on an opinion of M. Dolomieu; who having observed that pumice sometimes changes into glass, imagined that this glass, by an inflation of the internal air, might pass into the state of pumice. The former I readily admit, having adduced more than one example of it in volcanic products, not

to mention artificial fusions in which I have always observed this transition of pumices into glasses or enamels, which is, besides, extremely natural; the stone thus pass ing, by the action of a strong heat, from a less degree of vitrification to a greater. 1 tion. lind it, however, very difficult to assent to the latter hypothesis, as, in that case, we must d obsuppose that a greater or more perfect vitrification may pass into one less perfect, which ; but is certainly very unnatural; since glass re-melted by volcanic fire will remain in its forch, as mer condition; and supposing it should be inflated with aeriform gases, from solid glass, which it was before, it will become vesicular, but never, in my opinion, can it become being pumice, since it cannot return to that feeble degree of vitrilication which characterizes e volthat stone. Neither are gases an essential requisite in the formation of pumices, several reous. kinds of which are compact, and do not show the slightest indication of these elastic fluids: besides, many glasses already mentioned, and others hereafter to be enumerated,

show, by the bubbles with which they abound, that they have every where been penetrated by these fluids, without having the least appearance of pumice.

IV. The glasses of the Monte della Castagna which we have hitherto considered, are those that have a texture more or less porous; we will now proceed to those of a compact structure, of which kind is the fourth species, which may be said to compose nearly one half of the mountain. This glass, if viewed superficially, and as it is found on the spot, has rather the appearance of a red earth than a glass, occasioned by a red earthy coating that invests the glass disposed under it in immense plates; which covering, though in many places it but feebly adheres to it, since it may be removed by simply washing with water, in others is so closely united that it forms the last rind or outermost part of the glass, which induces me to believe that it is a superficial decomposition of it. Beneath this earthy coating the glass appears, which is extremely perfect, and as if it had just come out of the volcano. If we except a few pieces in which its structure is spong3; it is extremely compact and solid, and therefore much heavier than either of the other three kinds. It is of an olive colour, and transparent when in thin scales, examined by a bright light, but in the mass it appears opaque. It gives sparks rather plentifully with steel. Picees of perfect glass, it is well known, when broken, have their fractures striated, waving and cured. In this glass some of the fractures are the same; but in general they are conchoids, like those of flints. Its consistence is not perfectly homogeneous, as it contains many feltspathose points. Its aspect is not lively and brilliant, like that of glass, but somewhat unctuous and dull, from all these qualities this product appears to be more properly an enamel than a glass; unless we are willing to consider it as one of those volcanic bodies which constitute the middle substance between enamels and glasse .

In my description of the glasses of Lipari, I have observed that several of them are intersected with veins or earthy leaves, by means of which they are easily divided into plates. The same is observable in the present glass, in which we find the same quality as in some marbles, which being cut in the vein may be divided, without any great labour, into large slabs, but which break into small pieces if it be attempted to divide them in any other manner. Some of the workmen who dig the pumices, and were very useful companions to me in my excursions to Campo Bianco and the Monte della Castagna, at my request, drove with heavy hammers, an iron wedge into these earthy veins and extracted from the common mass of this glass large plates five feet long, three broad, and two in thickness. To the surface of each plate was attached a coating of hard earthy matter, which still more confirmed me in the opinion I have already given, that this matter had resisted fusion, and, being lighter than the fluid glass, had ascended to the

e it apure dethings i them-:ls, and distinrs who

i; who lass, by rmer I its, not surface; a conjecture further corroborated by the artificial fusion which I made of this glass retaining some portion of this earth, which with difficulty fused, though the glass was inflated and changed into a frothy channel.

This glass slightly cuts the factitions glass; and if the cutting angle of one piece is driven with force along the surface of another, it produces a white and impalpable powder.

V. This species of glass completely deserves that appellation, since it is not only the most perfect of all the volcanic glasses of the Eofian isles, but does not in the least respect yield to what is called the Iceland agate, or the gallinaceous stone of Peru, which is supposed to have been the obsidian stone of the ancients. In the large pieces its colour is extremely black, and it is entirely opaque, but the thin leaves are white and transparent. The opacity and blackness may be said to be in the direct ratio of the thickness. This glass, which is extremely compact, is free from actiform bubbles, and from every kind of heterogeneousness. It is somewhat harder than the fourth species, and therefore cuts factitious glass more easily, and gives more sparks with steel. Its edges are sharp and cutting.

M. Faujas, having obtained some specimens of the best glass of Lipari, has made some observations on it proper to be given here. He admits that this species is the same with that of Iceland; but he remarks, however, that it differs from it in the polish, which appeared to him more unctuous and less vitreous, besides that in the fractures it had not that waving, striated, sealy appearance, which is proper to the masses of true glass.

It must be remembered, however, that the specimens of M. Faujas were none of the best: the pieces, at least, which I collected, took so exquisite a polish and lustre, that I do not believe any kind of artificial glass ever received one more beautiful and brilliant. This glass, besides, when in the mass, being opaque, became a true mirror; and I therefore find no difficulty in believing that the ancient Peruvians used a similar kind of glass, cut and polished, for mirrors. This glass, likewise, could not be broken without exhibiting the undulating scales, lightly striated, which the French Vulcanist affirms he could not find in his specimens. While I now write, I have before me a piece with a recent fracture, in which these waves are circular and concentrical, occupying an area of two inches and a half, the common centre of which is the point that received the blow: they resemble in some manner those waves which a stone produces round it when it falls perpendicularly into a standing water.

I cannot omit another remark. M. Faujas says, that the edges of this glass where they are very thin, if presented to a strong light, are a little transparent. The transparency of the thinnest parts of the glass on which I made my observations, when compared to that of common factitious glass, is certainly not equal to it: it is not, however, so much inferior as this naturalist seems to suppose. A scale three lines and a half in thickness being presented to the flame of a candle afforded, in part, a passage to the light; and another, two lines thick, being interposed between the eye and external objects, permitted a confused sight of them. Another, half a line in thickness, being laid on a book, it might be read with the greatest distinctness. I have entered into these

minute details the better to show the perfect quality of this glass.

The opacity of this glass in the mass proceeds from a very subtile, and, perhaps, bituminous substance, incorporated with the vitreous matter, and rendering it dark like a cloud. The glass loses this substance if it be left for some hours re melted in the crucible, and it then becomes white.

Bergman observed that the Teclandic glass, when exposed to the fire, melts with difficulty, without the addition of some other substance as a flux. In this it differs from the present of Lipari, which soon begin, to soften in the furnace, and in a few hours undergoes a complete fusion.

This kind of glass, however, is not the most common to be met with on the Mont della Castagua. It is found only in a few places, scattered in large but solitary masses, nor can I pretend to say, whether these are remains of currents, or whether they were

thrown out by the burning gulfs.

It happens to this glass as to the different kinds of precious stones, that is, that the same piece is not always throughout of equal purity and value; for, on breaking some of these masses, we sometimes find one portion very pure glass, such as has been already described, and the other imperfect; either because the fusion has not been general, the substance containing bodies foreign to the base, or because that base is rather an enamel than vitreous. These bodies are feltspars, but of a new appearance. Nothing is more common than to find feltspars in lavas, and sometimes even in enamels and glasses; of which we have frequent examples in this work, as well as in the accounts of other wri ters. But these feltspars are always inserted immediately into these substances with out any intervening body. Here, however, the case is different: every feltspar is surrounded with a rind or coating, which, when it is extracted entire from the enamel, appears to be a vitreous globule, about one or two lines in diameter, of a clear cinercous colour. If we break this globule, we find within it the half fused feltspar, not divested of its coating, but forming one body with it. These globules are very numerous, and sometimes by their confluence form groups; and they are very distinctly visible, on account of the black colour of the enamel.

The manner in which this coating was formed around the feltspars I conceive to be as follows: when the enamel was fluid and inclosed the feltspars, it acted as a flux to their external parts, and combined with them; and from this combination was the rind or coating produced, while the internal part of the feltspars had only undergone a semifusion, because it was not in immediate contact with the enamel. There can be little doubt but that the feltspars likewise existed in the perfect glass; but the heat probably being more active in that than in the enamel, they were completely dissolved, and the entire mass reduced to one similar consistence. As a proof of this conjecture, the furnace produced a complete homogeneity of parts in the enamel containing these extrane

ous globules.

VI. When treating of the rocks of the eastle of Lipari, I said they were formed of a cincreous lava of a feltspar base, which in many places has passed into glass. I likewise remarked that the lava, as well as the large pieces of glass, was filled with globules apparently not dissimilar to the base. At the beginning of the Monte della Castagna, not far from a cottage, the habitation of one of the labourers who dig pumice, there is a current of similar glass that falls into the sea in several branches, and which I shall here consider as the sixth species. This glass however has a more fine and shining grain, and its fracture is exactly such as we observe in glass, yet in beauty it is little inferior to the fifth kind; and if whiteness, or more properly the want of colour, is particularly valuable in volcanic glasses (since those which have this quality are extremely rare) this certainly has considerable claim to our attention. Not that it is entirely colourless, as it contains a kind of obscure cloud, which gives it, when viewed in the mass, a blackish hue, but at the edges it appears white. The round einercous bodies with which it is filled, form the most pleasing and conspicuous contrast, and render the glass irregularly spotted. I have large pieces of the fifth sort cut and polished. Their colour, which is that of pitch, gives them a peculiar beauty. The blackest and choicest marbles of Varena and Verona are far inferior to them in fineness of grain and lustre; yet, from

1 1 2

there-

where transn comowever, half in to the enal obang laid o these

ips, bik like a :he eru-

th diffis from their uniformity of colour, they are less beautiful than this spotted glass, when it has received a delicate polish from the hands of the artist. On the shore, where the torrent fell into the sea, we find pieces of all sizes rounded and smoothed by the continual agitation of the sea; I have met with more than one of half a foot and a foot in diameter. Notwithstanding the powerful action of the waves which have beaten on them for so long a time, their internal parts are not injured, and, when cut and polished, they present surfaces very beautiful to the eye. Tablets of this kind of glass (and there is no want of pieces of a proper size to form them) would add much to the grandeur and splen-

door of any sumptuous gallery.

But disregarding the beauty which delights the eye, let us proceed to objects that attract and interest the curiosity of the philosophical inquirer. We shall find that the cinercous bodies included in this glass are only points of lava with a feltspar base; and on examining in various places the current of this glass, we shall perceive that it is a continuation of the same lava with the feltspar base, of which these orbicular corpuscles are composed; whence we shall not hesitate to conclude, that from this stone both the lava and the glass derive their origin, and that we find small particles of lava scattered through the latter, because it has not undergone complete fusion; whence we find some pieces composed partly of glass and partly of this same lava. In some of these pieces we discover small geodes, or thin filaments of an extremely brilliant and transparent glass resembling in miniature the husk of the chesnut.

VII. Though this glass in many particulars resembles the last species, it yet differs from it in others. It is perfect like that, but it is of a deeper colour. In it, likewise, the small globules abound, but they are earthy and pulverizable; every one is detached

in its distinct niche, or at most is only fastened to it by a few points.

The description of this seventh species of glass will render that of several others unaccessary, since the glasses I should have to describe contain a greater or less number of similar globules, differing only in the nature of the base inclosing them, which in some is more and in others less vitreous. I shall only make one observation, which I think to be of some importance, relative to the glasses I here omit. Several of them have, even in their internal parts, fissures frequently an inch in breadth and three inches in length. These are not entirely vacuities, but are frequently crossed by small threads of glass connected at their two extremities with the sides. The broadest of these threads are four lines in breadth, and the narrowest searcely a line. When broken they have the fragility of glass, and are found to be a most perfect glass, being colourless, and extremely transparent. It is easy to conceive that these threads have been formed in the same manner with those of the capillary glass found in similar fissures in the third species of glass.

VIII. The eighth and last kind of the vitrifications of the Monte della Castagna may be denominated an chained that has the colour and Instre of asphaltum, of a scaly grain, a very small degree of transparency in the points of the fractures, and of considerable weight and compactness, though it is extremely friable. It is found in solitary masses, not very numerous, and the broken pieces have the property of assuming a globose form. Some of these globes resemble those found by M. Dolomicu in the island of Ponz. I have been favoured with two of the latter by the abbe Fortis; but I find, that, excepting their globose figure, they differ in every respect from those of which I now speak. The globes of Ponza are composed of leaves over leaves, of an imperfect enamel, do not give sparks with steel, and contain feltspars and mica; whereas these of the Monte della Castagna rarely include a few teltspars, give sparks with steel, have a vi-

treous appearance, and not composed of plates or leaves.

Some pieces of this chamel, broken and detached from the masses, are in one part true chamel, and in another lava. The latter gives few sparks with steel, has a grain approaching to earthy, and, as far as I could discover, has for its base a soft horn-stone, from which, consequently, the enamel, likewise, derives its origin.

These are the principal vitrifications I observed in my excursions to the Monte della Castagna. Some I have omitted to notice, since, some trifling differences excepted, they are essentially the same with those described. It is proper, however, to remark, that more than one of them exhibits manifest signs of having once flowed down the sides of the mountain, in the thick threads and vitreons filaments they contain, similar to those we see, on a lesser scale, in glass fused in our furnaces, when it comes into con-

tact with the cold air, as it flows down an inclined plane.

Every one of these eight kinds of glasses and enamels may be completely re-melted in the furnace. When speaking of the compact glass of the rock of the eastle of Lipari, I remarked its extraordinary inflation in the furnace, and said that this tumefaction usually accompanies a re-fusion, in our fires, of solid glasses, and volcanic enamels. I then had in view those of the Monte della Castagna, five of which, though compact and solid, in the furnace, swelled high above the edges, notwithstanding that, before their re-fusion, they only filled a third part of it. In the description of other glasses of Lipari, I shall have occasion again to remark the same phenomenon, on which I shall make further observations in another part of this work.

Let us now proceed to consider the most remarkable lavas of the same place, which have an immediate relation with the glasses and enamels, from bearing some characteristic impress of vitrification. I then flatter myself I shall have given sufficient detail of

the volcanic products of this famous mountain.

The first species I shall describe has for its base the petrosilex; is hard and compact, and proportionably heavy, of a siliceous aspect, of a pale blue colour, giving sparks with steel, and abounding in black, rhomboidal, well preserved shoeris. When it was in a state of fluidity, it enclosed within it several bodies of a different nature from itself; which being angular, and having sharp edges, shew that at the time they were included in it they were not in actual tusion. Their colour, which is that of baked brick, their numerous fissures, and their fragility, incline me to believe that they have been calcined, probably when they were taken up by the current.

This lava is spotted, and, in many places, even veined, with a black and opaque enamel, harder than itself, but which gives but few sparks with steel. Its aspect is between the siliceous and the vitreous, and it has great compactness. The shoets it contains are unaltered. This lava is disposed in strata, and extends a considerable way in some

of the hollows of the mountain.

The extreme blackness and homogeneity of the enamel into which this lava is changed in the furnace, prevents the eye, at the first view, from discerning the shoerls it contains; but they are discoverable with the lens. They have lost their crystallization, and have assumed a globose figure, a certain mark of fusion, and their black colour is tinged with a dead green. The re-fusion shews that this lava contains a number of feltspar scales, which I at first could not discern even with the aid of the lens. Their white and somewhat changeable colour renders them visible on the extremely black ground of the re-melted enamel.

The second lava is of a feltspar base, partly white, and partly of a reddish yellow: it has a lucid grain, and includes amorphous feltspars, unequally distributed, being rare in some parts and abounding in others. In many places, it is a true glass, distributed

in small masses of various colours, some black, others chargeds, and others white: the latter is as transparent as factitions plass.

This lava is rather rare; at least 1 only met to he two pieces of it, about the middle of the mountain; and from their angles and hactures 1 judged that they had been detached from some larger mass.

It is one of the very few kinds which meh with deliculty in the furnace; but it is at length reduced to a black porous enamel, but without the fusion of the feltspars.

The third lava is of a gray colour, hard, compact, heavy, rough to the touch, and granulous. It has for its base the petrosites, and gives vivid spacks so copiously with steel that it may supply the place of flint. When viewed in the dark by the light of a candle, it shines so brightly in a number of points, that, at first sight, we might be induced to believe that it was full of small crystatuzed and extremely brilliant zeolites, or little lucid shoerls; but on more attentive examination we discover, especially in the recent fractures, that these points are only small particles of glass, scattered in great abundance through its whole substance.

On one side of the Monte della Castagna there are prodigious masses of this lava, but in Catached pieces, which leave us in uncertainty with respect to its origin.

In the furnace this lava produces a black homogeneous enamel, compact, and slightly transparent in those parts of the edges which are thinnest.

The fourth species has a feltspathose base, and likewise contains a number of vitreous particles, but which approach rather to the nature of enamel than to that of glass.

As this lava is extremely white, we might at first be induced to suspect that it has been decomposed by staphureous acids; an opinion which its friability appears to confirm. But there is more than one reason to convince us of the contrary. First, the minry which this lava had received from these acids would have extended to the enamel, as I have shewn that the enamels and vitrifications of Vulcano are sensibly altered by these volatile salts, whereas the present enamel is not at all affected. Secondly, as these vapours act on the surface of volcanic productions, the decomposition and whiteness do not usually enter very deep into them; and the nucleus of these products retains its corour and primitive compactness. An example of this we have already noticed in the layas of Soffatara and its environs;* and we shall soon have occasion to mention another in those of Lipari, not far from the stoves, or hot baths. The present lava, however, which is in detached pieces, many feet in thickness, has the same whiteness and friability on its surface and in its most internal parts. Lastly, these vapours, in decomposing volcanic products, take away the roughness of the parts, and render the surface smooth and more or less soft to the touch; but this lava retains the same roughness in every part. I must here add, that, in all my researches about the Monte della Castagna, I have not found any part of it which shew signs of the influence of these sulphurcous

The furnace in a few hours reduces this lava into a gross enamel of little adhesion, and of which many parts are not vitrified; but in a longer time, it passes into a true nonogeneous and extremely porous glass.

The fifth and last lava may be considered in many different points of view, each of which deserves to be distinctly noticed; the fire and elastic fluids having produced very different quantities in the same product. The following are the principal:

If we break a mass of this fava into s, veral pieces, we shall find that some or them have many cracks or fissures some extending lengthwise, and which seem to have been pro-

duced by the return; of the parts on congelation, and others or a management, prohably the effect of the action of the clastic gases. These figures are surrounded with fibres, knotted and twisted in a thousand ways, and resembling those found in the cava ties of some kinds of pumice; except that the fibres of the latter, the finest at least, her the lustre and colour of silver, whereas these are of a dark gray, and a structure not at

Other pieces of the same lava have not these fissures, and differ from the former like wise in other respects. Those before described are light, and have a sponginess similar to that of some burnt bones, as also great friability; whereas, on the contrary, these are compact, hard, heavy, and contain small and shining particles of glass.

Others instead of these particles or points have a vitreous ground, but scattered over

with small globules of lava.

Lastly, others have passed into glass, which would be very perfect were it not mixed with the above-mentioned globules.

The colour of this lava, where there are no vitreous parts, is einercous; and its base. as far as I can discover, horn-stone. In the furnace it produces a scoriaceous chainel.

Having thus described the principal volcanic products of Campo Bianco and the Monte della Castagna, which are pumices, glasses, chamels, and lavas, more or less vitreous, I shall here make a few remarks, before I proceed to describe the other objects

that drew my attention on the remaining parts of the shores of the island.

Though Campo Bianco and the Monte della Castagna are considered as two distinct mountains, they are so connected together and continued that they may very justly be esteemed only one; or at least as forming a single group in the island. The identity of the products in both, confirms in some measure the unity of this group. In the part abounding with pumices, we meet at every step with detached pieces of glass, and on the Monte della Castagna amid the glasses we find numerous pumices; a part of the solid kinds of which are dug here after removing the masses of glass under which they are buried.

It is further to be observed, that though this mountainous group when seen from the sca appears isolated, yet, on ascending to the summit, we find that it extends far to the west, as we shall perceive more distinctly when we come to treat of the Stoves of Lipari, Hocheve, therefore, I should not exaggerate were I to say that this group of mountains, taken in its whole extent, has a circuit of eight miles; nor is the extent of its vitrifications less, if in these we include likewise the pumices, which are in fact only a less per-

feet glass.

But how much more extensive, on the side of the sea, must have been this tract of vitrified substances in the ages immediately following the formation of the island! We have already seen how the rain waters, that drain toward the sea from the summit of Campo Bianco, have deeply corroded and furrowed its declivity. The ravages which the waves of the sea have made, and are continually making, have already been described, and are sufficiently proved by the heaps of pumices fallen along the shore, and those which float on the waves at the foot of Campo Bianco; for neither a nor h nor a north-east wind can blow without a prodigious quantity of these light stones being wafted into the harbour of Lipari.

The devastations which the vitreous mountain della Castagna has suffered, and is daily suffering, on the side beaten by the sea, are likewise very great. That these have formaily been very considerable, is proved by the small vitreous rocks within the sea, which there is no doubt anciently formed one whole with the mountain, and have been sepa-

rated from it by the corrosion and destruction of the intervening glasses.

In this extensive group of mountains and their environs, we find no characteristic marks of the existence of ancient craters. It is true, that in several places we find cavities that approach to a round form; but they leave us in absolute uncertainty whether they have been mouths of volcanos, since we meet with similar ones, and much more specious, in countries not volcanized. It cannot however be doubted, that Campo Bianco and the Monte della Castegna are the produce of successive cruptions, some of which have formed currents, and others been thrown into the air. Of the former we have seen many proofs both in the pumices and the glasses; and the detached and solitary

pieces of these same substances are sufficient evidence of the latter.

With respect to the glasses, besides those which are scattered solitarily on the Monte della Castagna, we must with them dispersed in like manner on Campo Bianco. The cjections of these substances from the volcanos have likewise extended beyond these places, as I began to find them scattered among the lavas before I arrived at Campo Bianco. We have also seen that some kinds of the pumices bear evident marks of having been thrown into the air from the volcanic gulls. This I now judge to have been the origin of the pulverised pumice with which Campo Bianco abounds. I at first imagined it was to be attributed to the superficial corrosion of the rain-water, and the influence of the atmosphere; but in more than one deep excavation made on the spot, where either the rains have not penetrated, or if they have, must have been unable to corrode, from want of injectus, I found the same abundance of pulverised pumice: I am therefore of opinion, this must have been thrown out by the same volcano that cjected the pumices. Such, in fact, is the constant effect observable in burning mountains; which, when they eject lavas and other ignited bodies, throw out at the same time clouds of ashes, which, when attentively examined, are found to be only a mixture of small particles of the larger bodies ejected. I have made the same observation relative to the fiery showers of Vesuvius and the ejections of Stromboli.

We have seen that the primordial rocks, which, by their fiquefaction, have given birth to Campo Bianco, the Monte della Castagna, and the vast rock on which the castle of the island stands, were for the most part feltspar or petrosilex, sometimes converted into pumices, sometimes into glasses and enamels, and sometimes into mixed lavas containing more or less vitreous parts. In describing these vitreous parts, and the large masses of glass that are a continuation of the lavas, I have not attempted to determine whether it has been the consequence of a more vehement heat, that the lava has in some places been changed into glass, or because that in some parts it was more easy vitrifiable. Both opinions appear probable, and possibly both may be true, according to the difference of circumstances. Where a lava retains the nature of lava for some extent, and then changes into glass, I find no difficulty in supposing that its vitrification has been the consequence of a more intense heat; but wherever large masses of lava exhibit points of glass, not only externally, but even deep in their interior parts, it does not seem very natural to suppose that these can have been the effect of a stronger action of the fire upon those points of the lava; they must rather be ascribed to a greater aptitude in the

hava itself to vitrify in those parts.

And here an opportunity presents itself to mention an appearance I observed, which certainly merits some attention. In making the circuit of the sides of Campo Bianco, and the Monte della Castagna, I sometimes met with isolated masses which any person without the least doubt would have pronounced to be glass, as in fact they were externally, this glass inclining to a yellow or blue cotour, being very smooth, and promising to prove extremely fine. But on breaking one of them it was found to be a pure and simple lava, coated with a slight varnish of glass, like the glazing of an earthen vessel. I

neteristic ind caviwhether ch more mpo Biof which we have solitary

d, which Bianco, by person re exterromising pure and essel. I

at first imagined that the heat had acted more powerfully on the surface of these laws when fluid, than on their internal parts: but a further examination convinced me this supposition was ill founded; for more than one of these masses were angular, and in some places discovered old fractures which sometimes had a conchoidal figure. I could also sometimes join two pieces together in such a manner as to prove that they had once formed a larger whole. In these cases the vircous varnish, which was about the thick ness of one-sixth of a line, was equally extended over the angles, the fractures, and even the surfaces by which the two pieces might be so exactly joined. It was impossible. therefore, not to conclude that this varnish had been produced posterior to the action of the fire. But by what cause? I candidly confess I know not: I can only say, that on examining volcanic glasses on the spot I have found that some of them, in the parts most exposed to the action of the atmosphere, and the elements, have contracted a kind of opal appearance, extremely agreeable to the eye, but entirely superficial. May not the same cause, whatever it be, which gives this pleasing polish to glass, by acting on the lava, cover it with a vitreous varnish? I shall not, however, venture to determine any thing positively.

I shall conclude my observations on these places with some remarks on the universal sterility that reigns through them, though their origin is anterior to the records of history. If we except a few lichens attached to the fissures of the glasses, there is no vestige of a single living vegetable over the whole Monte della Castagna; and on Campo Bianco, as has before been said, they are extremely rare. This sterility is a consequence of the vitreous nature of the mountain, which in so many ages has not been decomposed into a vegetable earth, and according to every appearance will continue the same for a long series of centuries to come. Among all volcanic products, the vitrified substances are the most refractory to the changes of the atmosphere and the action of the bumid elements. This simple observation may teach us how uncertain are all attempts to determine the epochs of the flowing of lavas from the greater or less change they may have suffered from the influence of the atmosphere combined with that of other destructive agents; the degree of such alteration depending on the nature of the lava itself, according as it may be more or less earthy, or more or less vitreous. We may indeed, with the utmost reason, ascribe an antiquity almost transcending our conception to a volcanic glass, or a vitreous lava, which shall naturally have been reduced to an earthy soil, proper for the production and nourishment of plants.

The abundance of the objects presented by this side of the island of Lipari, has compelled us to be somewhat diffuse; but this it was impossible to avoid, without failing in accuracy. This prolixity will, however, be compensated, by the brevity with which the other productions of the base of the island may be described; since, though we have searcely examined more than a third part, the remainder offer only a few facts deserving

Beyond the pumices the lavas again appear, beginning from the Punta del Segno Nero, and extending in a chain of several miles, which on the side of the sea descends in precipices and craggy declivities. These lavas, with respect to their composition, will not greatly attract the attention of the volcanist, since in that they do not differ from those of other volcanos; they will only excite his notice for their currents, which in some places descend separately, and in others intersect, and pass over each other. For the extent of three miles they do not appear to have suffered any alteration but that which is the effect of the atmosphere, and which in them is extremely small; but when we arrive opposite to Saline, and tack the boat towards the Strait of Vulcano, we find them all more or less decomposed by sulphureous acid funces. They present a highly

varied scenery, from the diversity of colours they exhibit; among which the red and white are most conspicuous. On a nearer examination they are found soft, and some of them pulverisable; but the decomposition only reaches to a small depth; these lavas still preserving, in their internal parts, their hard grain and natural compactness. Several of them are covered with a crust of sulphate of lime (selenite.)

The lavas thus changed by the action of these salts, extend only from the sea-shore to the part opposite Vulcano; leaving, however, some intervening vacancies. Such is that denominated La Grotta della Signora, formed by a spacious incurvation of the shore hollowed out of the lava, which may be termed a breezia, since it is composed of a number of angular and irregular pieces of lava of a petrosiliecous base, united together, and which, not being extremely solid, has easily been broken and excavated by the action of the waves.

Proceeding farther we find the sea make an incurvature, and form a small bay called the Valle di Muria, which, from the interesting objects it presents, merits to be somewhat particularly described. On its sides rise high and steep rocks of lava, half demolished, the fallen pieces of which lie in heaps on the shore. In several places this lava exhibits no traces of laving suffered any alteration from the action of the sulphureous acids; but in others a decomposition very sensibly appears; nor is it wanting in incrustations of sulphate of lime, of a red tinge, though some remain very white. But neither in these places, nor in others before mentioned, do these fumes any longer act, no smell of sulphur is perceived, nor any vapour seen; and it is probable that all remains of internal conflagration have long since been extinct.

Among these lavas we likewise find enamels and pumices. Sometimes the former are separated from the latter, and sometimes one part of the same piece is pumice and the other enamel. The latter is opaque, of a cincreous colour, friable, of a scaly grain, and, as I judge, of a petrosificeous base. The pumice is of the class of the compact and heavy, and of a filamentous grain. Both the pumices and enamels frequently contain feltspars, though scarcely discernible, and some scales of black shoerls.

Both these bodies produce in the furnace a black enamel, with many bubbles in that afforded by the enamel, but fewer in the product of the pumice: the shoerls and felt-spars fuse in both.

Among these decompounded lavas we meet with certain curious and beautiful objects, which derive their origin, in my opinion, from filtration. Two of these I will describe, after having given some idea of the lava in which they are observed.

This lava is white, friable to a certain depth, and manifestly shews a decomposition by sulphurcous acids. It is of a petrosiliceous base, in many places disposed in strata; and its stratification is probably that of the stone from which it originated. It is full of small cells, and other minute cavities, within which the objects I mentioned make their appearance.

The first of these consists of minute crystallizations of shoerls. From the internal sides of several of these cells and cavities project very slender shoerls, which form sometimes a kind of plume, at others a fan in miniature, at others a truss or bunch, and at others they are detached, and, when viewed with the lens, resemble minute bristles of a dark chesnut colour. A similar appearance I observed in the fissures of a lava of Solfatara.* I am of opinion it is to be ascribed to filtration, after the hardening of the lava; since, though it is certainly very common to find shoerls in lavas, they are always found incorporated within them, in the same manner as they existed in the stone, their original matrix, and never detached from the lava, as in the present case.

The second filtration has produced small quartzose crystals; and the manner in which they are distributed in the lava, and their prodigious number, render them a very sin gular phenomenon among volcanic objects. Wherever the lava is seabrous, wherever it has folds, sinnosities, cavities, or fissures, it is full of these crystallizations. The larger crystals extend to three lines and a half in dimension; but these are extremely rare, and almost always ill-formed. The greater part are about half a line. When we view a piece of this lava exposed to the sun, it sparkles in every part; but on a more attentive examination we discover the single, minute, quartzose crystals, which may be discerned

still more clearly by the aid of a lens.

These crystals generally consist of an hexagonal prism, infixed by the lower part into the lava, and in the upper terminated by an hexagonal pyramid, the sides of which are for the most part isosceles triangles. The form of these pyramids, however, is not al ways the same, neither with respect to the number nor the figure of the sides, and the same is to be observed of the prisms. Three crystals alone, among the great number I examined, were terminated by two pyramids: the prism was attached to the lava in a few points, and the pyramids projected out. This kind of crystals is extremely brilliant, and of the first water. There is scarcely one which is not streaked transversely like rock crystals. The most regular are in small cavities, without, however, entirely covering the sides of them, as is usual with the geodes. Not a few of them likewise are found out of these cavities, in some parts of the lava: these are frequently short and grouped, not without some confusion of the prisms and pyramids.

The lava which is embellished with these crystallizations forms immense rocks, and vast elevations hanging over the sea, which, wherever they are broken to a certain depth. are found to contain these crystals, accompanied by capillary shoerls, such as have been

already described; but the latter are not very numerous.

It is well known that rock crystals sometimes contain within them extraneous bodies, such as small tufts of amianthus or asbestus, metallic sulphures, earthy particles, and even crystaffized shorrls of various sizes. I have in my possession a group of needleformed crystals, from Mount St. Gothard, within which are seven small prisms of black and striated shoerl. The same may be observed in these minute crystals, relative to the eapillary shoerls, as will appear from the following facts: First, I have found in a fissure of the lava, a quartzose crystal, containing a group of capillary shoerls, in part included within it and partly projecting out. Secondly, the apex of a similar group or tult projected from one side of the same piece of lava, and buried itself, with extended threads, within the pyramids of three crystals that formed a knot. Thirdly, one crystal was perforated from side to side by a needle of shoerl, the two ends of which projected out; and many similar needles projected from the surface of another crystal. I might produce many other instances of these sports of nature equally curious; but these appear to me sufficient to prove my assertion, as also another truth, which is, that the formation of these capillary shoerls must have preceded that of the quartzose crystals; otherwise it is impossible to conceive how the former should have penetrated the substance of the latter.

I have generally experienced that the decomposition of lavas was an obstacle to their perfect fusion; and this was the ease in the present lava. In the furnace it vitrified superficially, with some beginning of internal fusion; but the pieces still preserved the form they before had. Having broken several of these pieces, I examined the cavities, which, according to the preceding observations, must contain the crystals of which I have been speaking. I in fact found them there, and, to my great surprise, perfectly unchanged; as I could not discern, in either the prisms or pyramids, the slightest flaw or scratch, and they even retained their brilliancy and transparency. I observed that some of them had been overflowed, if I may use the term, by the lava superficially re-melted, to one-third or a half of the prism, and some of them quite to the base of the pyramid; but the part which rose above the lava was perfectly well preserved. Very different was the case with the shoerls, which, by their melting, had left blackish spots on the lava, though in more than one of these the traces of the shoerl might still be distinguished.

A third stone, the origin of which I likewise ascribe to filtration, is a semi-transparent chalcedony, of a milky whiteness, with a slightly blueish cast. It is found in reniform or kidney-shaped pieces, within the layas of the above-mentioned Valle di Muria, and still more plentifully on the sea-shore. The smallest are an inch in diameter, but the largest eight, and some twelve inches. There are few of them which have not knobs and cavities; the latter commonly form geodes of minute quartzose crystals, but of which little more is discernible than the pyramid. It is well known that chalcedonics differ very much in hardness. The present are extremely hard, and, from the strength and quantity of the sparks they give with steel, equal the best flints. They will likewise cut factitions glass; but in this they do not excel the small quartzose crystals produced by filtration, of which we have just spoken.

On breaking some of these chalcedonies, one of them was found to contain two extraneous bodies; that is, a small piece of lava and some sulphate of lime crystallized; which were probably taken in by the particles of the chalcedony, while in a state of fluidity

or softness.

These substances, which are found on and within the lavas, and are foreign to them, derive their origin, in my opinion, from their decomposition caused by the sulphureous acids, or even by the injuries of the atmosphere. The coherence of their constituent parts being destroyed, particles of them are carried away and deposited by the water in the cavities and fissures of the lavas, where, from the affinity of aggregation, they produce stalactitical concretions of different kinds according to their respective natures. If the lapidarious moisture be a mixture of silex, alumine, magnesia, lime, and iron, in certain proportions, it will crystallize into shoerls; or if it be entirely or principally siliceous, it will produce quartzose crystals. If again this moisture, in which the silex is so abundant, contain likewise a small quantity of alumine, it will consolidate into masses of chalcedony, which will take the form of the eavities that have received the moisture.

This latter stone has been discovered in other lavas. Such are the Vicentine, called Enidri Vicentini, from the drops of water which they sometimes contain. My specimens have none; but I doubt whether any have been found equal to them in size in volcanic countries. In some of them, their milky whiteness is interrupted by rose coloured spots; which colour is probably derived from the iron that tinged the lava before its decompo-

sition.

Before I conclude this chapter, two things more remain to be mentioned, which I observed before I returned to the haven of Lipari, which is distant about three miles from

the Valle di Muria.

First, there are two rocks within the channel of Vulcano; one nearly of a triangular shape, a hundred and fifty-two feet high, and twenty in breadth. It is called Pietra Lunga, and is remarkable for a kind of gate in the middle of it, through which small vessels may pass. The other is of the same height, but has greater breadth, and is about two hundred paces distant from the former. The matter of which both are formed is the same; that is, a decomposed lava, of a petrosiliceous base, and extremely resembling that of the Valle di Muria, which contains the quartzose and shoerlaceous crystallizations; though in this none are to be found. The lavas of Lipari extending along the

shore, in front of these two rocks, are partly of the same quality, which inclines me to believe that anciently these lavas formed one continued whole with the two rocks, though the former is distant from them two hundred and forty feet, and the latter a full mile; and therefore that the channel which separates Vulcano from Lipari, and which is but narrow, must once have been much narrower. I have likewise frequently observed, when the sea has been perfectly calm, rocks under water, between the two above-mentioned and the shore of Vulcano; whence it appears to me not improbable that this island was formerly united to Lipari, and that the incessant beating of the waves has in time formed this channel or strait, in the same manner that many other straits, of much greater breadth, have been produced by the sea.

The second observation I had to make respects the appearance of Monte della Guardia as seen from the sea. It there appears bifurcated, from the projecting of a much smaller mountain, called Monte Gallina, from its north-east side. The roots of Monte della Guardia, on the south and south-east side, are in the sea; and some parts of them afford pumices, which higher up are buried under vast accumulations of lava that has flowed over them. Besides the pumices, several of these lavas, in the direction of the south-west, present large masses of glass, partly detached, and partly incorporated within them. If to these two kinds of vitrifications we add the others which lie under the castle of Lipari, and on its sides, and which make a part of the base of the Monte della Guardia, we shall perceive how much this mountain must have abounded in vitreous eruptions; an abundance which will appear still greater when we come hereafter to consider its more elevated parts.

These are the most important objects which presented themselves to my observation in my excursion round the base of Lipari; and If in describing them I may appear to have been somewhat too diffuse, their number and importance, and my desire to give the reader an accurate idea of them, must be my excuse. The interior part of the island, which I shall now proceed to consider, will alford me an opportunity to be more con-

cise.

VOLUME THE THIRD.

CHAPTER XVI

LIPARI

PART THE SECOND.

OBSERVATIONS MADE IN THE INTERIOR PARTS OF LIPARI, AND SEVERAL OF ITS MOUNTAINS.

Extremely irregular appearance of this island....No characterized crater discoverable in it.... Conjecture that the Monte San Angelo, and the Monte della Guardia, the highest mountains in Lipari, were produced by two distinct volcanos Efflorescences of muriate of aminoniac (sal ammoniac in two caverns near the plain called La Valle....Curious volcanic breccia... The volcanic tufa which, on one side, covers the whole mountain of the celebrated Stoves (or vapour baths) of Lipari, has every appearance of having been an earthy current; and is remarkable for containing true ligneous coal.... Conjectural inquiries into the origin of this The road that leads from the town to the Stoves, formed, in a great measure, of tufa corroded by the rainwater....Various bodies observable within this corroded tufa....Detached pieces of enamel, which include many small bulbons bodies that appear to be garnets....Comparison between these and the garnets of Vesuvius....Enamel of the Liparese garnets, which has for its base the hornstone....Detached lavas in the road leading to the stoves....Volcanic chrysolites in a lava with a horn-stone base These chrysolites compared with those of Etna... Large pieces of red porphyry which do not seem to have suffered fusion.... None of these bodies disposed in currents; whence it is probable that they have been thrown into the air by some volcano.... A spacious plain of tufa rendered cultivable, situated beyond the Monte della Stufe, which affords numerous pieces of the finest and purest glass found in Lipari....Local origin of this glass....Bed of pumices on the extensive current of tufa before mentioned ... Stoves of Lipari described Remains of conflagrations of sulphur under them, and in their environs.... Prodigious number of lavas decomposed by the action of sulphureous acid vapours....Oxyde of pure iron deposited on some of these lavas....Variety of colours which they present to the eye Their decomposition usually in the inverse proportion of the depth of their masses.... When freed from the decomposition which renders it difficult to ascertain their nature, they are usually found of a petrosiliceous base....This decomposition an obstacle to their fusion in the furnace....Explication of the cause of this change....Sulphates of lime variously coloured, and adhering to the decomposed lavas.... Iron, oxydated, and modified in various manners, the cause of the different colours of the decomposed layas, and sulphates of lime Discovery of several amorphous and crystallized zeolites near the stoves.... Jelly which they form with mineral acids.... Emit bright flashes when on the point of melting, and swell considerably on their actual fusion.... Terms of comparison between these zeolites and those of other countries.... Their production not by the dry but the humid way Though the zeolites of several volcanized countries are probably formed within the sea, this does not seem to be the origin of those of Lipari....Instances of zeolites produced in fresh water....Springs of hot water which supply the baths of Lipari....Another prodigious accumulation of decomposed lavas, and sulphures of line, on the southern side of the island.... Perhaps there is no volcanized country in Europe where the sulphurcous fumes issuing from subterranean conflagrations are so extensive as at Lipari....Vitrifications of Campo Bianco, and the Monte della Castagna, which are found attached to those of the Monte della Stufe, the

Monte San Angelo, and other places...Proofs that almost two-thirds of Lipari, which island is nineteen miles and a half in circumference, are composed of virifications...The materials of which this island is composed principally derived from the petrosibes, feltspars in the mass, and horn-stones, in part simply fused by subterraneous combustions and in a still greater part vitrified....Notwithstanding the immense accumulations of this vitrification, an extraordinary intensity of heat not necessary to be supposed...An exception in the pumices originating from granite....Few notices left us by ancient authors relative to the fires of Lipari; though we know from indubitable authorities, that both the island and the city existed before the Trojan war....No cruptions in this island described by history.....Feeble fires, visible by night, alone observed in ancient times....This island, the produce of subterranean conflagration, had arrived at its greatest dimensions, before it was noticed by any writer.

TO acquire a just knowledge of the interior part of a mountainous volcanized country, the best method, as it appears to me, is first to ascend the highest mountain, and, after having examined the summit, to turn the eye downward, and observe the chain of smaller mountains that surround it. We may thus, at one glance, discover the form of these inferior mountains, their interchangeable connection, and the relations which they bear to each other, and to the primary mountain, with other important objects, which had we first ascended one of the lower eminences, we should not have been able

to ascertain with equal precision and clearness. After, therefore, having made researches, with the greatest diligence, around the shore of Lipari, when I proceeded according to my original intention, to explore likewise the internal parts of the island; I first ascended to the summit of the Monte San Angelo, situated to the north of the city of Lipari; this being the highest mountain in the island. Here the whole of the island presented itself, at once, to my view, and I could perceive that, far from having a conical figure, such as is that of Stromboli, and in a certain manner of Vulcano, it is composed of groups of broken and half destroyed mountains confusedly heaped together; which give it a most irregular appearance. It is evident that the volcanic fires have raged in many places, and that, from their too great proximity to each other, they have not been able to form those distinct cones which are so observable in Vesuvius and on Etna. But the matters ejected by the superior volcanos, pouring upon those which issued from the lower, have produced in every part confusion and disorder. From the summit of Etna we may discover a multitude of subjacent craters, well characterized; but from that of San Angelo I could not perceive one. There are, indeed, many openings and hollows to be seen, which once perhaps were fiery mouths; but none of these cavities have at present the figure of an inverted tunnel, possibly because they have been in part filled up and destroyed by subsequent cruptions, or by time.

M. Dolomieu observed at the summit of this mountain a circular plain, surrounded by eminences shelving towards the inside, which he imagined might be the remains of an ancient erater. This conjecture, after a careful examination of the spot, does not appear to me improbable. The same naturalist likewise supposes that this mountain, the height of which is nearly a mile above the sea, was the first that was formed in the island through which the volcano burst forth, and which served as a base and support for the other mountains that were thrown up afterwards. This opinion is extremely plausible; but the fact may likewise be, in my opinion, that this mountain, at the time of its production, or very soon afterwards, had for its companion the Monte della Guardia, which looks towards the south, and of which I have before spoken; both because the latter is separated from the former, and because it is little inferior to it in height.

position siliceous From the ideas suggested by a view of the places themselves, I conceive it not improhable that these two mountains, which rise so much higher than the rest, have been produced by two distinct volcanos, and were the first that emerged from the sea; forming then two small islands, which afterwards, enlarging their base, united into one; for it is well known that other volcanic islands originally consisted of several parts, which afterwards were joined. To these two mountains subsequent cruptions made new additions, until at length the whole of the island of Lipari was produced, which, from the crosion of the rains and the sea, is now certainly less than it once was.

From Monte San Angelo, I passed to the Monte della Guardia, which on the side towards the sea presents only steep and rugged precipiees of lava, and consequently is deprived of all vegetation and verdure; but on the land side, which is opposite in one part to the city, it is formed with gentle declivities, and covered with vinevards; for, as its soil is tufaccous, it less resists cultivation than any other volcanic product. While standing on the summi. I was still more confirmed in the opinion, that this mountain is not an accessary to, or prolongation of, that of San Angelo; but that it forms a whole of itself, and may be called primary equally with the other, from the distance between them, and the wide valley, running from east to west, by which they are separated.

Having visited these two mountains, which are the lofticst in the island, I proceeded next to examine the lesser eminences, and found additional confirmation of what I have already observed; I mean that these eminences have entirely lost the true form of volcanic craters, so much have the matters ejected from them intersected each other, and confusedly intermixed. The long and unknown series of years that has elapsed since these cruptions must, no doubt, have contributed to increase the confusion. Excepting, therefore, some few flat places, and practicable declivities, which the inhabitants have rendered cultivable by great labour, Lipari is a ruinous pile of horrid precipices rugged cliffs, and enormous masses; and there is no summit or projecting part of a mountain which does not exhibit manifest indications of its future fall and destruction. The materials of which these ruins are formed are pumices, enamels, and glasses, which I shall not describe, because they are partly the same, and partly extremely analogous to those of which I have already given the description.

Some of the natives, by the accounts they gave me, excited my curiosity to visit a cavern situated in a small plain called La valle, about a quarter of a mile to the west of the city. This cavern has its mouth in a rock of decomposed lava, and a man may walk into it to the distance of fifty paces. Its sides are covered with efflorescences of muriate of animoniae, as were likewise those of another small cavern in the same rock. This salt must have been formed by sublimation, having been reduced to vapour by subterraneous fires, and thus attached itself to the sides of these two caverns, as it is found attached in many other volcanic places; but of these fires and ammoniacal vapours no

traces whatever now exist.

In this short excursion I found by the way a volcanic breezia, which, on account of the heterogeneous substances it contained, it would be improper to pass without notice. It is found in large isolated pieces, but I was unable to discover from what vein it derived its origin. Its principal substance is an earthy lava, of a blueish gray, a coarse grain, and little hardness. In this were inclosed the following bodies:

First, fragments of two kinds of fava; the one black, of a scaly fracture, and which moved the magnetic needle at the distance of two lines; the other of a gray ground, a very rough surface, an unequal tracture, which gave sparks with steel, and contained small plates of featspar. Both were of the horn-stone base, and emitted a strong argilla-

ccous odour.

Secondly, several pieces of vitreous lava, of a very beautiful colour, between a green and a blue: by its smoothness, clear fracture, its aspect, and want of hardness, it resembles the pitch-stone, or pitch-blende.

Thirdly, numerous small pieces of a cincreous compact pumice.

Fourthly, pieces of a whitish semi-transparent glass.

Fifthly, small pieces of a colourless glass, resembling in transparency factitious glass. The largest piece was fourteen lines in length, and eight in breadth, and was, like the others, buried in the breecia.

These five species of volcanic productions were certainly not natural to the substanct of the lava; for their fractures and angles are very visible, and by carefully breaking the lava they may be extracted entire. We must therefore conclude that they were absorbed and inclosed in the lava when it was in motion, and thus were consolidated into one body.

In making these observations a doubt suggested itself. Though to the naked eye, and likewise to the touch, the vitreous lava appears perfectly smooth, yet, when viewed with a lens of a strong magnifying power, its surface appeared full of very minute fissures. At least, if this was not observable in all, it was in several pieces of both these kinds of glass. I therefore conjectured, that when these substances were in an ignited state, a current of water might have passed over them; or that they suddenly came in contact with the cold air; unless we rather choose to suppose that these fissures were produced, when these vitreous bodies, in a frigid state, were suddenly enveloped in the fiery torrent.

But the celebrated Stoves of Lipari appear to be the object which most excites the curiosity of travellers; I could not therefore omit to visit them. I must, however, confess, that the road which led to them afforded me more instructive objects than the stoves themselves.

These stoves lie to the west of the city, at the distance of four miles, and somewhat beyond the summit of a mountain, which, after those of San Angelo and della Guardia, is one of the highest in the island. The road I went was that which leads immediately from the city to the stoves, and the only one which can be travelled without great difficulty. It is in a great degree the work of rain-waters, which have made a deep excavation in an immense mass of tufa. In more than one place in this work I have spoken of volcanic tufas but almost always incidentally. The present species of this substance requires to be treated of somewhat more at length.

At the beginning of this work, when speaking of the volcanic tufas of Posilipo, I said, and endeavoured to prove, that it was probable they were formed by slimy cruptions; though I would not deny that ashes, sand, and other subtile matters ejected by volcanos, penetrated either by the rain-waters or those of the sea when they covered the bases of the burning mountains, have been consolidated into some tufas.* The tufa of Lipari, of which I now speak, has every appearance of having been an earthy current. It begins at about a hundred paces from the city, and continues without interruption to bey ond the summit of the Monte della Stufe, or Mountain of the Stoves. This mountain, like most of the others, varies considerably in its different parts, in one place presenting gentle declivities, and in an another steep and rugged descents; here plains nearly level, and there precipices almost perpendicular. The tufa with which it is covered takes exactly the same course, and sometimes curves, and as it were waves on the surface: nor does it in the least differ in its sinuosities and windings, from the most completely cha-

racterized currents of lava, which it likewise resembles by being disposed in beds lying one over the other, as appears in those places which have been most corrolled by the rain. I therefore was of opinion that this tula had been a stream, if I may use the expression, of slimy substances that had flowed down the mountain; as examples are not wanting of similar cruptions produced in the humid way in the mountains Vesuvius, Etna, and Hecla.

But here a difficulty presented itself in opposition to this hypothesis. Had this part of the mountain been immdated by a torrent of water issuing from the earth, when its violence had ceased, the more heavy bodies must have subsided to the bottom in obedience to the laws of gravity, the tess heavy have remained above them, and the lightest have occupied the highest place; which, however, is not the fact, since, as we shall see, at a small depth within the tufa, are found large masses of lavas, enamels, and glasses. But it does not appear to me improbable that these masses may have been thrown out from some burning mouth, after the hardening of the tufa, within which they have not penetrated deep.

Not only the position and winding course of this tufa over the back and sides of the mountain sufficiently prove that it once flowed; its very nature is a strong confirmation of this fact. It is not an aggregation of ashes and sand; a mixture of fragments of shoerls, feltspars, and lavas decomposed, and rendered earthy, and fastened together by the action of the water, becoming so hard as to be cut into pieces proper for building, as is the case with many other tufas; but it is merely an argiflaceous earth, resembling, from its softness, the hardened mud of rivers. Its colour is a dull gray, its structure somewhat granular, and so yielding that it may be crumbled and pulverised between the fingers. It is light, adheres slightly to the inside of the fip, emits a feeble argillaceous odour, and, when immersed in water, greedily imbibes it in every part.

In the furnace it first acquired a reddish brown colour, and afterwards the black colour of iron. It became so hard that it gave sparks with steel, without however vitri-

fying, except that its surface assumed a kind of vitreous varnish.

The depth of this tufa is different in different parts of the mountain. In some places it is several feet deep, in others but a few, and in others there is so great a quantity of it that, notwithstanding the excavations made in it by the rains, I was unable to ascertain its depth. But in every place where I could discover the bottom, I observed that it rested on a bed of pumices, partly pulverised, and partly in detached pieces approaching to the globose form. They belong to the class of the lightest of these sustances. It appears, therefore, indubinable, that these pumices had been thrown out of

the burning mouth of some volcano, before the flowing of the tufaceous current.

This tufa presented a very unexpected phenomenon. On breaking it, its fractures exhibited small black particles, which were distinctly recognized to be true coal, from their blackness, lightness, dryness, the facility with which they broke, and their small degree of hardness. Some of them, likewise when exposed to fire in the open air, funded, and became red hot; others emitted a little flame. The latter had not been perfectly reduced to coal, as the fibrous parts of the wood were still to be seen. These coals were small cylinders from two or tree fines in length to twelve or fourteen, and of proportional thickness. They appeared to have appertained to branches of trees or shrubs; they are buried in the tufa at various depths, and are found, though thinly scattered, through its whole extent.

This fact, never before, to my knowledge, observed by others in volcanic tufas, might induce us to imagine that the two methods, the humid and the dry, had here been combined; and that the watery slime when it flowed down the mountain, had been pe

negated by the fire in such a manner that it had inflamed, and converted into coal, the vegetables it met with in its way. This explanation is certainly not free from difficulties, as the reader, no doubt, already perceives; it therefore may appear more probable that the earthy introducion had involved, and carried with itself, these carbonaceous substances, which existed previous to its cruption, and which derived their origin from a shower of ignited matter having burned, but not entirely consumed, the few plants which fee bly vegetated on the declivities of the mountain.

It has been already said, that the rapid descent of the rain-waters on that part of the mountain which leads to the stoves, has corroded the tufa to a great depth; and it is in the middle of these corrosions that we meet with various volcanic bodies, which, toge

ther with others lying in the public road, merit well to be described.

First, we find pieces of channel of every size, which, though they are smooth with out, when broken, have, within, an angular fracture. Their colour is a pale blue; they have no great brilliancy, nor are they very hard, as they fly in pieces when struck against the steel. The cause of the want of hardness in this channel, may be ascribed to the fissures, of which it is full; and these, perhaps, are to be attributed to the pieces of enamel being red-hot when they fell into the tufa not yet dry. The feltspars it contains have the same crack, and probably from the same cause.

In the same places is found another kind of enamed containing a great number of small bodies, which I will not absolutely affirm to be garnets, because I was not able to analyse them in the humid way; but their external characters, together with the proofs furnished by the dry way, almost induce me to conclude them such. In all my volcanic researches I have never met with any similar. In general they have a bulbous figure, and are of a blackish colour, which in some inclines to a red. Their surface is smooth and shining, their recent fractures lamellar, perfectly vitreous, and will cut, glass. The largest are about three lines and a half in thickness, and are opaque; the smallest, about the third part of a line, and are semi-transparent. They give sparks with steel, and melt in the furnace into a black and scoriaccous enamel. These characters, taken together, certainly give them a great resemblance to garnets: I shall not therefore hesitate to class them with that species of stone; as their not being crystallized is of little importance, since we know that there are also amorphous garnets.

While employed in the examination of these stones, I resolved to compare them with the Vesuvian garnets; for, in my excursion to that volcano, I had collected several different species of them on Monte Somma, which is the ancient Vesuvius. I made seve-

ral experiments on four of these, of which the following is the result.

The first species is found in a lava with a horn-stone base, of a yellowish gray colour, an unequal surface, and of a consistence little different from earthy, from the great alteration it has undergone; not, as far as appears, from sulphureous exhalations, but from the action of the atmosphere. The garnets it contains have likewise suffered injury, having lost a part of their native lustre, and being easily broken or crumbled to pieces from the multitude of minute fissures and cracks in them. They, however, retain somewhat of the vitreous character. Their colour is between a white and a gray. At first view their figure appears perfectly globular; but on extracting them from the stone, their matrix (which may easily be done) and attentively examining them, they are found to have facets, though it is not possible to ascertain the number of them, as many of the angles have been defaced by time. I shall only observe, that having broken one of these garnets into two equal parts, the perimeter of each half was octagonal. This fracture at the same time shewed the texture of the garnet, which is composed of

very thin circular teaves. These garnets are of different sizes, from four lines and a half to one-sixth of a line.

The furnace reduces the matrix-lava to a compact enamel of the colour of pitch; but it leaves the garnets untouched, which only become somewhat whiter, more vitreous, and more hard. The blackness of the enamel being a contrast to the whiteness of the garnets, a great number of the latter become conspicuous, which before were not visible in the lava; and, notwithstanding their extreme minuteness, they remain uninjured by the fire.

The garnets of the second species are contained in a lava which has for its base a soft horn-stone. They are larger than the former, and entirely opaque. They are white as snow, and more brilliant in their fractures than the preceding. Many of them are of a round figure, and manifestly shew a crystallization in various facets; which, however, it is impossible to number as they break in pieces if we attempt to extract them from

the lava. Many others of them are of very irregular forms.

Several of this second species of garnets inclose within them small prismatic shoerls, of the colour and fustre of asphaltum, which probably pre-existed completely formed, and were taken into the moisture from which the garnet derived its origin.

These garnets are, likewise, infusible in the furnace, though the lava is converted into

a porous scoria.

The third kind is strongly infixed in a heavy lava, which also has for its base the horn-stone, is of an iron-black, compact, but not sufficiently hard to give sparks with steel. The garnets, which are of a yellowish white colour, and some of them four lines in diameter, for the most part have clefts or fissures, but in such a manner that in the recent fractures the surface resembles a round polypetalous flower.

The furnace melted the lava, but not the garnets, which only acquired the red colour

of copper.

The garnets of the fourth and last species have four-and-twenty facets, and are semi-transparent, white, and vitreous. Their matrix is a compact lava of a horn-stone base, which emits an argillaceous odour. In the furnace it changes into a black enameller product, but the garnets remain untouched.

On comparing these results with others before detailed, we shall find that the structure of the Vesuvian garnets, so far as it is vitreous and lamellar, is similar to that of those of Lipari; but that, when exposed to the fire a difference is found between these two

stones, the one easily melting in the furnance, and the other proving refractory.

Finding, therefore, that these four species of garnets were infusible in the furnace, though continued in it for several days. I had recourse to oxygenous gas (or dephlogisticated air) by the action of which they all melted, though slowly. When the matrix lava flowed like common glass, the small pieces of garnet within it remained unchanged; but at length fused, though without incorporating with the lava, so as to form a homogeneous whole.

Those chemists and naturalists, who, before me, have made experiments with fire on the Vesuvian garnets, have described results similar to those I observed. Bergmann says these garnets melt with the blow-pipe alone, but a vehement fire is necessary.* Saussure tells us, that a spotted lava (lava a ocil de perdrix) which he found on Monte Somma, acquired, after fusion, a black vitrified ground, but that the polyhedrous grains of this lava remained unchanged in the most violent fire; and by polyhedrous grains it

fire on rgmann ssary.* Monte

Monte grains grains it is evident that he means what I and others have called garnets." With respect to the action of oxygenous gas upon them, we may refer to Ehrmano, in his work on the Air of Fire. "The white opaque garnet of Vesuvius," says this writer, "differs from garnets properly so called, in this, that it melts with extreme difficulty (with the assistance of oxygenous gas is here to be understood) and at length, after continual chullition, be comes a mass perfectly similar to quartz, even in its fracture, and which crackles in like manner between the teeth."

This kind of challition I have observed in the four varieties of garnets above mentioned, when they were in a state of fusion. The first and third likewise produced two small masses resembling quartz, but those of the second and fourth variety were spongy. It is very possible that this author only made his experiments on one species.

Some Larned naturalists are of opinion that the garnets of Vesuvius are improperly so denominated; first, because they contain no iron; secondly, because they fuse with difficulty; and, thirdly, because they differ in the proportionate qualities of their constituent parts from those of true garnets. These reasons, however, do not appear to me sufficient to exclude them from being classed with this kind of stones. It is true, that iron is usually contained in garnets, but it is not essential to them; as has been observed by Bergmann, who, in transparent garnets found only 120 parts of this metal. The absence of iron, probably, therefore, renders them so difficult to fuse. With respect to their constituent parts the Swedish chemist (Bergmann) has observed, that the principal of these is silex, the next alumine, and that which is least of all in quantity, lime. This analysis agrees with that made by Achard on some of the purest Bohemian garners; and such a proportion of the constituent principles is sufficiently suitable to that of the garnets of Vesuvius, in which Bergmann found about fifty-five parts of silex, thirtynine of alumine, and six of lime. And though the proportion of the silex to the alumine is not entirely the same in both these stones, the difference is not so great, in my opinion, as to induce us to consider them as two distinct species; as will appear by comparing the numbers 55 and 39, which express the quantities of silex and alumine in the Vesuvian garnets, with the numbers 48 and 30, denoting those of the same two earths in the Bohemian garnets, analysed by the before-cited chemist of Berlin (Achard.)

To return for a moment to the garnets of Lipari: these do not so tenaciously adhere to their base as we almost always find the feltspars and shoerls; but, like other garnets, are implanted in it in such a manner that they may be easily detached without breaking, leaving the exact impression of their figure in the enamel. This enamel, which is compact, heavy, and of a gray cincreous colour, is found in detached pieces, both in the road and in the tufa; and is the first production which presents itself, after leaving the city to proceed towards the stoves.

Continuing our journey still further along this road, we find in it, and likewise within the tufa, very curious mixtures of a white argillaceous earth and black enamel; both of which are so mingled and kneaded together, that we can scarcely find a quantity of this earth of the size of a pea, which does not contain several particles of this enamel; and very few indeed are the pieces of enamel that contain none of this earth. It has an earthy odour, and adheres to the tongue.

In the same situations where this peculiar mixture is found, we likewise meet with an enamel containing garnets, similar to those above mentioned, but larger, and more approaching to a globular figure. It is remarkable that this enamel, in some places,

^{*} Voyage dans les Alpes, tom 3.

forms one whole with some pieces of lava of a horn-stone base, which also contains garnets.

I shall briefly distinguish four species of lava, each of a horn-stone base, which are

met with, in detached pieces, on the road to the stoves.

The first has a fibrous fracture, the colour of iron, some appearance of porosity, sufficient hardness to give sparks with steel, and the power to move the magnetic needle at the distance of a line and a quarter. It emits an earthy odour, and contains feltspars.

The second is of a black-gray colour, and, though compact, rather soft. Almost one

half of it consists of rhomboidal feltspars.

The third only differs from the second by being somewhat more compact, harder, and

containing fewer feltspars.

The fourth, which in solidity, weight, and hardness, exceeds the three preceding, has a black ferruginous colour, an earthy fracture, adheres slightly to the tongue, and emits the usual argillaceous odour. It moves the magnetic needle at the distance of half a line.

All these four kinds of lavas are changed, in the furnace, into vitreous scoriæ, but

without the fusion of their feltspars.

Having mentioned these, it will be necessary to describe somewhat more at length, another species of lava, which is enriched with a great number of extremely beautiful

volcanic chrysolites.

This lava has for its base a soft horn-stone; it is of a dark brown colour, and unequal in its fractures on account of the fissures which separate its parts. It is found in detached pieces, like the four preceding lavas, but these pieces are rare. It gives but few sparks with steel, emits a slight argillaceous odour, and acts on the magnetic needle at the distance of a full line. In consequence of its numerous fissures it is rather light, and when struck with a hammer is somewhat sonorous. I omit to mention some small scales of feltspar incorporated in it, and proceed to the examination of the

chrysolites. These, when situated in the external parts of the lava, which have suffered by the influence of the atmosphere and elements, readily attract the eye by their lively colour, which is between a green and a yellow, but in the recent fractures they shine with much more brilliant colours. The most conspicuous are the golden-yellow, and the line grass-green, with which sometimes is mixed a fire-red, tempered with a tinge of purple. If these chrysolites are exposed to the immediate light of the sun, and viewed under certain angles, their colours become much more lively and bright. Many of them are amorphous, but some are quadrangular prisms. Their surface, in the fractures, shines with a glassy brilliancy, and is sometimes smooth, and sometimes rough, according as the plates of which the chrysolites are composed may have been broken. The small fragments of them are angular and semi-transparent. These chrysolites give sparks with steel, and cut glass nearly like rock-crystal. The largest are not less than three lines and a half in length, but the smallest can scarcely be discerned by the naked eye. They are so firmly infixed in the lava, that only fragments of them can be detached.

The fire of the furnace, and that of the blow-pipe, not only will not fuse the minute stones, but are unable to injure them either in their colours or texture. Oxygenous gas (dephlogisticated air) alone discolours them, and melts them into a globule of a white colour, but without brilliancy.

Though it was not known till the present time that Lipari afforded volcanic chrysolites, they had been before found in volcanized countries, as in Vivarais and Velay, by M. Fanjas, and on Mount Etna by M. Dolomien. But on comparing their chrysolites with mine, I find certain differences and resemblances, which it will be proper to emmerate.

The chrysolites observed and described by M. Fanjas, when examined with the lens, are found to be composed of an aggregate of arenaceous grains, more or less fine, and more or less adherent; scabrous, irregular, and sometimes forming crusts and small sandy scales; but for the most part having the appearance of angular fregments united by insertion into each other.

The chrysolites of Lipari have nothing of this nature in their structure. I broke several of them, and examined their fragments with the microscope; but they never appeared to me granular, but always smooth and glassy. The most minute parts of these chrysolites exhibited the same aspect they presented when whole.

I must not omit to mention another difference of importance, which is, that the chrysolites of Lipari are only a few lines in length, whereas those described by M. Faujas are sometimes several pounds in weight.

They agree, however, with mine in their infusibility in an extremely active fire; for those on which he made his experiments resisted the fire of common furnaces, however violent and continued it might be, and could not be reduced to a state of fusion but by the aid of oxygenous gas.

The colours of both arc sometimes the same. I say sometimes, for M. Faujas informs us, that several of his chrysolites were only of one colour; a green, or topaz-yellow.

The traits of resemblance and difference between the Liparese and Etnean chrysolites will be seen by comparing the description I have given of the former with what M. Dolonicu says of the latter, in the work I have frequently cited. He tells us, that some of the chrysolites be found there are amorphous, others crystallized in tetragonal or hexagonal prisms, sometimes with an hexagonal pyramid; that their fracture is partly conchoidal, and partly lamellar; that they are harder than quartz; that they are more or less transparent; that their colour is a greenish yellow, with various tinges, and that they are fusible in a strong fire. He does not give their size, but they cannot be large; both because he calls them grains, and because those which I observed in some lavas of Etna were very minute.

I have designedly called the chrysolites of Lipari volcanic chrysolites, not merely because they are found within a lava, but to preserve a distinction between them and a gem of that name; since I know that some respectable authors are of opinion, that the volcanic stones which, from their greenish yellow colour, and other circumstances, resemble that gem, and therefore are called chrysolites by the volcanists, differ from them entirely in their component parts, and several of their external characters. To this opinion I can make no objection, though in describing these stones I have adopted the name by which they are usually known. It must be observed, however, that some of their properties show they cannot be classed as shoerls, among which some naturalists generally place the chrysolites of volcanos.

It remains likewise to speak of a stone which was the last of the products that offered themselves to my observation, as I proceeded along the declivity of the mountain leading to the Stoves.

The stone is a porphyry, the base of which is the petrosilex, containing feltspars with several faces, and brilliant in the fractures, and blackish irregular shoerls. The base has the red colour of brick. It is found in detached masses, some of which weigh several

minute ous gas a white

not less

by the

thousand pounds. It is compact, and scaly in the fractures. The prode broken from a are irregular; the thinnest are transparent at the edges; and they you spirks moderately with steel. The colour of the base has given the teleparen reddish tinge, as we see in certain oriental porphyrics.

But has this port hyry suffered fusion, or is it in its natural state, and at most calcined when it is ejected by the volcano? I cannot pretend positively to decide; but I incline to the latter opinion more than to the former, since an alteration is visible, even in the

internal parts, which appears to be the effect of a true calcination.

In the furnace the substance of this rock becomes soft, but does not buse: the feltspars

remain unchanged, but the shoerls are vitrified.

The spacious and deep excavations made in the tufa by the rain-water, and which extend from the bottom of the mountain to the summit, afforded me an opportunity to discover and examine the stony substances I have described; for it was only in those excavations that they were visible: in every other part nothing appeared but the naked appelied crust of the tufa. None of these substances are disposed in currents; they are all detached; and thus render it probable that they fell into the tufa after having been thrown up into the air in volcanic ejections.

When we have reached the summit of the mountain, an ample plain opens, formed of the same tufa, but become earthy, in which corn is sown, and a f w vineyards are planted. Here we find numerous pieces of shining glass, which is semi-transparent, of a blackish colour, and some of the finest and purest to be found in Lipari. As I wished to discover the origin of this substance, I caused the place where it is found to be dug into. The tufaceous earth is there about three or four feet deep. The pumices lie annucliately in derit, and among them this glass is found in considerable quantities. It tas a rehably been turned up, and brought to the furnace, by the plough, or other simi-

har instruments used to prepare the earth for sewing the corn-

Beyond this plain there is a gentle descent of about two hundred feet in length, at the end of which are the Stoves. Whatever prepossession in their favour the traveller may have conceived from hearing so much of them, he loses it the moment he sees them. They form a group of four or five caves, more like to the dens of hears than the had itations of men; and which exhibit much less of art than the edifices framed by the Leaver. Every cave he s an epening at the bottom, through which the warm and handed vepours enter, and another in the top through which they pass out. I entered one of these, but was imable to remain long in it, less from the heat, for the thermometer stood at only 48% degrees, than from I know not what of a sufficient mature which the air had in it. These stoves now retain little more than their name, and are inearly deserted. In fact, though they still retained their virtue, and were efficacious in the cure of various disorders, how would it be possible to make use of them, when they are destitute of every convenience necessary to that purpose?

When M. Dolomicu visited them, the whole ground on which they stand was penetrated with hot vapours, which, under the form of a thick smoke, issued from small apertures of about an inch, or two inches, in diameter. When I was there, circumstances were much changed, as usually happens in volcanos, where the presence of fire manifests itself sometimes more and sometimes less. There was then only one aperture, or about an inch in diameter, from which from time to time issued a thin stream of smaller, with a strong sulphureous smell. Having enlarged this aperture, I found it surrounded by a small quantity of soft sulphures of iron (pyrites) generated by the union of iron and sulphur. The abbare Troyami, whom I have eited in another place, likewise at ests, that at certain times several streams in smoke ascended round the stoves; and I shall add, that besides the strong smell of suphur, which I perceived on approach

ing the place, the ground became hot, and the fetor increased, on dagging to about the depth of a foot: from which it may be concluded, that under the stoves and the ground adjacent, some remains of sulphureous conflagration still continue. The stoves and the warm baths, of which we shall speak below, are the only places in the whole island where any signs are to be found of as yet unextinguished volcanos.

M. Dolomicu, after having described the stoves of Lipari, proceeds to speak of the alterations caused by the sulphurcous acid vapours on the lavas of this place, remarking that all of them, besides having become softer and lighter, have lost their primitive co lour, and assumed a white tinge, mixed with yellow, red, violet, and other colours, which the oxydes of iron usually produce. He observes likewise, that they are coated with a thick crust of sulphates of lime (sclenite or gypsum) which sulphates penetrate likewise to the internal parts, and that some lavas are covered with that kind of iron ore which is called slimy (fangosa) or bog ore. He then very ingeniously explains in what manner, by means of a combination of the sulphuric acid with different earths, the lavas have become lighter and variously coloured.

As I visited the stoves three several times, and examined with great attention the lavas that had suffered alteration by the action of the sulphureous acid, I am enabled to add, to the observations already given, some others which I believe to be new, and which I shall here briefly state.

It was an object equally important and curious to ascertain to what kinds of lavas still remaining in the state in which they were left by the fire, those belong which we now see decomposed by acids; and as the observations I had made at Solfatara di Pozzuolo and other places, had taught me that the decomposition diminishes, the deeper it enters into the substance, I conceived that the most proper means to obtain this knowledge would be, to break fragments of the lava, and examine the internal parts, to find how far the decomposition had penetrated. The greater part of the decomposed lavas of the Monte della Stufe are externally of a reddish white; and some the of a blackish colour. I first examined the latter; and presenting their surface to the full light of the sun, I discovered something of a brilliant appearance which invited me to examine it with the lens. It proved an aggregate of innumerable globules of hæmatitic iron, which beautifully cover the surface of these lavas.

I detached a considerable number of these globules, and found that on trituration they assumed a red colour, which is the property of the dark hæmatites. This was therefore a pure martial oxyde, deposited here and formed into globules; and under that aggregate lay another oxyde of red, but earthy iron. The lava still deeper was of a white colour, intersected with parallel streaks of a reddish black, or lightly shaded with a vellowish tinge.

These lavas are soft, light and compact: they adhere to the tongue, have the consistence of clay, but do not emit its odour. They seem to be simple lavas, no extraneous bodies appearing in them. It is observable that every fracture is conchoidal; and that when struck they cause a sound similar to that of some kinds of petrosilex, which has induced me to suspect they belong to that species of stone: a suspicion which is confirmed by examining deeper within the fractures; since at the depth of two feet, or

[·] It has been shewn, in Chap. XIII, that the decompositions of different products of Stromboli and Vulcano do not derive their origin from the muriatic acid, to which, according to M. Sage, the principal alterations of volcanic substances are to be ascribed, but to sulphureous acid exhabations. The decompositions in the environs of the stoves of Lipari, I am of opinion with M. Dolomicu, are to be attributed to the same cause, the existence of which is sufficiently proved by the remains of sulphureous fumes, and the quantity of sulphates of lime, which I shall presently have occasion to describe

thereabouts, a gray colour takes place of the white, and the other external appearances diminish; the lavas begin to assume a siliceous aspect, and give a few sparks was steel. Still deeper we perceive without the least doubt that these lavas have a petrosiliceous base, and contain a few shoetls, which do not appear in the decomposed parts, probably be-

cause they are themselves decomposed.

These observations, which were made on some lavas of a black colour on the surface, are likewise true of several others, which externally are of a reddish white. The appearances in them are essentially the same. The red volour in the internal parts insensibly vanishes; the gray by degrees succeeds the white, which, still deeper, acquires a lustre, the lava at the same time becoming harder, and at length distinctly exhibiting all the characters of the petrosilex.

One of these lavas, streaked with white and a clear red like that of the peach-flower, is spotted on the surface with points almost pulverulent. These are decomposed felt-spars, though they still retain a residue of crystaltization. This lava has been more changed by the acids than the others, being softer, and even pulverable; though at the depth of two feet it is hard, neavy, of a black-gray colour, evidently has a petrosiliceous

base, and contains feltspars which are perfectly entire.

In describing the variously decomposed lavas of Solfatara, we have seen that feltspars are a kind of stones which strongly resist the action of acids. It frequently happens that their base is completely decomposed, while they are scarcely in the least changed. As therefore in the present lava the feltspars are decomposed equally with their base, we must be convinced that the strength of these acids must have been very great. In general these lavas at their surface are soft, like dough, and almost saponacous; characters that usually accompany these decompositions.

We must not omit to notice a lava of the breecia kind, the base of which is likewise petrosilex, and in which the action of the acids has extended only to the depth of a few inches. This base, even near the surface, has not entirely lost its natural colour, resembling that of iron, and in it are incorporated irregular small masses of whitened and pulverulent lava. These, therefore, have yielded more to the decomposition than the base that contains them. At a greater depth we find them unaltered; and they are then only

fragments of lava of a horn-stone base.

Though many of the lavas of the stoves of Lipari have suffered by the sulphurcousacid vapours, there are some that are entirely unchanged. I shall only describe one, which is so well preserved that it appears to have been produced but yesterday by the volcanic gulf. If we scale the surface of it, where it projects in large masses from the earth, it appears of a dark iron colour, has an extremely compact grain, and a conchoidal fracture. The scales at the edges are sharp and cutting, and give very lively sparks with steel. It is one of the heaviest and hardest among the lavas, and puts the magnetic needle in motion at two lines distance. It has for its base the petrosilex, containing very brilliant feltspar needles.

This lava, therefore, has not been in the least affected by these acids, not probably because it was able to resist their strength, but because it was not exposed to their action. The places under which the conflagrations of a volcano burn, have numerous apertures and fissures through which issue sulphurcous furnes; and when lavas are situated around or within these, they will be more or less affected by them. But in the same tracts of ground there are more places than one impenetrable to these furnes, and there, in consequence, the lavas suffer no other alterations than those produced by time. These interrupted exhalations of sulphurcous vapours I have observed at Vesuvius, Etna, and Stromboli, and have noticed them before in my accounts of these volcanos. It is only

probably in action. opertures d around tracts of in conthese intana, and It is only to be remarked that, at the stoves of Lipari, the quantity of decomposed lavas being very great, and extending for the most part to a great depth, the sulphureous-acid vapours must have there issued in extraordinary abundance, and at the same time have been of long duration. The intensity of them, and their consequently greater efficacy, might indeed have supplied the place of long continuance; for I have observed, that when the lava of Vesuvius flowed before my eyes, and several of its lateral branches had ceased to move, two of these, which had been penetrated by a thick cloud of the fumes usual there, were already half decomposed, though they were evidently parts of that current which but a few months before had been disgorged by the side of the mountain. Lastly, according to the different qualities of the lavas, and as they may be composed more or less of calcarcous, argillaceous, or martial principles, all combinable with sulphureous acids, a greater or less decomposition will be produced.

The different degrees of decomposition in lavas render them sometimes more, and sometimes less susceptible of fusion in the furnace. The parts not decomposed will fuse. A beginning decomposition renders them stubborn, and when it is complete. they entirely resist the fire. The cause of these differences appears to me sufficiently evident. The more earths are pure the more they resist fusion. All those hitherto known are infusible, except in very violent fires. Their mixture facilitates their fusion, as they thus become a reciprocal flux; and we know that fusion readily follows, when silex, alumine, and lime are mixed in the proportion of 3, 1 and 1. There was no lava on which I made experiments, in which I did not find these three kinds of earth; and though they might not be combined exactly in this proportion, their combination was yet such as to render almost every lava fusible in the furnace. The lime which, in the dry way, acts as a flux to the silex, is in a great degree diminished in the decomposition of lavas, forming sulphate of lime by its intimate union with the sulphuric acid; and hence we have one impediment to the fusibility of these lavas. The diminution of the alumine, arising from its combination with the above mentioned acid forming sulphate of alumine, which is afterwards detached and carried away by the rains,* will likewise be another obstacle; to which we may add a third, which is the loss of the iron, like-

wise an aid to fusion.

These sulphates, which for the most part accompany lavas, present a pleasing spectacle to the naturalist. Their colours are infinitely varied. Those which are most prominent to the eye, are the rose colour, violet, and orange, and they are the more conspicuous because they are generally placed on a white ground.

I have observed three kinds of sulphate of lime, independent of several varieties which I omit. The first is composed of thin plates, parallel to each other, closely united, brilliant, compact, and opaque. They form strata or beds of different thickness, sometimes more than a foot, and these strata are easily detached from the lavas to which they adhere.

The second species is filamentous, having either parallel or stellated filaments, in which latter case the filaments form a kind of pyramids, which have their apiecs in one common centre, and their bases at the circumference. We find some very large pieces of this kind, formed by the aggregation of these pyramids.

The third species is composed of thin and shining plates, somewhat elastic, transparent, very soft, and forms the indeterminate crystallization of sulphate of lime called

^{*} To prevent any ambiguity, it may be proper to repeat what I have said in Chap. II, that the pretended transmutation of silex, or any other earth, into argillaceous earth, in the decomposition of lavas, has no existence; since, in this case, that earth likewise is diminished, from the causes alleged above.

specular stone; but this species is rare, and its crystals are always very small. In these cases the determinate and primitive crystallization of this neutral earthy salt is always weating.

It is therefore evident that this variety of colours, such as yellow, red, or violet, exhibited by the decomposed lavas, is a consequence of the iron pre-existing in them; which being, if not decomposed, at least greatly altered, by the sulphureous acids, is variously modified, and assumes this diversity of hues. The same cause operates in like manner on the sulphates of lime, formed by the combination of the sulphuric acid with the lime, which is laid open by the destruction of the adhesion of the constituent principles of the lavas, and variously coloured by the oxydated metal. The white colour of the decomposed lavas then, it is evident, is produced by the loss of their iron; which agrees perfectly with experience, since, where the decomposition has taken place, the lavas are incapable of moving the magnetic needle, whereas they constantly produce motion in it, some at the distance of two lines, and some at more or less, in the parts not decomposed.

I shall conclude my observations on the productions of the stoves of Lipari, with some interesting remarks relative to several different species of zeolites, which I discovered in their vicinity. I shall describe them separately with their matrices.

First species. The matrix containing this zeolite is a lava of a horn-stone base, of a dark-brown colour, granular in the fractures, and which scarcely gives sparks with steel. It shows no indication of having suffered by the sulphureous acids. It is full of small long cavities, all in one direction, and which probably were produced when the lava was in a fluid state. It is in these cavities that this species of zeolite is found. At first view it appears rather to be a stalactical chalcedony, having the form of a cluster of grapes. It is of a white pearl colour, inclining to a light blue, and gives some sparks with steel. It has a siliceous fracture, and a degree of transparency. Three properties, however, especially characterize it: first, that it forms a jelly with mineral acids; secondly, that it flashes or blazes at the moment of fusion; and, thirdly, that it bubbles, and as it were boils, when in fusion: and though neither of these characters exclusively appertain to the zeolite, all the three together sufficiently fix the nature of this stone, which must be referred to the class of amorphous zeolites. The clustering grains may be extracted entire, as they attach to the lava but in a few points. The largest extend to five lines in length, by two or three in breadth. The figure which I have called clustering, is the most usual in this species of zeolite; though some are only oblong globules, of the same size with that of the small cavities which contain them. They are, however, by no means found in every eavity; for out of a hundred of these cavities, ninety contained no zeolite. This species is contaminated with a pulverulent, orange-coloured oxyde of iron.

The blow-pipe with difficulty melted it; and several seconds were required for its complete liquefaction, even with the aid of oxygenous gas. It then changed into a snowy-white enamel, full of bubbles. It has a lucid brightness when it begins to melt, and boils and bubbles up when in actual fusion.

Second species. This is found in some pieces of the former lava, but its characters are different from those of the preceding species. It coats over many of the cavities before mentioned with a thin crust, thus forming geodes, which, however, are not crystallized internally. This zeolite, which inclines to a white colour, is more transparent than the other, and, from its hardness, cuts glass almost fike rock crystal. The mineral acids have no effect upon it, not even when pulverised, though they convert the former species into a kind of jelly. When melted with the aid of oxygenous gas, it emits a thin brilliant blaze, and is changed, with ebullition, into a vitreous and white globule.

to melt,

It is not unusual to find within these zeolitic geodes, plates of very transparent suiphate of lime. A hundred grains of this pulverised were put into six hundred of distilled boiling water. A solution was obtained, and the oxalic acid precipitated the lime.

Third species. This consists of ovoid globules, externally dirty, from an earthy coaring, but which internally are extremely white. In the fractures we perceive that they consist of a number of opaque groups of fibres, striated, silky, and shining, which diverge from the centre to the circumference of the globules, and thus form so many inverted cones. These globules, some of which are more than four lines in diameter, perfectly fill the cavities of an argillaceous, light, extremely friable lava of a deep gray colour. Every cavity, however, does not contain a zeolite of this conformation: in some we find zeolitic stones with several facets, but so confused that the precise configuration of the crystals cannot be distinguished. On attentive examination, they evidently appear to be formed of the same zeolitic substance, which, when it occupied the whole space of the cavity, took the conformation of those fibrous groups that have externally a globose figure; but when a part of this space remained empty, it crystallized more or less. These zeolitic stones always have in the middle a small empty space, where they are crystallized, forming a number of very minute geodes.

The blow-pipe presently melts this third species, and with ebullition; a phosphorescence precedes the fusion, and the pearly globule which is the result, is a semi-transparent glass, abounding in bubbles. If this globule be broken, which requires rather a

smart blow, the sharp angles of the fragments will cut deep into glass.

This zeolite, soon after it has been put into acids, attaches to the sides of the containing vessel in the form of a crust, which crust presently resolves itself into a transparent

tremulous jelly, similar to that of hartshorn.

Fourth species. The lava which contains this zeolite is of a horn-stone base, and forms two species, at least two varieties; the one of which is glanular, rough to the touch, and extremely friable; the other has a kind of softness, a fine grain, and greater solidity. In colour, however, which is a gray, and in their argillaceous odour, both these varieties agree. This lava contains a multitude of zeolitic globules, from half a line to an inch in diameter. On breaking them, a vacuity is found within them, thus forming geodes of a crystallization more or less perfect. Wherever the zeolitic substance has been too confined in the cavity of the lava, the crystallization is extremely imperfect, in consequence of the prisms being half-formed and confusedly intermingled; but where that substance had a larger space to develope itself in, the prisms are no longer so indistinct; many of them at least are found to incline to a tetrahedral figure; and where the cavities of the lava have afforded a still greater space to the zeolitic matter, it has crystallized in tetrahedral prisms, of a distinct conformation. Every prism has therefore four faces distinctly separated. In some few places these prisms are terminated by a tetrahedral pyramid. Many of them are of a milky whiteness, and these are semitransparent; but others have a transparency almost equal to that of quartzose crystals. A single cavity sometimes contains several scores of such prisms, while another shall contain but very few.

The biow-pipe easily melts these geodes with the usual phenomena of coullition and phosphorescence, and the glass which is the result of the fusion is similar to that of the zeolite of the third species. A similar jelly is likewise produced from it, and with equal

promptness, in acids, except that it has a less degree of viscosity.

Fifth and sixth species. These two species of zeolites are contained within an argillaceous lava, of a dark-gray colour, light, and of an earthy consistence: they both merit to be distinctly described. The first species consists of a great number of small spheres.

white as snow, each occupying a cavity in the lava, and varying in size, the smallest being scarcely one-third of a line in diameter, and the largest more than three lines. The surface of these small spheres is not smooth, but somewhat rough, from an infinity of points which, viewed through the lens, are discovered to be so many minute tetrahedral prisms, distinctly defined. On breaking the spheres we perceive that the prisms are continued within them, and, becoming thinner, proceed to the centre; or, to speak more properly, we find that the spheres are only the result of a number of prisms joined together lengthwise. The portion of the prisms that is immersed within the spheres is opaque; but that part which projects out has a degree of transparency. It is to be observed, that though the greater number of these minute spheres are perfectly solid, many of them have a round vacuity at the centre, sometimes extending to one-tenth part of the whole sphere.

This acolite is the softest of all the species hitherto enumerated, and may be scraped or out with a knife.

The sixth and last species is one of the most beautiful zeolites hitherto discovered by naturalists. It consists of minute crystals, extremely clear and bright, which, having facets in every part, vividly reflect the light, and sparkle like so many diamonds. These are very numerous in the cavities of the same lava; but are unequally distributed, as some cavities contain but one of these crystals, while others have two, and others three, though the latter are rare. The largest do not exceed a line, and the most minute are scarcely a quarter of a line. While they remain in the lava, it is not easy to examine them as might be wished; but many of them may be extracted without injury, and viewed in every part with the lens at leisure. We then perceive that these zeolites, where they rest on the lava, are flat; but in their upper part incline to a globose figure; and that there their crystallization is apparent: that the isolated crystals, I mean those which in their formation grew without attaching to the other crystals, have eighteen facets, for the most part pentagonal, or tetragonal, but never triangular: that these isolated crystals are extremely rare; the greater number being aggregated, that is, confusedly heaped upon each other in their formation: that, lastly, though many of them may compare in clearness with the purest rock crystal, they are yet inferior in hardness, as they with difficulty cut glass.

I at first suspected that these zeolites were a simple modification of the fifth species, which, wherever it had a free space, had formed itself into these brilliant crystals, either isolated or aggregate. But this conjecture was not confirmed by observation. It frequently happens that the white minute spheres which form the fifth species, occupy only one half, or even less, of the containing cavities, without ever taking the form of the sixth species; but it is constantly to be observed that the tetrahedral prisms project farther beyond the convexity of the spheres, and have a greater transparency. They must

therefore be considered as two distinct species.

This difference is stal more confirmed by the action of fire and acids. The latter do not act, at least sensibly, on the sixth species, though they reduce the fifth to gelatinous flakes or tufts. The fire of the furnace, in half an hour, converts the crystals of the sixth species into globules of extremely transparent glass; whereas it only softens in that time the minute spheres of the fifth, which require a fire of much longer continuance for their complete liquefaction; and the globule which then results is an opaque glass, of the colour of milk. Both, however, have the property which is usually common to zeolites; I mean that of phosphorescence at the moment of fusion, as may be seen by employing exygenous gas.

After having made these experiments on the zeolites of Lipari, I was induced to examine one of those of Iceland, which have the character of being the most excellent for forming a gelatinous body. I certainly obtained from it very readity an extremely beautiful jelly; but not in the least superior to that produced by the third and fourth species. This foreign zeolite is very white, and forms a group of small conical bundles, closely conglutinated, and latersecting each other in various directions; terminating, at their diverging extremities, in a multitude of irregular cylindrical needles. In the furnace is becomes inflated and considerably lighter, but does not fuse. With oxygenous gas, a hard, milk-white enamel, full of bubbles, is produced.

If we compare these observations with the descriptions of other naturalists, we shall find that the zeolites of Lipari have a great resemblance to those of other countries; and it may be observed that the first species is very similar to that of the island of Ferro, which Born has described in his Lithophylacium, and which he has compared to the stalactical chalcedony.

The second species, from its hardness, resembles some crystallized zeolites of the isles of the Cyclops of Etna, which, as M. Dolomicu has observed, and as I have since found by experiment, are little inferior in that quality to rock crystal.

The three other species do not essentially differ from several described by Wallerins, Born, Bergman, Faujas, and others, and which are found in the island of Ferro, the Vivarais, and other volcanized countries. But the sixth species appears to me new; at least I have found no writer who mentions a zeolite, constantly crystallized with eighteen facets, as often as its crystals are detached; nor do I know that any zeolite has hitherto been discovered which is equally clear and brilliant.

It appears that the true figure of the zeolite is a cube; at least, that it always effects that form where its crystallizations meet with no obstacles. According to circumstances it is more or less modified; and the tetrahedral prisms of the fourth or fifth species are probably one of these modifications. The first and second are amorphous; but in the third we discern a beginning crystallization. One of these modifications may be seen in the sixth species; and we know that there are zeolites of other configurations, as some with twenty-four facets, and others with thirty.

Some naturalists have affirmed that the whitest and purest zeolite of Ferro is the only one from which a transparent and white glass can be obtained. I find, however, the glass of the sixth species preferable to it; for it has an aqueous colour, and its transparency is almost equal to that of quartzose crystal. I have found no zeolitic crystals, but those of the isles of the Cyclops, which have furnished a glass equal to this.

No mineralogist is ignorant that Cronstedt was the first who distinguished this stone from the carbonates of lime with which it was confounded, and made us acquainted with several of its qualities. He observed that mineral acids caused no effervescence with it, but slowly dissolved it into a gelatinous body: and this slow dissolution, and conversion of the zeolite into jelly, was afterwards confirmed by others; though experiments made on newly discovered species of this stone have shewn that more than one are not in any manner affected by acids, even when highly concentrated. From among six species of the zeolites of Lipari, we have seen that the third and fourth presently form with acids a transparent gelatinous body; which is less completely characterised in the first and fifth; and not produced at all in the second and sixth species.

M. Pelletier has analysed the zeolite of Ferro, and found that it is composed of 20 parts of alumine, 8 of lime, 50 of silex, and 22 of phlegm (or impure water.) Other analyses have been made of other zeolites, by the chemists Bergmann, Meyer, and Klaproth. The minute size of mine, and still more the small quantity I obtained of them.

prevented me from making a similar analysis of them with the requisite accuracy. I was, however, able to ascertain that the second and sixth species contained silex in a greater proportion than it was found in the zeolite analysed by Pelletier; which perhaps was the cause that these two species do not form a gelatinous sediment; the superabundance of quartzose earth not permitting the acids to extract the lime and alumine, and thus dissolve the union of the constituent principles of the zeolite.

The gelatinous dissolution of the zeolite is neither a quality found in every species, nor is it peculiar to it, since experience has shown that it is common to other stones, the constituent principles of which are the same with those of the zeolite, and combined in a certain proportion. This identity of principles, which in some species of stones affords, by means of the action of acids, the same gelatinous product, induced me to make an ex-

periment, of which I shall here give the result.

The colourless garnets of Vesuvius contain, according to Bergman, 55 parts of silex, 39 of alumine, and 6 of lime. As therefore I had collected a considerable quantity of these at Vesuvius, I determined to make experiments on them with acids, in the same manner I had done on the zeolites. But in the three first varieties which I possess, though I had first reduced them to powder, no gelatinous substance was produced. With the fourth I succeeded; though I did not make the experiment on the same garnets, for the attempt would have been in vain, but on others of the same species, which I have not mentioned, and which had been greatly softened by the sulphureous acids, though they retained their four and-twenty facets. These the nitric acid, after thirteen hours, reduced to a jelly, though not one so beautiful as that obtained from the zeolites. We may therefore conclude, that this aptitude to dissolution was produced in the garnets by the alterations they had suffered; in consequence of which the nitric acid, penetrating their internal parts, had acted on them as it acts in many zeolites.

It has been believed that zeolites appertain exclusively to volcanized countries, since they are most frequently found there; and my observations may appear to confirm this opinion. It however admits of no doubt that they are likewise often found in countries that exhibit no signs of volcanization; this having been incontestibly proved by Cron-

stedt, Linnæus, Bergmann and others.

It appears equally certain that the zeolites of volcanos do not derive their origin from fire, but are adventitious to those places; nor that they were pre-existent to the volcanic cruptions, and taken up by, and incorporated with, the currents of lava, as a celebrated volcanist has supposed. They were no doubt, generated after the extinction of the conflagrations; when their constituent parts being deposited by water in the cavities of the lava, and there combining by affinity, formed these stony substances, according to circumstances, sometimes amorphous, and sometimes crystallized; in the same manner that we have supposed, and indeed proved, the beautiful quartzose stones to be formed in certain lavas on the shores of Lipari, not far from Vulcano. The zeolites now described, likewise, afford a proof in favour of this opinion, those especially the prismatic crystals of which have for their base the sides of cavities in the lavas.

I shall conclude these observations relative to zeolites, with the following inquiry

concerning an hypothesis adopted by M. Doloma u.

That naturalist was of opinion that the zeolites of volcanized countries are only found in those situations which have been covered by the waters of the sea; and the arguments he addaces to prove this, appear to me sufficiently convincing with respect to the multiform zeolites observed by him. But what shall we say of those we have now described? I certainly did not neglect to make the most accurate researches on the spot. It has been already said that these stones are found in the vicinity of the Stoves. The

first species is met with about two hundred feet before we arrive at them, on the road from the city of Lipari; the others are sentered at a greater distance, in the steep side of the mountain towards the south. One certain proof that these places had an ciently been washed by the sea, would be the finding of the remains or impressions or sea animals. Thus the above-mentioned French naturalist remarks that, at Etna, the lavas of the isles of the Cyclops, and those of the mountains of Treaza, which abound in zeolites, have certainly been covered by the waters of the sea, since at the height of more than two hundred perches above these zeolitic layers, immense quantities of seashells are found. The same may, in like manner, be observed of the Vicentine volcanic mountains which afford beautiful zeolites, and also copious stores of marine remains. It is, however, certain that neither Lipari, nor any of the Eolian isles, present us with any vestiges of sea animals or plants. I do not mean to say that this is a playsical demonstration that these places have never been covered by the sea, since it is possible that the marine bodies its waters had left, may have been afterwards destroyed by causes which are not wanting in countries that, at various epochs, have suffered the action of fire; I shall only observe that we are thus deprived of one of the most convincing proofs of this supposed inundation; and I know not on what other we can rely, with respect to a country entirely volcanic.

That zeolites derive their origin from water and not from fire, is proved by the water of crystallization which is more or less abundant in them, and the numbers of them found in some provinces of Sweden, which have never been subjected to the action of fire. That this water has sometimes been that of the sea, the above-cited observation of M. Dolomieu will not permit us to doubt; but it has been proved that there are likewise instances of their having originated from fresh water; of which an observation by Bergmann may furnish an example. He has remarked that a spring of warm water at Laugarnes, in Iceland, when it issues bubbling from the earth, leaves no sediment of any kind, but deposits it at the bottom of a channel by flowing through which it becomes cooler: and this sediment is truly zeolitic, as has been proved by chemical examination.* The nature of this fact he satisfactorily explains as follows: "While the water is very warm, it holds the zeolitic matter in dissolution; but afterwards becoming cold, can no longer support it, so that it precipitates and forms this stalactical concretion." This excellent observation will account for the frequency of zeolites in many volcanos, since the water, whether salt or fresh, being strongly heated by the subterraneous fires, dissolves the zeolitic substances, which it afterwards deposits within the lava, where they crystallize, or remain amorphous, according to circumstances.

When the traveller has arrived at the summit of the Monte della Stufe, he has reached, in that part, the confines of the island; for he suddenly perceives the sea, about four hundred and sixty feet below him, as near as the eye can measure. Taking his way to the south, he then discovers several warm springs, which supply the Baths of Lipari, of equal antiquity with the Stoves, but like them now almost forsaken; and, proceeding in the same direction, meets again with a prodigious quantity of decomposed lavas similar to those of the Stoves, exhibiting the same varying colours, and coated in different places with crusts of sulphate of lime.

When the naturalist considers, and unites in his mind, these prodigious aggregations of decomposed lavas, which occupy an area of several miles, he will, no doubt, be astonished to find there is any volcanized country in Europe, in which the sulphureous vapours, issuing from subterranean conflagrations, have acted through such an extensive

space. Those of Solfatara di Pozzuolo, which have whitehed its crater, and which are mentioned with a degree of wonder by every writer on that volcano, are certainly inconsiderable indeed with respect to their extent when compared to these. Yet of all the sulphureous exhalations which must have spread themselves so widely over the island, not one now remains in action, except a few very thin fumes that rise from the ground near the Stoves.

I visited the Stoves three times: the two first I returned to the city by the same road I went, which is hollowed in the tufa; but the third I took my way back by Campo Bianco, and the Monte della Castagna, whence I proceeded to the high mountain of San Angelo. We have already seen that Campo Bianco and the Monte della Castagna are two mountains formed entirely of pumices and glasses, that is to say, of vitrified substances: but how extensive must be the roots of these substances! The declivity of the Monte della Stufe, and its ample plain covered with tufa, form, as has been observed, a bed of pumices, mixed with a great quantity of glasses and enamels. At about the distance of a quarter of a mile from the Stoves, towards Campo Bianco, the tufa disappears, and the pumices remain uncovered, forming a continuation with those of Campo Bianco. I have also found them in the road near Mount San Angelo, which contains great quantities, and every where they are accompanied with glasses. If to these we add the other parts of Lipari in which the same substances abound, I shall not exaggerate if I say that almost two thirds of this island, which is nineteen miles and a half in circuit, are vitrified.

This immense and almost incredible quantity of vitrifications may, probably, suggest to the reader the same idea which arose in my mind when I first viewed these places: that the fire which has acted on them must have been extremely powerful. This idea certainly appears very natural. But subsequent experience has taught me that this intense heat is not necessary for the production of this great accumulation of vitreous bodies by subterranean fires. It is certain that the production of pumices, enamels, and glasses requires a greater heat than the simple fusion of lavas, when these substances derive their origin from the same base; but we shall not find it necessary that this greater heat should be extremely violent, if we consider the kinds of stones from which these vitrified mountains have been produced. The greater part are feltspars and petrosilex, with some small quantities of horn-stone. As to the latter, it has already been shewn, that it easily vitrifies in a glass furnace with no very vehement fire; in which, likewise, many petrosilices and some feltspars are vitrifiable. † It has also been seen that the glasses, purnices, and chamels of Lipari are all completely re-fused in the furnace. It appears to me, likewise, that we have positive proofs that the volcanic fire was less viotent than that of the furnace, in the substances, as well crystallized as amorphous, which, without having suffered the least fusion, are found incorporated in the pumices, glasses, and enamels of Lipari, and which may be perfectly liquefied in the furnace.

It cannot, however, be denied that the generative fires of Lipari must, at some time, have been extremely vehement; since, according to the observations of M. Dolomieu, they have even fused granite, composed of quartz, feltspar, and mica, and converted it into pumice.

The ancient writers have left us very interesting and instructive accounts relative to the state of the conflagrations which in, and prior to their times had been observed in Stromboli and Vulcano; and we have made use of them when treating of those two islands. But we can say nothing of the ancient fires of Saline, and that chain of rocks,

ich arc nly int of all island, ground

ne road Campo of San gna are d suby of the served, out the disap-Campo ontains nese we xagge-

time, lomieu, erted it ative to

ative to erved in ose two f rocks, which once, probably, made a part of the island Emonimos, since with respect to these antiquity is totally silent; and we can only infer that the volcanization of these two islands was known to the ancients, from a passage in Diodorus, who informs us, that all the Eolian isles were subject to great cruptions of fire, and that their eraters and mouths were still visible in his time. With respect to Lipari, very few memorials have been preserved of its ancient conflagrations. We are indeed certain of the great antiquity of this island, and that it existed before the Trojan war; since we learn from Homer that, after the taking of Troy, Ulysses landed there, and was treated with the utmost urbanity and courtesy by king Eolus during a whole month, which he continued there; † and though we allow to the poet the usual licence of poetry, it is still most certain that he could not have named this island, and the city it contained, unless they existed at the time he wrote his poem, since which nearly three thousand years have now clapsed But if we consult other ancient and credible writers, we shall find that before Eolus, Liparus reigned in this island, which from him took its name, being before called Melogonis, or, according to others, Meligunis.

Another observation, likewise, here naturally presents itself. An island formed by depositions, and the subsequent retiring of waters, may, in a short time, be cultivated and inhabited; but it is not so with one that is produced by subterraneous eruptions, where the decomposition of volcanized matters is necessary; that is to say, a far longer time. If therefore Lipari had inhabitants and cities, and was a cultivated country before the destruction of Troy, it is evident that it must have existed many ages prior to

From the time, however, that mention is first made of this island in history to the present day, we may consider it as certain that no true craption, or current of lava, has taken place in it; as, otherwise, it is probable some memorial would have been preserved of it, as well as of those of Stromboli and Vulcano. Aristotle, indeed, mentions the fires burning in Lipari, but adds they were only visible by night; ‡ and the writers who followed him say nothing more. I hence infer that this island had attained its full formation and size, before it was known to men, which was not the case with Stromboli and Vulcano. I must not omit another observation. Many of the lavas of Lipari still scarcely exhibit the least sign of alteration, especially the vitreous, the enamels, and the glasses; though it is evident, from what has been said above, that these bodies must have existed above three thousand years. We hence perceive what an adamantine temperament, if I may use the expression, the fire can bestow on various substances, since they can thus resist the influence of the seasons and of time.

When I prove the antiquity of Lipari by the authority of Homer, I do not mean to consider the other neighbouring islands as of posterior date. I am likewise well convinced by the testimony of history that, except Vulcanello, they were all in existence in the time of that poet, who probably does not mention the other Eolian isles because Lipari was the largest, the most fruitful, and most generally known, as being the residence and seat of government of king Eolus.

CHAPTER XVII.

FELICUDA.

I'wo bays in this island capable of receiving small vessels....The products found there by the author, sufficiently prove it volcanic....Circuit of it by sea....Prismatic lavas falling into the sea.... Spacious cavern hollowed in one of these lavas....Inquiries relative to its origin....Curious alternation of stratas of tufa and lava....Other prismatic lavas along the shore....Observations relative to them....Excursion into the interior part of the island....A mountain near the center higher than the ree*, on which i. discoverable the crater of an ancient volcano, to which, probably, Felicuda owes its origin....Conjectures that another smaller volcano existed at the summit of a lower mountain....No other perceivable signs of volcanic mouths throughout the whole island....Qualities of the lavas forming the interior part of Felicuda....Glasses, pumices, tufas, and puzzolanas scattered over the island....Puzzolanas and pumices employed by the inhabitants of Felicuda in building....The substances of which the island is composed entirely volcanic, except a piece of gravite, which appears to be natural....Reflections on this rock.

IT yet remains to speak of Felicuda and Alicuda, the two extreme islands of those of Lipari towards the west; and I shall the more willingly undertake the description of them, as they have not, to my knowledge, been visited, at least described, by any other naturalist; M. Dolomieu, who was most capable of examining them, having only seen them at a distance, as to have touched at them would have led him too far from his intended route.

On the 7th of October, in the morning, I set sail, from Lipari for Felicuda, distant from the former island twenty-three miles, and arrived there in four hours. This island is not provided with a port; but it has two bays, one on the south, and the other on the northeast side, sufficient for the reception of small vessels, and so situated, that though the wind should render the entrance into one of them difficult, it will be easy to get into the

other: both of them are likewise sufficiently sheltered by a mountain.

I landed in the bay on the north-east side, and, in the first place, applied myself to discover of what materials the island was formed; and soon discovered incontestible proofs that it is truly volcanic. Not only is the shore of this bay lined with lava; but, having in the course of the day proceeded farther up on the south-east side of the island, I found among the earth of some fields a considerable quantity of pumices, glasses and enamels, which products I shall separately describe when I come to treat of the internal part of the island.

Being thus fully convinced of the ancient existence of fire in this island, I determined, the next day, to make the circuit and examine the shores of it in the same manner

as I had proceeded in the other islands.

Felicuda is nine miles in circumference. I began the circuit of it by examining the lavas that border the small bay which I entered. These have for their base the feltspar, which is of a scaly consistence, a light gray colour, not very compact, but giving a few sparks with steel and attracting the magnetic needle. Within its substance are included needles of black and fibrous shoerl, and small pieces of feltspar, which are easily distinguishable from the base by their whiteness, semi-transparence, and lustre. A part of the shores of the bay are composed of this lava with deep fissures running lengthwise, as we see in many other lavas. A number of round vacuities are likewise observable in it. They are of considerable depth, and give it the appearance of a honey-comb. I rather

mefine to ascribe them to the action of clastic gaseous substances, when the lava was in a state of fusion, than to corrosions produced by the influence of the atmosphere or any external agent. It is certain that the air of the sea will greatly corrode many fossil substances situated in its vicinity; and I have witnessed extraordinary effects from its action on any low rocks, on the shore of the Mediterranean, near Genoa, and especially at Porto Venere, the Golfo della Spezia, and at Lerici. I have also frequently observed the external part of many lowers and maritime buildings very much injured on that side which fronts the water. The city of Commachio in the territory of Ferrara, perhaps, furnishes some of the most complete examples of such effects. It is situated in the midst of salt lakes; and its porticos and edifices are so much corroded and damaged by the air, that they are obliged to undergo periodical repairs at the and of no very long time, as I observed with surprise during a short stay which I in the there in October 1792. The sea air, however, does not act thus on every fossil substance indifferently, but, with respect to stones, seems principally to attack the carbonates of lime; though not all of these, as appears from the hard Istrian marble with which the superb palaces and sumptuous edifices of Venice are built, and which remains uninjured for a long series of years. I likewise observe that volcanic stony substances are little, or not at all, injured by the air of the sea; and I am the more confirmed in my opinion that the incavations in the litoral lava of which I am now speaking must be attaibuted to the action of aeriform gases, and not to that of the sea air, from observing the same, likewise, in the feltspar, a stone much less liable to this kind of alteration than many ethers.

After having made these observations, I left the bay, and began to coast the island towards the left, on the northern side. I had scarcely proceeded one hundred and fifty paces when I met with a rock of lava, about thirty feet high, and equally broad, rising almost perpendicularly from the water. This rock presented a novelty I had not before observed in the Eolian isles. This was a number of prisms into which the lava divided before it plunged into the sea. The importance of this object induced me to bring my boat close under the rock, that I might make the necessary observations with more cer-

tainty and security.

About twelve feet above the level of the sea the rock is smooth and presents an equal surface; but somewhat lower it begins to be furrowed with narrower longitudinal excavations, which descend to the edge of the water, and form prisms with three unequal sides, the side behind remaining at ached to the rock, or, to speak more properly, forming one continued whole with it. These prisms continue to preserve their form under the water, of which I had indubitable proof. The sea, though then ealm, had a slight roughness towards the rock, to allay which I poured into it some olive oil, which I always carried with me in these excursions to calm the lesser waves of the sea, and thus enable myself to perceive subaqueous bodies at a certain depth as circumstances might require. By these means I discovered that the prisms were immersed in the sea to the depth of some feet. The breadth of some of the prisms was a foot and a half, but that of others less.

This prismatic lava merits to be very accurately described, since, in prosecuting my voyage along the shore of Felicuda, I met with it in several other places, and shall again have occasion to mention it. Its base is a horn-stone of the black colour of iron, and so compact that the smallest bubble is not perceivable in it; it must, therefore, be classed among the heavy lavas. The edges of the thinnest flakes of it are transparent, and give sparks with steel. Its fragments are amorphous, and receive a polish, but without lustre. It attracts the magnetic needle at about the distance of three lines. The powder of this lava is cincritious, and impalpable, and attaches to the finger. In it are con-

tained various grains of amorphous feltspar, and a greater number of small, long, rhomboidal shoerls.

The product of this lava in the furnace is a hard enamel, of the colour of pitch, and full of bubbles. The feltspars it contains remain refractory. It is to be remarked, that

this enamel does not lose the magnetic virtue.

The place where this rock langs over the sea is called Fila di Sacca. Beyond it the shore of the island, which continues to have a steep descent into the sea, offers only common lavas, except one species which has some rude appearance of prisms, that assume a more distinct form near the surface of the water.

Still farther, at a place called Saccagne, a number of small rocks rise above the surface of the water; one of which is called I. Perciato, because it is perforated in the middle, and the opening is wide enough to admit small vessels to pass through. The forms

of prisms are distinctly discernible in these rocks.

At the distance of fifty paces farther, a spacious cavern opens in the lava of the shore; an object highly interesting and beautiful in the eyes of the volcanist. It is the Grotta del Bove Marino (or Grotto of the sca-ox) perhaps because it was one, the retreat of some phoca or seal, as in the Lipari islands, and many other places, the phoca are called sca-calves. The mouth of this cavern, in the upper part, is oval, and is sixty feet in breadth, and above forty in height. The mouth opens into a kind of porch which leads into a spacious hali two hundred feet long, or nearly, one hundred and twenty broad, and sixty-five high. This hall terminates the cavern. The sea enters it; and as its force is broken by the narrowness of the entrance, small barks when surprised by a storm may there find shelter.

Some may perhaps wish to inquire, whether the roof of this cavern presents any of those stalactical concretions which are observable in many other encavations in mountainous countries. No such concretions are to be seen; the stone of which it is formed being evidently not of an aqueous but an igneous, that is, a lava distinguished by the

following characters:

Its base is shoerl in the mass; it is moderately porous, and therefore rather light; but gives sparks with steel. It is unequal in the fractures, has a somewhat argillace odour, and attracts the magnetic needle at the distance of half a line. It is of a gracolour; but interspersed with white, shining, rhomboidal feltspars. Their splendour is diminished in the furnace; but their whiteness appears heightened from the black colour acquired by the enamel produced by the fusion of the lava, which is opaque and extremely full of bubbles. The fusion, instead of diminishing or destroying, rather increases its magnetism.

This lava, which forms the large cavern, descends almost perpendicularly into the sea, and there assumes the form of prisms, but larger than those before described. It is worthy of remark, that these prisms, though in their lower part they sink deep into the

water, do not rise above it, in their upper, more than eight or nine feet.

But in what manner are we to explain the origin of this cavera? How great must have been the violence of the waves of the sea, to form by slow corrosion so vast an excavation within this mass of lava! To this cause I cannot consent to ascribe it; principally for this reason, among others that might be adduced, but which I omit for brevity, that no sooner has the water entered the mouth of the cavera but it loses all its force; besides that the hardness of this lava is such, that it does not easily yield to the stroke of the waves. I incline rather to think it the effect of the action of the gases in the lava at the time it was in a state of fluidity; as we have examples at Etna of caverns incomparably deeper produced by a similar cause.

Immediately beyond the Grotta dell Bove Marino, we meet with a mixture of tufa , rhomlava, which merits some attention from the curious alternation of its strata. They are found on a high precipiee which descends into the sea, the surface of which is covered with a tufaceous soil, resting on a bed of lava, above another of tufa, and so successively, that in a rent made in the precipice by the waters we may number eleven strata or beds of tufa, and as many of interposed lava. It appears, therefore, that the fire and water, by their repeated action, have produced this mixture of lavas and tufas.

The lava of the eleven beds is of the same kind, that is, of a horn-stone base, and containing, as usual, shoerls and feltspars. It has an earthy aspect, a blackish colour, and a strong argillaceous odour. It moves the magnetic needle at the distance of two lines, and the enamel into which it is changed in the furnace has the opacity and blackness of

pitch, and its magnetism is greater than that of the lava before fusion.

The beds of tufa, likewise, do not essentially differ from each other. They are an ill-kneaded mixture of lumps of argillaceous earth, more or less tinetured with yellow oxyde of iron, which earth is easily pulverable. With it are mixed numerous shoerls, that from the softness of the base may be separated entire, which they scarcely ever can be in the lava. Notwithstanding, however, the fecility with which they may be detached, it is difficult to determine their crystallization, not merely from their extreme minuteness, for some of them are two lines in length, but from their being scarcely ever found single, almost every one being a group of aggregated shoerls. When one, however, is found single and detached, it appears to be an hexagonal prism terminated by two trihedral pyramids. They are black, shining in the recent fractures, and are somewhat fibrous: in fine, they perfectly rasemble in their structure the shoerls incorporated in lavas.

The tufa, after remaining two or three hours in the furnace, assumes a red colour, and become hard; its magnetism is likewise strong, though before it was scarcely perceptible. A longer continuance in the same fire reduces it to a porous scoria, which does not lose its magnetism, and the black colour it acquires renders more conspicuous a number of white feltspars which before were not discernable in the tufa. The shoerls

are semi-vitrified, and assume a yellowish tinge.

In the remainder of my circuit round the island, till I returned to the place whence I set out, I observed no other interesting objects, excepting a long tract of prismatic lavas, similar to those I have already described.

I shall conclude what I have to say on these prismatic layas, which occupy a consider-

able part of the shore of the island, with the following remarks:

First, These prisms have never more than three faces, one of which always remains adherent to the lava.

Secondly, Their direction is never oblique or transverse, but, without exception,

perpendicular to the sea.

Thirdly, They are not articulated, as they have been observed to be in some vol-

canic countries, especially on Mount Etna, but form one continued line.

Fourthly, In their lower extremity they descend within the water, and in their upper, rise some feet above the level of the sea.

Fifthly, These prismatic lavas have for their base, either the horn-stone or shoerl in the mass.

I shall now proceed to describe the objects which appeared to merit notice in the interior part of Felicuda. This island, when seen from the sea, at a little distance, has the appearance of a number of mountains heaped together; one of which, situated in the centre, is much higher than the rest, rising perhaps half a mile above the level of

ch, and ced, that

id it the ly comassume

o the sea, d. It is into the eal mast

st an ck-; princi-brevity, ts force; he stroke i the lava s incomthe sea. After having examined the base or shore of the island, I proceeded, therefore, to the summit of this mountain, taking my way towards the east, as, on that side, the road is least difficult. The ascent is not one of the most fatiguing; for, though we meet with steep precipices in some parts of it, they are presently succeeded by gentle declivities, which relieve weariness and restore strength.

When I had reached the summit of the central monutain, I perceived that it inclosed a capacious hollow called Fossa delle Felci (the ditch of fern) because it formerly was over-grown with that plant; though when I was there it had been all rooted up, with the intention of sowing corn the next spring. This hollow is about half a mile in circuit, the sides approach as they descend, and its depth is not more than forty feet. These circumstances sufficiently prove that this was the ancient crater of the volcano; and that, perhaps, or rather viithout doubt, this was the first, which, by its cructations, contributed to the formatic.

It is likewise to be obe—d, that the external part of this crater corresponds to the internal; that it is a truncated cone; that its lavas, parting as from a centre, have diverged like rays down the sides of the mountain, while those on the side towards the north-west have poured rapidly into the sea.—The proposal to sow corn in this hollow argues that it must be earthy, as it really is.—It is formed of a half pulverulent tufa, under which, however, the lava is discoverable.

Three ridges rise on this mountain, one of which descends to the south; and, at about half way up, joins another mountain. The second of these ridges has its direction to the east, and the third to the west. From this summit I had a complete view of Felicuda, and looked round me with attention to see if I could discover the signs of any other crater. I thought I could discover the vestiges of one to the south-east, and afterwards, repairing to the spot, was more confirmed in my opinion. I found a hill about half as high as the mountain already described, and about two miles in circuit. It is isolated on every side, and has the figure of a broken cone, truncated at the top, where it sinks into a cavity growing narrower towards the bottom, which appears to be the relies of an ancient crater. Scattered pieces of various lavas, half-buried in an earthy tufa, occupy the cavity of this hill, and its external sides are formed of a number of currents of lavas.

Except these two craters, of the last of which I have expressed myself with some doubt, I know not of any throughout the whole island; as I shall not venture positively to consider as such a number of cavities, hollows, and caverns which we meet with in various places, such appearances not being sufficient to characterize a volcanic mouth.

The principal lavas of the shore of Felicuda have already been described singly: it is now necessary to specify those which form the internal and more elevated parts of the island. These, as far as I was able to discover, during the stay of five days which I made there, may be reduced to three kinds, if we omit those which are increly varieties.

The base of the first is a horn-stone of a colour between a black and a gray, of a fracture evidently brilliant, without any appearance of pores, and which gives sparks copiously with steel. The pieces into which it breaks have no determinate form, do not refuse a tolerable polish, and move the magnetic needle at the distance of a line and three-fourths. Minute grains of quartz, numerous scales of feltspar, and extremely small and brilliant needles of shoerlare incorporated in this lava.

The furnace fuses the shoerls, but not the quartz and the feltspars; and the lava is changed into a black, frothy, and opaque enamel.

ercfore, ide, the ugh we gentle

th some re posire meet volcanie

ly: it is s of the which I rely va-

f a fracks copido not ine and tremely

lava is

This lava extremely resembles the prismatic lava described above; though it has not that regular configuration.

The lava of the second species is likewise of the horn-stone base; not very hard nor heavy; of a cinercous and earthy aspect, without pores, attaches slightly to the inside of the $h_{\rm F}$, and emits an argillaceous odour. The shoerls it contains are rhomboidal, scaly, and of a violet colour.

In the furnace it is only softened, and the shoerls remain entire.

The third species has for its base shoerl in the mass. It is black without porcs, r_0 .

ther heavy, and of a granular fracture.

The heterogenous stones which are mixed with the substance of this lava, are of three kinds: small irregular quartzose particles, which, from their whiteness, are most conspicuous: a few minute feltspars, and numerous rhomboidal shoerls, of a dark violer colour, and remarkable for their size, some of them extending to seven lines.

The feltspars and quartzose grains are refractory in the furnace; though their base is

easily fusible, and produces a shining, opaque, and porous enamel.

The internal part of the island, as far at least as appears from the surface, is composed of these three lavas and their varieties; which lavas form currents, that, from their great antiquity do not exhibit those tumours, wavings, and inequalities, which are observable in recent lavas, or those of a moderate age. The same antiquity is, likewise, probably the reason why in Felicuda we do not find scoriæ, or scoriaceous lavas; these usually from their slight and feeble texture, and from their lying on the surface of the current, being the first which are altered and destroyed.

When treating of Lipari, I remarked the great effects which have been produced on the products of that island by the sulphurcous acid exhalations. The contrary is to be observed of Felicuda, there not being a single lava which exhibits the least sign of their influence; though they all bear the marks of the injuries of time and of the atmosphere. So much have I found them changed, especially near the surface, that had I not broken up the lavas to the depth of some feet, a practice to which I had accustomed myself in these researches, I should frequently have taken the same lava for others specifically different.

Having thus described the different kinds of lavas of this island, it will now be proper to proceed to treat of the other volcanic substances it contains. Among these are the tufas, which are found in great abundance in other parts of the island beside those above described. In general they are pulverulent, light, spongy, of an argillaceous nature, and greedily imbibe water. The places in which they are found, are the only parts of the island which the inhabitants can render productive by cultivation.

It is among the tufas that we discover glasses and pumices. We will treat of these

two substances separately, beginning with the first.

I have already said, that I had scarcely landed in Felicuda before I discovered several pieces of volcanic glass. In my subsequent researches, I afterwards discovered that this glass was not found among the lavas, but in the cultivated earth of the fields. The peasants of those parts confirmed the truth of this observation, and, finding I was in search of this substance, brought me more of it than was necessary, which they collected in the fields where they worked. As I was not, however, perfectly satisfied with this first observation, I directed them to dig a deep trench in one of the fields which most abounded in specimens of this substance, with a view to try if I could discover a vein, these being only detached pieces. The trench they dug was eight feet deep and five in breadth. For the depth of two feet I found only a tulaceous earth, containing some Vol. V.

of these vitreous pieces. At a greater depth the virgin tufa appeared, untouched by the plough-share, or any rustic instrument. This tufa likewise furnished a similar glass, but always in detached pieces; nor was any difference perceivable in the nature of these products, on continuing the research to the bottom of the trench, where the tufa was still found.

It appears, therefore, that the glass in the ploughed fields had its seat in the tufa; though it cannot be affirmed with certainty, that it was thrown out from the mouth of the volcano in the same state in which it is now seen; since it is only found in plates or flakes, and with those points and sharp angles, those cutting edges and waving streaks, which we observe in glass, whether volcanie or factitious, when it has been broken and divided into fragments by a hammer, or other heavy body. We must therefore conclude, that after the subterranean conflagrations had reduced the stony substance to glass, this glass has been thus broken and shivered by some convulsion of the earth, or by some

violent and tumultuary agent.

The larger pieces are about five inches and a half over, and two in thickness. Many of them are not inferior in clearness and brilliancy to the finest and brightest glasses of Lipari; others are less transparent, and of a cincritious, or gray coleur; while others are almost entirely opaque; and these approach nearer to the nature of enamels than to that of glasses. They are all, however, extremely compact, and will readily give sparks with steel, and cut common artificial glass. Several of these pieces contain within them small white particles, which have been observed and described in many of the glasses of Lipari, which particles indicate that the glasses containing them is not so perfectly vitrified as the rest. We also find pieces, though they are rare, the one half of which is a very black glass, and the other a simple lava. The lava, which thus forms a whole with the glass, is of a cincritious colour, and, as appears from some analyses which I have made of it, is of a petrosiliceous base.

This glass, like other volcanic glasses, changes in the furnace into a vitreous froth. It now remains to speak of the pumices, which are likewise enveloped in these tufas. These never form large masses, but are always found in detached pieces, of rather a small size, the largest rarely exceeding the bigness of the closed hand. In general they are more plentiful than the glasses, and among the tufas of uncultivated places, it is only necessary to remove the surface to find them by hundreds. During my stay at Felicuda I resided in a place called La Valle della Chiesa (or the Valley of the Church.) This is a small plain, on the east side of the island, in which stand the parsonage-house and the church, two indifferent buildings, suitable to the poverty of the country. This place, as likewise a spacious declivity to the south, abounded with pumices, both on the surface of the tufas, and below the surface, wherever they were dug into.

These pumices are of two kinds; the one cellular, extremely friable, fibrous, and which float on the water; and the other compact, heavy, without porcs, and of a smooth fracture; but which yet possess all the true characters of pumice. Some are of a reddish colour, others yelllowish, and many ash-gray. All are plentifully furnished with ex-

tremely brilliant vitreous feltspar-scales.

In my observations on the pumices of Vulcano I have remarked, that instead of swelling in the furnace, and being transformed into an ebullient product, as is almost always the ease with glasses and compact enamels, they become of less bulk, lose their pores, if they had any before, or at least contract, and therefore become heavier. The present pumices do not differ in this respect from those of Vulcano; and the enamel which they produce in the furnace has a black and shining ground, interspersed with whitish ied by glass, f these fa was

always pores, if present which whitish spots which are feltspars, that, having lost their histre and transparency, are become white. This enamel puts the magnetic needle in motion at the distance of a full line, notwith standing that it had no sensible effect on it when in the state of punice.

There is no reason to suppose that these pumices have ever formed currents, both because they are always found in detached pieces, and because their pores have not that direction which is usually observable in pumices that have flowed in the manner of lavas. The figure of the pores in pumices that have flowed, is usually more or less oblong, whereas in the pumices of Felicuda (I mean the cellular) the pores are almost always orbicular. We must therefore conclude that they have been thrown out from the mouths of volcanos; to which the globose figure of many of them is perfectly consonant.

I should esteem my account of the different productions of this island very defective, were I not to mention another which still more confirms its volcanization: I mean the puzzolana found here in several places, and which, when carefully examined, is found to be a mixture of minute fragments of pumices, tufas, and lavas. The inhabitants of Felicuda make use of it, as also the pumice, in building their houses, in the following manner: they bring carbonates of lime (calcarcous earths) from Sicily, and burn them in furnaces, which are erected for greater convenience on the sea-shore; and at the end of forty hours an excellent lime is produced. One-third of this and two-thirds of puzzolana, mixed together with water, form a cement which unites and binds the pieces of lava here used instead of bricks and stones; and to give, as they afterm, a greater strength and solidity to the cement, they mix with it pounded pumice of their own country.

Lavas are used as materials for the building of houses, not only by the inhabitants of Felicuda, but by those of all the other Eolian isles, each using those of their own island; and it is the practice, not only in the country but even the cities, to build with such stones as the environs afford, especially when they are mountainous. I therefore, whereever I went, constantly examined the materials of which the villages, towns, and cities through which I passed were built; which frequently afforded me a light and direction

in my inquiries relative to the fossil substances of those countries.

On reviewing the different volcanic bodies which I met with at Felicuda, we shall find that they consist of glasses, pumices, tulas, puzzolana, and lavas with a base of shoerl, feltspar in the mass, or horn-stone. The island at present exhibits no indication of subterranean fire, and even those signs which are uncertain and equivocal are wanting;

such, for instance, as warm springs.

In the various excursions I made, I was particularly attentive to observe if by accident I should meet with any body not volcanized, and found one only of this description. This was a piece of detached granite, lying on the shore near the Grotta del Boy Marino. Its elements were of the most common kind; mica, feltspar, and quartz. The mica was partly black, and partly white and silvery; both forming groups in which the black predominated. The quartz was in small semi-transparent masses, of a vitreous and brilliant fracture, soft to the touch, and of a colour between a blue and a white. The feltspar, which in quantity exceeded the two other principles, and therefore must be considered as the base of the stone, was in small masses of unequal surface, lamellar in the fractures, transparent in the angles, and of a changeable milky whiteness. Neither of the three principles has a determinate form of crystallization. I think I shall not be mistaken if I assert, that this granite has not suffered the action of the fire. In fact, a continuance of a quarter of an hour in the furnace produced in it so great an alteration, that every part of it was sensibly changed. The mica became pulverable, the quartz extremely friable and full of cracks, and, losing its transparency and vitreous brilliancy,

F F 2

became entirely white. The feltspar likewise contracted a considerable friability, losing at the same time its changeable colour, and becoming whiter. It is not therefore extraordinary that a slight blow with a lummer should now break this stone into small pieces; though before it would only strike off at most a single fragment. When exposed to the furnace for several days successively—the quartz and mica did not fuse; and the feltspar only exhibited at the angles, a beginning of fusion, which made it appear as it were unctuous. This experiment is perfectly agreeable to many others which I made in the furnace on the granites treated of in Chap. XII. We must therefore conclude, that this piece of granite was thrown out untouched from some volcano in the island, or, which appears more probable, that it is adventitions to it; for it is to be observed, that it was not found in the interior part of the island, but on the beach, where it had been beaten, and had its corners smoothed by the waves. Were I to indulge conjecture, I should incline to suppose it might have been brought by the sea from Capo Melazzo in Sicily, or that vicinity, which is only fifty-four miles distant from Felicuda, and where immense masses of similar granite are found.*

CHAPTER XVIII.

ALICUDA.

Danger to which the author was exposed, in a tempest, on his passage from Felicuda to Alicuda....Pumices and glasses found in the latter island....Examination of the coast of Alicuda....Several rocks formed of detached globes of lava....Inquiries relative to the origin of these globes.... Confirmation of the uncertainty of any opinions formed relative to the greater or less antiquity of lavas, from the more or less sensible decomposition they may have undergone....Isolated masses of porphyry, which exhibit no signs of having been attacked by volcanic fire....Lavas of another kind....Shoerls of a greenish blue colour contained in all these lavas....The coast of Alicuda more rugged and threatening than that of any other of the Folian isles....No mouth of any ancient crater in the sides of the island....The appearance of a true crater found only at the summit....Lavas in the interior part of the island similar to those of the shores....Improbability that Felicuda and Alicuda once formed a single conical mountain, the side of which has been opened and separated by the sea, as M. Dolomieu has supposed....Reasons for believing that each was originally a separate island....These two islands no longer manifest any signs of actual fire....The silence of the ancients relative to their fiery eruptions, a proof that they must have long ceased to burn.

ON the 13th of October, at sun-rise, I left Felicuda, in a small bark, with four rowers, which was steered by the parish-priest of Felicuda, who had the character of a skilful seaman. We sailed before a moderate east wind: the sky was clear, the sea smooth, and we flattered ourselves we should soon reach the place of our destination, as the distance between these two small islands is not more than ten miles. But scarcely were we half way, when the wind began to increase so that we were obliged to reef our sail, which it was dangerous to carry full; yet still we made more way than before; and the wind blowing with greater violence, and driving us rapidly towards Alicuda, from which we were now not far distant, endangered our being shipwrecked on the shore. Bays or harbours are things unknown in this island, and our bark driving before the wind, it was to be feared, might soon dash against a rock, or run upon a sand-bank; and we had the

less hope of being able to avoid this danger, as our sailors, from unpardonable negligence, had not brought with them any anchor.

The sea, in the mean time, ran very high; and the waves, which would not perhaps have given much alarm to a large ship, were very formidable to our little vessel, which they broke over from side to side, and from stern to prow, whirling it round with their violence; while the danger of being wreeked continually increased by our approaching the island, notwithstanding all the exertions we could make with our oars to keep off it. Our sailors, however, did not entirely abandon themselves to despair, but consulted whether it would be less dangerous to yield to the violence of the waves, and endeavour to run the bark on some sand-bank joining to the shore; or, avoiding the island, to adventure out to sea, and commit themselves to the mercy of the winds.

In this desperate situation, we perceived five men hastily descending from the eminences of Alicuda, and approaching the shore, which they quickly reached; when one of them called to us in a voice which might be distinctly heard notwithstanding the noise of the waves, advising us not to be terrified, but to endeavour to keep where we were, and he would exert his utmost efforts to deliver us from the danger by which we were threatened.

This person, as I afterwards found, was the parish-priest of Alicuda, who perceiving from a distance the situation in which we were, had hastened with four of the islanders to give us assistance. He had brought with him a strong pulley, which, when fixed on the shore, was to receive a rope, by means of which the vessel might be drawn upon the land. But to effect this, it was necessary to form a kind of inclined plane on the shore, along which the boat might be drawn; which was soon done, with the spades and shovels that had been provided for the purpose.

We were not more than fifteen acet from the land, and by incessantly plying our oars, made every effort to avoid approaching it nearer. We were obliged, at the same time, continually to bale the water out of the boat, to prevent its sinking; which was the continual employment of myself and my servant, the sailors being entirely occupied in using the oars. A rope coiled up was now thrown on shore by one of the sailors, and, after two or three unsuccessful attempts, caught by the persons on the beach and passed through the pulley; while the sailor drew it tight, and fastened it to the prow of the bark. We now committed ourselves to the first wave that rolled upon the shore; and, the five islanders pulling the rope with all their force, we were drawn with the bark up the shelving declivity they had made: but the wave on its return dashing impetuously against the prow, drove us again into the sea; and so violent was the shock, that the rope broke, and we lost all hope of getting safe on shore. At this unfortunate and unexpected accident the good priest struck his hand against his forehead, from vexation and disappointment, and our consternation was extreme.

We had now resolved to keep off from the island, and brave the fury of the winds and the waves in the open sea, whatever might be the event: but from this we were dissuaded by these islanders, who assured us it was impossible so small and crazy a boat as ours should long resist the violence of the storm in the wide sea; but that it must either overset, or bitge and sink. They advised us rather to coast the island towards the north, where we might possibly find some small inlet, where we might be less exposed to the waves; promising us but they would proceed the same way along the shore, and afford us every assistance in their power. This advice we followed, and bearing up to the north, without standing far from the shore, in about half an hour met with a cavity in a rock which, from being winding, was not much exposed to the agitation of the waves. Into this we happil, carried our bark without damage, and landed, with the assistance

of the worthy priest and the persons with him, towards whom I shall feel the warmest sensations of gratitude while life shall remain. He treated us when on shore with the utmost kinducss and hospitality; and when I had presented to him the circular letter I had received from the bishop of Lipari (in which I was warmly recommended to the parish-priests of those islands, who were requested to furnish me with every assistance necessary for my philosophical researches during my stay) he redoubled his civility, offering to serve me in every manner in his power; and his whole conduct sufficiently evinced the sincerity of his offers.

It was not yet moon by some hours when we landed in Alienda, but the fatigue I had undergone prevented my having any inclination to begin my researches that day; and the following night I slept in the bark, which had been drawn on shore; my deliverer (for so I may justly call the good priest of this island) having sent me a mattress and a coverlet to defend me from the moisture of the night, as I was too much fatigued to ascend to his habitation, which was situated half way up the mountainous island. He likewise hospitably invited me to share with him the provisions of his frugal table, and some bottles of excellent malmsey of Lipari, which revived my spirits and restored my

strength.

I remained at Alicuda two days (the 14th and 15th of October) during which I sufficiently gratified my curiosity, and acquired a satisfactory knowledge of the nature of the island. The observation of the ancient Greeian philosopher is well known, who having been driven by a tempest on the coast of Rhodes, and with great difficulty reached the land, seeing certain geometrical figures traced in the sands, immediately exclaimed, I perceive the vestiges of men: I, in like manner, the moment I set foot on the shore of Alicuda and surveyed it, might have exclaimed. I perceive the vestiges of fire. These were the pumices, glasses, and enamels, which presented themselves to my view on the skirts and sides of Alicuda, and which it is unnecessary particularly to describe, since they entirely resemble those of Felicuda, and are found like them mingled with turaceous substances.

Of the two days which I allotted to my researches in Alienda, I set apart the first to examine its circumference by sea, the night preceding the 14th of October having been sufficiently calm to permit me to make the circuit of it in my boat without danger.

I shall here, therefore, specify the principal products I discovered during my circuit round the shore of the island, this being the part which, more than any other, must interest the philosophical naturalist. I shall not name the places where I found them, since two of the inhabitants who accompanied me were unable to assign any names by which they were known; the different parts of the shore of the island having in fact no fixed names: I shall only indicate their distances from the place whence I set out.

At the distance of forty paces from that part of the island which fronts the east, we begin to find, as we turn towards the north, entire rocks formed of globes of a biackish lava, with a petrosiliceous base, which, though porous, is heavy from the compactness of the solid parts, which have a little lustre, are very hard, and in their fractures affect the conchoidal figure; they move the magnetic needle at the distance of more than a line, and give sparks tolerably freely with steel. The petrositiceous substance contains a few feltspars, and a considerable number of shoerls. These globes of lava are of various sizes, some of them being a foot in diameter. They are detached, and are never found in strata, but only in large accumulated heaps.

To what cause can we ascribe the division of this laws, and its conformation in the manner described? Lat first imagined that its figure might be the consequence of the agitation of the sea, when its waters reached to a greater height; as these accumulations

of globes are now some poles above its level. In fact, in my maritime excursions round the other Eolian isles, and at Etm., I have frequently met occasionally with similar bulls of lava, which clearly indicated that they had been rounded by being continually rolled by the waves of the sea, in the same manner as we find stones rounded in rivers. In the course of this work I have adduced several examples of this kind, even among the glasses and enamels of Lipari, which have taken a globose figure. But a more careful examination of these globes compelled me to change my opinion, on considering that the pieces of lava that have acquired an orbicular form from the agitation of the waters, are always more or less smooth on their surface; whereas these were rough all round; though their roughness, consisting in general of minute parts and points, must have been worn away by rubbing against any obstacle. I observed besides that these globes in many places had a shiming and scoriaceous appearance, extremely similar to that of the pieces of lava incessantly thrown out by the volcano of Stromboli. I am therefore rather of opinion that they are pieces of lava that have been thrown out from a volcano in Alicuda, and taken a spherical form in the air, from their great softness, as similar phenomena may be observed in the products of other burning mountains.

mena may be observed in the products of other burning mountains. About a mile and a half beyond the lava now described, proceeding still towards the north, we find a second, not in globes, but in an ample current, which falls like a cataract into the sea. It is of a petrosiliceous base, has the colour of iron, is siliceous, or rather vitreous in the fracture, and full of shocrlaceous crystallizations. Whoever has seen lavas which have lately issued from the mouth of a volcano, would imagine this of extremely recent date. On the surface it preserves that shining aspect, that freshness, which is peculiar to lavas that have not yet been exposed to the influences of the atmosphere. The specimens of it which I detached, might be taken for that scoria of iron which we find in the shops where that metal is fabricated. I have in my possession some pieces of the lava which was thrown from the highest crater of Etna in 1787, which I collected on the spot, and have described elsewhere. * These, with respect to the freshness of their appearance, are not distinguishable from the lava of which I now speak. Yet is the latter of an antiquity beyond our knowledge, for we have no record of any conflagration in Alicuda since history has been written. I have chosen to speak more at length on this peculiar property of the present lava, to prove, or rather to confirm what I have already proved, how uncertain are all conclusions relative to the greater or less autiquity of lavas, derived from the more or less sensible degree of decomposition which they manifest. Such conclusions may be well founded, when the lavas are of the same nature, and affected by the same intrinsic circumstances; since then those of a more ancient date must be most changed by time; but where their nature and qualities are different, one lava may be considerably altered in a few years, and even reduced to an earth, while another shall remain for ages perfectly preserved, and in the same state in which it was thrown out of the fire, of which the lava now described is an evident example.

At the distance of another full mile from the place whence I took my departure, the mountainous coast of the island becomes somewhat more level; and on this plain arise detached masses of porphyry, which shew no signs of having been touched, much less fused, by the fire. It is of a petrositiceous base, of the colour of brick, affords sparks with steel, and is extremely compact, and without pores, except a few superficial vacuities, coated with a thin white crust of carbonate of lime, sometimes studded with crystals of the same kind. These small geodes, which have been produced without doubt

by filtration, are decomposed in a few moments by the nitric acid, and dissolve with a strong effervescence. This porphyry, in its hardness, polish, and lustre, is not inferior to the Egyptian. Besides shoerls, it contains numerous cubical lamellar feltspars, of a changeable whiteness.

When exposed to the furnace for a few hours it becomes black, and after a longer time fases into a black, compact, and very smooth enamel, which sets in motion the magnetic needle, though it produced no such effect when it was porphyry. The feltspars

remain entire.

In this part of my circuit round Alicuda I have described two kinds of lavas, the one found indetached globules, and the other in a current; which, however, from the indentity of their nature, may be considered as one only; both having for their base the petrosiles, and containing shoerls and feltspars: they are therefore both porphyritic. And as the rock last described is a porphyry with a petrosiliceous base, it appears that they all three derive their origin from one common matrix, except that one portion of it has been suljected to fusion, and the other remained untouched.

A little beyond the plain above-mentioned appear some tufas, which cover a long and steep declivity descending into the sea, and beyond the tufas we again meet with lavas forming broad currents. These lavas have the horn-stone for their base, and their ex-

ternal characteristics are the following:

They are light, extremely porous, and therefore easily penetrable by with difficulty give sparks with steel, which breaks off fragments at every stroke. They feel rough under the finger, and emit an argillaceous odour. They contain numerous feltspars, which are conspicuous from their whiteness, on a dark red ground approaching to a black. Some shew a degree of calcination which they have suffered in the fire, and are in consequence easily crumbled. Others have suffered no injury; and the difference observable in them is rather to be ascribed to the difference of the nature of the feltspars, than to their having suffered a greater degree of heat, the lava in which they are both incorporated appearing to have been equally affected by that agent.

Alicuda is about six miles in circuit, and I have as yet made the tour of only the one half. On completing it, however I only met with lavas of the same kind with those already described, diversified by a few varieties that do not merit a particular description.

I have given some faint sketches of the appearance of the lavas in some parts of this island; but it would be impossible for me to give an adequate idea of the fearful wildness of the scenes which present themselves to the eye for two-thirds of this circuit. Among all the volcanized places I have visited, I have yet seen none so convulsed by subterranean fires, so torn and shattered, and so filled with accumulated ruins by the devastations of time and the sea.

In some places we find a lava extending for several hundred paces, which has been broken by the waves in such a manner as to form a rock surrounded by the water,

abounding in craggy cliffs and precipices of a fearful height.

In others the lava descends perpendicularly from the most elevated summit of the mountain, and buries itself in the water, surrounded on the sides by projecting erags, and huge overhanging stones, which threaten every moment to thunder down into the

deep.

Here the lavas do not form one continued body, but are composed of detached and loose globes, particularly dangerous to those who may attempt to ascend the mountain, as they roll from under and put in motion a great number of others, thus producing a destructive stony current. Even the large falcons, which frequent the highest summits of this island, if they chance to alight on these heaps of round loose stones, will often,

of the crags,

water,

ned and ountain, ocing a ounmits I often, as I have myself seen, by moving one put others in motion, till bird and stones fall all together headlong into the sea.

In another place lavas are found, not of one kind alone, but a confused mixture of several, pixel in disorder one on another to a prodigious height; and in many of them

there is no part which does not threaten immediate fall and ruin.

Through the midst, however, of these misshapen rocks and horrid precipices are formed, I will not say roads or paths, but narrow winding gutters, by which we may ascend to a certain height; and through these I took my way, when from time to time I landed from my boat and went in search of the lavas I have described, and examined them on the spot. I was obliged, however, to advance with the greatest caution, as to have made a single false step would have been to have fallen headlong down a precipice. I could not but recollect the lines of Dante, in which he describes the laborious passage over the horrid crags and precipices of one of the abysses of his hell:

"E prosequendo la solinga via
Fra le schegge, e tra rocchi de lo scoglio,
Lo pie senza la man non si spedia."

"And still along the solitary way,
Proceeding over rocks and precipices,
The foot without the hand no progress made."

And though the fatigue in again descending to the sea might be less, the danger was equal, if not greater, from the unstable and slippery nature of these described places.

Having completed the circuit of the shores of Alicuda on the fourteenth of October, I appropriated the next day to the examination of the interior part of the island. I could, however, only make my researches in the part which fronts the east and southeast; the remainder being inaccessible from the dreadful crags and precipices already mentioned.

When seen from the sea, on the south-east side, at the distance of two or three miles, this island has the appearance of an obtuse cone, but with a considerable incavation on one side. This incavation has no resemblance to a crater, and on a nearer examination we find it is only a lower part of the mountain. In fact, we perceive no marks of the mouths of ancient volcanos in the whole circuit of Alicuda; either because they have never existed there, or because all traces of them have been effaced by time or some other destructive agent. I have discovered the appearances of a true crater no where but in the highest part of the island, where there is a hollow, not very deep indeed, but about half a mile in circumference; and I incline to believe it to have been a crater, from finding there a group of lava diverging as from a centre over the body of the island.

I examined the lavas which cover the sides of this mountainous island, at least where I could reach them without danger, in the same manner that I did those which form the base or shore of it. I shall not describe them particularly, as it appears unnecessary, they generally having the petrosilex or horn-stone for their base, and abounding more or less, as usual, in feltspars. Their external surface is covered with a yellowish and friable coating, originating in a beginning decomposition. The deep fractures which we find in many parts of them enabled me to perceive that they must have flowed at different periods, forming beds or strata one above the other, as is frequently observed in other volcanized countries.

M. Dolomicu was of opinion that "Felicuda and Alicuda had once formed a single conical mountain, which had been opened and separated on one side."

VOL. V.

This is certainly not impossible, but I must say it appears to me extremely improbable If the sea, or any other violent agent, had divided this conical mountain into two parts. it is difficult to conceive that no record or tradition should remain of this convulsive separation. On the contrary, when I attentively examine and consider these two islands, they have every appearance of being each a distinct island, like Stromboli, Saline, and the others. Both likewise have on their highest summits the vestiges of their primitive crater, that is, of that which by its cructations has given birth to its respective island. The lavas likewise which have flowed from these summits, as from central points, and enlarge and extend as they take their course down the sides of the mountain towards the sea, seem clearly to prove that each was a complete island in itself; nor can I doubt but the French naturalist, had he visited these islands themselves, would have been of my opinion. He only viewed them from the highest part of Saline, that is, at the distance of five-and-twenty miles from Felicuda, and five-and-thirty from Alicuda. At that distance they seem very near to each other; so that M. Dolomieu, judging from appearance, supposes Felicuda to be only five miles from Alicuda, though it is in reality twice that number. As therefore at Saline they appear to be so little distant from each other, nothing was more easy than to imagine that they once formed a single mountain, which, either by carthquakes, the violence of the sea, or some other unknown cause, had been broken and divided into two parts, an arm of the sea taking possession of the interme-

From the summit of Saline he likewise estimated Alieuda to be only twenty miles from Cefalu, on the coast of Sicily; and, in fact, when I was on the same eminence, these two places appeared to me to be very near, and Felicuda seemed almost to join to Alieuda; yet it is certain that the distance between Alieuda and Cefalu exceeds five-and-forty miles. It is well known that this optical illusion takes place with respect to any object seen at a distance, either by land or water. Nothing happens more frequently to the traveller than to find that two rocks, mountains, or buildings, which when viewed at a distance he had imagined to be extremely near to each other, and almost to touch, are in fact separated by an interval of several miles.

The volcanic materials of Felicuda, as has been already seen in the preceding chapter, consist of lavas with a horn-stone base, shoerl, and felispar; not to mention pumices, tufas, and glasses. The latter three products are likewise found in Alicuda, but the greater part of the lavas have the petrosilex for their base.

Notwithstanding these two islands exhibit indubitable characters of fire, no signs of it in a state of activity are at present to be seen. It may indeed be conjectured that some remains still exist in the internal parts of Felicuda, from a warm spring, emitting the smell of sulphur, which issues from the northern side of a rock, a little above the level of the sea.

I shall here collect the notices that have been left us by the ancients relative to Felicuda and Alicuda, as they are extremely few and brief. We know that their names were Phenicusa and Ericusa (**\textit{\sigma}\) and *\textit{\sigma}\) which are said to have the following derivation: Aristotle, speaking of Phenicusa, or Felicuda, as it is at present called, says, "it received that name from its abounding in palm-trees;" *\textit{\sigma}\) in the genitive *\textit{\sigma}\) being the name of that tree in Greek.* Ericusa, or Alicuda, we are told by the author of the epitome of Stephanus, was so named from the crica or heath, which there grows plentifully. \(\frac{1}{2}\) Strabo likewise informs us that these two islands derive their

^{*} Εν μια των Αιολύ σροσαγοριομένων τόσων σλόθες τι Φασί γενέσθαι Φοντικών, οθέν και Φυπικώθο καλείσθαι. In Mirandis.

^{&#}x27;à Едингота, ми точ Лиски глост, ато фови надирет.

names from plants.* At present, however, though heath is not wanting in Alicuda, Felicuda does not afford a single palm-tree, nor is there one to be found in any of the

But neither the above-cited authors, nor any other ancient writers, make the least mention of any conflagrations in these two islands; probably because, though in their time, Stromboli, Vulcano, and even Lipari threw out fire, Felicuda and Alicuda, as we have seen was the case with Didyma and Euonimus, were entirely extinguished.

CHAPTER XIX.

OBSERVATIONS WHICH HAVE AN IMMEDIATE RELATION WITH THE VOLCA NIZATION OF THE EOLIAN ISLES INQUIRIES RELATIVE TO THE ORIGIN OF BASALTES.

Methods and instruments proper to raise stony bodies from the bottom of the sea surrounding the Eolian isles The bottom of the channels between Vulcano, Lipari, and Saline, entirely volcanic The same observable of the roots of the Eolian isles below the water Gravel and volcanic sand in the channel that divides Panaria from Lipari....The rocks in the middle of the channels between Saline and Felicuda, and between Felicuda and Alicuda, analogous to those of the same islands, but probably primordial....Decisive proofs deduced from these observations, that the shoerls and crystallized feltspars of the lavas have not been taken up by them when in a fluid state, nor formed within them at the time of their congelation.... Confirmation of these proofs.... The Eolian isles placed in a direct line from east to west ... A similar direction observable in some islands and volcanic mountains in other countries.... Not improbable that all the eight Eolian isles were formed at the same time, and perhaps very suddenly, with respect at least to their first rudiments.... Explanation of the cause why islands and burning mountains are sometimes produced disposed in a right line.... Materials of the Eolian isles for the most part porphyritic.... Analysis made by the author, proving that the red Egyptian porphyrics have not for their base the petrosilex, but rather the horn-stone Inquiry whether the vitrifications found in such prodigious quantities at Vulcano and Lipari, are found in similar quantities in any other volcanic countries....Uncertainty of this from the want of accurate mineralogical descriptions of the greater part of volcanos The accounts given of them usually general and wonderful, but little instructive.... Volcanic glass found in Iceland, but by no means in sufficient quantities to form mountains.... No notices of vitrifications in the volcanos of the islands of Ferro, nor in those of Norway and Lapland ... Little or no glass in the volcanized countries of Germady and HungaryNor in the extinguished volcanos of France....The quantity of vitrifications at Vesuvius, and several other parts of the Neapolitan territory, more considerable.... Scarcely any at Mount Etna, or the volcanic mountains of Padua... A more extensive tract of pumices found perhaps in no part of Europe than in the island of Santorine....This island, however, affords no glass....Great scarcity of vitrifications in the three other quarters of the globe....Conclusion: that Vulcano and Lipari offer a greater abundance of glasses than any other volcanized part of the world; but that Santorine exceeds them in the quantity of pumices....Inquiries relative to this scarcity of vitrifications in volcanos, whether burning or extinct....It seems to proceed less from the quality of the stones acted on by the volcanic fire, than from the inefficacy of that agent to produce vitrification ... A successively stronger degree of heat requisite for a stone to pass from the state of lava into pumice, and from that of pumice into perfect glass....Elucidation of the cause why

some volcanos produce punices, but not glasses....The formation of punices hitherto not attainable in our furnaces....Black the natural colour of panices, which are rendered white by external causes.

Inquiries relative to basaltes....These originate in the humid way, when the word basalt is understood in the sense in which it was used by the ancients.... The columnar stones which, from their prismatic configuration, resemble the basaltes of the ancients, originate according to circumstances in the humid or the dry way....Proofs of their origin in the dry way in Vulcano and Felicuda....Nature, in the fossil kingdom, produces crystals as well by the dry way as by the humid....This exemplified in the generation of basaltes An abuse of analogy to conclude from it one common origin of basaltes....When examined detached, they fre mently bear no peculiar character of their origin, which must be determined from local circumstances....Inquiry whether basaltiform lavas have become such by a sudden condensation within the sea.... Proof which shew, first, that many basaltiform lavas have assumed this symmetrical configuration on coagulation in the waters of the sea; secondly, that in others it has taken place only by congelation in the air; thirdly, that very numerous lavas have proved refractory to this figure, both within the sea and in the air.... The property of assuming a prismatic figure appears in many lavas not to depend on their being of a particular species, nor on their compactness and solidity, but on extrinsic and adventitious circumstances....These circumstances indicated, with an explanation in what manner, according to their presence or absence, lavas frequently assume a prismatic form in the air, while others remain irregular within the sea-

THE form, size, and structure of the Eolian isles, the different materials of which they are composed, and the primordial rocks from which these are derived; the fires which still burn in some, and the phenomena and changes which accompany them; with the comparison between the present conflagrations and those of ancient times, constitute the principal objects to be considered in writing the volcanic history of such a country. And though we have already employed nine chapters on these subjects, we conceive the candid reader will not accuse us of extreme prolixity; both because we have had to treat of seven islands, and because our object was to write the lithology of this ancient and celebrated country. The present chapter, we flatter ourselves, will, in like manner, be acceptable to the inquiring naturalist, as it contains various observations and reflections which have a direct and immediate relation to the deflagrations of the Eolian isles.

We have already observed and described these islands from the summit to the base, which buries itself in the waters of the sea. But it was impossible to examine their internal part in the same manner as the external; though the importance of such an examination merited that every effort in our power should be exerted to effect it. It would be equally interesting and instructive to ascertain the nature of the bottom in those tracts of sea which surround these islands, and separate them one from the other. I shall therefore here relate what I observed with respect to this subject, and describe the methods and instruments to which I had recourse to make my observations.

Where the depth was not great, I found extremely useful the large tongs, mentioned by Donati,* furnished with strong pincers, fixed to one or more bars, which by means of a rope may be closed or opened at pleasure, and thus take hold of and bring up any substances from the bottom. But where the water was deep, I found it more convenient to employ one of those nets which fishermen use to envelope, and tear from the rocks, coral and other subaqueous bodies. These nets I easily procured, as coral is fished

^{*} Saggio sopra la Storia naturale del Mare Adriatico. Essay on the Natural History of the Adriatic Sec.

up on these coasts; of which fishery I shall treat further in a subsequent part of this work.

Employing, therefore, these two instruments, the following was the result of my observations, which were not made on pieces that lay detached on the bottom, but on such as formed a continued whole with it, as was evident from the recent appearance of the

fractures where they were broken off.

In the channels which divide Vulcano from Lipari, and Lipari from Saline, the bottom is entirely volcanic, and affords products of the same species with the two shores. The same is observable of the foot of the islands, which foot in some situations descends perpendicularly; but in others has a considerable declivity, and thus enlarges the circuit of the island. The pieces of lava which I was here able to detach, did not differ from those of the shore, which I have already described.

But at a greater distance between island and island this was not the case. I made my experiments in three different places. The first was between Lipari and Panaria; but here, the water being very deep, I did not succeed in my attempts to bring up any stony body from the bed of the sea, but only testaceous and crustaceous animals alive or dead enveloped in sand and gravel, and forming a species of crust more or less thick. The

sand and gravel, it is to be observed, were volcanie.

The second place in which I made this experiment was between Saline and Felicuda, and the third between Felicuda and Alicuda, in both instances, at the point of greatest distance as nearly as the eye could measure, between the two islands. In each of these situations, besides drawing up from the bottom portions of the before-mentioned crust, I likewise obtained several stony fragments, which, from the great force it required to separate them, and the recent appearance of their fractures, evidently had an immediate communication with the solid and rocky bottom. The whole number of these fragments, great and small, was elements of which four were brought up between Felicuda and Alicuda, and seven between Saline and Felicuda. The base of five* of them was a petrosilex almost opaque, affording sparks with steel, compact, of a grain little scaly, but fine; the colour of two of these pieces was a lightish blue, and that of the three others a gray. The base of the seven other pieces was a dark green horn-stone moderately hard. None of them differed in their base, and shoerlaceous and feltspathose crystallizations, from several volcanic lavas of the Eolian isles.

These eleven pieces, however, excited in me a strong suspicion that the rocks from which they were detached had not been exposed to the action of fire. The particles of the petrosilex in them were more closely united, had greater hardness, and a more siliceous appearance, than in the same stone of those islands, which has been subjected to fusion. In like manner, the lavas, of a horn-stone base usually have somewhat of a fibrous nature, and a thinness in their texture which is not seen in the stone of the same

kind. These two rocks, therefore, appeared to me to be in their natural state.

I consider these experiments as very instructive with regard to the origin and formation of these islands. We may conclude from them: First, That the part of the islands which is buried under the waters of the sea, has suffered the action of the fire in the same manner with that which is exposed to the eye of the observer. Secondly, That Vulcano, Lipari, and Saline form one continued group of volcanized substances, which, at first, might probably have one common central conflagration that dividing into three branches, and affording a passage to three distinct mouths, gave birth to three islands,

^{*}The author must here have committed some mistake, as he, immediately before said the whole number of pieces was cleven, and now mentions five and seven. T.

which conflagration, by subaltern and successive ramifications, and ejections of new matters, afterwards increased in extent. No sensible remains, indeed, of such a fire are at present discoverable in the internal parts of Saline, nor are any observable in Lipari, its whole efficacy appearing to be confined to Vulcano. Thirdly, That Alicuda, Felicuda, and Saline do not appear to have any volcanic communication with each other, at least in the parts that form the bed of the sea, which separates these three islands from each other; since those parts, as far as the eye can perceive, shew no signs of the action of fire. Fourthly, That these three islands, and perhaps likewise Stromboli, are situated in the vicinity of analogous but primitive rocks the perfect resemblance of the shoerls and feltspars in these rocks, both in those that have suffered change from the fire and those that have not, is a demonstration that these crystallizations have not been taken up by the lavas when they flowed in currents nor formed in them at the time of

their congelation.

From the very beginning of this work, I have adduced facts of the same nature, which I have the satisfaction to confirm by the present; and which become of the greater importance, as I have lately read that a naturalist of eminence inclines to believe that the sheerls of lavas are formed when the latter condense and become cold, because then the homogeneous molecules separate from the beterogeneous, and unite by affinity in small crystallized masses. This ingenious theory is not only contradicted by the observation made above, but appears to me not to accord with the usual operations of nature. Were it well founded, I can perceive no reason why the shoerls in lavas should not re-appear after they have been fused within them in the furnace, and being removed into a cold place, have acquired their former hardness. But though I made experiments with fire on some thousands of pieces of lava, not one of them re-produced its shoerls, though many were continued a long time in a state of fusion, and afterwards suffered quietly and slowly to cool and consolidate; which two circumstances are known to favour the formation of crystallizations. Shoerls were indeed sometimes found in the lavas, after fusion, when cooled and hardened; but these had proved refractory to the fire, as appeared on exposing them again to the furnace detached from the lava.

The eleven pieces of primordial rock broken from the bottom, exhibited in the furnace the same changes with their congenerous lavas exposed to the same fire: the felt-

spars, however, remained refractory.

The Lipari islands extend in a right line from east to west the distance of about fifty miles, except that Vulcano makes a small angle. Stromboli is the first to the east, and Alicuda the last to the west. This is not the only instance of volcanos having produced islands, or rather mountains, arranged in a rectifinear direction. We find an example of this in the Moluccas, which are the produce of subterranean fires, and placed one beyoud the other in a right line. When, in 1707, a new island was thrown up by a submarine volcano, in the Archipelago, near Santorine, other small islands arose from the sea near it, to the number of seventeen in a right line, forming, as it were, a long chain of black and dark rocks, which visibly increased in dimensions and height, and, approaching each other, at length united, and, joining that which first arose from the water, formed one single island.*

Another memorable instance of this direction of volcanic mountains (for islands are in fact only mountains buried in part under water) is the production of seven lesser mountains by the cruption of Vesuvius in 1760; the account of the formation of which,

^{*} Vallisneri Oper. fol. t. i:

about fifty e east, an**d** produced n example ed one beby a subfrom the long chain , and, apfrom the

islands are ven lesser ı of which, as it may throw some light on that of the Eolian isles, I shall here give, from the accurate relation of professor Bottis, an ocular witness.

After repeated concussions of the earth, which where felt lifteen miles round Vesuvius, the sides of the fiery mountain opened in the territory of the Torre del Greco, and fifteen volcanos appeared, eight of which were soon after covered by a torrent of lava, which rushed from one of them; the other seven remaining entire, and incessantly ejecting from their mouths vast quantities of ignited substances, which, falling almost perpendicularly around the volcanos, produced, in the short space of ten days, seven small mountains, of various heights, disposed in a right line. During these ejections, the noise which accompanied them sometimes resembled that of violent thunder, and at others the discharge of a number of cannons. Several of the burning stones, even the largest, were thrown to the height of nine hundred and sixty feet, and some fell at a considerable distance from the mouth whence they were thrown. These cructations shook all the neighbouring country, and the roarings of the mountain were dreadful to the inhabitants. After the tenth day the eruptions ceased, and the newly-formed mountains, gradually cooling, permitted a nearer approach; when some were found to have at their summit a cavity resembling an inverted funnel, and others a simple hollow of greater or less depth.

The production of the Eolian isles being anterior to the records of aistory, we know not whether this took place at one time, or in different periods. The relation, however, just cited, of the origin of the seven Vesuvian mountains clearly proves the possibility of their being produced at the same time. It also proves, that the whole eight might be formed in no long space of time, with respect at least to their first rudiments, it having

been seen that they have received successive additions.

We also evidently perceive that the inflammable substances generative of the Moluccas in Asia, of the chain of islands at Santorine, of the Vesuvian mountains above described, and of the Eolian isles, have formed a direct subterranean zone incomparably longer than broad. This phenomenon may be explained by recurring to the clefts and fissures perpendicular to the horizon, existing in many places within the earth, as well in soft substances as in the more durable and solid; within which clefts should substances proper for the production of volcanos be found in abundance, and become inflamed, in separate heaps, burning mountains would arise, in a direct line, and more or less large, according to the quantity of the ejected matters.

From the particular descriptions of the islands of Lipari, we have seen that the combustible substances which have produced them have sometimes been contained within granite, as at Panaria and Basiluzzo, but for the most part within rocks which have for their base the petrosilex, the horn-stone, and the feltspar. It likewise appears, from the observations made at Stromboli, that, even there these burning substances have their seat in the horn-stone rock, though, from the size of the island they have produced, they must undoubtedly be buried at an immense depth. If we would simplify the facts relative to the materials of all these islands, we shall find that they are for the greater part porphyritic; as are likewise some of those submarine tracts, apparently not touched by the fire, and placed among them, as has been shewn above.*

When I compared the effects of the furnace on volcanized porphyritic rocks with those it produces on the natural, I mentioned some red Egyptian porphyries, the base of which I believed to be horn-stone rather than petrosilex, relying on the analyses of Bayen, as related by Delametheric, of an Egyptian porphyry of the same colour, and

^{*} See the Note at page 82, Chap. XI. in which I have spoken of the essential characters of porphyry

similar to those on which I made my experiments.* But not having then been able to analyse them from want of time, I determined to do it afterwards, and give an account of the result, in another part of this work, when I should again have occasion to speak of this species of volcanic rock. I shall here give this analysis, which affords a confirmation that the base of these porphyries is not petrosilex, as they contain magnesia, which is not found in that stone. From this circumstance, and the nature of their constituent principles, their base ought rather to be called a horn-stone, of the nature of which it at least participates. This analytical observation is likewise here very opportune, as it is an additional proof that I have properly called porphyritic the lavas with a horn-stone base, and containing feltspars, which are so numerous in these islands.

The red Egyptian porphyries which I analysed are of two species: the first has been already described; the second differs only in its colour being of a less lively red, and in the abundance of its feltspars. It is evident, that to render this experiment accurate the substance of these two stones should be first freed from the shoerls and feltspars which they contain.

Besides the porphyritic lavas with which the Eolian isles abound, we have seen that they contain great quantities of tufas; and that Stromboli is distinguished from the other islands not only by its volcano, but by the beautiful specular iron it affords; and Lipari by its chrysolites and zeolites, but still more by the prodigious quantities of pumices and glasses which it contains. I cannot, indeed, reflect on those enormous masses of vitrifications, without renewed wonder; which has been still more increased by the discovery, by means of the forceps and coral nets, that these vitrifications are continued from Lipari, till they join those of Vulcano, which on the north and north-east side abounds in pumices, and enamels, and glasses. The vitreous substances, therefore, of this island, and those of Lipari, which, as has been said, occupy about two-thirds of the latter, compose an accumulation of glass, not less than fifteen miles in circuit. It is impossible to attend to this stupendous phenomenon without feeling our curiosity excited to know whether it be peculiar to these islands, or found likewise in other volcanized countries. But satisfactorily to answer such a question, it would be requisite that we should be acquainted with the volcanic mineralogy of all the volcanos in the world; not only those at present burning, but those extinguished, which are infinitely more numerous; in the same manner as we are with that of Vivarais and Velay, the islands of Ponzo, Vesuvius, Etna, the Eolian isles, and the mountains of Old-Brisach, by the labours of Faubeen able ive an acceasion to a affords a stain magnature of of the nahere very the lavas se islands, t has been y red, and ent accud feltspars

ıs; in the

zo, Vesu-

s of Fau-

jas, Gioeni, Dolomicu, Dietrich, and myself. Of such a mineralogy, however, we are entirely destitute. The greater part of those who, either by chance, or from curiesity, have viewed burning volcanos, have only described in their relations the most common and general phenomena, less adapted to increase the knowledge than to amuse the imagination of their readers, and excite their wonder. Shocks and undulations of the earth; the sea in commotion, and raging without a tempest; here retiring and leaving its shores dry, and their inundating vast tracts of land; subterranean thunders, and roarings in the air above; the sun disappearing in thick darkness at noon; whirl winds of smoke, ashes, and flame, bursting from the yawning gulf: burning stones hurled towards heaven, and falling in a fiery hail; torrents and rivers of liquid lava, sulphur and bitumen, pouring down on the vallies below, and carrying terror, desolation, and death; islands, now suddenly produced by submarine cructations, and now torn from their foundations, and swallowed up by earthquakes; these compose the usual descriptions of volcanos, which, though they may not be useless when the facts are faithfully stated, and not magnified by the imagination of the narrator; yet they commonly want one essential requisite: that is, lithological descriptions of the bodies ejected by these burning mountains. As glass and pumices, however, are known even to those who are unacquainted with this part of natural science, we may, with certainty, or at least, with the strongest probability, conclude, that they are produced by the volcanos in the descriptions of which we find them expressly mentioned as making a part of the ejected matters, and that they are not produced when not mentioned. Thus in Iceland. the greater part of which Iceland is only an accumulation of volcanos either extinct or active, it is certain, from the accounts of travellers, that numerous glasses are found to which the name of Icelandic agate has improperly been given, only because they have the lustre and beauty of that stone. The present cruptions of this island, likewise, not unfrequently contain pumices; but no person has ever asserted that there are entire mountains of these stones, or of glasses.

The islands of Ferro are considered as volcanie, and produce the famous zeolites, mixed as it is said, with lava; but as yet we know nothing more of them. The minute account of each of these seventeen islands published by Jacobson Debes, in which no mention is made of the vitrifications, authorises us to co-clude they do not exist there.

Norway and Lapland have their volcanos, which from time to time burst forth in fearful eruptions according to the accounts of Pennant and others, who, however, give us no further information.

Leaving these cold regions, and passing to Germany and Hungary, we find some tracts of these countries that have likewise been subjected to subterranean conflagrations, which, however, have produced no vitrifications, or scarcely any. "I have sought in vain the black agate of Iceland, and the true pumice," says the above cited Baron Dietrich, in his long and circumstantial Memoir relative to the volcanos near Old-Brisach.

Proceeding to a milder climate, and approaching nearer to our own country, we find that the extinct volcanos of France afford no pumices or glasses; which assertion I can make on the authority of M. Faujas, who has written so well concerning them, than which one more unquestionable cannot be adduced.

It is not the same with Italy; the country in which fire has principally extended its empire. The Neapolitan territory peculiarly abounds in pumices, enamels, and glasses, as appears in the islands of Ponza, at Herculaneum, Pompeii, Miseno, Monte Nuovo, the Rock of Burnt Stones, Procida, Ischia, and the valley of Metelona.* Even in our

times Vesuvius has ejected similar bodies; but with respect to Etna, its fires rarely

produce the slightest vitrification.

The only place in Europe, which, in the abundance of its pumices, can equal, or perhaps surpass Lipari, is the island Santorine. On this subject we may consult Theyenot and Tournefort, two intelligent travellers, who at different periods examined this island, which has not hitherto, to my knowledge, been considered by volcanists in this point of view.

The former, who visited Santorine in 1655, observes, that "many of the inhabitants live in caves made under the earth, which is extremely light, and easily dug into, as it consists entirely of pumices." He afterwards relates a fact, which has a particular relation to our present subject, since it teaches us in what manner these light stones may be thrown up, immediately by the sea, in volcanic cruptions. His account is as

follows:

"About eighteen years ago, on a Sunday night, a violent noise began to be heard in the port of Santorine, which was likewise heard even to Chios, distant more than two hundred miles, and was thought to be occasioned by the Venetian fleet having engaged the Turks; in consequence of which great numbers of people got upon the highest places early in the morning to be spectators of the battle; and I remember the reverend Father Bernardo, a venerable man, perfectly deserving credit, told me he was one among the number of those who were so deceived, imagining they heard a violent cannonade. They could however see nothing. In fact, this noise was caused by a fire kindled in the earth, under the harbour, the effect of which was, that from the morning to the evening a vast quantity of pumices rose from the bottom of the sea, with such violence and noise as to resemble repeated discharges of cannon, and so infected the air that several persons died at Santorine, and many lost their sight, which they did not recover till some days after. This infection extended as far as the noise which had preeeded it had been heard; since not only in this island, but at Chios and Smyrna, all the silver became red, whether kept in coffers or in the pocket; and the religious who resided there told me that all their chalices became red. After some days the infection ecased, and the silver returned to its former colour.

"The pumices which were thrown up covered the Archipelago in such a manner, that for some time, when certain winds prevailed, the harbours were so blocked with them, that not even the smallest vessels could get out till a way was made for them by removing the pumices with long poles, and they are still seen scattered over the whole

Mediterranean, though in a small quantity."*

Tournefort, after having remarked from Herodotus that Santorine was once called Karanisa, or "the most beautiful island," adds, that "its ancient inhabitants would not at present know it, since it is covered with pumices, or, more properly, is a mine of those stones, which may be cut into great square blocks, as other stones are cut in the

According to this traveller and to Thevenot, Santorine is thirty six miles in circuit; whence it appears what a prodigious accumulation of pumices there must be in this island and the adjacent sea. It merits notice, however, that neither these two travellers, nor others who have written of Santorine, make the least mention of glasses of any kind; we may therefore venture to affirm that the subterrancous fires have there never produced them.

If from Europe we pass to the three other quarters of the globe, we shall find in each a great number of volcanos, which it would be superfluous to enumerate particu-

^{*} Voyages de M. de Thevenot, Prem. Part. † Voyage du Levant.

vould not a mine of cut in the n circuit;

be in this travellers, es of any nere never

all find in e particutarly, such an enumeration having already been made by Faujas, Buffon and others. I shall only mention those which afford products that have relation to our present subject.

We read that the island of Ternate in Asia throws out a considerable quantity of pu

mices, as does likewise one of the numerous volcanos of Kamschatka.

As to those of Africa, we have but very imperfect accounts of them, with the single exception of the peak of Teneriffe, one of the loftiest of volcanos; which, with respect to its situation, height, form, and crater, and the hot fumes which issue from it, has been accurately described by the chevalier Borda. But it were to be wished that we had a more complete description of the materials of which it is composed; as the French traveller only tells us that they are "sand, black and red calcined stones, pumices, and flints of different kinds."*

It admits of no doubt that the highest mountains of America, as Chimboraco, Coltopaxi, Sangai, Pichencha, &c. form a chain of burning volcanos, the largest existing in nature. We are indebted for the accounts we have of them to M. Bouguer; but these are such as only tend strongly to excite our curiosity without gratifying it. With respect to what relates to our present inquiry, we only learn from this writer, that "some mountains in the vicinity of Quito are composed entirely to a great depth of scoriæ, pumices, and fragments of burnt stones of every size."† As to volcanic glasses, he does not make the slightest mention of them; though it is well known that the famous gallinaceous stone, which is universally acknowledged to be a most beautiful American volcanic glass, of a black coiour, is found in Peru, and that, according to M. Godin, there is a mine of it, several days journey from Quito.

If we now consider those parts of these imperfect accounts which relate to glasses and pumices we shall find, with respect to the former, that the much greater part of volcanos produce none, and that those which do produce them, as in the Neapolitan territory, Iceland, and Peru, are by no means to be compared in this respect with Lipari and Vulcano. The same may be asserted of Alicuda and Felicuda, the glasses of which, though abundant in many parts of those islands, are only found in flakes and fragments. These observations might likewise be applied to the pumices, did not the immense quantity of them in the island of Santorine equal if not exceed, that of the two Eolian islands

above mentioned.

If we consider the volcanos known to us under one general point of view, we shall find that, though they have changed into lavas an infinity of rocks, by which they have produced mountains and islands very considerable both in number and dimensions, it is very rarely that they vitrify the substances exposed to their fires. Reflecting on the immense quantities of vitrifications at Vulcano and Lipari, which are almost all derived from felispars and petrosilex, the idea suggested itself to my mind, whether so great an abundance in these two places, and so great a scarcity in others, might not be attributed to these stones being here extremely abundant, and very rare elsewhere. But this supposition does not accord with fact; as we have seen in many other volcanic tracts, which I have described, and shall describe when I come to speak of the Euganean mountains, that both these stones may be changed into lava without that lava exhibiting the slightest appearance of glass. On the other hand, we have shewn that, besides feltspar and petrosilex, many pumices have for their base the horn-stone and asbestus, and many granite, as M. Dolomicu has observed. I am therefore of opinion, that the cause which has produced them should rather be sought in the volcanic fire, which rarely has sufficient activity to vitrify the stones and rocks on which it exerts its power; though I

^{*} Voyage en diverse Parties de l'Europe. † Acad. Royale des Sciences, 1774.

grant that the petrosilex and feltspar are more adapted to this vitrification than other stones. To produce a lava, a certain degree of heat is necessary; and a still greater to convert it into pumice. The lavas, at least those of the compact species, usually preserve the grain, hardness, and sometimes the weight and colour of the primordial rock; but the greater part of these external qualities disappear in the pumice, from the stronger action of the fire. This must operate still more in glass, in which the homogeneity and

fineness of the paste efface every trace of its primitive texture.

These gradual transitions of lava into pumice, and pumice into glass. I have several times observed, and indeed have already described, in the same volcanic piece. It has also been observed, that a lava frequently passes immediately into perfect glass, which must be caused by a sudden heat, greater than that required to change it into pumice. This theory satisfactorily explains why some volcanos produce pumices, but never glass; as may be remarked of Santorine. Their fires are only sufficiently powerful to generate pumices, but not to produce glass; an observation applicable to the prodigious eruption from the sea described by Thevenot. On the contrary, at Rotaro in Ischia, at Vesuvius, and other parts of the Phlegræan Fields, as also at Vulcano, Lipari, Felicuda, and Alicuda, glasses are found mixed with lavas; which shews that the fire has acted anequally in those places. It is to be remarked, at the same time, t'est the heat requisite for vitrification is not of the most violent kind, as I have shewn in Chap. XVI.

We must however observe, that as the production of compact lavas is a secret which nature has hitherto reserved to herself; since we are unable to imitate them with our common fires; so also are we ignorant of the precise causes of the formation of pumices. Among some thousands of fusions which I have made in the furnace, both of lavas and primordial rocks and stones, those likewise from which pumices are most frequently produced as petrosilices and feltspars, I never obtained a product which could be said to possess all the characteristics of pumice. It has always been either a glass, in chain, or scoriæ; nor do I remember to have read or heard, that among the imunicable experiments which chemists have made upon earths with fire, the result ever was a true pumice; and though in lime-furnaces we may frequently observe a change of certain stones into glass; yet they never produce lavas similar to the volcanie; and equally incapable are they to form pumices. It cannot be alleged that the fire of our furnaces is too strong to induce that slight degree of vitrification which characterizes pumices; since, when I have used a more moderate fire, the substances on which I made my experiments have either not melted, or been more or less vitrified.

I shall conclude these observations on the pumices of Lipari with a remark relative to their colour. Except a few that are dark, they are all white as snow. Hence the mountain of Lipari, which forms the great magazine of these stones, is called Campo Bianco (the White Fields:) but certainly there must have been a time when it should have been denominated Campo Nero (the Black Field;) at least it is certain that pumices when newly ejected from volcanos are of a black colour. This remark, which has been omitted by almost all who have made observations on this subject, who content themselves with saying that this or the other volcano throws out pumices, has been expressly made by Don Gaerteno de Bottis in his "History of the Conflagrations of Vesuvius."* He tells us, the pumices ejected at various periods by this volcano are black. He likewise remarks, that on comparing them with those which overwhelmed Pompeii, he found them perfectly similar in their structure. Their whiteness, was subsequently acquired,

and probably was caused by the impressions of the atmosphere.

Before I conclude these observations on the Folian isles, I think it necessary to say a few words on a subject which has a relation to the productions of Vulcano and Alicula, and on which the opinions of modern naturalists are divided; I mean the basaltiform layas which are found within the crater of the former island, and along the shores of the latter,* and which by their conformation cannot but remind the reader of the inquiries and disputes which have taken place within these few years relative to the origin of basaltes. To repeat all that has been written on the subject would fill a volume; but I am far from purposing to tire either my own or the reader's patience in any such manner. It, besides, appears to me that this long agitated question may, at present, be determined without any very profix augmentation. Literary disputes and differences of opinion frequently arise from want of previously fixing the state of the controversy; that is, from not defining in precise and clear terms the thing in question. Before we inquire what is the origin of basaltes, that is to say, whether they are the result of the action of fire or water, it will be proper to decide what we mean by the term: or rather what the ancients understood by this word, which is the name they gave to a certain kind of stones. It is now generally known, because it has been repeated by a hundred writers, though perhaps by the greater part without due consideration, that the word basaltes is used by Pliny and Strabo to denominate an opaque and solid stone, of the hardness, and nearly of the colour of iron, commonly configurated in prisms, and originally brought from Ethiopia; of which stone the Egyptians made statues, sarcophagi, mortars, and various utensils. This premised, it remains to inquire whether this stone was of volcanic origin or not, by repairing to the places where it was found, and attentively examining the country to discover whether it bears the characteristics of volcanization. This labour however has not, to my knowledge, been hitherto undertaken by any one; but M. Dolomieu, to whom lythology and the history of volcanos are so much indebted, has discovered, during his stay at Rome, an equivalent, in some measure, with respect to the solution of this question. Among the many noble monuments in that superb capital which are instructive not only to the admirers of the arts, but to the contemplators of nature, are a great number of statues, sarcophagi, and mortars brought from Egypt, which have all the characters attributed to basaltes, and likewise preserve the name. These he has studied with the greatest attention, and declares that the stone of which they are formed manifests no sign of the action of fire. Among other Egyptian monuments, he observed some of a green basaltes, which change colour, and assume a brown tinge, similar to that of bronze, on being exposed to the slightest heat. All those that have been burned have acquired this colour; which proves, as he very judiciously observes, that the green basaltes have never suffered the action of fire.†

The Egyptian stones, therefore, to which the ancients gave the appellation of basaltes, have been produced by nature in the humid way. These observations perfectly agree with those of Bergmann on the trapps produced in the same way; and which have, both

externally and internally, the same characteristics with the basaltes.‡

Werner, taking the term basaltes in a wider sense, and understanding by it all those columnar stones which, by their prismatic configuration, resemble the Egyptian basaltes, supposes both to have the same origin, and adduces as a proof of that origin, the basaltes of the hill of Scheibenberg, which are the effect of a precipitation by means of water; and concludes that "all basaltes are formed in the humid way."

Though I am willing to bestow the praise due to his discovery, I cannot admit his conclusion; for though many basaltes, taking that term in the sense of this author and

^{*} See Chaps. XIII, and XVII.

[†] De Productis Vulcanicis.

⁺ Rozier, tom. xxxvii. an. 1790.

[#]Rozier, tom. xxxviii. an. 1791

other naturalists, may derive their origin from water, many others are certainly the product of fire.

I shall not repeat what various volcanists have written on this subject, but merely refer the reader to what I have already said relative to the basabine lavas of Vulcano and Felicuda. With respect to the former island, I have remarked in Chap. XIII, that I found within its cracer a range of articulated prisms, with unequal sides and angles, which in part composed one whole with a mass of lava; and, in part, were detached from it. I have also there described the qualities and nature of these prisms. In Chap. XVII, I have particularly described the littoral lavas of Felicuda, which, near the

water, are prismatic.

It is therefore evident, that in these two situations the origin of the basaltes there found cannot be what it has been assumed generally, by Werner and other Germans, but that it is truly volcanic. It consequently appears that nature obtains the same effects by two different ways. In the fossil kingdom, one of her grand operations is crystallization; which, though it be most frequently effected in the humid way, is sometimes produced in the dry; as we see, among other instances in iron, which nature crystallizes within the earth, both by the means of water and of fire, in which latter way the beautiful specular iron of Stromboli is produced.* Nor are there wanting other instances, of the crystallization of the same metal by the action of fire. And did other metals exist in the entrails of volcanos, and the necessary circumstances concur to their crystallization, it is indubitable that this may be effected by fire as well as by water. Thus we see that, by taking certain precautions, metallic substances assume a regular and symmetrical disposition within the crucible. The same is true of basaltes, the prismatic configuration of which, though not strictly a crystallization, has the most exact resemblance to it. Observation likewise teaches us that the same combination of earths, according to different circumstances, forms prismatic basaltes, sometimes in the humid, and sometimes in the dry way. The stone called trapp, found in the mountains of Sweden, is configurated in prisms, though those mountains are of aqueous origin; and the hornstone, which is so analogous to the trapp, has the same configuration at Felicuda, notwithstanding it is a new lays. In the same island, likewise, other basaltiform lays have for their base shoerlin mass, and those of the erater of Vulcano, the petrosilex; which two stones, according to the observations of M. Dolomieu, form some of the Egyptian basaltes, which are a work of the waters. These two agents, fire and water, are not, in fact, so different in their action as we might at first be inclined to imagine. The prismatic figure in the humid way arises in the soft earth by the evaporation of the water; in consequence of which the parts dry, contract their volume, and split into polygonal pieces. The same phenomenon may be remarked in margaceous earths, imbued with water, and exposed to the ventilation of the air; and I have frequently seen the mud of rivers, when dried in the sun in summer, to make pottery-ware, divide, when it became dry, into small polyedrous tablets. Similar configurations are produced in different lavas by the congelation and contraction that take place by the privation of the fire which held them in a state of fluidity.

It appears to me, therefore, that the dispute relative to the origin of basaltes is at an end; nor would there be any difference of opinion if, instead of generalizing ideas and fabricating systems, naturalists would make an impartial use of their own observations and those of others. Some volcanists, perceiving that the generation of various basaltes is evidently igneous, have immediately inferred that all must have the same origin. In

erely reino and , that I angles, letached ins. In near the

gin. In

consequence of this principle, they have drawn lines or zones in different parts of the globe, indicative of extinct volcanos, which they have inferred from finding basaltes there a and thus pourtrayed a picture of prodigions dimensions, representing the ruins caused in the world by subterranean conflagrations. Other naturalists, on the contrary, being convinced that certain basaltes are the produce of water, having assigned to all the same origin. From the facts vow adduced, it is however sufficiently evident that both these hypotheses are erroneous. The basaltes, taking the term generally, when examined detached, do not bear exclusively any decisive marks of their origin. Local circumstances alone can determine to which of the two principles it is to be ascribed; to discover which we must attentively examine whether the places where these figured stones are found, exhibit any indubitable signs of volcanization. Yet even these are frequently not sufficient, as there are many hills and mountains which owe their origin to both the great agents of nature, fire and water; in which ease it will be necessary to redouble our attention, and fix it on the substances originating from each; to determine, by the relations these have to the basaltes, from which of the two the latter derive their formation. By diligently employing these means, we shall be certain, without fear of error, to clucidate, and advance the inquiries relative to basaltes, and be enabled accurately to determine which of them are to be ascribed to the action of water, and which to that of fire.

But here a second question occurs, not less interesting than the first, relative to the cause why certain lavas, differing from innumerable others, become basaltiform; since, if this configuration depended on congelation, it must be found in all lavas when they had ceased to flow. The first writer, to my knowledge, who has adverted to this is M. de Luc, who, in the second volume of his Travels, is of opinion that they have taken this regular figure in the sea, by the sudden condensation which took place on their flowing into it in a liquid state; other secondary circumstances, however, concurring, such as a

great homogenity, and a certain attraction of their parts.

Of the same opinion is M. Dolomicu; though he does not deny that even porous lavas may sometimes likewise take the form of prisms. The former of these opinions is little less than hypothetic, while the latter is supported by facts too important to be cursorily stated. M. Dolomicu observes that all the currents of the lavas of Etna, the periods of which are preserved in history, have constantly experienced two effects in their congelation. Those which have cooled in the air have divided, in consequence of the contraction they have suffered by the loss of their caloric (heat) into irregular masses; while all the others, which have precipitated into the sea, have, on their sudden congelation, contracted into a regular form, and divided into prismatic columns, which form they have only taken in the parts in contact with the water of the sea. Of this he met with evident proofs along the shore which extends from Catania to Castello di Jaci; and the famous lava of 1669, though unapt to the prismatic form, from being spongy and little in quantity, yet in some parts exhibits a kind of rude imperfect prisms.

Among the objects to which I was attentive in my volcanic travels through the two Sicilies, the prismatic lavas were certainly not the last. While making the circuit of the Eolian islands, of Etna and of Ischia, I constantly observed carefully the conformation of the stony currents which fall into the sea. I have remarked when treating of Ischia, that this configuration is frequently prismatic, and that the prisms are constantly formed in those parts of the currents which immerge into the water, and reach to a few feet above the level. This observation of mine certainly accords admirably with those of M. Dolomicu; the situation of these prisms clearly showing that they were formed at the time of the immersion of the lava into the sea, which, when it flowed, rose to where they begin to appear. But, though I agree with him in this I cannot in the

remainder of my observations. Alicuda, as well as Felicuda, presents us with numerous currents and rocks that descend into the sea; and they are likewise found at Saline, Lipari, Stromboli, Panaria, Basiluzzo, and Vulcano; but these rocks and currents, which together extend over a space of more than sixty miles, do not afford the slightest

indications of prisms.

As I went by sea from Messina to Catania, and returned to Messina from Catania, I had an opportunity twice to examine, at my leisure, that tract of shore, which, for the space of nearly three-and-twenty miles, is volcanic. One third of it, beginning at Catania, and proceeding to Castello di Jaci, consists of prisms more or less characterised, and such as they have been described by M. Dolomicu; but the other two thirds, though equally composed of lavas with the former, and for the most part falling perpendicularly into the sea, have no such figure; and only present, here and there, irregular fissures and angular pieces, such as are generally observable in all lavas, which separate more or less on their congelation.

In my circuit by sea round the shores of Ischia, I was particularly attentive, as I was every where else, to the conformation of the lavas; and here and there seemed a great probability of finding them prismatic, from the abundance of them which in different directions and angles fall into the sea: but I have already observed, when treating of the

island, and I now repeat it, that I did not find one with a regular form.

At Naples, the prismatic lavas of the currents of Vesuvius, under the park of Portici, have been much spoken of. When I made my observations on this burning mountain I had not time to visit these lavas. It is with great pleasure therefore that I learn they have been examined by a person so well experienced in matters of this nature as the chevalier Gioeni undoubtedly is. But the celebrated prisms disappeared in the presence of so accurate an observer. The following is the account he gives; which is of considerable importance to our present subject: "I wished to examine the basaltes which were pointed out to me as to be found on the sea shore, under the Royal Park of Portici; but they proved to be only a compact lava, with perpendicular and extremely irregular fissures, forming quadrangular, and sometimes trapezoidal pilasters, which have been employed in buildings. Similar fissures are likewise observed in tufas, and earths of different kinds, and can never mislead any person accustomed to them, and acquainted with their true causes."

By this faithful relation of facts I flatter myself I have clearly shewn that it cannot be supported as a general hypothesis, that flowing lavas take a prismatical configuration

from the sudden coagulation they suffer on falling into the sea.

It may perhaps be objected, that these prisms once existed in the lavas I observed, but that the irresistible violence of the waves, in a long series of years, has corroded and

destroyed them.

Every person acquainted with the subject must immediately perceive how little solidity there is in this objection. I admit that the violence of the sea may, in some lavas, have totally destroyed these prisms; but that it can have had that effect on all, and through so extensive a space is utterly improbable. Nor is it conceivable that Felicuda, among the Eolian isles, should still preserve its prisms perfect, while the rest of those islands have entirely lost theirs, notwithstanding they are all equally exposed to the shocks of the waves.

I cannot here omit another remark. It is certain that more than one of these islands were not formed by one cruption, but by successive ejections of lavas accumulating on each other: and in some deep fissures, occasioned by the sea, this successive formation is discoverable by the eye, as we may perceive five or six different strata of lava one

imerous Saline, currents, slightest

rved, but oded and

little soliome lavas, in all, and Felicuda, it of those sed to the

ese islands dating on formation f lava one above the other. The internal strata in very remote periods having flowed into the sea as the external flowed afterwards; it is evident that if the latter on touching the water became prismatic, the same change must have taken place also in the former; which being defended from the injuries of the sea by the external strata, must still preserve their prismatic configuration, of which however no traces remain. We must therefore conclude that innumerable lavas may fall into the sea, without having their external appearance in the least changed by the sudden congelation which then takes place.

That the prismatic configuration of lavas is not always the effect of their immersion in the waters of the sea, likewise appears from many of them taking the same form in the air; of which we have a distinguished example in the crater of Vulcano. Here certainly we cannot suppose any intervention of the waters of the sea. Similar observations have been made on Mount Etna by the Chevalier Gioeni. "I have observed," says he, in the work before cited, "basaltic columns at the summit of Etna, and nearly on a level with the base of its vast crater, where there is certainly no probability of the sea ever having reached; and I have frequently found polyhedrous basaltes perfectly characterized in excavations made by men in the centre of lavas, which have issued from the sides of Mount Etna, in periods much posterior to the retiring of the sea."

I should, however, appear deficient in candour, did I not mention that M. Dolomicu admits that lavas may sometimes in the air assume the prismatic form, if they fall into clefts and fissures where they suddenly cool, of which he adduces an example in the

islands of Ponza.

I shall only remark, that I do not perceive the absolute necessity of the fissures in this case; since we frequently find lavas with his configuration in perfectly open places, as I have seen in the great mouth of Vulcano. And with this opinion the observations of Gioeni on Etna certainly accord; for had he remarked the concurrence of such a circumstance, he undoubtedly would have mentioned it.

What conclusion then ought we to deduce from all these facts and observations?

First: that many basaltiform lavas have assumed this organization on coagulating

within the sea.

Secondly: that others have taken the same form, merely in cooling in the open air.

Thirdly: that innumerable other lay as have not taken this figure, either in the sea or in the air.

It appears at first view that these differences depend on the different nature of the lavas themselves. This opinion at least is rendered probable by what we observe in earths penetrated with water, which in drying take more or less prismatic forms, as has been observed frequently in the argillaceous kinds. I have seen when a turbid torrent has been introduced into a ditch through an argillaceous marle, the latter in drying divided into polyhedrous pieces; but when the water passed through chalk or calcareous marle, the greater part of the pieces were amorphous. When we however observe lavas with requisite attention, this conformation in them seems to be effected differently.

It has already been said, that several of the primatic lavas of Felicuda have for their base shoerl in mass; but it is true that other congenerous lavas of the same island, which form as it were walls perpendicular to the sea, are smooth over their whole superfices, A similar smoothness is observable in some of those of Mount Etna, on the shore between Messina and Catania, which have for their base the horn-stone; though others extremely resembling them, between Jaci Reale and Catania, are formed in prisms.

Compactness and solidity are likewise not a necessary condition in lavas, to this appropriate crystallization. This has already been remarked by M. Dolomicu; and I vol. v.

have observed that many amorphous lavas on the shores of several of the Eolian islands

are more compact than the prismatic lavas of Felicuda.

What then can be the intrinsic circumstance of the lava which determines it thus to cleave in the prismatic form? I confess I am ignorant: and who can say that we do not seek it in vain within the lava, since it may be extrinsic and adventitions? Such certainly appears to be the opinion of M. de Luc; and more expressly that of M. Dolomien, who, to explain the phenomenon of volcanic prisms, has recourse to a sudden congelation,

and instantaneous contraction of lavas.

The facts which we have adduced relative to lavas, both prismatic and not prismatic, it has been seen, do not always accord with those related by the French naturalist. But even on this supposition, which is incontestable, may we not retain the same principle of explanation, which, to say the truth, appears to be sufficient, with some requisite modifications? These I will endeavour to suggest, illustrating my conjecture by the two cases above adduced; the one, that of the lavas which take the form of prisms merely from the contact of the atmosphere, as in Vulcano and near the summit of Etna; the other, that of the lavas which refuse to take such a form even within the sea, as at Ischia, in some parts of the base of Etna, and in all the Eolian isles except Felicuda.

As to the former, may not a certain coagulation and contraction have taken place in some lavas from the mere influence of the atmosphere, though the lava was not included in any eleft or fissure? It is sufficient that it be suddenly deprived of the caloric (heat) by which it is penetrated, and which rendered it rarefied and fluid. To this deprivation a lava of little thickness will be very liable, since a body loses its heat the sooner the less its thickness and density. This sudden contraction may also be produced by the circumstances of the atmosphere; as should a strong wind, of a very cold temperature, blow at the time. The melted lavas in our crucibles will be found to give greater weight to this latter conjencture. If they are taken from the furnace, and caused to pass through a heat gradually less; their surface, as they cool, will only split in a few cracks, of little depth, and usually irregular; but when they are immediately, in the winter time, carried into the cold air, the fissures, besides being deeper, will frequently be disposed in such a manner, as to form polyhedrous prisms, which may easily be detached from the rest of the lava.

With respect to those lavas which do not assume a prismatic form though they fall into the sea, it is certain that, to take that confirmation, their mass must have a strong degree of effervescence and dilatation, and that it must be deeply penetrated with the igneous fluid, otherwise the contraction necessary to produce prisms cannot take place. But many currents which descend from the summit of burning mountains to the sca, must have lost their effervescence with their heat in so long a course, and scareely contain sufficient to continue their motion downwards, which perhaps would cease, were it not for the impelling gravity of the lava, which frequently falls into the sca perpen-

Such is the hypothesis by which I would explain the cause why some lavas have assumed a prismatic conformation without any concurrence of the sea-water, and others exhibit no appearance of it in places where they have immerged into the sea. I nevertheless leave every one to form his own opinion; and should an explanation of these important facts be discovered preferable to mine, which I consider as only conjectural, I shall receive the communication of it with sincere gratitude, and adopt it with pleasure. r islands

CHAPTER XXIV.

CONCLUSION OF THE ACCOUNT OF THE EOLIAN ISLES, IN REMARKS ON VARIOUS SUBJECTS NOT VOLCANIC.

- I. LIPARI....Population of that island....Useful vegetables produced in it; among which the vine furnishes the most considerable branch of its commerce....Celebrated malmsey of this country....Manner of making that wine Scarcity of corn, which might be rendered more plentiful by adopting a different system of agriculture....Great abundance of Indian figs in Lipari and the other Eolian islands Deficious taste of their fruit Description of that shrub; and remarks on the facility with which it may be multiplied ... Project to render it much more profitable by making use of its leaves to nourish the cochineal insect, as silk-worms are fed with the mulberry leaf....Fishes and coral found rear the shores of Lipari Account of a physeter, or kind of whale, observed by the author in that sea ... This fish, though internally organized nearly like others of the mammalia class, could remain under water a much longer time than they usually can....Very few cattle of any kind in Lipari....Cause of this scarcity....Rabbits the only wild quadruped in this island....Manner of hunting them with the ferret ... Stationary birds at Lipari but few; nor any birds of passage, at least at the time the author was there Some which with us are birds of passage, there stationary Curious manner of taking swallows in the streets of the city in winter.... Branches of foreign commerce which have begun to be introduced at Lipari within these few years Remarks on the assertion of Strabo, Diodorus, and Dioscorides, that Lipari derived a considerable profit from the sulphate of alumine (alum.)....Political and ecclesiastical state of Lipari....Physical and moral character of the Liparese Brief account of the city of Lipari.
- II. STROBBOLL....The great heat felt in this island not to be attributed to its volcano, but the sum....Nature of this climate....Frequency of tempests....The shore of Stromboli destitute of a harbour....Vessels used by the natives to navigate these seas....The great quantity of fish taken in the vicinity of this island, probably a consequence of the heat of its volcano....Plants which grow in this island.... Malmsey the principal product of the country.....Vines, and the manner in which they are defended from the wind....Number of inhabitants....The natives not fearful of their volcano....Hospitality of the Strombolese....Tien character....Account of a spring, the only one in the whole island....Animals found in Stromboli.
- III. Vulcano....An uninhabited island....Great quantities of sulphate of alumine (alum) once extracted here....Difficulty of the extraction of it at present....More profit might be derived from planting vines.
- IV. Saline....Abundance of grapes in this island....Spring near the shore, probably supplied by rain water....Muriate of soda (sea-salt) extracted from a small lake contiguous to the sea.....Means of procuring this salt....Curious phenomenon observable in this lake, when the sea water enters it.
- V. VI. Felicuda and Alicuda....Their population....The houses built not on the shore, or at the foot of these mountainous islands, but about half way up their declivity, that they may be less exposed to the incursions of the Barbary pirates, who formerly have frequently landed there in search of plunder....Such incursions sometimes still made at present....Well-grounded fears of travellers in sailing round these islands....Useful vegetables in Felicuda and Alicuda....The corn of Alicuda excellent though produced but in small quantity... Extraordinary industry of the inhabitants in its

^{*} Some chapters of a theoretic nature are omitted.

cultivation ... Fishing-boats of these islands ... Ridiculous and superstitious practice of the inhabitants when a husband or wife dies Boast of the people of the Lipari islands in general, that those islands contain no kind of serpent....Physical reason of this fact ... Extreme scarcity of insects there, and the cause ... Enviable tranquillity and content of the inhabitants of these islands ... Salubrity of the air Advantages experienced from that salubrity by the author during his stay there Comparison between this very pure air, and that of some of the low plains of Lombardy.

TO complete my observations relative to these islands, I shall now proceed to give a concise account of their population, the character, manners, and customs of the inhabitants, their commerce, the animals stationary and migratory found in them, and other analogous objects, agreeably to what was proposed in the introduction to this work.

I. LIPARI.... This island is the largest and much the most populous of those called the Eolian isles, the number of its inhabitants amounting to between nine and ten thousand, a considerable part of whom reside in the city of the same name, which is very ancient.

as it appears from historical records that it existed before the war of Troy.*

If the island of Lipari be divided into four parts, about two and a half will be found to be cultivated, and the remainder overgrown with wood and barren. These barren tracts, however, continually diminish, and are converted into fruitful fields, from a kind of necessity arising from the continually increasing population of the island.

Lipari produces cotton, pulse, and olives, though in but small quantities. The corn produced there, and which is of an excellent quality, amounts annually to fifteen hundred Sicilian salme, t or two thousand at most, and is scarcely sufficient to supply the

Among the useful productions of this island the principal are grapes, of which there are several kinds. The first furnishes the common wine which is drunk in the island, and of which there is so great an abundance, that they export annually two, and even three thousand barrels (barilli) of it without the least inconvenience. They press the grapes on the spot where the vines grow, and carry the must, in leather bottles, to their respective houses on beasts of burthen.

The passola and passolina, as they are here called, are two other kinds of grapes that are dried. The last is that sort which is usually called the Corinthian grape. Of this they commonly sell ten thousand barrels annually; and of the other about twelve thou-

From a fourth kind of grape is made the famous malmsey of Lipari, which name alone is sufficient for its culogium. It is a wine of a clear amber colour, at once generous and sweet, which fills and warms the mouth with an agreeable fragrance, and a return of sweetness some time after it is tasted. But as nature usually bestows on man her most precious gifts with a sparing hand, this grape is here scarcer than any other; and does not furnish at most more than two thousand barrels annually, which the Liparese sell for foreign markets, as they do also the passola and passolina. During my stay in the island, I could scarcely procure a sufficient quantity to revive my spirits after my fatigues, and carry with me a specimen of this rare and delicious liquor to Pavia.

I was desirous to learn the method employed by the natives in making malmsey. It is as follows: they do not gather the grape until it is perfectly ripe, which is known by its beautiful yellow colour and the sweet taste it acquires. When the grapes are ga-

unered, the rotten and spoiled berries being first picked out, they are exposed to the sun on mats made of reeds for eight or ten days, or sometimes longer, till they are dried. They then place them on a clean stone floor, surrounded with a kind of low wall, about two feet high, where they crush them, first with a stone fastened to the end of a small staff or handle, and afterwards with their naked feet, till all the juice is expressed; which is then let run off through an aperture to another similar floor, the sides of which are higher; and here the must is all collected. It is afterwards drawn off into vessels in which it is left to ferment, till it is perfectly depurated and become fit to drink, which it is by the following January.

The vintage is in the month of September, at which time the Liparese, leaving the city, resort in companies to some cottages near the vineyards, where they remain during the gathering of the grapes, resigning themselves to mirth and innocent pleasures; and the voyager, who chances to approach the island at that season, finds his surprise not a little excited by the numerous lights which are exhibited during the night, and illumi-

nate and embellish these rustic habitations.

Another plant, if it does not form a branch of foreign commerce, is yet of some domestic utility to the Liparese: I mean the opuntia, commonly called the Indian fig. (Cactus Opuntia, Lin.) This shrub with us will not live through the winter, except it is preserved in hot-houses; and being in a climate not congenial to its nature, grows to no great height, and produces but few fruits, and those small and of no worth. At Lipari, on the contrary, and in the other Eolian islands, it thrives so well that it usually grows to the height of ten, twelve, and sometimes fifteen feet, with a stem a foot or more in diameter. The fruits, which are nearly as large as a turkey's egg, are sweet, and extremely agreeable to the palate, and of very easy digestion. When unripe, their skin or rind is green; but when ripe, of a reddish yellow. This plant will take root and grow, in a surprising manner, in almost any situation which has a favourable aspect, and the most favourable is the southern. It thrives alike in the poorest and the richest soils, the fissures of lavas, among the ruins of ancient buildings, on fragments of dried mortar, and in the crevices of walls. It is well known that the fruits grow at the edges of the leaves; the number on each leaf is not constant, but they are frequently numerous, as I have counted two-and-twenty on a single leaf. They begin to ripen about the beginning of August, and continue to November. In some situations, indeed, where they enjoy the benign influence of the sun, they remain through the whole winter; and even where they have not that advantage, they may be preserved ripe and in good condition during the winter, by being gathered green in autumn, and left attached to the whole or a part of the leaf, the juice of the leaf, which is always thick and pulpy, affording a nutriment to the fruit.

The inhabitants of Lipari eat these fruits during several months of the year; for as there is great abundance of them, they are sold at a very low price. Besides those which nature produces here spontaneously, the Liparese industriously cultivate great numbers of these Indian figs, and the method of multiplying them is very easy. It is well known that this plant is propagated by means of the leaves, which are of an oblong shape, narrower at one extremity than at the other, and resembling a peel or shovel, by which name they are called by the Sicilians. Every leaf is thick and pulpy, and each side of it scattered over with small buttons or knobs, from which arise a great number of little prickles, with a large one in the centre, of the length of an inch. If these buttons only touch the earth they take root, let the ground be what it may. The leaf which has taken root puts forth other leaves that again produce others; and from being flat, as it was at first, becomes in time round, and forms a trunk which lengthens and

thickens in proportion as the other leaves grow and multiply. For the stem or trunk of the Indian fig, which, as I have already said, is sometimes more than a foot in diameter,

is only a series of leaves in an upright position, and adhering to each other.

Such are the different vegetable productions of the island in Lipari, which however, with respect to commerce, may be reduced to one only, I mean the grape. Corn, as we have seen, from its scarcity, searcely deserves to be mentioned; but this might be grown in far greater quantity, were the system of agriculture prevalent at present in this island changed. It is here the general practice to raise the vines two or three feet above the ground, and with poles and reeds to form a kind of squares by which they are supported. The consequence is, that the vines with their branches and leaves form a kind of covering, impenetrable to the rays of the sun, which renders the soil below entirely barren. Several of the natives of Lipari have had the good sense to perceive the inconvenience of this practice, and, disregarding the prejudices of their countrymen, have changed these pieces of barren ground into fruitful corn-fields, without the least detriment to the fruit of the vine. The abbate Gactano Trovatini, whom I have elsewhere mentioned with deserved commendation, is among the number of the few who have made this liberal experiment. I saw a field of his which, though not very extensive, nor of a better soil than others, produced both a plentiful harvest and an abundant vintage. Instead of planting the vines in the narrow squares there called pergole, he has ranged them in parallel espaliers with wide interstices of ground between them, in which he has sown corn in straight furrows, after the method of Du Hamel. Thus the air and the sun exert their influences freely between the espaliers, and not a foot of ground is lost to cultivation. The grain yields a luxuriant crop, and the vines are at the same time not less fruitful than those of the neighbouring grounds, where the old method is adhered to. It is true that Trovatini, like Caius Furius Cresinus in ancient times, is surveyed by many with an eye of ill-natured envy, when they compare the wretched appearance of their grounds with the copious produce of his. But even while I was there, several of his neighbours had begun to imitate his example. It is much to be regretted that Don Giuseppe Cippola of Palermo, the late bishop of Lipari and the adjacent islands, did not live some years longer. That worthy prelate seemed to have been born for the improvement of the soil of those countries, which before were wild and little productive. The number of clive-trees which he caused to be planted is incredible. I found above three thousand in Panaria alone. He also introduced mulberrytrees there, which have thriven extremely well. I saw one in a court-yard, planted eight years ago, which in size and strength did not in the least yield to ours of the same age, though the latter have the advantage of a more suitable soil. He has likewise enriched the island with another species of the Indian fig, brought from Palermo, the fruit of which is red and extremely delicious. I sincerely wish his successor, who is unknown to me, may follow his excellent example.

Since I have again mentioned the Indian fig, I cannot avoid noticing an idea which has occurred to me, and which, should it ever be carried into effect, must be productive of great advantage both to Sicily and the Eolian isles. The cochineal insect (Coccus Cacti, Lin.) is bred and collected in Mexico, and other Spanish provinces of South America, and the commerce carried on in it is estimated at many millions of dollars annually. Might not the advantages derived from this precious drug be shared with Mexico by the Lipari islands and Sicily, which may be considered as the most southern part of Italy, from which it has been separated by the irruption of the sea that produced the strait of Messina? To effect this, two things indeed are necessary; the plant on which the insect lives and propagates, and the insect itself. The plant is that usually

called the Indian fig, and which is found in such abundance in the Eohan isles and Sicily, where I have seen the foot of Etna covered with it. Travellers relate that the opinitias of Mexico, where they are cultivated with the greatest care, grow to the height of eight feet, and that the leaves of some of them are nearly a foot in length. We have said that those of Lipari, and the same is true of the rest of the Folian isles and of Sicily, rise to a greater height, and have leaves more than a foot long. If therefore these plants thrive as well in Sicily and the Eolian isles as in America, and perhaps better than they do there, why should not the cochineal insects, which feed on them, thrive equally in those countries? Will not the silk-worm, though originally from India, live and multiply in every country where it can be supplied with the leaves of the mulberry-tree? The only difficulty, in my opinion, would be the conveyance of this useful insect to so great a distance, principally because it could not be removed in the egg, since it is viviparous, and not oviparous. It should be observed, however, that as the Americans perpetuate the cochineal by means of the leaves of the opuntia, it no doubt would continue to live on the leaves of that plant; which might be brought, growing in large vessels filled with earth, from Mexico to Sicily. The important advantages to be derived from the success of the experiment, at least would sufficiently justify the labour and expense of the attempt. I am not ignorant of the jealousy and reserve with which the possessors of this insect, which is so valuable to them, guard it from foreigners to prevent their stealing it. Such a theft has, however, been practised on them to the advantage of some of the French provinces. I know likewise that the hint I have here given, should it ever be carried into effect, would not be agreeable to the political views of Spain; but an Italian and a philosopher may surely be permitted to propose it.

I shall now dismiss the vegetables, and proceed to say a word of the fishery of Lipari, than which nothing can be more wretched. Not that the sea does not contain fish; but because there are but few there who follow fishing as an occupation, and even of these the greater number are not provided with the necessary implements. They only use the fine and hook, and the sciabica, a kind of net, which they throw to a considerable distance into the sea, and then drag on shore. This mode of fishing is only used in the harbour, and not very frequently, at least in the summer, though I have been told that in winter it is more common, as they are then without other employment. I have often been present at their throwing the net, less from curiosity than to procure fish for my small table: but those days proved unpropitious to the fishermen, and not less unlucky to myself; since after three or four throws they either caught no fish, or those so

few and small, that had I nothing else to cat I might have died with hunger.

In June and July they likewise fish for coral, both round the shores of Lipari and at Vulcano. When I was there I procured a rare specimen, consisting of a branch of coral which had grown on a volcanic enamel under the eastle of Lipari. Fifteen barks, I was told, are usually engaged in the coral fishery; but either because they are ignorant of the proper methods of detaching this valuable animal plant from the rocks and caverns of the sea, or because they are not sufficiently expert in the use of them, this fishery is very unproductive. In the two months above-mentioned, every bark carrying eight men fished up ten or fifteen rotoli of coral; and the rotolo contains two pounds and a half, and the pound twelve ounces.

Formerly coral was likewise fished at the Secea di Santa Caterina, a place distant ten miles from the harbour of Lipari; but some barks having been wrecked there, the bishop of that time, Father de Francisci, a Dominican, fulminated his excommunication against any bark which in future should have the temerity to attempt to fish in that place.

In my various maritime excursions round the Eolian isles, I never met with any of those smaller cetaceous fish which are frequently found in other parts of the Mediterranean. But one day when the sca was calm, while I was sailing between Panaria and Vulcano, a large cetaceous fish of the genus of the physeter, and which, from a long fin on the back, I judged to be the Tursio of Linneus, suddenly rose to the top of the water. It approached within about seventy feet of my boat, and I had sufficient opportunity to observe it with some attention. It is well known to mariners as well as naturalists, that dolphins, physeters, and whales, properly so called, have need of respiration from time to time, and therefore frequently rise to the surface of the water with the upper part of their bodies, and throw up, from one or more apertures they have in the head, one or two ejections of water accompanied by the air they have taken in, and inhale fresh air. The ectaceous fish of which I now speak did the same; and when he came to the surface of the water, and drew along the half of his body above it, he was so near that I could estimate his dimensions with the eye. He was at least twenty-eight feet long, and the breadth of his body, where largest, not less than eight feet. The caudal fin was eight fect in length, and the dorsal two. At every expiration a hissing sound was heard of air and water, which he ejected to the height of eight or nine feet. A little before he made this ejection, he raised nearly the half of his huge body above the water, but after five or six minutes again sunk and disappeared. I wished to observe the interval of time between one ejection and another, as the animal continued this alternation for a full quarter of an hour. I perceived they were repeated after every sixteen or seventeen seconds, and I flattered myself that I had ascertained with sufficient accuracy the space of time that one of this species of fish can remain under water without being obliged to rise to the surface and inhale air; but I soon found this calculation erroneous. After my curiosity had been gratified with this scene about a quarter of an hour, the animal raised his tail vertically about three feet above the water, and plunging directly down disappeared; nor could I again discover him, though both I and the four mariners who were with me watched with the utmost attention during a quarter of an hour: and certainly had he in that time raised himself to take in air, we must have seen him, from his great bulk and the calminess of the sea. I then perceived that this animal, though in his organization in a great measure resembling the class of mammalia, and therefore, like them, under the necessity of respiring, could yet remain a much longer time under water than they can.

But if aquatic animals are of little advantage to the inhabitants of Lipari, their land animals are nearly of as little. Both large and small cattle are there extremely scarce; and the few oxen and cows which are slaughtered there are brought from Sicily, and are very lean. This is entirely to be ascribed to the poverty of the pasturage. The

Liparese cultivate themselves the small portions of land they possess.

With respect to wild quadrupeds, the country produces only rabbits, which make their burrows in the mountainous parts, where the volcanic matters, principally of the tufaceous kind, permit them to dig with their feet. They are hunted with the ferret (Mustello Furo, Linn.) and the chace is very amusing. Though this animal be originally from Africa, it will live and propagate in the southern countries of Italy. It is about the size of the common cat, and in its make something between the weasel and the pole-cat. I have seen them extremely tame at Lipari, where they breed as fast in the houses as when wild. The sportsman who goes to eatch the rabbits takes with him the ferret in a cage, and a dog. The latter, when he sees the rabbit, follows him to the hole in which he takes refuge; or, if he is under ground, discovers him by the

scent, and stops at the mouth of the burrow. The sportsman then puts the capestro, a kind of muzzle made of packthread, on the ferret, that he may not bite the rabbit; as otherwise he would kill it in the hole, and after having sucked the blood, leave it there. Being unable to seize it, he only scratches it with his claws, and terrifies it till it endea yours to make its escape out of the burrow, and is taken in a net placed for the purpose. The ferret follows it out, and is again put into the cage.

These rabbits are smaller than the tame ones, and, like others that are wild, are of a gray colour. Not that they are originally such; since it is within memory that they were first brought there by one of the natives, where they have, as is usual with them, multiplied prodigiously. But nature, put under restraint by man, never fails to restore to animals which regain their liberty, the size and exterior habit of body which they

had in their original state.

The birds stationary here are but few. They are the partridge (Tetrao Perdix, Lin.) the greenfinch (Loxia Chloris, Lin.) the sparrow (Fringilla Domestica) the goldfinch (Fringilla carduelis) the horn-owl (Strix Scops) and the raven (Corvus Corax.) The latter is usually found about the cultivated fields near the stoves, and on the steepest rocks, though sometimes in places sufficiently accessible for the young ravens to be taken.

Of those kinds of water-fowl which migrate from one sea to another, according as they find food in greater or less plenty, and pass indifferently from the salt water of the sea to the fresh of rivers, lakes, and ponds, such as the different kinds of sea-gulls (Lari Linn.) and the cormorant (Pelicanus Carbo) I did not see one here. Indeed it is very

rarely that any kind of water-fowl is seen in the Eolian isles.

It is not the same with the birds of passage. In April the turtle-dove (Columba Turtur) and the quail (Tetrao Coturnix) arrive here, and stay a few days. They come in the same manner in September. Several kinds of swallows are common here (Hirundo rustica, urbica, apus, melba.) The two latter make their nests in the fissures of the rocks, and in the highest walls of the city of Lipari. When I left that city, which was on the 15th of October, some swallows of the first and last species were flying over it. I shall likewise observe, that on the night of the 13th of the same month there was a dreadful tempest with lightning, rain, and hail; and the next day, early in the morning, a strong south-west wind blowing, I saw in the air, over the eastle of Lipari, at least a hundred common house-swallows, though they soon after disappeared. Reaumur's thermometer that morning stood at 15\(\frac{1}{2}\) degrees above zero (67\(\frac{1}{2}\) of Fahrenheit.)

In some conversations relative to swallows, which I had with Doctor Trovatini and several other persons at Lipari, they related to me a fact which I had before heard at Stromboli, and shall again mention when I come to treat of that island. It is that in winter, and when a sciroccal or warm southerly breeze blows, swallows of one or other of the four species above mentioned are frequently seen to skim the ground in the streets of the city, and are then easily knocked down with long sticks by children, as they are extremely wet. The two latter kinds are even taken with hooks and lines fastened to the extremity of a long reed. A small feather is fastened over the hook, and the boy who holds the reed conceals himself behind the corner of a street, and waves the feather in the air. The swallow, accustomed to eatch insects as it flies, takes the feather and is

caught by the hook.

From these observations we cannot but conclude, that these swallows do not pass into Africa at the approach of winter, as many have believed, but that they more probably remain in the island, and issue from their retreats in the warm days of winter in quest of food.

VOL. V.

I saw likewise at Lipari, while making the circuit of the island by sea, a fifth species of swallow, the swallow of the bank (Hirando riparia, Lin.) This bird is so denominated from building its nests in the banks of rivers, and sometimes the shores of the sea. I observed several of these swallows flying about the rocks of tufa, which descend almost perpendicularly into the sea; and having stopped there some time with my boat, I saw more than one of them go into and come out of the holes they had made in the tufa. I was told by the people of Lipari that this kind of swallow appears in March, and disap-

pears in October.

In the introduction to this work I have mentioned that it was my intention to add to the observations I should make on the swallows of Lipari and Sicily, others which I had made on the same species of birds in Lombardy; which addition would not have been so long, but it might have been here conveniently subjoined. But having afterwards more fully considered the subject, and made new and various experiments to chicidate the great controversy, whether swallows remain torpid during the cold weather, of which I have slightly treated in my other works (see my Annotations on the contemplation of Nature, and Tracts on Animal and Vegetable Physics;)* and having afterwards extended those experiments to other animals which are in like manner torpid in winter, and especially those whose blood is cold, as the common hedge-hog (Erinaceus Europaeus, Lin.) the marmot (Mus Marmota) the dormouse (Mus avellanarius) the bat (Vespertilio) I found my matter so increase on my hands, that I determined to publish my observations on this subject separately, after having finished the work in which I am at present occupied.

We will now proceed to notice some other particulars relative to Lipari and its inhabitants. Foreign commerce has begun to be introduced into the island by the mariners, most of whom traffic in what they call gallantry-wares. They every year buy, at the fair of Sinigaglio, linen, muslins, veils, and other commodities of that kind, to the value of from thirteen to fourteen thousand Sicilian oncie,† and sell them at Messina, Catania, Palermo, and other parts of Sicily. This trade is very advantageous to the country, and many have acquired considerable wealth by it. It has however considerably diminished

the fishery, and raised the price of fish.

Strabo, Diodovus, and Dioscorides, write that the sulphate of alumine (alum) was procured in great abundance at Lipari. The truth, however, is, that none whatever of that salt is now extracted in the island. I have passed over almost every foot of ground in it, and only found some traces or efflorescences of it, as I have mentioned in the proper places, which, with respect to profit, would not pay the labour of collecting. We must therefore conclude that the vein of this mineral has either been exhausted or tost; or that the Liparese procured it, not from their own island, but the neighbouring one of Vulcano, which is still rich in this sulphate. The latter is perhaps the most probable explanation of the authorities above alleged.

The political administration of Lipari is composed of a criminal judge, a fiscal, a governor who has the chief authority both in military and civil affairs, and who is com-

monly an old invalid, and a civil judge.

The bishop, seventeen canons of the first order, and fourteen of the second, and from a hundred and twenty to a hundred and thirty priests, form the ceclesiastical establishment.

The Liparese are in general of a prompt and lively wit, ready to learn, of acute penetration, and extremely desirous of obtaining knowledge. Hence, when any learned stranger visits their island, there is no end to their questions and inquiries. They willingly become his guides to their stoves and baths; and there is not one among them who is ignorant that his country was once produced by fire. The seat of the court of king Æolus is contested in the Eolian isles, as the birth-place of Homer is in Greece. He is claimed by each of the islands; but the people of Lipari are fully persuaded that the royal residence of this petty sovereign was in their island; and those among them who have some little tineture of literature, can cite the authority of Homer and other writers in proof of their assertion.

A beggar is scarcely ever to be found in Lipari; for even the poorest persons have some small piece of ground which they cultivate, and by the produce of which they

live.

The natives are usually robust, strong, rather of a large size, and comely. When young they have fine complexions; but latigue will diminish every kind of beauty, even that of the fair sex. This change is greatly accelerated by the heat of the sun; the effects of which are conspicuous in their tanned skins and swartly countenances.

If it was a disgrace in Greece to be unable to swim, it is not less shameful in Lipera and the other Eolian isles, to be ignorant either of that art, or that of managing the oar, or steering and handing the sails of a vessel. The priests are very expert in every exercise of this kind. The greater part of them have, like the sailors, their arms or handmarked with black indelible stains representing either the crucilix or some saint. I knew, at Lipari, a man of considerable property, and who was honoured with the title of baron, who was marked in this manner, having formerly been a mariner.

The city of Lipari is not of an extensive circuit, and consists rather of narrow alleythan streets. The eastle is surrounded with a wall on which are mounted a few can non, and is defended by a small garrison. The houses are very indifferent buildings, but three edifices are distinguishable from the rest. These are the palace of the bishop the house of the governor, and the eathedral church. The latter contains very valuable sacred utensils, and a great quantity of plate and silver images, among which is the statue of St. Bartholomew, their patron saint. These have been collected entirely at the expense of the people, and the value of this treasure is said by those who understand it to amount to ninety thousand Neapolitan scudi.*

II. STROMBOLI.... Though both Stromboli and Lipari lie nearly under the same degree of latitude, or 38° N, the former is much hotter in summer than the latter; especially near the sea, on account of the strong reflection of the rays of the sun from the large tracts of sand. It does not appear probable, however, that this heat is to be attributed to its volcano, since, excepting a few places near its mouth, if we dig into the

earth, we find the ground less warm at some depth than on the surface.

The winter here is always mild; it never freezes; and snow, which is seldom seen, if it fall one day, melts the next. Its greatest depth is about two inches; and it is related as a prodigy, that, some years since, snow fell on the first of November, to the depth of a palm (or nearly a foot.) On the summit of the mountain indeed, snow falls more frequently, and sometimes will remain for a fortnight; which proves the height of the mountain to be very considerable.

^{*} The Neapolitan scudo is worth about 4s. 3

The sea round this island is frequently agitated (i.e., 18, and the fact I am proceeding to mention will show to how great a height its (iii), billows beat.

About a mile from the land, on the north-east side of the island, rises a spacious naked rock, called the Rock of Stromboli. It consists of one entire piece, has rugged points at the top; and its base, where it is washed by the water, is about a quarter of a mile in circuit. Its greatest height is three hundred feet. This rock is a huge mass of lava, which, probably, once was joined to the island, and has since been separated from it by the violence of the sea. The natives of Stromboli have observed that, in very great storms the billows rise to one half the height of this rock; and some of them have assured me that they have twice in their time seen the waves rise above the top of the rock. As therefore, in general, the agitations of the sea are only a consequence of those of the air, we may form some conception of the fury of the winds, which are here more violent than in any of the other Lipari islands. These hurricanes, which frequently arise on a sudden, lay waste the plantations, and wreck the barks exposed to their fury. To avoid as much as possible the effects of their violence, the houses here are built very low.

The shore of Stromboli has neither port nor harbour, and vessels can only seek some little refuge, in case of heavy storms, on the back of the island. Large ships, except compelled by necessity, never anchor there, from fear of running on sand-banks. The vessels employed by the natives for their own occupations are feluceas, which, being extremely light, are easily drawn upon land, and as easily launched again into the sea.

The fish here are very plentiful and large, especially the sea-cels and murenas; and, during my short stay in this island, I saw a greater quantity taken than during the whole time of my continuance in all the other Eolian isles. They are likewise of an excellent taste. This abundance I am inclined to attribute to the volcano, which has continued incessantly burning from time immemorial; and which extending to an immense depth must necessarily communicate a part of its heat to the submarine base of the mountain, and to the waters that surround it, in the gentle warmth of which the fish find a more agreeable place of resort, and perhaps propagate in greater numbers than elsewhere. The fishery, however, produces here no branch of commerce, and only serves to supply the island, principally the foreigners who visit it; as the natives usually live on salt meat, and strangers can rarely find any food so agreeable to their palate as fish.

The vegetables that grow in Lipari are found here likewise, and nearly in the same proportion. Malmsey is the greatest article of traffic of the people of Stromboli; they convey it in barrels to Lipari, where they find a ready sale for it. The vines producing the passola and passolina grape, and that from which the malmsey is made, grow on the sea-shore; and those for the common wine, on the sides of the mountain. Some of them are fastened to trees; but they are all planted in vineyards; and, where these are situated high, they are surrounded with thick reeds, which at once support and defend them from the wind. The vines form a chain to the north-east, and are all planted in volcanic sand.

The habitations of the islanders are built in the same part, and under the same aspect. They are an irregular assemblage of cottages and fishermen's huts. The population of the island amounts to about a thousand persons, and has been for some time increasing; in consequence of which exertions have been made to enlarge the cultivable ground by clearing away the woods. They have no fear of their volcano. Neither they nor their dathers having ever seen torrents of lava burst forth from its furnace and spread desolation around, as has happened from time to time at Ema and Vesuvius; they survey its more constant fires with an eye of indifference and security.

Mr. Broydone, in his tour through Sicily and Malta, tells us that, notwithstanding his great desire to visit this volcano, the only one of its kind, he did not venture to land at Stromboli for fear he should be ill used by the inhabitants, whom he believed to be little other than savages. On the contrary, M. Dolomieu was very civilly received by them. The treatment I received from them, and the conversations I had with them, likewise convince me that the English traveller must have been very wrongly informed. The character of these islanders is nearly the same with that of the inhabitants of other villages at a distance from, and having no communication with, populous cities; I mean they are simple, honest, and, having but few ideas are contented with the little they possess. Their longest journey is usually to the city, which, though it is small, appears to them wonderfully magnificent; and when they first enter it, they are affected like Dante's rustic:

"Non altrimenti stupido si turba Lo Montanaro, e rimirando ammira, Quando rozzo, e selvetico s' inurba."

"Thus the rude clown who, for the first time, views Of some throng'd capital the wealth and pride, Gazes with open mouth, in wonder wild."

A little above the base of the mountain, on the east side, is a small spring, the scanty supply of fresh water from which would be inadequate to the wants of the inhabitants, were it not for a more copious and inexhaustible stream at a little distance from it, which furnishes them with water to dispel their thirst, and without which they could not exist, when, in summer-time, the rain-water they have preserved in their disterns is entirely exhausted. M. Dolomicu, who visited this fountain, supposes it to owe its origin to evaporation caused in the mountain by volcanic heat and succeeded by condensation at a certain height, it not appearing to him possible that this spring should have its reservoir in the higher parts of the mountain: as these are composed of sand and porous stones, and therefore are unfit to retain water. This hypothesis is certainly both ingenious and probable; but may not another be equally probable which supposes this spring to be supplied from the summit of the island, where the earth being sandy and full of pores, the rains easily penetrate it and collecting in the cavities below form a mass of waters at all times sufficient to supply the spring? According to this hypothesis, the reservoir will not be on the surface, but in the internal part of the mountain. The objection that the heat of the volcano would reduce such a body of water to vapour will be found to be of little weight, since the spring is more than a mile distant from the crater; and it is very probable that the activity of the fire does not extend so far; indeed it seems almost certain; for we do not perceive for a considerable space around it, not with standing the porosity of the earth, the slightest trace or indication of those fumes which are the most certain indication of subterranean fires. In fine, the origin of this spring, which never fails, can only be explained in the same manner as that of other fountains of Iresh water in other islands.

We find here no stationary birds whatever. Attempts have been several times made, but in vain, to naturalize partridges here. The experiment has succeeded better with rabbits. Those formerly brought have multiplied and continue to multiply; living in their natural wild state, in the woody part of the island. The musket and the ferret are their only enemies.

The birds of passage are the same as at Lipari. When I was at Stromboli in the beginning of October, I saw three swallows (Hirando rustica, Lin.) flying over the island; and several of the inhabitants assured me that they frequently re-appear in winter, when a warm wind has rendered the air warmer than ordinary.

III. Vulgano....This island is not inhabited, nor is it remembered that it ever was. It is more than probable that its numerous cruptions have occasioned it to be thus descreted. It is not, however, more than a century since it was of considerable utility to the people of Lipari from the quantity of sulphur and sulphate of alumine (alum) they procured from it; bringing away annually, if we admit the estimate of Pietro Campis,* to the amount of four thousand cantara† of the former, and six hundred of the latter. We have already mentioned the sulphur of this island, and the difficulties with which it is procured, in Chap. XIII. Sulphate of alumine still abounds here; but the extraction of it is attended with the same difficulties as that of the former mineral. These are occasioned by the numerous sulphureous fumes, and the heat, which exhale from the subterranean caverns, and which are found the strongest in the places where that salt most abounds. I am, therefore, of opinion that, at the time these substances were dug here, the state of the volcano must have been different.

The people of Lipari might, however, if I am not mistaken, derive another more stable advantage of which they have hitherto been ignorant, or have neglected, from this descrited island. This would be obtained from the productive plantations that might be made in the southern parts of the island, to which, for a great length of time, the fire has never extended its injuries. This part of the island consists of a softened and half-crumbled lava, similar to that of Stromboli, where vines thrive so well; nor can I discover why they should not succeed equally well in Vulcano. The same idea has occurred to Trovatini; and the bishop of Lipari, whom I have before mentioned with the respect which is due, told me that he had thoughts of attempting the cultivation of Vulcano by sowing corn, and planting vines and fruit-trees.

The bishop likewise communicated to me another idea which I did not expect. He said he had conceived the design of building a seminary in that island, for the education of twelve youths, sons of the peasants, who should be brought up to the service of the eathedral, and of the parish churches of the other Eolian isles. He very justly thought that these youths, having been born and educated in the islands, would be better fitted for, and more attentive to, the discharge of such duties. Whether since the death of this prelate any attempts have been made to carry his useful plans into execution, I cannot say. The little disposition which those who succeed to any office usually shew to complete the project of their predecessors, inclines me to think it very doubtful whether Vulcano will not stell remain in its former deserted and barren state.

IV. Saline....Didyme, or, as it is at present called, le Saline (or the salt-pits) is very different from Vulcano. This island in many parts has its skirts covered with cottages, and abounds in vines, the grapes of which yield wines not inferior to those of Lipari.

At a little distance from the sea, near Santa Maria, a continual spring of fresh water rises. The great heat of many such springs is usually an unequivocal sign, if not of the existence of a volcano, at least of subterranean effervescences. This, however, when I examined it by the thermometer, appeared to be two and a half degrees cooler than the temperature of the atmosphere. It formerly issued nearly on a level with the water

^{*} Disegno Istorico della Citta di Lipari.

[†] The Neapolitan cantara or quintal is of two kinds; the grosso, or the great, and the piccolo, or the fittle. The great cantara contains 100 rotoli, and 3 rotoli make 8 pounds 4 ounces Neapolitan weight, the pound containing 12 ounces. The little cantara contains only 100 such pounds. T.

⁴ I shall here observe that excepting some places in Stromboli, Vulcano, Lipari, and a spring in Uclicuda, I never could perceive, though I used the thermometer, that the Eolian isles, other circumstances being the same, are warmer than Messina, the coasts of Calabria, and other neighbouring countries which are not velocatic

ccolo, or the itan weight,

a spring in hereircumeighbouring of the sea, with which it frequently mixed, and thus became almost useless to the inhabitants; but this inconvenience has within these few years been remedied, by a vertical section being made in the shore; in consequence of which it now issues fifteen feet above the level of the sea. It is very abundant, and throws up five streams of water, each about an inch in diameter, which is very extraordinary in a volcanic island; at least

in any of those of Lipari.

This plentiful spring, there can be no doubt, is supplied by rain-water, as, in the present time, the opinion that fountains and rivers are immediately derived from the sea, is entirely exploded. The rains, however, by which it is nourished are not to be sought in remote countries; they can only be those which fall on the island. It must at the same time be confessed, as I was assured by the natives, that there has sometimes been no rain there for nine months, and yet this spring, in all that time, did not appear to suffer the smallest diminution. In what manner then shall we account for this, if we ascribe its origin to rain-water? I can see no absurdity in the supposition, on the contrary, it appears to me extremely probable, that, in the internal parts of an island which, like this, is the work of fire, there may be immense caverns that may be filled with water by the rains, and that in some of these which are placed above the spring, the water may always continue at nearly the same height, and a long drought consequently produce no alteration in the spring. By a similar hypothesis, which does not appear to me at all forced or unnatural, we have explained above the origin of the spring which continually flows in Stromboli.

I have already mentioned that this island received the name of Saline (salt-pits) from the muriate of soda (sea-salt) which is obtained in it. A brief account of this product, and the place where it is procured, may not be unacceptable to my readers. Close to the shore, on the south-east side of the island, there is a lake of about a mile in circuit, separated from the sea only by a bank of lava, not formed by art, but by the sea itself, which has raised it by the beating of its waves. It appears indubitable, that this lake was once a small bay or creek of the sea, which has been shut out by the accumulation of the lava, though its waters are still admitted by secret channels; since, notwithstanding the continual evaporation, the lake remains full. In consequence of this continual evaporation, however, the water in it becomes salter than that of the sea, and in consequence forms a crust of muriate of soda (sea-salt) on its banks. The lake has every appearance of being very ancient, but had been long neglected; until in the year 1750 an attempt was made to render it more advantageous, under the direction of a native of Trapani, who was unacquainted with the nature of salt works. He first drained the lake, and then dividing it into thirty square pits, each separated by high banks, let in the seawater to a certain height, which gradually evaporating by the heat of the sun, which in summer is there very great, left on the sides of the banks, and at the bottom a stratum of salt. This method has been continued since, and the salt collected twice or thrice every year, according as the heat of the season more or less favours the evaporation. The quantity procured is sufficient to supply all the Lipari islands.

The inhabitants from whom I received this account related to me at the same time a fact that excited my surprise. The sea in a violent storm making its way into the lake, carried with it a number of fish of the cephatus or chub species, which continued to live in the lake as in their native element. They multiplied very fast, notwith-standing the water by a new evaporation was rendered extremely salt; and when they were afterwards taken out, they were found to be very fat and well-flavoured. This the more surprised me, because some years before, in another part of the Mediterranean, that is, where the river Magra falls into the sea, near Carrara, I had observed this species of

ash delight in water almost fresh; leaving the open sea for the mouth of the river, and appearing to seek those places in which the sea-water, mixed with that of the river, and less saltness; to which places the saltermen resorted to catch them. Other species of sea-fish without number of a very different nature, not being able to live in water which is salter than that of the sea. Thus near Chiozza, in the Venetian state, I have found some which presently did when put in water saturated with muriate of soda (sea-salt) nearly the same with that of the lake above-mentioned, and prepared for the same use. Such a difference of temperament in animals formed to inhabit the sea must doubtless be the result of a difference of organization, though we are ignorant in what it consists, less perhaps from the difficulty of discovering it, than from our not having directed our

inquiries towards this part of the animal economy.

V. VI. Felicuda and Alicuda.... These two islands are the last of those of Lipari towards the west. In Felicuda the houses are scattered over the whole island, which contains about six hundred and fifty inhabitants; but in Alicuda, the population of which is not so great, they are built only at the south and south-east end of the island; it being in fact impossible to build them any where else, the rest of the island consisting only of cliffs, and crags, steep precipices and inaccessible rocks. It is observable that these houses, or rather cottages, are not erected at the shore, or base, of these mountainous islands, but about half way up on the side which has a very steep declivity, where likewise stand the houses of the two parish priests. I at first was unable to conceive why a situation so difficult to reach, from the steepness of the ascent, had been preferred for their houses to the lower parts of their islands, which is much less steep and nearly level with the sea. But I was told by both the peasants and the priests, that this situation had been chosen by their ancestors because that formerly Felicuda and Alicuda, being the most remote from the principal island, were greatly exposed to the attacks of the Turks, especially the Tunisian corsairs, who frequently landed there in the night, surprised the islanders while asleep in their houses near the shore, plundered them of their goods, and carried them away into slavery, as they have sometimes made similar predatory descents, in the present times, on the coast near Genoa. The people of Alicuda and Felicuda on this account built their houses where the danger was less. The Eolian islands are indeed still liable to such visits from their African neighbours. It is true the latter do not always succeed in their design, but sometimes pay dearly for their temerity; yet it is necessary for the islanders to take every precaution, on which account there is a centinel stationed on the Monte della Guardia at Lipari, who is on the watch night and day. This, however, does not deter the barbarians from frequently stretching over to those islands; where they lie in wait under a rock, a cape, or a point of land, till they see some small vessels, when they dart like vultures on their prey incapable of resisting their force, and setting their sails, if the wind be favourable, or abouring with their oars, are soon out of sight of the islands and in the open sea; where it little avails the unhappy wretches they have made slaves to lament their fate or sue for mercy. I will confess that, frequently while making the circuit of these islands, I was not without my fears that I might in this manner be carried to make observations of a very different kind on the neighbouring coasts of Africa.

Besides Indian figs and some olive trees, these two islands contain many vines, from the grape of which a good wine is made, though it is not malmsey, nor the grape the

passola or passolina.

The corn grown here is barley and wheat; of which, together with the grapes, there is produced in Alicuda to the value of about three thousand Neapolitan crowns; and about one third more in Felicuda. This quantity of corn is sufficient for the support

ot with-

very dif-

es, there ens; and support of Alicuda; but the produce of Felicuda is not sufficient for it; the Liparese, who are owners of a number of the small farms there, carrying away a considerable quantity.

The industry and patience of the people of Alicuda is incredible: they do not lose an inch of the ground they cultivate. There is scarcely a tract of cultivable land of a few perches in circuit, which is not interrupted with points of rocks, masses of laval clefts, and crags: yet all these tracts they render productive: they turn and break them with pointed spades, and render every foot of them fruitful; on which account the Liparese say, jestingly, that the people of Alicuda till their lands with the point of a knife. It is certain, at the same time, that in all the Eolian isless there is no better bread than that made in Alicuda. I have tasted it, and can affirm that it is most excellent.

Few fish are taken in these islands because there are but few fishermen, and these have no nets, but only use the hook and line. The whole number of boats, likewise, either used for fishing, or to pass from one island to the other, is only five or six in Felicuda, and three or four in Alicuda. When they no longer want to use them, they draw them up out of the water on the dry beach, where the sea cannot reach them, till they again have occasion for them. One or two of these boats usually belong to the parish-priest, who not only makes use of them in fishing, but for other purposes; as to go to market to Lipari, or to accommodate a stranger, in which case he will not refuse to act as pilot, or, on an emergency, as rower. Necessity, the mother of industry, impels these good priests to endeavour to find employment, as they could scarcely live, however wretchedly, one half the year, on their ecclesiastical revenues, which amount to little more than twelve sequins annually for each island.

At Felicuda, when the husband or wife died, it was a custom considered as a kind of sacred duty for the nearest relations to follow the body to the grave with loud and immoderate lamentations, and, as soon as the obsequies were finished, to throw themselves upon the corpse, embrace it, kiss it, speak to it with a loud voice, and give commission for the other world. This ridiculous practice, which is not modern, has been

abolished by the present priest.

In neither of these islands is there a single spring of fresh water. The inhabitants are therefore obliged to have recourse to the rain-water they can preserve in eisterns; and

when it happens not to rain for several months, their distress is extreme.

The people of Alicuda and Felicuda, in fact, of all the Eolian isles, boast that their islands are exempt from every kind of serpents; and, indeed, in all my excursions in them, I never met with one. The reason of this evidently is because the food necessary for these creatures is wanting: they feed principally on insects and other small animals, of which I found here very few. The searcity of these latter is likewise to be accounted for on the same principle; as it is known that they feed on vegetables chiefly of the herbaceous kind, which in these islands are extremely rare.

Of other animals of the amphibious kind I only met with the gray and green lizard (Lacerta agilis, Lin.) and with respect to insects, only some grasshoppers and the lionant (Myrmeleon formicarius, Lin.) which are found in great numbers among the dust

of the pumices and lavas.

VOL. V.

The prople of these islands may likewise boast of an advantage incomparably more important; I mean, that their sovereign, in consideration of their poverty, has exempted them from every kind of taxation, only paying tythes to the bishop, from which however the people of Lipari are exempted.

It is incredible, at the same time, how contented these islanders are amid all their powerty. Ulysses, perhaps, cherished not a greater love for his Ithaca, than they bear to their Eolian rocks, which, wretched as they may appear, they would not exchange

for the Fortunate Islands. Frequently have I entered their huts, which seem like the nests of birds hung to the cliffs. They are framed of pieces of lava ill joined together, equally destitute of ornament within and without, and searcely admit a feeble uncertain light, like some gloomy caves. Sometimes I have been present at their wretched meals, set out in coarse dishes, or on the bare ground on which they sat, and consisting of black barley bread and wild fruits, and sometimes, by way of dainty, some salt-fish, and pure water to quench their thirst. Attending only to the first impression of the scene, I thought I beheld the perfect image of wretchedness and misery; but on more mature consideration, I discovered in these rude huts, and in the midst of this hard fare, an enviable happiness, which, I doubt is not to be found in the palaces of the great, or among the delicious viands of royal tables. A cheerfulness and perfect tranquillity shone in the countenances of these poor people, and evidently possessed their hearts. Their ruinous cottages, which must be viewed with pity and contempt by the rich and great, to them were dear; and the food, which the luxurious would have rejected as insipid or nauscous, to their palates had an exquisite flavour. But the frugal meals of these islanders are always seasoned with a sauce which never accompanies the dishes at the tables of the great, I mean hunger and thirst, which render every meat delicious and every beverage grateful. The labour of their hands and the sweat of their brow secure an exquisite relish for their scanty fare.

As to the content and tranquillity of these islanders, and the affection they bear their native country, I do not think I should greatly err, were I to ascribe it to the happy temperature of the climate, and the quality of the air, which, when pure, so much contributes to maintain in us the proper harmony between the solids and the fluids, or the state of perfect health. A proof of this I experienced in myself. Notwithstanding the continual and great fatigues I underwent in my excursions among those rocks, and notwithstanding my advanced age, I felt in myself an energy and vigour of body, an agility and liveliness of mind, and a certain animation of my whole frame, which I had experienced no where else, except on the summit of Mount Etna. In countries infested with impure air and thick vapours, I have never been able to apply myself to my favourite studies immediately after dinner, but under this sky, which is so rarely overclouded with vapours, I could write on the spot, at any time, a part of those observations I am now about to present to the public. How immense the difference between this most pure and almost eclestial air, and the foetid and foggy atmosphere of some of the low plains of Lombardy, surrounded by stagnant and filthy waters and unhealthy ricegrounds, producing continual clouds and fogs in winter, and obstinate fevers in stummer; where the spirits are depressed, and rendered dull; and where to complete the catalonge of ills and inconveniences, innumerable hosts of frogs, in the warm season both by night

CHAPTER XXV.

STATE IN WHICH THE AUTHOR FOUND MESSINA AFTER THE EARTHQUAKE IN 1783....ACCOUNT OF THE CALAMITOUS ACCIDENTS WHICH BEFEL THAT UNFORTUNATE CITY.

Great numbers of the people of Scylla drowned by the waves of the sea....A long range of palaces adjoining to the harbour, almost ail destroyed....Prodigious number of edifices within the city either thrown down, or on the point of falling.... Wooden sheds erected by the people of Messina to lodge in till the houses could be re-built....Injurious effects produced by fear which had seized entirely on the minds of the inhabitants....Account of the different dreadful shocks which laid waste the city, and circumstances by which they proceeded and accompanied....Other shocks followed, but successively weaker....The buildings of which the foundation was granite least damaged....The mole, which was constructed in ground not sufficiently solid, entirely carried away and buried in the seaEnumeration of the more considerable edifices which were reduced to ruins....Incalculable tosses sustained by the destruction of the monuments of the arts, and the property buried under the ruins, or consumed by the fires which broke out after the earthquake in different parts of the city....Exertions of the king of the Two Sicilies to restore Messina to its former flourishing state.

IN the forenoon of the 14th of October, I left the Eolian isles, and sailed from Lipari, in a felucea, for Messina, which is distant from that island thirty miles, but where I did not arrive till the middle of the next day; partly from having stopped some time to make observations on the granites of Mclazzo, and from the want of wind, which obliged the mariners to have recourse to their oars. With these islands I was to dismiss every idea of volcanos either still burning or extinct, as that part of Sicily to which I was approaching exhibited not the least trace of that nature. I do not mean to say that at different times it may not have suffered by their destructive effects, if it be true, as I believe it to be, that partial carthquakes, that is, those which are felt through a not very extensive tract of country, and at a small distance from a volcano, originate either mediately or immediately from that volcano. In fact, what island has suffered more in this manner than Sicily, and that from nourishing within its boson the Etnean conflagrations? When I travelled in those parts, the dreadful effects of the carthquake of 1783 were the common subject of discourse. On my entering, in the felucea, the strait of Messina, some of the people who were with me pointed out to me the shore of Seylla where a great number of people were drowned at that calamitous time. A dreadful shock of an earthquake took place, about noon, on the 5th of February of the above year, which terrifying the people of Scylla, they fled in crowds to the shore, when, about eight o'clock the following night, according to the Italian reckoning,* another violent shock succeeded, in which the waves rose so high that they covered the whole shore, and out of more than a thousand persons who were there collected, among whom was the prince of Seylla himself, not one escaped to relate and mourn the fate of the rest, The furious waves, rushing into the strait, penetrated to the harbour of Messina, and nearly sunk the vessels there at anchor.

When I arrived opposite to the city, I began to see the fatal and ruinous effects of this dreadful earthquake. The curvature of the harbour was formerly embellished for the extent of more than a mile, with a continued range of superb palaces, three stories in

^{*} About on in d c morning.

height, usually called the Palazzata, inhabited by merchants and other persons of opulence, which formed a kind of superb amphitheatre. The upper story and a part of the second of these buildings were entirely thrown down, the lower greatly torn and dama-

ged, and the whole of this extensive pile deserted by its inhabitants.

When I entered the city, every object which met my view tended to awaken melancholy sentiments and commiscration. Excepting some of the wider and more frequented streets, the rest were all heaps of ruins, either piled up on each side, or scattered in the middle, and rendering it impossible to pass them. Many of the houses were still in the same ruinous state in which they had been left by the earthquake; some entirely destroyed and levelled with the ground, others half thrown down, and others still standing, or rather hanging in the air, merely from the support afforded by the ruins around them. Those which had escaped this destruction appeared as if preserved by a miracle, torn and rent as they were. The cathedral was among the number of these fortunate edifices. This is a spacious building, of Gothic architecture. Its interior has suffered little or no damage. It is embellished with a number of columns of granite brought from an ancient Grecian temple, which once stood on the Faro (or strait of Messina) and with elegant Mosaic work wrought with the most beautiful jaspers of Sicily.

The destruction of so great a number of houses as were thrown down by this dreadful carthquake obliged the people of Messina to take refuge in wooden sheds built for
the occasion, many of which were still standing when I was there. They had begun,
however, to rebuild the houses, but on a different plan from the old ones. They had observed that the highest had suffered most, and that, in the violent shocks of the earthquake, the beams, by continually and forcibly beating against the walls, had completed
the ruin of the edifice. They therefore resolved to build them lower, and to construct
the wood-work in such a manner that, in case of a similar visitation, the shock should be
sustained by the whole of the building, and not by a part only. This precaution, it is
evident, must be of the greatest utility, should the city again suffer a calamity of this

nature.

Though it was now nearly the sixth year since that dreadful disaster, considerable remains of the dread, consternation, and, I may say, stupefaction, which usually accompany great terrors, were still manifest in the minds of the people of Messina. They had still present in their memory all the circumstances of that dreadful time; nor could I

listen to the narrative they gave of them without shuddering.

That ancient city, which had so repeatedly suffered, was not destroyed by one but several earthquakes, which lasted in successive shocks, from the 5th to the 7th of February 1783. The most destructive was that of the 5th, but an interval of some minutes clapsing between the first and second shock, the inhabitants had time to quit their houses, and fly to the open plain. Hence the number of those who were killed was not propor-

tionate to the quantity of ruins. They did not exceed eight hundred.

In a memoir relative to the earthquakes in that part of Calabria opposite to Messina, which happened at the same time, it is said that, before the first shock, the dogs in the city began to howl violently, and were killed by public order. On my inquiring of the people of the country, they assured me that the fact was false, and that no other phenomenon preceded this calamity but the flight of the sea-mews and some other birds from the sea to the mountains, as they usually do on the approach of a tempest. A very violent noise, resembling that of a number of earriages rattling over a stone-bridge, was the first symptom, while at the same time a thick cloud arose from Calabria, which was the centre of the earthquake, the propagation of which was successively apparent by the fall of buildings from the point of the Faro to the city of Messina, as if at that point

of opuact of the ad dama-

Messina, ogs in the ring of the er phenopirds from

A very ne-bridge, ria, which oparent by that point a mine had been fired which extended along the shore and continued into the city. The shock was most violent, and the motion extremely irregular. In no part were any fire or sparks observed. The ground along the shore opened in fissures parallel to it; and though in some places these continued more than a month, the dread and consternation with which every one was seized, prevented any attempt to measure them.

After the first shock, which, as we have said, took place about noon, on the 5th of February, the earth continued incessantly to tremble, sometimes with a slighter and sometimes a more violent motion; till at eight the following night another tremendous shock, which was fatal to the people of Scylla, completed the destruction of the remainder of the fabrics of Messina. The earthquakes did not cease till the 7th, when another dreadful shock spent its rage upon the ruins.

From that time till my arrival at Messina, shocks have continued to be felt, but gradually diminishing in force and number; and in 1789 and 1790, only four or five were observed, and those so extremely feeble, that, in any other country less affected by fear and alarm, they might not have been noticed, or not supposed to be earthquakes.*

The loss was immense, and is difficult to calculate. Considering the buildings alone, it may be asserted without hesitation, that, dividing them into four parts, two were levelled with the ground; the third half laid in ruins, and the fourth greatly damaged. Among the latter were the houses situated on the declivity of the hills, which have for their foundation granite, as we shall notice again in another place. (Chap. XXIX.) Those which were most completely ruined, and likewise the first to fall, were such as stood in the plain, and especially on the curvature of the harbour, on a ground less solid, as it had been formed by the washing and depositions of the sea. The mole of the harbour, which extended more than a mile in length, and was resorted to for the beauty of the prospect, was entirely swallowed up by the sea, so that no vestige of it remained to point out where it once was.

Among the ruined edifices the most considerable was the above-mentioned Palazzata, called likewise the maritime theatre; the royal palace; the palace of the senate, of noble architecture; the exchange of the merchants; the celebrated college, with the temple annexed; the church and professional-house of the ex-jesuits; the archbishop's palace, with the basilica of San. Niccolo; the seminary of the elergy, the hall of the tribunals, the church of the annunciation of the Theatines; that of the Carmelites, and of the priory of the Hierosolymitans, with several other fabries both sacred and profane; without mentioning the palaces of the nobles and opulent citizens, all of an elegant architecture.

It is impossible to estimate the loss suffered by the destruction of the numerous monuments of the arts, libraries, and galleries of pictures, with which Messina was embellished, where the imitative arts had long flourished.

^{*} In the following years, however, earthquakes again renewed the terrors of the people. The following is the extract of a letter from the abbate Grano to me, of the 11th of May 1792:

[&]quot;Yesterday we had a whole day, as I may say, full of earthquakes. I counted as many as thirty shocks, but all slight, and which occasioned no damage."

I embrace with the utmost pleasure this opportunity of thus publicly expressing my gratitude to and doing justice to the merits of this my illustrious friend, the Messinese nobleman above-mentioned, and whom I shall again have occasion to cite.

As he is versed in the studies of philosophy and natural history, he had the goodness to accompany me in my excursions in different parts of his country, and his scientific assistance was of the greatest advantage to me. This assistance he not only afforded me when present, but even when absent, hursishing me with various local notices which might render my accounts relative to those countries more interesting; and his industry and circumspection in the examination of nature, and his sincere love of the investigation of truth, leave no doubt of the accuracy of his observations.

Equally impossible is it to calculate the loss sustained by the valuable effects that were buried beneath the ruins, or burned in the fires which after the earthquake broke out in various parts of the city. We must also add the expence of building the wooden sheds and buts necessary to shelter the inhabitants, and for the reception of such moveables or commodities as had been saved from the ruins; which expence was extremely great from the high price to which all the materials for building immediately rose, and the order wages required by workmen of every kind.

otwithstanding all these losses and expenses, which must greatly have impoverish a country, not a single merchant became a bankrupt; a circumstance which redounds highly to the honour of Messina, as it is certain that no event can happen which

furnishes a more plausible excuse to the fraudulent dealer than an earthquake.

The king of the Two Sicilies has omitted no means that may contribute to the restoration of Messina. He has exempted it from all public imposts, given considerable sums from his own purse, granted a free port, jurisdiction of magistrates, &c. Yet the immense losses the city has suffered, notwithstanding every assistance, cannot be repaired under a great length of time.

The buildings have since been considerably increased and improved, so that more than one half of the city is now rebuilt, and the people have left the sheds and taken

possession of the new houses.

It appeared to me that this concise relation of the late dreadful carthquakes at Messina, and their consequences, would be acceptable to the curious and learned reader. We will now proceed to the description of other objects deserving attention in this celebrated strait and its mountainous environs.

OBSERVATIONS ON SCYLLA AND CHARYBDIS

A kind of confused noise, like the barking of dogs, heard on approaching the rock of Scylla, produced by the dashing of the waves of the sea....Images highly resembling nature exhibited by Homer and Virgil in their personifications of Scylla... The appearance of this rock the same at present as in the time of the Greek poet....The sea there of the same height as formerly Great danger of dashing on the rock of Scylla when the current runs from south to north, and impetuous south wind blows at the same time....Mariners at Messina, whose business it is to assist vessels in danger....Slips easily wrecked without this assistance, though those who steer them should be very expert scamen.... Tempest observed by the author in the Strait of Messina, and the courage with which these Messinese sailors brought a vessel in distress safely into harbour....Precise situation of Charybdis....Until the present time considered as a true whirlpool ... The fragments of ships awallowed up in it carried, as some have believed, thirty miles....Ancedote relative to this opinion....Phenomena of the current of the Strait, which descends and ascends by intervals....Visit of the author to Charybdis.... Its appearance as first seen from the shore Observations made on a nearer approach, and on entering it in a boat Charybills not properly a whirlpool, but an incessant motion of agitated waters, which ascend, descend, dush, and pripping a Consequences which followed on throwing certain bo-whirlpool ... Origin of this error None of the numericus writers who have mentioned Charybdis, say that they had visited and examined it Charybdis (welve miles distant from Scylla, though flo-

SCYLLA and Charylidis, according to the fables of the poets, are two sea-monsters whose dreadful jaws are continually distincted to swallow unhappy mariners; the one situated on the right, and the other on the left extremity of the Strait of Messina, where Sicily fronts Italy.

> Desfrum Scylla latys, Lavum implacata Charybdis Obsidet, atque imo barathri ter gurgite vastos Serbet in abruptum fluctus, rursusque subauras Erigit alternos, et sidera verberat unda. ler. We lebrated Far on the right her dogs foul Scylla hides; Charyhdis roaring on the left presides, And in her greedy whirlpool sucks the tides. Then sponts them from below; with fury driv'n. The waves mount up and wash the face of heav'n. But Scylla from her den, with open jaws, Then dashes on the rocks; a human face, And virgin bosom, hide her tail's disgrace; Her parts obscene below the waves descend, With dogs inclos'd, and in a dolphin end.

DRYDEN.

I have no difficulty in availing myself of the description of a poet in a work dedicated to the investigation of truth; nor shall I hesitate to cite similar passages from another poet, since, however exaggerated these may be by the glowing colours of imagination, they contain truth, and afford a subject for interesting inquiries.

I should have thought myself to have merited the greatest censure if, when I was in the Strait of Messina, I had not visited two places of which so much has been written, and which have been rendered so famous by the numerous shipwrecks they have occa-

sioned.

I first proceeded in a small boat to Scylla. This is a lofty rock distant twelve miles from Messina, which rises almost perpendicularly from the sea, on the shore of Calabria, and beyond which is the small city of the same name. Though there was searcely any wind, I began to hear, two miles before I came to the rock, a nummur and noise, like a confused barking of dogs, and on a nearer approach readily discovered the cause. This rock in its lower part contains a number of caverns; one of the largest of which is called by the people there Dragara. The waves, when in the least agitated, rushing into these caverns, break, dash, throw up frothy bubbles, and thus occasion these various and multiplied sounds. I then perceived with how much truth and resemblance of nature Homer and Virgil, in their personifications of Seylla, had pourtrayed this scene, by describing the monster they drew as lurking in the darkness of a vast cavern, surrounded by ravenous, barking mastiffs, together with wolves to increase the horror.

Erea d' er Enuddh raisi deirer dedanuia The novi Park per con onudanes riogidhe Pirelai.

Hom. Opyss. XII.

Here Scyllabellows from her dire abodes, Tremendous pest! abhorr'd by man and gods! Hideons her voice, and with less terrors roar The whelps of lions in the midnight hour.

Pore.

The Greek poet, when he pourtrays the rock which is the habitation of Scylla, finishes the picture higher than the Latin, by representing it as so lofty that its summit is continually wrapped in the clouds; and so steep, smooth, and slippery, that no mortal could ascend it, though he had twenty hands and twenty feet.

'O, de dum σχοπελεί, ο μετ ευρατε ευρυν ικαπε
'Οξειη χοριφη νεφελη δε μετ αμφιδιθηκε
Κυατεη το μετ ευτοπ' ερωιι συθεποτ' αιθηη
Κειτου εχει χορυφητ, ευτ το θερεί, ευπ' ει οτωρη
Ουθε κετ αμβαίη βρεθες στης ευ χαθασιή
Ουθ' ει ο χειερε γε εεικοσεί, και σοθες ητο
Πέβη λαρ λειερε σε εριβερη ειχυια.

Hom. Op. XII

High in the air the rock its summit shrouds. In broading tempests and in rolling clouds.

Loud storms around, and mists eternal rise.
Beat its bleak brow, and intercept the skies.
When all the broad expansion bright with day
Glows with th' autumned or the summer ray
The summer and the autumn glow in vain:
The sky for ever low'rs, for ever clouds remain
Impervious to the step of man it stands;
Though borne by twenty feet, though arm'd with twenty have
Smooth as the polish of the mirror rise
The slippery sides, and shoot into the skies.

Pore

Such, three thousand years ago, or nearly so, appeared the rock of Scylla, according to the observations of Homer; and such is nearly its appearance at this day.

The accuracy of this truly "first great painter of antiquity," which has likewise been observed by scientific travellers in other descriptions which he has given, shows that the level of the waters of the sea was at that time at nearly the same height as at present, since, had it sunk only a few fathoms, it must have left the foot of the rock, which according to my observations is not very deep, entirely dry. And this I consider as one among several strong arguments, that the most remarkable sinkings of the sea are anterior to the time of Homer.

Such is the situation and appearance of Scylla: let us now consider the danger it occasions to mariners. Though the tide is almost imperceptible in the open parts of the Mediterranean, it is very strong in the Strait of Messina, in consequence of the ness of the channel, and is regulated, as in other places, by the periodical elev depressions of the water. Where the flow or current is accompanied by a wir the same way, vessels have nothing to fear; since they either do not enter both the wind and the stream opposing them, but east anchor at the entrance, or if both are favourable enter on full sail, and pass through with such rapidity that they seem to fly over the water. But when the current runs from south to north, and the north wind blows hard at the same time, the ship which expected easily to pass the Strait with the wind in its stern, on its entering the channel is resisted by the opposite current, and impelled by two forces in contrary directions, is at length dashed on the rock of Seylla, or driven on the neighbouring sands; unless the pilot shall apply for the succour necessary for his preservation. For to give assistance in case of such accidents, four-and-twenty of the strongest, boldest, and most experienced sailors, well acquainted with the place, are stationed night and day along the shore of Messina, who, at the report of guns fired as signals of distress from any vessel, hasten to its assistance, and tow it with one of their light boats. The current, where it is strongest, does not extend over the whole Strait, but winds through it in intricate meanders, with the course of which these men are perfeetly acquainted, and are thus able to guide the ship in such a manner as to avoid it. Should the pilot, however, confiding in his own skill, contenu or neglect this assistance, however great his ability or experience, he would run the most eminent risk of being shipwreeked. In this agitation and conflict of the water, forced one way by the current, and driven in a contrary direction by the wind, it is useless to throw the line to discover the depth of the bottom, the violence of the current frequently carrying the lead almost on the surface of the water. The strongest cables, though some feet in circumference, brake like small cords. Should two or three anchors be thrown out, the bottom is so rocky that they either take no hold, or if they should, are soon loosened by the violence of the waves. Every expedient afforded by the art of mavigation, though it might succeed in saving a ship in other parts of the Mediterranean, or even the tremendous ocean, is useless here. The only means of avoiding being dashed against the rocks,

I was in written, we occa-

edicated

ve miles Calabria, reely any se, like a e. This is called anto these and muldure Hodescribanded by

of Scylla, s summit no mortal or driven upon the sands, in the midst of this furious contest of the winds and waves, is

to have recourse to the skill and courage of these Messinese scamen.

In proof of the truth of this assertion, I might adduce many instances related to me by persons descring of credit. But I was anyself an eye-witness to the situation of a trading vessel from Marseitles, which had one day emered the Strait by the mouth on the North side, at the time that I was on a hill looking towards the sea. The current and a North wind, which then ble w strong, being both in its favour, the vessel proceeded under full sail into, and had passed one half of the Strait, when on a sudden the sky became overcast with thick clouds, and violent gusts of wind arose, which in an instant changed the direction of the current, and turned up the sea from its bottom. The mariners had searcely time to hand the sails, while the furious waves broke over the ship on every side. Whether they merely followed the practice usual with ships in distress, or whether they were acquainted with the laudable custom of the Messinese, I cannot say; but they fired two gams: inamediately upon which one of the barks employed on this service hastened to the assistance of the distressed vessel, and taking it in tow, began to make every exertion to carry it safely into the harbour.

If I had seen with fear and shuddering the danger of the sailors on board the vessel, which I expected every moment would be swallowed up in the waves; I beheld with wonder and pleasure the address and bravery of the Messinese mariners, who had undertaken to steer safely through so stormy a sea the ship entrusted to their care. They extricated it from the current which impelled it towards destruction; changed the helm to this side or to that: recfed or let out the sails, as the wind increased or abated; avoided the impetuous shocks of the waves by meeting them with the prow, or opposing to them the side, as either method appeared most proper to break their violence; and by these and other manœuvres which I am unable to describe, these brave mariners, amid this dreadful conflict of the sea and the winds, succeeded in their undertaking, and brought

the vessel safe into the harbour.

But enough of Scylla: we will now proceed to Charybdis. This is situated within the Strait, in that part of the sea which lies between a projection of land named Ponta Secca, and another projection on which stands the tower called Lanterna, or the lighthouse, a light being placed at its top to guide vessels which may enter the harbour by

night

On consulting the authors who have written of Charybdis, we find that they all supposed it to be a whirlpool. The first who has asserted this is Homer, who has represented Charybdis as a monster which three times in a d.y drinks up the water, and three times youngs it forth.

The Magical straight and volve,

The un yager amore er' made the d'angentale.

Διών.

Hom. Obyss. XII.

Beneath Charybelis helds her bolsterous reign
Midst touring whirlpools, and absorbs the main.

Thrice in her gulls the boiling seas subable.
 Thrice in dire thunders she refunds the tide.

Pore.

The description of Virgil above cited differs from that of Homer only in placing a deep gulf below. Strabo, Isidorus, Tzetzes, Hesychius, Didymus, Eustahius, &c. repeat the same. The count de Buffon adopts the idea of Homer in full confidence, and places Charybdis among the most celebrated whirlpools of the sea; "Charybdis, in the Strait of Messina, absorbs and rejects the water three times in twenty-four hours."* Strabo

tells us, that the fragments of ships swallowed up in this whirlpool are carried by the current to the shore of Tauromenium (the present Taormina) thirty miles distant from Charybdis.* In confirmation of this tradition, an amusing though tragical anecdote is related of one Colas, a Messinean diver, who, from being able to remain a long time under the water, had acquired the surname of Pesce (the fish.) It is reported that Frederick king of Sicily, coming to Messina purposely to see him, made trial of his abilities with a cruel kind of liberality, by throwing a golden cup into Charybdis, which, it he brought it up, was to be the reward of his resolution and dexterity. The hardy diver, after having twice astonished the spectators by remaining under water a prodigious length of time, when he plunged a third time appeared no more; but some days after his body was found on the coast near Taormina.

From the authorities here adduced, it is evident that Charybdis has hitherto been considered as a real whirlpool by both ancient and modern travellers who have given

any account of it.

As I was therefore so near to this celebrated place, I determined to endeavour to as certain if possible what it really is. It is distant from the shore of Messina about 750 feet, and is called by the people of the country colofaro, not from the agitation of the waves, as some have supposed, but from **alos** and **alos** i. c. the beautiful tower, from the light-house creeted near it for the guidance of vessels. The phenomenon of the calofaro is observable when the current is descending; for when the current sets in from the north, the pilots call it the descending rema,† or current; and when it runs from the south, the ascending rema. The current ascends or descends at the rising or setting of the moon, and continues for six hours. In the interval between each ascent or descent there is a calm which lasts at least a quarter of an hour, but not longer than an hour. Afterwards, at the rising or setting of the moon, the current enters from the north, making various angles of incidence with the shore, and at length reaches the calofaro. This delay sometimes continues two hours. Sometimes it immediately falls into the calofaro, and then experience has taught that it is a certain token of bad weather.

As I was assured by the pilots most experienced in this practical knowledge, that there was no danger in visiting the calofaro, I resolved to avail myself of the opportunity. The bark in which I made the experiment was managed by four expert mariners, who perceiving me somewhat intimidated as I approached the place, encouraged me, and assured me they would give me a very near view of the calofaro, and even carry me into

it without the least danger.

When I observed Charybdis from the shore, it appeared like a group of tumultuous waters; which group as I approached became more extensive and more agitated. I was carried to the edge, where I stopped some time to make the requisite observations, and was then convinced, beyond the shadow of a doubt, that what I saw was by no means

a vortex or a whirlpool.

Hydrologists teach us that by a whirlpool in a running water we are to understand that circular course which it takes in certain circumstances; and that this course or revolution generates in the middle a hollow inverted cone, of a greater or less depth, the internal sides of which have a spiral motion. But I perceived nothing of this kind in the calofaro. Its revolving motion was circumscribed to a circle of at most an hundred feet in diameter, within which limits there was no incurvation of any kind nor vertigi-

* Κατατοθητάν δε και δναλοθιστών τα ναυαγία παρασορεται προς ηιονά της Ταυρομείτας. Lib. vi.

[†] I have observed that at Messina, as well as in other parts of Sicily, words of the Greek language, which was once that of this island, are still retained. Thus the word rema, derived from gups, a flowing or stream, is used to signify the current of this strait.

nous motion, but an incessant undulation of agitated waters, which rose, fell, beat, and dashed on each other. Yet these irregular motions were so far placid, that nothing was to be feared in passing over the spot which I did; though our little bark rocked very much from the continual agitation, so that we were obliged constantly to make use of our oars to prevent its being driven out of the calofaro. I threw substances of different kinds into the stream. Such as were specifically heavier than the water, sunk and appeared no more; those which were lighter remained on the surface, but were soon driven out of the revolving circle by the agitation of the water.

Though from these observations I was convinced that there was no gulf under the calofaro, as otherwise there would have been a whirlpool, which would have carried down into it the floating substances, I determined to sound the bottom with the plummet, and found its greatest depth did not exceed five hundred feet. I was likewise informed, to my no small surprise, that beyond the calofaro, towards the middle of the Strait, the

depth was double.

I could not therefore but conclude from these facts, that at that time there was no whirlpool in Charybdis. I say at that time, since the case might be very different when the sea was tempestuous. I therefore made inquiry relative to this of the pilots, those especially who, from their tried experience, were appointed by the public to give assistance in storms to foreign vessels, and who had frequently seen Charybdis in its greatest

fury. The following is the substance of the answers they gave me:

When the current and the wind are contrary to each other, and both in their greatest violence, especially when the seilocco, or south wind, blows, the swelling and dashing of the waves within the calofaro is much stronger, more impetuous, and more extensive. It then contains three or four small whirlpools, or even more, according to the greatness of its extent and violence. If at this time small vessels are driven into the calofaro by the current or the wind, they are seen to whirl round, rock, and plunge; but are never drawn down into the vortex. They only sink when filled with water by the waves beating over them. When vessels of a larger size are forced into it, whatever wind they have they cannot extricate themselves; their sails are useless; and after having been for some time tossed about by the waves, if they are not assisted by the pilots of the country, who know how to bring them out of the course of the current, they are furiously driven upon the neighbouring shore of the Lanterna, where they are wrecked, and the greater part of their crews perish in the waves.*

If we consider maturely these facts, we shall find that a great part of what has been written relative to Charybdis is very erroneous. We have seen how many authors, from Homer to the present time, have described it as a real whirlpool, or great gulf revolving in itself, within the circumference of which should any ship enter it is immediately drawn to the centre and swallowed up. When the current is dying away, or when there is no current, this description has no resemblance to truth. Charybdis is

* The following account of the shipwreck of a vessel in the calofaro was sent me, after my return

from Sicily, by the Abbate Grano from Messina:

[&]quot;About three weeks ago we were spectators of the sinking of a Neapolitan polacea in the calefaro, on its passage from Puglia, laden with corn. A most violent south-easterly wind blew, and the vessel with all sails set, endeavoured to reach the harbour, standing off from the calofaro; but the head of the current from the entrance by the faro took her, and drew her impetuously into it; where, without being able to make use of her sails, she remained for some time tossed about by the waves, which at length either breaking over her, or opening her sides by their furious beating, sent her to the bottom. The crew, however, and a part of the cargo, were saved by the speedy assistance given by our mariners in two small barks, who had the courage to encounter the danger. You will perceive from this in what manner the waves may sink ships in Charybdis, without the necessity of supposing a whirlpool."

e callaro, the vessel ne head of e, without , which at ne bottom. our marifrom this chirlpool." then perfectly innocent, as I have been fully convinced by my own observations; and even when it is agitated and dangerous, it still contains no incavation or gulf of the nature of a vortex, but merely a strong agitation and dashing of its waves, which produces those small whirlings of its waters, which are only accidental, and not to be feared. So far likewise is Charybdis from drawing to itself and swallowing vessels, that it rather

repels them and throws them to a distance.

This error has arisen like many others with respect to the productions of nature. Homer, in relating the voyage of Ulysses through the Strait of Messina, was the first who described Charybdis as an immense vortex which absorbs and rejects the water, and the ships that approach it; exemplifying his account by the fate of some of the companions of his hero, who were carried away by the whirlpool. The writers who came after him, whether poets, orators, historians, or geographers, have followed him in this description, without any one of them taking the pains to repair to the place and examine it himself. Even Fazello the Sicilian, who was so industrious in ascertaining facts, and whose accounts of his country are so accurate, clearly shews in his description of Charybdis that he had never observed it himself; and concludes his narration with the erroneous supposition above cited, that the things swallowed up by Charybdis are conveyed by submarine currents to the shores of Taormina.

Among all who have written on this subject, we only find Cluverius who seems, at

least at first view, to have visited the place, I shall transcribe his words:

"Ego sane, cum Charybdis noscendæ gratia aliquot dies Messanæ subsisterem, et ab hominibus ejus loci, maxime vero nautis, non Siculis modo, sed et Belgis, Britannis et Gallis, qui hoc fretum frequentes navigant, diligentius cam rem seiscitarer, nihil omnino eerti ipsis perdiscere potui, adeo scilicet totum negotium omnibus obscurum et incognitum erat. Tandem tamen reperi Charybdim, quæ incolis, patriis vocabulis, dicitur calofaro, sub prædicta ad Messanensem portum pharo esse mare rapide fluens, atque in vortices actum: quod non क्षार क्ष्मिनी ut tradit Homerus, id est singulis diebus ter, absorbet ingenti gurgite, revomitque aquas, sed quoties vehementiori fluctu fretum comitatur."

"I remained some days at Messina, with a view to obtain some information relative to Charybdis: but though I made every inquiry of the people of the place, and principally the sailors, not the Sicilian only, but the Italian, Dutch, English, and French, who frequently navigate that Strait, I could learn nothing satisfactorily; so little was known by them on the subject. At length, however, I found Charybdis, which the natives call Calofaro, under the light-house before mentioned, near the harbour, to be a sea rapidly flowing, and forming vortices. It does not absorb the waters in its vast gulf, and reject them thrice in a day, as Homer tells us, but as often as the sea runs high in the

Strait."

From the expression "I found Charybdis" we might be induced to believe that he made his observations on the spot. It is certain, however, that he does not explicitly tell us so: and when treating of a phenomenon of which he was so anxious to obtain an accurate knowledge, which he could not procure even from the Messinese sailors, it is strongly to be presumed that he would not have suppressed a circumstance of that importance. As Charybdis may be seen from the shore, if he only went thither, and turned his eyes towards it, he might with truth assert he had discovered it. The other adjuncts to his account, that Charybdis is a rapid sea, and that it absorbs and rejects the water in a storm, convince me that he had not a just idea of it, but satisfied himself with the old tradition concerning Charybdis.

It may be observed that the situation of Charybdis, as it has been hitherto described, does not exactly agree with that assigned it by Homer. Let us refer to the poet. The goddess Circe gives the following directions to Ulysses, with respect to the navigation of the strait of Messina:

'Οι δι δυω στοπελοι, ο μεν ευραιτν ευροι εκαιει
Τει δ'ετιρον σνοπελεν χθαμαλατηρου εψει Οδυσσευ,
Πλησιτο αλληλών και κεν διειστευσειας.
Τα δ ιν 'ερισες 'εστι μεγας Φυλλοισι τεθηλας,
Τω δ'υποδία Χαριδδις αναρειείδει μελαν υδαρ.

Hom. Opyss. XII.

High o'er the main two rocks exalt their brow Close by, a rock of less enormous height Breaks the wild waves, and forms a dangerous strait. Full on its crown a fig's green branches rise, And shoot a leafy forest to the skies; Beneath, Charybdis holds her boist'rous reign Midst roaring whirlpools, and absorbs the main.

Pore.

The first of the rocks here mentioned by Homer is Seylla, which he describes at length; and near the other, according to this poet, Charybdis is situated. The distance from one of these rocks to the other is an arrow's flight, *** ** It for the does not at all accord with the present situation of Scylla. How are we to explain this disagreement? Shall we say that Homer, availing himself of the licence in which poets are indulged, has spoken hyperbolically? I know not whether the coanoisseurs in poetry will permit such a licence. Or shall we suppose that Charybdis was once much nearer to Scylla; but that in a long series of ages, it has changed its place and removed under Messina? Such a suggestion might perhaps be favourably received, if in remote times any considerable change had taken place in the strait; but we know not of any; and it is not probable that a change so remarkable as the removal of Charybdis from its place, would have been passed over in silence by Sicilian writers. Within the present century, it is true, this strait, of which so much has been said, has become narrower, as we shall see in Chap. XXIX; but at the same time we know that long before this event Charybdis was situated where it is at present. The ancient and uninterrupted tradition of the Messinese respecting this fact is confirmed by the authority of the most celebrated Italian, Latin, and Greek writers. Fazello tells us, "Charybdis ex parte Siciliæ, paulo supra Messanam;" "Charybdis is situated on the side of Sicily, a little beyond Messina. Ovid says,

" Hinc ego dum muter, vel me Zanckwa Charybdis Devoret!"

"Let dire Charybdis in Zanclæan seas Devour me if I change!"

And it is well known that Zancle was the ancient name of Messana, now Messina. Tzetzes in Lycophron says, 'H x σ ρ ρ ρ ρ ρ ρ γ και Μοσκινα τος ... "Charybdis is situated near Messina." Strabo likewise, after having mentioned Messina, proceeds, Διακοδαία και Καιροδοίς, μιακριν σερο της σολιας, νι τω συρθμα—"Charybdis is seen in the strait a little before we reach the city." Several other writers might be cited to the same purpose.

From all these reasons and historical testimonies we must then conclude that Homer was not exact with respect to the situation of Charybdis; nor can it be a great offence to say that, in this passage of his long poem he has certainly nodded. The accuracy of several of his descriptions of various places in Sicily cannot be denied. It is such that we must either suppose that he had himself travelled in those parts, as is the opinion of many; or at least that he had procured very faithful and circumstantial information

scribed. et. The wigation

elebrated

liæ, pau-

beyond

Messina. ar Messiar Xaev Go.c. we reach

it Homer offence to uracy of such that pinion of Cormation

from others. Of this the rocks of Scylla are an example. But as to the supposed whirlpool of Charybdis and its situation, I think we may venture to affirm he never saw it himself, and that the accounts he had received of it led him into error.

We will now inquire what foundation there is for the saying which became proverbial, that "he who codeavours to avoid Charybdis, dashes upon Scylla;" and which was applied by the ancients to those who, while they sought to shun one evil, fell into a

On this subject I likewise made inquiries of the Messinese pilots above-mentioned, and to what better masters could I apply for the clucidation of such a proverb? They told me that this misfortune, though not always, yet frequently happens, unless proper measures are taken in time to prevent it. If a ship be extricated from the fury of Charybdis, and carried by a strong southerly wind along the Strait, towards the northern entrance, it will pass out safely; but should it meet with a wind in a nearly opposite direction, it will become the sport of both these winds, and, unable to advance or recede, be driven in a middle course between their two directions, that is to say, full upon the rock of Scylla, if it be not immediately assisted by the pilots. They added, that in these hurricanes a land wind frequently rises, which descends from a narrow pass in Calabria, and

increases the force with which the ship is impelled towards the rock. Before I began to write on Scylla and Charybdis, I perused the greater part of the ancient authors who have written on the subject. I observe that they almost all represent these disastrous places in the most gloomy and terrifying colours, as continually the scene of tempests and shipwreeks. These terrors and this destruction, however, they are far from exhibiting in the present times; it rarely happening that any ships are lost in this channel, either because their pilots possess the knowledge requisite for their preservation, or because they apply for the necessary assistance. Whence then arises this great difference between ancient times and the present? Can we suppose that Scylla and Charybdis have changed their nature and become less daugerous? With respect to the former, we have seen that this hypothesis is contradicted by fact, Scylla still remaining such as it was in the time or Homer; and with regard to the latter, from the Strait of Messina becoming narrower, Charybdis must be at present more to be feared than formerly, as it is well known that an arm, channel, or strait of the sea is the more dangerous in proportion as it is narrow. I am rather of opinion that this difference arises from the improvement of the art of navigation, which formerly in its infancy dared not launch into the open sea, but only ereep along the shore, as if holding it with his hand.

> " Alter remus aquas, alter tibi ratat arenas, Tutus eris; medio maxima turba mari."

PROPERT. lib. iii.

"To shun the dangers of the ocean, sweep The sands with one o.r, and with one the deep."

But time, study, and experience have rendered her more mature, better informed, and more courageous; so that she can now pass the wildest seas, brave the most violent

tempests, and laugh at the fears of her childhood.

To exemplify and support the probability of this opinion, it will not be necessary to recur to the early and rude ages; much more modern times will furnish us with sufficient proofs. That part of the Adriatic which separates Venice from Rovigno in Istria, is certainly not the most propitious sea to navigators. The danger of being hurried in s'x hours from one shore to the other, and there stranded; the frequency of violent winds which prevail there; the shallows and sand-banks which break the waves, and render them wild and irregular, may certainly cause some serious reflection in those who embark to make the passage. So late as the last century, the shipwrecks in this sea were so numerous, and had so terrified the people of Rovigno, that when any one was obliged by urgent business or any other cause to go to Venice, he considered himself as more likely to die than live, and if he was the father of a family, used to make his will before he embarked. The Advocate Constantini, a native of that country, and a man of learning and ingenuity, told me when I was there, that he had read more than one

of these testaments, deposited among the public archives.

But at present I will not say it is a diversion or pleasure to make this passage, since, as storms are not unfrequent, it is necessary to be cautious; but serious accidents rarely happen. I have myself three times made it without meeting with any cause of alarm. To what can this difference be attributed but to the improvement of the nautical art? Besides that the mariners of Rovigno were not then so expert in the management of their vessels as at present; they made use of certain barks of so improper a construction, as I was assured by the above-mentioned Constantini, that it was impossible they should long resist the violence of the sea. Those on the contrary, that have been built since that time, being of a broad and flat figure, and very solid, are capable of withstanding the most furious storms. They are there called bracere, and are in great reputation in all the neighbouring countries. We here find a part of the sea, in which vessels were formerly so frequently wreeked, and which could not be traversed but at the risk of life, now deprived of all its terrors, and rendered easily passable, merely by the improvements

made in the art of navigation.

As a farther and still more convincing proof that the dangers of Charybdis and Scylla, though in themselves the same that they anciently were, have been diminished, and the dread they inspired removed, by the rapid advances to perfection which this art has made in modern times, I shall adduce an example in another sea no less an object of terror from tempests and shipwreeks, I mean the Cape of Good Hope, called the Stormy Cape by the first discoverer, and by the mariners of those times the Raging Lion. How dreadful were the dangers of this place, where the two occans descending down the opposite sides of Africa met and elashed together; where contending winds, whose power was greater in the boundless ocean; where mountainous waves, rocks, and whirlpools threatened inevitable destruction! What preparations, what caution, were thought necessary for the ship which was to make the dangerous passage! Able pilots who had frequently made the voyage; masts and yards secured by additional ropes; a large supply of sails and cables, thicker and stronger than usual; and a double rudder, that in case one should be damaged, there might be another to act. The mariners were to be fastened to their posts by strong ropes; the passengers shut down below, and the deck left clear for the crew, a number of whom stood with hatchets in their hands, ready to cut away the masts should it be necessary. The guns were stowed in the hold as ballast, and the port-holes, windows, and every kind of aperture, carefully closed. Such were the precautions taken in the last century on doubling the Cape of Good Hope; but how few of them are now necessary to perform this voyage in perfect safety! Of this I have had the satisfaction to be certified by an English gentleman, Mr. Macpherson, with whom I had the pleasure of conversing, in Pavia, in July 1790, and who had twice doubled this Cape in his voyages to India; a gentleman of great respectability for his information, for the various long voyages he has made, and the honourable employments he has held.

The facility with which this passage may now be made, is therefore the consequence of the perfection to which the art of navigation has arrived; and the same we may conclude with respect to Charybdis and Scylla, which at present have nothing terrible but

the name, to those who pass them with the requisite precautions.*

^{*} The minute objects of the concluding chapters are of little consequence.

A DISSERTATION

ON THE

EARTHQUAKES IN CALABRIA ULTRA;

WHICH HAPPENED IN THE YEAR 1785.

BY THE COMMANDER DEODATUS DE DOLOMIEU.

Translated from one of the very few copies published at Rome in 1784.

DEDICATED TO DE LASTERIE DU SAILLANT, COMMANDER OF MALTA.

I MIGHT adorn this dedication with the name of some of the great on earth, make display of their pompous titles, their imaginary virtues; I prefer that of my friend, a friend of twenty years standing, whose title to eulogy this circumstance will stamp, May be deign to accept kindly this public acknowledgment of my attachment.

The Chev. DEODATUS DE DOLOMIEU.

PREFACE.

THE prevalence of contrary winds detaining me on the shores of Calabria Ultra during the whole of the months of February and March 1784, and obliging me in succession to touch at almost all the towns in its western shores, I was enabled to make incursions into this unfortunate province; had time to examine all its ruins, and witness the extent of its misfortune. My inclination for lithology induced me to pay attention to the nature of its soil, and the composition of its mountains, and what I now present is the result of my researches. I have collected principal facts alone, such as local derangements will attest for years to come, and which for centuries may continue of interest to the student of nature. Other details form no part of my plan. I shall neither give a circumstantial journal of the earthquakes nor a statement of the population and loss at each several place. For this I should have only to copy previous accounts, and my intention is not to make a great book, or to repeat what others have said before. I adhere to that chiefly which has been somewhat neglected, that is to say, the explaining the nature of the soil, and deducing therefrom the principal phenomena which accompanied the shocks. I have yet further for object to do away that idea of something miraculous to which preceding accounts may have given birth, relating mountains to have dashed against each other, entire fields to have been transported to a considerable distance from their former site, or thrown from one to the other side of the valley, &c. facts, not wide of truth, which must appear highly extraordinary divested of their local circumstances, but which a knowledge of the soil will show to be natural enough. I venture a theoretic opinion also which appears to me very probable, but to which I do not attach an importance equal to that of an exact knowledge of the facts whence it is deduced. I say very little of Messina, or Sicily. In the account afforded by M. L'Allimand, the French consul, is given every thing of consequence relative to

nsequence may conrrible but

the destruction of that city, whose fate, dreadful as it was, is however no wise compa-

rable to that of the towns of the plain of Calabria.

A multitude of details which I have omitted may be seen in different relations published at Naples, particularly in that of Doctor Vivenzio. But facts, interesting to the naturalist, are there extremely rare, and indeed the work appears to be written (like many others on the subject) rather to strengthen the theory which ascribes earthquakes to electricity, than to give any description of the phenomena which accompanied the destruction of Calabria.

The account of sir William Hamilton is the perception of a good observer, who had

but a few instants to spare for examination on his trip to Calabria.

Had the commissioners sent by the academy of Naples to Calabria thought fit to publish the result of their researches, I should have suppressed this dissertation, since assuredly I could have no room to add any thing to the observations which they ought to have made.

I have added in notes some particulars, which, though unessential to the object of the dissertation, may yet seem to make the text more easy of comprehension; they contain

morcover some facts interesting in other points of view.

I was accompanied by the chevalier de Godechart, a young man full of zeal, ardour, and sensibility. He was of much utility to me in my scrutiny, the fatigues attendant on which he shared with me with great patience and resolution.

DISSERTATION, &c.

A tempestate nos vindicant portus; nimborum vim effusam et sine fine cadentes aquas, tecta pro pellant : fugientes non sequitur incendium : adversus tonitrua et minas caeli, subterranæ domus et defossi in altum specus remedia sunt. In pestilentia mutare sede licet. Nullum matum sine effugio est. Hoc malum latissime patet inevitabile, avidum, publice noxium. Non enim domos solum, aut familias, aut urbes singulas hausit, sed gentes totas, regionesque subvertit.

Seneca, Quest. Natur. Lib. VI.

OF all destructive scourges earthquakes are the most dreadful, the most calculated to spread terror and consternation wherever they are felt. Nature, convulsed, seems tending to destruction, the world towards an end. Similar to the electric shock which strikes ere the thunders be heard to warn of the threatened harm, earthquakes shake, overthrow, and destroy, without any thing foretelling their approach, without an instant's time to avoid the impending danger. † Animals, even the most stupid among them, have an advantage denied to man, a foreboding of these fatal events; their instinct, or their senses more delicate than ours, by impressions of which we have no conception, admonish them some seconds beforehand, when, by their cries and impatience, they shew their inquietude and dread.‡ Yet would a similar capacity at all times enable man to

* Ports secure us from storms, the sheltering roof from shower-effusing clouds and the continual torrent; fire follows not who fly; caves under ground, grots dug below the waves, shield from the bolts and threatening shafts of heaven; the plague is avoided by a change of place; for every ill beside there is a remedy: this widest spreads inevitable its avidity, and general its harm. For not only does it destroy houses, families, or single towns, it overturns whole nations, and lays whole regions waste. † The destructive shock of the 5th of February was sudden, instantaneous; nothing foretold, nothing

announced its happening; it shook and overturned at once, nor allowed of time to fly.

‡ The prescience of animals of the approach of earthquakes is a singular phenomenon, and is the more surprising to us from our ignorance by what sense they receive the intimation. It is common to tions pubing to the itten (like rthquakes anied the

se compa-

, who had

tur. Lib. VI.

deulated to sed, seems nock which kes shake, an instant's them, have ct, or their ion, admothey shew ble man to

he continual rom the bolts ery ill beside not only docs egions waste, told, nothing

id is the more s common to place himself in safety? No, not the quickest flight, the strongest * or the slightest and least elevated building, not all the precautions of human foresight could shield him from the threatened death. In the midst of his flight he is swallowed by the gaping earth; the ground on which is built his gorgeous palace, or his humble cot, is either sunk in an abyss, or carried away to a distance, entirely overthrown; now a mountain slips from its base and loads it with its ruin; and now the vallies close and give it burial. The loss of his property, although the whole should go, the loss of his family, his friends, nay death itself is not the greatest ill he has to dread. Interred alive beneath a heap of ruins, which yet break not the vault above his head where he has sought asylum, he is condemned to die of hunger and madness,‡ cursing his friends and family, whose indifference he accuses, and tardiness to assist: unwilling they have shared a similar fate,) unknowing that those who survive this almost general catastrophe attempt in vain to release him from the piles with which he is overwhelmed. They hear his voice, his

all species, particularly dogs, goese, and domestic fowls. The howlings of the dogs in the streets of Messina were so violent, that they were ordered to be killed. During eclipses animals evince a nearly similar inquietude; on the annular eclipse of the sun in 1761, the agitation and cries of domestic animals continued for a great part of the time, notwithstanding its light was no more diminished by it, than it would have been by the interposition of a dark, thick cloud: the difference of the heat of the atmosphere was scarcely sensible. What impression then can animals have of the nature of the body which eclipses the sun? How are they able to divine that it is a different circumstance from the sun's being veiled by a cloud which intercepts the light?

* Part of the misfortunes of Messina are attributable to the want of solidity in the buildings; the ruin of this town was promoted a long time before by the earthquakes which at different times since 1693 had shaken and loosened all the houses; and the want of population and means of reparation. A new convent solidly constructed in the middle of the town suffered no injury. But in Calabria nothing was capable of resisting the violence of the shocks. The handsome convent of Benedictines at Soriano, re-built with equal magnificence and solidity after the earthquakes of 1659, was nearly levelled with the ground; notwithstanding, for the purpose of avoiding the same fate it experienced at that period (an epoch similarly disastrous to Calabria) the walls were made extremely thick, and the foundations peculiarly good, and of excellent materials.

† A number of peasants belonging to the plain of Calabria flying across the country were ingulfed in large chasms, which opened under their feet, and disappeared:

Insuper tonitrua sub pedibus hiat abyssus.

‡ A fourth part of the victims of the earthquake of February 5th, who were buried alive under the crumbled ruins of their buildings, would have survived if they had been promptly succoured. But in such a general disaster there was a want of hands, every one was occupied with his own misfortunes or those of his family, and paid no attention to indifferent persons. At one instant the most affecting instances of filial and conjugal affection, even to the extent of self-devotion, were exhibited, and acts of cruelty and atrocity which make humanity shudder. Whilst here you saw a mother with dishevelled hair, and covered over with blood, hasten to the still undulating spot where a falling beam had struck her infant from her arms, there a bewildered husband braving death itself in search of a darling spouse; at the same time might be seen monsters dashing forwards in midst of the tottering walls, fearless of every danger, trampling beneath their feet the half-interred bodies of men who claimed their succour in their way, to satisfy their blind cupidity, by the plunder of the houses of the rich. They stripped the living bodies of such unfortunate beings as would even have repaid with usury their charitable aid. I lodged at Polistena in the but of a gentleman who was interred beneath the ruins of his house, his body immured, his legs aloft in the air. His own servant, in lieu of affording him assistance, after taking the silver buckles from his shoes, ran off with his booty. For the most part, the lower order of people in Calabria evinced incredible depravity in midst of all the horrors of the earthquake. The greater part of the farming-men were in the fields upon the shock of the 5th of February taking place; they immediately rushed to the towns still smothered in the dust occasioned by their recent fall: they flew to them, not to give assistance, not from any sentiment of humanity excited by such dreadful ciccumstances, but to plunder.

§ I have conversed with a great number of persons dug from the ruinsin the different towns I visited, all of whom fancied their houses the only ones that had suffered, having no idea of the extent of the de-

cries, the bulk of ruin resists their efforts, and hinders his liberation.* They are unable to afford him the slightest comfort, and to the very last does he preserve the atrocious, the heart rending idea, that all his friends on earth were only wretches and most ungrateful monsters. But when fire joins its ravage to that of the quivering earth, to what new horror then is he not subject? By slow degrees it gains the fallen beams and different wood-work of the ruined buildings; it reaches him at last; penned in the fatal spot, all effort fruitless to avoid his fate, he perishes the death of sacrilegious criminals and regicides,† and curses with apparent reason a destiny which confounds, with the guilty, the innocent.

Such nevertheless was the fate of a part of the victims of the earthquake of 1783. Who then without shuddering can contemplate the disasters of Calabria? Who without a tear behold the finest country in nature ravaged with unexampled fury by earthquakes? Who in short contemplate the site of towns where even the ground on which they stood has disappeared, and the position of which was only to be determined by the objects with which it was surrounded. Such are the first ideas that occur to those travelling through Calabria Ultra; such the sensations I experienced at every step I took on visiting this unfortunate province in the months of February and March 1784; such indeed are the impressions which prevent our considering objects with sufficient deliberation to examine into effects and thence ascend to causes. The student of nature

atruction, and wondered at the delay of assistance. A woman in the borough of Cinco frondi was found alive on the seventh day after the catastrophe. Two children near her had perished of hunger, and already were in a state of puttrefaction. One reclined on its mother's thigh had infected the place of contact so as to occasion it to putrify. Numbers were buried for three, four, and five days; I saw them, spoke to, and questioned them respecting their sensations in this terrible predicament. Of all the physical evils they endured the most dreadful to them was thirst. The first expression manifested by animals also, some of which were restored to light after a fast of fifty days, was want of drink; their thirst was insatiable. Several persons thus buried alive supported their misfortune with unexampled constancy, a constancy of which one should think human nature, but from complete stupefaction of the intellectual faculties, could not be capable. A pretty woman of Oppido, but nineteen years of age, was at that instant near her time; she was buried beneath the ruins for the space of thirty hours, and, being extricated by her husband, was delivered a few hours after as safely as if nothing had happened. I visited her but, and among a number of questions, I asked what were her thoughts at the time—"I waited," was her reply.

In many towns it happened that parents and faithful servants, in search of persons dear to them could hear their moans, could recognise their voices, were certain of the spot where they were buried; yet could not succour them. The piled mass resisted all their strength, and made of no avail their zeal and efforts. In vain did they implore another's aid; their groans, their tears, were listened to by none. Stretched on the ruins, they were seen involving death to release their relations from their horrid situation, invoking it for themselves, as the only alleviation of their misery. Yet even this comfort was denied them, as at times for days together they heard the moans of the wretched, buried beneath their feet.

Whole families were overwhelmed together, without a single individual escaping; in such cases the tombs were—ampled on where they were inhumed alive, their voices were distinguished, yet would not their face excite a single tear. At Terra Nova, four Augustine monks, who had taken refuge in a vaulted sacristy, the arch of which supported the immense ruius with which it was overwhelmed, made their cries heard from amidst the piled heap, for the space of four days even; but one of the convent was saved, and of what avail was the strength of one to remove the quantity of rubbish which buried his companions? By degrees their voices died away, and several days after their four bodies were found clasped in each others arms.

More than half the victims crushed by the fall of Terra Nova remained amid the rains, and when I passed by them on the 20th Feb. 1784, they exhaled a most insupportable and infectious stench.

† When all the buildings of the town of Oppido were levelled by the most violent shocks and elevations of the earth, the wood-work of part of the buildings overturned successively cought fire; hence it became impossible to forward any succeur, and most of such as might have been saved from the ruins were made a prey to the flames. Twenty nuns of the order of St. Clare were discovered calcined beneath the wrock of their convent.

must be on his guard against these attacks of sensibility as well as against the warpings of his imagination to enable him to see no more in the origin of the misfortunes of a auditude of families, and the destruction of forty thous and of his fellow creatures, than a slight effort of nature,* and to qualify him to strip the various relations of all those disfigurements with which they have been clothed by terror and superstition.

History makes no mention of any earthquake the clocks of which were so violent, the effects so destructive, as those which desolated Calabria in the year 1783. This phenomenon singular enough is sufficiently imposing to interest the student of nature, even when stripped of the marvellous in which it has been dressed in previous relations; and will be best explained by fewest words. The shocks were extremely violent; † this is an indisputable fact. They produced in Calabria Ultra effects, consequential in themselves upon regarding local circumstances; this is a second truth which may require farther clucidation, and which I shall endeavour to render equally evident with the former, in describing the nature of the soil and the country on which it exerted its greatest violence. Thence shall Ideduce the reason why certain towns were almost wholly exempt from the general scourge, notwithstanding they were comprehended within the space under which its strongest efforts were exhibited, near the centre where the most violent shocks were felt; why other towns adjoining them remain but heaps of ruins; and why again others leave behind them no trace of their existence.

The shocks of the earthquakes in Calabria however violent were experienced on a space by no means great, and appear to have had a local cause. Its limits were the extremity of Calabria Citra on the one side; castwards it exercised no great ravage beyond Cape Colonne; nor westward beyond the town of Amanthea. Messina is the only town in Sicily which participated the disasters of the continent; and if beyond this town any slight occillations were felt, they were no other than the result of a trivial revulsion. The space, therefore, on which this terrible scourge displayed itself, was a length of thirty leagues by the whole breadth of Calabria. Within this space, all places felt not equally the shocks, nor suffered all the same destruction. The variety of the consequences of this carthquake was as great as the diversity of positions. All did not receive similar shocks, and these effects remain inexplicable with those unacquainted with the nature of the soil and local circumstances.

Calabria Ultra, in its lower part, may be regarded as a peninsula terminating Italy, formed by the indentation of the opposite gulfs of Squilacei and Sant Euphemia. It is

† The shocks were so violent that men on the level plain were thrown down by them. Trees, supported by their trunks, bent even to the earth and touched it with their tops. Numbers were torn up

by the roots and others broken short to the ground.

An effort but little more violent on the part of nature might have proved sufficient to cause a general catastrophe, to change entirely the present face of things, to plunge in eternal oblivion the present age, and ages gone before, to annihilate all monuments of the arts and sciences of man, and bring back human nature to its most early infancy. We calculate the effects of nature from our means alone; she appears to us terrible, and clad in all her might on diverging from any of those laws to which we rate her subject, and by which to our vision she seems to be influenced. Yet what to her, compared with the globe, is the space of a dozen of leagues? What indeed with regard to the solar system were the entire mutation of our continents? How many the general revolutions which the globe has experienced that we inhabit! How often has it changed its form! On all sides we discover vestiges of its revolutions and catastrophes; our imagination, which cannot embrace the whole of them, is lost in the gulf of time, before the date of history. He who first conceived that the ocean had changed its bed; that is to say, that formerly an order of things existed the reverse of their present state, imagined that he had advanced a highly bold opinion; our globe however may have experienced twenty similar changes. The supposition of one alone explains nothing. We trample in security on the wreck of, possibly, a dozen of former worlds; yet shudder if nature vary the least from her general plan.

traversed by a prolongation of the Appenines, which, describing a species of arch, terminate at Cape Dell Armi, opposite to Taormina in Sicily, and fronting the Neptunian mountains, which, notwithstanding the channel which separates them, may be looked upon as a continuance of the same chain, being of similar nature, and running apparently in the same direction. Below the gulf of Sant Euphemia a ridge of the Appenines leaves the principal chain, extends almost at right angles in a western direction, forms the vast promontory terminated by Capes Zambrone and Vaticano, and encloses the gulf of Sant Euphemia. Another ridge proceeds in a similar direction below the immense mount Aspramot, and ends at the point of land called Pezzo, which jetting out opposite to Messina, incloses on one side the narrow channel called El Faro. The sort of basin formed by these mountains is what is called the plain of Calabria, or of Monte Leone, and most commonly the plain alone. This name causes a false idea, for the soil inclosed within this space is neither even nor horizontal, as its title seems to indicate, but of unequal surface, and is traversed by vallies and deep ravines. Possibly its designation may be given it in contradiction to the lofty mountains by which it is inclosed. The surface is a gentle slope from the foot of the mountains which run from north to south to the sea-shore, where it ends in a low beach of a circular shape, the radius inwards, making the gulf of Palma. Within this space, enclosed as I have described by three ridges of mountains, is it that the efforts of nature were most violent; this is the unfortunate soil which exhibits nothing but the ruins of the towns which formerly stood there; here it is that all the inhabitants seemed doomed to inevitable death; this therefore is that part of Calabria which I have most particularly to describe.

The Appenines, after running through Italy, and in their whole course exhibiting nothing but calcarcous mountains, here raise their heads aloft, and shew the naked granite and slaty stone which are exhibited to view in them alone, and form the extremity of this long chain. These substances, which one would look upon as primitive in comparison to the formation of all others, and lower than which they are almost uniformly situated, seem to present an immoveable base; and the mountains which they constitute fixing their roots in the centre of the globe, ought to be exempt from every vicissitude; nevertheless, at their base was it that the most violent shocks were felt, nor were they themselves free from such convulsive motions as destroyed whatsoever was

found at their feet.

The whole of the Appenines which overlook the plain, the summits or elevated groups of some of which bear the distinctive names of Monte Jego, Monte Sagra, Monte Caulone, Monte Æsop, Aspramonte, &c. is formed almost entirely of a hard and solid granite, composed of three substances, quartz, white feltspar, and black mica. It is almost the only kind of stone the fragments of which are found at the foot of mountains, it is the only stone that is carried away by the torrents, and such buildings on the plain as are composed of solid materials are constructed of these alone.* On some masses of this granite, on the back of some mountains and on certain summits, are adherent deposits of calcarcous stone, which look as if the remnants of larger masses, diminished by time and rain. On some summits, also, roche de corne is found, and slaty

^{*} Materials for building are exceedingly rare throughout all this part of Calabria. The houses of the wealthy, and the churches, are built of stones carried along by the torrents; the cases for the windows and doors of granite hewn in the mountains, consequently very dear on account of the labour and expence of carriage to other places. The houses and inclosures of the poor are made of clay, mixed with sand and straw, shaped into bricks and dried in the sun. This cartn of materials for building will prevent a change of the site of several towns which would be much better placed a few miles from their former position, but the inhabitants refuse to go to a distance, expecting to find in the wreck of their ancient habitations materials wherewich to construct new dwellings.

schoerle (hornblend) fragments thereof are met with in the ruins of Terra nova, Oppido, and Santa Christina. These mountains are very steep, their summits bare, and many of them inaccessible. They wear that appearance of age and degradation so commonly observed in mountains of the same description: at their base, which is prolonged, have been successively deposited, to a very great depth, layers of quartzy sand, galena, grav and white clay, and grains of feltspar and mica proceeding from the decomposition of the granite; the whole mingled with shells, and marine fragments. This mass of matters, which have no connection with each other, and are without consistence, appears to be a deposit of the sea, which driven by the western wind beat against the foot of these mountains at a period much anterior to the present order of things, frittered off certain particles from the rock, and brought with it from its undulating motion some others from distances very remote.

This deposit, at first horizontal, from north to south and inclined from east to west, as appears by the direction of the strata afterwards received a new surface, either owing to currents of the sea itself, or torrents from the mountains, and was formed into the succession of hills, vallies, and plains, which, reclining on each other, terminate in a low shore on the margin of the sea. The progress and the spoils of vegetation, and other causes with which I am unacquainted, have clothed this moveable base with a stratum of vegetable earth, argillaceous, black, or reddish, very strong, very tenacious, and from two to four or five feet in thickness. This kind of outward bark gives a degree of solidity to the soil which is additionally bound together by the numerous roots of trees growing on its surface. These roots penetrate to a great depth in search of that

humidity always contained in the lower part of the sand.

This part of Calabria is watered by streams from the upper mountains, well replenished in winter and spring, and which after rain or the thawing of snow precipitate themselves in torrents through the plain. Then do they bear away before them whatever they meet in their way, and when once they have made themselves a furrow through the vegetable earth, they easily work a passage in a soil which can make no resistance. Thus they make ravines of an extreme depth, at times six hundred feet, but the sides always remain steep and almost perpendicular, on account of the superior stratum of earth tessilated by the roots of trees, preventing the mass beneath from forming a sloping bank. The whole country therefore is cut in furrows, and gorges of great or smaller depth and width, in which small rivers run whose tributary waters form the two rivers Metramo and Petrazzo. These fall into the sea at a short distance from each other, flowing through the lower part of the plain, of which they continually increase the extent by the deposits they form at their mouth. Their banks, which are exceedingly fertile, and are susceptible of irrigation, are yet not the best cultivated part of this beautiful country; they are uninhabitable from the bad quality of the air.

This change effected by water has produced two consequences. In the first place it has formed a vast number of gorges and vallies, which have parcelled out and divided the ancient soil. Some of these vallies are susceptible of curtivation; others still are infertile, owing to their being covered by the floods of each succeeding year with a new deposit of sand, gravel, and different dilapidations of the upper ground. Almost all of them are increased by very lofty escarpments resembling walls; some of them, having acquired a degree of slope, are covered with trees which add to their solidity; none however have inclination sufficient to sustain their load on a base proportionate to the height. Such parts of the ancient plain as have not been affected by the torrents, remain above these vallies and form flats, the elevation of which is uniformly the same, the dimensions various; constantly are they intersected by the ravines I have described.

e houses of for the winlabour and clay, mixed or building few miles the wreck Some of these flats, perfectly insulated, resemble those calcarcous mountains with flat tops which are frequently found in plains, the strata in which corresponded with those of the rest in their vicinity. Nature might, by a violent motion of its waves in the body of waters which form the sea, have anciently effected the same operation on calcarcous masses, then much softer than what they are at present, as now before our eyes on the sandy plains of Calabria.

This part of Calabria of which I have afforded a slight sketch is by much the richest, not only from the extreme fertility of its soil, but from the great variety of its productions.* It is likewise the most peopled. An immense number of cities, towns, and villages are spread over its surface: many of them were situated on the slopes at the foot of the great chain, some on those flat elevations which the torrent had respected, and which I have before described; others again on small inclined planes, which have a view of the sea at considerable distance. There are but two maritime towns, Palmi and Baynara. The inhabitants generally selected elevated situations, in order to have the advantage of a more healthy, a more pleasant situation, and a more extended prospect. Many of these towns, however, that they might not be too far from the water which flowed into the vallies, were established near the escarpment on the brink of the ravines. This situation was the cause of a singular circumstance which accompanied their ruin.

The mass of the branch of the Appennines, which, as I have noticed, extend at a right angle and form a promontory terminated by Capes Zambrone and Vaticano, as well as its base is granite, but not always naked. It is entirely bare on the escarpments which line the coast between Capes Zambrone and Vaticano; there it is in enormous masses, in which I have never been able to discover either strata or symmetrical order. This granite is exceedingly hard; its granite and component parts are the same as those of the mountains which occupy the bottom of the plain. On them are visible large parallelopipedal stairs, produced by a confused crystallization occasioned by some sort of precipitation.

This promontory, which I shall call Tropaea, on account of the town built below it between the two Capes, draws back from its base towards its summit, and presents four small plains prolonged from one cape to the other in terraces, like the seats of an amphitheatre, and separated by steep slopes. Here you distinguish the gradation of the matter of which the body of the mountain is composed. Solid granite forms the first ter-

* It is impossible to form an adequate idea of the astonishing fertility of Calabria, particularly of that part called The Plain. The fields, covered with olive-trees of larger growth than any seen elsewhere, are yet productive of grain. Vines load with their branches the trees on which they climb, yet lessen not their crops. The country, from the immense number of trees with which it is covered, resembles a vast forest, and yet produces grain sufficient for its consumption. All things grow there and nature seems to anticipate the wishes of the husbandman. There is never a sufficiency of hands to gather the whole of the olives which finally fall and rot at the bottom of the trees which bore them, in the months of February and March. Crouds of foreigners, principally Sicilians, come there to help to gather them, and share the profits with the grower. Oil is their chief atticle of exportation, of which it may truly be said a river streams annually from Calabria. In other parts the principal production is silk, of which a great quantity is made there. In every quarter there wines are good and ptenteous. The people, in short, would be the happiest on earth if—but at forms no part of my plan to criticise either the government or the individuals who holds great possessions in Calabria.

† This granite is worked; it serves to make steps for stairs, clisterns, and other similar works. I believe that a part of the columns of granite which are seen at Naples and various towns in Sicily, and which are termed oriental granite, notwithstanding they are not red, were taken from these rocks. On examining them, I found in an escarpment on the sea-shore below the village of Paryhilia an ancient quarry, in which are a number of large handsome columns already cut, others begun, and fragments of a number broken in the operation of cutting them.

3. I believe which are examining quarry, in f a number

race; * above it is a great thickness of decompounded granite, the grams of which have lost their adherence, and fall asunder with the slightest shock. In this species of rotten rock the waters have opened deep ravines, particularly in Cape Zimbrone, in which they have made frightful cuts through the whole depth of the mountain; the sides of which however, although steep, have yet a trifle of inclination, being destitute of a solid crust at top to keep the earth together and prevent its giving way. Upon the granite in a state of decomposition is a layer of fine quartzy white sand, several hundred feet in thickness, in which I found a number of marine bodies, particularly a quantity of superb echinometres. Finally, the loftiest part of this mountain, that which forms its summit, is a white calcarcous stone in horizontal beds. This flattened summit is the single, calcarcous, insulated mountain called Poro, on which are the ruins of an ancient castle: it forms a sort of unequal plain, which is prolonged as far as the great chain passing below Monte Leone. But this lofty flat does not partake of the fertility of the plains or slopes which it commands.

The town of Tropea, on the sea-shore towards the base of the promontory, is situated, on a rock of granite projecting a little into the sea, which it commands. The exterior part of this granite is coated with a sandy calcarcous rock, feebly concreted and full of marine bodies. A similar calcareous concretion adheres to the granite in some other parts of the coast.

The side of this mountain towards the south, in that part adjoining which Nicotera is situated, exposes a naked mass of large grained granite of a superb quality, the blocks of which are very large, and fit for the most beautiful works. In the upper part the granite is decompounded, but is less friable than that of the neighbourhood of Tropea. It is crossed by veins of micaceous feltspar; one part of which resembles the petunze de Saint Yrie in the Limousin, and the other changes into clay.

As you examine this side of the mountain towards Miletto and Vallelunga; the solid granite appears to bury itself in the earth so as to leave only that part exposed which is in a state of decomposition, a quartzy sand, and white micaccous clay, rather unctuous and ductile, which possibly may also be the result of a decomposition of feltspar. These matters form the slopes, leaning against the mountain, which the waters easily penetrate, opening for themselves profound ravines and vallies. The town of Miletto was built on a slope of this description.

On the opposite side of this mountain, that is to say, towards its top on the northern side from the river Angitola to Cape Zambrone, the mass appears to be a mixture of gra-

^{*} In the midst of the fertile plain which forms the first terrace of the mountain of Tropea is the little borough of Paryhelia, remarkable on account of the industry of its inhabitants, whose character affords a perfect contrast with that of other Calabrians. They are all of them addicted to foreign Germany. They set off in the spring, and spread themselves over Lombardy, France, Spain, and They traffic not in the productions of their country, which furnishes but few objects of exportation, but in merchandise of easy transport, such as essences, silks, cotton counterpanes of exquisite workmanship, &c. &c. which they purchase in other parts of Calabria; and bring back in return some objects of luxury, which they afterwards diffuse through the province. The village is entirely deserted by the men during the summer. The harvest is gathered by the women and old men, and in the autumn they return with their gains to sow their lands. Almost all of them speak French; their conduct is milder, and their manner less savage than those of their neighbours. They enjoy those little comforts of life which are unknown to their fellow-countrymen. Among them it is remarkable that, although the women never travel, they yet acquire a degree of poish from the excursions of the men to foreign countries. The men are above the common size, the women pretty, and very fair complexioned. Some of them have blue eyes. The beauty of the women of this village is cited throughout the accidence of the volume of the v lage is cited throughout the neighbourhood. Another circumstance, as singular as the preceding is, that the example of Paryhelia has no effect on the town of Tropea, distant from it no more than half a league; the whole of the industrious habits of Calabria being confined to that village.

nite and foliated rock, in druses, and of roche de corne, in which prevails blackish micaceous rock, containing an immense quantity of garnets confusedly crystallized, and sometimes blended with pyrites.* These garnets by trituration have formed a most beautiful reddish sand, met with on the shores of the sea, and which is almost exclusively formed of these fragments. In the upper part of the mountain, above the rocks which I have just described, there are micaceous, calcareous stones, and lastly, calcareous stones

formed from shells.

The town of Pizzo, at the back of these black, schistous, and granitic mountains, is built on a rock which projects into the sea, and is enveloped exteriorly by an agglutination of calcareous and quartzy sand, mixed with marine bodies; among others I met with some very beautiful echinites. This sort of concretion forming a mass of but little solidity, is nearly similar to that of Tropea; it adheres to other schistous rocks of the same mountain. It covers itself by the concurrence of humidity with a kind of blackish crust or moss, which deceived the eye of Sir William Hamilton, who mistook it for volcanic stalactites or tophus. I can safely affirm, from the most studious examination and most diligent research, that in all this part of Calabria there is not the slightest vestige of any productions of fire.

To pursue our examination of the mountains which inclose the plain. It remains for me to determine the nature of the mountainous mass, the limits of which is opposite to Messina, and which bounds the coast from Pizzo to Bagnara, following the roundings of the promontory, which by its contraction forms the Faro, and opposite to which, on the north-western side, the town of Scylla is built. The mass or kernel is here still granite, sheathed with foliating and micaceous rock, surmounted in some spots by calcareous and

very tender sandy stones.

Micaccous and argillaccous schist predominate in the mountains which environ the rich fields of Reggiot which stretch to Cape Spartivento. These schists are crossed by ruins of quartz and metal. An attempt there was made to work a lead mine, which

was argentiferous, but the plan was afterwards abandoned.

The opposite side of the Appenines, that is to say, the part which fronts the east, presents a less bare, a less arid aspect than the west. The inclinations are not so abrupt, and the tops are more covered with wood. The mountains appear of slighter elevation on account of the neighbourhood of mountains of a secondary rank, and hills which extend to the sca, to which the centre of the chain is much nearer than on the opposite side.‡ This side presents a succession of varied sites, and most charming and picturesque

* This foliated and micaceous rock containing garnets, proves that its constituent particles were petrified simultaneously, and precipitated at the same instant from the fluid which held them in solution. In some the bottom of the stone resembles a paste of the nature of garnets, which envelopes the mica; in others, the garnet possesses its particular crystallized form, and buried in the mica by which it is

† Reggio, at the extremity of Calabria, is most deligntfully situated. The mountains which sursurrounded. round it are covered with shrubs used in France for the ornament of gardens, and which, almost continually in bloom, have a most charming effect. Such are the rose laurels, the genista odorisera, &c. The plains, the vallies are surprisingly fertile, a faculty they owe to the abundance of water with which they are nourished. In no part can you dig two or three feet in the sands of the river without meeting with soft water. This water descends from the mountains, filters through the soil, and thus keeps up a freshness and humidity which renders vegetation in such a climate abundant. Numerous clumps of agrumi adorn the fields of Reggio, affording delightful walks, and furnishing from their fruit, and the essences extracted from them, a considerable commerce. In Italy, the word agrumi is used as a generic term to express collectively all trees of the species of orange, lemon, citron, bergamot, &c.

† One is tempted to imagine that in ancient times the motion of the sea from east to west was more considerable and continual than the reverse, since on one side of the chain it has accumulated at the foot of the mountains a great quantity of sand and detritation from the loftier summits, whence what I have described as the Plain was formed; whereas on the eastern side it still continues to wash the

foot of the hills without an accumulation of any sediment whatever.

landscapes. The fields are astonishingly fertile; there are but few plains, but the vallies are delightful; the hills are covered with mulberry and fruit trees, while olives, less abundant than on the western side, leave to balance their deficiency a verdure much more lively, with superior charms. The centre or kernel of the secondary mountains and hills is solid; schist and calcarcous stone abound in them, and they are veined with metal-

The part of the chain of the Appenines which runs along the isthmus, or contraction made by the gulfs of St. Euphemia and Squillaei, is likewise composed of granite, foliating rock, and schist, covered in some parts by calcarcous stone; it is only beyond Nicastro and Catanzaro that all these substances are entirely enveloped with the same calcarcous stone, which is substituted for them throughout the whole of the upper part of this chain, until you come to the lava and ejections from Vesuvius, and the volcanic productions of the Campagna di Roma and Tuscany, where you see them again forced into view, from considerable depth, by the action of volcanic fire.

From this general examination results, that almost in every part Calabria has granite for its base; that the focus* of the earthquake was beneath this base; or at least that the momentum which occasioned these violent oscillations of the surface, acted beneath these solid masses; that there is not the vestige of a volcano in any part of this province that I could find; no matter which had undergone any change from the action of subterraneous fires, neither in the mountains, nor among the stones in the beds of the torrents; that throughout this province neither lava, tophus, nor scoriæ of any description is to be found. In the interior of the plain I saw no more than two springs of cold hepatic water; but near St. Euphemia, beyond the isthmus, there is a plentiful spring of hot sulphureous water: neither of these, however, can I ascribe to fire, since the spontaneous decomposition of pyrites is of itself sufficient to account for their production. I lay particular stress on this assumption, as it tends to invalidate the opinion of such as imagine a subterraneous fire to exist below this province: did it exist, it would shew itself less equivocally. Neither in the plain, nor in the mountains by which it is surrounded, or at least those which form the square, are there either mines, sulphureous matter, or bitumen, notwithstanding the assertions of historians. In almost the whole of this boundary the granite is visible, and the soil is composed of nothing but clay, sand, and pebbles.

Notwithstanding there was an almost uninterrupted succession of earthquakes from the 5th of February to the following month of August, three distinct epochs may be assigned them, as far as they regard the places under which diey acted with greatest violence, and their consequences. The first comprises the shocks from the 5th to the 7th February exclusive; the second that of the 7th February, at one in the afternoon, and all those by which that was succeeded up to the 28th March; and, lastly, all posterior to those.

The shock so injurious to the plain of Calabria, that which buried more than twenty thousand inhabitants beneath the ruins of their towns, happened on the 5th of February, at half an hour after noon. It lasted but two minutes, so short a space of time did it require to overturn every thing, and spread a general destruction. I cannot give a better description of its effect than by supposing a number of cubes of sand, moistened and fashioned by the hand, being placed at short distances from each other on a table; then by striking

^{*}I make use of the words focus and centre of explosion, not because I imagine the primitive cause of the earthquakes to have existed below Calabria, but merely to assist me in explaining the effects, until I deduce from the phenomena themselves the cause of the agitation of the soil of this unfortunate province.

the bottom of the table repeatedly, and violently shaking it in an horizontal line by one of its corners, an idea may be formed of the violent and various motion by which the earth was then agitated. At the same instant were experienced sudden leaps, undulations in every direction, oscillations, and violent whirlings. No building could resist this complication of motion. The towns, and all the houses dispersed over the country, were levelled in an instant. The foundations appeared to be disgorged by the earth which contained them. Stones were ground and triturated with violence against each other, and the mortar in which they were pounded was reduced itself to dust. This earthquake, the most violent of any that ever was known, occurred without the prelude of any slighter shocks, without any notice whatever, happening as sudden as the explosion of a mine. Some however pretend that a muffled interior noise was heard almost at the same instant. But who can place reliance on the account of those exposed to the rigour of such a shocking calamity? Terror, desire of safety, these were the first sensations of such as were in houses. Again in an instant, and the crash or falling buildings, and the dust raised by their ruin, would hinder them from all seeing or hearing whatsoever, nor even leave them power of reflection. To save themselves was a mere mechanical movement of such as escaped; the rest did not recover to a sense of their misfortune before the shock had ceased. I shall not attempt to picture the horror, silence, and despair which succeeded this terrible catastrophe. The first emotion among the survivors would be joy to find themselves alive; the second desolation. Let us turn from this scene of horror, and leave to others the detail of individual calamity, and particular circumstances, whilst we confine ourselves to physical effects.

The most violent upward shocks were felt in the territories of Oppido and Santa Christina. There also took place the most violent convulsions; which circumstance has caused the idea that these towns were placed over the focus of explosion. But unlike others I shall not say that the effect of the earthquakes, the ruin they occasioned, were in inverse ratio to their distance from the centre, or that the greater the distance thence the less the devastation. Supposing this, the towns of Sederno, Groteria, and Girace, which are not farther from Oppido or Santa Christina than Rosamo or Polistena, would have experienced injury alike; and the villages Mamola, Agnano, and Canolo, which are much nearer, would have been levelled with the ground. But all these places were on eminences on the other side of the chain, and notwithstanding they suffered greatly from the shock of the 5th February, they were not either overturned or ruined; their fate can be in no respect compared with that of the towns of the plain. I shall maintain with more reason, that all within the compass of the mountains before described was entirely destroyed; and that the buildings on solid foundations above the plain, or on the ridges of the mountains

tains which surround it, were far from being equally mal-treated.

The general effect of the earthquake on the sandy, argillaceous soil of the plain of Calabria, which, as I have described, is destitute of consistence, was that of augmenting its density by diminishing its volume, that is to say, of heaping it; of establishing slopes wherever there were escarpments or rapid declivities; of disconnecting all those masses which either had not sufficient bases for their bulks, or which were only supported by lateral adherence; and of filling the interior cavities. Hence it follows that in almost the whole length of the chain, the soil which adhered to the granite of the bases of the mountains Caulone, Esope, Sagra, and Aspramonte, slid over the solid nut, the inclination of which is steep, and descended somewhat lower, leaving, almost uninterruptedly, from St. George to beyond St. Christina (taking the base, a distance of from nine to ten miles) a chasm between the solid nut and the sandy soil. Many lands slipping thus

te plain of agmenting slopes ose masses pported by t in almost ases of the inclination tedly, from nine to ten pping thus

were carried to a distance from their former position, covering others entirely. Whole fields sunk considerably below their former level, without others adjoining them undergoing the same change, thus forming a species of basin, as was the case above Casal Nuovo; other fields assumed an inclination. Chasms and fissures traversed the flats and slopes in every direction, but generally parallel to the course of the gorges in their neighbourhood. In the immense olive grounds between Polistena and Sinopolo these fissures are visible at every step. But on the brink of escarpments was it generally that the greatest damage and ruin occurred. Considerable portions of land, covered with vineyards and olives, separated themselves upon losing their lateral adhesion, and fell in single masses to the bottom of the vallies, describing ares of a circle, the radius of which was the height of the escarpment from its base, in the same manner as a book standing on its edge which falls flat. In such cases the upper part of the soil upon which the trees grew were thrown to a distance from their former site, and remained in a vertical posture. I have seen trees which continued to push out leaves, and which did not even appear to have suffered, notwithstanding they had remained for a year in a position so contrary to that perpendicularity they so constantly affect. In others, enormous masses losing also their lateral adhesion, fell on inferior slopes, and descended thence into the valley; to the impulse received from their fall was superadded the further movement given to their course by other lands which pressed upon their rear, thus impelling them to a considerable distance; still they preserved their form and position, and after affording the spectacle of a moving mountain, established themselves finally in the vallies. It is here essential to remark, that the sandy soil of the plain, not forming a mass of connected particles, was a bad propagator of motion, so that the lower part would receive more impulse than what it would transmit to the surface. This is the cause why the bottom in most cases gave way first, and the base running away, almost similar to a fluid, from the upper part to which it served as a support, this latter sunk down, detached in very large masses, from the lands to which it was formerly connected. The surface of the soil being strongly bound by the interwoven roots of trees, and the thickness and tenacity of the bed of vegetable and argillaceous earth, it is nowise singular that many of these lands should be preserved almost entire, notwithstanding the falls, violent shocks, and long courses they made. But let us follow the effects of the shock of the 5th of February.

Where the upper part of the escarpment gave way first, or where the surface of the earth separated into fragments, which broke away as the base crambled from beneath, disorder was at its height; trees half interred presented indifferently their roots or branches; and where in such cases the wreeks of houses were mingled with those of the mountain, no semblance remained of what had existed before, and the whole formed a picture of chaos.

At times it happened, that a surface, which by its fall and the inclination of the declivity formed below it, received a strong impulse of projection, provided it was opposed in its course by any small intervening hills, it covered them, nor stopt till it had past beyond. Where a similar surface encountered the opposite declivity, it struck

^{*} Accidents of this kind have given rise to singular disputes. It has been requisite to decide to whom the lands belonged which buried those of others. The earthquakes of Calabria have caused the greatest revolutions in the fortunes of individuals. Many of those whose whole property consisted of moveables, debts, ready money, &c. have been reduced to beggary, however great their former wealth; others have acceded to inheritances who never could have nourished such hopes, and which would not have been theirs but for the entire destruction of the most numerous families. Atmost all the rich were losers, and gainers almost all the poor. The fatter over and above their plunder charged what they pleased for their labour, which could not be dispensed with by those who required huts to dwell in, or wanted assistance to redeem what was covered by the runs, and their charge was in consequence exorbitant.

against it with violence, and raised itself up a little, and formed a species of cradle. When the opposite sides of a valley fell away at the same time, their wreeks met together and their shock raised little hills in the centre of the space they covered. The most common effect, that, of which a number of examples is seen in the territories of Oppido and Saint Christina, and on the banks of deep vallies or gorges, in which run the rivers Maidi, Birbo, and Tricucio, is, where the inferior base having given way, the upper grounds have fallen perpendicularly and successively in great trenches, or parallel bands, each assuming its respective position, so as to resemble the benches of an amphitheatre; the lowest bench or terrace is sometimes four hundred feet below its first position. This among others is the case of a vineyard situated on the border of the river Tricucio, near a new formed lake, it is in this manner divided into four parts, which hang in terraces one above the other—the lowest part of the terrace fell from a height of four hundred feet.

The trees and vines that were growing on lands removed in mass received no injury; even men upon them, some on trees, others tilling the land, were thus transported in a curious manner for several miles, without suffering any harm; many such examples

have been quoted to me which are authenticated in different relations.

The consequences of the crumbling to pieces of these elevations have been, a straitening of the vallies, or the entire covering of them in various places where opposite banks have met, so even as to obstruct the current of water and form a great number of lakes; the filling up of gorges and rendering even the surface of intersected lands; transportation of the inheritances of certain individuals on to the possessions of others, an interruption of communication, and a new face afforded to the whole

country.

The other phenomena produced by the first shock, and originating therein were, a suspension of the course of rivers, the instantaneous drying up of some, and their after increase. The explanation of these facts is easily given, they were owing to the sudden percussions upwards and downwards which the earth then experienced; and to the eentre of the plain being raised and the slope of the currents of the river being increased which caused them to run with greater rapidity. The upper waters retained by a kind of dam were kept in stagnation; but, the cause removed, a level was re-established, and the streams somewhat augmented in volume ran muddy. In many places water spouted from the earth to the height of several feet, carrying with it mud and sand. All springs were more abundant. Some sulphureous and hepatic waters made their appearance for some days and afterwards disappeared. These phenomena are all the consequence of the accumulation. All springs have an interior reservoir; many subterraneau cavities are full of stagnant waters which acquire a taste and smell of hepar, either owing to putrefaction, or the decomposition of pyrites; if by the contraction of the soil or the fall of upper bodies the capacity of the reservoirs become less, they spring forward with a force proportionate to the lateral compression, and bear away with them the bodies with which they are mingled. This increase of springs is a further cause of the increased volume of rivers. Nobody has been able to tell me precisely whether the hepatic waters which ran at the time, were cold or hot. Those which I have seen and which mix now with the waters of Vacari, a river which runs by Polistena, and with those of the river Tricuccio near Oppido, are cold. The phenomena of water spouting is peculiar to the first shock; on the other shocks taking place it did not occur on account of the soil having acquired already the greatest density and constriction of which it was capable.

Moreover in the whole of the country I travelled through, notwithstanding the most diligent research, I found no indications or symptoms of a disengagement nor subterraneous currents of vapour, or any vestiges of either fire or flame. Every circumstance

of this description related in many accounts has been contradicted by the testimony of the very persons referred to by the authors. It is but an easy task to make a peasant, still full of terror, and who has no interest in the circumstances respecting which he is questioned, reply as might be wished. It is easy enough to make them answer yes to whatever they are asked. They are uniformly but half informed men; who have added to their relations the most singular and most contradictory circumstances, from their desire to attribute to the late earthquakes of Calabria all the phenomena of which they have an idea, from knowing what had occurred on similar occasions. Moreover the major part have had some petty system to support, and have been desirous of arranging circumstances so as to make them square with what they had traced the outlines of before.

Let us take a rapid view of the various towns destroyed by the second shock, and examine the chief circumstances attendant on their destruction.

Rosarno a small borough on a sandy hill, a short distance from the river Metramo, was overturned. The prince's eastle, the churches, and houses exhibit nothing but heaps of ruins; some low houses excepted, all of which are violently shook, and some bare walls which stand by themselves, the rest is a heap of ruins.

The course of the river Metramo was for an instant suspended near the bridge of Rofarno; but shortly after its waters flowed in greater abundance than before and were disturbed. It is even pretended that it was entirely dry* for the space of some minutes.

Polistena, a tolerably large, rich and populous town, was built on two sandy hills divided by a river which had a somewhat deep bed. This town is absolutely levelled,† not a single house remained, not a single piece of wall.‡ Many houses were precipitated into the river, the earth of the banks of which had given way. The thick and very solid walls of the Dominican monastery are fallen in large blocks. The hill on the right,

• The plain on the right side of Metramo near the bridge is condemned to sterility from the inundation of a torrent which leaves on it every year a fresh coat of sand and mud, making it a marsh, the atmosphere about which is infected. A trilling expence is all that is requisite to form a bed for this torrent and restrain its course. The government however disdains to trouble itself on such paltry affairs of administration.

† I had seen Reggio and Messina, and mourned the fate of those two towns; I saw not in them a single habitable house, not one but would require re-building from its base, yet the skeletons of these two towns remained, the greater part of the walls standing by themselves. What these towns formerly were is visible. Messina still at a distance presents an imperfect image of its ancient splendour. Every inhabitant might distinguish either his house or the ground on which it stood. I had seen Tropea and Nicotera, in which few houses remained but had received great damage, and in which many were wholly fallen in ruins. I framed no idea of greater misfortunes than those which had befallen these towns; but when I saw the ruias of Polistena, the first town of the Plain which presented itself, when I surveyed heaps of stones which were destitute of form, and gave no conception of its having ever been a town; when I beheld that nothing had escaped destruction but all was level with the dust; I experienced such a mixed sensation of terror, compassion, and horror, has for some time deprived me of my faculties. This spectacle however was but the prefude to still more wretched scenes on the rest of my excursion.

The impression made upon me by the sight of Messina was totally different. I was less struck by its ruins than the solitude and silence which reigned within its walls. One is affected by a melancholy terror, a mournful sadness, in traversing a large city and visiting its different quarters, to meet with no soul living to hear no human voice, no sound but the quivering of doors or shutters suspended to fragments of walls, and acted upon by the wind. The mind is then rather overcome by the weight of its feelings than terrified; the catastrophe seems directed against the human species, and the ruins which are seen appear to be no other than the effect of depopulation. Such would be the picture of a town where a pestilence had raged.

The whole population of Messina took refuge in barracks of wood without the city.

† This town buried one half of its inhabitants beneath its ruins. Such as survived this fearful catastrophe dwell in barracks placed on a flat which overlooks the ancient town and on which it is in contemplation that the new town shall be built.

near the Capuchin convent is considerably sunk. There are a number of fissures in the soil and its depression continues to the foot of the mountain a league from the town.

In the whole of the neighbourhood of the town are numerous fissures.

Saint Georges, a small town a league and a half distant from Polistena suffered scarcely at all from the shock of the 5th February, on account of its being built on an eminence, situated on a rock, adhering to the great chain of the Appenines. It afterwards received considerable damage from the earthquakes of 7th February and 28th of March.

Cinco Frondi, a pretty borough, half a league distant from Polistena, in a very fertile plain, was entirely ruined. An ancient tower of Moorish work, square situated in the middle of the town, and large enough to serve as a eastle and dwelling for the lord of the manor, was exceedingly solid as much on account of the great thickness of its walls, as the quality of its cement, which had bound the works together in such a manner as to make the whole as firm as a rock; it was overturned, and in its fall broke into a number of large blocks of astonishing volume and hardness. One of these blocks contain an entire stair-case. Here it seems as if the earth had disgorged from its bowels the very foundations of the different buildings.

In going from Polistena to Casal Nuovo, two leagues distance you pass the Vaccari, a river which has dug its bed in a soil entirely of sand; there is a source of cold sulphureous water, which empties itself into the river, a short distance from Polistena; this source was very abundant on the 5th of February and following days; the smell of it also was very strong, but by degrees it resumed its natural state. In the country through which this river flows, and on its banks, several springs spouted up water on the

first shock.

Casal Nuovo, a pretty town, situated in a pleasant plain at the foot of the mountain, with wide and straight streets, and low houses,* was entirely levelled, so as that one stone remained not upon another. This town was built after the earthquakes of 1638, which devastated Calabria. The utmost precautions were used to prevent a ruin similar to that we witnessed. But notwithstanding its streets were very wide, and its houses very low, nearly half the population was crushed beneath the ruins. The marchioness of Gerace, the lady of the manor, and all about her were the victims of this shock.

The whole of the soil of the plain which surrounds Casal Nuovo is sunk. This depression is particularly apparent above the borough at the foot of the mountains. All the sloping lands which leaned against this mountain have slided lower down; leaving between the moving ground, and the solid, fissures several feet in width which extend from three to four miles. Certain portions of those lands thus slipping down descended into the plains and overwhelmed others at considerable distance from their former site.

In going from Casal Nuovo to Santa Christina, within a space of six leagues one traverses a country intersected in a most extraordinary manner, by gorges, ravines, and deep vallies; a country, which has consequently been the theatre of great revolutions. Not a step can you make in this part without discerning either fissures in the soil or places whence the soil has fallen away.

Terra Nova, this was a small town situated on an elevated flat, on three sides of which were deep gorges, which gave it the appearance of being placed on a high mountain. But this elevated flat was at the extremity of a plain which extended to the foot of the

^{*} The appearance of Casal Nuovo was delightful when seen from a distance. At the corner of every house a tree was planted and a vine which gave shade; so that the streets had the appearance of the covered alley of a garden.

er of every uice of the

mountain and is of extreme fertility.* This town enjoyed an excellent air, a beautiful prospect and the advantage of excellent water. The position which secured it these advantages occasioned it to experience a destruction, reflection on which alone must make one shudder. A part of the soil gave way, and in its course to the middle of the river Maro carried with it the houses upon it. Their ruins, stones, and woodwork mingled with the sand which formed the body of the mountain, cover a considerable part of the valley commanded from the town. On the opposite side of the mountain by a perpendicular fissure from top to bottom became divided, and one part, separated from the other, fell in one block on its side in the same manner as a book opened in the middle which has one part upright on its back while the other falls to the table. That which was the upper part, on which were houses and trees, remains in a vertical position, of the houses it will easily be conjectured there is not a vestige remaining; but the trees have received little injury. At the instant of the formation of this fissure, and the separation of the mountain all the houses placed immediately above, were perpendicularly precipitated down more than three hundred feet, and covered the bottom of this chasm with their ruins. Nevertheless the whole of the inhabitants did not perish, the difference of their gravitation caused the materials to reach the ground before the men, so that many were saved from being buried or crushed to death in the ruins. Some fell directly on their feet, and immediately walked firmly over the heaped wreck, others were interred up to their thighs or breast, and were released with a little assistance. A third part of the town in crumbling to pieces filled with its ruins a little valley which was nearly in the centre, and in which were a fountain and some gardens. Never did any country experience a greater overthrow than that on which this unfortunate town was situated; never was there seen destruction accompanied by more singular and varied circumstances. The site of not a single house can be recognized; the surface is wholly changed, nor by what remains is there a possibility of divining what formerly this town had been. The soil in every part gave way, the whole was overthrown. That which was lofty is abased, that which was low appears, from the diminution of the height of its contiguous prominences, to have been elevated. For there has been no actual elevation as some pretend. A stone well in the convent of the Augustins appears to have been driven out of the earth, and at present resembles a small tower eight or nine feet in height a little inclined. This effect was produced by the consolidation and consequent sinking of the sandy soil in which the well was dug.

The ruins of the town, with those of the opposite hill, have stopped the current of the small river Soli on one side, as well as that of a plenteous spring which emptied itself into the bottom of the opposite gorge, and having thus formed two lakes, whose stagnant waters are the more impetuous from their being the receptacle of dead bodies and wrecks

of all descriptions.†

VOL. V.

In all the environs on the edges of the vallies there has been considerable shrinkings. The whole plain above the town is intersected by numerous crevices and fissures. A

* In no part have I ever beheld such large ofive trees; they resemble timber trees, and planted in quincunx, they form most superb woods as dark and as shady as a forest of oaks. 'The ground is cleansed and stamped round the foot of each tree in order to form a circular hollow ring into which the olives fall; the quantity is so considerable, that they are actually broomed into heaps.

[†] Unless art or nature dry up these lakes they will complete by their pestiferous exhalations the destruction of the small population which has survived the concemitance of so many causes of mortality. The atmosphere at present is so loaded, so much infected, so moist, that in the month of February there were as many insects and flies in the air as are wont to be in summer on the surface of stagnant pools.

considerable distance must be travelled over, ere a proper site can be found for the new town or rather hamlet, which the small number of the remaining inhabitants will have to establish.*

A large plantation of olive trees belonging to the Celestin monks on a level with the ground suffered materially. One part of it was overturned in the gorge in which the river Soli flows, and the trees, some of which were not rooted from the earth, have taken most singular positions, where they continue growing. Another part sunk some fathoms down; and all the remainder is threatened with ruin from the number of fissures and cracks which intersect it; and for the space of a mile, not a foot of ground is there remaining which can be regarded as firm and solid.†

The village of Moluquello or Moloquiello was situated opposite to Terra Nova and on the same level, on a small platform a mile in length and two hundred paces broad, compressed between the rivers Soli and Maro which ran in deep vallies at their feet. One part of the village fell towards the right, another towards the left, and of the ground on which it was situated no more remains than a ridge so narrow that you cannot walk thou.

Radicina, a pretty small town in the plain at some distance from the gorges, was entirely levelled, with the exception of a small square house of one story in the centre of the town, which kept firm, and indeed has hardly suffered at all without my being able to assign a reason.

I shall say nothing of all the small villages the ruins of which lay scattered about the

country, as they present nothing interesting.

Oppido, an episcopal see and pretty considerable town, was placed on the summit of an insulated mountain, or rather on an elevated flat level with the neighbouring Plain, of which it seems formerly to have made a part, but from which it had been entirely disjoined by the torrents which had formed all around it gorges of an extraordinary depth. Access to the town was exceedingly difficult on account of the rapid acclivity and escarpments about it. Notwithstanding this, trees and shrubs had got hold on the sides and enveloped the mountain with a girth of wood, the interwoven roots of which gave a kind of solidity to the mass, which of itself had none: for it is composed alone of sand, clay, and marine fragments, altogether similar to the compound of the opposite hills.

The town was entirely levelled, not a single piece of wall remaining erect. A part of the extremity of the flat on which a strong eastle was situated, a kind of citadel, with four bastions, fell away, and drew with it two of the bastions into the gorge below. This is the only subtraction the mountain experienced; the rest remained entire, notwith-

^{*} The ancient population of Terra Nova was two thousand souls. It is at present reduced to less than four hundred; rather more than fourteen hundred were buried in the ruins or croshed to death, and the rest have been taken off by putrid fevers. This small number of unfortunate people have built themselves barracks on a plain half a mile below the site of the former town; the damp and unsolid nature of the ground in this part will not allow of their ever building houses here.

[†] Hodged at Terra Nova in the barrack belonging to the Celestin monks, one only of all of whom escaped; it is in the midst of the plantation of olive trees. I had noticed the evening before how very deficient of firmness was the ground; my imagination was full of all I had seen; I was picturing to myself the sensations of the inhabitants of this town, at the instant of the shock; when I felt my bed moved by a pretty strong carthquake. I got up precipitately and with some inquietude, but on perceiving all was silent I conjectured that this shock though very strong was nothing comparable to those which had before been felt at the instant of the various catastrophe, seeing it occasioned not the slightest alarm to those who were at rest in the self-same barrack. I again retired to my bed, but it will readily be conceived not to rest during the remainder of the night.

whom eshow very cturing to It my bed at on pere to those he slightout it will standing its escarpments, in all likelihood sustained by the strong girth afforded by the roots of the numerous trees and shrubs by which it was encircled.*

If the soil of Oppido resisted in some measure the violence of the shock, this was not the case with the opposite banks; the crumbling away of the earth was there immense. The fall of the ground, and considerable portions of the hin, filled the vallies and formed lakes, by which the town is now surrounded. These takes which surround the mountain will, by degrees, be filled by the accumulation of sand brought by the torrents and the wreck of the higher grounds.† Already is there one which has been filled in this manner.

It is not, however, in the immediate neighbourhood of the town that the greatest devastation has been experienced; but, a mile or two miles from it, in the deep vallies formed by the rivers Trieucio, Birbo, and Boscanio. There all those accidents which I noticed in the beginning of this dissertation occurred. There sand and clay ran like torrents of lava or as if they were carried away by water. In other places, considerable portions of mountains ran for several miles in their way to the vallies, without falling in pieces, or even changing their shape. Entire fields, covered with vines and olives, were precipitated into the bottoms without changing the horizontal position of their surface; others were somewhat inclined, while others again were placed vertically, &c. &c. The fall of opposite escarpments, and their after rencounter have formed dams of several miles in thickness, stepped the course of streams, and produced great lakes, which the government is employed in attempting to dry. For this purpose it will be necessary that deep canals should be cut the length of three or four miles through the rubbish, which will take up a length of time, and prove extremely expensive; both the labour and expense of which might be saved, if the government but reflected that nature, in a few years, would fill up these lakes, as she has done many others; that an infected atmosphere is much less to be apprehended in such places at a distance from habitations, and that the expence could be much better employed in the neighbourhood of Terra Nova, or other parts of Calabria.

Below Oppido, at a distance of three miles, was situated the small village of Castellace, built on the brink of an escarpment, which gave way, and fell into the valley. The ruins

* Who would imagine that the inhabitants of Oppido after the destruction of their town and the various disasters to which it had been subject, should yet be partial to that unfortunate spot. Government pointed out a site for a new town. It chose a place called Latuba, a league distant from the former. The greater part of the inhabitants object to going thither. They consider as a sort of tyranny the attempt to take them away from their former place of abode to oblige them to inhabit a moist and unhealthy plain which centains no materials for building. They say in favour of their insulated flat, that it has proved its solidity by resisting the most violent shocks without flinching in the least; that the stones and wood-work of the houses in ruins will serve them to build others; that its air is excellent; that they are nearer to their possessions, and that, collectively, these different advantages more than compensate for the inconvenience of having no water on the flat; and assume that being accustomed to fetch it from the bottom of the vallies, use has made this labour of no consideration. A schism has hence arose among the remains of this population, part have complied with the wishes of government and are gone to Tuba; while the rest remain on the ruins of Oppido. I was surrounded by them on my going to visit that town. They seemed to have forgot the misfortunes occasioned by the arthquake, their minds being wholly engrossed by the injury which they pretended had been dene them. They particularly complained bitterly of being deprived of a mass which had been accustomed to be soid in a hut set apart for the purpose from the conuncement of their disasters.

† Before I reached the mountain of Oppido I could not conceive how it was possible to approach it; I was separated from it by the place where a lake had been, which was filled. This basin, full of a fine sand on which the river runs, seems a vast gulf of mud which the eye contemplates with fear, and which is a hundred paces over. My guide informed me we had to pass it in order to reach the old town. I risked a step or two with some apprehensions but made confident by the experiment, and finding that what appeared to me a gray and softish mud was firm, I crossed this lake of sand through a depth of water which reached my knee and took a little crooked path, by which I was enabled to

climb among the bushes up an escarpment which appeared to me inaccessible.

of some houses which remain on the mountain, are the only indications of its position, or former existence. The village of Cossoletto has experienced nearly a similar fate.

The town of Santa Christina, situated almost at the foot of the great mountain Aspramonte, on a sharp sandy hill, surrounded by gorges and deep vallies, was circumstanced nearly in the same manner as Terra Nova, and experienced similar destruction. The houses with part of the hill were precipitated from top to bottom. A number of chinks and fissures intersect it from its summit to its base, so as to give room to apprehend that the remainder will yet give way. The whole surface of the country is changed. The territory of Santa Christina, cut in a like manner by a number of gorges and vallies accompanied by escarpments, experienced the same fate as that of Oppido.

The territories of Terra Nova, Oppido, and Santa Christina, are those on which the earthquakes occasioned the greatest damage, and produced the most extraordinary results. This has made it conceived that the locus of the shocks of the 5th of February was beneath this part of the plain. I shall not deny that the concussion may have been more violent there than elsewhere; but the nature of the soil, and the gorges by which it is intersected, very much contributed to the destruction of the towns, and greatly assisted in occasioning the disorder observed in their neighbourhood.

Following the circuit made by the base of Aspramonte, we come to the small town of Sinopoli, and the borough of Saint Euphemia, both built at the foot of the mountain, and both destroyed, yet not levelled with the ground.

Bagnara, a pretty considerable town on the coast, built on an eminence, with an escarpment towards the sea, was entirely levelled. The houses were precipitated one upon another in such manner, that with difficulty can it be distinguished it had ever been a town.

Seminara, another town on the coast, was destroyed, but not levelled entirely, like the last.

Palma, a well-peopled trading town, is only a heap of ruins.

Without enlarging the list, what I have said will be sufficient to demonstrate that the singular circumstances attendant on the earthquake were the natural effect of a violent shock on a sandy ground previously opened and torn by torrents. It is furthermore visible that on a space six leagues in length by six in breadth, lying between the river Mutramo, the mountains and the sea, not a single edifice remained entire; one may even state that scarcely one stone was left upon another, and that there was not in this whole space a single acre of ground but what had either changed its figure, its position, or undergone material revolution.

While the plain was given up to total destruction, buildings in its neighbourhood, founded on solid bases on eminences, escaped from equal devastation. They felt the shock severely, and many houses were damaged. But if this shock of the 5th of February had been the only one, had it not been followed by those which succeeded it, almost uninterruptedly for six months, none of the upper towns would have been rendered uninhabitable. It seemed as if the power which in every direction had shaken the plain had not been sufficiently strong to raise a greater weight, such as that of the mountains by which it is inclosed. Hence Nicotera, Tropea, and Montedoone, towns built on the mountain of Cape Vaticano, or on its prolongation with the boroughs and villages dependant on them, suffered scarcely at all. Their overthrow was reserved for a more violent exertion of force, such as shook the bodies even of these mountains themselves, on the 18th of March following. The borough of St. George, only four miles from Potistena, as we have before remarked, but placed on a mountain, was before then but little injured. The boroughs and villages situated on the ridge of the mountain oppo-

site to Messina, and the small town of Scylla itself, were not entirely destroyed. On all these mountains the shocks were less violent, less momentary; the movements were not so quick, so irregular, nor even the upward percussions similar.

Reggio and the neighbouring places were rendered uninhabitable, but not levelled. It

was not even the first shock which damaged them the most.

On the opposite side of the Appenines, towards the east, the earthquake of the 5th February was very sensibly felt; all the towns in this quarter suffered either more or less, some planks gave way, steeples and several churches were thrown down, houses were damaged, but very few were wholly overturned. The number of persons who perished was inconsiderable.

Every where, except on the Plain, the shock was preceded by some slight oscillations

and a subterranean noise, which all agree proceeded from the south-west.

The earthquakes which succeeded the fatal epoch of the 5th of February, although sensibly felt in the plain, occasioned there no further injury. No more houses remained to be thrown down, and the ground was consolidated by assuming slopes; and moreover a greater density occasioned by the shocks. All acclivities had become less by an extension of their bases. The earth therefore was shook in vain in that unhappy countries the shocks are the strength.

try; it took no further part in this dreadful tragedy.

The shock which happened in the night of the 5th of February increased the damage done to Messina, Reggio, and other towns already affected by the first earthquake. It was fatal to the inhabitants of Scylla, owing to the fall of a considerable portion of the mountain into the sea, which raised the waves, and gave them a violent undulation. The billows broke with force upon the strand, and the lower part of the town, where the prince of Sinopoli, the iord of the manor, accompanied by all his attendants and a great number of inhabitants, had taken refuge; these billows threw themselves forward on the shore, and on retiring drew back with them all that were there.*

The earthquake of the 7th of February, at half past one in the afternoon, was very violent; but it did not exercise its greatest violence in similar places to the former; it seemed as if the focus or centre of explosion has ascended six or seven leagues higher up towards the north, and placed itself beneath the territory of Soriano and Pizzoni. This earthquake effected the destruction of the borough of Soriano, and the dependant villages, of a large Benedictine convent, very solidly constructed, subsequently to the earthquakes of 1659, and of the Chartreux convent, called San Bruno, or Stephano del Bosco; all of them places which had been respected by the first shock. It concluded with overturning Lauvana, Galatro, Arena, and other neighbouring districts. Of Mileto it made a heap of ruins, and perfectly laid waste the territory of a circle, the diameter of which might be from two to three leagues.

The territories of Soriano, Arena, and Soretto, the soil of which was sandy, and intersected by ravines, experienced likewise great mutation of surface from the fall of its eminences, and displacement of its lands. The mixture of sand, clay, and decomposed granite, of which the hills are compounded below the town of Miletto, gave way in se-

veral places, and apparently ran like lava.

It is highly worthy of remark, that the earthquake of the 7th of February was felt the most at Messina and Soriano, places very distant from each other; whilst it was mostly

[&]quot;This circumstance, attendant on the carthquake, which happened on the night of the 5th of February, has been the most variously related, and has occasioned the most comments of any, many falsities being added to the true account. It is well authenticated that the waves carried away twelve hundred persons, who had taken refuge on the shore, in the number of whom was count Sinopoli. But that the water was hot, that the bottom of the sea burnt! these are particulars neither true nor likely.

less violent in all the intermediate country, throughout which however a considerable

noise was heard.

The 28th of March was another fatal epoch which carried ruin and desolation into countries, the inhabitants of which were already half recovered from their apprehension of danger from earthquakes; for not having received material damage from the first shocks, they had flattered themselves with being without the pale of this terrible scourge. The centre of explosion changed for a third time, and again ascended seven or eight leagues higher towards the north, taking its seat beneath the mountains which occupy the isthmus that unites the upper part of this province to the lower, between the gulls of Saint Euphemia and Squillaci. The most violent upward shocks, indications of the spot where the strongest efforts were made, were principally below the mountains of Girafalco, about the centre of the contraction. On this occasion nature displayed a much greater force than she had done in the preceding shocks; she lifted up and shook the very bodies of the mountains, which cover the whole space where this earthquake exercised its ravages. In consequence the extension of its momentum was to much greater distance. Calabria Citra felt its effects, and even received some injury. All the provinces of the kingdom of Naples were sensible of its shock. It ravaged indifferently both sides of the chain; lofty sites or lowly spots were alike subject to its devastation; nothing seemed exempt. By drawing two diagonal lines, one from Cape Vaticano to Cape Colonne, the other from Cape Suvero to Cape Stillo, you will within these four points have the extent within which the shock was terrible, and the destruction greatest, and the point of intermission of the two lines will be nearly that of the centre of explosion.*

This earthquake was preceded by a very loud subterraneous noise similar to thunder, which was renewed at every shock. The motions were very complicated; some upwards, as if leaps of the earth; afterwards succeeded violent whirlings, which were ter-

minated by undulations.

It would be useless to give a list of all the towns and boroughs which received considetable injury on this occasion. It will be enough to observe that all the upper part of this province suffered materially that many towns were either almost wholly overthrown, or rendered uninhabitable. But notwithstanding the violence of the concussions of the 28th of March, the misfortunes suffered by these countries were in nowise comparable to those endured by the plain on the 5th of February. Here there were no towns levelled with their foundations; the ruin of several very badly built, such as Pizzo, was prepared by the previous shocks; and nevertheless the chief part of the walls are standing. Moreover the towns of Nicotera, Tropea, Montelcone, Squillace, Nicastro, Catanzaro, San Severino, and Cotrone, are capable of being rebuilt. Few buildings have been totally ruined, and some are only a little shook. The common people have already entered the lower part of these towns; and as soon as the great houses shall be reduced to one story only above the ground-floor, as ordained by government, and they shall be a little repaired, they will become habitable. It will however require a length of time to free the mind of the inhabitants from the terror excited by the earthquakes, particularly the shock of the 28th of March, before which they felt themselves in some measure secure; and to engage the rich to leave their wooden huts, in order to inhabit stone buildings again. As one is accustomed to judge of all objects by comparison, the fate of Calabria Ultra affects one but little, having witnessed the calamities of the plains, and overgone its ruins.

^{*}I repeat here that I use the expression of the centre of explosion, not to indicate the cause, but only to explain the effect.

ns, and use, but

stonc he fate The different effects of the earthquake of the 5th of February and that of the 28th of March, can only be attributed to the nature of the soils. In the Plain the base itself gave way, not a house there was built on a firm foundation. The motion of the concussions was more irregular, as modified by being communicated through the medium of a soil yielding more or less to the force which convulsed it, and consequently transmitting it unequally. In the mountains, on the contrary, notwithstanding the agitation of the surface was pretty considerable, they were less destructive. The rocks on which the towns were built communicated to them a more regular motion, being better conductors; the soil after each oscillation resumed its position, and the edifices preserved their fixity. So a glass full of water will bear great vibration without a drop being spilt, while it is emptied by the least irregular shake.

The earthquake of the 28th of March increased the disasters of Messina, where it acted with violence; it added new damage to Reggio, and overturned a number of houses in the small town of Santa Agatha de Regio and the neighbouring places. Nevertheless it was but little felt in the Plain, which lays between the two extremities of Calabria, where, as I have before observed, the shocks were exceedingly rough. It seemed as if the actuating force passed freely, as in an open canal, under the plain, to strike alter-

nately the two most distant points.

The earth continued convulsed throughout the whole of 1783. I myself even felt several shocks in the months of February and March 1784. But none of these can be compared to the three which form different epochs, nor even to those which immediately succeeded them; neither were they followed by any accidents worthy of mention.

The sea shared little of the convulsion to which the continent was subject in the earthquakes of 1783. The mass of waters experienced no general actuation of flux or oscillation, nor rose above their ordinary level. The waves, which beat against the coast of Seylla, and afterwards covered the point of the Faro of Messina, were raised by a partial cause. The fall of the mountain, which I have before noticed, elevated the water on the spot, which received a new undulating motion, such as constantly follows similar causes. The shore was covered three different times, and every thing upon them was borne away by the reflux of the waves. The undulation extended from the point of Sicily to the other side of Cape Rosucalmo, continuing along the coast towards the south, but gradually diminishing its rise from that to which it was swollen at Scylla. This elevation of the waves immediately succeeded the fall of the mountain. If it had been the consequence of a general motion of the sea, if the waves had been acted upon from a similar cause with that experience at Cadiz, on the occurrence of the earthquake at Lisbon, they would have had a different impulse, and the effect would have been remarked to extend much farther. A violent fluctuation would have been noticed at Messina, provided the sea had partook of the shock to which the earth was subject. The mole, which is even with the water, to which vessels are moored, whose heads project above it, would have been covered, and the vessels wrecked. The same effect would have taken place at Palma, which is higher up than Scylla, as well as upon the beach of Tropea; but in no part of this coast did the sea exceed its bounds. What moreover proves that the inundation at Scylla proceeded from the cause ascribed, is the circumstance of the sea not having risen in a small creek behind the shore, on which the waters rose with such violence, owing to its not being in the direction of the undulation.

Notwithstanding I made numerous inquiries, I could not gather from any of the accounts afforded me any indication of the electric phenomena mentioned in different relations, nor of any of the sparks, or disengagement of the electric fluid, to which the na-

turalists of Naples so positively ascribe the origin of the earthquakes.

The state of the atmosphere was not constantly the same pending the disaster. While tempests and rain seemed at Messina to have conspired with the earthquakes to effect its ruin, the interior of Calabria enjoyed fine weather. In the morning of that dreadful day there fell a little rain in the Plain; but during the remainder of it the weather was screne. The months of February and March were tolerably fine, and even warm. There were some storms and rain, but none other than are common at that season. The fine weather which reigned after the catastrophe of the 5th of February was even of great advantage to the interior of Calabria; but for that the unfortunate remains of the population, without shelter, or means of procuring any, for a length of time, owing to the want of boards and workmen, would have died of want and the intemperance of the season. On the 28th of March, in the upper part of Calabria, the weather was not bad, nor was the carthquake attended by any storm; there were only some showers. From this remark it follows, that the atmosphere is not so strictly connected with the interior movements of the earth as has been incessantly maintained; and it is highly possible that the tempests experienced in the canal of Messina, and on other parts of the coast, are attributable to other causes than the earthquake.

I ask therefore permission now to seek in facts alone the cause of the earthquakes in Calabria, and, laying all system aside, to examine into what may possibly have given rise

to the almost total destruction of this beautiful province.

The motive force appears to have resided beneath Calabria itself, since the sea partook nothing of the oscillation or convulsions of the continent. This force seems also to have advanced progressively beneath the chain of the Appenines, in a direction from south to north; but what power in nature is there capable in producing similar effects? I put electricity out of question, which cannot for a year together accumulate in a country surrounded with water, in which every thing concurs to place this fluid in equilibrium. But fire remains. This element acting immediately upon solid bodies, serves but to dilate them; in which case their expansion is progressive, and produces not such violent and in dantaneous motions. When fire, however, acts upon fluids, such as air and water, it gives them an astonishing expansion; and we know that on such occasions the clastieity they acquire is capable of surmounting the most obstinate resistance. These appear the only means which nature can employ to occasion such effects. But throughout Calabria there are no volcanos. Nothing announces interior inflammation, or any fire concealed, either in the centre of the mountains or under their base; and such fire could not exist without some external symptoms. Dilated vapours, airs, rarified by a heat always active, would have escaped through some of the fissures or crevices in the soil, and have produced currents. Fire and flame would likewise have found passage through the same vents. A passage once obtained, compression would have ceased; the motive force experiencing no longer any resistance would have become null, and the earthquakes would not have been of such long duration; none of these phenomena occurred; we must therefore give up the supposition of an inflammation acting immediately from beneath Calabria. Let us now consider if by having recourse to a fire foreign to this province, and acting upon it only as an occasional cause, we may be able to explain the phenomena which accompanied these shocks. Let us, for example, assume Etna in Sicily; and let us suppose large cavities beneath the mountains of Calabria, a supposition which cannot be refused. There can be no doubt but there are immense subterranean cavities, since mount Etna, being accumulated by its explosions, must have left in the interior of the earth vacancies proportionate to its enormous mass.

The autumn of 1782 and the winter of 1783 were very rainy. Interior waters, increased by those from the surface, may have run into the focus of Etna; they would in consequence be converted into very expansive vapour, and strike against every obstacle

to their dilatation. Provided these should have met with channels conducting them to the cavities below Calabria, they would have been capable of occasioning all those convulsions of which I have given a description.

Let us suppose now, in order to make myself more easily understood, that these cavities with their channels of communication imperfectly represent a retort laid on its side, the neck of which should be the length of the coast of Sicily, the shoulder beneath Messina, and the body below Calabria. The vapour rising impetuously, and driving before it the air with which these cavities were previously filled, would first strike against the shoulder of the retort, and afterwards turn to engulf itself in the body. The force of impulsion would act first against the bottom of the vault, and afterwards by re-percussion against its summit, whence it would be revolved and reflected on all sides, so as to produce the most complicated and singular movements. The thinnest parts of the retort will be those which would tremble most at the shock of the vapours, and most readily yield to their impulse. But this water, rarefied by fire, must condense by exposure to the cold which reigns in these subterranean places, and the action of its accidental elasticity cease as promptly as its first efforts were instantaneous and violent. The vibration of the external surfaces ceases suddenly, without its being known what can have become of the force which has occasioned such disorder. It only recommences when the fire resumes activity enough to produce sudden vapours ancw, when the same consequences result as long and as often as water falls on the burning focus.

But if the first cavity be divided from a hollow of similar description, merely by a wall or slender partition, and if this separating part be broken by the elastic vapours striking against it, the former cavity will then only serve as a channel of communication, and all the impulse will then be directed against the bottom and sides of the second. The focus of the shocks will appear to have changed its seat, and the oscillations, in the space before acted upon with greatest violence by the earthquakes, will be but feeble.

Let us now apply these necessary phenomena, and suppose one or more cavities placed below Calabria, the seat of the earthquakes. The plain, which indisputably was the thinnest part of the vault, is that which would first evince the impression it recieved. The town of Messina, built on a low shore, experienced a concussion which did not affect the houses built on eminences. The motive power ceased as suddenly as it acted violently and all at once. When on the 7th of February and 28th of March the focus appeared to have changed its position, the Plain suffered scarce at all. The subterraneous noise which preceded and accompanied the shocks seemed constantly to proceed from the south west, in the direction of Messina. It resembled thunder roaring under vaults. Thus without having any direct proofs to produce in support of my theory, it appears to me to meet all circumstances, and explain simply and naturally all the phenomena that occurred.

If then Etna, as I have said, be the cause of the earthquakes, I may further affirm that for a long time it has been preparing the misfortunes of Calabria, by opening gradually a passage along the coast of Sicily to the foot of the Neptunian mountains. For during the earthquakes of 1780, which threatened Messina throughout the whole summer, pretty strong shocks were felt all along the coast from Taormina to Faro. But near the village of Alli, and the river Nisi, which lie almost in the middle of this line, the concussions were so violent as to give room for apprehension that a volcano would open itself a passage. Each concussion resembled the effort of a mine, which should not have power to spring its object. It seems as though at that instant the volcano opened itself a free passage for the expansion of its vapours, since in 1783 the vibration was almost null on that part of the coast of Sicily, while at the same time Messina buried beneath its ruins a part of its inhabitants.

TRAVELS IN SPAIN:

CONTAINING

A NEW, ACCURATE, AND COMPREHENSIVE VIEW

OF

THE PRESENT STATE OF THAT COUNTRY

BY THE CHEVALIER DE BOURGOANNE.

Translated from the French of the third edition. Paris, 1803.1

ADVERTISEMENT PREFIXED TO THE THIRD EDITION.

THE absence of the author, who is at present in Sweden, has not prevented his paying attention to this new edition. He has been furnished with information, has made additions, and rectified errors which had occurred in the former editions; so that the present has at least one advantage over the preceding, that of laying before the reader an account of the changes which Spain has undergone since 1797.

It is deemed expedient in this place to make three observations, which may probably

be of utility.

1. That as rials are frequently mentioned in the work, and many calculations are made in them, it will be considered that the rial here meant is equal to five sous of French money, so that by taking the quarter we shall have the value in francs.*

2. That as frequently as hard or American piasters are spoken of, dollars are intended, which, according to the course of exchange, or value of silver, are worth from five francs to five francs eight sous; but the Spanish piaster, which is that of exchange, is an imaginary money, the value of which at par is about the livres fifteen sous. With-

out regard to this distinction, much error may arise in computations.

3. The title of Don should never be placed immediately before the sirname, as is the case in many French and some English works which speak of Spain. It precedes only the christian name. Thus Don Francisco de Saavedra should be said, and not Don Saavedra. When desirous of noticing a Spaniard by his family name alone, he is called Mons. de Saavedra, Mons. de Cevallos. When a man employs the Don without a christian name immediately succeeding, a Spaniard is used to consider it either as a mark of ignorance, unpardonable in the inhabitants of a nation whose intercourse with them is so continual; or what is worse, as a mark of contempt.

PREFACE TO THE EDITION OF 1797.

FROM the prejudices which the rest of Europe entertains with regard to Spain even at the present day, one is led to imagine that all the knowledge required respecting that country has been drawn from romance, or the superannuated notions respecting it handed down in ancient memoirs; rather should we conceive it, from our ignorance of it, to be situated at the extremity of Asia, than at that of Europe.

^{*} In the translation the value is expressed in English money.

The principal end of this work is to modernise these antique ideas, and to rectify these errors. Not but that within the space of the last twenty years many Descriptions of Spain have been published. Many interesting details, and much truth are to be met with in the Essays on Spain, by Peyron.

Three English travellers have written on Spain: Twiss, whose work is of little celebrity; Swinburne, whose observations are famous for their justice and acuteness; and latterly Townshend, who is somewhat reprehensible for the precipitation of his decisions,

and his reliance on the credulity of his readers.

Thantereau, in 1792, published his Lettres sur Barcelone, and has given a new edition of them; and although his style be not the purest, notwithstanding his having sacrificed exact delineations to his inclination of displaying captivating pictures, his work may be read with some interest and utility.

As for the Voyage de Figaro, which, at the remonstrance of the Spanish government, ten or twelve years ago was suppressed, and which since that time has been reprinted with emendations; I mention it for those only who think that poignant sallies are a compen-

sation for every other deficiency.

The author of the present work leaves to his two countrymen the merit of perpetual effusions of liveliness and malignity. Such as read travels merely for amusement, or having their wonder excited, will scarcely choose this for their perusal. In it the author has above all things sought to be just and impartial. But justice and impartiality, although they sometimes may astonish, seldom entertain.

The author of this work has perhaps no other advantage over his predecessors than what arises from his having sojourned for a number of years, at different periods, in the country of which he gives the description; from having had a long intercourse with almost all classes of the Spanish nation, and having studied with some attention its manners

and its language.

In 1789 he published the result of his first remarks, after a residence of eight years. Since then he has made two journies into Spain; at one time spending more than a year in the country, charged with a mission of importance. On this occasion he applied himself to obtain more recent and precise ideas of different objects. This edition differs therefore materially in many respects from the first, and presents many objects not treated of in the former.

In 1789 the author, for certain reasons, deemed it expedient to keep concealed. The same motives no longer prevailing, he now avows himself. He hopes that his work, far from losing by this circumstance, will possess an additional title to the confidence of his readers. Less under constraint in expressing his opinion than what he was seven years ago, he will now explain himself with that frankness which is the duty of every writer

who seeks to establish a claim to esteem.

He who is desirous to speak of any nation without giving room for offence, and at the same time would abide by truth, has two rocks which he must avoid splitting upon; flattery, which can but be insipid even to the object of adulation; and satire, which is as much repugnant to equity as to good nature. The author will endeavour to pursue a mean. Perhaps he may now be more fortunate than on his first appearance. On the one hand, readers strangers to Spain imagined that gratitude had made a parasite of his pen; on the other, some Spaniards rook umbrage at certain avowals which were dictated by truth. Emboldened by the innocence of his motives, he dares in this new edition to brave these double dangers, persuaded that in endeavouring to conciliate all, he runs the risk of pleasing none.

ain even ing that ecting it rance of The same course as he pursued in his first edition will be here followed. Entering Spain by Bayonne, he will proceed to Madrid, pausing by the way at whatever may appear worthy of digression. In the capital he will examine the different branches of administration, and those matters in particular which may tend to develope the real manners of the Spanish nation. Thence he will advance to the southern part of the kingdom. Returning to the capital, he will make some excursions in the neighbourhood, particularly one into Arragon; re-entering France through the kingdoms of Valentia and Catalonia.

His object is to present a Picture, of which the Travels will simply be the outline. His Travels might have appeared incomplete; he has used his best endeavours that

his Picture should not be so.

THE PICTURE OF MODERN SPAIN.

CHAPTER I.

CARRIAGES, INNS, ROADS. DETAILS RELATIVE TO BISCAY; ITS LIBERTIES; ITS PRIVILEGES, THE PATRIOTISM OF ITS INHABITANTS; BILBOA, ST. SEBASTIAN, VICTORIA, &c.

IN the month of November 1777 I went first to Spain, as secretary of the French embassy, a few months after the formation of the new ministry of that power; and at a time when, to sound its disposition relative to the grand quarrel between North America

and the mother country, was a matter of high importance.

Of the three roads* known from time immemorial, I fixed upon that of St. Jean de Luz. On arriving at Bayonne, instead of taking post horses from Bayonne to Orogne, which is five leagues distant from the former, and two from the frontiers, I exchanged my carriage, as most travellers do, for a vehicle not very elegant, called by the Spaniards, coche de colleras, and which, till we are used to it, excites many alarming apprehensions. This carriage is rather strong than commodious, and drawn by six mules, to which the voice of the conductors serves both for spur and bridle. On seeing them fastened to each other as well as to the shafts, with simple cords, and their straggling manner of going, as if without any kind of guidance, in the crooked and frequently unbeaten roads of the peninsula,† the traveller imagines himself at once entirely abandoned to the care of Providence: but on the appearance of the least danger, a single word from the chief muleteer, called el mayoral, is sufficient to govern and direct these docile animals. If their ardor abates, the zagal, who is his postillion, jumps from the shafts, where he is stationed as a centinel, animates them with his voice and whip, runs for some time by their side, and then returns to his post, where he remains until called by some similar circumstance to repeat his services. This incessant vigilance of the two conductors soon

• It is well known there are three frequented roads leading from France to Spain; the one from St. Jean de Luz to Irun; another from St. Jean Pied de Port to Roncevaux; and the third from Boulon to Jonquiero. What however is not generally known, and what I only learned in 1795, from an engineer who had examined with care, and taken drawings of the different gorges and defiles of the Pyrennees, is, that from the Col de Bagnouls, which is the nearest defile to the Mediterranean sea, to the valley of Aran, near the sources of the Garome, there are seventy-live passages through the Pyrennees, of which eight-and-twenty are practicable for cavalry, and seven for carriages or artillery. One of these latter, and of the existence of which no doubt can be entertained, is the Col des Orts, running parallel with that of Perthus, on the other side of Bellegarde; for, in 1792, the Spaniards, by this passage, entered St. Laurent de Cerdu, and there invaded two of our districts.

† This is the appellation usually given to Spain by the inhabitants, on account of its being surrounded by the sea, except on the side next the Pyrennees. This term was, without doubt, adopted at the time that Portugal formed a part of the kingdom; since its disunion, it is, as far as regards Spain, in-

correct.

relieves the traveller from his fears, who, notwithstanding, remains astonished that more accidents do not happen from so dangerous a manner of travelling. He reconciles himself, however, more easily to this than to the Spanish inns, which, for the most part, are entirely destitute of accommodation. Travellers are badly lodged and served; and those who wish for the least tolerable repast, must themselves apply to the butcher, baker, and grocer. In this respect, however, there has within these few years been a change perceptibly for the better. Before the administration of Mr. de Florida Blanca there were no public carriages in Spain, nor one road on which the traveller could go post otherwise than on horseback; and if that be excepted which passes through Gallicia from Pontevedra, almost to the Western Ocean and turns to Corunna; another North of Castile running from Revnosa to the sea; those of Navarre and Biseay, the fruits of the patriotic efforts of their inhabitants, not more than ten leagues of tolerable road was to be met with at any time throughout all Spain. This minister, who possessed an almost unlimited authority, would have rendered material service to his country, if instead of being satisfied with half measures he had followed up with vigour the resolutions with which he set out; he has however within the period of his fifteen years administration sketched out some useful improvements. From 1777 to 1789 he was not at all times faithfully a friend to the alliance with France, notwithstanding his professions of attachment. His irascible disposition, and the jealousy peculiar to his country, had given her more than one cause of complaint. From that period he stood forth one of the most bitter enemies of the revolution, and would gladly have strangled it in its birth. Were he still possessed of power it might be difficult to do him justice: disgraced, to do so becomes a duty.

In the first place then, Spain owes to him the establishment of a coach carrying six passengers which sets out twice every week from Bayonne to Madrid, performing the journey in summer time in six days, and in eight during winter. In the spaces of time which intervene between the arrival of the diligences, the mules used for drawing them are employed in forwarding persons who take their own carriages with them; and thus it was that I travelled in 1792 from Bayonne to Madrid. This establishment was carried on by a private person in 1789, but being taken the succeeding year out of his hands it has since been continued at the charge of the king, but was suspended during the war. That it should speedily be re-established is highly desirable, as a means of allowing an easy intercourse for the individuals of both nations, already prepossessed in favour of each other during the long continuance of a close alliance, and with whom a state of warfare has only tended to heighten esteem, serving at the same time by affording a flux to that hatred which transitory circumstances had accumulated, to make them for time to come sensible of the value of each to the other, notwithstanding the difference of their two governments. The bonds which unite courts are as transient as their caprices. Family interests, interests of even minor value, have much influence on their deliberations. A popular government once well consolidated is only acted upon by powerful motions. Intrigue, ceremonial trifles, the frivolous pretensions of vanity, have less sway over its determinations. How many sources of quarrel are there not thus annihilated! The responsibility to which it is liable prevents the capriciousness of levity. While it disdains to dissimulate the injuries it feels, it punishes those only which are of magnitude. Nay I am doubtful whether it be not better for a monarchical government to have to treat with a republic, rather than with one formed upon the same plan as its own, and whether it may not contract alliances more durable and less liable to convulsion with the one than with the other. Thus in a marriage we frequently perceive that domestic peace is more the result of an affinity of character than of an assimilation of feature: but we

are digressing widely from the useful establishments, of which the first idea is due to

Mr. de Florida Blanca.

The improving of the highways chiefly occupied his attention. In 1777 there were no good roads between Bayonne and Cadiz except those of Biscay, and Navarre, and that which leads from the Escurial and Aranjuez to the capital. In 1792, I met with one of an excellent description, running the whole distance from Irun to four leagues beyond Burgos; and which was continued, with short interruption, as far as Madud. It would have been completely perfected, but for the obstacles which war, however fortunate it may be, uniformly throws in the way of useful labours. There want at this time no more than twelve leagues to be completed, to make the road from Biclassoa to Madrid one of the finest in Europe. Very little is wanting to that from Madrid to Cadia. In 1778 the latter was almost impassable in bad weather. In 1785 it was in great measure repaired, and carriages began to run post upon it. It is now almost entirely finished; and communication between the two most important cities of the permantal is, at length, become both easy and expeditions.

As for inus, in spite of the attention of the before-mentioned minister, they are at present very far from perfection. Their improvement, projected and undertaken by him, is a more difficult task in Spain than elsewhere. This object meets with obstruction in regard to place, manners, fiscal rights, and, in a degree, from the constitution of the country, which authorises exclusive privileges and monopoly, and vests the power, as an appendage to signorial rights of selling certain commodities, in the lord of the manor, who delegates his authority to an inhabitant; and the latter strictly enforces his right. It was necessary to capitulate upon these hindrances, and, where they could not be done away with, to adduce a remedy as well as possible. Notwithstanding these impediments, for some time back very tolerable inns are to be met with in Spain. On the roads along which the coaches run, some are established, provided with beds, linen, and even plate; and the innkeepers are allowed to keep catables for travellers. Besides, on this road there are others which are pretty good, particularly in principal towns; but every where else to the present day one must expect imas entirely destitute of conveniences, and so

disgusting, in short, as not to falsify the accounts of travellers.

In this respect, the Spaniards have not to look for any speedy annelioration. Every thing is linked together in what constitutes the prosperity of a state. Without good highways, good inns are not to be expected; and where both one and the other are wanting, whence are to come the travellers whose concourse in turn supports the roads and imps? On the other hand, in order to entice travellers, a conatry must possess some advantages either on the side of instruction or gratification. One must either look to meet with amusement in visiting it, or improve one's health. Particularly if it be at one of the extremities of Europe, the traveller is there to be attracted by monuments of the arts, by the prospects of bustling industry, by a grand central commerce; and must not have to seek in vain the comforts of life, the charms of society, and civil and religious liberty. But who will take a trip to Spain merely to behold, here fine roads traversing arid plains, as is the case in the two Castiles; there, dreadful roads in countries blest with fertility and industry, as along the coasts of the kingdom of Valentia and Catalonia; to meet with towns descrited and in ruins, a court not abounding with delights, few monuments, the arts but in their cradle, a burning climate, and the inquisition?

[•] There has for a long time back existed a method of travelling in apain, very quick but very costly, by sending changes of cattle forwards to the different stages along the road. These teams of six mules, which are put to the carriages in the twinkling of an eye, will travel five or six leagues with greater dispatch than can be done post on any road beside in Europe.

Spaniards, estimable neighbours, allies worthy in so many respects to be better known, continue to improve your roads and your inns! We shall at least be able to traverse your country commodiously and easily; but in order to engage our stay, in order to please to, many advantages are wanting to your nation, some are refused it by nature,

to obtain the others must be a work of perseverance and time.

Leaving Bayonne we pass through St. Jean de Luz after traversing a very uneven and ill kept road for the space of nine or ten miles. Afterwards one has to cross a small arm of the sea over a bridge, on the other side of which is the suburb of Sibourre. Shortly after the steeple of Orogne is discerned at rather more than a league from Irun, the first Spanish village on the other side of the Bidassoa. This little r'er, which serves as a boundary, famous in the political history of Louis XIV, from the island which it forms at a small distance to the right of the place where the river is passed, was formerly called the island of Pheasants. The interview between Cardinal Mazarin and Don Louis de Haro, which took place upon it, and of which the result was the treaty of the Pyrennees, occasioned it to receive the name of the island of Conference. Small, uninhabited, and almost a desert; like many persons of moderate abilities in the world, it owes its fame to a fortunate occurrence.

As soon as the traveller has passed this island, he is in Biscay. The country which he leaves varies little from that he enters upon, but the difference between the last roads of France and those at the entrance of Spain even in 1793 were much in favour of the latter. The roads of Biscay, those at least which run from north to south, may be said to be among the finest in Europe. Few countries laboured, in this respect, under greater difficulties. Biscay which joins the Pyrennees, in this quarter much less elevated than towards their centre and eastern range, seems to be an extensive continuation of these mountains to the borders of Castile. In tracing a road in this part there were considerable descents to diminish, and high summits to turn with address. Such ground required all the art which can be displayed in the construction of roads. The three provinces (Guipuscoa, Vizcaya, and Alava) of which Biscay is composed, joined their efforts to accomplish this end, as is usual with them when their common interest is in question. This part of Spain, which forms a striking contrast with the rest of the peninsula, de-

Each of these provinces has its particular government. In those of Biscay and Guipuscoa the orders of the monarch are not attended to before the administration has sanctioned them by its exsequatur. They hold separately every year a general meeting, at which the administration renders an account of the manner of its employing the public money. Here the deputies assemble from all those commonalities which possess a right of delegation. These deputies are elected by the ayuntamienetos (municipal corporation) who themselves are annually elected by the citizens; and, in order to be competent to

this distinction, the possession of property is requisite to a certain amount.

serves a more minute detail.

These elements of representative democracy, although destitute of that perfection which certain modern publicists have imagined possible, caused a belief upon our invasion of their country, and even during the negotiation of peace, that these provinces were adapted, as well by their principles as by their position, to become an integral part of the French republic. It was an error. The Biscayans, however jealous of their liberty they may be, are yet attached to the dominion of Spain; and, if their pride cause them to reject the yoke of a despotic monarch, poticy engages them to agree very well with their royal protector. They possess besides a species of aristocratic pride, which could but ill brook our principles of perfect equality. Enjoying exclusively their real or imaginary privileges, they would care very little for that liberty which they would have to

participate with six-and-twenty millions of fellow-citizens. An incorporation would have tempted them much less on the score of finance. The three provinces tax themselves to defray their several particular expences, and all they pay the king is a free gift, (donativo) which is rarely required of them, and which, if it were other than moderate, would not be granted. The states divide the sum agreed to among the different commonalities, according to their separate assessments, which are frequently modified.

In other respects, nature has done little for the three provinces of Biseay; and to this circumstance is owing, in great measure, their love of liberty, and the indefatigable industry which has engendered the prosperity they enjoy: for, unless where particular circumstances temper the pernicious influence of a fine climate, the more delightful countries of the world are peopled but with indolent beings, whose docile minds are prone to

despotism.

of Alava furnishes enough not only to supply the two others, but a part or Co-life, and Navarre in addition; and in 1790 and in 1791, its crop produced a profit to us inhabitants of upwards of 60,000l, sterling. It is true, agriculture is almost its only reliance: it is on this account, although of greatest extent, the least populous of the three provinces, not having more than 71,000 inhabitants. The Senorio (thus Biscay proper is called) has 116,000, and Guipuscoa, within a space of sixteen or eighteen miles by fifty in length, comprises upwards of 120,000. The whole coast of this latter province is peopled with fishermen and sailors; the whole interior with peaceable farmers. Until circumstances occurred to excite an animosity, which declared itself in 1795, the people of Guipuscoa lived on tolerably friendly terms with the neighbouring French; there subsisted even between them, and particularly between the ports of St. Schastian and Bayonne, a commerce, partly of an illicit description, but highly beneficial to each nation, and which, at the return of peace, was eagerly renewed.

Bilboa is the most considerable town of all Biscay, although it contains no more than 13,000 or 14,000 inhabitants. Some, however, of its former manufactories have declined. Its tanneries, once so productive, cease to be so, now that the hides exported from America cannot be imported directly to Bilboa, and are subjected to heavy duties when shipped at one of the ports of the peninsula for theirs. Their economical mills, from which they were used to derive such material advantage, are no longer occupied. The trade of Bilboa is now its principal reliance. This is very considerable indeed, for all kinds of merchandise are imported at and expedited from Bilboa. There are shipped, most of the wool which Spain exports, a quantity of iron, many loads of chesnuts, the principal produce of the soil of Biscay proper, in other respects ungrateful; and it is at Bilboa that most of the articles are imported from the various parts of Europe, for the supply of the northern parts of Spain. Its principal commerce is with England, France, and America. In the town there are two hundred mercantile firms, among

which are some Irish, some German, and seven or eight French.*

Strangers, who reside at Bilboa, have little reason to speak well of their treatment. Liberty, jealous and suspicious, exercises there a sort of despotism, which deforms those qualities of the government that are interesting to the philosopher. The Senorio maintains with obstinacy against the crown its incomplete and, in a great measure, chimerical privileges; and, with great difficulty, admits to the enjoyment of them those who are born out of their territory. Formalities the most tiresome must be submitted to by

[•] Within these seven years Bilboa has experienced many changes. War has not been so injurious to its commerce as might be apprehended. The demand for Spanish wood has rather increased than diminished. In the mean time, a part of their funds remaining enemployed, they have laid them out in building, and the town has received much embellishment.

would those it feels disposed to receive; and the French, in particular, up to the period of the themlast rupture, were not the least ill used. A foreigner at Bilboa is not allowed even to ce gift, hire a house in his own name, but is obliged to borrow that of an inhabitant; and, in derate, order to be treated like a stranger by the Biscayans, it is sufficient that you be not a native. When a stranger is disposed to become naturalized in Biscay, even if he be a it com-Castilian, he is obliged to prove his filiation, that is to say, to certify that he be not ded. l to this scended either from a Jew, a heretic, or from parents who have carried on any base proable infession. The proofs required for the nobles of Biseay are long. To satisfy themselves, ular circommissaries are dispatched, at the expence of the candidate, to his native place, who ountries examine his papers, and make inquiries, and who have an interest in procrastinating their profitable mission. Doubtless there are modes of avoiding, or, at least, shortening these rone to formalities; but, whether owing to the predominance of envy, or malice, no part of the That inconveniences, particularly the expence, is alleviated; and I know more than one Caralie, novice, who had undergone every form to the letter. It is not every where that the at to 165 right of citizenship is purchased equally dear.

> Bilboa is situated near the sea, on the right bank of a river of no great length, but deep enough to receive merchant vessels of great burthen. This port is not the only one worthy of notice on the shores of Biseay: St. Schastian and Passage descree parti-

cular mention.

There is no road for carriages from Bayonne to Bilbon, and travelling all along the coast is very incommodious. But from Hernania, the first considerable boro igh which succeeds Irun, a very fine road leads to St. Sebastian, over a group of mountains, from the summit of which a bird's-eye view of it is obtained. This little city is only joined to the continent by a low and narrow tongue of land. Its port, if an artificial shelter, formed by jettys capable of receiving twelve or fifteen vessels deservs that name, is commanded by an eminence, on which an old castle in ruins is discerned. Its smallness is very perceptible from the spiral ascent to the eastle. The town is tolerably well built, and much bustle reigns throughout it. It is the capital of Guipuscoa, and the residence of the governor of the province.

From St. Schastian to go to Passage, a short league distant, you keep by the sea, passing over the mountains, into the bosom of which a large gulf projects, apparently inclosed on every side, and which, at first, more resembles an extensive lake in the middle of the country, than a bay of the sea: it is the port of Passage. It must be crossed in order to reach the town whose name it bears; and, with much agreeable surprise, the traveller here meets with a crowd of young Biscayan damsels, disputing in their native tongue, (unintelligible even to Spaniards) for the honour of guiding the rudder over the bay, which is about half a league wide. The town is built within the confined space between the foot of the mountain and the Bay; it is commanded by a eastle, whence on one side

you have a view of this vast basin, and, on the other, of the sea.

Port Passage, one of the largest harbours, and perhaps the most safe of any in Europe, is material to the prosperity of Biseay; and the sacrifice thereof, which it is said there was once on our part an intention of exacting from the inhabitants, as well as St. Sebastian, and Fonterabia, another little port, at the mouth of the Bidassoa, would have been much more grievous to Spain, than it could have been advantageous to us. Here I must remark, that grasping ambition sometimes makes wrong calculations; whereas enlightened policy looks into furnity. There are possessions extremely valuable to a neighbouring state, which, for the sake of mutual advantage, are much better in its hands than they could be in ours; distinct from their being by their position, as proved by many examples, subject to momentary subjugation; so that belonging to a neigh-RR

so injurious reased than e laid them bour of whom we may be desirous of making an ally, by leaving them in his hands they afford an additional pledge for his fidelity; whereas, by their entire subjugation, they might furnish an obstacle to a sincere reconciliation. Gibraltar, ceded to the English by the treaty of Utrecht, is, perhaps, one of the safest guarantees of the alliance between France and Spain; and by tradition we learn, that this view of the matter did not escape the penetration of M. de Tercy.

Happy Biscayans, peaceably then enjoy the three ports which are the chief sources of your prosperity; and let us hope that the French, again become your allies, will not

re-occupy them, except for their protection against the common enemy.

It is impossible in travelling through it to avoid admiring the country which they have ans without a monarch's assistance, who for them lays animated; work of those Urford. These three provinces are the asylum of liberty aside the title of king for that and industry. In crossing Biscay, we perecive that their presence has given animation to every object; nothing can be more delightful than the hills; nothing more cheerful than the cultivation of the vallies. For thirty leagues, the distance between the Bidassoa and Vittora, not a quarter of an hour passes but the traveller discovers some village or hamlet. The towns of Villafranca, Villarcal and Mondragon, have an air of independence and plenty. What a difference in the aspect of this country and that of the neighbouring province! I am far from wishing to throw ridicule on the Castilians, whose virtues I esteem; but they are silent and melanchofy as their plains; and bear in their austere and sallow visages the marks of lassitude and poverty. The Biseayans have a different complexion, and quite another countenance and character. Free, fively, and hospitable; they seem to enjoy their happiness, and wish to communicate it to those who

come among them.

I shall long remember what happened to us at Villafranca. Arriving there early, on a lovely evening in autumn, with another traveller, we wandered on the outside of the town, amusing ourselves with observing the varieties of its cultivation. Several groups of peasants in different parts of the orchards engaged our attention; in turn we excited theirs. A moment of mutual curiosity caused us to approach each other. We both spoke Spanish with tolerable facility; we knew that it bore no resemblance to the language of the Biseayans; but we could not imagine that in a province so long subjected to Spain, that that of the sovereign should be utterly unknown: we were obliged to have recourse to the primitive language, and gave these good people to understand that we wished to taste their fruit. They immediately strove who should be the first to oblige us; our hands were soon filled, and we were strongly solicited to fill our pockets also. Some of the peasants went to procure us fowl and fresh eggs; we had great difficulty in preventing them from being offended at our refusal, and regretted that we had no other interpreter than our looks and gestures. We were obliged, at last, to leave them; but as we had rambled without directing our steps to any particular place, and were unable, without a guide, to find the way back to our inn, our benefactors perceived our embarrassment, and each was emulous to become our guide. Those whose services were not accepted, kept, for a long time, their eyes fixed upon us. They could not but easily discover that we were surprised at their hospitality, and seemed somewhat hurt on the occasion. We left them some marks of our acknowledgment, which they received in such a manner as proved to us the disinterestedness of the reception we had met with. We seemed to quit those amiable natives of the south-sea islands, whom Messrs. Cook and Bougainville have taught us to love, and yet we were not twenty leagues from Bayonne.

These Biscayans, who are so different from the Castilians, seem the subjects of a different government. Their province is considered, in many respects, as beyond the

Spanish frontiers. Except a few restrictions, all merchandise enters, and is never examined or taxed but at the interior limits. The province has other privileges of which the people re very jealous, but which have recently been more than once attacked; for example tobacco and foreign muslins have been absolutely prohibited, so precarious a blessing is liberty in every country. Nevertheless the Biseavans yet preserve many of their forms. We have before noticed that the impost which they pay the king has the title and character of a free gift (donativo.) If the king be in want of a certain number of soldiers or sailors, he notifies his wishes to the province, and the people find the most easy means of furnishing their contingency. The monarch exacts nothing with an air of authority, he is almost always obliged to treat with them. On many occasions has Biscay set at nought the orders of the court, and the supreme decisions of the council of Castile, when it has judged them to be incompatible with its ancient statutes. It has beside a particular court of justice. In Biscay Proper an appeal lies from the sen tence of the corregidor to a magistrate called a chief justice (juez mayor) who is at the same time the guardian of privileges. It is true he is nominated by the king, and can look to his favour alone for attaining the more eminent stations to which he may aspire.

The Biseavans maintain, what they term their liberty, with an energy which does ho nour to their character. In its conduct towards them, the court appears to treat them rather with execut, than to be apprehensive of any insurrection. On the other hand, it must be allowed that, more skilful and better adapted for intrigue than what free men are in general, they have discovered a method, and particularly within the last century, of learning the whole value due to these appearances, having incessantly in the army, in the navy, in different offices, and even in administration, some of their countrymen for defenders about the throne. Notwithstanding this, they have oftentimes shewn them selves worthy of liberty, and to it have made more than one valuable sacrifice. They have an aversion to custom-houses, which on various occasions, has been shewn to be insurmountable. In 1778 the minister Patintro, being desirous of forcing them upon them, nearly originated a general rebellion. When, in 1778, the trade with South America was thrown open to several ports of Spain, the Biscayans, if they had been willing to admit of custom-houses, might have participated in the advantage with the rest; but in the officers of the customs they beheld so many satellites of despotism, and their noble mistrust rejected the intended favour of the sovereign. They can make no commercial expedition to America, without preparing it in a neighbouring port, so that the most industrious people of Spain, the most experienced in navigation, and the best situated for such a commerce, sacrifice a part of these advantages to that of preserving, at least, a remnant of liberty. Thus, before the war which gave independence to British America, all the inhabitants of one of the provinces engaged themselves, by an oath, not to eat lamb, in order to increase the growth of wool, with the intention of rendering useless the manufactures of the mother country.

In fact, the Biscayans have had from the beginning of the present century an advantage over all Spaniards in American commerce. The company of Caraceas, known also by the name of Guipuscoa, had warehouses at Port Passage, and thence made their shipments; but this company, in the last war with England, was unfortunate, which has induced government to relieve it from a burden, that, from circumstances, became highly inconvenient, to release it from the charges of administration, without excluding it from trading with the Caraceas.

Biscay is remarkable for its roads, cultivation, and privileges, but more particularly for the industry of its inhabitants, which is chiefly exercised upon iron, the principal production of the province. In order to improve this manufacture, the Biscayans have recourse to foreign correspondence, public lectures and travelling. At Bergara there is a patriotic school, where metallurgy is taught by the most able professors; some of which, such as our inestimable Proust, have been invited from the neighbouring states. Students in chemistry have been sent to Sweden and Germany, where they have acquired, as well in the bowels of the earth as in the shops of manufacturers, such knowledge as has already been profitable to their country; for this word is not a vain sound in Biscay. The inhabitants, separated by their situation, language, and privileges, and confined within narrow limits, are called by nature and policy to feel the spirit of patriotism, and are obedient to the call. This noble scutiment produced the school of Bergara, where the nobility of the country are brought up at the expense of the states, and those patriotic societies, which have served for a model to the numerous ones of this description spread over all Spain within these twenty years; and, not long ago, the same patriotism has given new employment to the industry of the Biscayans, by digging the port of Deva, between St. Sebastian and Bilboa.

We have given a sketch of Biscay as amateurs of liberty and public economy. We

shall now proceed through the province, simply as travellers.

CHAPTER II.

CONTINUATION OF TRAVELS THROUGH BISCAY, DETAILS RESPECTING VICTORIA, PANCORVO, RURGOS, CANAL OF CASTILE, VALLADOLID, THE TWO CITIES OF MEDINA. EXCURSION INTO THE KINGDOM OF LEON. RELATIONS CONCERNING SALAMANCA, SEGOVIA, &c.

THE first town we come to after leaving Irun is Hernani. It is surrounded by mountains, which, in the space between them, contain a valley of rather cheerful appearance. A small river fertilises it, the course of which is followed for some time after leaving Hernani, and is met with again at Tolosa; (the first place at which the travellers by the coach sleep); it is afterwards lost sight of until you reach Mondragon. In the course of this journey it is crossed several times over elegant and substantial stone bridges, a species of luxury to which, in constructing highways, the Spaniards are much

At some leagues from Tolosa, you pass through the small town of Alegria, the eradle of several distinguished subjects; among others, of the Mendizabal, well known in the navy. Villa Franca is the next town at which we changed horses; the following one is Villa Real, beyond which we had an immense steep hill to surmount. At the foot of this mountain is Anzuela, whence a fresh change of horses takes one forward to Mon-

dragon.

Two great leagues before you arrive there, the road divides into two branches, one of which leads to Madrid, the other turns to the right and finishes at Durango, upon the road to Bilboa. Beyond Durango the road is impassable for carriages; so that to travel commodiously from Bayonne to Bilboa, it is requisite to ascend as high as Victoria: but there is a road which is tolerably good, that runs direct from Madrid to Bilboa, passing

through Ordunna, where the interior custom house for Biscay is established.

From Mondragon to Victoria is five great leagues. They are travelled over in less than four hours, notwithstanding one has to pass the difficult mountain of Salinas, famous for more than one accident. A party in a coach, one of which was a friend of mine, met with one some years ago, which merits a slight digression, on account of its serving to shew the manners of a class of the Spanish nation. There are very few muleteers, few carters, on setting out on their journey, few coachinen, who, on mounting their box.

ver in less as, famous l of mine, its serving muletcers, their box,

omit making the sign of the cross, mumbling a prayer, few but what carry some relies or scapularies. With this preliminary, with this talisman, they consider themselves secure from all mischance. The conductor of the carriage alluded to had not neglected these wise precautious; yet were they useless. In climbing the mountain of Salinas, his mules beguiled his care, and drew the carriage with them over the preci pice. He escaped with a few scratches, and his passengers with some slight bruises. The muletter might have seen, in the slightness of his chastisement, a signal evidence of the protection of Providence, and its agents. But not so; while his passengers were extricating themselves, gathering up their straggled property, and bemoaning triffing losses or damage, he, in a fit of passion, which had little of sanctity in it, tears away his relies from under his clothes, and the scapularies with which he was loaded, rends them in pieces, and, dashing them on the ground, thunders out a litany of somewhat a new description: "Al demonio Santa Barbara; a los diables San Francisco; al infierno nuestra Senora del carmen," &c. &c. "To the devil with St. Barbara; to the congregation of hell with San Francisco; to hell with our Lady del carmen," &c. &c.; cursing one after another the inefficiency, or treason of all the saints of both sexes, to which he had addressed his vows; giving them an energetic notice that they had irrecoverably lost all his confidence. Less than this would have been sufficient to console, and even enliven his passengers.

After passing the town of Salinas, you continue to ascend for some time, when, descending again, the mountains appear to decline sensibly, become more unfrequent, and are at greater distance from each other. After entirely clearing them, the traveiler arrives at Vittoria, capital of the province of Alava. It stands in the middle of a well cultivated plain, abounding in villages; the town is ill built, and the streets badly paved; it, however, exhibits the appearance of activity and industry. Within these few years a square has been built, each side of which contains nineteen areades. This edifice, notwithstanding some defects, would be an ornament to a city more considerable than that of Vittoria; the plan was given by M. Olavide, a native of Vittoria. There is a pleasure in seeing a citizen thus dedicate his talents to the embellishment of his native

country, in which they were cultivated.

Vittoria being the last town of Biseay towards Castile, the traveller is subject to formalities, sometimes very rigid, but at all times troublesome. Every thing which enters or leaves the province is here minutely examined, suspected letters are here intercepted, and those which are mysterious are decyphered; couriers, those even which belong to the court, are sometimes detained here, when their passports are abused for the purpose of smuggling, particularly of coin, which of all offences against the revenue is deemed in Spain the most unpardonable. I had no right to complain of my treatment in 1792: notwithstanding it was the period when the animosity of Spain towards every thing that related to our Revolution began to exhibit itself in every shape. On the contrary, I had great reason to speak well of every one with whom I had to do. M. d'Alava, who filled the office of governor, took upon himself to permit my entrance into Castile, simply upon my shewing my passport, although a formal permission from court was then necessary for going beyond Vittoria. In conformity to a recent law, the object of which is to encourage the building of carriages in Spain, a tax of ten per cent, on the value, as ascertained by an officer, is exacted on every carriage entering Spain, a certificate of which is given to the traveller; which levy is however returned upon its repassing the frontiers. Through the interference of a very obliging person in office, to whom I was recommended, I was exempted from the exaction, this gentleman taking upon himself to become my socurity.

These were not by many the only nor most precious demonstrations of kindness which I received from the obliging inhabitants of Vittoria. Some months afterwards, my family arriving from the north of Germany resided among them, while waiting for directions to proceed to me. One of my children was attacked with a serious illness. They shared our sorrows with us; they paid every possible attention to the child, and every tribute of consolation to the mother. Their extreme benevolence is stamped on our hearts in indelible characters. Respectable Alava, you, to whom beneficence is so natural, accept the homage of my gratitude; share with him my heart felt thanks, you inestimable women, matrons, who so frequently bemoaned your having no other medium to convey your cheering assurances, than that of a language unknown to the object of your commiscration; and above all, you, Don Antonio, whose sensibility is not inferior to your medical ability, and who seemed to attend your own child while warching over the health of that we were threatened with losing. And you, reader, pardon these effusions of a father's heart!

For those who value the quiet of the mind, the enjoyment of nature unadorned by art, and the means of living in plenty with cheapness, Vittoria is not without its attractions. Its climate is temperate, although the mountains which skirt its horizon, particularlarly towards the north, render the winter severe. The plain which surrounds it produces every requisite of life, and particularly excellent fruits and vegetables. The amusements, the luxuries of large towns, are here very little known; but here one may relish those innocent pleasures, delicious enjoyments of the heart yet uninfected with the refinements of civilization. At certain periods of the year, the festival of boys is celebrated, that of maidens, and that of married people; ceremonics interesting by their simplicity, which at once indicate the purity of their manners, and insure their preservation.

Leaving Vittoria, on its right is perceived the river Arriaza, which is crossed over a stone bridge. Afterwards you pass the villages of Publa and Arminon; then ascending a hill, about a league of high road presents itself, straight and of a superb appearance, being a raised causeway which leads to Miranda. Midway, on this road, a marble column rears its head, to denote the limits of the province of Alava and Castile; a monument possibly more pompous than the subject requires.

Miranda, a small town, at five leagues from Vittoria, is divided into two unequal parts by the Ebro. This stream, which formerly was the boundary of the conquests of Charlemagne towards the south, and as of ours in 1795, is one of those objects aggrandised by the magic colours of history, which is found much inferior to its reputation. It is true, at Miranda it is near its source, which is at the foot of the mountains of the Asturias; but the Ebro, which traverses the greater part of northern Spain, running from north-west to south-east, has, up to late times, remained almost wholly useless to navigation. In the course of this work we shall notice what has been done towards ren-

dering it serviceable to the provinces it waters.

It is crossed at Miranda over a tolerably handsome bridge. Fronting is seen a stony hill, with a dilapidated eastle on its summit, of no ornament to the arid scene. Shortly after we discover the high rocks of Pancorvo, which have a most picturesque appearance, and have already exercised the pencil of several travellers. At Mayago, two leagues farther, we enter the narrow valley inclosed between these rocks, half a league beyond the village whose name they bear. Shortly after, we meet with two other vallies, Santa Maria del Cubo, and El Cubo, where the wretchedness and idleness of Castile are visible in all their deformity. We then traverse vast plains tolerably well cultivated as far as

s which , my far direc-They d every on our s 50 naks, you medium bject of

unequal quests of aggranoutation. is of the running scless to ards ren-

n a stony Shortly carance, leagues : beyond es, Santa e visible as far as

Bribiesca, a small town inclosed by a well, which has four gates placed at equal distances. The road leaves it on the right. In 1777 and 1785 Briblesca wore a melancholy anpearance, it was destitute of verdure, and worthy of Old Castile. In 1792 it possessed some gardens and orchards. This was not the only change for the better which I remarked during my second journey to Spain.

The road from Irun to Bribiesca has always been excellent. It is generally lined with trees, which succeed but ill, and a profusion of stony limits. In parts it may be considered scarcely wide enough; for, desirous of avoiding the profuseness evident in the highways of France, they have nearly gone into the opposite extreme, notwithstanding

Spain has less reason to fear a waste of land than France.

From Bribiesca to Burgos is six leagues, where you travel over a country the most arid and naked of any in Europe: passing through two of the most dirty and frightful villages in all Spair, Monasterio and Quintuna; near to which you cross a stone bridge, which is rather elegant. Burgos, the capital of Old Castile, is pleasantly situated on the right bank of the Arlancon, at the foot of a hill, on the top of which are seen the ruins of an old castle. This town was formerly opulent, industrious, and commercial; it now presents the image of poverty, idleness, and depopulation. It contains no more than 10,000 inhabitants. Its only business consists in the transport of wool to the northern coast for shipment. Its manufactures scarcely deserve mentioning, if that of leather be excepted, which is of no more than twenty years standing. It proves more than any other city in Spain, that the luxury of churches absorb and keep stagnant wealth sufficient to vivily entire cantons. The magnificence of its cathedral offers a shocking contrast to the sorry buildings which surrround it. This imposing and well preserved edifice is a master-piece of elegance in the Gothic taste. One of the chapels contains a picture by Michael Angelo, representing the Virgin dressing the infant Jesus, who is standing upon a table. The noble air which he gave to his figures is very observable in these, as is also the strength and correctness of design, to which he frequently sacrificèd grace.

The cathedral is almost opposite one of the three bridges over the Arlancon. On the other side of the same bridge is a suburb, where a miraculous image, know by the name of Santo Christo, is to be seen; which is much better known, and attracts more notice than the picture of Michael Angelo. It is kept in a dark chapel, perfumed with incense, and full of ex-veto's and silver lamps, and into which persons are introduced in a manner so mysterious, as to have something awful in it, even to those who are no way inclined to superstition. The crucilix is conecated behind three curtains, that are drawn one after another with a studied slowness, which adds to the religious solemnity. Simple people believe that its beard grows. Devotees attribute to it many miracles, but

impartial eyes can discover in it nothing extraordinary.

Burgos is the birth-place of two famous captains, known even out of Spain; Fernando Gonzales and the Cid Campeador. In the time of Charles V, a triumphal arch of some taste was creeted in memory of the former; and, latterly, Burgos has paid a similar tribute to the Cid, in creeting a monument on the spot where his house is supposed to have stood. The justice is due to the Spaniards to acknowledge that they reverence the remembrance of their heroes, and speak of them with the same delight as ruined persons of their former opulence; or rather let me say, with that national pride which evinces that, if their predilection for the noble and grand be fulled for a term of too long duration, it is not extinct, and only awaits opportunities to call it into action.

The new square at Burgos, consisting of uniform, but small and mean houses, deserves notice upon no other account, than its having in its centre a statue of Charles III, in bronze. It is a bad likeness, and ill executed. It is remarked merely for being almost the only monument of this description in Spain. The Spaniards, however much devoted in general to their sovereigns, have been less prodigal than any other people of

these tributes of adulation.

If the interior of Burgos presents little but what awakens gloomy recollections, its environs are yet embellished and fertilized by the course of the Arlancon. This river waters verdant meads, has three elegant stone bridges over it, within the space of half a league, and bathes the walls of two remarkable edifices situated below the town; the one, the monastery of Las Huelyas, a convent of women, the abbess of which possesses considerable privileges, and a jurisdiction bordering on sovereignty; the other, the king's Hospital, famous for its extreme cleanliness and salubrity. The Spaniards might give lessons to the best polished nations on these monuments of charity. No heart-deadening foresight as yet has made them apprehensive, lest the unhappy should find themselves so much at ease in this asylum, as to see its doors open to receive them without regret.

Near Burgos is still another building which merits the attention of the traveller: it is the chartreuse of Miraflores, where are the tombs of John II, and his wife, magnificent, at least in their materials, and the colouring of the paintings which adorn them.

Burgos has a sufficient number of trees in its neighbourhood for the ornament of its avenues and walks, although throughout the country, which is the coldest in Spain, there is a great scarcity of wood; a want felt through almost all the interior of the kingdom. In 1753 it began to excite the attention of government. An order of the council of Castile, the execution of which was entrusted to men of little intelligence, enjoined every inhabitant to plant five trees, and penal laws seemed to ensure its effect, but the government was deceived. In some places malevolence, in many, particularly in Old Castile, the established opinion, that trees attract birds to the destruction of grain, and, in several others, bad management, contributed to render this measure inefficacious; here, saplings which began to flourish, were cut down by passengers, and there, such as were in an apparently prosperous state, were transplanted from the spots where they grew, to others, where for want of care they perished; almost every where the order was fruitless. At length, towards the end of the reign of Charles III, recourse was had to the most effective means, those of example. The king, in the neighbourhood of Madrid, and at his residences; the Infant Gabriel, in his grand priory of Malta; several grandees in Spain; many rich individuals, in what are called their domains; some patriotic societies, prelates, and even rectors; all, animated with that public spirit which gives enjoyment by anticipation of that wealth which, individually, few can look to enjoy, all these, reasoning like the old man of La Fontaine "our grand-children will here sit in the shade;" conjointly formed better conceived plantations, sheltered from the devastation of travellers, as well as of animals; and already some orchards, and copses, variegate the monotony of the horizon, and entiven with verdure part of the naked and arid soil of La Mancha and the two Castiles.

The Arlancon again presents itself to view on leaving Burgos, and is scarcely ever lost sight of in any part of the road to Villadrigo; a miserable, although agreeably situated village, to the right of the river, at the bottom of a vast plain, on which are some

paltry vineyards.

We next perceive the Pisuerga, another small river, which runs from north to south, and the waters of which it was intended should be made to supply that canal of Castile, projected and begun in the reign of Ferdinand IV, afterwards almost abandoned to the injury of Old Castile, which has great occasion for such an opening for the sale and in-

The canal was to begin at Segovia, and, following the course of the Eresma, which falls into the Duero, ascend again as far north as Reynosa, receive from the little rivers, in its passage, the tribute of their waters. Reynosa is but twenty leagues from Saint Ander, a sea-port. A road, but which will be ruined before the canal is finished, has been made to facilitate a communication by land with Old Castile. In 1792 the suburb road which I had travelled along all the way from Irun, ended at Estpa; since then it has been continued some leagues beyond Valladolid.

Continuing our way along the banks of the Pisucrga, and after having passed two steep hills, the feet of which are washed by the river, we arrive at Quintana de la Puente, near to a bridge of eighteen arches, and Torquemada, one of the most dirty and wretched towns in Spain. The Pisuerga is again crossed here over a bridge of twenty-six very solid arches, and which has lately been almost wholly rebuilt. Afterwards we arrive at the village of Magorz, where the Arlanza joins the Arlancon. A little farther, near Duennas, these two rivers unite with the Pisuerga, and run by Valladolid before they fall into the Douro, or Ducro. Were it not for the course of the Pisucrga, the banks of which are extremely pleasant, and embellished at small distances by groups of trees, nothing can be more dull and less varied than the road from Valladrigo to Duenna. Before we arrive at the latter town, which stands upon rather a steep hill, by the side of the Pisuerga, we see on the left a great monastery of Benedictines, called St. Isidro, fronting a new road, begun in 1784, by the governor of Palencia, which is one of the best in

This road, undertaken at a time when the project of rendering passable the great road leading to France was rewly conceived, was constructed at the expense of the circumjacent communes, and may serve as a model for other nations to copy. It proves that an intendant may, in some circumstances, be good for something, as Mr. Turgot heretofore proved in Limousin. I shall further observe, that it may tend to shew that, in every district, an administrator acting by himself, severely attentive to his duty, responsible in himself, and long in office, is better able than any union of transitory administrators, however well chosen, to infuse into plans of a certain extent, that connexion, activity, and emulation, which are necessary to ensure success; as well as that economy, which

admits of the multiplication of useful undertakings.

Palencia is indebted to the attention of the intendant of its province, seconded by the chapter of the bishopric, for other ornaments and improvements. Situated in the centre of a canton renowned for its fertility (the Tierra de Campos) it has, like many others, fallen off from its ancient splendour, and is no longer famous, except for the filthiness of its streets, the magnificence of its cathedral, and its manufactories of blankets, bays, and light stuffs, which are in great demand.

Duennas, which is only two leagues from Palencia, although agreeably situated, ranks yet amongst the saddest and dirtiest towns on this road. Some years back it possessed an inn, which travellers took pleasure in noticing as an exception. That which the coach stops at, on the contrary, is one of the most incommodious in Spain. Duennas has, however, some manufactories; among others, one of feathern bottles, which are the only vessels used for holding wine in this country.

After leaving the hills of Duennas the whole country, as far as Valladolid, is perfectly flat and naked. Immediately after leaving Cabezon and its great stone bridge, the steeples of that city are perceived. On this side, the entrance into Valladolid is pleasant, being through an avenue of trees, which has adjoining alleys serving as public walks.

In 1777, when I first beheld this eary, I was shocked by the want of cleanliness every where discernible, and which disgues a more of the senses than one; eight years after I perceived an alteration for the beauty, and, in 1792, I found Valladolid not only much less dirty, but greatly improved. Agreeable plantations had been established a little previous along the banks of the Pisuerga, and on the Campo Grande, a square situated at one of the extremities of the city, remarkable for its immense extent and its thirteen churches.

It has another square much more regular than this, with three ranges of balconies, in which it is asserted twenty thousand persons might be seated. I had an opportunity of judging of its capacity on my first journey into Spain, when I chanced to arrive at Valladolid at the precise time of a bull fight, an exhibition which happens but once in three years. How fortunate would this have been for an amateur: for my part, I was none, and the sight did not make me one. I was nevertheless struck by the concourse of curious people that the shew attracted from all quarters for several leagues around. The famous Torreador Pepchillo, whom, since that time, I have frequently seen, had been sent for on the occasion from Madrid. He presented several bulls which he? A slain to the ambassador that I accompanied, a custom generally followed where dist ished persons happen to be spectators; and each of these bloody tributes was a s. or a handful of gold thrown from the box of the corregidor, where we were seated, on the floor of the theatre of the exploits of Pepchillo. He certainly did not require such a stimulus, but I never beheld him more skilful nor more fortunate than on this occasion. Every thing in this spectacle, which was a three hours duration, was new to us; the scene itself, the treatment we received, the manners, the dress, and the language. At the end of this entertainment, the box of the corregidor was transformed anto a refectory. We saw glasses of water handed round, chocolate, candies of every shape, and every colour; and knew not how to refuse the obliging importunities with which we were besieged. Gestures were the only expression of our declining them, and of returning thanks. After this who shall say let a man know French and he may traverse Europe. However from this exposure we formed an high opinion of the affability of the Spaniards, and their taste for sweetmeats.

The churches of Valladolid, those especially of the Dominicans of San Benito, are elegant, according to the Spanish taste, that is, spacious and full of altars richly desorated and gilt. They moreover contain some tombs of white marble, admirably sculptured. The sculptures, as well in coloured wood as in marble, in detached groups, or bas relief, may be traced back to the revival of the arts in Spain; an epocha which produced Juan de Juni, Berruguete, Becerra, and others, who though little known out of the peninsula would yet do honour to more enlightened ages.

The new cathedral of Valladolid is represented by Pabbe Pons as a fine building. I saw in it an enormous mass of dark coloured stone pilasters round the nave of the Dorie order, and a high wall which forms the back of the choir, and prevents those who enter from viewing the rest of the church. The abbe Pons, who travelled as an amateur of the arts, frequently lavished praise, and criticism, on objects worthy neither of the one, nor the other.

Valladolid is one of the most considerable cities in Spain: it is the residence of a bishop, the seat of an university, of a patriotic society, of one of the seven grand colleges of the kingdom, and of one of the supreme tribunals called the chancery. Notwithstanding all this it scarcely contains twenty thousand inhabitants, while in the time of Charles V, it had a hundred and twenty thousand. At that time it furnished

all the necessaries of life; and was a bustling cuy, with a great trade; but indolence, and the great increase of priests and monks have annihilated almost all its advantages. The court which sometimes resided there, removing in the reign of Philip HI, to Madrid, drew along with it most of the opulent families; and at present, nothing is seen but empty houses crumbling into dust on every side. Nor aught of its ancient splendour, but a prodigious number of sacred buildings. Without its walls, is a perfect waste, notwithstanding the feeundaty of a territory fit for every sort of culture, and abounding with water; within, an equal deficiency of industry; its only manufactures which were a prospect of success, are light stuffs, and coarse camblets. Its gold and silversmiths were formerly celebrated, and deservedly so; there are still as many in one of the best peopled quarters of the town, but, at present, they are not the most ingenious.

Individuals have endeavoured for some years back to raise Valladolid from its state of insignificance. A school for drawing has been established there, and an academy, at which mathematics are taught; under the directions of the police, many quarters of the town have received improvement, and its neighbourhood, by new alleys and plantations of mulberry-trees; and two leagues off, a superb highroad towards Madrid, and eight leagues to Palencia have been completed, across a country stilt perfectly bare of trees; for the scarcity of wood, which caused Philip III, to quit Valladolid, has continued since his time to increase.

In the convent of Fuensandalgne, a good league from this city, the amateur of the fine arts meets with three paintings of Rubens, equal for their freshness of colouving to his best pieces. Semaneas, which continues to be the chief depot of the archives of the monarchy, is but two leagues from Valladolid.

Madder is cultivated with success in a part of the neighbourhood, as well as in the provinces of Burgos and Segovia, in the Asturias, Andalusia, Arragon, and Catalonia. This plant, which for a long time has been known to agree with the climate of Spain, did not awaken the attention of government before 1742. The cultivation thereof, which has made perceptible progress, saves Spain an annual tribute, which she was before accustomed to pay the Dutch, of 10,000,000 of rials. Spanish madder is cheaper, and better than any other, and foreigners begin to appreciate its value; even during the American war, the English drew it from the vicinity of Medina, and Cindad Rodrigo, through the medium of the Portuguese sea-ports. This new branch of industry is the more valuable, from the great increase of the manufacture of chintzes in different parts of Spain: and, in order to encourage the cultivation of it, a duty of 45 rials per cent, is imposed on foreign madder imported.

That part of Castile which is on the right, travelling from Burgos to Segovia, a lost country to the modern tourist, who rarely passes over it, yet contains two cities, which deserve particular notice, were it only for the contrast which their present appearance affords with their former prosperity.

Medina de Rio Seco, formerly renowned for its manufactories, is reduced from a population of about thirty thousand to fourteen hundred chimnies. To it, its fairs were a source of so much opulence, that Spanish exaggeration surnamed it the Little Indies, India Chica. There is no more than the ruins remaining of its strong eastle, which was in vain besieged by Henry de Transtamare, in the war between him and the king Don Pedro.

A more lively subject of regret is met with in another town of the same name, Medina del Campo. This city, formerly the residence of several kings, the theatre of great events, and the emporium of an extensive commerce, and peopled with from fifty to sixty thousand inhabitants, has now no more than a thousand chimnies. Its celebrated

fairs, its trade in bills of exchange, its large sale of Segovian cloths, the beauty of its edifices, the elevaliness of its streets, exist no longer but in the annals of history. What the ravage of centuries, joined to the havor of those long and terrible wars which overturn whole empires, have searcely been able to effect on the ancient cities which were any ways famous; two centuries of neglect and bad administration have operated on Medina del Campo, and some other cities of Spain. Time, with respect to her, seems to have hastened his course with tenfold rapidity; and, from the depth of the sepulchre wherein it is entombed, its grandeur may be looked upon as contemporary with the splendour of Persepolis and Palmyra. Singular example in modern Europe! what subject for reflection does it not furnish for some of its people?

After the churches, on which opulent idleness has alway's some funds to lavish, the most handsome building of Medina del Campo is that of the slaughter-houses. Philip II, whose extravagant undertakings so greatly contributed to the deterioration of Spain, has left, at least in this town, a monument of his benevolence.

The two cities of Medina bring us near to the kingdom of Leon; of which we shall

just say a word before we resume the road to Segovia.

This part of Spain is one of the most arid and waste. On the road from Palencia to Leon, its capital, the canal of Campos is met with, begun under the administration of Ensenada, and designed to enliven the commerce of Castile and Leon; but no more than twelve leagues of it are yet completed; that is to say, six leagues in one part, and as many in another. It was intended to end at the Douro, running by Palencia and Duennas, but was relinquished for a long time, afterwards resumed by the minister Florida Blanca, and again abandoned for schemes more vast, but possibly not more useful. It is not by such a vacillating system, that the regeneration of an empire can be effected.

Leon, a city pleasantly situated, and of importance up to the period of the union of its crown to that of Castile, contains no more than fifteen hundred chimnies, divided into thirteen parishes, with nine convents. Its neighbourhood is, notwithstanding, tolerably fertile, and adorned with plantations. It has some manufactories of linen, which are not constantly employed throughout the year, and of which many have latterly been given up.

Salamanca, the second city of the kingdom of Leon, deserves more particular men-

Desirous, from the reputation of this city, so much celebrated in the romances, and scientific history of Spain, to gratify my curiosity in seeing it, I made a journey on purpose during my first residence in Spain. The court was then at St. Ildefonso, which is twenty-seven great leagues from Salamanca.

Although the Spaniards, and even the abbe Pons, complain of the depopulation of this part of Spain, it did not strike me in passing through it. For example, I noticed that in the neighbourhood of Arevalo twelve villages were discernible from one spot. The whole canton, notwithstanding it be arid and poor, is nevertheless fertile and tolerably well cultivated; the result of individual possessions not being so considerable as in other parts of Spain

After passing Segovia, of which, as we proceed, we shall say something farther, I arrived at Santa Maria de Nieva, a town of six hundred chimnies, which possesses the singular privilege of having a bull-feast every year, frequented by all the amateurs of the sport in the neighbourhood.

From the eminence on which it is situated, a tolerably fine country is distinguished, of a vast extent, without any running streams, without trees, verdure, or country-houses, y of its

and which only presents one uniform tiresome aspect, if immense corn-fields deserve that appellation.

After pussing a wood of fir-trees, the land is naked, and perfectly flat. In spite of the drought to which it is subject, it is very well cultivated, even up to the gates of Arivalo, a town which formerly must have been a considerable city. Its massive gate leads to a bridge, whose solidity braves the violence of the floods, and seems to contend with time. This double monument has been deemed worthy of one of those pompous inscriptions of which the Spaniards are by no means niggard. It informs the passenger, that the communes for thirty leagues around contributed to the building of it. Within the walls of Arevalo one sees with disgust the remains of ancient columns, on which are constructed miserable huts and baleonics, of wood half rotten. The clergy alone preserve their wealth in the midst of the wretchedness about them.

Beyond Arevalo, as far as Penaranda, nothing is seen but rich and well cultivated land. Its inhalitants, notwithstanding, display every symptom of indigence. Content, like the greater part of the inhabitants of the interior of Spain, with the enjoyment of the absolute necessaries of life, they pay no regard to its comforts. Cut off from communication with strangers, and a comparison of their modes with better, they seem to be destitute of either a desire for, or knowledge of, the pleasures of life. It never occurs to the individual, that he may improve his possessions. A garden, nay, even a kitchen-garden, is an object of luxury that their parsimony denies them. Idleness enforces privations, and the habitude of accommodating themselves to privations nourishes idleness. In this circle will they revolve till such time as roads, canals, and more easy modes of transport, shall demonstrate to them the advantages of commerce. Travellers, who judge of Spain from patterns such as this, are excusable in treating it with rigour.

One becomes somewhat reconciled with this canton on entering Penarauda, a pretty little town of about a thousand chimnies. It contains many architectural remains, which shew it to have been formerly a place of greater consideration.

Its inhabitants have a strong reliance on a miraculous image of the Virgin. Without its patronage, say they, "twenty times should we have sunk under our misfortunes." Sweet illusions, which modern philosophy has the cruelty of ridiculing, and which, on the contrary, it might be well to encourage for the comfort of the poor, where the constituted authorities possess the power of preventing the abuses of superstition! Certainly they are perfectly innocent; such illusions are even valuable, were nothing else the fruit of them, but nourishing patience and hope in the bosom of the wretched. The inhabitants of Penaranda, in common with most of the provinces of Spain, appeared to me to be in need of these resources. Loaded with taxes, they earn most hardly the little which they gain, so that their misery stifles their industry. Their lords, who frequently are ignorant even of the geographical position of their estates, abandon the administration of them to intendants, treasurers, and alcaldas, who draw down maledictions on names, which might be reverenced upon closer knowledge of the persons who bear them.

I shall not quit Penaranda without observing that its inn is, perhaps, the most commodious, and the cleanliest of any in Spain. A matter unusual in this country too, I found the landlord complaisant, and some catables in the house.

I afterwards traversed a district in which, I was assured there were droves of cows, whose male calves were without horns; this then appeared to me an idle tale; I give, however, more credit to it now that I understand Doctor Johnson, in his return from his journey to the Hebrides, found, at Auchinleck in Scotland, some cattle without horns; and that, in Norway, whole races of bulls are met with of this description, between Christiana and Frederickshall. When I understood that such were met with in England,

and, after seeing in a country house at Altona a bull of this description entirely without horns, and not apparently descending from any degenerate east, as some travellers, who have met with such beasts, have imagined; I was led to conceive, that this singularity was not uncommon among the ancients; and did not consequently appear incredible to them, since Tacitus, speaking of the Germans, says, ne armentis quidem honos aut gloria frontis; "their bulls have no honoauts but a hornless brow.*

Whether these animals without horns exist or not in the district of Penaranda, I learned that the labourers at least, had some means of acquiring a competency; that the greatest part of the lands were held by them under the simple condition of rendering to the proprietor about a fourth part of the crop, themselves bearing the whole expence of the culture, gathering, &c. It is consolatory to find this class of men, so valuable in themselves, sometimes reap advantage, if not from the disinterestedness, at least, from the heedlessness of proprietors; but these examples are as unfrequent in Spain as elsewhere.

From Penaranda, after passing by Ventosa, a miscrable village on an eminence, I arrived at Huerta, where I, for the first time, remarked a custom, in some particulars, worthy of imitation. It was in having a board fixed at the door of the inn, whereon was described by the alcalde, the manner in which the hostess should behave to travellers, the price to be charged for lodging, the food of their horses or mules, &c. Thus far all was reasonable, but the foresight of the prescription went farther; it forbid the hostess keeping pigs and poultry, and suffering play at certain games in her house, receiving armed men, or women of light conduct.

It is by similar incumbrances, by which much accommodation is lost, without serving morality, that Spain, for a long time, will feel the want of good inns, and remain a dread to foreigners.

On leaving Huerta, the towers of Salamanca are distinctly seen, and not lost sight of afterwards. At a certain distance, the position of the city on the banks of the Torme is very picturesque; and, were the country somewhat more adorned, would put one in mind of Tours. Half way towards it, I passed through one of the vast pastures, called Valdios, not very frequent in Spain, but which are destitute of that beautiful verdure which is the finest ornament of country scenery. A great drove of cattle (all with horns) were there feeding in this meadow. I was now in one of the districts which supply the amphitheatres of Madrid and Valladolid. After having frequently witnessed their bloody combats, it was not without emotion, that I beheld myself surrounded by these fearful animals; but they ranged in freedom; no one provoked them; they had laid aside their ferocity. Nature has formed very few animals instanctively malevolent. Some become so, when dictated to by hunger or self-defence. Do men always wait for these powerful provocations before they manifest the rage of the irritated bull, or the fury of the hungry tiger?

On entering Salamanca, one passes at first through dirty, narrow, and ill-peopled streets. It then wears the appearance of the most wretched city in Europe; and we readily credit its population formerly so numerous, being reduced to two thousand eight hundred houses; but view with surprise, on advancing, its new square, equally remarkable for its cleanliness, and the regularity of its architecture. It is adorned by three rows of balconies, which are continued uninterruptedly; its ground-floor is formed of

^{*} In the spring of 1800, near Altona, I again met, not with the same bull which I had seen some years before, but several of his descendants, which had horns notwithstanding his being destitute of them himself; a phenomenon perhaps not uncommon.

seen some estitute of ninety arches, within the arches are placed the likenesses of the most illustrious persons Spain can boost. On one side arc seen, those of all the kings of Castile, to the time of Charles 111, in the other those of all the best known Spanish heroes, such as Bernard del Carpio, Gonzalvo de Cordova, and Fernandes Cortez. The arches of the eastern side are yet empty, how soon will they be filled?

The cathedral of Salamanca, although built in the time of Leon X, is badly imagined; however the striking boldness of the nave, and the exactness with which its Gothic ornaments are finished, make it one of the most remarkable Gothic edifices in all Spain. When further we learn that Salamanca besides this cathedral has twenty-seven parish churches, twenty-five convents of men, and fourteen of women, one is no

longer astonished at its poverty and want of inhabitants.

From an earlier period than that of the reign of Philip II, the fame of its university attracted students, not only from all parts of Spain and Portugal, but even from France, Italy, England, and Spanish America. The great vogue in which it was, has somewhat gone by, although from the new form it has received by the council of Castile, the university of Salamanca possesses at present sixty-one chairs, and a college for the Hebrew, Greek, and Latin tongues; and notwithstanding it has even now some skilful professors, who are occupied in hunting in its last coverts the pretended philosophy of Aristotle.

Another establishment of more modern date than the university of Salamanea, and at present more celebrated, is that of the grand colleges, colegios mayores. In Spain there are seven places of education of this name, four of which in Salamanea alone.

They are all of them buildings which astonish by their stupendousness; the oldest that of St. Bartolomeo has been recently re-built; and on account of its front and its principal court, claims the none of architects: it contains a library rich in manuscripts, and several learned men have been educated in it; among others Alphonso Tostado, whose immense erudition, and prodigious fecundity, serve to this time for a proverb among the Spaniards.*

Among the crowd of sacred edifices which Salamanea contains, the church of the **Dominicans**, was pointed out to me as worthy of description, that o' San Marco, and

the front of the Augustins.

The first has a Gothic front, worked with great nicety, a spacious nave and richly decorated† chapels; but I looked in vain for the fine paintings I had heard so much vaunted. The platform of the choir is painted by Palomino in fresco. In his history of Spanish painters, Palomino has given some lessons on the fine arts. According to my conception, in his works at Salamanca, he does not appear to have joined example to precept.

Instead of master pieces of painting I was shown a magazine of relies. I was pathetically invited to advance my chaplet, but this characteristic of Spanish catholicism, I did not happen to be provided with. I was however obliged to pay my tribute of respect, in which I but imitated all the attendants, and to have refused which might have been

dangerous; this consisted in kneeling before these venerated objects.

To enumerate all the sacred treasures that were exhibited to me would little entertain the reader: I shall therefore only mention the bible of the famous antipope, Bene-

^{*} When desirous of representing the number of works of any author, the Spaniards say, "Ha escrito mas quo eso Tostado." He has wrote more than that of Tostado.

[†] In Roman Catholic churches, the places where the priests read mass are called chapels, in large churches there are frequently several.

dict XIII, who was born in Spain and deposed by the council of Constance. Take care, said my conductor (who was a friar) that you do not confound him with a pope of the same name who was a Dominican; he was a true pope. The Irony of Moliere will

thus suit all countries: You are a goldsmith Mr. Josse.

In the portal of the Augustins, I saw nothing but the ornaments with which it is loaded, that were remarkable. It fronts a castle or palace of the duke of Alba, a part of whose domains is situated in the neighbourhood of Salamanca. These domains, these palaces, sadly feel the absence of their lords. This reflection is excited at every step you tread in Spain. So long as opulent proprietors cease to vivify by their presence their too extensive inheritances, at least occasionally, patriotic societies, manufactories, encouragements to agriculture, and a thousand other salutary plans, will be but useless palliating to the evils, which for two centuries continue to undermine the Spanish monarchy. This is not one of the smallest inconveniences arising from the despotism of an individual. The monarch attracts about him, by his favours, all such as can add splendour to the throne, or put it in danger by a distant exhibition of power and pomp. Vanity requires, that all should shine for its advantage, and by its means, and mistrust is apprehensive of the lustre that is distant. This was the system of Richelieu, and this is the picture of all the kings of Spain from the time of Charles V. They have consolitated their authority at the expence of the prosperity of the state.

The remaining church which they boasted of, is the old college of the Jesuits given to a community of regular canons, under the name of the church of San Marcos. Except a magnificent portal of the Corinthian order it exhibits nothing curious. The old seminary of the Jesuits was consecrated, in 1778, to the education of thirty young ecclesiastics. The ceremony of their introduction is described in a picture by Bayeux,

one of the most able scholars of Mengs.

Before I left Salamanea, I went to see an old Roman bridge of twenty-seven arches,

which is at the end of the town, over the little river Tormes.

Seven or eight leagues from this city, and on the right bank of the Douro, is Zamora, which, notwithstanding its being situated in the ancient kingdom of Leon, has, for a long time back, been the seat of the military government of Old Castile; and is

not a whit the richer for it.

Lastly, from fifteen to eighteen leagues, S. W. of Salamanea, and not far from the Douro, is a sort of arsenal, formerly in a flourishing state, and situated in a territory fit for all sorts of culture, at present it is in a wretched state, without population, and without industry. Roads almost impassable, from whichever side you proceed towards it, vestiges of ruined villages, and the worst inns in Spain, such are the attractions of Ciudad Rodrigo, and its environs.

This, I conceive, will be deemed sufficient to say of the kingdom of Leon, in order to prevent any one from undertaking an excursion to it. Let us now again enter the

road from Burgos to Segovia.

Olincdo is separated from Valladolid by eight leagues of sandy soil. In all this distance there is no other verdure to be seen than that of a dull forest of pines, and heath.

Valdestillas is half way, a town consisting of two hundred and fifty houses. I lodged there in 1792, at a farmer's, whose pride of birth would have farmished matter for an excellent connedy. His nobility he told me was incontestible; he produced the proofs of it before me, in a sort of certificate, which his grandfather, removing from Biscay into this district, had obtained from the chancery of Valladolid; for these tribunals, besides other functions, have that of pronouncing on the validity of titles of nobility, and granting a consequent certificate, which is called executoria. In each of them even

there is an apartment in which the principal business transacted is of this nature, and which apartments on this account are called Salas de hijos d'algo, (apartments of the sons of somebody) words from which by corruption hidalgo is deduced, signifying noble. My illustrious innkeeper did not fail to inform me that at Valdestillas there was a score of inhabitants, as much hidalgos as himself, but they had not such well authenticated certificates. Notwithstanding all this he was not above talking to me of the revenues proceeding from the lands of his master, which as well as the whole district produced abundance of wines. A nobleman, and have another master besides the king! Thus in Spain as well as in other countries, vanity easily reunites itself to meanness. Such an event as I have described was necessary to engage me to mention such a place as Valdestillas.

Ofinedo is seated upon an eminence, in the middle of a plain, which appears almost unbounded on every side, except to the north-east, in which direction are seen some barren hills. This city, which was formed strong is still partly inclosed by thick walls three quarters of a league in extent. It has very few inhabitants or manufactures, and its whole internal appearance announces decay. I have no where been more struck by symptoms of degradation and misery. Seven parishes and as many convents; some brick grounds and vineyards, and a few kitchen gardens under the ancient walls; these constitute all the riches of Olmedo.

From Olmedo you may go either to Madrid or Segovia, according as you take the right hand road or the left. If the former, after passing through seven or eight miserable villages, one arrives at San-Chirian, one of the stages of the diligence, and at which in 1792 I found a tolerable inn. The road, which even at that time was very bad to San-Chidrian, is afterwards most excellent as far as Madrid, that is to say, for a space of fifteen great leagues; but as far as Guadarama, it runs through one of the wildest countries in Europe, along the thick curtain shaggy with rocks, which separates Old Castile from the New. In this unpleasant journey, before you ascend the most steep part of these enormous mountains, you make a halt at a new inn, called E1 Diversorio de San Rafael. Beyond is the village of Vellucastin, where the barrenness of the country increases, and rocks are more frequent. On the top of the mountains the immense plains of New Castile are distinguished; shortly after succeeds a turnpike, where travellers pay a toll for keeping the road in repair; descending then a long slope you reach Guadarama, where it finishes.

Madrid is but seven leagues from this place. The Escurial is in the road two leagues distant. St. Ildefonso is seven leagues off, at the foot of the mountains just passed, and on their opposite side, and which project considerably with great sincosities towards the left. Nothing announces that Guadarama is so near the capital, and the two residences of the court. To behold the distance from each other, and destitute state of the inns, one would imagine Madrid could be frequented by none but pilgrims and muleteers. But before we enter that city for a long stay, we will return to resume the road to Segovia, which we swerved from at Olmedo.

Segovia is eleven leagues from Olmedo. The country round this city is the most barren, poor, and depopulated of all Castile. We pass through some large towns, such as Santa Maria de Nievi and Giusti, which we have before noticed, and perceive the turrets of the castle of Segovia, and the steeple of the cathedral, at a considerable distance. The traveller suffers much from impatience before he arrives at this city; he has several circuits to make, with many painful and tedious efforts before he has climbed, as it were, up to the square of Segovia.

VOL. V.

As he approaches, he sees to the right an old castle, built upon the summit of a steep rock; and to the left, he looks down on a valley watered by a little river from which it receives its verdure. Intent on the fine prospects by which he is surrounded, he forgets the destitute country he has journeyed over, and which on leaving Segovia he will meet with again.

This city was formerly famous on several accounts, and notwithstanding its dirtiness, and the small number of its inhabitants, is still not unworthy the attention of the travel-

ler. Its principal edifices are the cathedral and the eastle of Alcazar.

The cathedral is a mixture of the Gothic and Moorish architecture. The inside is very spacious and of majestic simplicity, and the great altar has been lately decorated with the finest Grenadian marble.

The Alcazar of Segovia, formerly the residence of the Gothic king, is a well preserved edifice. Charles III, established in it a military school, for young gentlemen intended for the artillery, in which their education is most carefully attended to. This

establishment is under the direction of the inspector-general of artillery.

The Aleazar was for a long time made use of as a prison for the crews of the Barbary corsairs who fell into the hands of the Spaniards. It was impossible to see without compassion those robust moors, condemned to a painful idleness, which was more irksome to them than their captivity, and devoting themselves to sedentary employments, for which nature seemed not to have designed their indignant arms. They were, however, never treated with rigour, and the court of Spain has restored them to their country, since the Spanish monarch has formed connexions with the emperor of Moroeco.

But nothing is more remarkable at Segovia than the aqueduct.

Segovia is built upon two hills, and the valley by which they are separated; a position which made it very difficult for a part of the citizens to be supplied with water. The difficulty was removed a considerable time back, according to the learned, in the reign of Frajan, by an aqueduct, which until this day is one of the most astonishing, and the best preserved of the Roman works. It begins on a level with the rivulet it receives, and is at first supported by a single line of arches three feet high; it runs then to the summit of a hill on the other side of the city, and appears to become more elevated in proportion as the ground over which it is extended declines. At its highest part it has the appearance of a bridge boldly thrown over an abyss. It has two branches which form an angle, somewhat obtuse, relative to the city. It is at this angle that it becomes really awful. Two rows of arches rise majestically one above the other, and the spectator is struck with amazement comparing their slender base with their height. Its solidity, which has braved in words of sixteen centuries, seems inexplicable on closely observing the simplicity of its construction. It is composed of square stones, placed one upon another, without any exterior appearance of cement, though we cannot now be certain whether they were really united without this aid, by being cut and placed with pecular art, or whether the cement has been destroyed by time. One sees with regret the wretched houses reared against the pillars of the areades, which seek in these durable ruins a support for their instability; in return for this great benefit, de grading a manument which even time has respected; but these searcely rise to a third of the height of the aqueduct, and serve at least to give an appearance of a greater projection to its grand and awful mass. A small ill-built convent has been creeted behind the augh which form the two branches. But what nation has not been guilty of like profavarious? Let those of my countrymen, whose indignation may be excited by this, remember that it is but lately that the amphitheatre at Nimes has been relieved from a similar outrage.

It is needless to observe that the houses near which this beneficent aqueduct passes, lay it under contribution on paying a certain duty, and that it was of the greatest utility to the houses, formerly much more numerous than at present, in which the wools of Segovia were washed and dyed. These wools are the most famous of all, and will form the subject of the following chapter.

CHAPTER HI.

THE WOOLS OF SPAIN. ATTEMPTS TO NATURALIZE THEM IN FRANCE. DETAILS RESPECTING THE MESTA. EXPORT OF SPANISH WOOL. MANUFATURES OF GUADALAXARA AND SEGOVIA TRAVELS OF THE SHEEP. SHEARING AND WASHING.

THE best wools in Spain are those of the districts of Segovia, those of the country of Bnytrago, seven or eight leagues east of Segovia, and those of Pedraza to the north, and stretching towards the Douro. The intercourse which I have had as well with the people of the country as with those of my countrymen,* who have reared Spanish sheep in France itself, for a period of years, have enabled me to collect detailed accounts respecting them, the most interesting of which I must beg excuse from light readers for inserting, as those of a different description will perhaps be pleased with seeing them.

In the first place, it is an almost universal opinion, although combatted by several well informed Spaniards, that the wools of Spain do not so much owe their fineness and quality to the temperature of the climate, or the nature of the soil on which the sheep are bred, as the custom of driving the flocks to different parts of the country. But what proves to conviction that Spanish sheep yield not only very fine wool without their periodical journies, but even far from the climate and soil to which the quality of their valuable burthen is attributed, is the success of the flock which originally came from Spain, and which is under the care of Mr. Danbenton, as well as that which I was employed on the part of Louis XVI, to obtain from his catholic majesty in 1785, for the park of Rambouillet; both which have constantly, from the period of their introduction up to the present time, afforded wool, which connossicurs have been mable to distinguish from that of the fleeces sheared in Spain.

The flock of Rambouillet suffered, but in a different manner, from the change of climate and food. Of three hundred and sixty which I forwarded from Spain, nearly sixty perished on the road, notwithstanding the Spanish shepherds, who had the care of them, drove them very gently, and notwithstanding they were wintered in the heaths of Bourdeaux, for the purpose of accustoming them by degrees to the climate of France; but this increase of mortality is the ordinary effect of emigrations from the south to the north, and men are even less exempt from it than animals.

In the first year of the removal of the Rambouillet flock forty perished; this was attributed to the scab which shewed itself soon after its arrival. The loss has each year

[•] In this number I must not in silence pass by M. Leblanc, an agriculturalist at Marcuil le Port, near Epernay, a Frenchman who has signalised himself by the longest series of success in his treatment of sheep, and who has had the charge of forty-five from Rambouillet; M. Cramayel as well, who at his estate of that name, has attended very much to this species of industry; M. Chabert, one of the most skilful persons of all Europe in the veterinary science, who at one of his farms at Maisons, near Charenton, keeps a flock of Spanish sheep, which refute all the objections of scepticism and malevolence; but above all, those inestimable members of the commission of agriculture and arts, in the number of which I owe particular thanks to Mr. Gilbert, who had the particular superintendance of the Rambouillet flock, for his intelligence, zeal, and civility. Mr. Gilbert was a man of excellent disposition, and a good citizen; unfortunately for the arts, and for his friends, by whom he is much respected, he died last year. To the member above noticed may be added M. Chemilly.

diminished upon that of the foregoing, if the last be excepted, in which nearly a score of the flock has perished; but this mortality must be attributed to other causes, since it affected nearly at the same time almost all the flocks of the country, and with a greater

proportionate loss.

The Rambouillet flock, so well preserved, has required no other attention than what every intelligent farmer, stimulated by interest, can afford. At first it was kept like those of Spain, constantly in the open air. The influence of a change of climate then began to be distinguishable. These animals, withdrawn from a warmer temperature, felt the effects of the cold, the wind, and the rain, which their close and oily fleece imbibed, it is true, with difficulty, but was long in getting rid of. Without continging any longer the experiment, their keepers hastened to profit by what they learned, and inclosed the flock in large covered folds well aired. They had reason for congratulating themselves upon the change. Some lambs died of cold in the severe winter of 1794. 1795, even in these pens. This is the consequence of a circumstance in which Spain has an advantage over France, and which cannot be shared by the latte. In Spain the lambs are fallen in the month of October, whereas in our climates they fall not before January. But nothing can be argued upon an extremity of cold which does not occur more than four or five times in a century.

The change of food has not tended to deteriorate either the Rambouillet flock, or those which have proceeded from it. The soil of the districts where the Spanish sheep feed, as well in Castile as in Estremadura, is in general dry and stony; the grass there is fine and short. It might be difficult to find a situation where the climate and herbage differed more from those of Spain, than the district of Rambouillet. The greater part of its park is covered with wood: its soil is almost every where argillaceous, clammy, humid, and cold. It was impossible to have begun under more vexatious circumstanccs; but the happy results of this first trial have falsified the predictions of all the cultivators of the country, and have proved that Spanish sheep may be naturalized upon every soil. It is known that where attempts for that purpose have been made in Saxony, in the duchy of Wirtemberg, in Denmark, and in Sweden,* they have not degenerated; but it is in France only that these experiments have been followed up in so fortunate and general a manner, as to forebode a speedy national benefit from the acquisition of Spanish

sheep.

For some years back success has crowned all the experiments of this description made with ewes and rams,† from the sales which government annually makes at Rambouillet. As these the animals have always been sold very dear, as well as their fleece; and their

 Of this I have been convinced either from seeing them, or from creditable testimony, during my residence in these two kingdoms. At Fredericksburg, a castle of the king of Denmark, I saw a flock of the Spanish race which, down to the fourth generation, had not degenerated. It is true, this flock was selected in Spain itself by a Dane, well versed in every thing relative to agriculture and the veterinary art, and is attended to by himself with as much care as the best Spanish shepherd could do; this is Mr. Nilsen inspector of the breeds of the king of Denmark, and one of his most useful subjects. In Sweden I have also been assured, that some proprietors of lands possess flocks which they have had for years, and which prosper with nearly equal success.

† Except this year, in which a taste for simplicity, the offspring of circumstances, a necessity of economy, and other causes more afflicting and less transitory, have sensibly lessened the price of the sheep, as well as their wool, for which the dealers offered no more than 10d. English in the grease, whereas in 1792 it sold at 8 livres 10 sous (or 7 shillings and 1d.) while our common wool fetched 30 sous (10d.) As early as 1795, the dealers had combined to give no more than 100 sous (or 50d. English); and one sees with regret, that the personal advantage of the dealers in Spanish wool may possibly prove an obstacle to the entire denizenation of Spanish sheep, more difficult to surmount in itself

than all those of a physical nature.

excessive price is a certain guarantee of care for their preservation. Proofs can be adduced among all the intelligent proprietors who have devoted themselves to this kind of industry; a pacific victory, much more valuable than any acquisition which could result from our military successes in Spain; a victory which has been increased by our treaty of peace with that power, that secures us an additional flock of those precious animals, the export of which is so rigidly prohibited by the government.* The only measure which can preserve to France the possession of these advantages has at last been definitively decided on. It has now been determined that the sheep of the Rambouillet flock shall be freely sold at high prices. Every other means would have been ineffectual, for Frenchmen are more the slaves of custom than is imagined; and the country people above all are repugnant to all innovation. Rams and ewes from Spain, gratuitously distributed as they were at first, would infallibly have perished in the hands of ignorant and prejudieed men, for want of care. These animals have nothing engaging at first sight. Their dirty, close, and curled fleece, their small stature, their shape, present nothing, in the eyes of the simple inhabitants of the country, of what appears to them to characterize the beauty of sheep. The mode of selling them by auction was conceived the most certain of all, on account of its dispersing these chosen animals among connoisseurs, and making self-interest an inducement to the care of them. As to interest, the worst informed grazier, however obstinate he may be, must soon be convinced that he will find it in adopting the Spanish breed, whether pure or crossed. Sheep of either of these descriptions ask no more care than what the common ones of the country require to be preserved healthy, and in good condition. The same climate, the same soil, the same food, serve for one as well as the other; they exact only a little more cleanliness, on account of the greater closeness of their fleece, and its being more oily; and yet the wool of them sells for almost double the price of that of the other, and the fleece is as heavy again. It is well known that the common weight of the fleece of one of our sheep is from three to four pounds;† that of the Spanish breed, whether pure or crossed, is seven or eight. Some well authenticated examples prove the extreme difference between the weight of the fleeces of our sheep and that of the Spanish breed. At his last shearing M. Hamerville, of the neighbourhood of Bourges, met with a fleece in his Spanish flock which weighed eleven pounds and a half; and this year, at Maisons, near Charenton, I kept one myself which weighed nearly twelve pounds; and yet it was not from a sheep purely Spanish, but from a breed of the third cross. The proprietor of this flock has even had two rams of an unmixed breed, which for three years together yielded thirteen or fourteen pounds of the finest wool, possessing, if not a perfectly equal fineness, at least all the elasticity, and every other good quality of Spanish wool.

A double profit is certainly thus afforded to the farmers who renounce their prejudiees. There can be no reply to such arguments.

There are few departments into which this Spanish breed has not been introduced. Since their obtaining a high price they succeed every where, on account of their value

† I do not here include certain districts where it is well known sheep of a very poor description yield from ten to twelve pounds of wool.

^{*} Divers obstacles have retarded for three years the completion of that article of the treaty of Basle, by which the king of Spain allows the exportation to France of six thousand sheep in the course of six years. It was not till 4798 that Mr. Gilbert was dispatched to be present at the purchase and selection of a part of the Sheep stipulated for. He sunk under the fatigues of this voyage, as tollsome as it was useful. Nothing now remains but to follow the road he had chalked out. Hearn that a society, authorized by government, has recently taken upon itself to export, at its own expence, four thousand Spanish sheep, part of those which the treaty of Basle guaranteel to us.

insuring those cares which animals removed from their native fields imperiously demand, of whatever species they may be. That part of France whose climate and pastures appear to be most congenial to Spanish sheep, (Roussillon) is precisely that in which there are none;* doubtless because its inhabitants are not aware of the profit they bring,

Experience and time perhaps will teach them better.

But it will be asked, do these transplanted sheep, do their descendants of the pure race yield a wool equally fine as in their native country? In order to answer this question faithfully which Spaniards may propose in spite, and Frenchmen with distrust, we will frankly confess that our government, twelve years ago, caused Van Robais, of Abbeville, to manufacture the wool or a small flock of the Spanish breed which was at the veterinary school; that the cloth when made was as handsome and fine as could be, yet did not possess altogether the softness of Spanish wool. This experiment is perhaps the least favourable one of this description which has yet been made, since from every other it has been demonstrated that if the French wool is not altogether so soft as that of Spain, it is yet equally fine, and has increased somewhat in length, without losing its principal quality, and this length renders it very fit for the warp. To sum all, the samples preserved annually since the arrival of the Rambouillet flock, are sufficient to satisfy the most incredulous, that in the course of fifteen years it has experienced no change whatever.

Nor let it be said that fifteen years are insufficient for determining that the wool of the Spanish flocks transplanted into France will not in the end degenerate. For if a degeneracy be to take place, the first appearance of it would have shewn itself after such an interval. Moreover, the flock of M. Daubenton destroys all doubt, since it has maintained itself in its pristine purity for more than thirty years upon the most ungrateful soil; and this inestimable agriculturist has published certificates of our most celebrated manufacturers, which attest that having employed without distinction wool coming direct from Spain, and that from his flock, they had absolutely found no difference whatsoever. M. Leblane, of Marcuil le Port, assured me at the close of 1796, that for ten years that he had manufactured the wool from the unmixed Spanish breed, descended from that of Rambouillet, the workmen he employs distinguish nothing more between this and that sent from Spain, than that the latter is in a triffing degree stouter. And let us as we proceed remark, that this very slight inferiority of softness in the wool, is perhaps the only consequence resulting from the change of climate, this quality being principally ascribable to the great transpiration excited by the temperature of Spain, and which generates the very unctuous oil with which the wool of the sheep is impregnated in that country.

Morcover, it is not those sheep brought from Spain, or deduced from purely Spanish breed alone, which give these results. Those which proceed from the cross with the French breed at the fourth generation, and even sometimes earlier, produce as fine wool as such as are entirely of the Spanish breed, provided the males which are conceived of the mixed breed be either kept apart or spayed, and the female cross be employed with rams of the pure race only, for it is demonstrated that the ram has influence double that of the ewe upon the produce of propagation; provided further that these delicate animals be not confined to narrow, low, or close pens; and, lastly, that they be intrusted to vigilant and intelligent shepherds, such as that of M. Chabert, at Maisons, who affords a model deserving of imitation in this respect. It seems, be whatever part of France it will in which sheep are thus taken care of, and thus crossed, the

^{*} This was the case at least in 1797.

wool of For if a er such it has ingratest celeol comficrence that for escendoctween . And wool, is y being in, and egnated

Spanish vith the ne wool re conbe emfluence at these at they at Maie whated, the results are the same. Government for some time back maintained a flock at Seeaux, purposely designed for comparative experiments upon the crossing of rams of the pure Spanish breed, with sheep of the different departments. But these experiments have not yet been sufficiently numerous to serve as a basis for positive assertions. All that can be positively affirmed is, that the Spanish breed crossed with sheep of the coarsest wool, yield at the latest at the fourth generation produce equal to the pure race; that if the pure breed be coupled with large sheep of a great fleece, the produce is the longer in arriving at the desired degree of purity, but at length is better furnished with wool; and that if it be crossed with sheep of fine wool, such as those of Roussillon, Sologne, and Berry, superfine fleeces are sooner produced, but are not so heavy.

Thus it is sufficiently evident, that the famous quality of Spanish wool does not depend exclusively on the soil or climate of that country, no more than that the wandering sheep, called Tras Humantes, or Ganado Merino, receive the benefit which is ascribed from their travelling. The Spaniards have no occasion to seek the proof of this second truth in our fields, they are themselves in possession of it. It is beyond dispute, that in Estremadura there are flocks which are never driven to any other place, the wool of which does not perceptibly vary from those which are kept travelling. It is equally true, that, in the neighbourhood of Segovia, there are small flocks which never leave it, and whose wool is as beautiful as that of those which do. I have been assured by the people of this district, that of the twenty thousand arrobes of fine wool grown there, near a third was produced by the stationary flocks.*

To what then is the practice of driving these millions of sheep all over Spain to be attributed? To what but that which tends to cause, to propagate, and consolidate abuses, the personal interest of the powerful, which has engendered the ruinous privileges of

the mesta in Spain.

This is a company of great proprietors of flocks, composed of wealthy religious communities, grandees of Spain, and opulent individuals, who find their account in feeding their sheep at the expense of the public in every season of the year; and who, by impolitic laws and regulations, have given sanction to a custom which necessity first established.

The mountains of Soria and Segovia, condemned to sterility by the climate, soil, and the steepness of their sides, were formerly the asylum of some neighbouring flocks. At the approach of winter, their temperature was no longer tolerable. These delicate animals sought, in the circumjacent plains a milder air. Their masters soon changed this permission into a right, and formed a company, which was augmented by the addition of others, who, having acquired flocks, were desirous of enjoying the same privileges. The theatre was extended in proportion as the actors became more numerous; and, by degrees, the periodical excursions of the flocks were extended to the plains of Estremadura, where the climate was more temperate, and pasturage in plenty. When the abuse began to appear intolerable, it had already taken deep root, and affected the interest of the most powerful citizens. The consequence is, that, for more than a century, there has been a continued struggle between the company of the mesta, on one part, and,

^{*}In the sixteenth century the travelling sheep were estimated at seven millions: under Philip III, the number was diminished to two millions and a half. Ustariz, who wrote at the beginning of this century, made it amount to four millions. The general opinion is, that at present it does not exceed five millions. If to this number the eight millions of stationary sheep be added, it will make nearly thirteen millions of animals, all managed contrary to the true interests of Spain, for the advantage of a few individuals. For the proprietors of stationary flocks also have privileges, which greatly resemble those of the members of the mesta.

on the other, the Estremenos, or inhabitants of Estremadura, who have all friends to the

public good on their side.

In fact, how can they view with patience the millions of sheep, tras humantes, which fall from the mountains of Old Castile upon the plains of Estremadura and Andalusia in the month of October, returning in the month of May; and which, in coming and going, feed along the whole of the road in every commune; while the ordonnances of the mesta allow them a breadth of road of ninety varas (about eighty yards) and, while the pastures which await them are let at a moderate price, an augmentation of which has been for a long time solicited in vain. In short this unfortunate Estremadura, which is fifty leagues long by forty wide, and which might furnish subsistence for two millions of people, scarcely contain a hundred thousand houses; and this want of population can be attributed to nothing but the scourge of the mesta; since the provinces which are not subject to such dreadful privileges, such as Gallicia, the Asturias, Biscay, and the

mountainous country of Burgos are well peopled.

This erving abuse has been attacked by many enlightened Spaniards, as well of our time as of former ages; by Leruela, Usturiz, Arriquabar, even by that humorous philosopher Cervantes, who, under the veil of pleasantry, has given such wise lessons to mankind, and to his fellow-citizens, and much more recently by Don Antonio Ponz, by Count Campomanes, &c. &c. Their voice has been "a voice crying in the wilderness." This abuse does not even depend on the credit of powerful people alone, it is a consequence of idleness, and misconecived interest, which prefers the grazing of sheep to agriculture. Within a century wool has doubled in price, whereas grain, the culture of which is so toilsome, and so precarious, has very little increased in value. Ten thousand head of sheep will yield, communibus annis, two thousand arrobes, or five hundred pounds of wool, at the rate of five pounds per fleece. And rating the arrobe at no more than 100 rial, or 25 livres Tournois, these ten thousand sheep will produce about 50,000 francs, or £2000 sterling; from which, it is true, the cost of their food is to be deducted, the expences of their travelling, the rent of their winter grazing, the wages of the shepherds, and other incident expences; but which yet leaves a net profit of sufcient amount to render this species of property highly valuable.

As to the practice of driving the sheep to different pastures, besides its being sanctioned by law, and long custom, it is not only excusable, but rendered necessary by circumstances. Either the number of sheep must be diminished, or some must travel a field. Those which, during summer, find pasture on the mountains of Soria, Cuenca, Segovia, and Buytrago would die of hunger, if left there in winter; and where can they find a better asylum than in Estremadura, a province badly peopled, not opulent, and whose pastures are its only reliance? I am well aware that this argument may be looked upon as begging a question; but, up to this time, government has been willing to look upon

it as conclusive.

Others excuse the mesta from that long endurance which perpetuates a system. He who reasons thus would be scrupulous, however despotic his nature, of infringing on the property of the proprietors of flocks by violent reforms. And how is it to be expected, that they should be prevailed upon to renounce voluntarily a benefit, the management of which is neither very complicated, nor very expensive; the produce of which (nearly certain) finds an almost inexhaustible demand, from the avidity with which Spanish wools have hitherto been bought by manufacturing nations? Besides, the exchequer is interested in the maintenance of this branch of trade; for the duties which are paid on the export of wool, form an important branch of its revenue. Latterly it has amounted to from twenty-seven to twenty-eight millions of rials. A government

will scarcely consent to dry up a source of such benefit without having a ready substitute.

There is a slower, but a more certain mode of obliging Spain, in spite of herself, to diminish this immunerable host of animals, which devour her, if I may use that expression in speaking of an animal, whose name alone imparts ideas of innocence and peace. It is that which France is about adopting whose success may induce other nations to follow her example, which have hitherto imagined that they were obliged to have recourse to Spain for wool. Then will the covetous and idle proprietors of these immense flocks feel themselves obliged to employ their capitals in a different manner, in one less lucrative to themselves, but more advantageous to their country. Fortunate will it be for Spain, if, calculating on the consequences of this species of revolution, she prepare her territory beforehand for its new destination, by increasing and perfecting her roads, her canals, and the other modes of vivification in which she is deficient.

In the present state of things, that in which they are likely to continue for a long time, wool forms one of the principal staples of Spain. Before the war of 1793, the common exportation at Bilboa was annually from twenty to twenty-two thousand bales, of from two hundred to two hundred and fifty pound weight; and from St. Andero about a third part of that quantity. These are the two ports at which incomparatively the largest part of the wool of northern Spain is shipped. If we are to judge from the year 1792, England is the country which receives the most, and Holland the next largest quantity. France only standing in succession. That year there was exported,

For England,				From Bilboa, 16,176 bales,	-	From St. Andero. 4,678 bales.
For Holland,	-	•	-	6,180	-	1,909
For Rouen, For Ostend,	-	-	•	1,186 -		1,200
For Hamburg,	•	•	-	654		
ror rrambing,	-	•	-	356		

But the year 1792 ought not to serve as a guide. At that epoch, the commerce of France already began to feel the effects of the revolution, and the war which began in the month of May. Commonly the export to France amounted to nearly four times as much, or about eleven or twelve thousand bales, that is to say, more than half the quantity exported from the rorthern harbours. If these bales be valued at no more than 1,400 rials per hundred (the average price of 1792, when superfine Leonese was worth 18 to 1900 rials, and the commonest 1100 to 1150) and the bale be rated at two hundred; it follows, that the common annual importation of France, before the Revolution, amounted to upwards of 32,000,000 rials.*

Our manufactories of Louviers, Elbœuf, Rheims, Abbeville, and Scdan, particularly that of Duretot, could not do without Spanish wool; the wool of Champagne and Berry, of which their consumption, is considerable, serving only when used by themselves for common cloths, a part of it alone being used in the others. Some cloths, cassimeres for example, are wove purely of Leonese, and admit of no admixture whatever. If, then, France should succeed in extending the propagation of the Spanish breed so far as to render unnecessary the importation of wool, it will be freed from an annual contribution

^{*} As in this computation every thing is taken at the lowest, since superfine Leonese is the quality of wool, of which the largest quantity is exported, and many of the bales weigh two hundred and fifty pounds, it may be deemed not too much to add a fourth part of this sum of thirty-two millions, which will agree with the account of the balance of trade, furnished by Mr. Flandrin; by which it appears, that, in 1782, we received Spanish wool to the amount of 13,600,000 livres. See Flandrin sur P Education des Moutons, p. 213.

VOL. V.

of 12 to 13 millions. Let us hope, that the birth of public spirit among the inhabitants of the country will find in this a sufficient incentive for directing the attention of agriculturists to this improvement, separate from the immediate advantage arising to themselves from a branch of industry, which, it is true, exacts care, but which requires few expensive advances; which, without detracting any thing from the value of the land, exhibits a means of reaping a crop, which does not grow from its bosom, and of which crop almost the whole is profit. Let us now turn to what relates to Spanish wools, where Spain alone is concerned.

Of them she is capable of exporting 52 to 33,000 bales, of from 200 to 250 pounds weight. The exportation of 1792, through the ports of Bilboa and St. Andero, was to that amount, without including five or six hundred bales of lambs wool in the grease; for now almost all the Spanish wools are washed before exported. Before the increase of the duties on wools in the grease, which took place in 1787, almost all the lambs wool of the Leonese, Segovian, and Sorius Cuballeros shearings were shipped in the grease, and amounted to about 1800 to 2000 bales, of eleven or twelve arrobes each

(297 to 324 pounds.)

For these thirty years back, the necessities of the exchequer, and the persuasion that foreign nations could not do without her wool, however high its price, have caused a

successive augmentation of the export duties.

Between 1766 and 1787, these duties were increased from 42 rials 12 maravedies per arrobe for cleansed wool to 66 rials 28 maravedies, and from 21 rials 6 marav. per ar-

robe, for wool in the grease, to 50 rials 4 maravedies.

In Spite of these successive augmentations, the exportation of wool has rather increased than diminished. It is one, but not the principal cause of the dearness of cloth, the chief being the greater price of the staple itself. Within these thirty years the value of wool in the grease has increased, the superline Leonese from 75 to 80 rials per arrobe; and those of an inferior quality from 100 to 120 rials: notwithstanding this, the demand of the manufacturing nations has not discontinued; on the contrary, at the conclusion of the war which began to convulse Europe in 1792, the exportation appeared to be greater. It is at Madrid, although at so considerable a distance from the centre of the fine wool country, that the most extensive dealings in this article take place. In this capital are four or five houses employed in it. They buy up the shearings of the flocks in advance of several years together, of those proprietors who possess the best; * but it is not every Spanish house that possesses either the necessary capital, or the courage to enter into such speculations; and by far the greater profit is left to the adventurers of the commercial nations. The French, the English, the Dutch, fetch Segovian and Leonese wool from Bilboa and St. Andero, and do not even leave the Spaniards a comission upon the sales, buying the wool, when in the custody of the shepherd, and washing it themselves. The Dutch, in particular, purchase, in this manner, a very large proportion; not that they themselves manufacture the whole of the wool they export, but to enable them to supply those who resort to them under a certainty of being accommodated to their liking. They pay in money for the wool which they have to shear, and give long credits to those who apply to them to select what may suit. The manufacturers of Viviers and Aix la Chapelle have endeavoured, in vain, to lay aside their interference, and supply themselves directly from Spain; in the attempt they subjected them-

The duke de l'Infantado, for example, made a bargain in 1791, by which he disposed of the produce of his shearings for eight years to come, for the sum of 100,000 piastres. The company of the Gremios, in particular, speculate considerably in this article. On the return of peace, it possessed aine hundred bales, which is found great difficulty in disposing of.

selves to the greatest inconvenience. They were displeased with the wools which were shipped to them. They had disputes about the price, and the credit, which they insisted on having extended to fifteen months, and finally ended in resuming their old plan.

Notwithstanding all the statements we have collected, it is difficult to ascertain with nicety the quantity of fine wool annually shipped from the ports of Spain, including Se ville, at which that of the southern provinces is exported. In 1790 I was assured that it exported to the amount of 60 millions value in rials. The following calculation may

serve to show that this quantity is even less than the truth.

Be it allowed, that no more be shipped from Bilbon, than 22,000 bales, nor than 8,000 from St. Andero: to them let the 4,500 bales be added, which are exported by Seville; collectively these will form a total of 34,500 bales. Those rated at no more than 200 lbs. per bale, yield an amount of 6,900,000 lbs. which at the low price of 10 rials per lb. give the sum of 69 millions of rials. In this computation, every thing is taken at a low rate, particularly the price of the pound of wool, since in 1792 superfine Leonese obtained 1886 rials, and common 1150 rials the hundred weight, consequently the former cost more than 18, and the latter more than 11 rials per lb. We shall therefore keep much within compass in estimating the value of the annual exports of wool at 80 millions of rials at least.* Will France continue to be one of the principal importers. and take annually, as before the rupture between the two powers, her 10,000 bales? Doubtless; for should the plan she has adopted become established, should certain interested views no longer oppose its progress, should the calculations of avariee among the French be stifled by a love for their country, prejudice will yet for a long time prevail over reason, and custom over interest among the farmers. Yet should this change universally prevail, would Spain be the loser in proportion to the acquisition of France? Certainly not. This revolution in her political economy produced by degrees, would necessarily conduce to improvement, and the adoption of regenerating plans. Proprietors, pampered hitherto from the easy manner of their acquiring wealth, and some rich individuals would suffer without doubt, but the mass of the nation could not fail to gain by it.

Spaniards, allies, look not then with a jealous eye on the fortunate experiments we are making, to do without your wool! As yet we are far off our aim, and years must roll before it can be effected. Continue to trust to that versatility, of which the revolution has not cured us. Continue to trust to the strength of root, which prejudice has taken in the country; and if ultimately you should lose us, as purchasers, reflect that the loss, with which you are threatened, does not create concern among those of your citizens, who are the best informed on your real interests.‡ Two of the most en-

† I am sorry that a Spaniard whose opinions are worthy of respect should think differently. I have been told that a French land owner to whom a detachment of the Rambouillet flock had been forwarded under the guidance of one of the Spanish shepherds, having brought this man to Paris after the lapse of a year, and thinking it a duty to present him to his ambassador, was very coolly received and

A more nice computation than what is here exhibited by Mr. Bourgoanne might have been adopted by him. In the course of the work he lays before the reader, the statements made by Lauren, the Spanish minister in 1789, by which it appears, that the duties collected on the wool in the year 1787 amounted to 27,449,246 rials, and a few pages past he mentions that the duty per arrobe was for wool washed from the grease 66 rials 28 maravedies. Consequently, separate from what might be smuggled out; and taking for granted (which would not be emirely the case) that none was exported but what paid the superior duty, the entire quantity will still have been upwards of 400,000 arrobes which at 1600 rials per 100lbs, will give 160,000,000 of rials, or near 2,000,000l, sterling. However large this may appear, it is less than half the value of her exports in this article since 1787. Translator.

lightened ministers of this century, Campillo, under Philip V, and La Enzenada, under Ferdinand VI, considered your immense export of wool, as one of the greatest obstacles to your industry; for as they observed, the people who receive it, return it manufactured, and sell it back at a high price; while those of an inferior quality, which remained in Spain, are manufactured there at a great expence; your manufacturers indemnifying themselves, by the dearness at which they sell their goods, for the small quantity of wool left them to make into cloth. Finally, many well informed persons among you imagine, that by our concurrence towards causing a diminution of your too numerous flocks, we rather acquire a claim to your gratitude, than merit your resentment.

Let it not, however, be conceived that Spain does not draw some advantage, even at present from her wools, in a manufacturing point of view. For a long time all low wools are worked up at home for the clothing of the troops, and the common people;

and the exportation of them is forbidden.

By much the greater part of the sheep, which furnish this kind of wool, are black, and the cloth is left of the colour of the wool. Hence the great number of brown cloaks, which add to the sad and dirty appearance of the inhabitants of the country, particularly of the two Castiles. There is as well wool of a secondary quality, such as that of Valencia, the export of which is not forbidden, which is employed in the French manufactories in Languedoc, but which for the most part is worked up in the country, where it is grown. Fine wool also is used in several districts of Spain with great success, and particularly in the manufactory of Guadalaxara. Whimsical occurrence! its existence is due to two foreigners, who made a rapid fortune in Spain.

It was cardinal Alberoni, who founded this manufactory in 1718, and gave the management of it to Ripperda. At first cloths of a second quality only were made here, notwithstanding wool from the best districts was used. Under Charles III, the manufactory of San Fernando, at which superfine cloths only were made, was removed to

Guadalaxara. Guadalaxara then had two manufactories of fine cloth.

This establishment in 1783, was one of the most complete that can be conceived. It had within itself every thing necessary for perfecting the manufacture of cloth, and all the instruments and tools which are used in it were made upon the spot. It had eighty looms for cloths of the first quality, properly called San Ferncandos; one hundred for those of second quality, and five hundred and six for serges, by means of which they hoped in time to do without recourse to England, to whom, for the single article of woollen cloths Spain annually pays 2,000,000l. These looms, collectively distributed in two buildings, gave work to \$825 persons, all paid by the king, without reckoning a much larger number, dispersed among the fields of La Mancha, and the Castiles, and employed in spinning the wool designed for Guadalaxara. Except in what regarded economy, the want of which has been repaired, it would be difficult to meet any where with a manufactory better organized. Guadalaxara consequently offers a striking contrast with the towns about it. I did not observe one beggar, one idle person among the 15 to 16,000 inhabitants, of which it is composed. Manufactories, and particularly that of cloth, have many minute operations, of which children, old men, and infirm people, are capable. They are a supplement of labour, furnished by the arts for the advantage of feeble or suffering humanity, to nature condemned without to languish, unserviceable itself, and burthensome to others.

obtained for answer to the thanks he gave him as representative of the court which had bestowed this benefit on France: "No thanks to me; Sir; for if I had been consulted, never should a sheep of our country have gone from Spain to France." I did not in this answer recognize M. D'Arandu. He was from habit more alive to the true interests of his country; and above any paltry national jealousy.

intage of

rviceable

These manufactures have experienced many changes since 1783, according to who had the superintendance of them. Valligio, one of the last superintendants, made some useful although expensive additions to them. His successor, Don Santjago Romero, pays less regard to shew than utility. He has used means to secure a sale for the cloths, and to cause them to be manufactured so as to suit the taste of the consumers. The Spaniards already vie with Abbeville in their own esteem, and do not greatly flatter them selves. But will it be believed, although they have their wool from 25 to 30 per cent, cheaper than us; although there be a sufficient population about these manufactories; although there be no want either of wood or water, their cloths were notwithstanding, at least previous to the war, even dearer than ours.?*

It must however be confessed, and unprejudiced Spaniards allow, that their manufacturers have yet somewhat to learn in dyeing and fulling their cloths. But when, as is the case with them, the materials are not wanting, a few hands skilled in those branches, are sufficient to perfect many manufactories. Government is watchful to procure them. All these arts of seduction, which rival states mutually endeavour to make abortive, but which they tacitly agree in overlooking, have been employed by the court of Madrid to decoy such workmen, and skilful artists, as are still wanting to the national manufactures, from England as well as France. Towards the end of 1784, I discovered that a manufacturer of one of our towns, whom I shall not be so indiscreet as to mention, suffered himself to be seduced by the Spanish government, which offered him 160,000 piastres towards establishing a manufactory of cloth in Old Castile, and for bringing a hundred families from his country for the purpose of working it. No doubt the project was unsuccessful, as upon my second journey into that country I could find no trace of it. About the same time two of our artists (whose names I shall mention with pleasure) Quartremire d'Isjonval of the Academy of Sciences, and Chardron a manufacturer at Sedau, received similar propositions, and rejected them. I have since heard that similar attempts have been made in England, and not without success.

The Spaniards have, however, now among them some skilful persons, capable of giving their cloths the highest degree of perfection. Such is Don Gregorio Garcia, who has the direction of that manufactory, established by the minister Lerena at Valdemoro, the place of his birth, situated between Madrid and Aranguez, and one of his pupils,

Don Pedro Ciusta, a manufacturer at Segovia.

Guadalaxara is the only place in Spain, where the famous Vigonian wool is manufactured, the precious produce of Peru, brought to Spain by the way of Buenos Ayres, and which is met with in no other country. In France they have endeavoured to manufacture this wool, and those who have compared the cloth with the Spanish, agree that the French has better face, but theirs a greater consistency, either because the Spanish workmen understand the manufacturing of it better than the French, or because the best qualities of wool are reserved for their own use. Very few cloths, however, of this description of wool are made even among the Spaniards themselves, nor is there a possibility of getting them, without their being ordered several months beforehand. Some are worked on account of the king, who makes presents of them to different sovereigns. In 1782 Charles III, sent 20 pieces to the Grand Segnior, on the occasion of a treaty

^{*} Charles IV, who visited the manufactories in 1791, found there 300 looms for fine cloths of first and second qualities, and 350 for serges. They afforded employment to 24,000 persons within and without the city, and manufactured cloths annually to the amount of from 13 to 14 millions of rials. The finest and dearest cloths on account of their colour, but of the second quality, sold at 84 rials the vara; the superfine San Fernandos at 94; those of Brihuega at 74 and serges at 13. The vara compared with the French ell is as 5 is to 7.

concluded between him and the Porte. It was observed at the time, that Spain would not be sorroy to give the Turk's a taste for their cloths. But is it likely that Spain should attempt to rival nations, who, in possession of long continued trade, an almost insurmountable bar to success in itself, have in addition an advantage over her in their superior knowledge in the art of manufacturing? Will she not decta it more prudent to labour beforehand at answering from her looms the demands of two-and-twenty millions of men subject to her sway; but she knows herself to be yet far distant from such a state of prosperity. It is not by the methods tried in 1788 that she will make any progress towards it. The director of the royal manufactories could then pitch upon no expedient to get rid of a stock of cloth, of about 200,000 piastres value, without loss to the concern, than by obtaining a decree, forbidding the exportation of all foreign cloths to South America. This decree drew upon the government numerous reclamations on the part of England and France, as well as those Spanish merchants who had large stocks of foreign cloths. The ediet was modified. It could not fail of being nugatory, from the necessity that existed of rendering it so, and necessity is ever fertile in fraudulent resources.

On the return of peace, the manufactures of Guadalaxara, and Brihuega, a town situated four leagues from the former, and which has a hundred looms employed on fine cloths, were in a flourishing state, and found a more secure consumption for their produce. In the course of 1796 they had a warehouse at Madrid, which vended from 9 to 10,000 pieces per month.

Segovia, famous at all times for the excellence of its wool, was formerly not less so for the perfection to which its numerous manufactures were carried. How fallen from

its ancient splendour!

The patriotic society of that place pretends, that at its most brilliant period Segovia had 600 looms employed on five cloths. In 1697 it had no more than 250. Until towards the middle of the 18th century they increased. In 1748 it had 365 looms, which gave employment to 4300 persons, and consumed 50,000 arrobes of wool in the grease. Latterly, government has been greatly, perhaps too much, occupied in regenerating its manufactures: for in 1785, it established regulations in organizing them, the consequences of which were, that for the five subsequent years there was an annual diminution of 40,0 of the pieces worked. The cause of this was the nature of the Segovians, so much bigored to custom, and adverse to all innovations.

One, and one only, did justice to the encouragement of government. Don Laureano Ordz, in 1779 established a new manufactory of superime cloths, to which the king gave assistance, by granting certain privileges, by no means injurious to the other manufacturers. It shortly began to prosper. In 1786 it kept 70 looms at work, and employed 2800 persons. Ortiz has made this an undichable property in his family. His country lost him in 1788, but his successor has inherited his zeal and his talents; and in 1792 I convinced myself that the manufactory had not fallen off. The manufactory of Ortez, with that called de San Fernando, at Guadalaxara, are the only ones in Spain at which superfine cloths are made, a matter of astonishment in a country which produces in such abundance the finest wool in Europe.

Before we leave Segovia, we will finish what there is to say on Spanish sheep. It is in the mountains adjoining this city, that a great part of the travelling flocks graze during the summer. They as well as those of the mountains of the ancient Numantia (Soica) leave them in the month of October, pass over those which separate the two Castiles, cross New Castile and disperse themselves in the plains of Estremadura and Andalusia. Such as are within reach of the Sierra-Morena, go thither to pass the winter: the length

of their day's journey is in proportion to the pasture they meet with. They travel in flocks from a thousand to twelve hundred in number, nader the conduct of two shep herds; one of whom is called the Mayoral, the other the Zagal. When arrived at the place of their destination, they are distributed in the pastures previously assigned them. They set off on their return in the month of May; and whether it be habit or natural instinct that draws them towards the climate, which at this season becomes most proper for them, the inquietude which they manifest, might, in case of need, serve as an almanae to their conductors.

Each flock, belonging to one proprictor, is called a cavana, and the collection of the shearing of one of these flocks is called pila or pile. They take the name of their proprictors. The most numerous cavanas are those of Bejar and Negretti, each of which consist of sixty thousand sheep. In that of the Escurial, one of the most famous, there are fifty thousand. Prejudice or custom gives a preference to the wool of one cavana over that of another. Thus, for instance, no wools except those of the cavanas of Nigretti, the Escurial and Paular, are made use of at Guadalaxara.

In 1785 the rams and ewes, which were sent to Rambouillet, were, as may be imagined, selected from the choicest cavanas, and the following were chosen in addition to the three we have before mentioned, those of the marquis d'Iranda, the marquis de Perales, Manuel de Balbuena and the count de San Rafael. Among these cavanas that of St. Paulur is reckoned to produce the finest wool in all Spain; and the flock of Negretti is considered to be the finest, with respect to the strength of the sheep, and the weight of their fleece: on this account ten rams were selected from it for France which cost from 60 to 80 rials each, ewes selling at from 50 to 60 rials.

While on their return, in the month of May, they are shorn, an operation of considerable magnitude in Spain, because there it is performed in great buildings called esquileos, contrived so as to receive whole flocks of forty, fifty and sometimes sixty thousand sheep. Harvest time and vintage in corn and wine countries are not seasons of greater festivity. The sheep shearing is a time of rejoicing, both to the owner and workmen. The latter are divided into classes, each of which has its distinct employment. A hundred and twenty-five workmen are necessary to every thousand sheep. Each sheep produces four sorts of wool, more or less fine according to the part whence it is taken.

When the shearing is finished, the wool is made up in bags and sent to the sea ports, where it is shipped without any other preparation; or to the washing or scouring places in different parts of Castile. There are several in the district of Segovia. I particularly examined one of the most considerable, that of Ortijosa, three leagues from St. Ildefonso. I was there convinced that this operation, imperfect as it appears at first sight, because foreign manufacturers repeat it before they make use of the wool, sufficiently answers the intention, which is to preserve the wool, so that the longest voyage shall not after its quality. Through this single scouring place there annually passes about 10,000 lbs. of wool. The place is of great extent, and forms a kind of basin, the inner sides of which are gently sloping meadows, which receive the rays of the sun in every direction.

The wool is carried thither in the state it was then taken from the sheep:* each fleece is as it was first made up. In this form it is given to the Apartadores, who divide it

^{*} Flandrin, who made a journey into Spain on purpose to study the nature and treatment of sheep, differs in some measure from me in his account of the manner of washing and drying. I shall not dispute the point with this valuable farmer, who as well as myself, has had recourse to the best authorities. If the seasons and places be looked to, we may both be right.

into three heaps of different qualities. They are so much accustomed to this business, which requires a long apprenticeship, that they can tell, at first sight, from what part of the animal each flock of wool has been taken. These three sorts thus separated are extended upon wooden hurdles, where they are spread, beaten and cleansed from the dust and dirt adhering to them; they are afterwards taken to the washing place.

As soon as the water in the great copper is on the point of boiling, it is let out by two great spigots that open or shut certain pipes by which it is conveyed into three square wells, fined with hown stone, and about three or four feet deep. The hot water falls upon a bed of wool, which covers the bottom of the well. The wool thus disposed is turned in every direction by three men. Each sort of wool is washed separately; and, according to its lineness, requires the water to be more or less heated.

After this operation, the wool is again spread upon hurdles, to drain off the water and filth, which has begun to dissolve. The coarse locks are also separated from the rest, and sold for the benefit of the souls in purgatory; for, in Spain, religion is connected with every thing. The Spaniards sanctify by this frequently whimsical association, their

occupations, riches, and even their pleasures.

The hurdles are afterwards placed between the wells, and a narrow aqueduct, through which runs a stream of cold water. A man placed at the entrance of the aqueduct receives the wool, and throws it in; while five men, who stand by the side below the first man, press and rub it with their feet as it passes, and forward it from one to the other. Still lower down are other workmen who stop it in its passage, and throw it on a stone slope, where it drains, while the water runs off into a gutter contrived below the slope. A net, placed at the extremity of the aqueduct, retains the locks which slip from them, and might be carried away by the rapidity of the current.

When the wool is well drained, it is spread upon the declivity of the meadows which we have before mentioned, and four fine sunny days are scarcely sufficient to dry it thoroughly. When it is quite dry it is put into bags to be carried away. Initial letters upon the bags indicate the sort of wool contained in each; and, besides these, there is a mark which distinguishes the flock by which it was furnished; in this condition it is exported, in this state traverses the country, so that on seeing those bales pass by, their

quality and the place they came from are easily recognized.

Not far distant possibly is the time, when the roads of France will be covered, with this precious article, and their ports serve but as entrepots for the surplus, not wanted for its own consumption. Let not Spain behold with an eye of envy this possible success. Let not her allies appear to her as dangerous rivals. Should they even eventually bear away from her children the exclusive possession of this advantage, does she not possess undividedly a sufficiency of others? The field for human industry is so wide, so various its resources, that all nations may cultivate it, without rivalry, or injury to each other. Oftentimes in order to prevent grand quarrels, as to avoid law suits between individuals, the whole that is wanting is reasen, and a clear understanding of each other.

In the mean time I learn from very recent intelligence, that at the period of the conclusion of peace, there were in the ports of Spain 16,000 bales of wool, whose exportation had been suspended by the war; and that since the peace was signed, our manufacturers of Sedan, of Louviers, of Elbeuf and even some houses at Paris, and Orleans, have expedited orders for Spanish wool, but to much smaller amount than before the war. We should be astonished at our manufacturers having occasion to order even these, after the rich prizes of this merchandise made by our cruizers; were it not known that they were carried for sale to Amsterdam.

CHAPTER IV.

RESIDENCE OF ST. BEDEFONSO. ETIQUETTE OF THE COURT. BULLES. DIGNILIES. GRANDIA. ORDER OF ENIGHLHOOD.

I SHALL now leave Segovia, its wool, and its environs, and conduct my reader to the eastle of St. Ildefonso, which is only two leagues from it. The high mountains which command it are seen at a great distance, and searcely has the traveller quitted Segovia before he discovers the eastle itself. Its environs by no means announce the residence of a great court. The country is barren, and a few wretched hamlets, at small distances, are scattered about the most arid country that can be conceived; yet what better could be expected in this part of Old Castile, surrounded by barren mountains, and without roads, canals, or navigable rivers? What, however, has principally tended to the devastation of this district is the numerous herds of deer which live here in peace, and never have their repose disturbed but by the king and his family, who pass there about two months in the year. Searcely had Charles IV, ascended the throne before (in spite of the hereditary taste for this annuscment) he began to make regulations for the gradual destruction of these animals, and hastened the execution thereof by giving himself the example.

The country, however, becomes more beautiful as we approach St. Ildefonso; a number of rivulets meander through the fresh verdure, and the deer wander in herds in the copses, or bound upon the hills in a security which could not be expected in these timid animals; the tops of a few handsome houses appear above the green oaks; and the group, formed by the eastle and the adjoining edifices, crowned by mountains, some naked, others covered to their summits with trees and shrubs, present a very pleasing prospect. At length we arrive at the gate fronting the royal residence, which is separated from it by a spacious court in form of a glacis.

The whole has an imperfect resemblance to Versailles. One at first imagines that Philip V, who built St. Ildefonso, wished to have about his person such objects as might recal to his recollection the abode so dear to him in his early youth. He seems to have had the same intention in establishing his military household.

Of the old guards of the kings of Spain there remains but one company of halbardiers, which may be compared to that of the hundred Swiss. Philip V, established three companies of body guards, each of two hundred men, modelled, with respect to form and clothing, after those of the French court. To these three bodies the king has joined a fourth, called the American company. Two regiments, which guard the exterior of the castle, that of the Spanish guards, and the regiment of Walloons, are also perfect copies of our regiments of French and Swiss guards. A company is detached from each of them to do duty werever the court resides.

The command of each of these six military corps which form the interior and exterior guard of the kings of Spain, is given to the most distinguished persons of the nation. The commander of the halbardiers is always a grandee of Spain. The captain of the Spanish company of body guards is one of the most illustrious families. A licute-nant-general has been placed at the head of the new American company. That of the Italian company is generally an Italian nobleman, and the captain of the Flemish corps is either a noble Fleming, or some stranger related by his family to Flanders. The same rule is observed with respect to the Walloons. The captain of the Spanish

guards is always chosen from the most distinguished grandees in Spain.

D'Ossuna holds that station at present.

The proofs of the predilection which Philip V, had for the residence of St. Ildefonso nave survived him. His remains are deposited in a chapel within the eastle. I visited this mausoleum more than once, which has something awful in its simplicity.

The appearance of the tomb which contains an illustrious person, always excites secious reflection. What then must be the impression made by that of a prince, whose reign holds so distinguished a place in modern history, and forms the epocha of the last exploits of Louis XIV, and of his greatest disasters; of a prince for whose interests Europe was agitated by three wars within less than half a century, and to whom the conquest of the greatest monarchy in the world was not the accomitant of happiness; but proved in the gloomy melancholy which obscured the last years of his life, that the most

brilliant successes of ambition are ever followed by satiety and uncasiness.

More pleasing are the thoughts one cherishes in the enchanting abode which Philip V, prepared for himself in the midst of sequestered woods, surrounded by steep mountains. There is nothing magnificent in the palace, particularly in its exterior. The front on the side of the garden is of the Corinthian order, and not destitute of majesty. Here are the king's apartments, which look upon a parterre surrounded with vases and marble statues, and a cascade which for the richness of its decorations, the purity and clearness of its waters, may be compared with the finest of the kind. Philip V_2 was in this respect much better served by nature than his father. From the mountains which shade the palace descend several rivulets, which supply the numerous fountains, and diffuse life and verdure through these magnificent gardens. They are on the inside a league in circumference. The inequality of the ground affords every moment new points of view. The principal alleys answer to different summits of neighbouring mountains; and one in particular produces the most agreeable effect. It is terminated at one end by the grand front of the palace. From this point are seen at one view five fountains, ornamented with elegant groups, rising into an amphitheatre, above which appear the summits of lofty mountains. The most clevated of these groups is that of Andromeda fastened to a rock. When seen at a short distance it is somewhat defective, the rock appearing too diminutive by the side of the monster which threatens Andromeda and Perseus, by whom it is attacked; but the whole contributes to the beauty of the view. The most remarkable indisputably of the five groups is that of Neptune. Genius presided both at the composition and in the choice of its situation; the god of the ocean appears creet, surrounded by his marine court. His attitude, his threatening countenance, and the manner of holding his trident, announce that he has just imposed silence on the mutinous waves; and the calm which reigns in the basin, defended from every wind by the triple wall of verdure by which it is surrounded, seem to indicate that he has not issued his commands in vain. How oft have I scated myself, with Virgil in my hand, under shade of the verdant foliage, beside the silent water, reflecting on his famous Quos Ego!

There are other fountains worthy of the attention of the curious; such as that of Latona, where the limpid sheaves, perpendicularly, and in every direction, fall from the hoarse

^{*} It is he who in 1799 passed several months at Paris with all his family, and who gave aspecimen of the sumptuosity of the grandees of Spain of the first order, and at the same time of the simplicity of their ceremonies, their affability, and in short of every thing which tempers in them the splendour of a great fortune with a great name. The revenue of M. le Due D'Ossuna is nearly 3,000,000 of francs.

ecimen licity of idour of francs throats of the Lycian peasants, half transformed into frogs, and spouting them forth in such abundance, that the statue of the goddess disappears under the wide mantle of liquid crystal; that also of Diana in the bath, surrounded by her nymphs; in the twinkling of an eye all the chaste court is hid beneath the waters; the spectator imagines he hears the whistling of aquatic birds, and the roaring of lions from the place whence this momentary deluge escapes by a hundred channels. The fountain of Fame is formed by a single jet-d'eau, which rises a hundred and thirty feet, exhibits to several leagues around the triumph of art over nature, and falls at length in a gentle shower upon the astonished spectators.

There are some situations in the gardens of St. Ildefonso, whence the eye may collectively distinguish the greater part of these fountains. The traveller who wishes to charm all his senses at once, must take his station on the high flat in front of the king's apartment. In the thick part of the foliage are contrived two large arbours, through the windows cut in which are seen twenty crystal columns rising into the air to the height of the surrounding trees, mixing their resplendent whiteness with the verdure of the foliage, uniting their confused noise to the rustling of the branches, and refreshing and embalm ing the air. Ascending towards the grand reservoir of these abundant and limpid wa ters, after having traversed a superb parterre, and climbing for some time, you reach a long and even alley, which occupies all the upper part of the gardens. In the middle of this alley, turning towards the castle, a vast horizon appears as far as the eye can reach. The immense gardens, through which you have passed, become narrower to the eye; the alleys, fountains, and parterres all disappear; you see but one road before you, which in the form of a vessel, upon the prow of which you seem to stand, has its stern on the top of the palace. Afterward, on turning, you have a view of a little lake behind you, of which the irregular borders do not, like what we call our English gardens, merely mimic the captivating irregularities of nature. Nature herself has traced them. The alley from which you enjoy this prospect is united at each end to the curve which surrounds the reservoir. The waters, which stream in abundance from the sides of the woody mountain in front, these waters, whose distant murman's alone disturb the quiet of the scene, meet in this reservoir, and thence descend by a thousand invisible tubes to other reservoirs, whence they are spouted in columns, sheaves, or areades upon the flowery soil which they refreshen. The image of the tufted woods which surround it is reflected from the unmoved surface of the lake, as is also that of some simple and rural houses under their shade, thrown, as by accident, into this delightful picture. The streams which feed this principal reservoir formerly lost themselves in the valleys, without affording either profit or pleasure to any one. At the call of art they have become both agreeuble and useful. After climbing the pyramidal mountain where their source is concealed, you reach the wall of the garden which was hid by the thickness of foliage. Nothing in fact ought here to strike the mind with ideas of exclusive property. Streams, woods, the majestic solitude of mountains, these are blessings which man enjoys in common. The rivulets which escape from the grand reservoir serve by little channels, some visible, others running under ground, to water all the plants of the garden. In their course, in one place they moisten hastily the roots of the trees, in others they cross an alley to nourish more slowly the plants of a parterre. From the basin of Andromeda they run between two rows of trees in a hollow and sombre channel, the too sudden inclination of which is taken off by cascades and windings. At length, after dissecting the garden in every direction, after playing amongst the gods and nymphs, and moistening the throats of the swans, tritons, and lions, they sink under ground, and enter the bosom of the neighbouring meadows.

The task were endless to enumerate all the statues, groups, and formains which de corate the gardens of St. Ildefonso. I shall be content with noticing that, a very few pieces excepted, all the sculpture is the work of French artists of a secondary rank, such as Fermin Thierry, whom Louis XIV, sent to his grandson, and their pupils, who are somewhat their inferiors; they have displayed more magnificence than taste in the square ty, to this centre; the other terminating in one of the fountains, dispersed through the gardens. Plats of verdure fill up the intervals between the alleys, and each has an altar under a portico of white marble by the side of a basin sacred to some god or goddess. These eight altars, placed at equal distances, are decorated with several jets-d'eau, particularly by two which rise perpendicularly on each side of their divinities, and have a ridiculous resemblance to the wax lights of a christian altar. This cold regularity displeased Philip V, who a little before his death, when visiting the gardens, made some severe reproaches to the inventor upon the subject. Philip had not the pleasure of completely enjoying what he had created; death surprised him in 1746, when the works he had begun were but half finished.

This undertaking was the most expensive one of his reign. The finances of Spain, so deranged under the princes of the house of Austria, thanks to the wise calculations of Orry, to the subsidies of France, and still more to the courageous efforts of the faithful Castilians, would have been sufficient for three long and ruinous wars, and for all the operations of a monarchy which Philip V, had conquered and formed anew, as well as to have resisted the shocks of ambition and political intrigue; but they sunk beneath the expensive efforts of magnimence. Sovereigns of every state, learn from this example, that your glory, your disasters even, are sometimes less dear and burthensome to your subjects than your pleasures! Will it be credited (it has however been precisely ascertained) that Philip V, expended forty-five millions of piastres in the construction of the castle and gardens of St. Ildefonso; and that this is the exact amount of the sum in which

he was indebted at the time of his death.

This enormous expence will appear credible when it is known that the situation of the royal palace was at the beginning of this century the sloping top of a pile of rocks; that it was necessary to dig and how out the stones, and in several places to level the rock; to cut out of its sides a passage for a hundred different canals; to carry vegetative earth to every place in which it was intended to substitute cultivation for sterility; and to mine, in order to clear a passage to the reots of the numerous trees which are there planted. So many efforts were crowned with success. In the orehards, kitchen gardens, and parterres there are but few flowers, espaliers, or plants which do not thrive; but the trees naturally of a lofty growth, and which consequently must strike their roots deep into the earth, already prove the insufficiency of art when it attempts to struggle against nature. Many of them languish with withered trunks, and with difficulty keep life in their almost naked branches. Every year it is necessary to call in the aid of gunpowder to make new beds for those which are to supply their place; and none of them are covered with that tufted foliage which belongs only to those that grow in a natural soil. In a word, there are in the groves of St. Ildefonso marble statues, basins, cascades, limpid waters, verdure and delightful prospects, every thing but that which would be more charming than all the rest, thick shades.

After the death of Philip V, the eastle of St. Ildefonso was entirely abandoned by the court of Spain. His second wife, Isabel Farnese, was the only one who resided there; and during the reign of Ferdinand VI, the son of Philip's first wife, led there a most retired and private life, without ever going out of the apartments of the eastle, at least

without once exceeding the boundaries of the gardens. This singularity I have had attested by many who accompanied her in her retreat. She divided her time in the most strange manner, sitting up always the whole night long, dead as it were to the world, and to the light of day. She seemed occupied with nothing but her bodily and ghostly health, when her son Charles III, then king of Naples, coming to the throne in 1759, upon the death of Ferdinand VI, that ambition which did but slumber in her began to show itself a new. She again appeared at court, and there exercised for the remainder of her life as much influence as in the reign of Philip V, the weakest of monarchs and of husbands. Charles III, inherited the taste of his father for St. Ildefonso. Throughout his reign the court came hither annually during the heat of the dog days. It arrived towards the end of July, and returned at the beginning of October. The situation of St. Ildefonso, upon the declivity of the mountains which separate the two Castiles, and fronting a vast plain where there is no obstacle to the passage of the north wind, renders this abode delightful in the summer months. The mornings and evenings of the hottest days are agreeably cool, and the tops of the mountains are covered with snow during a major part of the year. Yet as this palace is upwards of twenty leagues from Madrid, and half of the road which leads to it (that which begins at Guadarrama) crosses the broad tops of mountains, frequently very steep, it is much more agreeable to the lovers of the chace and solitude than to others. The reigning queen, when princess of Asturias, had an aversion for this place, which she manifested upon all occasions. Charles IV, coming to the throne in 1789, it was imagined St. Ildefonso would be entirely abandoned. In effect, the first summers passed over without the court's visiting it, the king being satisfied with short excursions to it. By degrees this repugnance diminished. The happy temperature of St. Ildefonso has enforced its rights, and the expeditions to this place take place at their usual periods. On my first appearance, in September 1775, the court was here; and here it was that I saw it for the last time in the month of August 1792; events which rapidly succeeded each other after that period, preventing my attendance there up to the time of my departure, which was the signal for hostilities between the two powers. Never was this residence more brilliant than on the occasion of the visit of the two French princes, the count d'Artois and the duke de Bourbon, to Charles III, in 1782, on their way to be present at the siege of Gibraltar. Since the beginning of the reign of the house of Bourbon in Spain, this was the first interview of this description. The old monarch, who always had 5 great portion of natural affection, displayed upon the occasion as much kindness as magnificence, shewing a solicitude and delieacy upon account of these two relations, which it was difficult to reconcile with his simple manners. The count d'Artois and all his suite had apartments in the palace. The whole house was at his service. Especial carwas taken that his near attendants in their dress, their manners, and language, should retrace as much as possible the image of his father's court. Those attentions had no other limits than what were prescribed by the propriety of not overwhelming him with ceremonies, and leaving him in perfect freedom. Charles III, lived a very regular life. all his hours were appropriated. Hunting, fishing, prayer, labour in the cabinet, every thing was continued as before. The duke de Bourbon, who went by the name of Dammartin, was treated with less form, but not with less affection. Young and strangers to the etiquette of the Spanish court, the two princes felt the want of a governor, and submitted themselves to the care of the count of Montmorin, the French ambassador at that time. He was my patron. He perished by the hands of cannibals amid the storms of the revolution. Party spirit ascribed wrong conduct to him; for me, I know best his misfortunes, and far be from me the fear of acknowledging his kindness, and

rendering him that tribute of justice and gratitude which I paid him in his prosperity. His adversity but more enhances my obligation. I shall therefore observe, that during the six years of his embassy we proved in him what the Spaniards were disposed to doubt, that Frenchmen may possess gravity without pedantry, wisdom without sternicss, dignity without assumption, and prudence without fimidity. I should add, that received by the king with all that respect he was entitled to, he acquired the confidence of the ministry, the friendship of the grandees, and the esteem of the whole nation; and notwithstanding the reservedness of his manners, I know none who possessed his intimace but what were highly prepossessed in his favour. There is no court in Europe, where the persons of ambassadors are more generally known. During the reign of Charles III. they were even subject to an assiduous attendance which was fatiguing, particularly the family ambassadors. They almost all accompanied the court to St. Ildefonso, the Escurial, and Aranjucz, and regularly attended the table of the king and his family. They had daily a private audience of his majesty, both before and after dinner, and the rest of the foreign ministers as well as them were admitted for a short time into the cabinet. They now make their appearance at court no more than twice a week. Charles IV, still more simple in manners than his father, has done away with superfluous ceremony, although in his private life he maintains the same uniformity and regularity. He is as partial to shooting as Charles III, but his partiality has been rendered of much less injury to the neighbourhood of his residences. He has a taste for the fine arts, and agriculture, as we shall notice on speaking of Aranjuez, for athletic exercises, to which his strength and robust constitution are peculiarly adapted, and for music, which he as well as the queen, enjoys in very circumscribed parties, every evening after returning from shooting, and being closeted with one of his ministers; for nothing is so rare, even at the court of the reigning family, as public rejoicings and nois; pleasure.

This court, so much retired, so regular in its deportment, is very far from being defieient either in etiquette or magnificence. Charles III, a widower from 1761, always dined in public by himself, surrounded by his officers. The reigning monarch dines with the queen. Each has behind their chair the grand master of the household, the chief almoner, the captain of the guards on duty, and an exempt of the guards. They are waited upon by two gentlemen of the presence, who are grandees of Spain, one of whom serves the dishes, and the other hands the wine, kneeling on one knee. The same ceremony is used by the ladies of the palace to the queen, and to the infants and infantas by titled persons in their service. The philosopher may smile at this vilifying homage, but it does not belong exclusively to Spain. It is well known the same forms are made use of towards the sovereigns of London and Vienna, and to their families, where the power of the monarch in many respects is limited. This homage, however, is more particularly displayed on gala-days. These are of two kinds, the greater and lesser galas. In the time of Charles III, there were ten of the first description every year, to celebrate the birth-days of the king, the prince and princess of Asturias, and of the king and queen of Naples, the one as son, the other as daughter in law of the king. There are now only six; four for the king and queen, and two for the prince of Asturias; the other lesser or demi-galas, are in honour of the other princes and princesses of the royal family, and at present are twenty-two in number. These require but little more attention to dress than ordinary; but at the grand galas, the greatest pomp is displayed by all except the hero of the day, in which, however, taste does not always preside. Every person in the service of the court, from the grand master to those who hold the most inconsiderable employments, have a uniform suitable to their places, and which they wear on these occasions, on which account these

are called galas con uniforme. In the morning of these great days, all those who have any connexion with the court, whether by their military service, their titles, or civil functions, the ecclesiastics, and always some monks, pass before the king and the royal famliy, bending one knee and kissing the monarchs hand. This is a species of loyalty and homage, and renewing of the oath of fidelity, which, besides upon galadays, is also paid to the monarch on returning thanks for any favour, or on taking leave to execute his

orders any where apart from his residence. Republicans, should they not even be philosophers, may be allowed to smile with pity at these grave minutiæ. They yet are deserving of detail, as they furnish additional means for acquiring a knowledge of the human heart, its pride and its weakness. This abasement, which, without being noble, may be looked upon as vilifying, has, however, nothing more revolting in it than the ceremonial at which our ancient knights did not disdain to kneel, upon receiving the collar; or, than the investiture which, in our days, is accompanied by the same act of submission. But what is truly singular, to say no more of it, women of the greatest distinction not only kiss the hand of the monarch, but that of all his children, whatever may be their age or sex, and the most charming dutchess prostrates herself before the youngest infant even when at the breast, and presses, with her lips, the little hand which mechanically receives or refuses the premature homage. Thus is the fair-sex destined to meet every where with insult; denied in France the privilege of citizenship, it has no share in the honours of freedom. In Spain, it is admitted to the honours appertaining to slavery. I shall, however, observe in behalf of Spanish etiquette, that it favours the delicacy of the fair-sex. Men kiss hands in public, but the ladies only in the inner apartments. None but the ladies who have employment in the palace, kiss the hands of all the royal family. The others, who are received at court, pay this homage to no one but the queen and the princess of Asturias. This class is composed of all the female grandees of Spain, and ladies of title; which denomination must not be understood in the sense affixed to it in France. It here becomes necessary

Princes of the blood, as we called them, have not hitherto been distinguished as such at this court. Next to the infants and infantas of Spain, and the sons, grandsons, and nephews of the sovereign, immediately come the grandces; and the dukes of Medina Celi, the immediate and legitimate descendants of the infants of La Cerda, and consequently of royal origin, are only grandces of Spain. These are divided into three classes, differing from each other by such trifling distinctions as are scarcely worth notice. All the grandces of Spain, of whatever class they may be, are covered in presence of the king, and have the title of excellence; when they pass the guard-room, a person in waiting stamps on the ground, in order to give notice to the centinel to port arms; in these are comprehended all their prerogatives. Beyond this, they have no honorary distinction pertaining to their title. They do not form a body, as formerly the dukes and peers of France. It seems as though the kings of Spain, unable to deprive this order of its hereditary dignity, were desirous, in revenge, of keeping them in entire dependance,

to treat of the dignities and titles of the court of Spain.*

^{*} Certain rigid republicans have looked upon, at least as superfluous, the preceding and following details. I readily grant their philosophy the right of a smile of contempt, but it is not for them alone I write; to some of my readers they may be interesting: short would be the works that should contain those things only with which every body would be pleased; the most famous books cannot boast so much. Of what value to merchants are the philosophical declamations of Raynal, which, however, in great measure, made his fortune? Of what value to sprigs of fashion the calculations with which his work is replete? In the immortal works of Montesquieu, deep thinkers look upon his epigrammatic sallies as superfluous; whereas the ladies and their beaux would willingly dispense with his learned dissertation on the establishment of the Franks in Gaul

and subject to their caprice for any additional lustre. There is no place which is exclusively attached to their rank, if we except that of grand master, that of grand equerry, and that of sumiller de corps, which has some relation with the place of grand chamberlain, and the commission of captain of halberdies; and these places, as well as all the others, are conferred solely at the king's pleasure; but there are several others which infallibly lead to the rank of grandee.

The band of gentlemen of the chamber on duty is for the most part composed of grandees; but there are also some persons of quality, who, without the former rank, obtain this dignity. It is true, none of the latter are employed immediately about the person of the sovereign, or the heir to the crown, and the queen and the princess of

Asturias are served by none but grandees.

The queen has other females of a less illustrious rank for her internal service: these are ladies of distinguished families, which, under the name of Carmeristos, act nearly in

the character of chamber-maids.

As to the grandees of either sex attached to the king's person, they are taken indistinctly from either of the three classes; there are some whose extraction is from the most ancient and illustrious families, and who belonging to the two latter orders, but who do not esteem themselves inferior upon that account. Philip V, who conferred many titles of grandee, created not one of either of the second or third class. He contended for a long time for the crown, as well against internal as external enemies; and, when he came into possession, he looked upon the favours he had to distribute as actual rewards for very signal services, either of a political or military nature; and, doubtiess, thought he ought to proportion his gratitude to the importance of the services rendeted; or, possibly, the haughtiness which he brought with him from Versailles to Madrid, made him fancy, that those who had had the honour of being serviceable to him, had a right to step at once into the most illustrious rank. Whatever were his motives, Ferdinard VI, imitated his example; but Charles III, has revived a distinction almost imaginary, which was falling into oblivion; and, in the last promotions, created several grandees of the second class.

They do not all enjoy the privilege of being covered in the royal presence, except when they are received for the first time, and when they accompany his majesty at any eremony. This honour does not, however, belong to them exclusively; they enjoy it in common with the nuncio, the family, ambassadors, and some generals of orders, who have the title of excellence as well, and as long as their dignity continues are by these two circumstances assimilated to the real grandees. Thus, there is not one single invention of human vanity which cowled humility disdains to sanctify by its adoption.

There are some titles of grandee that become extinct at the death of the possessor, and some obtain that honour for themselves and their descendants only. These bear the title of excellence, but are not covered in presence of the king. A more marked distinction in the different classes of grandee, and which is not founded upon law, but more imperious custom, is that which the grandees of ancient families establish between themselves and those of more modern or less illustrious extraction. The first speak to each other in the singular number on all occasions, and whatever may be the difference in their ages, or the places they hold. I have more than once heard such young grandees, who searcely had the rank of colonel, speak in this apparently familiar manner to the minister of war, who, at the time, happened to be a grandee of Spain. Had he been of less illustrious extraction, they would have given him respectfully the title of "your Excellency." They thou and thee'd him, because by birth he was on a level with themselves. And an additional proof of that trivial axiom, extremes meet. A strong aversion

to every sort of distinction, and a desire of equallizing every thing, caused the French to adopt the same habit during the Revolution. In Spain, among the chief grandees, it has become the most subtile distinction that pride can suggest. They have placed it in the summit of the pyraunid of nobility. But these great privileged persons are not prodigal of this honourable familiarity. In conversation, in epistolary correspondence with the great, whom they do not deen their equals, they coremoniously give and receive the title of excellency. New grandees of Spain solicit, as a favour, the honour of being thou and thee'd, and should they at last obtain it, consider it as a triumph; the new grandees solicit the honour of speaking to each other in the singular number, as they would

do the favour of the sovereign.

ssor,

In the course of my first residence in Spain, I saw a striking example of this. The old duke of Losado, who was then sumifier du corps, and who, perhaps was the only real friend of which Charles III, could boast, had accompanied him in his youth, when he left Madrid to take possession of the dutchy of Parma, and afterwards of the kingdom of Naples. His extraction was from the inferior nobility. In time, he was loaded with dignities and made a grandee. Coming back again to Madrid with the same prince; on his accession to the throne of Spain, it was with great difficulty, notwithstanding the favour he enjoyed, that he, at length, attained the distinction of being spoke to in the singular number by the individuals of the ancient race. The king himself, in order to procure his initiat on to this privilege, interposing in his behalf, not by using his authority, for that would have been ineffectual, but by entreaty and solicitation. On other occasions, this familiarity is sometimes spontaneously granted by the most distinguished grandees to branches of some illustrious houses, who have not yet obtained the title, and who, thinking they have well-founded pretensions to such an honour, are distinguished by the name of casas aggraviadas-injured families. On the other hand, the sovereign and his family treat all their subjects, who are about their persons, or approach them, with familiarity; this is at once a testimony of benevolence and superiority. All distinction is lost before them; and all Spaniards of whatsoever class, station, age, or sex, whether grandees, magistrates, prelates, or married women, young or old, are indiscriminately addressed in the singular number; and would anticipate disgrace if, in addressing them, the royal family should decorate them with those honorary titles of which otherwise they are so jealous.

The title of grandee, when hereditary, is so in both males and females, unless the patent formally expresses the contrary. There are many houses in Spain that, by marriages with heiresses to this title, have ten or twelve hats; which is the vulgar term to denote the dignity of grandee of Spain. But the head of these houses has not the power of distributing the hats among his children. The right of primogeniture is established. There are but few families, in which the second son has a title and grandeeship in his own right. All the eldest sons of grandees receive by anticipation, the title of excellence, but not their brothers; they simply bear the name of their family, preceded by that they receive in baptism, much in the same manner as in England, where the brother of lord Chatham is called William Pitt; the brother of lord Holland Charles

Fox

This distinction must not be lost sight of by a stranger, who does not wish to be deceived by the vain words count and marquis. There are many grandees of Spain who have no other title. There is no mark of extraordinary distinction in that of duke. It is given according to the pleasure of he sovereign, when he confers the title of grandee, even to the second class, of which there are recent examples; the patent alone is a little more expensive.

VOL. V.

The title of prince belonged hitherto exclusively to the heir of the monarchy. All those who were decorated therewith at the court of Spain were foreigners. The duke de la Alcudia, who, on account of the signature of the treaty of peace between France and Spain, was called El Principe de la Pas, is the first instance of a king of Spain granting that title. Is it the importance of the service rendered to his country upon this occasion, which carned him this exception? or, is favour, when at its height, always secure

of it in spite of laws and custom?

Formerly there was a sort of hierarchy in the order of titled nobility. The barons (which are not to be confounded with the ancient Varrones) which were met with, and are still found in Arragon, were of the lowest class; to these succeeded viscounts; then counts, and last and chief were marquises. Formerly it was requisite to be a viscount before a person could become a marquis, according to the order of the title of Castile. But all these distinctions have now been done away with; and simple plebeians in this century, without any intermediary step, have been raised to the rank of count and marquis. But much is wanting of all those being grandees of Spain who are invested with these dignities. Most of them are no more than what are called titulos, or titles of Castile. These titles prove not an illustrious race, but the favour of the sovereign, commonly the reward of some important service. The king generally grants to him whom he thus honours, the liberty either of applying his title to one of his estates, or to his family name; sometimes even he adds a denomination which denotes the service he wishes to recompense. Thus under Philip V, admiral Navarro, who commanded the Spanish squadron at the battle of Toulon, received, gratuitously enough, the title of marquis de la Vittoria; he, who in 1759, escorted Charles III, from Naples to Barcelona, that of marquis del Real Transporte; and more recently, during the last reign, the minister of the Indies took that of marquis de la Sonora, from the name of a colony in the neighbourhood of the Vermillion Sea, which his zeal and talents had acquired to his country by peopling and improving it, and by freeing the whole settlement from the incursions of the savages; and thus a magistrate named Caraseo received the title of marquis de la Corona, as a recompense for services rendered the crown in reclaiming certain property in land, of which it had been unjustly dispossessed; thus some grandees of Spain add to their titles such names as call to mind any glorious or important transaction in which they have figured. The duke de Crillon, following this method, after taking the fortress of Mahon, preserved the remembrance of it by adding that name to his own: and the prince of the Peace owes, as we have before mentioned, this title to the most important, and possibly the most fortunate circumstance of his administration. These titles have somewhat of grandeur, somewhat Roman in their object; and, if they depend in measure upon the caprice of fortune, they are much less dependant on favour than the rest.

The titles of Castile give to those who bear them, and to their wives, the qualification of lordship, Vuestra Senoria, by contraction spoken Ussia. The refusal of this in matters of ceremony carries with it a mortification; but the greater part are too reasonable to require, or even suffer it from their equals, in the ordinary intercourse of society; though their inferiors bestow this honour upon them very lavishly. There are every where flatterers, as well as persons who love to be flattered. But those who are more particularly exact in rendering them their due in this respect, are such as have a right

to the title of excellency in return, and delight in the gratifying distinction.

There is a title between this and lordship; that of Ussia Illustrissima (most illustrious lordship) which is given to archbishops, bishops, the principal members of the council of the Indies (called Camaristas) and to the president of the two supreme tribunals, called the Chanceries.

ess de-

strious council ls, callThe dignity of grandee, as well as the titles of marquis and count of Castile are not only unaccompanied with any pecuniary advantage, but are not even bestowed gratis. Those who obtain them, unless formally dispensed from it, pay a duty which has been received ever since the reign of Charles V, known by the appellation of Demi-Annates.

The grandees pay about twenty-five thousand livres (1,040l.) This duty is paid as often as the title descends, and is more or less, according to the greater or less distance between him who inherits it, and the person from whom it is derived. Besides the duty on taking up the title, the grandees annually pay another under the name of lanzas. This is the remains and faint image of the military service, which the great vassals of the crown formerly performed, by furnishing a certain number of spears. Foreigners, who

are grandees of Spain, are exempt.

According to an arrangement mutually agreed to between the courts of Madrid and Versailles, since the same family has been in possession of the two thrones, the grandees of Spain ranked with the dukes and peers of France. This acknowledgment of equality was not obtained without much opposition on the part of the former. When the question was agitated at the beginning of the reign of Philip V, the duke of Arcos, in the name of the grandees, remonstrated against it to that monarch in the strongest terms. He asserted, that the grandees could not but be greatly surprised and offended at finding themselves considered as on a level with the peers of France. At their own court, said the duke, the grandees see no one between them and the throne, but the sons of their sovereign, whilst the peers of France must give place, first to the princes of the blood, next to the legitimated princes, and lastly even to foreign ones, not only to those of Italy and Germany, but also to those who, although descended from royal families, hold places in the service of the king of France, such as the dukes of Loraine, de Bouillon, and others.

On the opposite side, the grandees in Spain constituted the first order of subjects immediately after the royal family. He gave instances of kings of Spain, and even of emperors, who had treated them as equals with the princes of Italy and Germany, and proved that the grandees had always enjoyed the same honours as the princes descended from sovereigns, when they were not royal; that, when the courts of France and Spain had named representatives, those of France were princes of the blood, and those of Spain grandees; without the least difference being made in the respect and honours paid to each. From all these proofs the duke concluded, that the dignity of grandee of Spain corresponded with that of the princes of the blood in France, and not with that of the peers.

These arguments were but ill received by Philip, who had contracted at the court of his grandfather a taste for despotism. The answer he returned to the duke was, that he would do well to go and signalize his zeal with the army in Flanders. This order was obeyed, and the duke, on his return through Paris, was the first who desisted from the pretensions of which he had been the advocate. He made the first visit to the princes of the blood, gave them the title of highness, without receiving the same, and addressed the dukes and peers by the title of excellence, without requiring more in return; thus the

cause of the grandees was lost for ever.

Their number rapidly increased; their dignity was granted to several foreign noblemen; and, as all things are diminished in value by being multiplied, the grandees have become accustomed, by degrees, to see themselves considered as on a level with the dukes and peers of France. We are not to suppose, however, that the grandees of Spain, who derive their dignity from the reign of Charles V, do not think themselves superior to others, as in Germany the princes of ancient families esteem themselves more

noble than those who were created by Ferdinand II, and his successors; but this difference, so flattering to vanity in secret, vanishes from before the eyes of the nation, and

especially from those of the sovereign.

These grandees, possessed of high notions of their own dignity, in other respects are extreme. The ble and obliging. They are void of that repulsive pride attributed to them in Europe lany of them substitute a gentleness of manners and goodness of heart, instead of coast haughty and forbidding dignity, common to the noblemen of other countries. Not but that they possess, if not a motive, at least an excuse for airs of pride, in high employments, illustrious birth, and immense fortunes. Indeed with respect to the latter, they are superior to those of the most opulent at the court of France, even before the Revolution.

Except those of the princes of the blood, there were no fortunes at Versailles to be compared to those of the duke of Medina Celi, the duke of Alba, the duke D'Ossuna, the count Altamira, or the duke of Infantado. But their appearance seldom corresponds with their fortune. They do not ruin themselves as in France, in country boxes, entertainments and English gardens, and as to the luxury of splendid furnitures, it is unknown: their pomp is more obscure, but perhaps not less expensive. Numerous sets of mules, rich liveries which are displayed but three or four times a year, and a multitude of servants, are their principal articles of expense. The management of their estates is also very costly to them. They have stewards, treasurers, and various officers, like petty sovereigns. They keep in their pay, not only the servants grown old in their service, but those even of their fathers, and the families whence they inherit, and even provide for the subsistence of their relations. The duke of Arcos, who died in 1780, maintained thus three thousand persons. This magnificence which disguises itself under the veil of charity, appears to have more than one inconvenience; it encourages idleness and causes waste and extravagance, which, while dependants are thus multiplied, must escape the most careful vigilance. Netwithstanding all this, there are fewer great families ruined in Spain than in most other countries. The simplicity of their manners, their little taste for habitual ostentation, and the scarcity of sumptuous entertainments, are great safeguards of their fortunes. But when desirous of imitating the example of those of other courts, their splendour is equal to that of the most brilliant. This may be judged of by the appearance some have made in foreign countries when the dignity of their nation required a display of magnificence.

They have hitherto indeed but little trod the paths of ambition. At the beginning of the present century, when divided between the two princes who aspired to the throne, their passions being roused, they made efforts and displayed talents, which were not always employed in that course which success determined to be the best, but which proved that the latter reigns of the princes of the house of Austria had not benumbed their faculties. A kind of supineness which has continued half a century, has succeeded to this fermentation; but in the reign of Charles III, they shook it off, and proved that the most distinguished subjects in a nation are not always the most useless. They embraced with eagerness the profession of arms, which in fact offered but few temptations, and which in Spain is more full of constraint for courtiers than it was in France.

At this moment, among eighty lieutenants general which there are, are twenty grandees; and general count de la Union, who after several defeats perished gioriously on the field of battle, fighting against us, was one of their order. In the political department they had in the time of Charles III, more than one distinguished statesman to boast of, a count D Aranda, yet regretted; count Fernan Nunez, whom death ravished at the instant he was about to retain among us; a duke de Villahermosa, &c. &c.

Some years past the duke D'Ossuna was nominated ambassador to the court of Vienna, and the duke del Pargue to Petersburg, but did not proceed to their destinations: at present no more than these grandees are employed beyond the frontiers; the count de Campo Alanzo, as ambassador at Lisbon; the prince of Castel Franco at Vienna, and the duke de Trias at London; the first of these however, has been elevated to the grandeeship but lately, and the second is a Neapolitan nobleman.*

None are however occupied with any diplomatic mission at this instant, a circumstance which has not happened before since the beginning of the last century, as up to the period of the Revolution Spain was constantly represented at Versailles by a grandee.

It appears for a long time back to have been the secret practice of this court never to grant situations to her grandees which might put any great power in their hands, and from this practice she has swerved only upon very particular occasions. For example it has scarcely ever happened that one of those American vice-royalties which for pomp, homage, and authority, are on a par with real sovereignties for the time, and equal by the means whether legal or illegal, of acquiring wealth to the most lucrative offices of the revenue; it has, I say, scarcely ever happened that an appointment of this importance has ever been confided to a grandee; either on account of the jealousy of the monarch who may dread so great an accumulation of title in one person, or because he would see with regret the absence of any, whose presence added brilliancy to the splendour of his throne.

The body of the grandees furnishes at present but few members to the church, the dignities of which are not, as in many other catholic kingdoms of Europe, engrossed by a few individuals of the principal nobility. The only dignity with which any of them is at present invested, is that of patriarch of the Indies, who at the court of Spain performs the functions of grand almoner. He who holds this place is constantly in waiting near the person of the sovereign. No other grandees, except those in actual service, are near the monarch; the remainder have their fixed residence at Madrid, whence they are absent but for a short time to pay their court. A few reside in the capitals of the provinces; but I know none who implifibile to side on their estates.

are absent but for a short time to pay their court. A few reside in the capitals of the provinces; but I know none who indifficult is side on their estates.

The dignity of grandee is not distillated if it is any exterior insignia. Those of its order who are gentlement if the chamber well golden key the same as the rest. There are six orders of knighthood in Spaint, besides the order of Malta; but not one to which the grandees have the exclusive right. The thirst distillation of the order of the golden fleece, founded by Philip the Court of the thirst distillation which the court of Vienna continues to confer in concurrence will that if which, although the former had renounced this prerogative, by the treaty which terminated the great quarrel between Philip V, and the archduke. The lampler of knights of the golden fleece is very limited in Spain. In no other order of Enlarge has the pride of nobility been more scrupulous; it is only lately that this decoration has been granted to some ministers of state who were not of an illustrious family.

There are also four other military orders, founded at the time of the crusades; and since the time of Ferdinand the Catholic, the king has been grand master of them all. They are those of Santiago, Calatrava, Monteza, and Alcantara. The three first are distinguished by a red ribbon, and the last by a green one. These four orders have

^{*} Up to the period of the Revolution, the embassy to France was always filled by a grandec who was generally admitted into the order of the Holy Ghost.

[†] The patria chate of the Indie and grand almonership of the court has been vested for some years in cardinal Sentmanat, a descendant of that marquis de Castel dos Rios ambassador at the court of Louis XIV, at the time of the arrival of the wift of Charles II, the first grandee created by Philip V.

commanderies, which are conferred by the king. Sant Iago has eighty-seven, the richest of which is reckoned to be worth 200,000 rials a year; Calatrava fifty-five, one of which is valued at 358,000 rials annually. Montoza has but thirteen and Alcantara thirty-seven, the commanderies of the two latter orders are the least considerable of the whole. They were for a long time given to every class of persons, provided they could bring the requisite proofs. Charles III, recalled them to the spirit of their first institution, and restricted the grant of them to military men. Upon this an honourable distinction for the rest of the subjects was wanting. This he supplied in 1771 by creating a fifth order, which bears his name, and is dedicated to the conception of the virgin. It is composed of two classes: that of the great crosses and simple knights. The great crosses wear the great ribbon of the order, sky-blue, edged with white. On days of ceremony they are clothed in a long mantle of these two colours, and wear a collar upon which are alternatively displayed the arms of Castile and the king's cypher.

The number of the great crosses should be limited to sixty, according to the statutes of the order; it consists at present of eighty-three including the princes of the royal family and some foreigners. When the order was first established the members were chosen from among the grandees, except two of the great officers, of the order. A short time afterwards the king made an exception to this rule, in favour of his marine minister, the marquis of Castejon. This exception was afterwards extended: though the order is still confined to the most eminent personages of the kingdom, such as the min-

isters and some general officers, distinguished either by their zeal or services.

The simple knights were two hundred in number, each enjoying a pension of four thousand rials (about forty pounds.) A fewy cars since the king bestowed this lesser order upon some persons in France, not included in the two hundred. On their account they departed from the statute which rendered this order incompatible with all others,

by permitting it to be associated with the cross of St. Louis.

In addition to the orders for men, the queen in 1792 instituted one which bears her name Maria Louisa in favour of the fair sex; it consists of sixty ladies, principally grandees. In the selection of its first members favour alone appears to have predominated.

Proofs of nobility are necessary to qualify for the small order of Charles III, as well as the four military ones; but from the facility with which it is obtained one is led to doubt this; although no great efforts of intrigue are requisite to elude this law; as nobility in most of the provinces of Spain, is not difficult to establish. And it is sufficient that he who aspires to this distinction prove himself, and his ancestors, to have lived nobly, without having exercised any of the small number of professions, which law and prejudice declare to be vile; he is then reputed a gentleman by descent; hidalgo; for in Spain nobility by creation is unknown. Some humourists have observed, that there are whole provinces of which all the inhabitants are gentlemen; nor is this any great exaggeration. Philip V, ennobled all the Biscayans. All the Asturians are believed to be descended from the ancient Goths, who took refuge in the mountains of Asturia, and were never subjected by the Moors, and are reputed noble on account of this honourable origin. But there cannot be a more glaring absurdity than to imagine that two or three hundred thousand men who settled some centuries ago in a small province, are all noble in the strict meaning of the word. If all men were of the same height, the words giant and dwarf would be obliterated from the dictionary. Nobility necessarily supposes a more numerous class, who are less noble, not it is true of that description, condemned in some places by absurd laws to a species of abasement, but obscure inhabitants inferior to a small member in credit and consideration. Thus, in fact, there are

on Biscay and Asturia, as in other parts of Europe, distinguished families, in the opinion of the public, who have made a great figure in the district in which they reside, either by their opulence, or the places they have held; and whatever may be the pretensions of obscure neighbouring families, the former affect a pre-eminence, which these acknowledge by their homage: this, however, prevents not the latter from cherishing ideas of grandeur, which preserve in their mind a noble pride undoubtedly preferable to the chimerical nobility of blood: so that if by some fortunate circumstance they obtain some employment less obscure than their birth, they consider that they have only regained their proper station, and are less insolent and vain than most upstarts in other countries.

I have more than once remarked this distinguishing characteristic, even in the lowest ranks of the Asturians and the Biseayans. They have, in their appearance, something more haughty, and are much less humble in their submission. They are not awed either by titles or riches. A man in place is in their eyes a fortunate man, who obtains a prize in the royal lottery, in which they all have a ticker, and may win in their turn; and this prejudice, ridiculous as it may seem, keeps them on their guard against meanness, and even against degrading crimes. This reflection is more or less applicable to all the other provinces of Spain, where hidalgos are more numerous, and where the members of the third class (pecturos) are distinguished from them by no humiliating subjection; so that nobility here excites less eavy, and a desire of throwing off its yoke would less easily than in other places act as an incentive to general insurrection.

Notwithstanding those imperceptible gradations, which in Spain separate nobility from the inferior ranks, the proofs required in certain cases are closely examined; but there, as well as in other countries, money and interest procure genealogists who are not over secupulous. A reflection, applicable to every nation, may be made with respect to the mobility of Spain, which is, that the less a monarch is limited, the more arbitrary are these distinctions, and the more irregular the gradations. Despots, even those the least tyrannical, prefer or neglect their subjects according to their caprices. Unlimited monarchs exercise this kind of influence in a greater or less degree; and there are few states in which the sovereign authority is less circumscribed than in Spain.

Under the ancient form of government it was more confined; but it has changed by degrees, and without exciting commotion. The intermediate ranks scarcely exist in name. The supreme coancils, particularly that of Castile, which is the chief, have frequently tendered remonstrances, where they have apprehended that the measures of the crown would be disastrous, or have deemed them in opposition to the laws; but all the members of the councils are nominated by the king, and may be displaced at pleasure. It is from him alone that they look for advancement in the civil career; and as the inscription of the royal orders, which relate to their different departments, is made in their different registers without any legal power of avoiding it on their part, being in fact a mere matter of form; it does not appear that they possess even that power which was vested in the ancient parliaments of France, of tacitly resisting the will of the sovereign.

CHAPTER V.

REMAINS OF THE CORTES. COUNCIL OF STATE. STRICTURES ON MR. D'ARANDA, MR. FLORIDA BLAN-CA, AND THE PRESENT MINISTERS. OFFICES.

THE Cortes was the only dam which could arrest the progress of despotism. The history of Spain sufficiently proves how great an influence this species of states general had in the most important affairs of government; but for a long time past, they have

not been assembled, except for the sake of form; and the sovereigns, without violence, without formally rejecting their intervention, have found means to clude their authority. They render them however an homage in mockery, when they promulgate ordinances from the throne under the name of pragmatic, the preambles of which state that they claim the same respect as if they had been published in the assembly of the Cortes; which are never convoked except at the accession of a new sovereign to the throne, to administer to him an oath in the name of the nation, and swear fidelity. On this occasion, letters of convocation are sent to all the grandees, to all titled persons of Castile, to all the prelates, and to every city which has a right to send deputies to the Cortes. The two first classes represent the nobility; the priests, the body of the elergy, and the cities which depute one of their magistrates, represent the people.

The last time that the Cortes was assembled was in 1789, at the coronation of the reigning sovereign. Its session was continued for three months, the count de Campomanes acting as president, who on this occasion received the title of governor of the council of Castile, the functions of which office he had excercised alone for several years before. The Cortes were composed of at most a hundred persons; for it is not every province of Spain that sends deputies to them. Gallicia has her own separate. That part of Old Castile known by the name of Montanas de Sant Ander, is represented by the city of Burgos, which disputes the precedency, at the assembly of the Cortes, with Toledo. Navarre, the lordship of Biscay, and Gurpuscoa, have their particular states, and these different provinces take an oath to the new sovereign by means of deputies, which for that purpose they dispatch to court.

This national assembly, however unshapen, and incomplete it be, at one instant seemed to feel its authority, and was on the point of manifesting it. Already had some intrepid orators prepared themselves to express their grievances, and to point out the most into-scrable; (it might have been the signal of a revolution;) when the court anticipated the intention, as if it foresaw what was about to happen in France; and civilly dismissed the Cortes, who patiently dispersed.

Except these convocations, of which there have been but three in the present century, and which only gave room for vain formalities, recollection, and regret the Cortes of the whole kingdom have not been assembled since 1713, when Philip V, convoked them to give their approbation to the pragmatic sanction, which changed the order of succession to the throne.

It is well known that by a law, of which it would be as difficult perhaps to indicate the real origin, as that of our pretended Salie law, women ascended the Spanish throne in case of proximity of blood. This mode of succession is known under the designation of Castiliaro or Cognato, in opposition to that called Agnato, which excludes females entirely. Philip V, being desirous of assimilating in measure the course of succession in Spain, with that of the country which gave him birth, in spite of his predilection for despotic resolutions, conceived it would be wise to obtain the consent of the Cortes towards sanctioning this resolution. He was in possession of great authority; in a twelve years' war he had effected the subjugation of his kingdom; he saw all Spain unequally divided between subjects devoted to him, who could have no motive for resistance to his will, and discontented subjects that he had effectually curbed. He relied therefore upon the docility of the Cortes, and was not disappointed. They acknowledged, and adopted the new order of succession, which calls to the throne the male heirs, to the exclusion of the female, however near the consanguinity; who cannot accede to it, but in case of the total absence of any male descendant from the reigning family. There is however something more absolute than the authority of the most despotic monarchs; I mean public opinion.

and the indelible predilection of a people to its ancient laws and customs. An attachment to the old mode of succession still exists in the hearts of the greater part of the Spanish nation, and it is more than probable, if once a question were to arise which might have to be decided either according to this ancient law, or the pragmatic sanction of 1713, it would not be determined in a peaceable manner. Happily for Spain this possible position is not likely soon to occur, since among the six children of his majesty there are three males. In the time of my first visit to Spain, there was a period when this delicate question without being considered an idle one, was much under discussion; this was, when the present king, then prince of Asturias, saw most of his male children fall off in their infancy, and was threatened with having no progeny but what were female. In case of the realization of this apprehension, the Castilian order of succession would have nominated to the throne the eldest of the Infantas, while the pragmatic regulation of 1713 would have pointed to one of the two brothers of the king, or their male descendants, and Europe might again have been ensanguined for the purpose of deciding the dispute.

But let us return to the Cortes, and see what remains of their authority. They are still consulted, for the sake of form, in certain cases, when for example it is in agitation to grant letters of naturalization to a stranger, but then the members of which they are composed correspond with each other, without assembling. A faint image of them, however, remains in an assembly, which constantly resides at Madrid, under the name of Diputados de los Reynos (deputies of the kingdoms.) At their breaking up in 1713, it was regulated, that they should be represented by a permanent committee, whose office it should be to watch over the administration of that part of the taxes, known by the name of Millones, and which had been granted in the reign of Philip II, with the formal consent of the Cortes, upon certain conditions, which the monarch swore to observe, and to watch the performance of which the committee of Diputados was appointed. The Cor tes also authorised it to superintend the disposal of the Millones. But in the year 1718, the Cardinal Alberoni, whose ardent and imperious mind disdained all restraint, transferred it to the hands of the sovereign. From that time the committee held no more of the state revenues than the small portion necessary to pay the salaries and defray the enpences of the members. These are eight in number, and are chosen in the following

But first it will be proper to observe, that the division of Spain into kingdoms and provinces, such as Gallicia, the Asturias, the kingdom of Leon, the kingdom of Valentia, Andalusia, &c. as described in maps and geographical treatises made out of the peninsula, are scarcely known in practice. Spain presents as strange and even a more

complicated medley, than what France did previously to the Revolution.

The three provinces of Biscay, Navarre under the title of kingdom, and the Asturias as a principality, form separate states which are without custom-houses, intendants and almost every thing pertaining to fiscal sway. The rest of the monarchy, subject to its authority is divided into twenty-two provinces belonging to the crown of Castile, and four belonging to that of Arragon. These twenty-six provinces differ materially in extent; for example, all Catalonia which pertains to Arragon forms but one province, while in Castile some are no more than three or four leagues square; each has its separate intendant, and may be compared to our generalities.

The twenty-two provinces of the crown of Castile are the kingdom of Gallieia, the provinces of Burgos, Leon, Zamora, Salamanea, Estramadura, Palencia, Valadolid, Segovia, Avilas, Toro, Toledo, La Mancha, Murcia, Guadalaxara, Cuenca, Soria, Madrid, and lastly Andalusia, which comprises four provinces still designated as kingdoms;

a name which they bore in the time of the government of the Moors, that is to say, Sc. ville, Cordova, Jacn, and Grenada.

The four provinces of the crown of Arragon, are the kingdom of Arragon, that of

Valencia, the principality of Catalonia, and the kingdom of Majorea.

This is not the only division by a great many. Spain is divided into thirteen military governments, twelve of which have chiefs, who bear the title of captains general of provinces; the commandant of Navarre alone having that of viceroy. It is moreover divided into dioceses, which have different boundaries to what the provinces have; and

into justiciary partitions which we shall notice as we proceed.

But the principal of all these divisions, notwithstanding it does not comprise the whole monarchy, that which the greater part of the acts of government are to have effect upon, is the division which partitions Spain into the provinces of the crown of Castile, and those of the crown of Arragon. Two parts of the monarchy which differ from each other as well with respect to the administration, as the species and collection of taxes; a distinction which had its origin at the time when Castile and Arrogan were united by

the marriage of Isabella and Ferdinand the Catholic.

Los diputados le los Reynos, weak remnants of the Cortes, are chosen according to this division. All the provinces of Castile unite to name six; Catalonia and Majorea one; and the regencies of Valencia and Arragon elect the eighth. These deputies sit but for six years, at the end of which a new nomination takes place. As a reliet of their ancient rights, they still retain the privilege of being, by virtue of their places, members of the conneil of finance, by which the sovereign communicates to the nation the necessity of levying any new tax; and the approbation they are supposed to give to the royal will is a shadow of that consent of the Cortes, without which taxes could not formerly be augmented. But it is easy to perceive how feeble this rampart of liberty must be, which is only formed of a small number of citizens, who possess but little real power, are under the controul of government from which they expect favours and preferments, and who, after all, represent only a part of the nation.

The provinces of Biscay and Navarre, which hold assemblies and have particular privileges, send also, on some occasions, their deputies to the throne, but they form no part of the Diputados de los Reynos, and their constituents fix at pleasure the object and

duration of their temporary mission.

We may perceive from this sketch how little the sovereign authority is limited in Spain. The councils are the organs of his will, and at the same time the depositary of the laws which emanate therefrom; his ministers are the agents of it. For a great part of the late century they have been the only persons connected. The king is habitually closeted with each of them separately. In any knotty case they are assembled in a junta, in order that he may obtain their collective opinion. Up to 1718, their authority was counternally the council of state, but the ambitious cardinal Alberoni, at that epoch, thought fit to release himself from its interference. The council of state continued to be the most honourable corps in the nation but ceased to assemble. The place of conceillor of state is now only honorary, with a considerable salary annexed to it, and furnishes the sovereign with the means of rewarding those of his subjects who have deserved well of the state. The various offices of administration generally lead to this appointment at the end of a few years.

But in the month of February 1792, a few days after my arrival at Aranjuez, count de Florida Blanca, who had drawn on himself the displeasure of the queen, and who had either the boldness, or impolicy to slight the young duke de la Alcudia, whose credit with the royal couple was every day augmenting, Florida Blanca whose thoughtless

audacity was about to plunge his country into a war which had no motive, and was wanting even of a specious pretext in the midst of the most perfect security as he conecived, was dismissed to make room for Monsieur D'Aranda, who was as little prepared for this return of favour. He was made prime minister, and spite of his long experience he did not look upon himself as possessed singly of a sufficient ability to support the weight of the administration in such a critical juncture, and consequently urged the necessity of having recourse to a council of state, which was immediately assembled, and of which he was made the president. Notwithstanding these wise precautions, Monsieur D'Aranda was blamed for having accepted the administration, for relying upon an apparent favour of the instability of which the least insight into what was passing at court must have satisfied him. His friends would have deemed him much more honoured by a noble refusal, than in the acceptance of a situation, the splendour of which could yield no addition to his fame. His enemies, his rivals, the ministers of the powers, who had already secretly conspired against France, which he was supposed to favour, already predicted his sudden fall, and no doubt gave their assistance towards it. For my part I who look for nothing, who fear nothing, from one side or the other, who for the seven months of his administration was continually near his person, I must say, that preserving at all times a dignity frequently bordering on stiffness, he employed his means at this time in keeping the scourge of war at distance from his country, and that I cannot hold opinion with those who conceive that this last scene of his political life has diminished his pretensions to general esteem.

Succeeded in the month of October by the duke of Alcudia, under pretence that his great age rendered it necessary he should take repose, he supported this mortification with the serenity of a philosopher. He preserved the title of president of the council of state, and filled the functions of it, until having expressed himself at one of the sittings of this council with that rigid frankness which is peculiar to him, on the subject of the war with France, and which certainly should have met with an apology in his experience, he was exiled to Jain, a city of Andalusia. On the return of peace the king, banishing him for ever to a distance of thirty leagues from his coast, and capital, permitted him to withdraw to his estates in Arragon.

At this moment the council of state is composed of thirty-two members, thirteen of which are a distance from Madrid upon different accounts, there are eleven other individuals of distinction, for the most part absent, who without being admitted to the council, are considered as honorary members; the value of which is little more than entitling them to be qualified your excellency.

The title of councillor of state, now but an honorary appellation even for those who possess it in its plenitude, is the most distinguished recompense or rather favour, which the king of Spain can confer. It is the reward of personal merit, of long service in a political career, or in some important branches of administration: for some years back it is an appendage to the offices of ministers of state. The administration is divided into six principal departments.

1. The minister of foreign affairs is the directing minister, and receives, as a mark of distinction, the title of secretary of state.

2. The minister of war has but a circumscribed authority. He is president of the council of war, which is rather a tribunal than a board of administration; but the inspectors of the infantry, and those of the cavalry, dragoons, and provincial regiments, draw up a statement of whatever relates to the corps of which they have the direction and the minister at war has only to present the memorials they give in to the king.

3. The minister of the navy has no associates. The chiefs of the three departments and the inspectors of the navy are named by the king on the representation of the minister; the naval ordinances prepared by him require only the sanction of the sovereign.

4. The minister of finance should properly be under the inspection of the superintendant-general of that department; but these two offices were some time since united, or account of the separation of them multiplying without necessity the springs of government. Charles III, had three ministers of finance: Squillaci, disgraced to satisfy the nation; Musquiez and Leruna, who maintained their situations for life. No one will presume to affirm that the finance department was well managed during their administration; but would their having an inspector over them have caused them to be better managed? The council of finance opposes frequently but a weak barrier to the acts of the minister of that department. The president of this council for a long time was the minister himself. An uncle of the prince of the peace at present holds the situation.

5. The minister of the Indies had the most extensive department in all the monarchy; for in him was centered the civil, military, ceelesiastical, and financial government of Spanish America, and it may be said, that in the whole political world there has never been a minister whose power was so extensive, since it comprehended the whole of that immense country which, from the north of California, stretches to the straits of Magellan. The authority of this minister was curbed only by the intervention of the council of the Indies; but for some years back the presidency of that council has been joined to the situation of minister for the Indies. Charles IV, in suffering a council to exist whose establishment is as ancient as the conquest of America, has divided the ministry for the Indies among the five other ministers. The largest portion of this division has

fallen to the lot of the minister of favour and justice.

6. The department of the minister of favour and justice comprises what relates to judiciary and ceelesiastical affairs, as well in Spain as in the Indies; but his authority is circumscribed by the great chamber (Camara) of the council of Castile in Europe, and by the council for the Indies in what regards America. In 1796 there were no more than five ministers, the ministry for foreign affairs being filled by Don Manuel de Godoy, who in 1792 was created duke de la Alcudia, and who after terminating a war which he entered into no doubt with great reluctance, received the name which above all others is glorious to a minister, that of the Prince of the Peace. I have known him intimately, and have observed his conduct on critical occasions. I shall neither be his censor nor apologist; all that I shall say of him is, that history furnishes few examples of so much good fortune, and that so rapidly attained: his success no doubt creates envy; however, few are displeased with it, since he supports his station with dignity, and shews, by the use he makes of the favour he enjoys, that he is not altogether unworthy of it.

In his person is concentrated almost every dignity in Spain. He is a knight of the grand order of Charles III, as well as of the golden fleece; he is a grandee of the first class; he enjoys the title of prince, which no nobleman of Spanish extraction ever bore before him; in addition to these, he is prime minister, a councillor of state, captain-general of the armies, inspector and chief of four companies of gardes du corps, &c. &c. To sum up all, nature, in unison with fortune to bless him with every qualification which can entitle him to claims on happiness, has endowed him with a captivating exterior, and

what is of greater value, a sound mind, and a good and benevolent heart.*

^{*} In 1798, the French government conceived it had right to complain of him, and employed its miluence at the Spanish court to drive him from the ministry for foreign affairs; but it could not

In 1793 the administration of finance was in the hands of Don Diego Gardoqui. He had been dispatched from Bilboa, where he had a house of business in 1781, as chargedraffiaires to the United States on the part of Spain. He was afterwards appointed consul-general in England, and then succeeded Lezena, who died, in the administration of finance. He began his career with favourable auspices, having to succeed a man who had rendered himself so odions to the people, that it was with difficulty his remains could be carried in quiet to the tomb. Some address notwithstanding was requisite to M. Gardoqui to maintain his ground, surrounded as he was by the embarrassments into which his department had fallen; and some courage to support the burthen of the war in which Spain was engaged with France. After having conducted the vessel of finance for the space of six years, with more good fortune than capacity, through the dangerous navigation which it had to pass, he was nominated ambassador to Turin: M. de Varela succeeded him, who, recently promoted to the ministry of marine, had evinced greater aptitude for financial matters than for military affairs.

They both died shortly after; and at present the ministry of finance is in the hands of Don Michael Cayetano. This nobleman had filled the post of administrator of the little island Ivica, one of the Balcares, for several years, and had vivified it by establishments which manifested at the same time his wisdom, and his attachment to regularity. On his return he was recommended to the prince of the peace, by the Dutch ambassador Walkenaer, a man of sense, and an eminent judge of merit of different descriptions. The account he gave of his little administration, the warmth with which he disclosed the plans of amelioration which he had conceived, made him be esteemed capable of employing his abilities in a much wider field; he was raised to the station of minister of finance; a verse has been applied to him, which I am at a loss to determine whether the offspring of envy or rigid justice,

" Who shines within his proper sphere. Promoted is no more a star."

In 1793 M, de Valdez was minister of the navy, and had managed his department with lovalty and wisdom from the period of the death of Castejon. The court and the nation would yet have been better satisfied with him, if during the war with France he had joined to these good qualities that activity which circumstances exacted. On the con clusion of peace he obtained what for a long time he had been desirous of, an allowance to resign, and was succeeded by Don Pedro Valera, who had acquired considerable experionee in the administrative department of the navy: he found that great neglect had existed in this office, and on his succession pursued his plan of repairs with a circumspection bordering on slowness. His promotion to the ministry of the navy did not meet with general suffrage, and shortly his conduct disgusted many of the most distinguished persons in the navy, a dangerous matter at the eve of a new maritime war: he was therefore removed to the head of the department of finance, and Don Juan de Langara took the administration of the navy. This admiral, notwithstanding the species of disfavour into which he had fallen, from the famous check which a Spanish squadron under his command met with in 1780, had acquired the esteem of the public by his talents and his loyalty. At that time he commanded the squ. Iron at Cadiz; it was not long, however, that he maintained this appointment, to which he had been called by the

estrange him the royal favour, which he incessantly enjoyed. It may, on the contrary, be affirmed that these attempts so far from injuring him, but served to enhance his credit, although less openly shewn; he is, in fact, the prime minister, and invisibly the chief of every department. He has been succeeded in the office for foreign affairs by three other ministers, of whom we shall speak as we proceed.

voice of the nation. At present he is captain-general of the navy, and councillor of state, and lives peaceably at Madrid, in possession of that esteem he has so well earned. After his resignation, the ministry which he left vacant was given ad interim to Don Antonio Caballero. But at the beginning of this year an admiral generally esteemed.

Don Domingo Grandellana, was appointed minister of the navy.

The administration of the war department, after the death of Lerena, was entrusted to count Campo Alange, who retained it up to the conclusion of peace with France; he was then named ambassador to Vienna, and is now gone in that capacity to Lisbon. His successor as war minister was Don Miguel Joseph de Aranza, a soldier of distinguished merit, who, after being employed in foreign negotiations, had filled the intendancy of the kingdom of Valencia with general approbation. Soon after he made way for Don Juan Manuel Alvares, the nucle of the prince of the peace, and was sent as viceroy to Mexico, then in rather critical circumstances, which were not however above his capacity. A sort of fatality rapidly snatched him from this destination, and he now lives retired, but not in disgrace, at Madrid, and is a conneillor of state. He has recently been pointed at as a fit person to be employed on some important mission.

Don Juan Manuel Alvares did not long retain the war department; he as well has taken his place in the council of state. His successor ad interim was the same Don Joseph Antonio Caballero, already employed in the departments of favour and justice, and the navy, who thus was for a time the minister, with the most upon his hands of any in Europe, and who, if competent to the duties he had to fulfil, must at the same time have

been one of the most skilful.

The administration of favour and justice, which was the allotment in 1792 of Don Pedro Alenna, a friend of the duke de la Alendia, passed afterwards to Don Eugenio de Laguno, an enlightened, and at the same time a modest man, for a long time at the head of the office for foreign affairs; and who, when that department was rather prematurely confided to the duke de la Alendia, assisted the young minister, by imparting the fruits of his long experience. He did not long retain the office of minister of favour and justice, which perhaps required a man of greater activity, but sought for the otium cum

dignitate in the council of state, and died shortly after.

His immediate successor is one of the most enlightened men in Spain, one of the most perfect philosophers I have ever met with, Don Gaspard Melchior de Jovellanos, a person who at the close of my last edition I had pointed out as one among the men of merit who languished in oblivion. It is pretended that the hopes formed of him have not been realized. But may not this be the language of envy, or at least of those enemies among a certain class of men, which will yet be formidable to Spain for a length of time to come, and whom the philosophical intrepidity with which he has opposed certain abuses has rendered inveterate against him? However it may be, the disgrace of M. de Jovellanos was as sudden as that justice which called him from his state of inaction has been tardy in his operation. He is retired to his province, where he cultivates literature and the useful sciences.

He was replaced by the same Don Joseph Antonio Caballero, of whom we have before spoken, and who thus had at once three important employments, being minister of favour and justice for constancy, war minister ad interim, and minister for naval affairs, the functions of which office he attended to up to the period of the recent nomination of

admiral Grandellana.

At present (May 1802) there are four ministers in Spain. Don Pedro Cevallos, for foreign affairs; Don Miguel Cayetano Soler, for finances; Don Joseph Antonio Caballero,

icilior of dearned, i to Don steemed,

ve before ter of faffairs, the nation of

allos, for Saballero, tor the department of favour and justice, as well as that of war, and Don Domingo Gran dellana, for naval affairs.

The stability of the ministry under Charles III, was one of the most remarkable circumstances of the Spanish government. When this sovereign had once given his confidence to a minister, incapacity, misfortune, nothing caused him to withdraw it. His ministers were consequently almost certain of retaining their employments for life; and this certainty, valuable upon many accounts, was not the less a spur to their activity. If it left them a wide field for the plans which they formed, it secured them impunity for prevarication, and afforded time for abuses to take deep root. Under the present government, has not the other extreme been rather too much followed? The chief administration in the year 1792 alone has passed into no less than three hands, and I had to treat with three successive ministers of different character and opinions, upon the most knotty points.

Five years after, the administration of foreign affairs was entrusted to Don Francisco Saavedra, with the public voice in his favour, to which I ventured to join my recommendation. Bad health was either the cause or the pretext of his premature retirement. He was succeeded ad interim by a young man who, after displaying some genius abroad in a political capacity, was made chief of the office for foreign affairs. Don Louis Marcano de Urgueya, who quickly became a great favourite, but this favour it appears was misplaced. Public disgrace became the price of his imprudence, and he was confined in the eastle of Pampeluna.

The department which he filled was definitively given to Don Pedro Cevallos, the head of an ancient family of Old Castile. After studying at Valladolid, intendedly for the bar, he was sent as secretary of embassy to Portugal. On his return to Madrid, he married a relation of the prince of the peace, and was afterwards appointed as ambassador plenipotentiary to Naples; but in consequence of differences arising between the two courts, was prevented from proceeding. From what is known at present of this minister of state, it appears that his modesty and prudence afford a striking contrast with the conduct of his predecessor. One cannot here help observing, that in four years that Charles IV, has reigned, he has had six ministers of foreign affairs; while his father during the whole of his reign of nine-and-twenty years, had but three, two of which, M. Wall and M. de Grimaldi, spontaneously resigned, and the third survived him.

Fewer changes in the present reign have taken place in the other departments of ministry.

The Spanish ministers are enabled to give themselves up to the labour which their different employments require better than those of any other court. Nothing can be more regular than the life which they lead, an airing is almost the only amusement they take. From the areana of their closets they hold correspondence with the extremities of the globe; without, their horizon is circumscribed within half a leagues diameter. Their chief company is their clerks, who are accustomed to live at their table. This mutual constraint has some trifling conveniences; but the consequences are, a more close union between the principal and his subalterns, and a greater regularity of connection in public affairs. Those who expedite them under the eyes of the ministers are not, it is true, simple clerks, they may with more propriety be compared to our head clerks in different offices. In order to obtain appointments of this description, it is generally necessary that proofs of talent should have been manifested previously in some occupations of trust. In the office of foreign affairs, for example, almost all the principal clerks have been attached as secretaries to some diplomatic mission, and from that employment frequently pass to the situation of plenipotentiaries or ambassadors. There

are at present six of them who represent their sovereign at foreign courts; remarkable singularity in a despotic government in which one should imagine intrigue and favour would dispose of places, and which in this respect may serve as a model for free governments.

I have oftentimes in these Spanish officers met with at least the appearance of haughtiness, but frequently it is no other than a veil thrown over kindness; it does not prevent the administration of justice; and, let whatever will be said, I have reasons for believing that corruption is as rare in them as discretion is common. But how slow, how methodical, how wearisome their progress! How much are they to be pitied, those who play the part of petitioners, whether upon their own account or that of their country.

CHAPTER VI.

AMUSEMENTS OF THE COURT OF SPAIN. GALLERY OF PAINTINGS, STATUES. MANUPACTORY OF PLATE GLASS. HUNTING MATCH. THE CHARTEEUSE OF PAULAR.

THE residences of the court of Spain (Los Sitios) have very few resources of amusement. They have no plays, no public games, no large assemblies, except on days of coronomy; and consequently these places are not inhabited, except by a very few persons whose simulations oblige them there to, at any other period than that of the excursion to Aranjucz in the summer; that of St. Idelouso is almost deserted, so that the society of the royal personages is for the most part restricted to those whose services require their attendance. The queen when princess of Astorias, except when taking an airing at the stated hours, passed the greater part of her time in private, where she enjoyed no other amusements than music and conversation. The prince, her husband, never left her, except to accompany the king his father to the chace, oftentimes twice in a day. Since their accession to the throne, they have swerved very little from the same uniform life; but the strict cliquette observed has been somewhat lessened. They occasionally appear for a short time at the entertainments given by the grandees and foreign ministers; a condescension never shown by Charles III, but they never go to the play, nor even to the bull-fights.

The king during his father's life patronised the line arts; he had made a collection of good paintings of the different schools, before he inherited one of the largest and most

valuable galleries in Europe.

The collection of the court of Spain is not considered inferior to any, unless it be to that of the court of France, and that of the elector of Bavaria. It is principally at the Escurial and Madrid. The palace at Ildefonso formerly contained a great number of paintings, but the galleries of Madrid and Aranjuez have been enriched by their removal. There remains, however, still a sufficiency to occupy the attention of an amateur for several hours.

As soon as you enter the anti-chamber of the king's apartments, there passes in review, as in an historical gallery, first an elegant portrait of Louis XIV, by Rigaud; and next, that of Louis XV, when a child; those of the regent, the duke of Vendome, the last duke of Parma, of the house of Farnese, and his dutchess; as also those of Charles III, when he went to take possession of the kingdom of Naples; of Philip V, on his arrival in Spain; and of the archduke his rival. The chamber adjoining has a view of one of the finest cascades in the garden. This room is decorated with several paintings, among which are some by Muriilo and Solimena. In the adjoining apartments, a fine one of St. Schastian by Guido; a Flemish family by Rubens; a picture by Poussin; two heads by Mengs; the portraits of the princes of Conde and M. do Turenne, upon the same canvass, by Vandyck, &c. &c.

In a gallery on the ground floor, and which occupies the whole front towards the gardens, besides some line paintings, and two charming heads in mosaic, there is a con iderable number of antiques, the greater part of which was bought in Italy by Philip V. and formerly composed a part of the cabinet of Christiana of Sweden. Those which most engaged my attention were a cylindrical altar, on which the procession of Silenus is sculptured in bas relief; a colossal Cleopatra; a statue of Jupiter wielding his thun der; several Venuses of the natural size; eight muses a little mutilated, in which mo dern and unskilful hands have endeavoured to repair the injuries of time, and of which the drapery is remarkable for its lightness; two groups which are banished to a corner, as they retrace the unimproving fictions of mythology, the adulterous amours of Jupi ter with Leda and Ganymede, who caress with suspicion the immodest birds, whose figure the god has assumed, &c. But the antique sculptures which more particularly merit the attention of connoisseurs, are young Faunus carrying a kid, and a group of Castor and Pollux, two original master-pieces of antiquity in perfect preservation, copies of which are met with every where by the side of those of Venus de Medicis, the Laocoon, the Apollo Belvidere, and the Farnesian Hercules.

In an apartment in the gallery the finest marbles of Spain, in columns, vases, and busts, seem to vie with the productions transmitted to us from antiquity; yet notwith standing the excellence of these modern performances, they only serve to make more conspicuous the superiority of their forerunners. A small corridor, adjoining to the gallery, contains in piles every thing for which no place could be found in the latter, Egyptian statues, fragments of columns, bas reliefs, busts, and other antiques, consigned to dust, destructive insects, and whatever anticipates the ravages of time.

Without the castle of St. Ildefonso, proofs of the attention of the monarch, and his taste for useful establishments, appear on every side. The count de Florida Blanca, who had at heart the public weal, and possessed much information on many points, was affected at the sight of the crowd of women and children who led an idle and wandering life about St. Ildefonso. In order to afford them employment, he proposed the establishment of a linen manufactory at the very residence of his majesty, and immediately under his eyes. At the beginning of 1781 it had not been thought of; and, rare example of celerity in Spain, before the month of August 1783, there were upwards of twenty looms employed in the new manufactory, and two great machines for pressing and washing the linen.

To set them going, a skilful person, whose manufactory was on the decline for want of encouragement, was sent for from Leon. Since its first institution this establishment at St. Ildefonso has been visibly improving.

Near this new established and much wanted manufactory there is one of luxury, begun in the reign of Philip V, this is a manufacture of plate-glass, the only one of the kind in Spain. It was at first no more than a common glass manufactory, which still exists, and produces tolerably good bottles, and white glasses extremely well cut: this was the first step towards a far more enlarged undertaking. The looking-glass manufactory of St. Ildefonso may be compared with the finest establishments of the kind. It was begun in 1728, under the management of a Catalan, and was brought to perfection under Ferdinand VI, by a Frenchman named Sivert. Glasses are run here of all dimensions, from common squares to those of the greatest size. They are not so clear, and may be less polished than those of Venice and St. Gobin; but no manufacture has yet produced them of such large dimensions. In 1732 I saw one east a hundred and thirty inches long by sixty-five wide. The enormous table of brass on which the liquified matter was east, weighed 19,800 pounds, and the cylinder which rolled over it to vol. v.

render the surface even weighed 1,200 pounds. In the vastedifice where this operation is carried on, an operation well worthy of examination throughout its whole process, there are two other tables somewhat smaller, and twenty overs, wherein the glasses yet hot are placed, and remain hermetically closed for the space of from lifteen to five-and-twenty days, in order to cool by degrees. Such as split, or have any defect, are then cut to make mirrors, glass squares, or carriage plates. The maintenance of this manufactory is very expensive to the king. I reckon that if the general cost of the establishment, and the numerous drawbacks be computed, some of the plates stand him in 160,000 rials.

In a long gallery adjoining the manufactory they are made thinner by manual labour, by rubbing one upon the other, sand and water being placed between, the sand of different degrees of fineness, according to the stage of the work. The upper-glass being kept continually in motion, while the under one is at rest, it consequently becomes thinner much the soonest, so much so, that five of the first are reduced to their proper thickness before the latter is sufficiently ground. This labour is wearisome and monotonous in the extreme; one glass keeping the same workman employed constantly for more than two months.

When sufficiently ground on both sides, they are polished in the following manner: the largest in the manufactory itself by the hand; the smaller are carried to a machine, where thirty poushers are moved by water: these polishers are a sort of square boxes, placed firmly on the glass, and shod with very even felt, loaded with lead internally, and are moved horizontally by the impulse of a handle of wood to which they are fastened; beforehand the plate is rubbed over with a species of emery, the production of a quarry in the neighbourhood of Toledo. This emery is divided into three classes, the coarsest of which is used first, that of a middling quality is next used, and the finest the last; after this, the glass is covered with a red earth (almagro) and is placed under the potisher. This process is carried on for each side of the glass, and takes up from eight to ten days.

An attempt was made to substitute mechanism for manual labour in grinding down and thinning the plates, and for this purpose, machines were transported from France to St. Ildefonso; but the directors of the establishment perceiving that their adoption did not greatly accelerate the operation, and was equally expensive, returned to the original plan.

The plates thus ground and polished are at length taken to Madrid to be silvered. The king reserves some of the finest to decorate his apartments; of others he makes presents to the courts most intimately connected with that of Spain. In 1782, Charles III, sent some to Naples one hundred and thirty inches in height by fifty-four inches in breadth, and some time after his majesty added some of the same dimensions to the presents he sent to the Ottoman court, with which he had just concluded a treaty.

The rest of the produce of the manufactory of St. Ildefonso is sold at Madrid, and in the provinces, for the king's account. In vain has a prohibition of introducing any other glass within a circle of twenty leagues around been issued in order to secure a sale; it may easily be imagined that the proceeds cannot answer the expences of so extensive an establishment, which, except the article of wood, is distant from all the raw materials it employs. Situated as it is, far inland, surrounded by lofty mountains, and at a considerable distance from any navigable river or canal, it deserves to be numbered among those costly and ruinous establishments of luxury, which contribute to the splendour of the throne, but to the impoverishment of the people.

e a sale; etensive naterials a conlamong lendour At the distance of a quarter of a league from the eastle runs the little river Eresma, which afforded Charles 111, one of his most favourite recreations, that of fishing. Its banks were rugged and crooked, he levelled them, and made a causeway, or, where the ground required it, stone or sod steps. This river, or rather streamlet, is inclosed between two piles of rocks, grouped in the most romantic manner. Its linapid waters sometimes run tumultuously over lesser rocks in the bed of the river, or precipitate themselves by natural cascades, at intervals forming small basins, which serve as asylums to the trout, which are met with in abundance. In some places this river is separated by little meadows from copses of green oak, with which that part of the country abounds. In others, tufted shrubs are seen upon the tops of the rocks, or hang waving from their sides.

In the reign of Charles III, the court went once a year to alarm the Naiades of the Eresma, with the noise of a general hunt. The rendezvous was about a league from the eastle. Some days previous, a number of peasants were sent to the neighbouring woods and hills to drive before them the game with which the country plentifully abounds. The limits were by degrees narrowed, until the time fixed for rousing the game. The sport then was excellent: the deer ran in small herds on all sides, seemingly perceiving the danger into which they were driven, after which they faced about and endeavoured to brave the running fire of musquetry that threatened then, in the rear; but, obeying the impulses of fear, and failing in their attempt, they passed in closer herds through the fatal defile where the king, his sons, and the other princes, placed in ambuscade, waited their arrival. Their agility now became their last resource, and saved the greater number. Out of three or four thousand, and sometimes more, which thus passed in review, about a hundred fell. Some were killed dead upon the spot, others carrying away with them the mortal wound, flew to conceal their agony in the thickets. Their bodies, yet pulpitating, were brought and arranged upon the field of battle. These were numbered with a cruel pleasure, for which a philosopher would reproach himself, but which it is agreed to pardon in hunters. The whole court, and the foreign ministers commonly took part in this amusement, which was repeated towards the end of every visit to the Escurial. The counts of Artois and Dammartin were invited to a hunt of this nature, as they returned from the camp of St. Roch in 1782. They perhaps would have wished for a less easy victory over the timid inhabitants of the woods, which they were accustomed to chase, and not coolly to massacre; but the forests of Compeigne and Fontainbleau never produced such legions of fleet herds, filing off by thousands before them.

Since the accession of his present majesty to the throne, these hunts have not been periodical, but very frequent; their principal object has been to exterminate the numerous herds of deer, which lay waste the fields of the countrymen who live in the neighbourhood of the royal residences. On one journey to Aranjucz Charles IV, destroyed more than two thousand, by having them driven before batteries of cannon loaded with grape-shot; and in 1792 and 1795, I perceived that this praise-worthy project had been followed up with ordinary precision in the pointh praise-worthy project had been

followed up with sufficient precision in the neighbourhood of his residences.

There is another place to which, during the visit to St. Ildefonso, his late eatholic majesty once went annually to spread the noise and terror which accompany the chace. I mean the environs of Paular, a monastery of Carthusians, at the foot and on the other side of the steep mountains which command the castle. El Paular, one of the richest convents of the Carthusians in Spain, and famous for its fine wool, is situated in a charming valley, watered by a considerable rivulet, which runs gently through the groves

and meadows. This stream drives a paper-mill, the noise of which is the only sound repeated by the solitary echoes of the neighbourhood. A Frenchman managed this manufacture on the account of the monks some years ago, and seemed in this corner of the world to have forgotten both his country and language.

In the monastery of Paular there is nothing remarkable, except the great cloister in which Vincent Carducho has painted the principal events of the life of Saint Bruno.

I shall now accompany the reader to the eastle of Rio Frio, three leagues from St. Ildefonso. Charles III, came here once a-year to hunt after the Spanish fashion; that is, to shoot, as the animals pass by, at the herds of deer which, at all other seasons of the year, browzed in quiet in the woods round this place. The eastle of Rio Frio is situated in an extremely sandy soil. And it appears inconceivable wherefore queen Isabella, who began to build it, resolved on making it her last asylum. That it might recal to her memory the new palace of Madrid, which neither she nor her husband had the good fortune to reside in, even for a single day, she ordered it to be built after the same plan, but of less dimensions. Her son Charles III, being called to the throne of Spain, her project of retreat vanished, and the eastle of Rio Frio was abandoned even before it was finished.

CHAPTER VII.

THE MONASTERY OF THE ESCURIAL PAINTINGS, PANTHEON, LIBRARY. ENVIRONS OF THE ESCURIAL.

LET us now proceed towards the Escurial. At about three quarters of a league from St. Ildefonso we pass the Eresma over a bridge, and arrive at Balsain, a village situated in a hollow shaded by thick woods. The kings of Spain had formerly a hunting-seat here, to which Philip V, occasionally resorted, and where he conceived the project of building St. Ildefonso, in this wild country, intending to gratify at once his taste for solitude, and the chace. The French ambassador, before the king built him a house in

the village of St. Ildefonso, resided at this old castle.

As soon as we have passed it, we climb, for two leagues, the tops of the high mountains which separate the two Castiles. The road is shaded by high pines, the tops of which are frequently lost in the fogs which rise from the bottoms of the deep vallies. The air becomes gradually colder as we approach the summits of the mountains; and when we arrived at the seven points of rocks (los siete picos) which, from St. Ildefonso, have the appearance of an immense parapet wall, a new object presents itself to the admiring eye. Before us we view the vast plains of New Castile, and perceive Madrid considerably within the bounds of the horizon over which the sight wanders to an immense distance. We are here in another country, and find another climate and a different temperature. The traveller frequently leaves behind him clouds above clouds, to which the mountains seem to serve as boundaries, and instantly passes into the most serene air. He afterwards descends from this magnificent betvedere by a road which, for a long time, more resembled a precipice, but the declivity of which about the year 1785, was made more gentle, and, at the end of two leagues, arrives at the town of Guadarrana, through which the great road passes from Paris to Madrid. He crosses this road to follow that which leads to the Escurial, at which the court resides six weeks in the latter part of the summer.

This famous monastery is situated at the midway, on the opposite side of the chain of mountains which terminate Old Castile. The choice which Philip V, made of this steep and bare situation, indicates the savage and gloomy character given to him by history. We will not, however, repeat its censures. Let us not speak ill of him, as we approach

only sound maged this is corner of

the chain of of this steep by history, we approach this royal convent, where we perpetually hear him called our holy founder; where his ashes are deposited, and where his image every where meets the eye. This foundation, as is well known, was in consequence of a vow made on the day of the battle of St. Quentin, at which, however, Philip was not present. It is known also, that he dedicated it to St. Lawrence, on whose festival it happened. In Spain it is called by the name of this saint (San Lorenzo) and every thing in the Escurial reminds us of the instrument of his martyrdom. It is not only seen upon the doors, windows, altars, rituals and sacerdotal habits, but the edifice itself bears its form. It is a quadrangular building with the principal front to the west, behind which is a mountain; the opposite side which faces Madrid, takes the form of the shortened handle of a gridiron reversed; and the four feet are represented by the spires of four little square towers which rise above the four angles.

I will not undertake with the abbe de Vayrae and Colmenar, to give the number, no doubt exaggerated by him, of all the doors, windows, courts, &c. of this famous convent. In the whole, it certainly has something awful, but it does not perfectly correspond to the idea formed of it, from its reputation. There is nothing magnificent in the architecture; on the contrary, it has rather the serious simplicity suitable to a convent, than the splendid elegance which should announce the residence of a great monarch. The front to the west alone has a fine portal formed by large columns of the doric order, half sunk in the wall, and on each side two great doors of noble dimensions. By this portal we pass to an elegant square court, at the bottom of which is the church. This principal entrance is never open for the kings of Spain and the princes of the blood, except on two solemn occasions. When they come for the first time to the Escurial, and when their remains are deposited there in the vault which awaits them. Emblem of the gates of life, and eternity.

On this side, the door of the church is preceded by a fine peristyle; over the front of which are colossal statues of six kings of Israel, which appear as in equilibrium upon their slight pedestals. These six kings had some share in the founding or rebuilding of the temple of Jerusalem, as we are informed by the inscriptions upon the base of their statues. The two in the middle are David and Solomon, to whom the sculptor has endeavoured to give the likeness of Charles V, and Philip II, his son; so ingenious at

all times is flattery, availing itself of the slightest resemblances.

The front to the south is entirely destitute of ornament; but in its four stories, including the basement, rendered necessary by the inequality of the ground, there are nearly three hundred windows. The two great doors of entrance are on the opposite front. The whole edifice is built of hewn stone of a species of bastard granite, which by its colour, become brown with time, adds to the austerity of the building. The quarry where it was dug is in the neighbourhood of the Escurial, and it is said that this was one motive for the choice of its site. It furnished blocks of such considerable dimensions, that three stones were sufficient to form the chambranle, or case of the greatest doorways, and each step of the principal stair-case is composed but of one.

When the court is not at the Escurial, it is a vast convent inhabited by two hundred monks, of the order of St. Hieronianus. At the arrival of the court the convent is transformed into a palace. The monks are banished to the apartments in the south and west sides, and the principal cells become the habitations of the royal family, and the nobility and gentry of both sexes, by whom it is accompanied. The king himself has his in the narrow space which forms the handle of the gridiron. Philip II, seems to have wished to make this a retreat, where sovereign greatness might retire to hide itself beneath the shade of altars, and become familiarised to its tomb; and his successors

to this yow of humility, still content themselves with the same modest habitation. It communicates, by a stair-case with the church and vestry, in which the arts united have

displayed all their magnificence.

The church is in the form of a Grecian cross, above which is a dome. The whole building rests upon pillars rather disproportionately thick, within which are scooped out several altars. The architecture is simple but majestic. Several subjects from holy writ, and some sacred allegories are painted in fresco in the dome, by the magical pencil of Luca Giordano. The great altar, which is ascended by twenty steps, contains three different orders of architecture, one above the other, in the form of a mutilated pyramid: no expense has been spared in its decoration. Richness and elegance are united in its tabernacle. The columns are of the most precious marble; the interstices are filled up with paintings by Lucas Cambiaso and Pellegrino Tibaldi. Yet the whole has something mean in its appearance, which forms a striking contrast with the majesty of the edifice. But in revenge its two monuments are really beautiful; these perfectly accord with the first of the three orders of which it is composed, that is doric with fluted columns. The tombs are those of Charles V, and Philip H. These two sovereigns are on their knees, and their majesty seems to bend before that of the King of kings.

They occupy the fore part of a kind of open chamber lined with black marble, by the side of the altar. There is something at once solemn and pompous in the two monuments. The spectator, while contemplating them, cannot but profoundly reflect on the vain insignificance of human greatness, and the abyss in which it is sooner or later swallowed up. These reflections become still more serious when applied to two sovereigns, whose ambition, during their lives, put the whole world in commotion, and who are now condemned to eternal silence by the only law which they had not the power to

avoid.

The two nearest alters to the high alter are those of the Annunciation and St. Jerome; these possess attraction for none but devotees and goldsmiths. Two great doors, upon which are two indifferent paintings by Lucas Cambiaso, open and leave the eye dazzled with innumerable relies in vases, and cases of silver and silver gilt, enriched with precious stones. There is also a large St. Lawrence of solid silver, upon the breast of which are some relies of this Martyr which his disciples, no doubt, saved from the flames.

The church contains also some good paintings by artists of the second order, but in the two vestries, master-pieces of painting are displayed in such profusion as even to weary the admiration of connoisscurs. In the first, which is badly lighted, are three pieces by Paul Veronese, one by Titian, two by Tintoret, one by Rubens, and one by Espagnolet. The principal vestry contains a much greater number, and is sufficient of itself to give a sanction to the fame, which the Escurial enjoys. We shall content ourselves with noticing the pieces which will strike those the least accustomed to value the productions of the arts. That which has the greatest effect is the altar-piece, by Claude Coello, a Portuguese, otherwise little known. It retraces a scene, of which the vestry was the theatre. Charles II, accompanied by the nobility of his retinue, is represented on his knees before the holy sacrament, held by the prior of the monastery; the monarch went thither publicly to supplicate pardon for the profanation of a host, lacerated by impious hands, and revenged by a miracle. And although it be far from the best piece, there is none which leaves a greater impression upon vulgar minds. Real connoisseurs, and those who are dazzled by great names, prefer a fine holy Virgin by Guido; two paintings by Vandyck, one the woman taken in adultery, the other St. Jerome naked to the middle, and writing as he is dictated to by an angel, whose freshness of complexion d have

produces the most agreeable contrast with the sallow skin of the aged saint. A large picture by Tinoret, in which this painter has indulged all the caprice of his imagination, in giving a representation of the Lord's supper. An assumption by Annibal Carracei; several pieces by Titian, two of which are admirable for the colouring, one a St. Sebastian of the natural size, and the other our Saviour disputing with a doctor of the law; three by Raphael; one called the pearl, on account of its superior excellence, is a holy family, in which the infant Jesus has a grace, a justness of expression, and an exactness of drawing which belongs only to this great master; and another, the visitation, in which the modesty of the virgin, and her embarrassment on appearing before Elizabeth with the unexpected and already apparent signs of her pregnancy, cannot be too much admired.

Less celebrated artists have also contributed to the decoration of the vestry. I shall mention but two: the chevalier Maxime and Romanelli. The first has exhibited the beauty of Guido's forms in the painting where Christ disputes in the temple with the doctors, and the graces and sweetness of the pencil of Albano appear in that of the latter; the Virgin seated, caressed by her only infant, and St. John the baptist. It may be imagined, without my saying it, that this vestry contains, in large drawers, sacerdotal ornaments, chandeliers, sacred vases and the like, of the richest description, which illus-

trate the magnificence of the kings of Spain more than their picty.

The same observation may be made on the pantheon, their sepulchre, to which a door in the passage from the church to the vestry opens. The staircase is entirely covered with marble, as is also the inside of the pantheon. This is divided into several chambers, each of which has its particular distinction. One of them is what is called the podridero, or the rotting place. Here the bodies of the kings and the royal family are delivered up to the first ravages of corruption. The bodies of the princes and princesses of Spain, who have not reigned, are deposited in another. It is in this august and dismal assembly that the duke of Vendome is placed, as was M. de Turenne at St. Denis, among the remains of our kings. This I ascertained from the register of the monastery, in which I found an account of his remains being brought thither, the 9th of September 1712.

The real pantheon serves as the last asylum for the kings and queens of Spain alone. A few rays of half extinguished light with difficulty penetrate this cold abode. To supply the defect, a superb lustre, pendant from the cupola, is lighted up on extraordinary occasious; but except in these cases the curious are conducted by a flambeau into the middle of this motionless and silent assembly of sovereigns. By the unsteady light of the flambeau we discover, opposite the door by which we enter, an altar and a crucifix of black marble upon a pedestal of porphyry. The rest corresponds to this melancholy magnificence. The cases which contain the bodies of the kings and queens are placed on each side of the altar, in three stories, and in different compartments, formed by fine fluted pilasters of marble; the cases are of bronze, simple, yet noble in their form. The pantheon is not yet full, but the empty cases are ready to open to receive their deposits. A salutary yet terrible lesson, which kings have not refused to receive from the bold designs of an able architect.

Philip II, reposes in the most elevated tomb of the first division. He it was who laid the foundation of the pantheon; but it was not finished till the reign of Philip IV. It has yet been open but to three sovereigns of the house of Bourbon, the young king Louis I, who ascended the throne in 1724, and died the same year, and queen Amelia, wife of Charles III, and Charles III, himself. Philip V, and his queen are interred at St. Ildefonso; Ferdinand VI, and queen Barbara his wife, at Madrid, in a convent

which they had founded.

The following well-known line cannot be applied to this temple of death:

Le temps, qui detruit tout, en affermit les murs.*

The ravage of time, seconded by the damps, has not spared even the marble. Here we are at once led to reflect on the frailty of man, whatever his rank, and the perishable

nature of those works, which in his pride he dared to conscerate to immortality.

The choir of the monks of the Escurial is above the great door of the church, and opposite the high altar. The walls are decorated with paintings in fresco, the subjects of which have relation to St. Jerome and St. Lawrence. The pulpit, notwithstanding its enormous size, turns upon a pivot with surprising facility. Behind the choir is a master-piece of sculpture; a Christ in marble, of the natural size; it is the work of Benyenuto Cellini, by whom the constable de Bourbon was killed upon the walls of

From the sides of the choir begins a gallery which runs along the two fronts of the church, and communicates by four doors to the first story of the monastery; it is intersected by several spaces between the joints and pillars which support the congregation. Thither I frequently went, that I might feel those sensations, which the minds of persons the least devout are susceptible of at the solemn aspect of a temple. That of the Escurial disposes one more than any other to such meditations. Its mass, the solidity of which has already survived its founder, who sleeps within its walls, almost two centuries, and will survive him for twenty more; the memory of this imperious monarch, which for a long time past receives no other tribute there than funeral prayers, and whose shade is supposed to wander in this melancholy monument of his fear and his piety; the volume of a hundred voices making the roofs echo with the praises of the eternal Being; all these dispose the mind to that serious reflection, which is far more pleasing to the soul than the giddy dissipations of the world.

But let us finish the description of the other beauties contained within the Escurial. On leaving the gallery, one of which is on each side the church, we pass a long corridor, called The Hall of Battles, because the paintings represent several between the ancient kings of Spain and the Moors. The attitudes, dresses, and lively colouring excite the

admiration of all connoisseurs.

I cannot, however, avoid mentioning the two great cloisters: they are paved with marble, and are excellently proportioned. The paintings in fresco of the lower cloister arc, perhaps, more extolled than they deserve. In seeking for the effects of perspective, and brilliant colouring, one meets with disappointment; but the admirer of heads full of expression, and the great and vigorous forms of the school of Michael Angelo, will return more than once to examine the principal events of the life of our Saviour, painted in almost colossal figures by Pellegrino Tibaldi, round the cloister.

Both the cloisters are entered by narrow and obscure corridors. The chief defect in the architecture of the Escurial, is that, in general, the principal objects are not placed so as to have the best effect. The portal and great staircase are seen but by accident. There is a fine inner court ornamented with two rows of arches, of a simple but noble style of architecture; the centre is occupied by a small temple, which is perhaps the most regular piece of architecture in the Escurial: but it seems to hide itself from the eyes of

the curious.

The great cloister below, which communicates with the capitulary hall, is hung with several paintings by Titian, and one by Velasquez, representing the sons of Jacob bring-

^{*} Time which destroys all things, has given strength to its walls.

ing him the bloody garment of their brother Joseph; a painting the effect of which is admirable; a virgin by Raphael; a St. Jerom by Guerchino; three pieces by Rubens, and three by Spagnoletto. But the pieces most to be admired in the capitulary hall, are three masterly paintings by Guido.

The grand cloister below has a communication with the old church of the monaster. This as well contains some paintings worthy of attention; several by Titian; three by Spagnoletto remarkable for beauty of colouring; and one, by Raphael, which, foits beauty, nobleness of its figures, correctness of drawing, and every excellence that characterises the inimitable talent of this great master is superior to all. I have seen connoisseurs view it with transport, and shed tears of admiration, before this sublime master-piece, without these delicious impressions being weakened by the fantastical union of persons it presents: these are the Virgin Mary, Christ, and St. Jerom in a cardinal's habit, reading to them the bible, while the angel Raphael introduces to the divine group young Tobit, advancing with a timid air to present his fish. The last circumstance has given this piece the appellation of Madonna del Pez (our lady of the fish.*) It is in conceivable how the genius of Raphael could stoop to this strange composition, undoubtedly prescribe him, and yet in the execution leave no marks of such compulsion. If his exquisite taste was not disgusted by a dissonance which shocks the least delicate, what becomes of the rules of art, and the precepts of reason?

Even after admiring the Madonna del Pez, one may look with delight on the superb piece of Titian (the last supper) which takes up the whole breadth of the refectory of the

monks.

In the upper cloister, among some paintings, not above mediocrity, we may notice a few by Spagnoletto, one particularly which represents Jacob guarding his flocks, and one by Navarette, known by the name of the dumb, and whom Philip II, called the Titian of Spain.

The staircase which leads from the lower to the upper cloister, must not be passed over in silence. The four sides of the frize and the ceiling are painted in fresco by Giordano, and represent the battle of St. Quintin, the accomplishment of the vow of

Philip II, and the arrival of that monarch at the celestial court.

On the first landing-place of the staircase there are little cloisters, which lead to the library of the Escurial, less remarkable for the number of volumes it contains than for the choice of them, and more particularly the Arabic and Greek manuscripts. Art is exhausted in its decoration; and if there be a defect, it is perhaps in its being too much ornamented. Every vacant space is filled with paintings; the ceiling, which is vaulted, is ornamented with Arabesques and figures for the most part colossal. Tibaldi, the master of Michael Angelo, has here displayed the frequently exaggerating vigour of his pencil; his forced attitudes resemble contortions; his forms are so great as to become gigantic and almost monstrous; the shelves which contain the books, and which are of precious wood, beautifully carved, appear triffing by the colossal figures of Tibaldi. Above the shelves are paintings in freseo by Barthelenii Carducho, which also suffer from the cause already mentioned; the subjects are taken from sacred or profane history, or have relation to the sciences of which the shelves below present us with the elements. Thus the council of Nice is represented above the books which treat of theology; the death of Archimedes at the siege of Syracuse, indicates those which relate to mathematics, &c. The middle of the library is occupied by globes and tables; upon one of the latter is a small equestrian statue of Philip IV, upon another, a little temple of solid silver, orna-

* The engraving of this piece, published in 1782 by Selma, one of the most able artists in Spain, gives but a faint idea of the noble appearance and harmony of the characters in this magnificent painting VOL. V. 3 R

tors of Ann Neuboung, wife of Charles II.

In the intervals between the shelves are portraits of Charles V, and of the three Philips his successors to the throne of Spain. Ye philosophers, who, after having read what I have written, shall visit this library, stop before the portrait of Philip II, painted vith great exactness by Pantoja de la Cruz; contemplate his grave and austere physiognomy, and you will read an abridgment of the history of his reign; but communicate not the result of your reflections to the monks who accompany you, this would be a bad re turn for the obliging reception you will meet with. Should you bring prejudices with you to the Escurial against the Spaniards in general, or, what would be more excusable, against the monks in particular, you will certainly lay them aside, after having passed a quarter of an hour with the Jeronymites of this monastery; you will be convinced that, even under the religious habit, the Spaniard frequently conceals much complaisance and real goodness of heart. For the truth of what I here say, I may appeal to two learned Danes, who arrived at the Escurial in 1783 to satisfy their learned curiosity, and who were perfectly well received by the monks, notwithstanding the difference of their manners, language, and religion.* They were lodged in the convent, and provided with every thing they could wish with the most generous hospitality. All the treasures of the library were opened to them, and they passed two months in examining and making extracts from such manuscripts as excited their curiosity.

The obliging generosity they experienced on this occasion was the more remarkable, as the manuscripts entrusted to their inspection were then unknown to the public, except by a few extracts given of them by a Spaniard, named Cassiri, in two volumes in folio, which are far from completing the extensive plan the monk proposed to himself. After

his death, they were consigned to another of the fathers of the Escurial.

The manuscripts are not kept in the great library, which is open to all comers every morning and evening during the stay of the court, but in a large hall above, always shut up: and to which all the books proscribed by the Spanish orthodoxy are sent. The portraits of such natives of Spain as have distinguished themselves in the sciences, arts, or in literature are hung round the hall, and the number of the learned in Spain is more

considerable than out of that country is generally conceived.

In the library of the Escurial the books are placed the contrary way, so that the edges of the leaves are outwards and contain their titles written on them. I asked the reason for this custom; and was told that Arius Montanus, a learned Spaniard of the sixteenth century, whose library had served as a foundation for that of the Escurial, had all his books placed and inscribed in that manner; which no doubt appeared to him to be the most commodious method of arranging them; that he had introduced his own method into the Escurial; and, since his time, and for the sake of uniformity, it had been followed with respect to the books afterwards added. This explanation proves nothing but the oddity of one man, and an attachment, common to most men, to established customs, especially when in themselves they are almost indifferent.

In a small room adjoining the great upper cloister one is delighted with an annunciation, by Paul Veronese; a nativity, by Tintoret; a descent from the cross, and a St. Margaret, frightened by the apparition of a dragon, by Titian; but more especially one by the same master, which is called the glory of Titian, either on account of its excellence,

Mr. Moldenhauer, at present Chief Librarian at the Royal Library of Copenhagen, and Mr Tychsen, Professor of the University of Gottingen. Both have enriched German literature with the truits of their labour in the Escurial.

and Mr with the or because it represents Charles V, and Philip II, admitted to celestial glory, in presence of the principal patriorchs of the ancient law.

A small cabinet adjoining to this hall contains several relics, one of the miraculous urns at the marriage of Cana, an old manuscript of the life of St. Theresa, written by herself, &c.

Shall I yet speak of several chef d'œuvres which are seen on descending from the king's apartment to the church? of a descent from the cross, by Spagnoletto; and a large picture representing Lot and his daughters, one of the most striking in the Escurial, by the chevalier Maxime; of another much smaller, by Reubens, in which several martyre are grouped in suppliant attitudes round the throne of the Virgin.

This last piece is placed near the small saloon, and faces the door of the apartment, according to the tradition of the monastery, in which the unfortunate Don Carlos lost his life; not by order of Philip II, but by starving himself to death through despair; a circumstance, it is said, much more attributable to the violence of his untractable character than the severity of his father. It is not, however, in the Escurial that the true account of a transaction, which stamps with horror the memory of its holy founder, can reasonably be expected to be met with.

I should never finish, were I to describe all the curious paintings in the Escurial. Those who wish for a more complete nomenclature of the curiosities of the monastery, called by some the eighth wonder of the world, may consult the description, in folio, given of it by Father Kimenez, one of its monks, and the work of the abbe Pons, a lover of the fine arts who died lately, and who, in the seventeen volumes of his Travels in Spain, has consecrated one entirely to a description of the Escurial. What I have said is sufficient to inform my readers, that it is to its rich collection of pictures the Escurial owes its reputation; and that if it were despoiled of this part of its riches; if the court should not come to reside there every year, with its train, the Escurial would be nothing more than a great convent, much more striking from its mass and solidity, than the magnificence of its decorations.

It has a narrow terrace on each side, whence the eye commands, towards the cast, a very extensive but little varied prospect. The abbe de Vayrae and Colmenar particularly speak of its extensive park. For my part, I saw nothing in the environs but thinly planted woods full of rocky eminences, intersected with meadows, which are seldom green, and stocked with innumerable herds of deer, but no inclosure, no park, according to our acceptation of the word; in short, nothing presenting that appearance of grandeur and magnificence, which we naturally expect should accompany a royal mansion.

From the terrace you descend by steps cut in the side to a garden neither large nor handsome; not even carefully cultivated. At the end of the terrace, to the west, is an out-house adjoining to the grand edifice, but of a more elegant architecture. It communicates behind with a new building, parallel to the principal front of the convent, and which comprises the sleeping rooms of the Casa de los Infantes.

This building, placed immediately at the foot of the mountains, and fronting the winds which force their way through the narrow passes, contributes to check their violence. It, however, does not prevent their effects from being very perceptible, especially during the season which the court passes at the Escurial. They are the more trouble-some from their passing along the front to the north, and impetuously sweeping the oblong space which separates it from the apartments allotted to the ministers, and some of the clerks in office, and which you are obliged to cross to go from the convent to the village. If the exaggerated accounts given to strangers are to be believed, these

3 2 3

furious winds not only stop those who are walking towards them, make them stagger and sometimes throw them down, but they blow with such violence against the earriage-stationed before the palace, as sometimes to remove them from their places. I, however, have never met with any of these wonderful exhibitions in my different visits to this place, although on this walk called Lanja, leading from the convent to the village, there are frequent whirlwinds; to do away the inconvenience of which to foot passengers, a few years ago a subterraneous and vaulted gallery of hewn stone was constructed, called La Mina, which runs under the whole ceiling; sheltered by this impenetrable roof, one may brave the fury of the elements in all weathers, and disregard the winds which roar above one's head. The idea is said to have been given by M. de Massones, a grandee of Spain, who died soon after the gallery was finished, and whom we have seen ambassador in France, after having attended the congress of Aix la Chapelle, which brought him into notice. This is a mode of obtaining celebrity at easy expence.

The situation of the Escurial renders the walks in the environs painful; you may wander with pleasure, however, in a valley between the front to the south and a mountain, which opposes to it its high a 1 woody top. The inequality of the ground produces fresh prospects at every step, and favours the rapid fall of several rivulets which

meander through the copses.

A pleasing melancholy erceps over one listening to the distant murmurs of these rills, which are heightened by the rustling of the trees, often rudely treated by the north wind; to these are added the hollow bellings of the deer, which in rutting time restlessly wander under their shades. This valley slopes in a gentle descent from the Cazino of the infant Don Gabriel to that built by the present king when prince of Asturias. These two little houses are fitted up within with more eleganee than could be expected from their modest exterior. That especially called the Prince's, contains some of the richest and most highly finished sculpture, gilding, joinery, and locksmith's work that can be; Charles IV, collected there a great number of paintings, some of which with respect to their size and subject, might be better placed elsewhere than in this pleasing habitation; the heads of the apostles, for example, melancholy productions of Spagnoletto whose pencil seems to have been exclusively employed on penitentiary subjects. This palace in miniature would be far better furnished, were no other pieces left than cheerful landscapes, some of the best paintings of Madrid of a small size, and the two sea pieces by Vernet, of which Louis XVI, a few years ago made a present to the prince of Asturias, who testified a desire of possessing at least some of the productions of that grand master. These are not the only ones; Vernet painted the whole of the pannels of a cabinet, the dimensions of which were sent to him by the prince. The inimitable talent of Vernet is conspicuous in them all, and if posterity should be ignorant of their being painted in 1782, they will be thought to be the productions of his prime.

The little lodge of the infant Don Gabriel, which his brother Don Antonio now inhabits, is less than that of the prince his brother, and not so much ornamented. It had three or four of the best pieces of Spagnoletto, especially a St. Peter, remarkable for accuracy and expression, though it might be more admired in another place. But none would banish from the collection two heads, one by Corregio, the other by Murillo, both of exquisite grace and softness. The infant Don Gabriel, as much as possible in a prince, who united the knowledge of a connoisseur and the zeal of an amateur, not satisfied with encouraging the arts, cultivated them himself, and hung with drawings by

the greatest masters one of the cabinets of this lodge.

CHAPTER VIII.

THE PALACE AT MADRID. BUEN RETIRO, FICTURE OF THE THREE LAS, REMAIN, THE WALK CALLED EL PRADO. BOTANIC GARDEN. CABINET OF NATURAL RETIONS. ACADEMY OF THE FINE ARTS. THE PLAZA MAJOR.

WE will now take leave of the rocks, the mountains, and gloomy heauties of the Escurial, and conduct the reader to Madrid by one of the finest roads, it is true, but across one of the most barren countries in Europe. There is, however, as we descend from the hill on which the monastery stands, a small forest of beech, which affords an agreeable prospect. To the end of the reign of Charles III, innumerable herds of stags, which paid but little attention to the noise of carriages passing, were seen feeding among horses and oxen. Startled by a false alarm they were seen to file off, bounding before the traveller, whom they appeared to challenge to the course. The measures adopted by Charles IV, have lessened their number and increased their timi-lity. In passing through the forest between the trees several ponds are discovered, whose rural banks invite to contemplation; farther on a solitary house offers an asylum to lost wanderees. This is the farm-house of the monks of the Escurial, whom, in spite of their affability, I cannot forgive enjoying such hurtful opulence. According to a calculation, the exactness of which cannot be suspected, their annual revenues amount to upwards of seven hundred thousand livres (above 29,000L)

After having quitted this forest we meet with no more trees until we approach the Manzanares. This very small river runs at some distance from the foot of the heights upon which Madrid is situated. It is almost always shallow enough to allow carriages to ford over. There are, however, two great bridges over it, that of Segovia, and that of Toledo. The former, built by Philip II, is so disproportioned to the breadth of the Manzanares, as to have caused that remark which attention would convince an observer is greatly out of place; that fine bridge only wants a river. At the bottom it merits neither the praise nor the point of the epigram. The apparently disproportion te dimensions of many bridges beside this in Spain have a very reasonable origin. Spain is intersected in almost every direction by long chains of mountains, whose summits, notwithstanding the heat of the climate, are frequently covered with snow; the rivulets, and the rivers which descend from their sides, have usually but a small stream of water, because droughts are frequent in the provinces through which they run; but when abundant rains, or the melting of the snow increase their volume, the beds of the rivers are the more extended for their not being deep, and filling with sand; to answer which circumstance, although it seldom occurs, the dimensions of their bridges are calculated. They are solidly constructed on account of the sudden risings of the rivers, and their apparently disproportionate length is to obviate the inconvenience which might arise from an overflowing. Whole ages and nations must not be accused of ignorance and stupidity, because we cannot at first discover the reason for certain customs and practices.

Madrid makes a good appearance on entering it from the Escurial. After having passed the Manzanares, we proceed along a part of a fine road, planted with trees, which leads from the capital to Pardo, a royal mansion about two leagues from Madrid, where the court resided during the reign of Charles III, for two or three months in the year, but which his successor but seldom frequents, to shoot in the woods about this mournful chateau. The road runs for some time along the banks of the Manzanares, and on the opposite side we see an ancient country residence of the kings of Spain, the Casa del Campo, but which has been neglected by the family of Bourbon.

The gate of St. Vincent, by which we enter, is new and tolerably elegant. We after wards ascend with much difficulty to the palace, which standing alone upon an eminence, without either terrace, park, or garden, has rather the appearance of a citadel than that of a residence of one of the most powerful monarchs in the world; but as we approach, it strikes one differently. Its form is almost square, and there is a spacious court in the middle, around which are large piazzas. The apartments and offices of the principal persons of the court are upon the ground floor, which they wholly occupy. A fine marble stair-ease leads to the first story, the sides of which are righly decorated. The king's apartments are of the most magnificent dimensions. The hall, in which the throne is placed (cl salon de los reynos) may be admired even by those who have seen the gallery of Versailles. The different dresses of the Spanish monarchy are painted in fresco upon the ceiling by a Venetian named Tiepolo. Fine vases, little statues, and antique busts are distributed upon all the tables. Almost the whole of the ornaments are of Spanish production. The looking-glasses, perhaps the largest in Europe, were manufactured at St. Ildefonso, as well as the glass of the windows. The tapestry was neede in a manufactory near the gates of Madrid; and the inexhaustible and variegated quarries of the peninsula furnished marble for the tables and floors.

The apartment adjoining is that in which the king dines. Mengs, who painted the ceiling, the subject of which is the assembly of the gods and goddesses on Olympus, has displayed all that rich and brilliant colouring for which he is admired. During the summer, the portraits of Philip II, Philip III, and his queen, Philip IV, and the duke d'Olivarez, all on horseback, painted by Velasquez, and those of Philip V, and the queen Isabella Farnese, his second wife, by Charles Vanloo, are substituted for the tapestry. It is not necessary to be a comoisseur to be struck with the astonishing superiority of the first of these. The fine form of the horse of Philip IV, its spirit, and the firm posture of his body, are above all praise.

This apartment opens into that wherein the king gives audience. The ceiling, which represents the apotheosis of Hereules, is a master-piece of Mengs. His last painting, on which he was employed at Rome when the fine arts and his friends were deprived of him by death, is placed in the same apartment; it is an annunciation. The Virgin has an admirable expression of modesty and sweetness; but one laments the angel Gabriel should not have a countenance and attitude more suitable to his message. There is, moreover, in this apartment a large painting by the same master, the adoration of the shepherds, in which the men, women, and children are finished pieces, equally beautiful and full of expression. His works composed the principal decoration of the bed-cham-Ler of Charles III, who was delighted with the productions of this eminent painter. His descent from the cross, however, in the opinion of connoisseurs, celipses every thing else-The eye is never tired with contemplating the deep and tender grief of the beloved disciple; the sublime attitude of the Virgin, who in despair expects no comfort for her sorrows but in heaven; and the softer, but not more affecting affliction of the Magdalen, who preserves all her charms in the midst of the general grief; and lastly, the body of Christ, which a friend of the author, the chevalier Azara, perfectly qualified to judge of what he speaks, pronounces to be admirable, for the truth, the divine appearance, and beauty of the flesh, which, unlike other painters, Mengs has not presented torn and discoloured from long suffering.

The chamber next to that in which the throne is placed, is entirely filled with admirable paintings of the Italian school. Among more than a dozen capital pictures of Titian, is a Venus blindfolding the eyes of Love; and its companion, the subject of which is two females of exquisite beauty, with a warrior between them creet, a copy of

which is in the Musuem at Paris: Venus at her toilette; a Sisyphus; a Prometheus, and above the rest, a painting of Adam and Eve, which has for its companion the copy which Rubens made from it; but which, in the opinion of Mengs, served only to make more conspicuous the inimitable excellence of the original. Two pictures by Paul Veronese, several by Bassan, and a Judith by Tintoret, are seen with pleasure in the same chamber; and in the next apartment a few by Luca Giordano, and one by Spagnoletto.

The succeeding apartment is in like manner hung with pictures; particularly two admirable picces by Velasquez, one of which represents the forge of Vulcan, the other

a Spanish general, to whom the keys of a city are given up.

In the adjoining apartments, among a great number of paintings by the first masters, are an adoration by Rubens, and a carrying of the cross by Raphael, which alone are worth a collection. In the first Rubens has displayed all the magic of his pencil, his richness of drapery, and all the magnificence of composition. It is impossible not to be struck by the noble air and grandeur of one of the kings. His carriage, attitude, and retinue seem to announce him commissioned by the universe to congratulate its divinauthor upon an event of such importance to all mankind; but the painting of Raphael inspires sentiments more affecting, though not less sublime, The Saviour of the world sinking beneath the weight of his cross rather than that of his grief, and preserving in the midst of his persecutors, who force him along and ill-treat him, a resignation and serenity which would disarm crucity itself; appearing less concerned for his own sufferings, than carnest in endeavouring to console his afflicted mother, who strives to soften his persecutors, and the supplicating women who are overcome with grief for his fate. The impression which results from these two great compositions, renders the mind almost insensible to the beauties of the other paintings of Titian, Vandyck, Raphael himself, and even of little master-pieces of Corregio.

There are paintings of a different kind in the late apartments of the infanta,* Maria Josephine, sister to the king; this is the profane side of the palace of Madrid. In the first chamber is one by Giordano, in imitation of Rubens, it represents the painter himself working at the portrait of a princess; there are also several voluptuous paintings by this master of the Flemish school; a combat of gladiators, in which the vigour of Lanfrane's pencil is easily discovered; and a capital piece by Poussin, the subject of which forms a singular contrast to the devotional paintings of which we have already spoken. This is a dance formed by a troop of nymphs about the statue of the god of gardens; the variety of their expressive and graceful attitudes, their easy shape, and the beauty of their form, all breathe the pleasures of youth and love; some crown with garlands the statue of the lascivious god, others—but we will draw a veil over this part of the painting, which

the modesty of the painter has purposely placed in the shade.

The adjoining apartments are filled with paintings of less merit, if we except a grand

composition by Paul Veronese, and a piece by Lanfranc.

The dining-room of the infanta is highly embellished by the indefatigable peneil of Luca Giordano, whose fertile imagination astonishes at first, but ends with fatiguing. In a cabinet adjoining to the dining-room are also some pieces by Rubens, and one of the best portraits of Titian; that of Charles V, of natural size to the knees. An engraving was lately made from it by a young man of Madrid, named Selma, who promises to become an excellent artist.

I could yet mention many other paintings contained in the apartments lately occupied by the two infants, brothers to the king, particularly some by Rubens, in which his

^{*} This infanta died in 1801; the simplicity of her manners and her benevolence have made her universally regretted.

heches of colour, and his liveliness of fancy shine in their highest splendour; but I desich lest I should fatigue my readers by a barren catalogue: I have already said enough to satisfy them that the collection of the king of Spain is one of the most valuable in Europe. It is true there are but few paintings of the French school, but the best productions of those of Italy, Flanders, and Spain are found in abundance; those of the latter especially, less known than they deserve to be, are worthy of all the attention of some issents; the names of Navarrette, Alengo, Cano, Lurbaran, Zerezo, Cabezalero, Blas de Prado, Joanes, &c. who among their countrymen enjoy a well carned reputation on many accounts, are searcely known out of Spain. It is even only by hearsay that names much better known enjoy any reputation in France; such as Rivera, called there Espagmolet, who although a Spaniard born, belongs rather to Italy than Spain; Velasquen, remarkable for his correctness of design and perspective; and Murillo, one of the first painters in the world for the freshness and vivid colouring of his flesh, and his softness of expression; Murillo, whose productions for a long time sought after in France, at length occupy a place in the museum.

The chapel of the palace contains nothing remarkable of this kind, but its architec

tural proportions are exact and beautiful.

The palace of Madrid is entirely new. That which Philip V, inhabited having been burned, the monarch wished to have it re-built upon the same foundation. An architect from Piedmont laid before him a most magnificent plan, the model of which is preserved in a neighbouring building. Philip V, was deterred by the expence from carrying the plan into execution, and adopted one more simple, which, notwithstanding it already costs as much as that of the Italian architect would have done, is not yet finished. Two wings have been building to it for these twelve years past, which will give to the

whole a less heavy appearance, but must hide the principal front.

One approaches towards this front through a large irregular square, at the extremity of which is the armoria or arsenal, which contains a curious collection of ancient and foreign arms, arranged with great order and carefully preserved. The most remarkable things here are neither eimeters set with diamonds, nor complete sets of armour of different kings of Spain, not even that of St. Ferdinand: but those of the ancient American warriors. A long enumeration of all these curiosities is carefully made to the traveller. when he is admitted into the arsenal, and although he were a Frenchman, the sword worn by Francis I, at the battle at Pavia would not be forgotten. The kings of the Austrian dynasty only inhabited the palace occasionally, which looked on the Manzanares, and which stood on the site of the new palace. They resided during a part of the year at a sort of country house, situated on an entinence at the opposite extremity of the town, called by them Buen Retiro. Philip V, was highly partial to it, and made it his sole residence while at Madrid after the destruction of the ancient palace by fire. Ferdinand VI, had no other, and Charles III, passed the first years of his reign in it, greatly against the inclination of his queen Amelia of Saxony, who was continually drawing vexatious comparisons between the magnificent horizon about Naples, which she had just left, and the naked and confined prospect of this residence. No royal abode had ever less the appearance of a palace than Buen Retiro; it is a deformed collection of symmetrical parts entirely devoid of any thing striking. It nevertheless contains a long suite of rooms, which might at a trifling expense be made inhabitable. The gardens, which they front, are without water, much neglected, and are now used as a public walk. There are a few statues worthy of the attention of the curious; that of Charles V, trampling upon

ere are a

ng upon

a monster, which is supposed to be the emblem of heresy; and an equestrian statute of Philip IV, by an able sculptor of Florence. The palace of Retiro contained also many valuable pictures; but the greatest part of them have been removed to the new palace. The sumptions apartment called the Cason is remarkable for its ceiling, painted by Giordano. It is an allegorical representation of the institution of the order of the golden fleece.

I shall mention only two other paintings in this palace. One of Philip V, in years, seated by the side of his wife Isabella of Farnese, and surrounded by all his family Charles Vanloo has perhaps displayed too much magnificence in the decoration of the hall; the figures he has painted have in consequence a paleness from the surplus of brilliancy in the furniture; nevertheless one cannot behold without interest an assemblage of so many persons who have filled eminent parts on the theatre of the world.

The other picture is less remarkable from the merit of its composition than from the scene it presents. This is a faithful representation of the last solenn Auto da fe, which was celebrated in 1680, in the Plaza-Mayor of Madrid, in presence of the whole court of Charles II. The balconics appear full of spectators, excited equally by devotion and curiosity. The fatal tribunal is raised in the middle of the square. The judges there wait for their pale and disfigured victims, who, covered with melancholy emblems of the torments prepared for them, are about to hear their sentence. Some receive the last exhortation of the monks, others stagger and faint upon the steps of the tribunal. How many reflections naturally rush on the mind of the spectator; but let us turn our effection from these afflicting objects.

The theatre of Buen Retiro is still in good preservation: the house is small but well contrived. The stage, which is spacious, opens at the bottom into the gardens of the palace, with which it is on a level; this is favourable to theatrical magic, when it is required to extend the perspective and permit the display of bodies of troops or a train of cavalry. All these illusions are vanished; the theatre is described, its decorations are covered with dust; and this theatre which in the reign of Ferdinaud VI, resounded with the most harmonious voices, is now condemned to mournful silence, which has

been but twice interrupted for these seven-and-thirty years.

Thus do courts change their appearance according to the taste of the sovereign. The brilliant taste of Ferdinand VI, naturalised in Spain the fairy seems of the Italian theatre under the direction of Farinelli the musician, whose talents acquired him a distinguished favour, at which no person murmured, because he modestly enjoyed without abusing his good fortune. Under Charles III, Euterpe and Terpsiehore lost their influence: this monarch, more simple in his manners, more uniform in his taste, and inscusible to profane pleasures, banished them from his residence, and confined himself to the protection of the silent arts, the sciences, and virtue. A stranger to the tender passion; and although benignant, yet almost entirely insensible to friendship, during his whole reign of thirty years continuance, if the marquis Sqillaci be excepted, who was near being fatal to him, and an Italian valet de chambre (Pini) who yet never enjoyed but an obscure and subaltern degree of esteem, he had not one favourite; and protected from the seduction of the senses by his religious disposition, he passed twenty-nine years of his life (rare example among sovereigns!) without either wife or mistress. In order to be admitted to the presence, the libertine was obliged to follow his pleasures in scereey; so that never was there a court where less gallantry was displayed than at that of Charles III.

At that of Charles IV, tess austere than his father, although pleasure be not expelled, it is yet entertained without parade; and if favour prevail, it is excusable, since it is nobly dispensed, exercised with benignity, and makes as few enemies as possible. This

vol. v. 3

court has a superiority over that of the preceding, by its confiding its principal trusts to the hands of Spaniards; even the queen, although an Italian, has identified herself with the nation for a long time past; whereas in the three latter reigns strangers for the greater part filled all the offices of trust. This circumstance is of itself sufficient to hinder the explosion which other matters are calculated to promote. Finally, to complete the parallel of the four reigns of the house of Bourbon in Spain (for I shall say nothing of that of Louis I, which did not last a year) we shall observe, that they present the rare display of an uninterrupted succession of four kings, if not great, or illustrious for brilliant qualities, yet virtuous, humane, and sincerely pious; who may possibly have erred in their intentions of doing good, yet who never did intentionally wrong.

In the gardens of Buen Retiro the monarch has established a china manufactory, which strangers have not hitherto been permitted to examine. It is undoubtedly in tended that experiments shall be secretly made, and the manufacture brought to some perfection, before it be exposed to the eyes of the curious. Its productions are to be seen no where except in the palace of the sovereign, or in some Italian courts, to which they have been sent as presents. Charles III, rendered their due homage to our manufactures when he excepted the court of Versailles from his distribution, notwithstanding the latter regularly forwarded some of the finest works of our seive manufactory to the princess of the Asturias. Louis XV, established this custom, on account of his grand-daughter, and his successor did not discontinue the practice.

Certain kinds of inlaid work which are not yet much known in Europe are wrought in the same edifice. Generally speaking, the Retiro, its apartments, and its gardens, are nearly abandoned by the court; in recompense, however, Charles III, has richly

This ancient palace commands a public walk, which has long been famous in Spanish comedy and romance, El Prado. Its contiguity to the palace, its shades, the unevenness of the ground, every thing was favourable to intrigue, but every thing as well increased the danger; Charles III, by levelling it, by planting it with trees, and lighting its avenues by providing for its being watered, and adorning it with fountains, some of which, that of Cybele, for example, is very handsome, made a superb promenade of it, and such as may be frequented at all times with pleasure and in safety. It forms a part of the interior inclosure of the city, and is in length about the space of half a league. Several of the principal streets terminate here. That of Alcala, the widest in Europe, crosses it, runs by the side of the gardens of the Retiro, and terminates at the gate of the same name, which, although somewhat heavy, is one of the finest pieces of architecture in the capital.

The inhabitants from all quarters resort thither on foot or in carriages to meet and breathe beneath the shade of the long alleys, an air freshened by waters spouted from the fountains, and embalmed by exhalations from the fragrant flowers. The concourse of people is frequently prodigious. I have sometimes seen four or five hundred carriages filing off in the greatest order, amid an innumerable crowd of people on foot; a spectacle which at once is a proof of great opulence and population. But a better taste were desirable in the carriages, and a greater variety for the eye. Instead of that mottey appearance of dresses, which in other public places of Europe afford a change, without which there would be no pleasure, thare is nothing seen in the Prado on foot but women uniformly dressed, covered with great black or white veils, which conceal a part of their features; and men enveloped in their large mantles, for the most part of a dark colour; so that with all its beauty, at the best it is but a theatre of Castilian gravity; this is the more apparent, where every evening at the first stroke of the angelus all those

who are on the walk, suddenly stop as if struck with palsy, pull off their hats, leave off in midst of the most interesting and tender conversation, and call home their thoughts a few minutes for devout contemplation. Woe to the wretch who should dare to disturb this silence of devotion, which the impious may ridicule, but which nevertheless possesses somewhat affecting, somewhat imposing event of the philosophical observer. The prayers of the angelus ended, the promenade is continued, and discourse is resumed. A whole unanimous people concludes, beneath the vault of heaven, its homage to the Creator. Of what consequence that it be through the intervention of the Virgin Mary, it is not therefore less pure, nor yields the mind a less sweet consolation.

The botanical garden adds not a little to the embellishment of the Prado; it was formerly upon the road which leads from Madrid to the eastle of Prado; but Charles III, a few years before his death removed it to the side of the Prado with a low inclosure, by which it is ornamented without being concealed; it is daily increasing in beauty. The botanist attached to the science, who readily obtains allowance to view the garden may entertain himself here delightfully for hours in the undst of trees and plants from all the four quarters of the world. The productions of the vegetable kingdom are ranged in squares according to the system of Linneus, and the names of the plants are inscribed on tickets inclosed in little tubes of tin stuck in the ground at the foot of each plant; a very commodious and useful means of reference to the beginner. The monarch of Spain it will be easily conceived must have within his power the means of collecting, particularly from the vegetable reign, the most precious collection: in whose vast states gave rise to this line of Piron,

"The orb of day shines ever more on Spain."

In so great a diversity of climates and soil, this immense monarchy must produce every tree, shrub, and plant which grows on the bosom of the earth. It is only with in five-and-twenty years that the advantage which these possessions hold out has been put to profit. Galvez, upon his accession to the administration of the Indies, ordered all the officers in the civil employment in the colonies, the military, and the clergy to trans port to Spain whatsoever belonging to the three kingdoms should be deemed worthy of attention. Not a year passes without producing the metropolis either some new plants from Spanish America or seed bulbs or slips which are reared in the botanic garden of Ma-The young botanists employed by the court in Mexico, Peru, and other parts, accompany their exports with a description of the plants, which they make upon the spot of their growth; the soil that suits them, the kind of exposure which is most favourable to them, and the care which they require. Following these instructions the botanical professors and above all Don Casimir Ortega entrust the diminutive seed to its nurse; and surrounded by their young care contemplate with delicious anxiety the different stages of their growth as they trace the features by which they have been described. More than once have I attended their sittings, as instructive as they are amusing, in which nature is seen to prove here subjection to regular laws, and her disposition to make common to all mankind the advantages and pleasures with which she has overspread the earth, at intervals which stagger the imagination. Oftentimes at these meetings questions occur which are difficult of solution. Many a foreign plant demonstrates the insufficiency of the classes invented by our learned men in Europe, and sometimes it is impossible to give a plant its place without assigning it an arbitrary one.

What has been attempted with success in plants, I have frequently pleased myself with the fancy of having extended to the three kingdoms at one scope, by allotting all the

3 6 9

herself herself hers for hient to be comhall say ey preprillus ay pos-

wrong factory, dly in some re to be o which anufactanding ctory to at of his

Spanish evenness acreased; its aveof which, f it, and a part of ue. SeEurope, e gate of architec-

meet and ted from oncourse dred carn foot; a etter taste that motge, withfoot but ceal a part of a dark gravity; all those

space which the botanical garden leaves vacant by the side of the walk to a destination certainly extraordinary in Europe, and which the monarch of Spain only could be capable of carrying into effect. I would have it divided into as many parts as this sovereign has principal colonies under his dominion; in these should be settled a family of Peruvians, another of Mexicans, another from Calefornia, another from Paraguay, from Cuba, from the Canaries, the Philippines, &c. All of them should preserve their peculiar dress and manner of living, each should have built a simple habitation upon the model of that they had quitted; and cultivate the trees and plants bro ght from their own country; so that surrounded by these pleasing illusions with greater reason than the young Polanore of Bourganville they might still suppose themselves in their native soil. With what delight would the curious of Europe flock in crowds to behold this living cabinet of natural history; this cabinet unique in itself, in which the objects of his attention would themselves be the Cicerone of the traveller. Here the Mexican would be seen beneath the shade of his fig-tree, shaking it and gathering the precious miscets which colour our European garments; there the inhabitant of Guatimala would cultivate his indigo; and he of Paraguay the herb which constitutes his principal riches; the Peruvian, accompanied by the docile animal which partakes of his labours, feeds and clothes him, would in concert with the Luconian endeavour to introduce the same cultivation they had been accustomed to at home. Thus the exulting inhabitant of the metropolis, without going from the capital, might pass in review, as if delineated on a map, all the colonies to which his sovereign gives laws. The imported colonist would become accustomed to an exile, which every thing would concur to render agreeable; and his fellow citizens, separated from him by immense seas, informed by him of the benevolence and magnificence of their common monarch, would form a higher idea of his power, pride themselves upon being his subjects, become more attached to his government, and accustom themselves to see in the Spaniards of the old world, their countrymen instead of their oppressors; gently and pacifically effecting a revolution which might prevent or at least retard the misfortune and danger of a sudden separation.

Such a project may be considered as romantic, yet the king of Spain has entered upon one of the same kind, which proves his zeal for the advancement of the arts and sciences. In the street of Alcala is a large belilding in which the king has established a cabinet of natural history, and which alread contains one of the completest collections in Europe in metals, minerals, marble, precious stones, corals, madrepores, and marine plants. The classes of fishes, or birds and especially of quadrupeds, are yet very incomplete; but the measures taken by government will in a little time make them

as complete as possible.

The minister in 1782 received an ample contribution from Peru: this was half the rich collection made during an eight year's residence in that country by Mr. Dombey, an able naturalist, whom the court of France, with the consent of that of Spain, had sent thither, and who brought back with him the fruits of his labour to Cadiz. On his arrival at this port he did not meet with that generous demeanour which is the boast of Spain. Malevolence, jealous of his mission, excited a persecution against him which injured his health, already impaired, and seemed for a short time to have even influenced his reason. He was as it were a prisoner at Cadiz till he gave up to the commissaries of government the moiety of his collection, which he had conceived was exclusively intended for his country. Fortunately these commissaries had less intelligence than ill will and in the division which they made in the presence of Dombey, the lot which they fixed upon was not the most valuable of the two. He hastened, shortly after his depar-

ture, from a country which had treated him so inhospitably, and carried with him to France what he had been able to save from the rapacity of this invidious people. He confided to one of our first naturalists, his friend Mr. L'Horitior, the care of classing the rich remains of the collection, and making them known to the public. The health of Dombey never recovered from the shock it received, either in Peru, or at Cadiz; he died some years ago in the flower of youth, exciting the regret of all the learned, and the tears of friendship.* He left several Spanish naturalists at Peru, whose learned researches will greatly contribute to enrich the cabinet of natural history at Madrid.

The same edifice that contains this cabinet, and which with the custom-house, built also by Charles III, constitutes the principal ornament of the street of Alcala, is the place of meeting for the academy of the fine arts (las nobles artes;) a circumstance which

produced the inscription on the building, a motto equally happy and just :

Carolus III, naturam et artem sub uno tecto in publicam utilitatem consociavit. Anno 1774

The honour of instituting this academy is, however due to Philip V, but Ferdinand VI, being particularly devoted to it gave it the name of his patron San Fernando; and Charles III, by providing a comfortable residence has made it much indebted to him. The minister for foreign affairs is president, and every three years distributes premiums to the young students who have produced the best pieces in sculpture or painting, and the best designs in architecture. But though there are several members who have distinguished themselves in these three arts, it must be confessed that their works of real excellence are yet but very few in number, and that the prizes given are rather to be looked upon as encouragements than merited rewards. The Spanish court, however, maintains at Rome some young students, who give the most flattering hopes; and some of the members of the academy are employed by it on engravings of a part of the nume.

rous master-pieces which embellish the different palaces.

It is not only by forming artists that the academy contributes to the progress of the arts in Spain, it is also the supreme tribunal, to whose decision the plans of all the sacred and profanc edifices creeted in the kingdom are to be submitted; an institution which, in the end, must establish a good taste upon the ruins of that barbarity which is but too visible in most of the edifices of former times, and of which traces still remain in some of the gates, in the ancient fountains, and in most of the churches in the capital; deformed efforts of art, then in its infancy, which has taken more pains to bring forth monstrous productions, than would be necessary at present to produce works of transcendent merit. Modern edifices already prove the revolution that has taken place under the house of Bourbon. Besides the new palace of Madrid, we may instance the gates of Alcala and St. Vicente, the custom house, and the post office: and particularly a superb building by the side of the Prado beyond the gardens of Buen Retiro began less than ten years ago. It is designed for a museum to which the cabinet of natural history is to be transported, and there several academics are to hold their sittings. The war interrupted the progress of the work for a time but on the return of peace it was resumed. This fine monument of architecture will be the most superb of any in

^{*}The two Spanish botanists who accompanied Dombey, Don Hypolito Chens, and Don Joseph Pavon, published a work in 1794 under the title of Floræ Peruviensis et Chilensis Prodromus, in which they gave an account of the state of botany in Spain. Four years after their Systema vegetabilium Floræ Peruvianæ et Chilensis appeared; and in 1799 their large work in two volumes folio Flora Peruvianæ et Chilensis which has excited the curiosity of the learned throughout Europe.

the capital, and will add no small portion of fame to the reputation of the architect, Vil-

lanueva.

At Madrid, however, there are few handsome buildings, it is in general well laid out: the streets, although not in a direct line, are for the most part wide, and tolerably straight, it is three leagues and a half in circumference and about three quarters of a league broad at its widest part. The infrequency of rain, and the vigilance of the modern police, make it one of the cleanest cities in Europe. But except the Prado and its avenues, the city has no elegance to boast. The famous Plaza Mayor, which the Spaniards take so much pleasure in extolling, has nothing in it which justifies their partiality; it is quadrangular, but at the same time irregular, surrounded by buildings of five and six stories, sufficiently uniform, but without ornament, under which are long areades. It is illuminated on public occasions, and then it really has an agreeable appearance. The auto da fes were formerly celebrated in this square, with all their terrible apparatus. It is still the theatre of those bull-fights which are called at the royal feasts filstar reales. The hotel de ville, or town-house, is in this square, in which the historical academics holds its assemblies, and in which is its library, its muscum, its manuscripts, and its medals. Here also is the market for eatables and merchandise of every description. This concurrence of circumstances has made it the most remarkable publie place in the capital, and has given it a reputation which, at the time it was first built, was perhaps deserved, but which must have vanished since architecture has improved in Europe, and produced forty squares preferable to the Plaza Mayor.

It was much disfigured by the fire which reduced to ashes seven years ago almost the whole of one of its sides. What tends to take off from its appearance, is a number of stalls which prevent one from crossing in every direction. It is nevertheless that quarter which gives the most favourable idea of the population of Madrid; and if we judge of it by the concourse of people upon it at all times of the day, and in the adjacent streets as far as, and including La Puerta del Sol, a street which is the resort of the newsmongers, one shall be led to imagine there must be a mistake in the enumeration of its inhabitants, taken at no more than 155,672 of residentiaries according to the census of 1787. According to Thomas Lapez, who wrote in 1797, Madrid contains 7100 houses, 77 churches, 44 convents of friars, 31 of nuns, and 130,980 inhabitants, exclusive of the garrison, the hospital and the foundlings, the addition of which three classes of inhabitants will raise the population to nearly the amount of the census taken in 1787. Government has published a new census of Spain made in 1797, and which the official gazette announces as more exact than that of 1787 taken under the direction of countrollar Blanca, with the principal results of which I shall present the reader.*

CHAPTER IX.

POPULATION OF SPAIN. PRINCIPAL CHURCHES OF MADRID. PAINTLES, ENGRAVERS. THE PRESS. RELIGIOUS FOUNDATIONS.

IN 1768 the Spanish government made a census of the people, which it had reason to look upon as defective; in the first place, on account of the want of care in taking it, but principally because it was imagined that it had for object the imposition of a new

^{*} I am hitherto ignorant of the result of the census of 1797. The population of Spain will however hereafter be known as well as that of any other country of Europe. The rectors of parishes having been instructed to forward to government a monthly list of the deaths, births, and marriages within their different parishes, beginning with the present century.

tax on houses, which engaged a many to deceive the commissioners by false declarations; this first enumeration, therefore, produced for amount no more than 9,159,999 persons, whereas that of 1787, made with more rigour on the one part, and given with less apprehension on the other, gave a total of 10,268,150, the difference is an increase of

1,108,151.

The severity of government brought to light still greater deceptions. In 1787 there were found to be fewer than there were in 1768:

ere found to be fewer than t	there were in	1700 :		11,044
Of nuns and friars	belonging to	the clergy	1.00	17,213

270,989 tradesmen and artisans, 280,092 servants, 50,994 students, 39,750 manufacturers.

The population of the different provinces was at the same time ascertained, and what was only suspected before became apparent; that is, that the resources which the neighbourhood of the sea affords, added to the quality of the food, which it produces, where the soil is fruitful, are sufficient in themselves to counterbalance the evils of a bad administration; since Galicia, the clergy in which possess more than half the lands, notwithstanding it be destitute of canals and navigable rivers, and possess scarce any roads; notwithstanding its whole reliance be on its manufactories of linen, its trade, and its fishery; yet blest with a soil capable of receiving every species of culture, situated so as to have the sea on its two sides, and free from that devastating scourge the Mesta, Galicia is beyond comparison the best populated province in Spain, although it be far from having an equal extent with others. In 1787 it contained 1,345,893 inhabitants, while Catalonia, far more industrious, and of nearly double the surface, comprised but 814,412, Arragon but 623,308, and Estremadura, one fourth part larger than Galicia, no more than 417,000 persons.

To return to Madrid; as to its population, it has ordinarily from 6 to 10,000 men in garrison, is the rendezvous for petitioners from all parts of Spain and the Indies, as well as of a great number of strangers; hence it may not be considered an exaggeration to compute its inhabitants at 180,000.

Its sacred edifices have nothing in them very remarkable, although the abbe Pons has devoted a volume to the description of them; several, however, contain highly valuable collections of pictures, which may be seen with admiration even after the paintings of the Escurial, and the new palace. The small church of St. Pasqual, upon the Prado, within its narrow and dirty walls contains two Titian's, several paintings by Spagnoletto, one of the best of Bassano, two by Guerchin, &c. The church of St. Isabella has also some master-pieces of Spagnoletto, particularly the assumption of the chief altar, a capital piece which has been engraved; but no church at Madrid has a larger or better collection than that of the barefoot Carmelites, in the street of Alcala. How frequently have I been to the large vestry of these monks, who are the most opulent in Madrid, to reekon, admire, and envy treasures so ill appreciated, and so badly placed; numerous paintings of Spaniards, so little but so much deserving of being known, such as Zurbaran, Zerizo, &c. others by Spagnoletto, Murillo, Giordano; Charles V, haranguing his army, by Titian; a Lord's supper, by Vandyck; many by Rembrandt, particularly a Tobit, scated and pensive, in which the only light of the piece proceeds from a dull fire to which he is turned. Excepting on account of their paintings, these three churches possess little claim to notice. Bad taste reigns throughout them, as is the case in almost all ti-religious edifices of Madrid. The church of St. Isidoro alone, which heretofore belaged to the Jesuits, has a portal which is handsome, although not exempt from Its interior is not destitute of beauty, and, among other paintings rather common, it contains a large one by Mensy, and an adoration by Titian.

There is another church much more modern, which, on account of its mass, has a venerable appearance, and has some valuable paintings: it is that of St. Salesas, or the visitation, founded by Ferdinand VI, and the queen Barbara his wife. The ashes of this royal pair repose here, under two pompous mausoleums. On that of the king, an inscription in Latin, which appeared to me a model of the lapidary style; the Spaniards

themselves have expressed their disapprobation of the whole edifice by these words. Barbara reyna, barbaro gusto; barbara obra; a play upon words which has effect but in the Spanish language, in which the expression barbara is equally applied to the name of the foundress, to the bad taste of the edifice, and to the enormous sum it cost in building. It has, however, one landable appendage, a certain number of young ladies are there educated at the king's expence; it forms a part of the seminary for the nobility, a kind of military school which has been for some time back under the direction of Don Jorge Juan.

And fastly the convent of St. Francis has been some years building at an immense ex pence, and there were hopes that it would become one of the finest productions of architecture in the capital. It is lately finished, and is rather a solid than an elegant edi fice. The church, in the form of a rotunda, ornamented with pillars, is yet a striking object at first sight: the best masters in Spain were employed on paintings for its altars, for the most part the pupils of Mengs; M. Maella and M. Bayeux, otherwise called El Arragones, for example, who, by their taste and colouring, in some manner recompense the Spaniards for the loss of that great painter. The other co-operators were Don Antonio Velasquez, Don Andres de la Calleja, Don Joseph Castillio, Don Gregorio Ferro, who excels in copying the best paintings of the most esteemed artists; Don Francisco de Govemerits also by his talents an honourable mention; he pourtrays in a pleasing style the manners, customs, and games of his country; neither must Carnicero be omitted in the list, a copyist in miniature, possessed of much taste, and who faithfully imitates the masterpieces with which the king furnishes his smaller apartments. Nor need the genius of design disdain the names of Don Ventura Rodriguez, de Villenueva, d'Arnul, a Frenchman by birth, and Don Francisco Sabattini, † an Italian, director of the king's buildings; all of them eminent as architects.

In the art of engraving, they have several who excel; Don Salvador Carmona, married to the daughter of Mengs, who has in part inherited the fine pencil of her father, is deservedly to be placed at their head. Mr. Carmona is advantageously known in France by several prizes gained in the academy of painting. Were we to criticise with acumen, it might be observed, that his talents too little, or at least too late encouraged, have not produced altogether what they at first promised. Several other engravers, Messicurs Ferro, Muntaner, Fabregat, Ballester, and especially M. Selma, have, by happy efforts, proved that their art still makes some progress in Spain.

The academy of the Spanish language, which in the year 1780 gave an elegant edition of Don Quixote, in four volumes, quarto, enriched it with the embellishments of the engraver. But the engravings, for the most part not above mediocrity, do not answer to the merit of the edition, equally admirable for the quality of the ink, the beauty of the paper, the clearness of the character, and deservedly ranked with the finest productions of this kind in any other nation. It is of itself sufficient to give celebrity to the press of Ibarra; it is truly a national work, by which the Spaniards have refuted the charge of the arts with them being yet in their infancy. The ink is a composition made by Ibarra himself, to whom our printers have frequently applied in vain for the secret; the characters were cut by a Catalan, the paper was manufactured in Catalonia, the learned preface and the analysis of Don Quixote, placed at the beginning of the work, are written by a

^{*} Goye excels also in portrait painting, as well as Aciene and Estore. In historical painting Don Francisco Rumis justifies the hopes formed of him by the paintings which five-and-twenty years ago he sent from Rome to the academy of the fine arts at Madrid.

[†] He, at the same time, was chief of the Corps de Genie; he died lately, and has been succeeded in this latter appointment by Don Joseph de Urrutia, the general who last commanded the army in Catalonia, vol. v.

member of the academy of the Castilian language, Don Joseph de Guevaru; the binding even, although inferior to the rest, sufficiently demonstrates that the Spaniards are by no

means behindhand in any thing which relates to typography.

This is not the only proof they have given of their ability. Every connoisseur is acquainted with, prefers to the editions of Baskerville and Barbou, and reckons equal to the works of Didot, the Sallust, which the Infant Don Gabriel has translated into his own language; and some other works from the presses of Ibarra at Madrid, and from those of Benediet Montfort at Valencia, such as Mariana, Solis, Garcilaso, the poem on music, El Parnasso Espagnol, by Sedano; and, above all, the master-piece of Benediet Montfort, that learned work of Bayer, the preceptor of the Infant Don Gabriel; entitled De Numis Hebræo Samaritanis, 2 volumes, in folio.

Latterly the Spanish artists have been employed in multiplying, by the means of the graver, the portraits of a score of illustrious persons, kings, generals, famous writers, &c. and many grandees of Spain, who have galleries of paintings which were lost to

the world, and to the arts, have had engravings taken from them.

But if the pleasing arts be cultivated at Madrid, the most useful of all, that of beneficence is not neglected. Charitable foundations, worthy models for every nation, are found in that city; among those two brotherhoods whole funds are consecrated to the relief of misery; a public pawn shop, at which money is lent to the necessitous, and which in the period between 1724 and 1794 (72 years) had advanced 111 millions of rials; a receptacle for orphans, and, above all, three hospitals which annually receive from nineteen to twenty thousand patients.* The principal hospital near to, but on the outside of the Atocha gate has been lately rebuilt. It is a large edifice, which by no means disgraces the walk leading from this gate to the canal of Aranjuez, and which the Spaniards have estimated rather too highly in honouring with the name of Las Delicias.

CHAPTER X.

OTHER ACADEMIES. FATE G. THE NEW UNCYCLOPEDIA IN SPAIN. APOLOGY AND LITERARY TITLE OF THE SPANIARDS.

THE academy of the fine arts is not by many the only one that Madrid contains. It may even be said, if the number of literary institutions were the measure of progress in sciences, this capital ought to be considered one of the most enlightened and learned in Europe. There is an academy of physic; an economical society of the friends of their country, to which is annexed a (Junta de Signoras) a junto of ladies impressed with desire of signalizing their affection towards the public good, and some other insignificant juntos, as little worthy of notice for their titles, as for the advantage derived from them, and whose existence serve only to show, that a patriotic zeal has infused itself latterly into the minds of people of all classes; one of Spanish and general law; one of theoretical and practical jurisprudence; one of the canons of the church; one of civil, canonical, and patriotic law; the Latin academy of Madrid, &c. &c. But the only ones deserving of particular mention are, 1. The academy of the Spanish language, founded by Philip V, and which the French academy has constantly looked upon as its sister. On the appearance of the very first edition of its dictionary, it was allowed by the most eminent grammarians to be the completest work of the kind which ever appeared in any

^{*} The general hospital, which is for men, in the course of the year 1801, admitted 14,254 persons. The hospital De la Passion (for women) 5,297; and that of Sant Juan de Dios, for both sexes, 3,271; total 22,809 persons.

language. The academy has instructed its librarian, the abbot Marillo, to condense it into a single volume for common use.

This academy is composed of twenty-four ordinary members, but the number of supernumeraries is not limited; the president is a grandee of Spain. The present is the marquis de Santa Cruz, the governor is the prince of Asturias. But few examples, however, tend to shew that it considers itself honoured by the admission of nobility. The Spaniards do not require a revolution to teach them that high birth should not be a substitute for personal merit. As well as other nations, Spain has its unqualified per sons, perhaps in greater number, but such are kept in their due stations, that is to say, are unregarded. 2. The academy of history was founded and endowed by Philip V, in 1738, its first president was don Augustin Montiano, a distinguished literary character but little known out of Spain; its present director is the count de Campomanes,* who, by the rank he holds in the magistracy, as well as by his great crudition and virtues, is one of the most distinguished noblemen of modern Spain. He was ever one of the most attentive members of this academy, even at times when his various occupations left him the least leisure for application.

The Spaniards have always been greatly partial to the study of their own history; it searcely contains a city which does not possess its individual history or a chronicle. Of late they have reprinted their best historians, and within these twenty years have published editions of several authors; among others, for the first time, several works of Sepulveda, particularly that entitled De rebus gestis Caroli V. It has for these five andtwenty years been employed on a task equally interesting and arduous, that of publishing all the ancient chronicles relative to the history of Castile. Several of these works had never been printed; all are enriched with notes and commentaries, which at once prove the sound criticism and the crudition of their authors, the chief of which are Don Francisco de Cerda, Don Miquel Florez, Don Eugenio de Laguno, and several other members of the academy of history.

The academy contains one of the most valuable collections of which a literary society can boast. This is all the diplomas, charters, and other documents given, since the earliest period of the monarchy, to every city, borough, community, church, chapel, &c. in Spain; the whole collected with the greatest care, arranged in chronological order, and consequently adapted to furnish every branch of the Spanish history with the most abundant source of authentic materials. It is in this immense repertory that the academicians have collected the elements of a work which is recently published, and which has already run through several editions, a Geographical Dictionary of Spain; it has had some considerable additions made to it, the last volume of which appeared in June 1796. Others, among which are the librarians themselves, have undertaken to give to the public a catalogue of the Greek manuscripts in the library of Madrid. One of the most learned among them, Don Juan Iriarte, died in 1776, leaving behind him three nephews of distinguished abilities; one of them, Don Thomas, died a few years ago a great literary character; a second, Don Domingo, after signing the peace of Basle, went ambassador to France, where he died much regretted, as well by his country as by the friends he had acquired among the French; the eldest, Don Bernardo, is still living, and divides his time between the arts and his duties in administration.

^{*} He has for some years back resigned all such situations as require application, and, a member of the council of state, peaceably enjoys the esteem which he has so well merited; his country, to which he was an honour, as well on account of his virtue, as his talent, was for a long time much indebted to him; so that he became justly entitled to spend in quiet the remainder of a life so well employed.

To Father Florez, a monk, Spain is also indebted for several volumes of ecclesiastical history, which in his hands was, in truth, only an irregular compilation, but it has acquired a more pleasing form under the management of his continuator, Father Risco.

Several other writers, well acquainted with what relates to their country, are employed in giving a clear history of it, and instructing their fellow citizens in matters of policy, and the science of government. They have naturalized in their language such French and English works as the Spanish orthodoxy would permit; not only those, for instance, which treat of trades and arts, but also works of literature and philosophy. It is twenty years since they began the translation of the works of Linnaus, and the natural history of M. de Buffon. At present their literary characters are more than ever given to translations, but show a deficiency of judgment in the choice of their subjects. While they select Clarissa Harlowe, they adopt at the same time our most insipid romances; they place beside the Philosophical Essays of Maupertuis, the works of Bernardin de St. Pierre and Condillac, our most insipid books on asceties. They have even attempted to make the Spaniards acquainted with the Philosophical History of the abbot Reynal; a work which gave rise to so much indignation in the Spanish government, that I have more than once been witness to the minister for the Indies, Galvez, entering into a paroxysm of rage at the bare mention of the author; looking upon such as attempted to introduce in a contraband manner the copies of this work into the Spanish settlements in America as guilty of treason. The duke d'Almodovar,* one of the grandees of Spain who cultivates letters (few are the number of his rank that do) has given less a translation of it than an extract, in which he has taken pains to omit whatever might be obnoxious to superstition and despotism, rectifying at the same time a number of errors relative to the Spanish colonies into which the abbot had fallen. A short time before. the Dictionaire Encyclopedique was undertaken to be translated by subscription; and the world was not a little surprised to see the name of the grand inquisitor at the head of the list of subscribers. Towards the close of my first residence in Spain, there was a very numerous list of subscribers for the New Encyclopedic, with the subjects classed under distinct heads; but a Frenchman, writer of the article Spain in the section on geography, wantonly vilified a whole nation, which its weight in the balance of Europe. and its intimate connexion with our own, ought to have made respected. The Spanish government resented this insult, and the French court determining to redress its conplaints, the author, censor, and printer were severely reprimanded; and the publication of the New Encyclopedie was suspended in Spain by order of the court. The Spanish minister, however, though offended, was not desirous of excluding knowledge, and soon afterward revoked the suspension, at the same time he took measures to erase the errors and invectives from a work of which he knew the merit, and subjected the numbers before they were distributed to the subscribers to the examination of the council of Castile. The council in consequence nominated a committee for examining the books as they appeared; a ceremony which greatly retarded the work in the first instance, and the commissaries not having either leisure, inclination, or the requisite intelligence for such a task, three hundred subscribers long awaited their decisions in vain. The matter became worse when the holy office, following the suggestions of intrigue, even more pertinaciously than those of religious zeal, produced new obstacles to the delivery of the parts; first, by forbidding the agent whom Panckoucke had sent to Madrid receiving any new subscriptions; afterwards, by extracting an engagement from him to deliver

^{*} In the reign of Peter III, he was the representative of Spain at the court of Russia, afterwards went ambassador to Portugal, and lastly to England, where he continued in that capacity up to the period of Spain taking part in the American war: he died lately

no further copies; and lastly, by seizing on all they found in his possession. The ruin of this citizen, and a consequent pecuniary injury of considerable magnitude to Panek oucke, were the result of these violent measures. The stormy times during the revolution, and the war engendered by them, have prevented the injured parties from obtaining a reparation for their losses. Peace now happily restored allows the hope of retribution.

Throughout this matter the Spanish government has to reproach itself on more than one account. Was it necessary that it should interfere in a matter chirely of a literary nature, and take offence at the inculpations of ignorance? Is the fame, the honour of a nation at all compromised by the insulated assertions of an obscure individual? By displaying authority in similar cases, calumny, so far from being refuted, obtains additional force, or at least additional publicity. Spain should have left to her learned men, to her writers, the task of demonstrating to the world that she was not so destitute of intelli gence, not so barren of titles to the esteem and gratitude of Europe, as Masson de Mer villiers had affirmed. Thus it is that a great nation shows its vengcance. Such an example has long been held to view by the English and French. Not only do they themselves even in the time of peace treat each other with severity, strangers as well are frequent in lavishing on them the most bitter railing and invective. Their governments, however, have never felt disposed to make affairs of state of these national animosities. A noble pride, the conviction to the mind of inherent worth should be sufficient to make every one impenetrable to similar attacks; and surely the Spanish temperament is of a nature to be safe behind this rampart. It was not requisite for their court to appoint defenders. The abbot Cavanilles,* who had been at Paris for several years, spontaneously undertook the defence of his country against the shafts of this imprudent journalist; but his countrymen themselves determined that through excess of zeal he had overshot the mark. He was still more prodigal of praise than his antagonist had been of reproach. The one allowed nothing, the other laid claim to every merit; so that to sustain his assertions, he was obliged to cite a long catalogue of learned men and artists, the major part of which were unknown even to the Spaniards themselves.

Another apologist has more recently ascended the stage to defend his country, not with less warmth, but in a more specious manner, and has sent me his manuscript.

In this he takes a view of the different branches of science and literature, and proves that Spaniards are ignorant of none. Above all he particularly vaunts of their military skill. The works of the marquis de Santa Cruz,† says he, are they not translated into all languages? Do not Frenchmen themselves quote the treatises on artillery of Louis Collado and Christopher Lechuga?

The inquiry of Masson de Mervilliers, What does Europe owe to Spain for two centuries past, nay for four, for these thousand years? enrages beyond measure my anonymous correspondent. And thus he answers him: "Has he then forgot? No, he never can have known, this ignorant Frenchman! He never can have known how Ferdinand the catholic drove the Saracens from Grenada; that Isabella patronized the discovery of the New World; that Charles V, triumphed at Pavia, while Magellan was penetrating the Straits

* This is the same person who is favourably known to the world of late by some estimable works on botany.

[†] For a specimen of the generalsh p of the marquis de Santa Cruz, see the account, of an expedition to the islands of Tercera, under the command of the commander. De Chaste, which forms a part of this work. With a thousand Frenchmen he made head during a whote day against thirty thousand men under the marquis, and actually dispossessed them at last of a post they contended for, and maintained it the whole of the succeeding night.—Translator.

which bear his name, and taking observation of the coasts, the rivers, and parts of South America? that Cano, first of all, made the tour of the world, and certified its figure and extent? that Cortez, in Mexico; that Pizarro in Peru, fought, conquered, and secured to Europe the valuable productions of both Americas; that the domestic animals which so prolificly abound in those regions were carried there by Spaniards; that they introduced there the use of iron, and taught all those branches of industry of which the present colorasts reap the benefit; that they analysed the productions of those countries; they established the culture of sugar, source of such advantage to French and lengthsh commerce; they established that of cocoa, of indigo, of cochineal, of tobicco, of cotton, and proved the value of back, of balsams, sarraparida, and a munitude of other salutiferous productions of nature?

"In the middle of the sixteenth century, when some triumphed at Lepanto under Don John of Austria and Bazara, others penetrated to the Pailippines; while these coasted along the shores of California, certifying it to be a peninsula, and discovered New

Mexico, those again were traversing the vast extent of South America.

They caused their religion, their manners, and their language to be adopted by millions of inhabitants, and made them agriculturists, artisans, and soldiers, patriotically identifying them with the metropolitan country; while the other nations of Europe taught the Indians what they discovered, the baneful use of arms and strong liquors, establishing no other than a paltry traffic for skins; and fitted them by their lessons, and by their

chample, to become like themselves perfidious.

"Compare with the state of these Spanish colonies, the object of so much declamation, the miserable situation of Cayenne; that of Louisiana also (notwithstanding the moustrons conceptions of the French) at the time of its eession to Spain. And shall the English be quoted as a model for us? Have they, in their usurpations on the shores of Campeachy and Honduras, done aught towards civilizing the inhabitants? Have they at dline reased their happiness? No; they have so attered them abroad, sunk in barbarity, and shown them no other example than that of piracy and snauggling. And further, Athough at present Surinam has attained a certain degree of prosperity under the man-

gement of the Dutch, how stands the rest of Dutch Guiana?

"Nevertheless, these are the most industrious, the most powerful, the most commercial nations of Europe: behold their archievements for the welfare of the two continents! These English, these French, these Dutchmen, had they a greater right than we to the colonies which they subjected? and how have they treated them? Where are the Caribs of their Antilles? Have they been more disjutcrested, more humane than Spaniards? Are they not highly fortunate in profiting by the successes of the brutal buccaneers? What cruelties have they not been guilty of in the East Indies, in order to secure to themselves, not only the trade and industry of its inhabitants, but even their persons, which they have enslaved? Neither are these adventurers, whom a nation disavows, that are guilty of such horrible acts. No; they are traced by the finger of the most able politicians in the most enlightened age, and in the country of Milton, of Newton, of Montesquieu, and of Dalembert."

Thus it is the anonymous writer answers the charges of Masson Mervelliers, and the numerous declamators who spake by his mouth. But what do these recriminations show? Go they farther than to demonstrate, that not any of the modern nations can throw the first stone, where the charge is the crookedness of policy, or the shameful abuse of power? They certainly decide nothing is favour of Spain as to her progress in civilization, in science, or in letters. The abbot Cavanilles enters the lists to com-

but the charge of deficiency in these. Has he proved victorious?

I'wo other Spaniards have lately run over the same course, which they have made by much longer than the matter would seem to furnish ground to. Lampillas has consecrated six volumes to the cammeration of the treasuries of modern Spanish Interature and Don Juan Sempere has published, in six volumes in octavo, a work entitled, Specimen of a Spanish Library of the best writers in the time of Charles III. Would not our conceive, on herring the titles of these two books, that the Spanish nation was vastly fertile in great writers: the most learned, the most enlightened, among all the states of Europe? The truth is, in this instance, met with, where in discussions it is usually found, between the exaggerated inculpations of the French author, and the vain and pompous assertions of his antagonists. Doubtless there are in Spain more learned men who modestly cultivate the sciences; more men of crudition who are thoroughly ac quainted with the history and jurisprudence of their country; more distinguished men of letters, and a greater number of poets, possessed of energy, and a fertile and brilliant imagination, than is generally imagined; but, according to the Spaniards themselves, the present state of letters and the sciences are far from what they were in the times of Mendoza, Ambrose Morales, Herrera, Saavedra, Quevedo, Garcilaso, Calderon, Lopes de Vega, Villegas, Cervantes, Marina, Sepulveda, Solis, &c. The Spanish universities can no longer boast the reputation they formerly possessed; industry and population are much inferior to what they were under Ferdinand the Catholic, and his two successors.

The three last monarchs have been zealously and successfully employed in endeavouring to revive those happier times; but frequent wars, the disorder of the finances, and other more active causes, have allowed of but feeble encouragement, and produced but a tardy progress. Knowledge, however, is much more diffused than it was fifty years ago; the reign of Charles III, produced distinguished persons in various branches of the sciences and literature: such as Father Feijoo, known from his Theatro Critico, in which he has begun to familiarise the Spaniards with a just mode of thinking, and to bring them to

hazard the bold flights of philosophy.

eful ress om Father Samiento, author of several good critical works.

Don Jorge Juan, a skilful mathematician, and particularly well versed in ship-building. Don Juan Yriarte, famous for several literary works, which do honour to his learning and his taste: these four died about five-and-twenty years ago.

And among those which Spain has lost more recently:

Father Isla, a Jesuit, author of several pieces full of wit and philosophy, among which his Fray Gerundio will long be celebrated; in this he has snewn himself among bad

preachers what Cervantes formerly was to knights errant.

Don Francisco Percz Bayer, governor of the infant Don Gabriel, has enriched literature with many works replete with erudition; besides these, many poets, who, if they have not possessed the strength, and feeundity of their predecessors, have yet evinced a taste to which they were strangers; such as Cadahalso, La Huerta, Don Thomas Yriarte, known abread as the author of a celebrated poem on music, and some entertaining fables.

Among the living, the count de Camponianes deserves particular mention as a learned historian, a well anormed lawyer, and one of the first among the Spaniards, who by his writings h s awakened the attention of his countrymen to the means of resuscitating industry.

Card al Lorenzano, formerly archbishop of Toledo,* a prelate as enlighted as beneficent.

[•] He is no longer such. Towards the end of the reign of Pius XI, he was delegated to this pontiff, in order to console him under his misfortunes, as a public testimony of the lively interest which his

The Chevalier Azara, so well known to all those whom an attachment to the fine arts entices to Rome; the elegant editor of the works of Mengs, whose friend he had been, and who has lately given a most excellent translation, in four volumes, of the life of Cicero by Middleton, ornamented with a preface, and some engravings from his cabinet of antiques.

Don Joseph Guevara, Don — Murillo, Don Francisco Cerda, and several other learned

men, who well deserve to be better known.

Don Eugenio Izquierdo, a naturalist, highly esteemed by our learned characters; and who at present is the director of the cabinet of natural history.

Don Casimir Ortega, botanist, member of the royal society of Loudon.

Don Antonio Joseph Cavanilles, another botanist, better known abroad than the preeeding; who published in 1791 a first volume, and in 1794 the third of a work entitled, Icones et Descriptiones Plantarum quæ, aut sponte in Hispaniam crescunt, aut in Hortis hospitantur; in which are described and delineated one hundred and thirty-six plants of the botanic garden, fifty-six of the kingdom of Valentia, and a great number of the vicinity of Madrid.

Some comic and tragic poets, of whom we shall speak in our description of the theatre;

and a number of authors of light poetical pieces.

Literature is generally much more cultivated in Spain, particularly of late, than what is commonly imagined. Although not yet released entirely from their shackles, they are not without means of learning what passes in their own country as well as abroad. At the beginning of our revolution, and even during the war, they were very anxious to obtain our newspapers, and in spite of all interdict obtained them. They themselves possess some periodical works.

Besides the court gazette, published twice a week, in which a very succinct account is given of all new works, they have Uno Mercurio historico y politico, which for a long time has made its appearance monthly, and presents a tolerably impartial account of

pelitical events.

They have another work totally of a literary nature, which, since 1784, has been published almost uninterruptedly once a month, under the title of Memorial literario; the author Don Joachim Ezquerra gives in it an interesting account of all new productions, besides several pieces on morality, literature, political economy, and even on philosophy.

The Spaniards had for a long time possessed a periodical work, called El Espiritu de los Diarios majores de Europe, which in 1798 was succeeded by Las anales de Literatura, Ciencias y Artes, o miscellanea, instructiva, y curiosa; which contains extracts from the best foreign journals, and many original pieces on statistics and geography.

On the same rank may be placed a journal modelled after the Spectator, which is

printed monthly from 1795, named Seminario erudito y curioso de Salamanca.

Were I to detail the whole of their periodical works besides the Mercurio historico y politico, a monthly journal for external politics, and Las Corres mercantes de Espagna y de ses Indias, which since 1792 is published weekly; I should have to mention a number of newspapers and journals published at different cities in Spain, but which have little interest out of that kingdom.

catholic majesty felt for his concerns. Cardinal Lorenzano remained with him up to the period of the pope being transported into France. After that period he continued to reside in Italy, furnishing a proof, that the unexpected mission which removed him from his benefice was not occasioned wholly by an inclination of sending a comforter to the sovereign pontiff. The archhishopric of Toledo has since been given to the infant Don Lewis, called the count de Chinchon

It must to allowed that Spain has generally very useful andvery complete works, of what regards their own country.

This valuable dictionary of their own language has before been noticed; they have is well an excellent Grammatica Castillana, the fourth edition of wheh was published

by the academy six years ago.

They are now actually employed in reprinting their last national works, particularly La Biblior eca vetus Hispanica, and the Bibliotheca nova Hispanica, by Nicholas Antonic, two works in high esteem among the learned, and of which a new edition has recently been published.

Their Geographical Dictionary of Spain, by Monpalau, considered a complete work

has already run through four editions.

Their Maritime Spanish Atlas comes nearer to perfection than any maps of the interior of Spain; for that published by Don Thomas Lopez, in 1792 leaves much to be wished for, as I had more than once occasion to notice in my long excursions ome time after its publication. The Spaniards, best acquainted with their country, nave, however, assured me, that the map of the Asturias is delineated with the most exact nicety.

In 1784 there appeared a publication, entitled Historia Critica de Espana, by Fray Masden, who, notwithstanding his being a Catalan, wrote it in Italian, from which language it has been translated into Spanish. This work, which begins with the earliest known time, is full of learned and curious researches, and displays much crudi

tion and sound criticism.

This praise is especially due to the brothers Mohedano, two friars of great sense and intelligence, but warped a little by their enthusiastic bias towards their own country. The work is called La Historia Literaria de Espana: it was begun in 1779, already in 1786 had nine volumes in quarto been given to the public, when, displeasing the holy

office, it prevented its continuance.

 Λ work less pleasantly indited, very diffuse, but more useful, has been published by Don Eugenio Laruga, which extended to twenty volumes, Memorias politicas sobre la Industria, las Minas, &c. de Espana. This work contains the most circumstantial details on the productions of the soil, and the manufactures of every description in all the provinces of Spain. It serves to prove, that the Spaniards of the present day are acquainted with their natural riches, and the utility of labour; as well that they are employed in augmenting and putting them to profit.

Most of the patriotic societies likewise publish interesting memoirs upon the same

subject, and assist in establishing their experiments.

The taste for arts and sciences has spread from the capital to the provinces. Seville and Barcelona have each of them an academy of Belles-lettres; Saragossa and Valentia an academy of the fine arts; Valladolid one of geography and history; and Grenada one of mathematics and drawing.

CHAPTER XL

TRUE STATE OF LITERATURE IN SPAIN. EDU 'ATION. MANUFACTURES. ROADS. CANALS. PATRI OTIC SOCIETIES.

THE preceding chapter has displayed the title of the Spaniards of the present day to literary fame. It will, perhaps, be sufficient to clear them from the imputations of idleness and ignorance.

Yet let us not exaggerate; their literature is very barren in many respects. They possess some works relative to the progress of the arts, such as that of dyeing, the

VOL. V.

veterinary * art, &c. an elementary treatise on mathematics, by Joseph Radon; a summary history of Arragon up to its reunion with Castile; a chronological history of the Spanish nobility; literary notes on Spain, by Mandel; numerous translations from the Latin, Greek,† English and French; some romances, at the head of which are deserving to be placed three, published by an ex-jesuit retired to Italy since the extinction of his order, Father Montenjon; called El Antenor, o de la Crienza de un Principe (on the education of a prince;) La Endoxia, on the education of a woman: and El Eusebio, a work in five volumes in many respects resembling the Emilia of Jean Jaques Rousseau; but not one single work truly philosophical; although to make amends they have an immense number of books of picty, both original, and translated. This is the sum of the modern productions of Spanish literature.

It must be owned: great obstacles even yet oppose the ambit of this aurora of the arts and sciences, and prevent the lustre of meridian day, which has been looked for from the beginning of the present century.

1. Those who apply themselves to the study of them, do not yet enjoy that conside-

ration so necessary to the natural encouragement of gening.

2dly, They still meet with too much opposition from fanaticism, and its hirelings, less disposed certainly to persecution than it has been in former ages; but its silent presence, in its numerous adherents, is in itself sufficient to extend the sovereignty of

religious terror much beyond the sphere of its activity.

Eddy, Education is yet much neglected; or what is worse than neglect, the rising generation is taught erroncous principles, and imbibe prejudices which make abortive the happy conceptions of nature, perhaps of greater promise among the Spaniards than any other nation. Will it be credited that the expulsion of the Jesuits has only tended to pejorate this essential branch of administration? At the period when this took place the inconvenience of confiding youth to the care of religious orders was, perhaps, too much magnified. That of the Piarestes, known in Spain by the name of Escolarios, is the only one which is left in possession of some schools, and these are among the best or rather the least bad. The place of the Jesuits has been supplied by professors, who may either be ecclesiastics or lay persons, but who form no collective body nor reside under the same roof. The Jesuits, besides the property of the society, had foundations for different Professorships. These are the only funds appropriated to the support of the new professors. They were sufficient for monks living in a community, but are very inadequate in the present state of things. Professorships so little lucrative cannot be sought after by persons eminent for learning and talents. The education of youth suffers therefore by the change, and this is a circumstance of sufficient importance to deserve the attention of government.

It has of late attempted something in favour of a part of the establishments for education. Spain for a long time has had seven principal colleges at which the most distinguished youths of the country are educated. All who hold situations in administration were formerly instructed in these. This prerogative and many other abuses nourished idleness and arrogance in these colleges, and discouraged the other schools, with which the youth of people in easy circumstances, belonging to the law, were obliged to

^{*} One particularly by Sigismund Macati; who was for some time in France, where he perfected himself in this art at the best school he could have chosen, that of Chabert and Gilbert; on his return to Spain, he published les elementos della arte veterinaria. He is now first director of the school established at Madrid in 1791.

[†] Among different translations from the Greek we must notice those of Anacreon, Theocrites, &c. Dion by Condi.

be satisfied. The latter had however their turn in the reign of Charles III. Their pupils attained the highest stations and took advantage afterwards of their influence to lessen the defects of the chief colleges. Following the stimulus thus given, government made new regulations respecting them in 1777 from which much good was looked for. It is looked for yet.

Much, however, his already been done for military education. Charles III, established a school for artillery at Segovia, a riding school at Ocana, one of engineers at Carthagena, and another for tactics at Avalia, whence it has bitely been removed to Port Santa Maria: at first all of them flourished. Every one produced individuals which did honour to the several institutions. The two last however disappeared with the credit of their founders generals Recardos and O'Reilly, who died lately, one in battle fighting

against us, and the other while in preparation for the same purpose.

We have already said enough to establish the opinion of the reader as to the actual state of the fine arts. As to matters of industry, manufactures at the beginning of the present century were greatly on the decline, since then government has been active in restoring those manufactories which the Austrian dynasty had left in the most deplorable situation. Philip V, readily adopted the idea, but did not persist. Ferdinand VI, pos sessed a minister in the marquis de la Eusenada, who enjoyed great credit, and joined energy to perseverance: he surrounded himself with useful co-operators, and availed him self of their talents and character. Among other useful works, he established all kinds of manufactories in Spain, and, in order to make them succeed, laid heavy duties on the export of raw materials, totally prohibited that of silk, and received with open arms the workmen which emigrated to Spain. Valentia and Saragossa soon found the beneficial effects of this conduct. In the two following reigns, some of those manufactures were carried to a still higher degree of perfection. We have already noticed how much was effected by Charles III, for those of Segovia and Guadalaxara. There are manufactures of common cloths at Escaray in Biscay, at Bocairente, at Onteniente, and at Alcoy, &c. in the kingdom of Valentia, and at Grazalema in Audalusia.
- In the course of this work we shall have occasion to speak of several others, and it will be seen that those of silk in particular have engaged the attention of government; that of galoons particularly has arrived at great perfection lately, so much so that little difference is observable between their galoons and those of France. There is a manufactory for hats at Madrid, as also at Badajoz and Seville, and for some years back foreign manufactorics have felt the competition.

Spain also owes to the sovereigns of the house of Bourbon the few roads and canals she possesses. We have already noticed what her government has effected towards the making of roads; as for canals they are yet in their beginning. There is one at the entrance of Madrid, intended to join the Maneanares with the Tagus, and facilitate a communication between the capital and Aranjuez. Two or three leagues of it are com-

pleted; and so it remains.

That of Castile, long since began, is nearly abandoned. The canal projected in Murcia, after taking the necessary levels in a bad manner, and afterwards ratifying them, after having obtained funds for carrying it on by the pompous prospectus held out, has been pronounced impracticable; the subscribers, instead of the profits which their avidity grasped at, must content themselves with the moderate interest the king has pledged himself to pay them.

In 1784 the minister adopted a project much more brilliant and useful than that he was obliged to abandon; that of a canal, which, beginning at the foot of the mountains of Guadarrama, was to proceed to join the Tagus, afterwards the Guadiana, and terminate

at the Guadalquivir above Anduxar, and which consequently would give new into and activity to the centre of Spain. A Frenchman, named le Maur, gave in the plan, and was preparing to carry it into execution, but died soon afterwards: however the plan was resolved, its branches settled, and the funds for carrying it on were ready; the undertaking was entrusted to the sons of le Maur, heirs of their father's plans, and in part of histalents. It was afterwards interrupted upon some dispute respecting its course. War afterwards breaking out brought on an additional obstacle; however since the return of peace its continuance is scriously contemplated.

But that which should more particularly contribute to the prosperity of Spain, which however has not yet produced all the benefit expected, is the modern institution of patri-

otic societies, known by the name of friends to the country.

The first institution of this kind took place in Biscay. It was soon followed by the other provinces, and by the capital, in which a patriotic society was established in 1775. At the end of 1778 there were already forty-four, and in 1795 sixty-two. The name of these institutions indicates their or p The members of which they are composed, encourage the progress of the arts, the a alture and industry of their provinces. They propose questions relative to these objects, and give premiums to those who discuss them best. They awaken the industry of their fellow-citizens, animate their zeal, solicit their information, give encouragement to artisans, assistance and advice to the peasants, and cause the patriotic ardour, with which they are animated, to circulate through every class of citizens. Never did a laudable institution make more rapid progress or produce more general effect. Those who never see the advancement of good but with an invidious eye, or whose methodical supineness is disgusted with novelty, whose self-love is mortified by success to which they do not contribute, such have endeavoured to throw ridicule upon these societies; they have pretended that the members talked much but performed little; that they exaggerated their importance, discussing trifles with pompous gravity. Undoubtedly they have not yet done every thing which may be done; their Sender funds circumscribe their progress; but the great point was to rouse their country from its stupor, to offer a stimulus to the talents of artists and the labour or husbandmen, to excite their emulation by the prospect of fame, and their interest by the expectation of profit. This is what the societies have already effected. The leisure and sa rings of peace from 1783 to 1793 have been employed by government to furnish means for increasing their beneficence. In the beginning the funds of these societies consisted chiefly in voluntary contributions: government joined to this slender stock the funds of the stock called Spolios y vacantes (the produce of vacant benefices and fines, which belong to the king.) Charles III, in spite of his religious scruples, did not hesitate in granting thus a part of the property of the church to the encouragement of these socie-

The patriotic societies have received other encouragements from government. Enlightened by them, it has revived laws which had fallen into disuse. It has excluded such foreign merchandise as might be prejudicial to the national manufactures, and has procured to these such workmen as may improve and perfect them. These measures have already been prejudicial, and will become still more so, to other manufacturing and commercial nations; they may excite in them murmurs and alarm, they will doubtless reanimate their activity and vigilance, but must meet with the applause of real patriots, whatever be their country. France itself might even follow the example of Spain, and form similar establishments. Her new organization is readily adaptable to the measure. A patriotic society in every principal town of her departments would contribute to vivify that industry which in many places has arrived at perfection in different branches.

and is every where of fruitful growth. Similar societies would have in France a better ground to work upon. Its crops would undoubtedly be of more speedy growth and more abundant. Let us show our affices that if we criticise with sharpness we yet can

Sometimes take example from them.

The patriotic society of Madrid is distinguished from the others only by the more immediate protection of government, and by its situation, which gives it a greater facility of acquirit g information and assistance. It has, perhaps, fewer objects, on which to excreise its zeal, because the productions of New Castile, in the centre of which it is placed, are less various than those of the other provinces, and because its industry is more confined. But it is attentive to the improvement of agriculture in the environs of Madrid, and to furnishing the children of both sexes and the poor of that capital with em

A perfect equality is the most sacred law of all these societies; rank is unknown in them; the archbishop of Toledo, and the duke of Medina Ceh, may be met with placed by the side of an artisan, and information is welcomed from whatever source it may

spring.

CHAPTER XII.

COUNCIL OF CASTILL. CORREGION AND ACALDES. LEGISLATION INSECURCE OF THE MONKS; OF THE KING'S CONFESSOR PARTICULARLY. ACTHORITY OF THE COCKET OF ROMI REPRESSED. THE CONCORDAL OF 1753. BIGHES OF THE CLERGY. PROGRESS OF PHILOSOPHY RELATIVE TO THE PRIESCHOOD.

AS Madrid is the centre of arts and sciences, so is it that of government. Although the monarch resides there but a few weeks in the year, and his ministers be always near his person, this city is the seat of government, and all the supreme tribunals. We shall take a view of them collectively; which will naturally lead us to speak of the laws, religion, finance, and military force of Spain.

The council of Castile holds the first rank among the councils and tribunals of the kingdom; it is at once a council of administration and a sovereign tribunal that has an exclusive cognizance of certain causes, and in certain cases receives appeals from the other tribunals. As a council it has the inspection of all interior operations interesting to the commonweal.

It is composed of five chambers:

1st, The Sala de Govierno, which is confined to the affairs of administration; it receives references brought to the conneil, but it is only to send them to the second Sala de Govierno, or to the Sala de Justicia.

2dly, The second Sala de Govierno judges the causes sent to it by the former; and is particularly charged with matters relative to manufactures, bridges, and causeways.

3dly, The Sala de mil y quinientos, or of one thousand five hundred, thus called because those who appeal to it from the sentences of the sovereign tribunals are obliged to deposit fifteen hundred ducats, which they forfeit in case of losing the appeal.

4thly, The Sala de Justicia, has an exclusive cognizance of certain causes; but for

the judgment of such as are capital is united to the others.

5thly, The Sala de Provincia judges the appeals in all important cases, and receives those made from the decision of the two civil lieutenants of Madrid (Tenientes de Villa) and from those of the Aleades de Corte in civil affairs.

These collectively form a sixth chamber, called the Sala de los Alcaldes de Cosa y Corte, resembling that known formerly among the French by the name of La Tournelle. The city of Madrid is divided into a certain number of quarters, and the police of each is superintended by an Alcalde de Corte: who judges causes in the first instance, in concur

rence with the civil lientenants. The decisions of any separate one may be appealed from to the whole chamber assembled, which alone can finally pronounce upon criminal causes within its jurisdiction. It is in extraordinary cases only that they are carried before the Council of Castile.

The chamber of the Alcaldes de Casa y Corte was formerly the tribunal which always accompanied the court of Spain. Since this is fixed at Madrid, the tribunal has been fixed there also; and as it formerly had a provincial jurisdiction around the residence of the sovereign, it has still preserved such a jurisdiction to a certain distance from the capital.

The Council of Castile is the only one acknowledged by the grandees of Spain, and all its members have the right of committimus, like those of the French parliaments.

Spain is divided into two chanceries, those of Granada and Valladolid, which have an exclusive cognizance of certain causes. Their decisions are not appealed from to the Council of Castile, except in two cases, when the appellants address themselves to the chamber of Milly quinientos, or upon a denial of justice. Each chancery has a particular chamber, called Sala de Hidalgos, or chamber of nobles. Its office is to authenticate nobility, and to hear causes relative thereto. It has also an exclusive cognizance of the criminal causes of the Hidalgos.

Besides these there are eight audiences, without reckoning the particular tribunal of Navarre, which has the title of Royal Conneil. The four audiences of the crown of Arragon are those of Saragossa, Barcelona, Valentia, and Majorea; and of the crown of Cas

tile, those of Seville, Corunna, Oviedo, and the Canaries.

Each chancery and each audience has a criminal court, Sala de Crimen, which defini

tively pronounces criminal sentences, and causes them to be executed.

Except a few restrictions, these tribunals have equal power. The principal difference between the chancer is and the audiences is, that the first act in the king's name like the Council of Castile. There are also some cases in which appeals lie from the audiences of Corunna and Oviedo to the chancery of Valladolid, and from the audience of Seville to the chancery of Granada. But from the four audiences of the crown of Arragon the ppeal (in certain cases) is immediately made to the Council of Castile, where the causes in question must be determined according to the laws of Arragon.

The limits of these different jurisdictions are not clearly enough defined to prevent frequent come at between the courts. Whilst the Council of Castile loses no opportunity of extending its jurisdictions, the chanceries and audiences incessantly struggle to support their supreme authority. Unless in cases of appeal, which are rare exceptions to the general rule, there is no resource against the decisions of all the sovereign tribunals, but revision, which in Spain is called supplied. Appeals, in that case, are made to

the tribunal itself, praying it to revise the process.

The heads of the chanceries are called Presidents, and those of the audiences Regents. The head of the Conneil of Castile has the title of President or Governor; these two dignities differ but little, except in honorary rank. The President of the Council of Castile must always be a grandee of Spain. When he appears in public, he has particular privileges.

After a long interval, this place was renewed in the person of the count d'Arunda in 1766, in one of those critical moments which call for men of reputation; as he was at the same time captain-general of all Castile, this union of civil and military power gave him a very extensive authority, which he manifested possibly with too much energy. He made some enemies, and gave umbrage to the monarch himself; he was consequently obliged to forego his presidency in 1773, in order to go ambassador to France, which

character he filled for sixteen years. Whatever may be said of M. d'Aranda, during and since his administration of seven months, he conducted himself in such a manner that Spain will for a long time remember the talents he displayed. Madrid, in particular, will not forget what he effected towards its embellishment, its security, and even its amusements. It is to his care and prudence that Spain owes the expulsion of the Je suits, prepared with the greatest secreey, and executed without tumult. He also procured an account of its population, respecting which before him, there was but a very vague idea. Thanks to him, the dissipated and frequently licentious lives of the monks were reformed, and their manners rendered more suitable to their profession. The abuses of the asylum which the greatest criminals found in the churches were suppressed The temporal authority was defended against the pretensions of the holy see; bounds were set to those exterior practices of religion, the daily processions known under the name of Rosarios, more favourable to idleness than devotion; and in some respects, as we shall hereafter find, the power of fanaticism was subject to controul. He would have proceeded much farther but for the fatal interference of the confessor of Charles III, who, in everything which regarded conscience, counterbalanced the weight of Arunda with his majesty. Since his forced resignation of the presidency of the council of Cas tile, the court abstained for eighteen years from nominating another; he was succeeded by a sensible and moderate ecclesiastic, M. de Figueroa, who had only the title of governor of the council. After his death the count de Campomanes, as oldest member of the council, discharged the functions of governor, without having the title fill several years afterwards; but on my returning to Spain in 1792, I found the court de Cessuentis, a Spanish grandee, president. He died that year, and has had three successors, who only bore the title of governor; that is to say, an old magistrate, the count de la Canada, afterwards the bishop of Salamanca, and lastly, the present governor, Don Joseph Eustachio Morena, who before that held one of the highest situations in the magistracy. The presidency appeared at that time to be again suppressed.

In general, the oldest members of this conneil form what is called in Spain the Camara, which is the chamber of the council. It is properly the privy council of the Monarch, and at the same time a sovereign tribunal for certain causes, such as all which have relation to the succession of the royal family, and all contests relative to the rights of cities (Ciudades.) It is also the council which issues all patents of royal favour; and recommends to his majesty, through the medium of his minister of favour and justice, three persons to fill every situation in the magistracy, and the king chooses one of the

three.

No place in the magistracy is venal in Spain. This, like all human institution, has its advantage and inconvenience. It leaves a greater opening to caprice, favour, and intrigue, it prevents the tribunals from being dishonoured by incapacity and ignorance, and diminishes the temptation to sell that justice of which the right of dispensing is bought. It is true, that the integrity of magistrates frequently without fortune must appear suspicious, and that their moderate fees seem but a weak rampart against corruption. However, notwithstanding the declamations of dissatisfied clients, iniquitous and partial judges are not more common in Spain than in other countries. On the other hand, the Escrivanos, a sort of lawyer corresponding with our solicitors and notaries, do not seem to me to have ill deserved the reputation they generally hold for rapacity and pettyfogging tricks.

There is a kind of gradation in the Spanish magistracy of which the degrees are regularly ascended. All the members of the Camara are former counsellors of Castile: these seldom obtain their places without having been presidents of a chancery or an

audience, or at heast formerly counsellors of one of these tribunals, or Alcalde de Corte. In the same manner it is from among the advocates, corregidors, or alcaldes mayores that the latter are chosen. It is here necessary to give some account of these Alcaldes, of whose offices foreigners in general have but a very confused idea. First, there are two classes of simple Alcaldes, who are established in the cities, boroughs and villages. The Alcalde ordinario judges in the first instance, where there is no corregidor, but in places where there is one, has cognizance of civil causes in concurrence with him, and those alone the Alcalde pedanco, who is commonly taken from the common people, has no other function but to arrest delinquents, and execute the orders of the corregidors, or the deader mayor.

The simple Aleades are differently appointed, according to the privileges of the different communes. In some places they are chosen by the municipality (ay unlaminous) in others, by lot; while in different ones they are named by the council of Castile, the tribunal of the province, or the lord of the manor, who chooses one from three persons

proposed to him. They are changed every year.

The Alcaldes Mayores, or Corregidors, are all named by the king upon the presenta tion of the Camara. This inferior degree of magistracy was formerly under very im proper regulations, which government has lately reformed. The place of corregidor was bestowed on persons of small fortune, who held their places three years, when their office expired, and they were again obliged to have recourse to new solicitations. How could it be hoped, that men with want staring them in the face, would not be violently tempted to insure themselves resources at the expence of those over whom they possessed a transient authority? It was, at length, determined to furnish them with motives for cinulation, and keep them from tempiation by enacting, that for the future they should continue in office six years instead of three; that there should be three classes of Corregimientos; from one class of which they should pass to another, after having well discharged the duties of their former place; that their emoluments should be increased at every removal; and that having thus gone through the three classes to the satisfaction of his majesty, they should have what in Spain is called the honour of Togado, that is, the title and prerogatives annexed to the place of counsellor of the superior tribunals. This plan, worthy of a well organized republic, was conecived by M. de Campomanes, and executed by M. de Florida Blanca, when minister of favour and justice, an effort which may be looked upon as meritorious on the part of the latter, for these two men, formerly colleagues, and then rivals, were never friends.

Besides these three classes of corregidors, there is one of another kind: it is those of Madrid and Seville, two cities in which the magistracy is peculiar and distinct. The corregidors are for life, and must not be taken from the profession of the law; they are no more than chiefs of the police who preside at city meetings, bull-fights, and the public acts of the city. The civil licutenants, Tenientes de Villa, have a jurisdiction independent of their authority, but these supply their places in presidencies. Besides these, Madrid and Seville have Regidores, a kind of inspectors, who maintain the police in concurrence

with the corregidor. *

At Madrid in every quarter there is an Alcalde de Barrio, a sort of commissary who, subject to the Alcalde de Corte, superintends the maintenance of the peace. Lastly, there is a magistrate, called Superintendante, especially charged with the management of the police in concurrence with the Alcaldes de Corte, the Corregidor, the Tenientes de Villa, and the Regidores. This place, which much resembles that of the former licutemants de Police at Paris, invests a considerable power in the hands of the holder; by means of which he not only becomes formidable to all the disturbers of public order, but, at times, alarms with his vexatious vigilance the most obscure and inoffensive dwellings. Such as may have lived at Madrid towards the end of the reign of Charles III, will not hesitate to place at the bottom of this portrait the name of Charles the police, who for more than ten years was the scarrerow of the weak much more than the guilty at Madrid.

From this constitution, which is certainly somewhat complicated, result incident lashings of jurisdiction among the magistrates; but, on the other hand, there are few gittes in Europe in which the police is better regulated than at Madrid, where then is more safety, or where fewer crimes are committed which escape the vigilance of justice.

It now remains to consider, by what code of laws justice is administered in Madrid as well as in the rest of the kingdom. It might be said, strictly speaking, that the Roman, or civil law has no power there. This, by some old ordinances of the kings of Castile is even forbidden, under severe penalties to be quoted. These laws, however, are to quently consulted in practice; and lawyers, without looking upon the code as intallible, derive from it frequently both information and precedents. The form of process in Spain is conformable to the Roman law, except a difference in terms and in the production of documents. They are reported, not as in France by members of the tribunal, but by particular magistrates, called Relatores, whose places are very lucrative, and consequently much sought after. In important cases, one of the counsellors is deputed to examine the process, and make his report to the tribunal.

The only authentic laws by which justice is administered, are registered in the codes published by the ancient kings; such are the Ley de las fiete Partidas, the Ordenamiento Real, the Fuero-Juzgo, and Fuero-Real. The principal code, that which is in constant use, is called Recopilacion. It is a collection of various and distinct edicts of the monarchs of Spain from the earliest ages to the present reign. A new edition is given from time to time, in which all the laws published since the last are inserted.

It was pretended in certain foreign prints, that Charles III, intended to give a new criminal code to Spain. The assertion was untrue. The rumour had its origin in the council of Castile, by the agency of the count de Camponanes, who was then one of its fiscales, having proposed the revision and reform of the old criminal laws, some of which were absurd or disgusting. I know not whether this work be yet completed, but it has already produced a tract on the penal laws, the work of a young lawyer named Lardizabal, which appeared in 1784, and may be read with pleasure and advantage, even after the celebrated essays of the marquis of Beccaria.

This is the proper place to speak of the torture; that barbarous institution against which that modern philosopher has so forcibly exclaimed. It is not yet formally abolished in Spain, and still finds some defenders. A few years ago an ecclesiastic, named Castro, undertook a formal apology for it; but his work, which inspired almost general indignation, was victoriously refuted, to the great satisfaction of the reasonable part of the nation.

The canon law is the received code in Spain in all ecclesiastical affairs. It must not, however, be imagined, that the court of Madrid pays implicit obedience to the orders of the Holy See; as one is tempted to conceive from the part played even now in Spain by the numerous legions of modern Rome, which, like the ancient, aspires to universal dominion. Religion and its ministers are without doubt still held in the greatest veneration, and the priests and monks, under the pretext of directing consciences, take part at times in temporal concerns, and abuse the confidence placed in them by credulity. But these abuses, even under the reign of the more pious monarchs, were in many respects suppressed; after being for a great part of the last century encouraged by their example. The dangerous influence which Father D'Aubenton, and his successors of the same order enjoyed at the court of Philip V, is remembered with indignation; as likewise that of Father Raba, o, the last Jesuit who sat in the confessional chair of the Spanish monarchs, with Ferdinand VI. The confessor of the last king for a long time

701, 7,

Was the Franciscan, who afterwards became bishop of Osma, who would willingly have so Fir mortified his humility as to have accepted the Roman purple. Or an austere and fret ful disposition, he was very attentive to his penitent; but (whatever may have been said of hun) meddled very little with matters foreign to his function. Charles III, although be continually treated him with that deference due to the director of his conscience, more than once repressed the fervency of his zeal. Nor, spite of the devour character of the king, could be make any attempts upon him with impunity. On my first visit to Spain, when the theatre at Saragossa was consumed by lightning, the fither confessor was desirous of impressing on the mind of his majesty, that evidence was thus afforded by heaven itself, how obnoxious profane spectacles were in its sight, and entreated him, consequently, to cause them to be shut up throughout the monarchy. He continually wearied him with solicitations to this effect, but Charles III, little disposed as he naturally was to irritation, cut him short with a firmness nearly approaching to anger. M de Florida Blanca, who, after a long residence at Rome, had imbibed more philos sophical ideas than religious ones, frequently opposed the prevish scruples of the director of the royal conscience, and consequently was little beloved by him. The confessors of the present court no longer possess this blind fanaticism. The king's confessor is a Cordelicr, who has obtained his station through the favour of the prince of the peace, his countryman, and had an archbishopric speedily attacked to his office. That of the queen has for a long time back held the confessional chair. Both are reputed to be men of sense and address. Both are admitted to the intimacy of the royal couple; but their credit is small; it is relipsed, like that of every other, by the splendour of the luminary from whose centre all rays of favour diverge.

Throughout almost the entire reign of Charles III, his confessor was consulted upon filling the vacant bishopries and other ecclesiastical dignities, which were at the disposal of the king, and in this point of view might be considered as possessing the nomination to benefices. But even in this respect, his influence was afterwards circumscribed, and the appointment to vacant sees vested in the count de Florida Blanca, as minister

of favour and instice.

This right of the kings of Spain to nominate to the great benefices of their dominions has been peaceably allowed only since the year 1753, the date of the compact between the Spanish court and the Holy See: till then the collation to benefices had been the object of frequent contests between the two courts. Negotiation was at last resort-*d to as the best mode of determination; for this purpose, Spain deputed the abbe de Figueroa, a man of a mild and conciliating character, and who has since been at the head of the council of Castile. The result was the compact which has irrevocably setalcd the relations between the crown of Spain and the court of Rome.

The Holy See confirmed the ancient right of the kings of Spain to the nomination

to all consistorial benefices. The principal contest turned upon regular and simple benefices. The popes claimed a right to confer those at least which became vacant in the apostolical months; but the compact enumerated fifty-two benefices which should be at the nomination of the Holy See, with obligation to confer them upon none but Spaniards; and it was also stipulated that the pope should not delegate this power of collation; that the benefices should be exempt from pensions, and that the titularies should pay no cedulas bancarias. These were contracts made with the apostolical chamber, by virtue of which the candidate engaged to pay a certain sum. This sum he frequently did not possess; in which case the apostolical chamber advanced it at an enormus interest, and kept agents in Spain to see these engagements fulfilled. These ruinous abuses, which it was wondrous should subsist in Europe in the 18th century, sent to Rome, one year with mother, a finh of the revenue of all the benefices.

This was not the only impropriety abolished by the complete. Precious that the poperhad always disposed of the spolios yeven ites, that is of the property of deceased problets and the revenues of yearnt benefices. The administration of these funds was confided to an office composed of Italium, so espect in this business that a forath of the produce of these henefices disappeared by the improposious management. By the composet the Holy Secrenomical these revenues under the single condition that the administration of the spotios yevenues should be granted to none but an each custice, which tripling restriction does not however prevent the kings of Spein from disposing of them according to their pleasure. The name of the value couples into a 4-them in miking edvances to the new prelates who went money for their establishment. The holy been it marked, to the praise of the dignified Spenish chergy, that the repsyment of the solves cess has rever been known to be reglected.

Although it be stipulated by the complet that the produce of the spohology various shall be wholly consecrated to pious uses, the king, as we have observed, in the site serious ple of couploying a part of them in the circomagnitud findostry, and even a reward of mintag services; but the chapters commonly chosen to regulate the property of decreased prelates, and to administer to the revetus of great vie int benefites, sanctimes reduce them to one dourth of their real value.

As the compact deprived the Holy Schol some revertes, the court of Madrid in compensation engaged to pay it for one part thereof, six hundred thousand Roman crowns, bearing interest till paid of three per cent, and on the other a sum of three hundred and ten thousand crowns bearing the same interest. Lastly, the bull of the crusade was rendered perpetual. Besides these contributions which Spam pays to the Holy See, the produce of marriage dispensations still remains in the possession of the latter, and may be estimated at fifteen hundred thousand heres (62,566k) a year.

Since that period the court of Madrid has warmly defended the rights of sovereign authority against the pretensions of the Holy Sec.—It is not forgotten in what manner it received the admonition of Clement XIII, to the infant of Parmir. The conneil of Castile suppressed all the copies, and commanded the same to be done with all the letters, balls and briefs which should be found contrary to the royal rights or to the measures taken by government, renewing the ancient law which denomiced the pain of death and confiscation against any persons who should dere to note them.

On this occasion the councit of Castile, of which the count d'Aranda was then president, put in force every public act by which the kings of Spain, from the time of Charles V, had endeavoured to hinder the admission of the bull in Casta Domini, so far as it was prejudicial to the swereignty and jurisdiction of the temporal tribmais, and commanded all archbishops and bishops of the kingdom to prevent its publication and inforcement in their several dioceses.

Spain has besides the resource of its appeals from abuses against the court of Rome. In 1784 a Spanish work appeared, on this subject, intitled Maximus solar recursos de fuerza y protection. The clergy, and especially the hely office, the ancient constitution of which was printed at the end of the work, endeavoured to prevent its publication; but the council of Castile and the minister openly protected the author.

It was at the same period also that the powers and privileges of the nuncio in Spain were confined to a distinct extent, for notwithstanding the ordinances of the preceding sovereigns, the nuncios frequently took advantage of the deference which the Spaniards paid them to exceed their rights.

Under the present reigning family, they made other attempts in which they taken At length, in 1771, the court of Madrid obtained from pope Clement XIV, a bries which gave a new form to the nunciature, and substituted in lieu of the auditor of the minerio, who was the only judge of this tribunal, a rota modelled by that of Rome, and composed of six coelesiastics, named by the sovereign pontiff it is true. but presented by the king of Spain.

It must besides be observed that Spain has long since adopted maxims, with respect to the independence of the sovereign power, very similar to the four famous articles which were said ioned by the assembly of the elergy of France in 1682, and which all subjects, upon taking upon them public employments, are obliged to swear to observe.

There still exists in Spain, however, a very great abuse arising from wrong notions of religion. This is the extreme riches of the monks and clergy. Next to the ceclesiistical principalities of Germany, the richest catholic prelatics are found in Spain. The archhishoprics of Toledo, Seville, St. 1930. Valentia, and Saragossa, have larger revenues than any had in France. There are monasteries, and particularly some of the Cartnusians, the property of which extends to the greatest part of the districts in which they are situated; and these religious foundations, while they depopulate and impoverish the acighbouring country, increase poverty and idleness by indiscriminate charity.

Government, however, which becomes more and more calightened, is endeavouring to remedy the consequence of this state of things. In the first place the wisdom manifested in the choice of prelates hinders that display of offensive luxury which, by irritatmg indigence, diminishes the respect due to religion; and notwithstanding there yet remain some few fanatics among them, they are, collectively, venerable from the auste rity of their manners and their charitable dispositions; all of them employing a great por tion of their income in alms-giving and many conscerating a part to the encouragement of industry; and this is not the only manner in which the riches of the clergy contribute to the good of the state. As well as that, by being obliged to residence at their sees, their income is consequently expended on the spot, to the great emolument of the country; it will be seen, when we come to treat of the taxes, that they pay considerable contributions. Besides these, the court of Madrid has obtained from the Holy See, the power of charging all the great benefices with the payment of pensions even to a third of their produce; and by a brick in 1783, this power was extended to all the simple benefices, which produce upwards of two hundred ducats, or about five hundred and fifty livres, and during the last war, which rendered fresh taxes necessary, ecclesiastical property, with the consent of Rome, has been laid under contribution even in a higher proportion than that of the laity.

The Spaniards saw, perhaps more clearly than other states which pretend to more platosophy, the absurdity of having religious orders, and suffering the heads of them to reside out of the kingdom. In consequence of this, notwithstanding the remonstrances I was instructed to make in 1785, the Carthusian monasteries in Spain were delivered from their dependance upon the grand Chartrense; and the minister Florida Blanca assured me when I left Madrid that there were but two monastic orders, which had their principals or generals at Rome; and the death of these two was only waited for to detach their orders from such a dangerous insubordination. It does not appear however

that the intention has hitherto been effected.

A philosopher in some respects, this minister must be allowed to have had very just ideas of certain matters. For a many years he had been a close spectator of the Holy See, and its profane adherents, and had brought back from Rome the habitude of conlanen briet of the ic, and sented

very just the Holy e of con templating the objects of the veneration of the faithful without cultius as in. Rod i, his predecessor in the ministry of piercy and justice, had also resided a long time at Rome, as anditor of the rota. On his return, notwithstanding he was officially surrounded by monks and priests, he entergoned, and even professed opinions respecting the usurpanous of the court of Rome, which were fooked upon as rash, which were on the contrary but reasonable, and to these he conformed humselt in his transactions. Were Spain to have an uninterrupted succession of administrators similar to these two, and resembling some of the ministers of the present day, soon would she be released from the holy gyves which have so sorely galled her for the list two centuries.

Throughout the present her progress is perceptible. Other proofs exist of it beyond what we have hitherto mentioned. The severity with which the court of Madrid has treated the Society of Jesus, the continued vigour with which it pursued the Jesuits, even to their extinction in the court of Rome, the tranquility of the nation whilst these messures were carrying into execution, prove that Spain crouches not so much as it is commonly believed beneath theyoke of superstition, and the absolute empire of the mont's

CHAPTER XIII.

CRARGES AGAINS, AND DITING OF THE ASSCRIPTION FROM HARDON OF THE AUTO BEFFES OF A RECENT DATE. ADMINISTRATE OF MEDICAL ADMINISTRATION OF THE INCUST THOSE OF THE SANTA HERMANDAL, OR HOLD BROTHLERGOOD

THERE is yet one religious institution in Spain to which philosophy mourns to see that nation subject, I mean the Holy Office, that tribunal to which every odious epither has long been applied, and which has still in Spain two powerful supporters, policy and religion.

The frank impertiality with which I explained myself on the subject of the Inquisition in my first edition, drew upon me reproaches of a very different complexion. On the one hand, some Spaniards, in other respects well informed, accused me of having too much heightened the colours in which I had painted the Holy Office; on the other, the French, after reading the description I gave of it, accused me of too much moderation, and even of imposture. Placed between these two shoals how am I to steer: should I relate what I have seen, and give my own opinion? I did so before; I shall continue the same line of conduct.

Its defenders alledge that the authority of the sovereign finds in the Holy Office a means of making itself respected, since by enchaining the consciences of the subjects, it provides additional security for their obedience, and prevents those variations and incertitudes in religion which have but too frequently disturbed the peace of society. They assert that by its means the true faith preserves its unity and purity, and attribute to the Inquisition the trenguility which Spain has in this respect constantly enjoyed, while the other Christian states of Europe, at different periods, have experienced all the bitterness of dogmatic quarrels, and the turbulent zeal of innovators.

Others go still farther. Will it be believed that a magistrate, otherwise distinguished for learning, and who presented some energetic representations to Philip V. upon the usurpation of the Holy Office (I allude to Macanaz); will it obtain credit that such a man shou! I be their partizan? He, however, wrote a work in 1756, not reprinted, however, until 1788, which has for its title, Defensa Critica de la Inquisition.

In it he states that, by the allowance of hereties themselves, the Holy Office never seizes apon any one before the crime with which he has been charged has been substantiated by five witnesses; nor condemns until two additional testimonies appear to

authenticate the charge of the first, where it is not rendered unnecessary by the confession of the culprit; that for the first and second offence it grants absolution, upon the accused person craving pardon; that it judges errors only according to the counsel of the most enlightened doctors of the church; that the culprit is well taken care of in prison, and heard as often as he may require; that the heads of the charges of which he stands accused are read to him, hiding nothing but the names of the witnesses; but if error in him be proved, and not retracted, secular justice administers the penalties applicatory to

the crime according to law.

In this account much truth is contained, which, however, should it be entirely correct, does not tend to lessen the horror which the Inquisition inspires. It appears to be proved (if proofs can be expected at all where the parties concerned are enjoined to secreey, under the pain of the most dreadful punishments) that the prisoners of the Inquisition, although inaccessible to any visit from the exterior of their prison, are well treated and well fed; that the physical tortures to which it is pretended they are subject are mere chimeras, invented by resentment, and propagated by credulity, so foud of matters which have any things of extraordinary to recommend them; or, if they be

at all practised, that the occasions have been exceedingly rare.

Macanaz adds, that agreeable to the comession of the greatest enemies of the Inquisition, such as go of themselves to declare their crimes, and repent, are treated with mildness; that those which they arrest, if they retract, they obtain forgiveness; that is charging them with seizures for the sake of gain, they are calumniated, since the coali oution is for the advantage of the sovereign. But what must one think of Macanaz a a of his apology, when with ridiculous gravity he affirms that the Inquisition "imposes no punishment" on those who are fixed in their error, and "asks for nothing but the salvation of the life of the guitty?" that if they become converted, it confines itself to applying canonical punishments, but that the sword of the law, which the monarch preserves in the tribunal for the chastisement of the guilty, "is sometimes reddened with the blood of criminals?" Yet even then it is done with the holy view of converting many by the punishment of one, "as it commonly happens." Reasoning is unnecessary, silent indignation is the only reply such phrases claim; and these from a magistrate! from a pretended philosopher! and in the eighteenth century!

Recrimination is one of the principal modes of defence adopted by Macanaz. In this view he presents a horrible picture of the persecuting reign of Elizabeth; and cites the atrocities exercised in France by the hercites. According to him the procedure of the Inquisition is a model of justice and mercy, compared with the horrible treatment they experienced. Thus, according to Macanaz, and doubtless the same sentiments existed in those who have caused his works to be printed and reprinted; because our ancestors were blind and atrocious, our contemporaries, who are perhaps a little less so than they were, or rather let me say, than of our contemporaries, who give the form and title of justice to the cruelty of enthusiasm (and who are much less pardonable, since they have not for excuse the delirium of the passions) those have just pretensions to esteem and respect; so because they do not exterminate by invriads, like Pizarro, they possess the

humanity of a Fencion!

The antagonists of the Inquisition, both ancient and modern, maintain, on the contrary, that it has constantly excluded knowledge from Spain, that it has pampered surestition and fanaticism, and kept the mind in that servile subjection calculated to repress those vigorous efforts of genius by which great works of every kind are produced; that in freezing the heart with fear, it prevents the sweet effusions of confidence and friendship, destroys the most intimate connexions which constitute their charms, and confeson the l of the prison, stands rror in tory to

dy cors to be I to se-Inquire well re subso fond they be

In this cites the re of the rent they s existed ancestors than they ad title of they have steem and ossess the

the conpered suted to reproduced; lence and arms, and for two entire ages has sentenced Spain to ignorance and barbarism. This picture is not in truth an exaggeration in any great degree; but as I have interdicted all declamation on my part, in spite of the horror which I feel for the Inquisition, I will maintain that it is sensible in Spain of the revolution which has been effected in the manners of the age in all the countries; and if this revolution has not altered the primitive constitution of the holy office, it has at least tempered its severity, and rendered it less visible and less frequent. Auto de fes are not the same pompous solemnities as formerly, whose gorgeous display, under the pretence of honouring religion, insulted humanity: heretofore the whole nation ran to them as to a triumph, and the sovereign and all his court were present; imagining that thus they performed an act of the most meritorious nature in the eyes of the Deity, and enjoyed the torments of the victims which were delivered up at once to the executioner, and the maledictions of the people; the particulars of these barbarous rejoicings as well were related in books written expressly to describe the part taken in them, and the pleasure received from them by the spectator.

After the auto de fe in 1680, a work was published, giving the most circumstantial relation of that terrible solemnity. The author seems to have taken as much pleasure as if he were describing a public festivity. "I am about," he says, "to relate, with an interesting exactness, all the circumstances of that triumph so glorious to the faith, with a list of the nobility present, and a summary of the sentences passed upon the criminals."

The censors afterwards approve, in the most distinguished manner, a work which, say they, "for the majesty of its subject ought not only to be read in Spain, but by the whole world."

The examiner surpasses the censors. "The author," says he, "has answered the public expectation at a time that curiosity made it the object of every wish, and the pious impatience of all true believers complained of delay." He is above all culogium for "having given, with a scrupulous attention, all the particulars of this wonderful ecremony."

In the course of his narrative, the author frequently celebrates the pious zeal of the monarch, who was himself present at the ceremony.

"This prince," says he, "having given i to be understood that he should be glad to be present at the celebration of an auto-general, the council of the Inquisition thought it would be shewing him a mark of respect to afford him an opportunity to imitate the admirable example of his august father Philip IV." The grand inquisitor went in consequence to kiss his majesty's hand, "assuring him that he would take the most speedy measures for the accomplishment of a work which was so agreeable to him."

"It was a great consolation," says he, "to the zealous, a subject of confusion to those of a lukewarm zeal, and of astonishment for all the spectators, to witness a constancy worthy of being admired for ages to come. From eight o'clock in the morning his majesty remained in his balcony, without manifesting the least uneasiness from the heat, or the prodigious concourse of people, or appearing wearied by so long a ceremony. His zeal and devotion were so supperior to the fatigue, that he did not even withdraw for a quarter of an hour to taste refreshment; and at the end of the ceremony he asked if there were any thing else to be done, and if he might retire."

The Spaniards of the present age are far from that cool cruelty which shuts the heart against pity; and are at liberty to compassionate the very small number of unhappy victims who suffer the severity of the holy office.

They have indeed been very rare in the present century, for there has not been one general auto de fe similar to that of 1680.

In 1714, some monks, whose monastery was in the neighbourhood of a convent of nuns, were convicted of having abused the ascendancy they had gained over their minds, by making them guilty of disorders which they concealed under the veil of religion. The holy office condemned to death those who were most culpable, and, according to custom, delivered them over to the secular power.

Eleven years after, the Inquisition exercised another act of severity, which I will not undertake equally to justify. A family of Moors was discovered at Granada, peaceably employed in the manufacture of silk, in which it excelled. The ancient laws, supposed to have become obsolete, were for this time renewed with all their rigour, and the un-

happy Moors were burnt alive.

In 1756, seven persons from among the lower class of people were taken from the prisons of Madrid to hear their sentences pronounced. One of them, a schoolmaster, who had been falsely accused, was acquitted. The three false witnesses who had deposed against him, one of whom was his wife, were banished for eight years, and condemned to receive two hundred lashes, which were never inflicted. Another culprit really received the lashes, and was the only person then corporally punished, because, as the sentence declared, he was heretic, apostate, inclined to Judaism, and unsettled in his faith. The only crime of one of the seven, who was from Toulouse, consisted in his being a free-mason; his sentence was perpetual banishment, and the confiscation of his

These divisions were the appearance of ignorance rather than cruelty; but in 1763, property. a particular auto de fe was celebrated at Llerena, when some hereties were delivered to the flames. The obscurity of these victims prevented their punishment from becoming generally public; and the universal terror which the name alone of the Inquisition inspired, seemed to be less prevalent. The king, the year before, had restrained the powers of this tribunal. The grand inquisitor having, against the express will of his majesty, published a bull which proscribed a French book, was exiled to a convent thirteen leagues from Madrid. Whilst in exile he endeavoured to excuse himself by alledging the immemorial usage, which gave to the holy office the exclusive right of prohibiting dangerous books. At the end of a few weeks he obtained his pardon; but the king, after having taken the advice of his ministers and the council of Castile, issued an

ordinance, which stated: 1, That for the future the grand inquisitor should not be allowed to publish edicts,

except when they were sent to him from his majesty. 2, That when he should receive briefs, by which books were to be prohibited, he should conform to the laws of the country, and publish the prohibition, not supporting himself by the brief, but by his own authority. Finally, That the holy office should, before it condemned a book, summon the author

before the tribunal, to hear what he might have to say in his defence. This little triumph of reason and sovereign authority promised to be but short. The year following, the influence of the king's confessor produced a revocation of the edict; but the count de Aranda managed so as to revive the order of 1762, by gaining over a mixed assembly of magistrates and bishops who had been created on the occasion of the expulsion of the Jesuits. This was not the only effort of that wise minister, to circumscribe the power of the holy office; he had long meditated the depriving it of the right to seize the property of the criminals it condemned: but it was objected, that it furnished a part of the salaries of the officers of the tribunal; and that to supply the failure of this property, it would be necessary to create a fund of upwards of six hundred thousand livres

(25,000l.) This consideration suspended the revocation which was ready to be propounced.

operty, it nd livres The count succeeded better in another attempt. Being president of the council of Castile, which has always been the zealous defender of the rights of sovereignty, and gaining over, by the ascendancy of his character and talents, some powerful prelates, whose secret dislike to a tribunal, enriched by episcopal spoils, he took every means to increase; he obtained in 1770 a royal mandate which confined the jurisdiction of the inquisition to the cognizance of the crimes of heresy and apostacy, and forbade it to imprison the subjects of his majesty, unless these crimes were first clearly proved.

imprison the subjects of his majesty, unless these crimes were first clearly proved.

This went to contract its limits greatly. The victory which he thus obtained was obnoxious in Spain to a very small number of weak and finatic people. It was highly celebrated and exaggerated in foreign countries. The moment was supposed to be at hand when the hydra, which philosophy had long before condemned, was about to be destroyed.

The resignation of the count de Aranda, which happened soon after, did not prevent similar measures from being pursued, because distinguished and enlightened persons were still at the head of administration, who, notwithstanding their zeal for religion, had imbibed the same principles. Security was re-established in the minds of men without banishing the respect due to religion and its ministers. This was insured by the goodness and moderation of the monarch, and the tolerating maxims of those in whom he principally confided. The time of rigour and cruelty seemed to be passed, and the Holy Office appeared to slumber, when in 1777 it suddenly shook off its supineness at the expense of an illustrious victim, and terror and false zeal were again roused through all Spain; while throughout the rest of Europe the indignation of every rational friend to the blessings of a wise toleration was again excited.

Don Pablo Olavide, born in Peru, had been raised by his distinguished abilities to one of the first employments in the state, that of intendant of the four kingdoms of Andalusia and Assistente of Seville. His sage measures in this important post had excited admiration and gratitude, when new opportunities presented themselves to signalize his zeal. The king had conceived the project of clearing and populating that part of the Sierra Morena which is crossed by the road from Madrid to Cadiz, a district formerly inhabited and cultivated, but lately overgrown with wood, and become a retreat for robbers and wild beasts. M. Olavide was appointed to earry this plan into effect, and acquitted himself of his commission in the most distinguished manner; he however, could not avoid the ordinary rock of all great enterprises. He made himself enemies; and drew upon him the hatred of Father Romauld, a German capuchin, who had brought into the Sierra Morena a patent from the general of his order, by which he was declared prefect of all new missions, and by which he arrogated to himself an unlimited authority in every thing which could be made to have the least connexion with religion. He was opposed by M. Olavide, who otherwi gave him a good reception, and received him into his intimacy. The disappointed ambition of the monk became furious. Some indiscreet expressions from M. Olavide, in an unguarded moment, supplied him with an opportunity to gratify his revenge. He fomented the discontents of some of the settlers who were his own countrymen, and made use of them to discredit the new establishment and its principal conductor. The memorials which he presented to the council of Castile were full of the most serious charges against M. Olavide. The council caused them to be examined by an impartial judge, and M. Olavide was sud-VOL. V.

dealy ordered to court in the month of November 1775, there to confer concerning dif-

ferent objects relative to his mission.

Whilst he resided tranquilly at Madrid, he discovered by accident the treacherous conspiracy intended for his destruction. He learned from intercepted letters that Father Romuald had planned his ruin, to enrich himself with his spoils, and that he was not without a hope that the court itself would favour his detestable plot.

M. Olavide was further informed by some friends whom he still had in the Sierra Morena, that the preceding year the vindictive monk had accused him to the minister of foreign affairs, of being wanting in respect to divine worship and ecclesiastical discipline in the new colonies, and of having in his possession prohibited books; and also

that he had but a short time before accused him to the holy office.

However alarming this information might be, M. Olavide confided in the rectitude of his own conscience. He solicited the ministers to convey to the foot of the throne the proofs of his innocence. He went to the grand inquisitor protesting the purity of his faith, and offered to retract the expressions which might have escaped him to the prejudice of religion. For more than a year that he had resided at Madrid, his conduct was of a most exemplary nature; but nothing could avert the storm which threatened him.

The 14th of November 1776, a grandee of Spain, in quality of Alguasil Mayor of the Inquisition, accompanied by some officers of justice, arrested him in his house, and

conveyed him to the prison of the holy office.

At the same time his wife, who was at Carolina, where she had remained during the absence of her husband, saw the officers of the Inquisition arrive and seize all his property, books, and papers; whilst another detachment did the same at his house in Seville. Until the day his sentence was pronounced he was lost to his family, who knew not whether he was dead or alive, and had given over all hopes of ever seeing him more.

I arrived in Spain for the first time when this event was quite recent, and was witness to the sensations which these proceedings occasioned in the minds of different men. The rivals of M. Olavide, the invidious, and some devotees, constant in their zeal for the cause of religion, considered it as a triumph. Several of his more rigid countrymen thought it a just chastisement for the imprudencies attributed to him; and which might have had other judges elsewhere, but would not have escaped unpunished. Consternation was however the most general sentiment. Each began to tremble for himself, fearing lest he should find in his most intimate connexions both spies and accusers. How were it afterwards possible to enjoy the sweet communications of confidence and friendship? What man could be prudent enough and sufficiently sure of himself to concert all his actions, weigh his expressions, and never furnish matter of accusation for a secret enemy, a corrupted servant, a friend, or even a son led astray by his seruples? The holy office is perhaps more just than severe; but its proceeding is dreadful! How can an accused person disculpate himself when he neither knows his crime nor accusers? And how is it possible to avert the thunderbolt prepared in silence in the shades of its impenetrable maze?

Such were the reasonings dictated by terror during the imprisonment of M. Olavide. The apparent supineness of the Inquisition had re-established security, but its sudden revival terrified every one. The first impression was besides rendered more lasting by other circumstances. The monks thought the time at hand to regain their lost power. Scarcely was M. Olavide arrested before it was known that a mission of capuchins at Seville had abandoned themselves to an excess of zeal, and loudly exclaimed against

against

profane theatres to which he had given encouragement in that city. At the same time the Inquisitions of the provinces partook of the triumph of the capital, and made an essay of their returning power. The Inquisition of Cadiz renewed a ceremony which had been neglected there for half a century, and which is annually repeated at Madrid, that of so lemnly reading all the decrees of the holy office, the bulls upon which its power is founded, and all the anathemas fulminated against heresy and irreligion. It seemed as if the holy office wished to make a mockery of the alarm of the public.

In the mean time the prosecution of M. Olavide was carried on with the utmost secresy. His fate was at length decided after a rigorous imprisonment of a year and seven days, during which he had not the consolation of having even one of his servants suffered

to approach him.

On the 21st of November 1778, an assembly was held in the hall of the Inquisition, to which forty persons of different orders were invited, among whom were several grandees

of Spain, general officers, priests, and monks.

The criminal appeared clothed in yellow, carrying in his hand a green taper, and accompanied by two ministers of the holy office. All the proceedings were read. The most interesting part was the circumstantial relation he himself had given in of his whole life. In this he confessed that in his travels he had frequented the society of free-thinkers, namely, Voltaire and Rousseau; that he had returned to Spain with many prejudices against the clergy, and persuaded that the privileges and opinions of the church of Rome were repugnant to the prosperity of states; that since he had been placed over the colonies of Sierra Morena, he had openly, and without reflection, avowed his opinion concerning the obstacles which retarded their progress, the infallibility of the pope, and the tribunal of the Inquisition.

Afterward were produced the depositions of seventy-eight witnesses, who accused him of having frequently spoken the language of free-thinkers, and ridiculed the priests. To several of the charges made against him he pleaded guilty, and denied others, asserting that in all these cases his words had never expressed his true sentiments; that his object had sometimes only been to animate the industry of the settlers confided to his care, among whom the exterior practices of religion were frequently nothing more than pretexts for idleness; and that when he declaimed against the ill consequences of celibacy, his view had merely been to encourage population, so necessary to the prosperity of his

country.

This defence appeared neither respectful nor satisfactory. It was alledged against him as a crime, that he had used every means of eiuding the justice of the holy office; had intercepted letters to engage the witnesses brought against him to retract; and these

circumstances were all proved by writings under his own hand.

In short, the tribunal adjudged him attainted and convicted of every charge made against him; and, in consequence pronounced his sentence, which declared him formally an heretic. He interrupted the reading, by denying that he deserved so harsh an appellation. This was, during the final and terrible sitting, the last effort of his firmness. He fainted on the bench on which he sat, and as soon as he recovered himself, the reading of the sentence was continued. It confiscated all his property, declared him incapable of holding any employment, exiled him to twenty leagues from Madrid, from every place of royal residence, from Seville, the theatre of his fallen authority, and from Lima his country; it condemned him to be shut up eight years in a monastery, where he was to peruse such works of piety as should be put into his hands, and go to confession once a month. He afterwards made his solemn abjuration, and, with all the ceremony prescribed by the canons, was absolved from the censures he had incurred.

Those who were present, it will readily be conceived all orthodox, declared that he showed the most unequivocal marks of resignation and repentance, and that it was im

possible to refuse him their compassion.

It has been asserted that the personal elemency of the monarch, and that of even the grand inquisitor mitigated the rigour of his sentence; that some of his judges were of opinion he ought to suffer death, and several a public punishment; one of these rigourous sentences was supported by the king's confessor, whose fanatical zeal for the cause of God, made him believe the scandal could not be repaired but by a public example.

It was however difficult to learn the rest of the secret particulars of this affair. Curiosity and indiscretion were restrained by fear. A conjecture, a question, might be misinterpreted and embitter the life of the author. People were in a situation something like that described by Tacitus, in the life of Agricola: Adempto per inquisitiones et loquendi audiendique commercio;* or that of a more modern and still more dreadful period.

It must however be observed in favour of the Spanish government, that this crisis did not continue long. The mind became more easy by reflecting upon the known benignity of the disposition of Charles III, and the enlightened character of his minister, who

was adverse to fanaticism.

Even the situation of the victim contributed to dissipate public terror. His talents and good fortune had excited the notice of envy before he had incurred that of the holy office; and citizens, somewhat calmed, trusted to their obscurity for shielding them from the rigour of this tribunal. The result shewed that it was but transitory, and that the

privy councils of the king were governed by milder maxims.

M. Olavide was scarcely confined in a convent of La Mancha, before, complaining of the ill state of his health, he obtained permission to go and drink the mineral waters in the neighbourhood; and afterwards the liberty to go to others in Catalonia, which he hoped would prove more efficacious. There near the frontiers he easily deceived the vigilance of his keepers, and bidding adien to his country, which still was dear to him, escaped to France, where he was preceded by his reputation, and received as a martyr to intolerance. Some months after his flight the court of Spain reclaimed him, but that of France replied in a friendly manner, that the offences of M. Olavide, however heinous they might appear in Spain, did not come within the description of those, the authors of which civilized states had reciprocally agreed to give up; and the court of Madrid insisted no farther.

Ten years after his evasion, the French revolution which he had predicted, and, no doubt, desired, taking place, towards the end of his career, presented him with a spectacle of a novel description. He heard the rumbling of the thunder about him, and had, at a time, some apprehension from the storm. He underwent the dreadful horrors of suspense in the memorable reign of terror, and learned what fifteen years before had never entered his mind, that there was under heaven somewhat even more terrible than the Inquisition. Since then he has retired to a country-seat near the Loier. In this spot his busy brain has attained a calm, without his heart being chilled. A religion, better understood than that of which he was about to die the victim, offers him its consolation, literature its resources, and solitude its sweets; so that by a strange concatenation of circumstances, the Inquisition for once, doubtless the first time, has made one wise and happy man.†

· Spics put an end to the use of the faculty of hearing and speech.

⁺ When I wrote this in 1797, M. Olavide little thought of revisiting that country which had proscribed and punished him, and from which he had escaped as a fugitive: but age, misfortune, and at-

Since this event the Inquisition has, in one case, justified the apprehensions it excited. Toleration, or, which is the same thing, humanity, shuddered at the torments inflicted upon a poor woman, who, having been convicted of sorcery and witcheraft was burned at Seville in 1780, in consequence of the sentence of that tribunal.

undergoing a trilling penauce.

I was at Madrid in 1784, when a circumstance happened which proves that this tribunal, notwithstanding the terror its forms have ever inspired, is sometimes less severe than many secular courts of justice.

A beggar, who generally took his stand at the door of a church, had employed his leisure in inventing and selling a species of powder to which he attributed miraculous effects. It was composed of ingredients, the mention of which would make the reader blush. The beggar had drawn up some singular formularies to be repeated at the time of taking the powder; and required, to give it its effect, that those who took it should put themselves into certain postures more easily imagined than described. His composition was one of those amorous phitries, in which our ignorant ancestors had so much faith; his, he pretended, had the power of restoring a disgusted lover, and of softening the heart of a cruel fair one.

Whatever flatters our passions has some claim to our credulity. The impostor wanted not for customers in that class over which the marvellous has so much empire; and a few accidental successes gave reputation to his nostrum. He associated himself with some women who distributed it. His powders, however, as it will easily be believed, were often employed without effect. Most of the persons whom he deceived, less irritated than ashamed, kept profound silence; but, at length, others made complaints which were soon carried to the holy office. The beggar was arrested, and led with his accomplices to the Inquisition, where they were prosecuted in form.

The impudent empiric avowed every thing; he explained the composition of his powder, and gave up his receipt and formularies. The result was one of the most singular proceedings which ever came before a tribunal. The day of vengeance arrived. The judges, criminals, and a crowd of spectators of both sexes assembled in the church of the Dominican nuns at Madrid. Divine service was begun, but afterwards interrupted to read the strange proceedings. The temple of the Most High was not supposed to be profaned by a recital of the obscenities contained in the summary. Such were the laws of the holy office, nor were these dispensed with in the least in favour of some women of quality, who hid their confusion behind their fans. Even the nuns, less attached to their scruples than to the privileges of their church, lost no part of the ceremony, and their modest ears were insulted with the shameful relation. The sentence was pronounced, and executed after mass was over.

tention to the conduct of others, brought him back a convert to that religion he was charged with contemning. Not only did he frankly profess christianity, he employed his leisure in composing an apology in a long work which he published, and which being known in Spain, caused the sincerity of his conversion to be no longer disputed. He met with advocates about the throne, and what was more difficult, even in the formidable tribunal, the author of his persecutions; which for once recalled to mind that the Divine Legislator, whose vengeance they state themselves called upon to execute, desireth not the death of the sinner, but rather that he turn from his wickedness and live. M. Olavide obtained permission to return to Spain, and arrived in Madrid in 1793. Ambition has now lost all empire over his soul, as well as all resentment; he shortly after withdrew to Andalusia, to the house of a female relation, the object of his earliest affection, perhaps the only one who survived his long banishment.

The beggar was declared attainted and convicted of malpractice, profanation, and imposture, and condemned to perpetual imprisonment, after having been whipped in the principal quarters of the city. Two women, his accomplices, were treated with more

indulgence.

The three criminals soon left the church; they were mounted upon asses, and each clothed in a sambenito, covered with painted devils and other symbolical figures. They were on their heads the fatal pyramidal bonnet called coroza. The man was naked down to his waist, and exposed to the eyes of the public a plumpness which could be attributed

to nothing but the lucrative and extensive sale of his powders.

The procession was headed by the marquis of Cogolludo, the eldest son of the duke of Medina Celi, who, in quality of Alguasil Mayor, presided at the ceremony. He was followed by several grandees of Spain, associates of the holy office, and other officers of the tribunal. The windows were filled, and the streets thronged with curious spectators. The triumphant entry of a hero, returning to his country after having saved it, could not have been more pompous than the ceremony of which a vile criminal was the object; and this spectacle by which enriosity was so much excited, unlike to others of the same kind, offered nothing which might wound sensibility. Never was a sentence so well deserved executed with greater mildness. The criminal stopped from time to time, and scarcely did the executioner touch his shoulders with the whip, when some charitable hand presented him with a glass of Spanish wine to enable him to finish his career. It

were to be wished that the holy office had never exercised greater severity.

In fact, this tribunal (I averred it in 1789, and repeat it in 1803) is far from being so dreadful as in other countries it is generally believed; I shall not become its apologist by stating that our lettres de eachet were formerly equally revolting; neither shall I excuse it, by stating, that in the eye of philosophy in that nation which passed for the most enlightened and humane, for eighteen months together we have witnessed the most shocking representation of judicial iniquity that ever stained the page of history. It is not by citing superior atrocities that the smaller can be mitigated, I shall therefore own that the forms of the Inquisition are terrifying, even to those who are persuaded of its equity. Prosecutions are carried on with the greatest secreey; the advocate granted to criminals to make their defence cannot speak to or see them but in the presence of the inquisitors. But the most edious proceeding of all is, that when the depositions received against any person accused are communicated to him, the names of the accusers are carefully conecaled. If the holy office were to prosecute criminals publicly, and name and confront their accusers; were it to allow them every means of proving their innocence, would its laws be less observed, or would the sacred interests committed to its care be less attended to? Let it not be said, that most informers would be restrained by a false shame by the fear of exposing themselves to the indignation of the public and the resentment of the accused. No, surely the holy office dare not avow an apprehension lest its victims should be fewer! Is that God which it worships so thirsty of human blood, so covetous of guilty persons and victims? If this were his religion, never was a more dreadful present to mortality.

I am withing to allow to those who consider this as the only true religion, that its pure doctrine, and a respect for the worship of its followers, are conducive to public happiness and tranquility; and that such as presume to make violent attacks upon either are deserving of being restrained, and even punished. But gratitude towards benefactors, fidelity of servants to their masters, charitable indulgence towards our fellow-creatures; is the exercise of these virtues, inquisitors, less acceptable in the sight of Omnipotence

i, and in the more

than orthodoxy? and would the cause of the Almighty suffer from motives powerful as these preventing accusations?

Besides how do other tribunals find means of detecting the guilty? The public body whose duty it is to prosecute offences, is it insufficient to discover those whose apprehension is necessary for the sake of society or religion; and is it common for crimes against

either of these to escape the sword of justice?

And as for such as might escape without the concealment of the witness whose indignation they may have incurred, does not the publishing of their transactions or language occasion more real injury to religion than what their being left unpunished could possibly do? And when the God you worship (I was about to say that you to traduce) cursed "the man who first invented scandal," did he not intend to include the publisher of scandal?

Thus in case of my having to appear before the Holy Office, thus should I address myself to it. But I would acknowledge at the same time, with no expectation of disarming it, but merely with a view of doing homage to truth, that the Inquisition, if its forms were overlooked, and the object of its institution, might be cited as a model of equity. Let it not be said that the malice of a secret enemy is sufficient to call down its vengeance; it condemns no one upon the testimony of one accuser, nor without discussing the proofs of the charges. Serious and repeated crimes are necessary to incur its censures; which, with a little circumspection in words and conduct relative to religion, may be avoided, and men live as little molested in Spain, as in any other country in

Europe.

I will say more, during my last stay in Spain, which was for the space of more than a year; I do not remember to have once heard the name of the holy office, nor was I able to obtain one other single anecdote to add to the horror to which I had devoted it, notwithstanding the apologetical manner with which I was reproached with having spoken of it. Not that at the time I speak of (1792 and 1793) it had become less rigid; but more immediate objects, more imminent dangers, the consequence of the progress of our revolutionary principles, called for and seemed to absorb all the faculties of the Spanish government. Persecution was less extended towards the atheistical French, than the French imbued with maxims formidable to despotism, and too much inclined to the propagation of them. The Alcaldes, the Corregidors, the commandants of towns, the governors of provinces, all had become political inquisitors more vigilant and far more formidable than the reverend fathers; so that the latter relying upon the active zeal of their substitutes seem to hold vacation for a period of time.

It was consequently in my first journey into Spain that I acquired the greater part of

the materials from which I have attempted a draught of the Inquisition.

I must add to what I have before observed, that, of all strangers, the French have been

constantly the principal objects of its restless vigilance.

The troublesome zeal of many of its commissaries in the provinces, occasions them to be persecuted for the slightest matter, frequently disturbing the quiet of the inhabitants, by domiciliary visits for the purpose of seizing licentious prints, or prohibited books; oftentimes it is true this excess of zeal is condemned by the court, or the grand inquisitor, which office, during the last and the present reign, has been uniformly occupied by prelates of sense and moderation. I have seen some specimens thereof, one of the most striking of which is the following.

About fifteen years ago, some French merchants at Cadiz, having received a consignment of leather from one of our manufactories, were much alarmed at seeing the officers of the Inquisition enter their houses. They desired to see the leather newly ar-

rived and having observed that it bore the image of the holy virgin, which was the mark of the manufacture, exclaimed against the profanation; remarking that the leather being intended to make shoes, the image of the mother of Christ ran the hazard of being trodden under foot, and consequently it was confiscated. The affair was referred to the supreme tribunal at Madrid. The charge was made out and was for some time in my possession, for the merchants, much alarmed, had recourse to the court by means of their ambassador. The court and the tribunal received the complaint in the manner it merited. The officers of the Inquisition were enjoined not to molest strangers under such triffing pretexts, and the merchants recovered their leather without further trouble.

On other occasions, still more recent, the minister and the grand inquisitor himself, have protected the inhabitants against the cavils of the subalterus of the holy office. At Barcelona they attempted to give disturbances to a French house, because its members were Protestants; and when it was observed to them that the English and other northern nations were tolerated in Spain, notwithstanding they were heretics, they answered, that the Catholic religion was the only one in France. The cause, however, of this perse-

cuted house was no sooner brought before the court than it was gained.

In fine, though it must be admitted that bigotry is more prevalent in the provinces than in the capital, no great inconveniences can ever arise from it; because the sentences of the provincial tribunals have no force until they have obtained the sanction of best of Madrid, which on that account, bears the name of Suprema. Besides, the court scrutinizes more strictly than ever the proceedings of the holy office, and certainly not with an intention of increasing its severity. It was enacted, in 1784, than when the office should have finished the prosecution of any grandee of Spain, any of his majesty's ministers, any officers in the army, member of a tribunal, or any person in place, the whole proceedings should be laid before the king to be revised and examined. By this law the principal persons in the kingdom have obtained an additional security against the arbitrary rigours of the holy office. It is to be regretted, that it was calculated to defend those who cannot want protection rather than those whose obscurity frequently renders their complaints ineffectual, and who consequently are exposed to be unjustly treated with more impunity. But where they have no part in framing the laws the people are almost every where either forgotten or oppressed.

The holy office to this day receives a certain tax from each vessel that arrives in any of the ports of Spain, in consequence of the examination it is authorised to make in order to see that the vessel contains nothing that may be offensive to religion. The search has for a long time been neglected, but the duty is still paid to the office. Were this the only complaint against the Inquisition, we should easily be reconciled to it.

In 1789 I concluded this long article on the Inquisition with a hearty desire that the sovereigns of Spain might consider themselves sufficiently sure of the submission of their subjects, of the watchfulness of their temporal courts, and of the enlightened zeal of its prelates, to make this tribunal wholly unnecessary. I am however apprehensive that after what has happened latterly in Europe, the object of my desire is wider of its completion than ever. I fear that sovereigns, however wise they may be, from a jealousy of a diminution of their authority, will foster more than ever such supports to their empire (shaken by the violent convulsions which have happened) as may yet remain; and that they will gain an additional argument in favour of institutions which tend to prevent the disorders of irreligion from the excesses of the loose philosophy which in France has exceeded all bounds. There appear more than one ground for this opinion. Since the establishment of peace between Spain and France, priests have again acquired

their pristine ascendency, the professorships of public right have been abolished, and the works of Macanay on the Inquisition have been reprinted. Whether to preserve quiet it be advantageous to muzzle and hoodwink a generous nation; whether it be a safer way to conduct it through the paths of darkness than by affording the use of the light of reason; whether in short, to use the language of despotism, a moderate government be not the most proper one for protecting the governed from the explosion of liberty, time must discover.

Before I quit the subject I shall take notice of a political body, which many stranger-confound with the Inquisition, but which has no other relation with it than their com-

mon epithet.

This is the santa hermandad, much spoken of in Spanish novels; it is no more than a confraternity, dispersed over different parts of the kingdom of Castile, whose object is to watch over the safety of the country by apprehending those who disturb the public peace. It is subordinate to the council of Castile, from which it receives its regulations. One of the strictest is that which prevents its jurisdiction from extending to cities. The principal detachments from it are Toledo, Ciudad Rodrigo, and Talavera.

Let us resume what remains to be said respecting the interior administration of Spain. We began with the council of Castile which lead us to the administration of justice, to legislation, and finally to the tribunal of the holy office. In the succeeding volume we shall take a view of the other different councils of the monarchy

VOLUME THE SECOND

CHAPTER I.

COUNCIL OF FINANCE IN SPAIN. TAXES.

WE are now about to enter the vast career of finance, revenue, imposts, debts of the state, public debt, &c. tiresome eareer, which frequently exhausts the patience of the minister who has to levy the taxes, and more frequently that of the persons who have to pay them; a barren subject, which possibly may weary many of my readers, on which account I shall be as short as exactitude will allow.

The finance department in Spain is under the direction of a sovereign permanent

council, called El consejo de Hacienda.

This Real Hacienda, the name of which inspires a sort of terror, does not badly resemble the cave of the lion described by La Fontaine:

Towards this cave
I trace full many a footstep go, but none
Of beast returning.

The supreme guardian of the Real Hacienda, the council of finance, is, as well as that of Castile divided into several chambers, or Salas, la sala de govierno, sala de justicia, sala de millones, and la sala de la unica contribucion.

Their names sufficiently indicate their functions.

The contaduria mayor is a sort of chamber of accounts whose decisions are sanction-

ed by la sala de justicia.

It must not be confounded with la contaduria de valores, a particular office whose business it is to keep an account of the rental of the kingdom, of grants, and privileges.

Nothing can be more complicated than the forms which are to be gone through in passing the different offices before you attain the royal treasury; forms which owe their origin as much to a salutary mistrust as to chicanery. Woe to creditor, woe to the solicitor who has to trace the windings of this labyrinth.

The royal treasure is kept by two general treasurers, who are alternately in office for

a year, and pass the year they are out of office in clearing their accounts.

Three general directors receive the royal rents, and have under them the collectors, and commissioners of duties, and their numerous fiscal agents, a legion formidable for its number and its talents. There are none in their way in Europe superior to these people; if they were as incorruptible as they are vigilant they might be taken for models. I had occasion on my first journey to Spain to appreciate the value of this class of Spaniards; and on my return in 1792 I perceived to my cost and that of a number of appellants of whom I was the organ, that it had yet made improvement towards fiscal perfection. Events, augmenting the animosity of the underlings of office towards the French, tended to sharpen their intermeddling genius, which at times was at its ne plus ultra. Whenever desirous of comforting myself for having no longer any relation with Spain, I have but to recollect its administrators of the customs, its judges of smuggled goods, and inspect its whole tribe of tax-gatherers.

Let us examine how much arrives at this treasury, so well defended against besiegers, so frequently pillaged by its defenders; how much these revenues so harshly collected amount to. Up to 1714 all the revenues, as well of the interior as of the customs, were farmed. At that epoch government took the collection into its own hands. Two years afterwards the taxes of the interior were farmed and continued so until 1742. The people suffered, as is the case where the taxes are farmed in every country. Representations were made to Philip V, which stated all the irregularities in the collection. The representation of 1734 may be found in the Economia politica de Zabala; and in the institute of Don Martin de Loynaz, that of 1747. It is only necessary to read these to be convinced, that wherever there are men there will be abuses, and to learn the lesson of being ourselves less affected at those to which we are witnesses or victims.

Campillo, however, who had passed through all the offices of administration, and who possessed firmness and extensive knowledge, had frequently asked the Spanish farmers-general what they gained by their farms; according to their own accounts, they were constantly loosers. Campillo, determining to learn the truth, suddenly put six of the twenty-two provinces, of which Castile is composed, into commission. In 1747 the marquis de la Ensenada extended this measure to the remainder, and since that time nearly all the collection of Spain has been managed by commissioners.

Two years afterwards Ferdinand VI, adopted a project which had often been agitated in Spain, that of converting into one contribution those which form what are called provincial rents. In 1749, a commission was established for this purpose, under the name of Sala de la Unica Contribucion. It employs thirty thousand persons, and its annual

expence is upwards of three millions of livres (125,000l.)

Until the operations of this chamber shall have answered the purpose for which so much care and money have been applied, the defective form of the chamber of finance will remain; the people suffer by it, and good citizens loudly complain; but the sovereigns of the present family have not yet been able to find a remedy.

The finances of Spain are divided into two classes, which compose almost all the re-

venues of the king: General Rents and Provincial Rents.

The first arise from duties paid at the frontiers upon merchandise entering or going out of the kingdom. The duties are different with respect to their name and propor-

tion in different provinces. In those where the Moors longest resided, they have preserved the Arabian name Almojarifazgo, first given to a custom-house duty that has been successively increased, and upon which the Spaniards have speculated more or less advantageously with commercial nations. It is still known by the same name in the Canary Islands, where it produces the king six per cent, upon all merchandise.

In most of the other provinces it has been increased by degrees to fifteen per cent, upon every article of importation or exportation. In Catalonia, they are not so much as four

per cent, ad valorem.

Notwithstanding its privileges in Navarre, a duty is paid of five per cent, upon every

commodity entering its exterior frontier, and three and a half on exportation.

Hence it already appears, that the finances of France were not the only ones which were complicated, different in different places, full of exceptions, and exposed to the caprice of collectors. What I have mentioned is but a slight sketch of the complication of those of Spain.

Besides these general laws which extend to the greatest part of merchandise, there are several articles, such as cocoa, chocolate, sugar and paper, which pay particular

The whole produce of the general rents when they were farmed did not amount to six millions and a half of livres. A few years after they were put into commission they produced ten millions, and have since rapidly increased.

In 1783, at the close of the American war, they produced a total of nincty-six millions of rials; 1784, one hundred and twenty; 1785, one hundred and twenty-eight and

There are some other duties which may be included in the general rents, although differently collected, and their produce enter not the same chest; such are

The duties of the office of health, first established at Cadiz, and since extended to the other sea ports of the kingdom.

The duties of the grand admiral, which were appropriated to the treasury by Ferdinand

Two other duties, one under the name of Lanzas, the other of Medias Annatas, which we have spoke of under the head of titles, and which collectively in 1787 produced 5,400,000 rials.

The rent of wools, which is the duty paid according to their quality on exportation, It was farmed at less than 12 millions of rials. In 1777 it produced more than 20 and in 1789 nearly 28 millions.

The produce from the sale of salt, which is in estanco, that is, exclusively sold for the king's account, throughout all his European dominions. This tax was for a long time very unproductive. In 1785 it scarcely yielded 16 millions of rials, but then the measure of from 60lb. to 80lb. weight was sold for a rial (that is, 2\flactdd. sterling); but the price of the measure being raised, it produced in 1789 about 56,000,000 rials. It has been further productive, from the war having caused the price to be augmented. For, in Spain, to the injury of the country and to the misfortune of its inhabitants, objects of the first necessity are those on which all taxes and augmentations are imposed.

In other respects, the price of salt is eniform through Spain, with an exception of some drawback afforded in the ports for such as is used for the fisheries. The salt-pits of Andalusia, and the dry salt-pits collectively, are insufficient for the consumption of the kingdom; great quantities are therefore brought from Portugal. Seizures and executions are rare in Spain with respect to salt; the avidity of the treasury being less rigorous

with respect to this article than others.

The duty on tobacco is a particular branch of revenue in Spain. It has been collected by commissioners ever since 1731, and has a particular administration. In 1785 there were but two sorts of tobacco: viz. smoking tobacco from the Brazils, which Portugal, by virtue of a contract, delivered at 2 rials per lb. and which the king re-sold at 40 rials; and tobacco pulverised, or snuff, known every where by the name of Havanna, or Span ish smill, and which comes from Cuba. The king pays rather a higher price for this than for Brazil tobacco. In 1785 it was sold at the same price of 40 rials per pound; from the sum of the produce of the sale the salaries of the persons employed were to be deducted, and the expences of the manufactories, the principal of which is in Seville; all which charges increased the cost to the king per lb. to 8 rials.

For a long time the government prohibited the use of all other kinds of snuff, called cappee, to distinguish it from the real Spanish snuff, which is powdered exceedingly fine, and coloured with a kind of other called almazaron, which gives it its tinge and

unctnosity.

In spite of, or rather on account of the rigorous laws, and the vigilance of the persons employed, who on this occasion take upon themselves to behave in the most insolent manner towards strangers, particularly such as arrive by sea; Spain was inundated with smuggled tobacco; and the only persons who gained by the prohibition were those who sold it underhandedly, charging even as high for it as a guinea per pound, in order to cover the risk they ran in thus satisfying the decided taste of men for what is forbidden. This taste was participated by all classes of Spaniards, by those especially who should have recommended abstinence by their own example. The members of the diplomacy alone were exempt from the regulation, and even they required an express permission from the minister of finance, for allowing the entry of the quantity of rappee requisite for their consumption. The two predecessors of the reigning sovereign had a settled objection to the use of this tobacco, which had somewhat of mania in it; and should any about them have presumed to take it, it would have been exceedingly difficult for them to «scape disgrace.»

At length, the Spanish government was convinced, that the only mode of curbing this addiction to smuggling, was to cause rappee snuff to be manufactured, and vend it for its own account. No nation had more advantages for this kind of speculation than she herself possessed: the cultivation of tobacco has succeeded in the greater part of her colonies; in Mexico, on the coast of Caraccas, at the isle of Trinidad, and particularly in Louisiana. As for Mexico, in which country the culture of tobacco was not begun before 1765, the king in 1778 drew from it four millions of hard piastres, and six millions in 1784. Galvez, the minister for India, intended the tobacco of Louisiana, which is cheaper and better, should furnish the consumption of Mexico, and by degrees the rest

of Spanish America.

The sale of tobacco is one of the most considerable branches of the royal revenue. In 1776 it amounted to more than 87 millions of rials. In 1777 to 85 and upwards. In 1784 to about 73. The introduction of rappee snuff rapidly increased this receipt.

^{*} Charles III, himself had a great predilection for rappee shuff, but only indulged his inclination by stealth, and particularly white shooting, when he imagined himself to be untoticed. The following ancedote will serve to show how much Ferdinand VI, in other respects humane and good natured, was looked upon as severe towards those who infringed the laws relative to proscribed tobacco. One day in his presence, a grandee of Spain drew a snuff-box from his pocker full of rappec. The king cast a threatening look upon him; when the French ambassador (M. de Duras) perceived it, and, advancing towards the Spanish nobleman, exclaimed, "Oh! it is your excellency who has my snuff-box. I could not think what had become of it." This fortunate expedient released the delinquent from his embarrassment, and dispersed the anger of the king.

In 1787 it amounted to 129 millions, and since the last war it must have been much more. The king, in order to meet the current expences, having been obliged to augollected ment the greater part of the indirect taxes, raised the price of rappee from 26 rials the 35 there pound to 42. Possibly this augmentation will long survive its origin. ortugal, Many sorts of rappee are manufactured in Spain, some of which are equal to the 40 rials , or Span-

snuffs of other countries; this however does not hinder the latter from being sought af ter with nearly as great avidity as before, having a double attraction, in being prohibited

first, and secondly in being less dear.

There are also other articles in estanco besides salt and tobacco. These are lead, gunpowder, eards, Spanish wax, and stamped paper. Brandy and other spirituous liquors are not properly in estanco. The sale of them has been free throughout the kingdom since 1746; but the following year the council proposed to establish a magazine for the king's account, and most people prefer purchasing there because the liquors are better and cheaper. Such a monopoly is commendable, and cannot fail of being admired.

I omit several other small impositions, the detail of which would exceed the bounds

prescribed to my work.

But the most reprehensible part of the taxes of Spain is the provincial rents: a species of impost which, chiefly falling upon the consumption of the most necessary articles, burdens the people, and is one of the greatest obstacles to industry. For two ages and more the good citizen has exclaimed against this impost. Government is indeed convinced of its impropriety. The minister Campillo conceived the project of a total reform, but was dismayed by the trouble and the danger it presented. La Ensenada, one of his successors, with greater power and more courage, went a little farther, but we have seen his unica contribucion is only yet a project. Unhappily the system of Spanish finance depends on circumstances which it would be necessary to change for its amelioration. Besides which, the continual urgency of state necessities has never permitted government to risk the security of its revenues by experiments which might create confusion, or the success of which might be dubious. We have seen in France what it cost M. Turgot and M. Necker to plan a similar reform. To produce it in Spain favourable opportunities are necessary, and a sovereign and ministers who should not be alarmed at the clamours ever excited by innovations, or a French revolution would ensue. But it is not every country which is alike disposed to provoke, nor equally susceptible of bearing one; and if Spain be destined to experience this happiness, or this scourge, it is not improbable that the cause will be its finances. Those who are the greatest sufferers are too widely dispersed, too ignorant, have too few means of communication, and are consequently too easy to be kept in restraint, either by a military force or the clergy, for government to fear; and France has given a lesson to sovereigns which they will not fail to profit by, so as not to neglect the two supports in their possession for upholding their authority, the sword and the gown. The most moderate, the most beneficent will doubtless endeavour to render their yoke supportable, They will lessen the burthen of taxes, will avoid giving cause of complaint to their subjects; but they will take especial care not to invite them in a fatherly manuer, to come and present their quires of sufferings; and the States General of France have dealt a death blow to the Cortes of Spain.

Until some circumstances may operate a reform, the subjects of the Spanish monarchy

are exposed to a most destructive system of taxation.

The provincial rents are,

1st, The produce of a duty upon wine, oil, meat, vinegar, candles, &c. Philip II, overwhelmed by the weight of the ruinous enterprises to which he was impelled by his ambition, proposed it to the Cortes in 1590, who consented upon conditions, most of

iclination by he following good natured, obacco. One The king d it, and, adny snuff-boxinquent from which have been violated. This grant, which has since been renewed every six years, and has had different augmentations, is called the servisio de los millones, because it was levied to raise a certain number of millions of ducats. This impost is collected in two modes, either immediately by the commissioners of finance, or by way of subscription; nor encabezamientos.

The second method has only the edvantage of diminishing the number of persons employed by the treasury; but it is in reality more oppressive to the people. The contribution for which many cities, boroughs, and communities subscribe is arbitrarily exacted by the magistracy of each, who establish a public magazine or warehouse (abasto) where individuals are obliged to purchase by retail the articles subject to the duty. The lower classes of people who cannot, like persons in easy circumstances, lay in a stock, feel all the weight of this odious policy. Their houses are searched to see that they consume nothing but what they purchase from the abasto; hence arise oppressive prosecutions, which sometimes to those least able to afford, causes their proportion to be double what it should be towards the sum the city or community to which they belong has subscribed.

2dly, The provincial rents comprise the alcabale, a duty paid upon the sale of all moveables and immoveables.

This was first granted by the Cortes in 1342. It was then but a twentieth of the thing sold. In 1349 it was increased to a tenth, and rendered perpetual. In the sixteenth century it received four additions, each an hundredth part; whence it received the name of cientos.

These two duties united, and collected together under the common denominations of alcabale y cientos, ought therefore, strictly speaking, to amount to fourteen per cent, but they vary in different cities and provinces according to the privileges granted by the sovereign, which in some places have entirely superseded them; and they are no where levied to their utmost extent. According to Ustariz, and such observations as I have been able to make, their average is about six or seven per cent. Notwithstanding these modifications they do not prevent the tax being highly burthensome to trade and industry.

3dly, The tercias reales are another impost jointly collected with the provincial rents, it is the two-ninths which the court of Rome since 1274 permits the kings of Spain to receive upon all the tenths of their kingdom. It is received in kind from the produce of the earth, and is afterwards sold for the king's account. This impost scarcely produces six millions of rials; and would be susceptible of a considerable augmentation, did not government, in collecting it, trust to the unfaithful statements of the ecclesiastical offices.

4thly, The ordinary and extraordinary service, and its fifteen in the thousand, is a species of tax paid by the plebeians only, who in Spain are known by the denomination of estado general. It is collected with the alcabale y cientos, according to an assessment made by the tribunals, in proportion to the known property of each of the contributors.

5thly, There is besides an impost upon the sale of souda and barilla, with some other particular taxes, which cannot be enumerated in this general account.

Lastly, The duties of entry into Madrid form another source of revenue to the king; they are at present farmed out to the community of Gremios, at seven millions and a half of reals. All the interior contributions of the provinces of the crown of Castile produce about 120 to 140 millions of rials (or somewhat above one million four hundred thousand pounds sterling.)

ie king; is and a tile proiundred The provinces of the crown of Arragon have another form of taxation. They are exempt from the alcabale, for which equivalent duties are substituted; they pay one general contribution, which each city, borough, and community assesses proportionately on its inhabitants. As these provinces were the last to acknowledge the authority of Philip V, that monarch, to punish their obstinacy, deprived them of a part of their privileges, and established a form of taxation different from that of the crown of Castile. But his intention was evaded; and, in fact, they are better treated in this respect than the rest of the kingdom.

The provinces of the crown of Arrage vare besides subject, like those of Castile, to the impost called tereias reales, and obliged to take, at a fixed price, the articles salt, to-bacco, lead, &c. which are sold for the king's account. Both are alike liable to the

bull of the crusade.

The primitive object of this bull was to grant indulgencies to those Spaniards who should contribute, either by personal service or subscription, to support the war against the infidels. The destination of the produce of the bull is still the same, since the Spanish monarchs who receive it are obliged to apply it to the support of their fortresses and garrisons upon the coast of Africa. Until the reign of Ferdinand VI, this grant of the court of Rome was to be renewed every five years; a subjection of the inconvenience of which Philip V, was sufficiently sensible on three different occasions, when his quarrels with the holy see prevented him from obtaining a renewal of the bull. It was not until the compact of 1753 that it was made perpetual: since that time it has become a constant source of revenue to the treasury; and if Spain, influenced by motives of policy and humanity, should become reconciled to every infidel nation, as she has been under the present reign to the Ottoman Port, and some of the Barbary regencies, this tax, though inapplicable to its original purpose, would not the less continue to be levied.

The price of the bull is fixed at 21 quartos, about 14 or 15 sols (7d. or 7½d.) No Catholic in Spain can dispense with buying it without having his orthodoxy suspected. Provided with this bull, besides the indulgencies annexed to it, he has the liberty of eating meat, with the consent of his physician and confessor, as also to eat eggs and milk

on fast days, and during Lent.

This species of voluntary taxation is received by the magistrate, who bears the title of commissary general of the cruzada; it produces to the king from eighteen to twenty millions of rials.

The elergy are not exempt from it, nor is this the only tax they pay.

In the first place, they are in part subject to that of los millones; but to this it is necessary the pope should consent of rysix years by a brief. As there are many places where separate accounts are not kept for ecclesiastics, they pay the whole tax in common with the laity; but the consumption which each ecclesiastic makes in wine, oil, and other articles subject to the millones, is carefully estimated and always in their favour. In this manner a calculation is made of what they ought to pay of the tax, and they are reimbursed whatever they have paid above this estimation.

But, as in most cases, actual fact differs a little from right, the elergy pay next to nothing of the millones, in the smaller districts, where they easily acquire a preponderance,

and the weight of the tax falls upon the body of the people.

There is another trifling impost called subsidio, to which ecclesiastics are also subject. But the greatest contribution levied upon them is the escusado, which also is denominated casa dezmera, tenthed house, because it consists in the right granted by the holy see to the kings of Spain, to appropriate to themselves the most advantageous tythe of each parish, as well of the crown of Castile as that of Arragon. This contribution, were it

exactly levied and collected, would bring a very considerable sum to the Spanish treasury; but it has been made an object of speculation and subscription, which has considerably diminished its produce. Under the reign of Ferdinand VI, a resolution was taken to discover what it really would produce, and for this purpose it was for some years managed by commissioners. But before sufficient information was obtained, the marquis of Squilace, coming to the administration of finances almost at the same time that Charles III, ascended the throne, was too much in hister to farm it. And notwithstanding it was proved in 1756, that for the crown of Castile alone it might be stated at 16 millions of rials, the minister of finances farmed out the whole of the escusado, for Arragon, as well as Castile, at twelve millions, to the corporation of merchants at Madrid, commonly called the Gremios; and since then a part of the clergy have obtained a power of managing it on their own account, with which privilege they were allowed an abatement of one-third, so that in 1779 it did not produce more than ten millions.

Notwithstanding these restrictions, if we observe that the tercias reales are still an indirect impost on the clergy, and at the same time recollect that the kings of Spain have the power of granting pensions upon all benefices, even to a third of their produce, we shall find there is little foundation for the assertion that the Spanish elergy do not contribute to the expenses of government. Moreover, subsequent to the war terminated by the treaty of Basle, with the permission of the holy see, the elergy was even more heavily taxed than the rest of the nation; the extraordinary assessments upon it on this occasion amounted to 36 millions of rials. This preference it certainly well deserved. It had exerted very successful efforts to inspire the people with the opinion that the cause of God was identified with the war against France. I have been satisfactorily assured that an offer was made by the general of an order to the king in 1793, to raise a corps of 40,000 monks, to be commanded by himself.* The offer was however not accepted. But the Spanish elergy not being admitted to serve the sacred cause in person, the government thought it reasonable it should contribute from its immense revenues.

It may be imagined, that Spanish America is one great source of revenue to the royal treasury, but hitherto its produce has been but trifling, if the revenue arising from the mines of Mexico and Peru, and the duties paid on the importation of its produce into old Spain, be excepted.

For a long time the expences of the administration of these immense colonies were not defrayed by the revenues they produced; and it is only since the administration of M. de Galvez, that Mexico has yielded a surplus by the establishment of the farm of

All the duties and contributions, of which I have given a summary account, produced in 1776 no more than 440,000,000 rials, in 1784 they produced 685,068,068, in 1787 only 616,295,657. This is the result of the account given by Lirena, the minister in 1789. This account, which will long be famous in the history of Spanish finance, although it be not the first of its kind, yet deserves some notice. Lerena, who up to the day of his death was considered a novice; whose rapid and inexplicable fortune caused in 1785 astonishment mixed with indignation, and who carried with him to the grave the hatred of the public, earned by his rigidity, his violent measures, and his persecuting, ungrateful, and vindictive spirit; Lerena was however firm and laborious; his account gives sufficient evidence of this. The new king, being desirous of establishing that reform in his finances which the happiness of the nation and the public voice

establishbli**c v**oice required, ordered to be laid before him an account of all the suppressions that could possibly take place of officers employed in collecting the taxes. Lerena in his account began with an assurance, that, taking the diversity and complication of the imposts inteconsideration, any suppression whatever was impracticable.

In order to prove the inconvenience which, as he termed it, a pitiful economy would occasion, he cited, on one hand, the example of England, which, for the simple branch of the customs, had nine directors with large salaries, and drew from it on an average £3,789,274 sterling (this was previous to the first war with France) and, on the other, that of our famous general, who, having neglected to appoint inspecting clerks agreeably to the additional convention of 15th Jan. 1787, for the purpose of valuing the English merchandise allowed by the treaty of commerce to be imported into France, the revenue of that country was defrauded of two or three millions of livres, and France was inundated with a flood of English goods, to the material injury of her own manufactories.

It had been asserted, that the salaries of the officers amounted to at least one half of the taxes collected. Lerena affirmed this to be a manifest falsehood; and proved it by the following detail:

Thus did they each absorb more than a tenth of the whole revenue. Lerena added, that on his coming into administration, Spain had an annual deficit to cover of 40 millions of rials; that he had augmented its revenue more than 100 millions, and expected still to increase it 50 millions more. Death, however, did not allow him to realize these brilliant hopes; and the expences to which Spain became afterwards subject would otherwise have obliged him to forego his plan.

The remainder of his memoirs is but an apology for the courage and activity that he had displayed; a little master-piece, of arrogance, in which he is neither modest with respect to himself, nor parsimonious of injurious expressions against the great, the rich, and the ignorant, in which classes alone, he assures the king, are there any calumniators

of his administration.

As a representation of the revenues of Spain, there is nothing war	nting in this piece.
A display of its debts and expenditure is however a desideratum whice	h is elsewhere to be
sought for.	Rials
In 1776, the sum of its expenditure was	505,586,474
Of which the army cost more than -	200,000,000
And the navy above	127,000,000
It is true in that year the navy incurred the greater part of this	
expence in a very short war with Portugal.	
In 1777, the total expence was	476,385,565
Out of which the army cost more than	210,000,000
And the navy but little above	86,000,000
And as the whole of the revenue this year amounted to no more that	
There was consequently a deficit of	104,038,681

Let us proceed to detail it, and advert to its source.	

CHAPTER II.

ANCIENT AND MODERN DEBTS OF SPAIN, GREMIOS. ROYAL NOTES. PROJECTS FOR THE AMELIORATION OF THE FINANCES.

THE sovereigns of the Bourbon family inherited from those of the house of Austria debts, called Juros, which however, bear but a moderate interest. This is yet a charge to the state of about 20 millions of rials (203,000l.) the payment of which is made from different branches of the revenue.

Philip V, left debts to the amount of 45 millions of piastres (about 7,500,000l. sterling.) At his death, Ferdinand VI, terrified at so enormous a burden, and hesitating between the fear of making the state support it, and the scruple of depriving the creditors of their right, assembled a junto, composed of bishops, ministers, and lawyers, and proposed to them the following question: Is a king obliged to discharge the debts of his predecessor? It was decided in the negative. The conscience of his majesty was quieted, and bankruptey resolved on.

Ferdinand VI, carried his inconsiderate economy still further. Wholly employed in making savings, he suffered every branch of administration to languish; the army, fortresses, and colonies were neglected. When Charles III, ascended the throne in 1759, he found in the royal coffers upwards of 6,000,000l, sterling, and thought it incumbent on him to repair the fatal omission of Ferdinand VI. In 1762, he paid six per cent, of the capital due from Philip V, and continued paying annually the same for five years. In 1767, the dividend was reduced to four per cent. The following year sixteen millions of rials were distributed among the creditors; and in 1769, the expenses of the state were so increased as to necessitate a suspension of further dividends; an interruption which gave the finishing stroke to the credit of royal effects. Whilst I was in Spain the

first time, people were glad to sell their claims at a loss of eighty per cent.

However, there are some opportunities of disposing of them to greater advantage. Sometimes on treating with government upon any enterprise it wishes to favour, a certain portion of them is received at par. They are, moreover, received in payment of the medias annatas; but, except in these particular cases, the claims upon Philip V, are almost of no value; they hear no interest, and the entire liquidation of them, if ever it should take place, can only be considered as very distant, particularly to foreigners. For them, however sacred their claim, however powerful their advocates, they must seek in vain for exception from the law which forbids the payment of foreigners until such time as the nation's creditors be wholly satisfied. I have frequently heard the following proof related at Madrid: A valet de chambre of Louis XV, was a holder of one of these securities, and imagined he might profit by the favour shewn him by the king to obtain an exception. Louis XV, wrote with his own hands to Charles III, requesting he would grant it; but the Spanish monarch answered the king, that he was obliged to refuse his request.

Charles IV, upon his accession to the throne, testified his wish of paying the debts of Philip V, and Ferdinand VI, pointing out those which he was desirous should be wholly paid, and those which the treasury might receive in payment of duties. Scarcely had these measures been sketched out, before preparations for an useless war, and shortly

after the consequent expences, obliged him to suspend them.

So many aberrations from their purpose cannot but have greatly weakened the credit of the Spanish government. Of this Charles III, whose honest nature inspired universal

esteem, twice had a vexatious proof.

In 1783, he endeavoured to open a loan of 180 millions of rials (about 2,000,000l.) One of the conditions of which loan was, that the claims upon Philip V, should be received to the amount of a third of the subscription. This, however, did not raise the value of the claims so much as was expected. At the beginning of the year 1785, it had searcely produced 12 millions of rials, and it was soon afterwards closed. Foreigners were unwilling to expose themselves to fresh hazards; and as for the Spaniards themselves, they are in general suspicious, and have no disposition towards stock-jobbing. They prefer a moderate gain to hazardous speculations so eagerly adopted in some other countries; and are more than any other nation attached to ancient habits.

For a long time past, far from being tempted by foreign speculations, they confine their confidence to a company of merchants at Madrid, known by the name of Gremios, which

we have already mentioned.

The treasure of the Gremios is a kind of public bank, in which individuals may place their money at the moderate interest of two and a half and three per cent. The foundation of the confidence it inspires, is the constant support which government has given

the Gremios, and the regularity with which they have always paid the interest of the capital in their hands; and although they may have hazarded speculations beyond their ability, and they be continually in advance to government, nothing hitherto has shaken their credit. They hold, as we have observed, the farm of the duties on entry at Madrid, and a small portion of the escusado; and are concerned in the principal manufactories in the kingdom. The government, which has frequently had recourse to them in cases of necessity, has long considered their bank as the chief pillar of the state.

Administration, however, has lately perceived that it could do without them. Necessity even made this a law. At the beginning of the American war, the state no longer having at hand the extraordinary resources required for the maintenance of its forces by sea and land in both hemispheres, and deprived of the periodical treasures brought from Spanish America, which it was unwilling to expose to the seizure of English privateers, thought it necessary to make use of a resource, until then unthought of in Spain. It made application to some French merchants established at Madrid, and negotiated by their means a loan of nine millions of piastres (about 1,500,000l. sterling) and issued paper to the amount of the same sum. This was divided into sixteen thousand five hundred bills, or vales reales, of six hundred piastres each, at an interest of four per cent. Government were blamed for not having established at the same time a bank, at which these bills might have been paid in cash on presentation; but disposeable funds would have been requisite for such a measure, and the simple creation of paper-money proved that of such they were delicient.

The court was blamed, with more apparent reason, for having negotiated the loan upon disadvantageous terms, which betraying its embarrassment could not but diminish public confidence. In fact, the bankers who by their credit realized the loan, asked ten per cent. commission, and obtained it. But in such negotiations the lender calculates his risk, and the borrower his necessities; hence arises the law which one imposes and the other receives.

However this may be, as soon as the negotiation was made known of the motives and securities, alarm became general. All exclaimed against a measure which, said they, the most extreme distress could scarcely excuse; a measure sometimes taken to discharge pressing debts, but never to contract new ones. Foreign bankers, who had advanced their money, stated, through the medium of Mr. Necker, that they were taken by surprise, and intimated deception, seeming to suspect that the Spanish government had conceived the wild scheme of re-imbursing them in paper, or the ridiculous hope of giving this paper a value out of Spain. It lost not a moment in removing their fears, and proving to them by actual reimbursements, how little foundation there had been for alarm.

Nevertheless the bills circulated in Spain. But the temptation of a greater interest than that commonly paid for ordinary subscriptions was not sufficient to give them credit. Every person took as few of them as possible, and was eager in passing them again. In course of the war they were at a loss of twenty-six per cent, and the people exclaimed loudly. They knew not that at the same time the Americans, fighting for their liberty, almost entirely destitute of coin, saw their paper-money fall to forty and fifty per cent. It was not foreseen that a neighbouring nation, struggling for the same cause with almost all Europe, would have paper of which four and five hundred should be given for one, and yet survive the crisis.

This momentarily critical situation of government was a new triumph for the Gremios. The credit they enjoyed was increased by the diffidence with which the bills were re-

intage.

ceived. Their bank seemed an asylum to which people resorted to lodge in security

the money they thought exposed to danger in the hands of government.

In the mean time, the necessities of government increasing with the continuance of the war, new bills to the amount of five millions of piastres were issued in the mouth of February 1781; in short, the following year others were issued in bills of 300 piastres each, to the amount of 221,998,500 rials (2,500,000L). Its whole debt of this description then amounted to 431,998,500 rials (about 5,000,000L) sterling) without reckoning obligations of a less apparent nature, which raised it to near 800,000,000 of rials (9,000,000L sterling.)

At the time the first bills were issued, Charles III, engaged to withdraw a part of them annually from circulation. But as at the beginning of the war he had been obliged to overborthen his people by an augmentation of a tax on some of the principal necessaries of life; at the return of peace, he preferred alleviating this burthen, to keeping his engagement with the creditors of the state; and it was not before the moach of June

1785, that bills to the amount of 1,200,000 piastres were withdrawn.

A few weeks afterwards, to the astonishment of the public, other paper was issued, to the amount of 48,000,000 of rials; these last bills, it is true, had for object the continuation of the canal of Arragon, the profits of which were to serve as security, so that this could not be considered as a charge to the state.

In the mean time, the alarm which the real paper-money had excited was dissipated by degrees. The royal notes were taken at par, and at the close of 1786 they began to

be sought after, and even bore a premium.

The war which took place in 1793 made fresh emissions necessary; yet the vales were at the most critical period at no greater discount than 25 to 30 per cent.; which, as this kind of paper is destitute of any special security, if the precarious guarantee of a despotic government be excepted, is rather a matter of surprise. Towards the middle of 1796, these notes upon the frontiers were at a discount of 10 to 12 per cent, while in the capital they were at no more than 6 to 8 per cent, loss. At a later period, when a rupture with England was apprehended, they fell to 18 per cent, discount; and it was foreseen that in case of its taking place, the loss upon them would be unlimited.* The amount in circulation at that time was 1490 millions of rials (17,000,000l, sterling); and far from lessening the amount, a loan took place in 1796 for 240 millions more, at 5 per cent.

What a lesson for governments, whether monarchical or republican! A suspension of various useful enterprises, a spoliation of part of three of her provinces, the death of from forty to fifty thousand of her subjects, the loss of a valuable colony, which however did not in truth attain prosperity under her government, an increase of taxes and debt; these were the fruits which Spain reaped from a transitory abandonment of its real interests, in striving to avenge the death of a king, and the violation of its holy religion. At the instant of war being resolved upon, (I was witness to the general enthusiasm) the whole nation, with the exception of a few enlightened individuals, participated the indignation of the court. Religious communities, grandees, rich proprietors, all made it a duty to second its every effort. But the events of the war, almost wholly unfortunate, the obstinacy with which we defended a cause that the Spaniards at first considered so odious, the necessity of rest after such violent agitations, the tardy convic-

^{*}In effect, they fell 75 per cent. discount in 1801. But after the signing of preliminaries with England they rose rapidly. As early as 1802, they were but at 20 per cent. discount; and in the month of April, they were at Amsterdam at only 15 per cent. loss. The arrival of the treasure so long expected from America may possibly raise them to par.

ries with I in the Isure 50 uon of the slight interest which Spain had in weakening a neighbouring state, its natural ally; these collective circumstances abated its pristine warmth. Indifference with respect to the war at first, and successively impatience brought about peace; and never was peace more looked for, nor received with greater transport than that, the basis of which I was charged with establishing at Figueres; and which was definitively signed at Basle the 22d of July 1795, between the French republic and the king of Spain.

It was then hoped that the court of Madrid would employ its leisure and the savings of peace in repairing the breaches effected in its finance by a war, to say the best of it, useless and without object. But shortly afterwards a second rupture suspended the return of its external resources, and delayed the period of its employing the means of restoration. Government has, however, effected the discovery of them within the king-

dom, even in midst of the calamities of war.

Spain contains an immense quantity of funded property, known by the name of Memorias y Cosradias. The first consists in foundations made in favour of different churches, under the obligation of saying mass for the soul of the testator. The Cosradias are bequests of religious persons, consecrated to the particular service of the images of the Virgin Mary and various saints. For too long a time had the destination of these different properties made them to be considered as sacred. Under a less enlightened, and less courageous government, never would a minister have dared to touch them; and if the Spanish nation were so generally or so blindly superstitious as it is esteemed to be, they could not have been touched with impunity. This measure has, however, been taken, and happy has been the result since its adoption in November 1800.

The soil, palsied through the piety of the faithful, inalienable like other ecclesiastical property, was badly managed and worse tilled. Government exposed lands of this description to sale, for the purpose of successively cancelling the royal notes. In the early part of 1802 these sales had already produced ten millions of piastres (1,250,000l. ster-

ling.

Spain has reaped advantage from this measure in every shape, in spite of scruples, purchasers flocked in abundance. In the hands of their new proprietors these lands double their former crops. Thus has government made a long stride towards the amelioration of agriculture, and the increase of population. A few such additional efforts of courage will tend to rescue the country from that prejudiciable langour, more hurt-

ful perhaps to its interest than bad administration itself.

But in Spain perhaps more than in any other country, boldness must be tempered with caution. Innovations are there disliked: it is a country which clings to aucient prejudices; and this propensity has hitherto prevented the adoption of certain useful measures which, while they would have benefited the revenue, would not have been oppressive to the people. In the reign of Charles III, government had it more than once in agitation to appropriate to itself the property of the four military orders, which would have produced much more in the hands of the sovereign than under its present bad management, and besides bringing an increase of revenue, would have furnished the means of compensating by pensions the commanderies annexed to these orders. But the scruples of the monarch prevented the adoption of the project.

Another equally reasonable would be a general tax upon all the lands in the kingdom, not excepting those of the nobility and clergy. But this project, against which those two powerful bodies would certainly exclaim, and whose intrigues would present obstacles which the Spanish government might find it difficult to overcome, without calling in a dangerous support, will perhaps oblige Spain to await, in the slow resources of economy, the advantages she might propose to herself from a sudden but dangerous

change.

Under Charles III, the government, for from being alarmed at the treatment her returning credit first met with, did not defer a second attempt, intended to give to her paper an advantageous circulation, to awaken the Spaniards from their lethargy, draw from their chests the money there lying useless, both to themselves and the state, and throw it into circulation to the advantage of commerce and industry. Such were her great objects in establishing in 1781 a national bank, which has scarcely any thing in common, except its name, with the banks of other states in Europe.

CHAPTER III.

BANK OF ST. CHARLES. NOIES. COIN

THE idea of a national bank was given by a French banker, M. Cabarrus, established at Madrid, who began to insinuate himself into the favour of government at the time the first bills were issued. M. Cabarrus had a vigorous and firm mind, with talents cultivated in secret to the period which brought him into notice. The favour of the minister would not have sufficient to enable him to combat with success the numerous obstacles he had to encounter. Embarked in a project, in which a thousand prejudices concurred to prevent his succeeding, he has at once acquired great honour, and an immense fortune, diminished no doubt by the persecutions he has since undergone. Nothing but partiality can attribute to chance alone such brilliant and continued success. M. Cabarrus has had very ardent friends and bitter enemies. This is not the lot of common men.

In 1781, after having profoundly meditated on the resources of Spain too long unproductive, the causes by which they had been obstructed, and the means of giving them

activity, he digested the plan of a national bank.

Its principal object was to give employment to a large sum of money, which was either unemployed, or placed at a very moderate interest. The first means he proposed was to establish a capital, which would discount, at four per cent. per annum, all bills of exchange drawn upon Madrid. This expedient was trifling; Madrid is not properly a commercial city. The wool Spain sends abroad is the principal article paid for in that metropolis, and this alone would not have furnished any very fruitful employment for the capital of the new bank.

The profits of the realgiro were superadded, a particular species of bank, from which the court takes the money it has occasion to send abroad, either for the payment of ambassadors, envoys, consuls, &c. or for other purposes. This still was but a weak assistance, no more than two or three millions of livres annually passing through this bank.

But the chief source of profits which M. Cabarrus proposed to open to the national bank was the victualling and furnishing of the navy and army. Contracts for the first had heretofore been given to different persons. The second was held by the Gremios, and the several leases and contracts with these and the government were upon the point of expiring. The bank might therefore soon obtain possession of their privileges.

Government was easily induced to favour a plan, which went to distribute among a great number of citizens those profits hitherto confined to a few. The capital of the proposed bank amounted to the sum of 300,000,000 of rials (3,400,000l. sterling) divided into 150,000 shares, 2,000 rials each. No one who had property to purchase shares was excluded from the profits they might produce, and these, according to the prospectus, were very promising. Besides idle money to which a deposit was afforded

mong a l of the ing) diourchase g to the afforded that yielded a benefit, it was hoped that a great part of that in the hands of the Gremios, at a moderate interest, would be removed from their coffers to those of the national bank. The surplus of the levies of cities and communities were also counted upon. These were in the administration of the council of Castile, whence the national bank was to take, and place them for the advantage of the persons concerned. In Spain there are magazines of grain in most of the cities, boroughs, and villages. Their surplus is converted into money. This was also an unfinitful capital, which the bank might make productive.

The project appeared to promise great advantage to every class of citizens. It is not therefore astonishing that it should have been adopted by the administration.

It was discussed in 1781, in an assembly composed of members from the chief branches of government, and who came to a determination that the national bank, or bank of St. Charles, should be charged with victualling and clothing the army, and furnishing the navy with the articles above-mentioned, that it should be allowed an interest of four per cent, on account of the advances made to government, and a commission of tener cent.

The prospect held out was apparently seductive; however, the greater part of the people were unmoved by it. Few withdrew their money from the bank of the Gremios; who were only obliged to raise the interest they paid to three and a half per central new establishment had some partizans, but these appeared suspicious. Its antagonists, armed with the pretence of public good, forcibly declaimed against it; they kept up a mistrust for which anterior events had laid a foundation, and gained many over to their opinion.

The enemies to the new bank were, in the first place, all those who are equally so to every novelty; others whose calculations were deranged by it, and those especially who from jealousy or national prejudice looked with an evil eye upon a foreigner, supported by the ministry; who, said they, takes advantage of a transient credit to overturn a nation which might find among its own citizens men who understands its interests much better. The parallel already drawn between the creation of paper credit and the system of the famous law was then recollected.

The project in France was that of an ambitious stranger, who had given a mortal blow to the eredit of the kingdom, by endeavouring to render it flourishing. In Spain it was that of a stranger also, who pretended to animate public credit and commerce, and aspired to seduce the nation, by tempting it with a chimerical profit. Each had finished the plan of a bank; therefore the resemblance was perfect. Thus judge the greater part of men. Malevolence pretended, and echoed upon by credulity and ignorance, that the bank of St. Charles presented to the public a plan of operation illusive in its nature, and totally incompatible with the true interests of the nation; and which instead of favouring the liberty of commerce, must be prejudicial to that, as well as to agriculture and industry; that it naturalized an evil until then unknown in Spain, a class of useless annuitants who should live in opulence and idleness on the labours of their fellow-citizens; and that after having held up to public hatred all exclusive privileges, it carried on itself the most odious of monopolies.

What furnished a pretext for the last accusation, was a grant which the bank of St. Charles obtained soon after its establishment, for the exclusive exportation of piastres. This money it is well known is employed to pay the balance of accounts due from Spain to the other nations of Europe.

The exportation of piastres for this purpose cannot be dispensed with. In less enlightened times the Spanish ministry conceived the idea of turning it to advantage vot. v. 3 k

to increase the revenue of the state, such exportation was subjected to a duty of three per cent, which, in 1768, was augmented to four, and although the ministers are now convinced that it is only an additional tax on their own traders, to whom foreigners self their goods four per cent, dearer, the state of Spanish finances, and, perhaps, the remains of an attachment to old prejudices, have not yet permitted them to take it off.

The consequence is, that the duty being sufficiently high to give temptation to smuggling, it is cluded in every shape, and although a sufficient quantity be exported to cover the balance, the royal treasure is deprived of a part of its duties thereupon.

To remedy this inconvenience, the bank wished for the exclusive privilege of exporting all the piastres necessary to discharge the balance due from Spain, and represented that the grant would prevent the value of money from being increased, which must be the necessary consequence of multiplied negotiations; and diminishing the fraudulent exportation of piastres, by an extraordinary vigilance, such as could not be expected from the agents of government.

Its wish was granted and it was ordered, that to prevent the piastres from being fraudulently withdrawn out of the country, they should all pass by the way of Bayonne, and that those who should have money to send into foreign countries, should be oblig-

ed to take bills from the bank.

In spite of numerous exclamations proceeding chiefly from private interest, the bank of St. Charles was put in possession of its privilege in the month of November 1783. The first use made of it proved very advantageous to the subscribers. The return of peace brought with it a prodigious quantity of piastres. The bank exported upwards of twenty millions in 1784, and the year following nearly twenty-two millions. The revenue itself gained by the new arrangement. The most advantageous preceding years had not produced six millions and a half of rials; it received from it in 1784 upwards of fifteen millions, and from sixteer to seventeen millions in 1785. The bandage then fell from the eyes of ignorance; malevolence was dumb, and the bank triumphed. The single article of piastres affords twelve millions of rials as a dividend to the stockholders.

In the mean time the expiration of the contracts with government for the victualling of the army and navy had put the bank in possession of these principal sources of its revenue. Its dividends were consequently enlarged by it. That of 1784, the first it

made, was nine and a half per cent.

The triumph of the bank was then complete, and as men in all countries ever pass from one extreme to another, invective was soon changed into enthusiastic panegyric. The bank took advantage of this revolution, to increase, at different times, the shares which it had yet to dispose of, and thus enable itself to increase future dividends. The fermentation reached foreign kingdoms, which were then much addicted to stock jobbing. In a little time the shares of the bank rose in France, Geneva, and other places to 3040 rials; and the Spaniards, having less faith or more foresignt than foreigners, en-

couraged this inconsiderate ardour.

It was, however, but momentary, although it lasted long enough to produce pernicious revolutions in several fortunes. Some persons took upon them to oppose the predilection it had excited. Mirabeau particularly, that insurgent of public opinion, as he called himself, with an energy too natural to him, attacked the bank of St. Charles. He even wrote a thick volume against it, in which he was prodigal of his malediction, predicted the most baneful consequences to its proprietors, and loaded its author with innocent invectives. He affirmed, that great commercial nations had reason to fear lest their subjects, who had great capitals, should embark too much of their property in the bank of St. Charles, as they had need of all their aid to lighten the burden of their own debts;

luce pernise the pren, as he callarles. He ction, prewith innoar lest their the bank of own debts; and that individuals who exposed their fortunes in so hazardous an enterprise, acted like bad citizens as members of society, and like madmen as fathers of families.

The court of Madrid, in June 1785, proscribed the publication, but this proscription did not prevent the work from having effect. The cuthusiasm of French stock-jobbers abated, and never after revived. A great part of the shares of the bank, originally sold to foreign countries, have returned to Spain. The directors of the establishment redeemed thirty thousand shares in 1787 and 1788, so that at present there are no more than one hundred and twenty thousand in circulation.

Four years after its foundation M. Cabarrus projected a new source of profit by connecting it with the Philippine Company, of which he had just laid the first stone. He induced the stockholders in 1785, to add to the funds of the company the sum of twenty-one millions of rials, deducted from the dividend of 1784. Whatever may be the issue of this new institution, this partnership cannot at any rate be prejudicial to the funds of the bank.

The epoch of the infatuation which it caused is gone by, probably never to return, that of its aspersion should also be passed, the public opinion with respect to it appearing now to be settled. It is clear, in spite of the authority of Mirabeau, that without ceasing to be a good citizen or a good father of a family a man may buy stock in the bank of St. Charles; since it may be considered as firmly established, having overcome the storms which threatened it in its cradle.

Since 1785 almost all its meetings have been tumultuous. Lerena, who at that epoch became minister, began his career by manifesting his antipathy against its institutor; he intrigued against its former managers, and displaced them in a scandalous manner, substituting their enemies instead of them. He took away from the bank their commission for victualling the army and navy, which, according to treaty, they possessed a right to three years farther, and the profits of which might have repaired the losses arising from misfortunes of previous years; and gave the management of it to the Gremios, who had long impatiently waited for revenge. So many proofs of malevolence discredited the shares to such a degree, that towards the end of 1791 they scarcely sold for 1800 rials, dividends included.

The animosity of Lerena did not end here. Jealous of the credit and success of M. Cabarrus, whom he looked upon as a dangerous rival, and irritated by the incautious language which the latter allowed himself when speaking of him, he obliged him by his vexatious conduct to resign his situation in 1790, as perpetual director of the bank. Shortly after, having intercepted a letter of insignificant consequence, which he had addressed to one of his correspondents, he made it a pretext for arresting him. His detention lasted more than five years, and Lerena, as capable of nourishing as he was calculated to excite hatred, carried with him to the tomb the satisfaction of leaving his victim in prison. His successor M. Gardoqui had an injury left him to repair. Whether for want of credit, whether owing to the tardiness, which however left room for disagreeable interpretations, he was not ready in fulfilling this duty. The case of M. Cabarrus underwent those dilatory forms which are but too common in Spain, and which secret malevolence possesses many means to prograstinate. At length, in the course of 1725, he obtained a late but brilliant retribution. He was absolved from all the charges against him, reinstated in all his appointments, and authorised to prosecute the heirs of his persecutor for the damage which his fortune had suffered from his long detention.

Since 1796 M. Cabarrus has undergone great vicissitudes. He was honoured with the title of count; resumed almost all his prisone influence over the bank of St. Charles, which was his offspring. In a meeting where he was present, it was engaged that all

animosities and prosecutions should cease. By intimacy with the prince of the peace he recovered a part of his credit, and this supreme minister condescended in measure to take counsel of him in the nomination of two persons to the ministry, who where more indebted to public opinion than favour.

The count de Cabarrus was afterwards entry ted with some external missions of consequence. On his return to Spain, his enemies had given out that certain connections he had at Paris rendered him a proper person to be employed in the principal embassy

which Spain was then about to fill.

He was consequently appointed ambassador to France. When on his way to occupy this new character, it was remarked to the executive directory, that being born a Frenchman, he could not represent a foreign power in his own country; and his appointment

was not accepted.

This was an affront to him; it was made the subject of blame; from that period his credit declined, which was succeeded by a species of disgrace. After travelling for some time, returning to Spain, he found that his enemies had taken advantage of his absence. He soon saw that a philosophical retreat was what befitted best his situation, and in consequence retired to an estate some leagues distant from Madrid, where he has given himself up to agriculture and establishments of industry. But let us return to the bank of St. Charles.

Fifteen years after its foundation, it was in a far different condition to what it was at its beginning. It was to have been entirely independent of the government: it is totally under its controul. The court has appointed a conservatory judge, and has the greatest influence in the nomination of its directors. During the war with France its shares scarcely produced 1500 rials, although if one of the late years be excepted, it has constantly distributed a dividend of 6s. $5\frac{1}{2}$ d. 5, or at least $4\frac{1}{2}$ per cent.; a circumstance scarcely credible, if the diminution of its sources of profit be taken into consideration. It discounts but few bills of exchange, its external payments on account of government may be looked upon as next to nothing, the provisioning of the army and navy has been taken away from it entirely, and little remains by which any considerable profits can account to it beyond the exportation of piastres.

Such is the bank of St. Charles, so much more famous than it has deserved to be. It has neither justified the pompous promises of its founders, nor the sinister predictions of its enemies. But it must be allowed that all things considered, it has produced more advantage than inconvenience. It has electrified many heads which seemed destined to stupidity. It has developed and put in activity talents which were not suspected; and

has thrown into circulation much treasure which laid idle and unemployed.

This naturally leads to our saying a lew words on the circulating medium, and coins

of Spain.

It is not easy to ascertain exactly the amount of the currency in Spain. It has, within its dominions, mines which produce all the metals of which its coins are made. Stranged coins do not leave America without paying an impost; a second is paid upon their importation into Spain, and a third upon their export thence to foreign countries. It should seem from this, that by attention to the custom-house receipts it were easy to ascertain the existing circulation within the country. But of this money manufactured in the Spanish colonies, a great part is smuggled direct to different parts of Europe: another is carried away in a clandestine manner, for payment of foreign merchandise, before it touches a Spanish port, and lastly, as re-coinage is not common in Spain, sufficient data are wanting to determine the amount in the country with any nicety.

A short time before his death, Musquiez, who had been employed in the finance department either as head clerk or minister for twenty years, had not even a guess as to the amount. He acknowledged this in my presence before some Spaniards more enlight ened than himself, and it was in consequence of the discussion which took place on this occasion that I obtained information that the currency amounted to about eighty millions of hard dollars. Spain was at that time engaged in an expensive war, and had not then made the ruinous attack on Gibraltar. She has since been effecting, or preparing certain military operations, the consequence of which has been an extraction of capital without the country, which has not entered it again. In the war (notwithstanding its extreme shortness) which she waged with France, she has experienced losses which are not repaired for years, and in the succeeding one with England, all her means of prosperity being suspended, she cannot fail of having become still more embarrassed. Thus, although her commerce has been more extensive since 1782, and the produce of her mines be greater than before, her effective money may yet be deemed no greater than at that period. Perhaps it may appear surprising, that Spain, in possession of almost all the mines of silver, and a great proportion of the gold mines, should be reduced to so trifling a currency, particularly when one recollects, that at the time of Charles V, she was in possession of almost all the gold and silver in Europe, and (what is of infinitely more value) of the means of existing without intercourse with other states; from the fertility of the soil, and her abundant employment for the industry of the nation.

How is it that, in less than a century, this kingdom has fallen from this state of splendour? To what is so rapid and complete a revolution to be attributed?

To many causes, and firstly, to the abundance of its precious metals which have increased the price of commodities, and the wages of workmen.

To the decline of its manufacturers, which was the consequence; to its depopulation, caused by the numerous emigrations to America; and the expulsion of the Moors and lews.

It may also be more particularly attributed to the ruinous wars undertaken by Philip II, against the low countries, and which from the year 1567, to the truce in 1612, cost upwards of two hundred millions of piastres.

But let Spain enjoy some years of peace, let her government second the venerable disposition of modern Spaniards for all useful enterprises, she will then no longer see the greater part of her circulation withdrawn to pay her balances to foreign industry, and receive in other countries of Europe the stamp of other sovereigns.

The first coin, as well gold as silver, which was struck in Spanish America, was clumsy in its shape as well as its impression, which on one side was a cross, and on the other the arms of Spain. Some of it is still in circulation.

The impression varied until the year 1772, when a new coinage took place, in which the head of the sovereign was struck on one side, and on the other the arms of Spain on an escutcheon.

We are now about to give an exact prospectus of the different kinds of gold and silver coin stamped in Europe and America.

ANCIENT COINS NO LONGER STRUCK IN THE DOMINIONS OF THE KING OF SPAIN, BUT WHICH ARE CURRENT.

GOLD COINS.					The	ir valt	e.

value of the gold coin, without changing the weight or standard. By this operation, the quadruple, or doblon de aocho, which before was worth but fifteen great piastres, was increased to sixteen, and all the other gold pieces in proportion. The nations which possess precious metals give laws to the rest with respect to the standard of their money; and those who do not follow them must sooner or later be the victims of their obstinacy. This just observation, constantly confirmed by experience determined our ministry shortly after to increase the value of gold coin without altering its denomination.

There is in Spain a sovereign court which regulates and decides affairs relative to coin, under the title of real junto de commercio, moneda, minas, &c. it is composed of one member of the council of Castile, two of that of the Indies, and some of the members of the council of finance; and is as independent in its circle as the other sovereign councils

of the monarchy.

CHAPTER IV.

COUNCIL OF WAR, AND ITS ATTRIBUTES. MILITARY BANK. OF THE DUKE DE CRILLON. INFAN-TRY. METHOD OF RECRUITING. QUINTAS. MILITIA. CAVALRY. SCARCITY OF GOOD HORSES. ARTILLERY. ENGINEERS. MILITARY EDUCATION. OF COUNT O'REILLY. MILITARY REWARDS.

THE council of war is at the same time a tribunal and a permanent board of military administration; the king commonly consults it on issuing orders relating to his troops. Until the reign of Philip V, this council appointed the superior military officers. But the Bourbon family, laying aside by degrees every impediment that hindered the exercise of power, assumed this prerogative of the council of war. The king names to all military employments, upon the presentation of the inspector of each army. The inspectors adopt military measures on many occasions without the interposition of the council of war; but, for the sake of form, such as are taken without its concurrence receive its sanction. Thus it was, that our parliaments registered generally without de mur the edicts of the king. Sometimes indeed they pretended a shadow of opposition to his will. But even this feeble restraint to arbitrary power is beyond the force of the council of Spain. Despotism there is neither irritated nor provoked to excess by any lawful obstacle. There is no rallying point against it. If it be but moderate, in spite of predictions, it may yet endure for a length of time.

The chief functions of the council of war are, to administer justice to those who are in a military capacity, and bring their causes before that tribunal. It is divided into two chambers, or salas, the sala de govierno, and the sala de justicia. The former is especially employed in matters of administration. It has for counsellors the inspectors, who are the most accient captains of the body guards, and the oldest of the two colonels

of the guards.

The sala de justicia is confined to litigations. If parties are dissatisfied with its decision, they may require the other chamber to be joined to it to examine the cause anew.

According to treaty, the causes of strangers are carried by appeal to the council of war; and foreign nations who have intercourse and connexions with Spain, particularly the French, derive great advantages from this tribunal, the equity of which is rarely prevented by national prejudices; without being more accessible than the others to the solicitations of favour or corruption, it appears to be much more open to reason. In my frequent transactions with it I have had great room to admire its wisdom and justice; and could wish, that, for the interest of our commerce, the citizens of France may always preserve its members for supreme judges.

The highest military rank in Spain is that of captain-general; which is equal to that of marshal of France, and not incompatible with it; since these honours were united in the person of marshal Berwick. This preferment is not easily obtained in Spain. it was confined in 1785 to two persons in the army, the count de Aranda and the duke de Crillon. At the end of 1795 there were ten, three of which had been recently ereated; this number was shortly after reduced to nine,* by the death of the conqueror of Mahon. His posterity is now in existence. What will it say of him? His family will long speak of the qualities of his heart, his friends of those amiable points which caused his society to be courted, and excused the trilling follies naturally consequent on a lively temper and an easy character. As for history, it will say, Crillon merited the title which for ages had been an apendage to his name, he was a brave man not on such a day alone but constantly. He had had a long experience, but less possibly of the military art than of the dangers of war. He was active and indefatigable. By his humane disposition, by his engaging and familiar manners he conciliated the minds of the soldiery His example recommended to them, at the same time, both true courage and gaiety. He was brilliantly fortunate in having, like the Cardinal de Richelieu, effected the cap ture of a fortress that had been deemed impregnable, although he failed before another which experience has stamped with that character. If he was the sport of the passions of his satellites, and perhaps of his own, he yet, at least, displayed that energetic constancy. that pertinacity, which levels and overcomes all obstacles. In the military memoirs which he has left behind him, without being aware of it, he has faithfully delineated his own character; in them precept is supported by example, his frank honesty is distin guishable, his undisguised benignity, and even the pleasing disorder of his fancy.

Next to the captains-general, rank, as in France the fleutenants-general, field mar shals, and brigadiers; three classes of general officers which the war with France caused the number of to be greatly augmented.

In 1788 Spain had forty-seven lieutenants-general. In 1796 as many as one hundred and thirty-two. At present there are no more than eighty-one. The number of field-marshals in 1788 was sixty-seven; in 1796, one hundred and sixty. At present there are one hundred and twenty-six.

In 1788 the Spanish infantry consisted of forty-feur regiments of two battalions each, without including the Spanish and Walloon guards, each containing four thousand two hundred men, in six battalions. Of these fourty-four regiments thirty-five were Spanish, two Italian, three Flemish, and four Swiss.

One of the Italian regiments has been disbanded, so that there now remains only the Neapolitan regiment.

The three Flemish regiments, called the Little Walloons (Flanders, Brussels, and Brabant) have been incorporated into the national regiments.

The Swiss regiments have been increased from four to six.

The national regiments have been augmented by fourteen new ones, two of which, the volunteers of Terragona and of Girone, were created in 1792, and the twelve others during and since the war with France.

The eighty-eight battalions in 1788, at six hundred and eighty-four men each, would have made the infantry amount to 60,192. However I frequently heard it repeated, during my first residence in Spain, that there were scarcely 30,000 in actual service.

VOL. V

^{*} At the end of 1801 only seven remained, including the brother-in-law of the prince of the peace, the marquis de Brancifate, but exclusive of him made superior, even to the captain-general, through the favour of the king, under the title of generalissimo of the army.

The last war demonstrated, that it was capable of greatly increasing even the former

number.

A short time previous to the declaration of war, a new form was given to the Spanish infantry. Each regiment was composed of three battalions, two of which took the field, and one remained in garrison, serving as a depot for furnishing recruits, and deficiencies arising in the two others. The two first should have each five companies of 177 meneach, one of which grenadiers, and another chasseurs. Their complement in peace was 700, and in war 800 meneach. On my arrival in Spain in 1792, this new regulation had the central sketched out, and only one regiment, at that time, had a third battalion agreater part of these regiments at the beginning of the war were composed of scarcey 1000 or 1100 men. In a great number, the first battalion could not be carried to its complement of 800 men, without disfurnishing the ranks of the other two. The battalions sent to the frontiers comprised four companies of musqueteers of 160 men each, and one of grenadiers of 120, total 760.

Each company in the Spanish regiments had a captain, with the peace appointment of 700 rials per month; a first lieutenant with 400, a second lieutenant with 320, and in ensign with 250 rials per month. There were two ensigns in the foreign regiments.

Each soldier received 11 quartos per diem (about 3½d.) out of which two were retained for linen and shoes, seven for their mess, and two for other necessaries. They were new clothed every thirty months, and every lifteen months a new pair of shoes, two pair of stockings, and two shirts were delivered them.

It is easily receivable, that in war these allowances must necessarily be greater.

If the two first battalions of the forty-four regiments had been complete, Spain would have had an army of 70,000 men; but they were very far from being so in 1792. At the beginning of the war, and even before, every method that could be thought of fer filling up the different complements was adopted, and twelve additional regiments were formed. If then we add to the first mentioned 70,000 men the strength of the twelve new regiments of 19,200, the 30,000 militia, and the 8400 of Walloon guards, Spain will have had in arms 127,600 infantry. But as well as that the greater part of these regiments could not be filled up to the war complement, a considerable deduction is necessary for the garrison of Madrid, and to guard different places in the interior: so that the greatest army Spain at any time had in the field could not have exceeded 80,000 infantry, not including, however in this number 20,000 peasants which the armed, and incorporated for the service of the campaign of 1795.

It is not long since a part of this infantry was abroad. In 1782 thirty-six buttalions are in America. Since that time permanent corps have been established there, and at the close of 1792 there were searcely any battalions out of Europe. I say nothing of the places which Spain possesses on the coast of Africa, Centa, Mililla, El Penon, and Albucemas; these places, known under the name of African Presidencies, form a distinct

government, and are maintained by troops belonging to the European army.

The means of recruiting this army are very confined. The Spanish nation, brave as a is, has for some time had a dislike to the foot service. Each regiment finds a difficulty in procuring men; the colours are raised in places in which it is supposed most dupes and libertiaes are assembled, and thus, as in France, the regiments are formed by the disorders of society. The soldiers of our regiments, impelled by their inconstancy to pass the frontiers, used to take advantage of the gorges of the Pyrenees to desert and engage themselves to Spanish recruiters. Foreign regiments in the service of Spain were recruited at the expense of ours; and as the Spaniards are void of that rest lessness which characterises their neighbours, and induces them to wander to every part

brave as is a diffised most to formed ir inconrences to service of that rest very part at the globe, and besides the French army being much more considerable term unit of Spain, all the inconvenience of the proximity of the respective garrisons was on the debof the French; hence the court of Madrid has been solicited in vain to establish a care tor reciprocally giving up deserters; all that it would listen to was, that each denile restore the arms, horses and baggage of deserters.

It is true there is a second method of recruiting the army called the quantas, which resembles the drawing for the militia, but which in Spain is perfectly distinct, both having existence, the one for filling up the companies of the regular troops, the other for the provincial regiments. The ordinance of 1705 enacts, that for the first, lots shall be drawn in each village for one person in five; but then the drawing of the militia shall be saspended. This undoubtedly is the etymology of the word quintas. As it always happens, the thing is changed and the word remains. The quintas do not at present requires o great a number; and as the people base on some recent occasions shown how odnors it was to them, government has recourse to this expedient only in the fast of tremity. She refrained from enforcing it in the American war, but had recourse to it twice in the with France.

Besides these regiments of infantry Spain has forty-two of minitia, di tributed in the provinces of the crown of Castile. They are assembled only during one month in the year, in the principal place of which they bear the name; and for that time the officers and soldiers receive pay. It were needless to state that they are paid also in time of was when they replace the regular troops in garrisons, or join the army, of which they certainly do not form the least valuable part; this was sufficiently evinced in the war with France, when eighty-four companies of grandiers and light infantry, comprising 6.50% of their number, were marched to the frontiers. In time of peace, excepting their month of assembling, they remain in their villages and follow their respective occupations. These regiments an consist of one simple battalion of 720 men, except that of Majorer which has two, and must always be complete. As so on as a soldier of the militia dies deserts, or is discharged, lots are drawn in the Village whether he was taken, to replace him.

These regiments of militia have a particular inspector. Their colonels are chosen from among the most distinguished gentry of the district; and their authority is very extensive over the men. They have the power of inflicting punishments, and there is no appeal from their sentences but to the halps through the hydrium of the conneil of war. Few states in Europe have a better regulated lightly of militia; or which more deservedly sustains the reputation of a four, ascribed in the nation.

The Spanish soldiers have long been justly required if the opposite Europ. For their cool and persevering courage, and the resolution with what have the opposite theory. It is and hunger. Those of our country into who is the opposite the desired and before Gibraltar, do them complete justice on that head, and those where the last war took revenge on them for their transitory successes in the Boussillon, and on the banks of the Bidasson, sufficiently well understand the interest of hear glory to allow that, on most occasions, they met in the Spaniards with enemies worthy of hear courage.

Even the officers, respecting whom while I was in Spain I heard the most severes marks, in the course of this war have constantly mantested both courage and talents. And here let us observe, that if the Spaniards have in any way degenerated, it is to be imputed to circumstances foreign to their character. Courage and military talents require almost continual aliment. A toolg peace may effect a change in the martial spirit of the most valourous nation. And although Spain has taken a part in all the wars of this century, it may still be said, that, since those of Italy terminated in 1748, her troops have made no real campaigns. The Spaniards themselves presume not a give this name to

. 1 :

the short war with Portugal, in which they encountered but few obstacles and little dan ger. The expeditions to Algiers in 1774, and Buenos Ayres in 1776, were soon ended and afforded but few opportunities for the display either of conrage or experience. Add to this as an apology for the Spanish officers, that the life they lead is only calculated to stupify their faculties. Most of their garrisons are solitary and ill provided, without resource either for instruction or innocent pleasures; the officers have either no leave of absence, or seldom obtain it, even to regulate their private affairs. It is undoubtedly a means of making excellent officers of those who are obliged uninterruptedly to attend to the duties of their profession. But man has always need of a stimulus to excite him, and this obscure and monotonous life, unrelieved by any maneuvres on a grand scale, by any large assemblages, finishes in paralyzing all activity, or diverts the mind to improper objects. It has besides the inconvenience of rendering the service less desirable, and keeping from it those to whom a small fortune or a liberal education offers other resources. The Spanish army however has lately undergone an advantageous reform in this respect. The different schools that have been established, furnish it with persons of distinguished abilities. A martial spirit has been awakened in the nobility of the first disfunction, who embrace the profession of arms; and some of its members, renouncing the pleasures and idleness of the capital, gave their countrymen during the last war examples of devotion and conrage worthy of imitation.

All I have said of the infantry is applicable to the other corps of the Spanish army. It has eight regiments of dragoons consisting each of three squadrons. The heavy cavalry consists of fourteen regiments, including the brigade of carabineers of queen Mary Louisa, raised in 1793, and one of Spanish hussars formed in 1795. Besides these it has a

corps of royal carabineers which has a perfectly different organization.

Each regiment of cavalry is composed of three squadrons, excepting two which has four; each squadron consisting of 100 men in peace, and 180 in time of war.

Were the different corps complete, Spain would have an army of 11,880 horse. I have been however assured, that in 1776, at the approach of a war, which soon after took place, she had no more than 8000 effective horse. In time of peace, the heavy cavalry and diagoons are far from having their complement of men; and of this reduced number 80 are dismonated.

The consequence is, that the cavalry is less agreeable than it otherwise would be to the Spaniards, because the new recruits remain three or four years on foot, waiting for

their turn to have spare horses.

How comes it that there exists so great a scarcity of horses in a country, which, under Philip IV, could have furnished 80,000 for military service, a contingent to which almost all the provinces could then have contributed; for Andalusia was not the only one renowned for the beauty of its horses. Piny praises those of Gallieia, and the Asturias. Martial, those of his province, Arragon, &c. But the multiplication of mules has almost annihilated the race of good horses in the two Castiles, in the Asturias, and Gallicia.

In order to obtain a large number of these indefatigable animals whose utility and length of service more than compensate their mean appearance, the finest marcs in the kingdom are exclusively set apart for breeding them in every part of Spain. Notwith standing this the supply is insufficient for the demand, which is every day increasing, so that Arragon, Navarre, and Catalonia are supplied by a lesser species from some of the French provinces. The number imported is so considerable that it may be fairly rated at 20,000 annually, without danger of exaggeration. It is evident that the extravagant multiplication of mules is the cause of the degeneracy of horses, in the greater part of

the provinces of Spain; for Andalusia, where the laws prohibit the covering of mares by asses, is the only province in which the horses retain their original beauty. And one would be led to imagine that even these, although they may have lost nothing of their life, figure, and docility, have yet lost somewhat of their eigour. For, from the account of our best officers of cavalry, nothing can be more brilliant than the first charge of Span ish cavalry, may, even the second, but at the third their horses are spent.

Hence it appears, and it is allowed by all imparted Spaniards competent to give an opinion, that the best racers have lost somewhat of their strength. They have no other

method consequently to renew it but by crossing the breed.

In the laterval of this complete regeneration, some grandees on their own estates, and the king at Cordova, and at Aranjuez, are sufficiently occupied in the preservation of the fine race which remain. Some study of horses have made their appearance at Madrid, and at the different royal feats. Should this fashion become general, study of mules will be out of vogue, and a greater number of people will find themselves interested in mul-

tiplying and perfecting the breed of horses.

Already has the prince of the peace, who appears to be seriously intent on whatever may contribute to the prosperity of the state, attempted an experiment which probably may occasion a renewal of the excellent breed of Spanish horses. He has caused to be brought from the breed of Normandy a hundred handsome mares, for the study of Cordova and Aranjuez. Spanish naturalists pretend, that, from the union of our Norman mares with the Spanish stallions, foals will be dropt uniting the shape and strength of the female, with the beauty and swiftness of the male. Analogy drawn from similar consequences in other animals seems to support the opinion, but experience, the best teacher, must determine as to the effect. The experiment however, without being very costly, may eventually be useful, and possibly renumerate Spain for the acquisition we are about to make from the crossing of sheep of the Spanish breed. Thus it is that great nations, rivals without being jealous, renouncing exclusive endowments, and multiplying benefits, average themselves one of the other in a beneficial and laudable manner.

Nature, which has been so bountiful to Spain in all the necessaries and comforts of life, who denies her scarcely any of the enjoyments of peace, has not been sparing towards her in the materials of war. She is prodigal to her of iron, copper, lead, and saltpetre; and the excellence of her artillery enables her to dispense with foreign dependent

dance

It was in 1711 that the Spanish artillery took its present form. At that period it was collected into one regiment, composed of five battahoas, which have recently been extended to six, without including the cadets, who are brought up at Segovia.

This regiment has 304 officers, and its commandant-general for colonel, who, at the

same time, is inspector of the corps.

Count Gazola, recalled from Naples by Charles III, when he ascended the throne of Spaio, began the improvements in the artiflery, which had been neglected under Ferdigued VI. like several other branches of administration. The new monarch requested the court of France to send him a founder. M. Maritz was accordingly sent, and made several great alterations in the Spanish founderies. He adopted a method of easting the camon solid, and boring them afterwards. Envy created him many obstacles, and some unsuccessful efforts seemed to justify the ill will with which he was received; for many of the camon east in this new manner were found defective. He was moreover unpardonably culpable in easting a great quantity of Mexican opper, without ascertaining whether the metal was sufficiently solid. Most of these cannon failed in the proof, and the clamour against him became general. His natural courage, and the

es in the Notwith casing, so ne of the rated ravagant of part of

protection of the king, supported him ugainst the tempest; and he continued to employ his best endeavours in the service of Spain, although he despaired of ever being useful to it. At length he quitted it, leaving behind him his method and principles, with the precautions and improvements he had been taught by experience. At present, even his memics acknowledge that he has been of real service to the Spanish artillery. The manner in which it was served in the war with England, particularly at the siege of Mahon, and even during the war terminated by the treaty of Basle, have proved that Spain in

this department of the military art has not been retrograde.

Count Gazola, an Italian, was at his death succeeded by count de Lasey, an Irishman by birth, who had been successfully employed on some missions of a political nature in the north, and whose being placed at the head of the artillery as a recompence, excited some surprise. At his death, in 1792, count de Colomera obtained his place, formerly Don Martin Alvarea, who presided for a time at the siege of Gibraltar. Upon his resignation, Don Joseph de Urratia took his place, who commanded the Spanish army at the time of the conclusion of the treaty of peace at Basle, and was afterwards made captaingeneral. His military talents secured him the manimous suffrage not only of his own country, but even of the enemies to which he was opposed. Wherever wisdom and in formation are necessary, he is in his element.

The Spanish artillery has many distinguished officers. The superior merit of general Seriosa, who commanded at the siege of Mahon, has been acknowledged in foreign

countries.

Spain produces more lead than is required for her arsenals. Its principal mine, that of Linarcz, in the kingdom of Jacu, yields much more than is sold in Spain for the king's account; and notwithstanding the others be imperfectly worked, not yielding more than

8000. Spain can yet export a thousand tons per annum.

There are several copper mines also in Spain. That of Rio-Tinto is the most productive; it supplies a part of the artillery. But the copper of the Spanish Indies is also laid under contribution. That of Mexico and Peru is refined and manufactured in the two royal founderies of Barcelona and Seville. The cannon cast there have two-thirds

of Mexican copper to one of that of Peru.

Biscay and the Asturias furnish the iron necessary for the Spanish artillery. Cannon made of this metal are east at Lierganes and Cavada. Before the war with France the cast iron came from the forges of Eugui and Muga. In the phrenzy of conquest these two establishments were destroyed by our armies, as if we were combating an irreconcileable enemy, whose means of defence we were desirous of annihilating. Since policy so frequently occasions war, it ought not only to pardon, but minutely directing its operations, to act as a corrective to the heedlessness of elated victory. Since the peace Spain, taking advantage of this lesson, has established new forges in places at a greater distance from her frontiers, and a manufactory of fire-arms at Oviedo. She has besides manufactories of muskets at Placentia and Ripol; and, lastly, one of sword-blades at Toledo, which has been twenty years established, and which even at its first setting off promised to revive the ancient reputation of the blades of that city.

Spain is one of the richest countries in Europe in saltpetre. La Mancha and Arragon had the reputation of furnishing this article of an excellent quality. A French company had undertaken the preparation of it, and for this purpose sent M. Salvador Dampierre to Spain. This agent, though crossed in his plans, failed in his undertaking. On a piece of ground near Madrid he made some unsuccessful experiments, by which government wisely profited. The ground in question is found to contain saltpetre of a quality superior to that of La Mancha and Arragon; in consequence of which a ma-

nufacture was begun there in 1779, which was entrusted to the management of Don Rofendo Parayuelo, one of the commissioners-general of rents. In 1785, it was one of the most curious establishments in the capital; it kept four thousand men in employ. After two boilings the saltpetre is fit for making powder. The first boiling requires eight or ten days, but a few hours are sufficient for the second. Water is conveyed in abundance to this manufacture by subterrancous pipes. Neither has wood been wanting since this opening affords a consumption for that, which the inhabitants of the hills of Guadarrama did not before even give themselves the trouble of cutting.

The earth which produces the saltpetre recovers itself with surprising promptitude. The caput mertuum is brought to the environs of the manufacture; and sometimes in less than a month the air, impregnating it afresh with nitre, renders it fit for a second operation. It has been remarked, that after the continuance of a certain wind, the neighbouring soil becomes whitened, as if snow had fallen upon it. In 1792, I found

this manufactory surrounded with walls, and in full work.

The saltpetre is sent to the powder-mills at Alcazar, St. Juam in La Mancha, to Villa Fetiche in the kingdom of Valentia, to Murcia, and Granada, the employment of which mills has been considerably increased since the establishment of the manufacture at Madrid. When in its infancy, the proprietors engaged to furnish government annually with eleven thousand quintals. During the war they exceeded their engagement, and the director flattered himself, in 1784, that the establishment would soon yield thirty thousand quintals a year. The manufactory, however, could not supply the enormous consumption of powder at the camp of St. Roch: and although 35,000 quintals were sent thinher when the attack was to be made on Gibraltar, government was obliged to hasten the arrival of more from Genoa, France, and Holland. At present it wholly supplies the demand of Spain, and will soon become a new branch of exportation.

Hitherto the quality of this new powder is incontestably good; it is said to carry twice as far as common powder; for which reason Charles III, and the infants made use of no other in shooting; and the king of Naples some years ago used to receive a small quantity of it by every weekly courier from Madrid. Spaniards as well as foreigners were eager in the purchase of it. I saw our admiral Guichin at the time of his visit to the Escurial, where he had an opportunity of witnessing the excellence of it. He begged half a score pounds of it of the king as a favour; and as simple in his manners, as he was brave and religious, with no other luggage than his night-cap, his bre-

viary, and his ten pounds of powder, he set off on his journey to Madrid.

Spanish America will soon be independent of the mother country with respect to this commodity. The minister Galvez ordered three manufactories of saltpetre to be established at Lima, Mexico, and Santa Fe de Bogota. For the improvement of these manufactories he sent the same Salvador Dampierre to America, who failed in his attempts in Europe. Thus the Spanish colonies possess within themselves these means of defence. Will not the metropolis have cause to repent this? The seeds of discontent, which at different intervals for several years back, have shewn themselves in such an alarming

manner, have they been entirely stifled in their growth?

The corps of engineers is separate from the artillery, as is the case in France; it was not established before the year 1711. It consists of ten directors, ten colonels, twenty lieutenant-colonels, thirty captains, forty lieutenants, and forty second lieutenants: in all, one hundred and fifty officers, who are indiscriminately occupied in the superintendance of fortifications and civil architecture. There is but one commander for each of these works; and he who presides over the latter retains at the same time his rank in the army, although he cannot properly be considered as a military man. The person

who at present hold the place is truly a military character, general Urrutia. It was previously held by Don Francisco Sabattine, an Italian architect of ability, who at the same time was a licutenant general in the army, he filled this situation for twenty years before his death. In right of his station, general Urrutia has under his direction the three academies at Barcelona, Cadiz, and Zamera, established for the instruction of those intended for engineers, as well as such cadets or officers in the army as may be studious of learning the mathematics.

In 1796 a new description of engineers was formed, under the title of Royal Corps of Cosmographic Engineers of the State; it has, like the other, somewhat of a military frame,

its director and four principal professors holding the rank of captain.

As to the distinguishing marks of the different ranks in the various regiments, I shall only observe that the general officers have an uniform very much resembling that worn formerly by French officers of the same rank. The colonels, lieutenant-colonels, and majors wear no epaulettes. The captains wear two epaulettes; the lieutenants, one upon the right shoulder; and the second lieutenants, one upon the left. All officers who are not at least field-marshals are obliged continually to wear their uniform even when they appear at court. These uniforms are white for the national infantry, except the Spanish and Walloon guards, who wear blue. The uniform of the cavalry is indifferently blue, green, red, or yellow. The artillery and the Swiss regiments wear blue. In every regiment the men wear its name on their buttons; this is for the most part that of a town or a province; the Swiss regiments alone bear the name of their colonel. According to some late regulations, no person can become an officer without having been a cadet.

An establishment has been formed about twenty years, very well calculated to produce officers of merit, I speak of the military school, which we have before noticed more than once. Its founder, count O'Reilly, possessed the talent suited to the presidency

of a similar establishment, and making it prosper.

Born in Ireland, of catholic parents, he entered the Spanish service very young, and in Italy served in the war of the Austrian succession. It was there that he received a wound which caused him to limp the rest of his days. In 1757 he was under the command of general Lascy, and until 1759 when he joined the French army. Marshal Broglio conceived a particular esteem for him, and recommended him to the king on his return to Spain. He afterwards made a campaign in Portugal, where he distinguished himself. Peace being made, he was made field-marshal, and lieutenant-commandant at the Havanna, whence he afterwards passed over to Louisiana, the colonists of which province were refractory under the Spanish yoke. The means he exercised for restraining their insurrection drew on his head the most bitter execrations. In the course of his long career O'Reilly experienced all the shades of favour and disgrace. The affection which Carles III, entertained for him was for a long time insufficient to protect him from the hatred of the people.

Few men have inspired the same degree of enthusiasm and hatred. His conduct at Louisiana, where his name will long be coupled with maledictions; and his unfortunate expedition to Algiers in 1774, caused him to be ranked among wicked men and bad generals; possibly he neither deserved the one title nor the other. Skilful, insinuating, active, even physically, notwithstanding his lameness, and well acquainted, at least in theory, with his profession; he possessed at the same time the art of rendering himself necessary on different occasions. After languishing in a kind of exile, not however without maintaining his dignity, he was made commandant-general of Andalusia, and had his favourite bantling, the military school, removed from Avila to Port St. Mary,

near Cadiz, his place of residence. In this command he displayed genuine talents for every branch of administration. He was not beloved; but he concealed his despotic character under the mask of such engaging manners, that he appeared to be obeyed less through fear than devotion, and was regretted when the implacable Lerena, who had had some sharp altercations with him while intendant of Andalusia, caused him to be removed to Gallicia. Upon the accession of Charles IV, he thought he might again appear at court, but was received under circumstances more mortifying than belitted his confidence, and was ordered to the kingdom of Valentia. Ever indefatigable, he sought there to render himself of service in proposing plans, and giving his advice, at the time that war broke out in France. The command of the army of Catalonia was entrusted to his friend general Ricardos, who was also by descent his countryman, his father, an Irishman, having married the daughter of the duke de Montemar. Ricardos, any more than O'Reilly, was no great favourite with the new court, notwithstanding his talents and his long and useful service. Ricardos dying, after some success which justified his appointment, O'Reilly was named to succeed him. This unexpected triumph was his last. While on his march to take the command of the army, luckily for his fame, he died. Striking reverses befel his successor, the count de la Union; young, brave, and full of ardour, but with all these qualities, without experience. Probably the same fate would have awaited O'Reilly; he was no more, and we gave him our regret. He survived, however, the establishment which he had founded; the military school, after having produced distinguished officers for the Spanish infantry, died away in his last exile.

The government does not forget the declining years of their military men. There is a corps of invalids in Spain, as well officers as soldiers, but the forty-six companies, of which it is composed, are distributed at Madrid, and in the provinces, where they perform an easy duty. Those incapable of all service form another corps of twenty-six companies, divided between Seville, Valentia, Lugo, and Toro. Both these corps are under the inspectors of the infantry.

In Spain there is no order of knighthood particularly destined to the reward of officers. Charles III, however, made a point of conferring on none but these the four military orders; yet without excluding them from that he has himself founded. But these favours depend entirely on his pleasure, and not upon the length of service. Other means exist of rewarding old officers; the king bestows on them pensions, or rank on the staff at his different garrisons.

Neither are their widows forgotton in his beneficent distributions. In 1761, he established a fund from which they receive pensions according to the rank of their husbands. Eighteen thousand rials a year are paid to those of captains-general, twelve thousand to those of lieutenants-general, and in proportion to the widows of petty officers. This fund consists of a grant of 360,000 rials (4,0901.) anterior to its establishment; a contribution of twenty per cent. upon what the king receives from the spolios y vacante, half a month's appointment paid once by all the officers of the army, and a deduction of eight maravedis from each crown of their pay; and all the property of officers dying without heirs, or intestate. Truly valuable institution, and worthy of imitation, which by ensuring a subsistence to the widows of officers, without their standing in need of credit to enforce their claims, greatly encouraged military men to marry. A nearly similar plan has been adopted by the other classes of society, even by artisans.

The place of commandant-general of a province is an opening to general officers, but obliges them to almost a perpetual residence; for in Spain, bishops, intendants, governors, and commanders reside where they are employed, notwithstanding the resiver. v.

3 M

dence of the foreign, and the capital have the same temptations for ambition and dissipation as in other countries.

All the commandants of provinces bear the title of captain-general, which however must not be confounded with that of the military rank. They sometimes, but improperly, receive the title of viceroy also, which regularly belongs to none but the commandant of Navarre, and those of the principal provinces of Spanish America.

The stations of these commanderies or captancies-general are, Madria, for New Castile; Zamora, for Old Castile; Barcelona, for the principality of Catalonia; Valencia, for the kingdoms of Valencia and Murcia; Palma, for the kingdom of Majorca; Pembeluna, for the kingdom of Navarre; St. Sebastian, for Guipusova; Port St. Mary, for Andalusia; Malaga, for the coast of Granada; Corunna, for Gallicia; Badajoz, for Estremadura; Ceuta, for the presidencies of Africa; and Santa Cruz de Teneriffe, for the Canaries.

None of those idle appointments created by favour, to the injury of the finances of the country, formerly so common in France, are met with in Spain. Our neighbours hence have two abuses less than we had to provoke a revolution, and which were in some measure the instigation of ours, this and the fastidious display of splendour which individuals of all ranks who held the chief places of the monarchy came to make at court. So dearly in every respect is a revolution purchased, that the philanthropist dwells with pleasure on every circumstance which tends to remove to a distance the dangerous necessity of such a measure. Let us now proceed to the Spanish navy.

CHAPTER V.

SPANISH NAVIGATORS, ANCIENT AND MODERN. DEPARTMENTS OF THE NAVY. OFFICERS OF THE NAVY. SAILORS. CONSTRUCTION OF SHIPS. NAVAL FORCE. ITS APPOINTMENTS. BARBARY REGENCIES. M. FLORIDA BLANCA.

The Spanish navy for more than half a century acted the first part upon the theatre of Europe, whether the spirit of discovery with which it was actuated be considered, or its character in war. The world will never forget the names of Colon, Magellan, or Cano, nor the power which encouraged their illustrious enterprizes. Neither will the names of Quiros and Mendana, less known although not less deserving of distinction, for their vast knowledge and sagacity, which modern observations have done justice to, be ever obliterated from the memory of the geographer. At the same period their navy could equally boast its warriors; but they disappeared with the invincible armada; and under the reigns of the three Philips it scarce preserved a vestige of its former fame. Charles II left the navy, as well as the other departments of the monarchy, in the most deplorable state.

The efforts made by the Spaniards during the war of succession restored a momentary activity in naval affairs; but their skilful seamen were irremediably lost. In the two last reigns they have endeavoured, and not altogether ineffectually, to revive this part of the glory of their nation. I shall say nothing of Don Jorge Juan, or Don Antonio Ulloa, who accompanied Condamine in his expedition; the object of it was only to make astronomical observations. The Spaniards have more recently undertaken voyages of discovery, or for the purpose of taking the bearings of coasts hitherto badly known; but these appear to be kept back from the public eye, an affectation for which they certainly deserve the reproof of the lovers of science; although, in spite of their jealous secrecy, the details and result of the greater part of their voyages are pretty well known to the world.

In 1768, a vessel which sailed from Montevideo, coasted along that little frequented shore which intervenes between the river of Plato and the straights of Magellan, and

thence proceeded to reconnoitre the Falkland islands, a cruize which threatened to cause a rupture between England and Spain.

In 1769 and 1770, by orders of the marquis de Santa Cruz, viceroy of Mexico, and under the direction of Don Joseph Galvez, who was then fitting himself, by his attention to the interests of his country, for the office of chief minister, which he has since filled with so much honour to himself, two expeditions were dispatched at the same time, the one by sea, and the other by land, from San Blas, a port in Mexico, under the 21° of north latitude, to examine the port of Montirey, which, notwithstanding it was laid down in the charts with tolerable exactitude by Vezcayno, who discovered it in 1692, the naval detachment had great difficulty in finding again.

About the same time, other Spanish mariners, namely, Don Philip de Gonzales, and Don Antonio de Monte, the one commanding the St. Laurence, of 70 guns, and the other the Rosalie frigate, of 36, sailed from Callao de Lima, on an expedition to the islands of the South Sca, and fell in with Easter island, not for the first time, (for the merit of the discovery is indisputably due to Roggewein, the Dutchman) but before Cook and Peyrouse; and under conviction of its not having been before discovered, took possession of it in the name of the king of Spain, and erected crosses on three little hills, giving it the name of San Carlos.

In 1775, Bucarelli, viceroy of Mexico, dispatched two officers from San Blas, Don Juan de Agala, and Don Francisco de la Bodega, to take bearings of the coast of California, as high up as to the 65th degree. They were, however, unable to proceed higher than 57 degrees, and returned, after having taken the plans of different small havens on the coast, such as Los Remedios, de Los Doleres, &c. Don Antonio Morelle, who afterwards obtained, possibly on too slight grounds, the title of the Spanish Cook, was on this voyage pilot to the vessel commanded by Don Juan de Agala.

He since, at his individual expence, has made several voyages, which, on account of the difficulties he had to encounter, obtained for him some degree of reputation. He undertook more than once, in spite of the monsoons which reigned at the time, different voyages from the Philippines to the western coast of America; and thus it was that in 1780 and 1781 he arrived from Manilla at San Blas on board the Princess.

It was well known also that the Spaniards had touched before Cook at Otahcite, the discovery of which belongs neither to our contemporaries, nor commodore Wallis, nor even our admiral Bouganville, whose relations respecting this island have taught us to speak of it with the tenderest emotion. It is to Quiros that we are indebted for the first discovery. It is seen in the second voyage of captain Cook, that the Spaniards left two of their countrymen there; but we have as yet very few details of his expedition, the work being yet in manuscript.

There is yet a later voyage of theirs which has been published. It is that which Don Antonio de Cordova made in the Santa Maria de Cabeza, in the years 1785 and 1786. The anonymous author, who has given an account of it, under the title of, Relacion del ultimo Viage al estucho de Magellanes, in los anos 1785 and 1786, and who appears to be well versed in nautical knowledge, has added to it a description of all anterior voyages, and extracts from several valuable manuscripts which were not hitherto known.*

M. Fleuricu, in a work, meritorious in every point of view, published in 1799 and 1800, entitled A Voyage round the World by captain Marchand, treats both the ancient and modern navigators of Spain with some severity; but the Spanish government, which principally deserves these reproaches, in order to disculpate itself and them, laying mistrust and jealousy aside, and imbibing the same desires of propagating knowledge with the other powers of Europe, will doubtless ere long permit them to be given to the world.

1; but

Lastly, still more recently, a naval officer of talents, M. de Malaspina, sailed from Cadiz on a voyage round the world. His expedition was of the same intent with that of Peyrouse; and as well as the unfortunate French circumnavigator, he departed furnished with proper instruments for all kind of observations. On his return to Cadiz he deposited his manuscript in the hands of father Gil, a learned monk, who while employed in looking it over, and preparing it for the press, having in common with the captain, for a cause but too well known, incurred the anger of the court and its advisers, was, together with him, put in prison; the work was suspended, and the satisfaction which the learned in Europe promised themselves to enjoy was adjourned sine die.* How silly for such as are calculated to go round the world, to give the history of the voyage, and enlighten mankind, to lose their time in following court intrigues.

This is the extent of what the Spaniards have latterly effected to increase the extent of navigation. Their ships of war present them other palms to gather. Let us see what they have done, and what they are capable of, in this dangerous career.

Charles III, found the pavy in an imperfect state, notwithstanding Ferdinand VI, had less neglected this than other branches of the administration, and notwithstanding his minister, the marquis de la Ensenada, be esteemed its restorer. It is divided into three departments, those of Ferrol, Carthagena, and Cadiz.

The first presents real inconveniences, in the unhealthiness of the climate, and the frequent rains which retard operations in the port, from which no vessel can sail but with one particular wind. This department were perhaps better at Vigo, for the northern coast of Spain, the climate of which is very healthy, the soil fertile, and the harbour safe and spacious; the change has more than once been in contemplation; but arsenals and magazines must have been established at Vigo, where at present there is none; the harbour, now an open road, must have been fortified at a very considerable expence; and, lastly, its vicinity to Portugal, which has long been considered as the natural enemy of Spain, for no other reason, perhaps, than because it is its nearest neighbour, seemed a forbidding circumstance. These considerations of economy and policy have collectively prevented the execution of this project.

The department of Carthagena has many advantages over that of Ferrol. The safety of its harbour is known to a proverb among seamen, who say, There are but three good ports for vessels, the month of June, that of July, and the harbour of Carthagena. This safety extends to the arsenals and dock-yards, which in a narrow and insulated space, may, if I may use the expression common with the Spaniards, be locked up by a single skey. Carthagena is consequently the port at which the greatest number of ships are built, caulked, and careened. It possesses besides an artificial dock, deserving of admiration, even after seeing the famous forme at Toulon. Charles III, in 1770, established there a corps of engineers for the navy, under the direction of M. Gauthier, of whom I shall hereafter speak.

The department of Cadiz is, however, the most important of the three, from its favourable situation for the departure of fleets. As I mean to conduct my reader to Cadiz, where I resided some time, I shall refer him to my account of it for the information I have been able to collect relative to its port, dock-yards, and arsenals, which will serve as a supplement to what I shall here say of the Spanish navy.

It is officered much in the same manner as that of France before the revolution. Instead of vice-admirals, there are captains-general, who enjoy the same honours as those.

^{*} In 1797, it was expected that the voyage of Malaspina would shortly be published. The expectation has not been satisfied, which has given rise to an opinion that a different cause to that suspected acts as a preventative to its publication.

of the army. At present (1802) there are but two captains general of the navy, the Bailli de Valdis, who has been minister of this department for fourteen years; and Don Juan de Langara, whom we have before noticed; but above them all, as well as above all the captains-general of the army, is one more highly privileged, for whom the rank of generalissimo of the navy has been created, I allude to El Principe de la Paz. Immediately after the captain-general, rank, as in France, the lieutenants-general, who were in 1788 seventeen in number. There were thirty in 1790, ten of which had been made the year before, at the conclusion of a war which had afforded but few occasions of displaying their courage and capacity. At present there are but eighteen.

We have lately had an opportunity of judging of the value of several of them; admiral Mazaredo, for example, who for more than a year that he resided at Paris, charged with a mission of importance on matters relative both to politics and naval affairs, and who at present (1802) is displaying his activity in the department of Cadiz, where he resides. Admiral Gravina, who commanded the Spanish squadron during the time of its anchorage at Brest, and who so justly deserved the praise lavished upon him by our admiral, for his conduct in the command of the auxiliary squadron at Saint Domingo. Admiral San Domingo Grandellana, whose zeal and capacity have advanced him to the ministry of the navy. Admiral Don Juan Moreno, who, in spite of the deplorable accident which befel two of his ships before Cadiz, did not yet forfeit the well-carned title given him by our sailors, the witnesses of his courage and his misfortune, of a brave and respectable admiral.

Beside them may be placed several admirals who in former wars had acquired distinguished reputation, and who have only needed opportunities to enhance it in the two last.

In this number are the marquis de Socorro (formerly Don Francisco Solano) known by that name for several voyages, in which he displayed considerable nautical abilities; and who had the command of the Spanish squadron, in 1783, which laid off the coast of Terra Firma, and which was destined to second us in the decisive attack of Jamaica in 1783, when a frigate brought us the news of peace; Don Francisco de Borja, at present captain-general of the department of Carthagena; Don Felix de Texada, captain-general of that of Ferrol; Don Gabriel De Aristezabel, &c.

After the lieutenants-general of the navy come the commodores, who were no more than fifteen in 1788; they were raised to the number of forty-four at the end of the war in 1795, and are now reduced to thirty-four.

Among the commodores are many who do honour to the Spanish navy; such as Don Francisco Munoz, known for his boldness; Don Thomas Munoz, by his rare talents for hydraulic architecture; and Don Antonio Cordova, for misfortunes which his bravery but ill deserved.

The Spanish navy has an intermediate rank between a commodore and a post-captain, which is that of brigadier; there were in 1788 forty-four of this description; at the peace of 1795 fifty-five, thirty-two of which had been promoted for service during the war. At present their number is forty-two.

The number of captains in 1788 was only forty-five; at present there are one hundred and twenty-three.

By this comparison it is visible, that whether war be fortunate or otherwise, it presents the advantage of numerous promotions. But on an element so perfidious as the sea, success does not always attend upon courage and skill, and skill and courage yet deserve reward.

One rule, to which there are very few exceptions, is, that to acquire rank in the navy, it is necessary to have passed through the Garde-marine. This corps was established in 1717; it consists of three companies, divided among the different departments, each containing ninety-two cadets, for whose instruction there is an academy, composed of a director and eight professors.

With these means of obtaining the theory of that difficult and perilous art, navigation, with the facility which the vast extent of the Spanish monarchy presents of acquiring practical knowledge, from frequent and distant expeditions, malignity may find room to criticise with severity the conduct of the officers of the Spanish navy; and we know that even in Spain this prerogative was freely used in the course of the American war.

It is not for me to form an opinion of these decisions, I leave that to our sea officers who in that war sailed and fought by the side of their allies, from 1779 to 1782; let them declare if such decisions were not frequently dictated by prejudice and injustice. The war which Spain waged with us from April 1793 to the peace of Basle in 1796, may make our opinions appear too severe, from their officers being judged by enemies. Yet, if the bay of Rosas be excepted, whence a small squadron, commanded by the intrepid Gravina, defended with great zeal the citadel of the same name, and the little fort Bouten, and the port of Toulon, which the combined squadrons got possession of, owing to treachery; where during this war did the Spanish navy shew itself to any advantage? Its own nation groaned and blushed for its inactivity. But we know that their irksome sensations were participated by the navy itself, which was prevented shewing its value by the extreme circumspection of the chief of its department; a wise and cautious man, better adapted to organize fleets during peace, than to sketch out plans for their active service in war; while in addition, happily for us, there existed in the combined fleets that want of intelligence which was to be expected between two nations, one of which haughty, although weak, is the least of all others disposed to crouch before the capriciousness of arrogance; two nations momentarily united by interest, but which could but ill agree as to their object or plan of action.

As soon as this unnatural union was abolished, to the great sorrow of the one, and the complete satisfaction of the other, the Spanish navy instantly shewed itself disposed to cancel the past errors of its government; and if in the succeeding war, in which she beheld as her enemies those who before had been her allies, it has failed of signalizing itself as it wished, circumstances alone were to blame.

It is well known that a considerable part of her navy having entered Brest, at the particular desire of our government, shared there the same fate with our own, and was for a long time blockaded by superior force. But it cannot be forgotten, that otherwise, on every occasion which offered, the Spanish sailors gave satisfactory proofs of constancy and intrepidity.

The English, in particular, must recollect their long and fruitless blockade of Cadiz; the reception which they met with at the Canaries in 1797; before Ferrol in 1800; particularly their expedition against Cadiz in the month of October in the same year; and, lastly, their vain attempt on the coast of Algesiras in the month of June 1801, where the glorious efforts of our sailors were so well seconded by the foresight and valour of their allies; and, on our part, we shall not forget the manner in which they assisted us recently, on our expedition to St. Domingo.

At any rate, the most severe judges will agree, that there exists much intelligence and theoretic knowledge in the Spanish navy. Recent proofs have been afforded of

this, in the works contained in the depot for naval charts at Madrid; and in works given to the world latterly by some officers in the navy, truly learned in their profession, although but young, Messrs. Mendoza, Guliano, and the two brothers Ciscar.

The officers of the navy are, with respect to military rewards, upon a footing with those of the army. Vice-royalties, governments of provinces, or places in America, are indiscriminately given to general officers of the army and those of the navy. But the latter have, in the exercise of their profession, means of enriching themselves, which are looked upon as lawful in Spain, which they sometimes abuse, and which render less necessary the bounty of the king. This cupidity might be excused in conquerors; but what title does it deserve when, as is pretended, it has been the cause of their failure of success?

The sailors are classed as in France, and divided among the three departments. The registers of the classes make the number of the whole amount to from 55 to 60,000. But a good fourth of this number must be deducted for those unfit for sea service, and who cause their names to be inscribed for no other purpose than to enjoy the privileges attached to the character of an inscribed sailor. Let the department of Ferrol serve for a specimen, which furnished scarcely 15,000 seamen out of 20,000 inscribed in the year 1792. And even of this smaller number, there are many on whom little reliance can be placed. The Catalans, for example, notwithstanding they are good seamen, are very unfit for ships of war, from their being accustomed to the luttin sails, with which they navigate to the Baltic, and even as far as Spanish America, and consequently are aukward on board of vessels differently rigged. They are moreover lofty, and rebellious, and prefer merchant ships, on board of which they meet with better treatment, and receive larger pay.

To rate the number of sailors which Spain can furnish higher than 36,000 to 40,000, would be an exaggeration. In 1790, when Spain was on the eve of a rupture with England, she found it difficult to equip 32 sail of the line; she might, however, send a much larger number to sea, provided she were able to man them. Let us now trace the progress of the Spanish navy from the beginning of the reign of Charles III.

After the peace which followed the disastrous war of 1671, Spain had no more than 37 sail of the line, and about 30 frigates.

In 1770, she had 51 sail of ships, carrying from 112 to 58 guns; 22 frigates, 8 horcas, 9 xebecs, and 12 other small vessels; in all, 102 vessels of war.

In 1774, she had 64 sail of the line, 8 of which were three-deckers, 26 frigates, 9 xebecs, and 28 other small vessels; total 14%.

In 1776, she possessed 67 sail of the line, 32 frigates, besides smaller vessels; in all, 163; and at the end of the war, notwithstanding her losses, she had nearly the same number.

At the end of 1792, upon her declaring war, she had 80 ships of the line, 6 of which unserviceable, and 14 in very bad condition. At this epoch, then, she had 60 remaining to oppose to us. She lost four ships in this war. In that which succeeded with England, she had greater losses to repair, and already her government is employed with great activity in this department.

The complement of men on board Spanish vessels differs according to circumstances. Properly there ought to be ten men to each gun, yet vessels of 74 guns have scarcely 650. At the end of 1792 some had no more than 500; and the scarcity of good sailors frequently obliges them to be content with 300 men for their vessels of two decks.

But how comes it that Spain, in proportion to her population, has so few sailors? Is it not because the merchant service is the real nursery for the navy? And the commerce

of Spain is rather of a passive than active nature; its interior navigation being reduced almost to nothing and its trading vessels to nearly the same condition.

A few years ago its merchant vessels amounted to between 4 and 500, of which Catalonia furnished three fourths, and Biscay almost all the rest. What a difference between this number and that of England, who with a population greater by no more than four or five millions, possessed before the war which has lately terminated 7000 merchant vessels; and with Holland, which with no more than a third part of her subjects, has 6,500 vessels. However, within a few years the number of Spanish traders has sensibly increased; "circumstance imputable to the establishing a free commerce with America.

To compensate for her deficiency of sailors to man her vessels of war, Spain has a marine infantry, composed of twelve battalions, each of six companies which should form a corps of 12,384 men, divided among the three departments. But these battalions are far from being complete. When I left Spain in 1793, the four battalions of Carthagena, for example, mustered no more than 2,300 men.

Besides these there is a particular corps of artillery, divided into twenty brigades, which should consist of 3,320 men; but at the epoch above adverted to, it was but 1,500 men strong for all the three departments.

There is also a society of pilots, divided among the departments, with schools of pi-

lotage in each.

In the reign of Ferdinand VI, the Spaniards adopted English principles in building their ships. Don Jorge Juan, one of the most able naval officers as well in theory as in practice, had studied ship-building from its true source, and afterwards drew to Spain some English ship-builders. When Charles III, came from Naples to take possession of the vacant throne, he found the building of the Spanish ships entrusted to individuals of a nation which had but too much power in the cabinet of his predecessor, and which at that time was at war with France. An implacable enemy to England, ever since the imperious lesson she gave him at Naples, and moreover religiously attached to the glory of his house, he was not tardy in joining us. In this war he became a victim to his affection for France. The English took from him the Havanna, and twelve ships of war which were in that port. This cheek given to the Spanish navy was a new motive with the monarch to put it upon a respectable footing. He renounced the English manner of building, and requested of the court of France a French ship-builder. The duke de Choiseul sent him M. Gautier, who, although a young man, had already given proofs of great talents in his profession. This stranger was looked upon while acting for the navy, as M. Maritz had been while employed on the artillery. Spirit of party, national prejudices, and more especially the jealousy of some individuals, created him, as they had done M. Maritz, such difficulties as almost suppressed his zeal. The marquis d'Ossun, then ambassador from France, supported him in his experiments, and enabled him to triumph over his enemies. He began his labours, and displayed in them equal activity and intelligence. His first efforts, however, were not followed by complete success. The form of the vessels of every rate which he constructed enabled them to sail with a velocity until then unknown to the Spaniards; but they were found not to have sufficient room for the management of the guns, which made it very difficult to fight them in bad weather. He has since improved his method to such a degree as to leave but little to desire in that respect. A great part of the Spanish vessels employed in the large war were built by M. Gautier; and several of them excited the admiration of both French and English seamen. The Conception, built according to his plan, was judged by intelligent persons of both these nations, to be the finest vessel in Europe. But while we do justice to the shape and solidity of the Spanish ships, it must be admitted that all

seamen exclaim with reason against their heaviness of sailing. This I have been told was owing to their manner of rigging and bad stowage, which appears probable, since those taken in 1780 by admiral Rodney from M. de Langara, acquired under the management of the English, a celerity of which they were deemed incapable.

Gautier is not the sole author of the change. He has formed artists who share that merit with him; and Spain has national ship-builders, who, without his aid, have improved their art, and will render his loss less sensible to the Spanish navy. The displeasure of the minister Castijon, formerly his friend, had for some years condemned M. Gautier to inactivity; and the court of France took this occasion to reclaim from her ally a subject who seemed to have become useless. The king of Spain restored M. Gautier to his country, continuing the salary he enjoyed in the Spanish navy. But with the restriction that he should again dedicate his talents to the service of Spain, if hereafter need should require them. The revolution robbed him of this income. Gautier for all revenge furthered it to the extent of his power, and was nigh perishing in midst of its storms. A sort of justice was done him by placing him in office, but in a situation less brilliant than that which his talents and his sacrifices might justly claim.*

Since he left Spain I have been witness to the regret which his departure occasioned, even in those who had opposed or were hurt at his success, which proves that with this naiton, truly loyal and generous, justice still gets the better of her prejudice against foreigners.

My own experience has proved to me that this is exaggerated, or at least that it deserves excuse. What nation, in the same circumstances as Spain, would not have shewn more of this odious sentiment? Can it be supposed when Louis XIV, pensioned learned foreigners; when he sought beyond his frontiers for renowned artists or skilful manufacturers, that he did not excite against them the hatred of the French, who imagined that they had a greater right to his bounty; or that their indignation did not manifest itself at the contempt shewn their talents by a preference to foreign industry? In the retinue of the French prince, coming to receive his crown, appears a crowd of foreigners, who fill all the avenues to the throne; French favourites,† French valets de Chambres,‡ and French confessors.§ The princess Des Ursins and the French ambassadors reign by turn in the cabinet. A Frenchman repairs to Spain to reform their finances; || and French generals are placed at the head of their armies.¶ Shortly after an Italian ecclesiastic,** invited by the se-

*He died at Paris in 1800, in a state of mediocrity approaching want. Had he remained in Spain he would have finished his days in ease; for there old servants are never neglected, although their services be no longer needed nor even where they have reason to be dissatisfied with them.

† The marquis de Louville.

‡ Almost all the valets of Philip V, were French. During my first residence at Madrid I was acquainted with two (Toussaint and Amand) who towards the close of his life enjoyed great credit, and in whose arms he died. They were still alive when I left Spain in 1785. Thus by an uncommon destiny they survived for forty years that favour which they enjoyed to no other end than to do all the good within their power, particularly to their countrymen. Philip V, notwithstanding the lessons he received from his grandfather, never ceased looking upon himself to be a Frenchman. I was told an anecdote by one of his valets which he had frequently repeated to them, and which at once shewed his good nature and attachment to his country. The return of the infanta, designed for Louis XV, excited vexation at the court of Spain which bordered on rage. On the first news of it, queen Isabella, more irritated than any one, launched out into injurious language against the French, and obtained from her too easy spouse an order for all Frenchmen without exception to be banished from Spain. The order was just signed when Philip V, calls for his valets, makes them open his wardrobes and get ready his trunk. In the interval the queen comes in and asks the motive of these preparations. Do you not insizt, said Philip ingenuously, that every Frenchman should leave Spain. I am a Frenchman, and am packing up for my journey. The queen smiled, and the order was revoked.

VOL. V.

cond wife of Philip V, shakes the very pillars of the monarchy, by the agitation which his turbulent character excites in Europe; nor does his disgrace, the proper punishment of his tumultuous administration, till after a long time restore the Spaniards to their former state. A Dutchman,* still more extravagant, gains the favour of the monarch, seizes in one year on every dignity and every favour, and soon afterwards escapes loaded with the curses of the people, carrying from Spain nothing but the stigma of a state criminal. Under the succeeding monarch two foreign nations; reign by side the throne; an Irish minister; raises himself by that intrigue, of which the court was the theatre, but by the easiness of his yoke, his being a foreigner is overlooked, and he preserves his influence under the new sovereign, who quits the throne of Naples for that of Spain. One of the Italians, who accompanies the monarch, soon presides over the depart. ment of finances; and a few years afterwards another Italian minister | succeeds M. Wall. The discipline of the infantry is reformed by an Irishman, whilst two Frenchmen improve,** one the artillery, the other †† the building of ships. At London, Stockholm, Paris, Vienna, and Venice, the Spanish sovereign is represented by foreigners, ‡‡ Strangers establish manufactures, \$\dagger\$ and preside over the construction of great roads and canals, || direct sieges, ¶¶ command armies, *** cause plans of finance to be adopted, ††† and offer money to government upon the most advantageous terms. ‡‡‡ In commercial places these are still the persons who supplant the Spaniards by their activity and success. At Barcelona, Valentia, Cadiz, Bilboa, and other great trading cities, the richest merchants are foreigners. I have frequently heard the hatred they inspire in Spain declaimed against. I confess, that if any thing has surprised me, it is the quietness with which the Spaniards tolerate them in their country, and the kind disposition they have towards them, provided it be not damped by their haughty manners and insulting behaviour: and should some of the natives look upon them with an eye of envy, or be offended at the concourse of fortunate strangers, whose success of every kind seems incessantly to upbraid the Spaniards with idleness and ignorance; would not this be excusable by that attachment to national glory so natural and praise-worthy, and which so justly deserves the title of patriotism?

However since the end of the last reign, Spaniards exclusively have filled all those situations occupied before by strangers. The dominion of Frenchmen, Irishmen, and particularly of Italians, which was used to be tolerared with the least patience by the Spaniards, is drawing to its close; and if the viceroyalty of Mexico, given to the Neapolitan marquis Branciforte, brother-in-law to the prince of the peace, be excepted, and which in two years afterwards was taken from him to be given to a Spaniard; the post of grand master of the queen's household, occupied by a Neapolitan in disgrace at his own court, with a lieutenancy general held by a man, an Italian by the father's side, a Fleming by the mother's, the prince of Castel Franco who commanded the army

on the float-Aadrid. which Spain opposed to us on the side of Biscay, and some general officers, or commanders of corps, Spaniards are in possession of the principal favour of all the offices of administration and all diplomatic appointments.* This is an additional pretext wrested from disuffection which in every country has owed its origin chiefly to similar circumstances. How many the governments which have been overturned or endangered through the dominion of foreigners, which dominion if it be any where tolerated must indeed be mild. In France there has been a Medicis, Concini, Mazarin, and Law; in Flanders a duke of Alba; in Switzerland a Gesler; in Portugal, when for a short time incorporated with Spain, the agents of that power; Spain itself has had an Alberoni, a Ripperda, a Squillaci. Sovereigns are most inclined in fact to give full confidence to those who owe their all to them, who have no other country than their court; no property but their favour. Do they rightly calculate their interests? Do they not rather thus invite the dangers they would shun? More prudent sovereigns have less mistrust; and since they must have subjects, deem it best to attach them by affection. This is the only Machiavelism which such permit themselves, and which most willingly philosophy allows; this is the only true means in short to secure the permanency of their power.

With this they may manage without foreign favourites; inefficient ramparts against the fury of the populace, objects almost always odious, they are more adapted to provoke than to calm a tumult. In the insurrection of 1775, did the Walloon Guards protect Charles III, from the shame of flying precipitately from the capital? Were the Swiss

Guards able to save Louis XV1?

But, let us resume what remains to be said respecting the Spanish navy.

The three divisions in Europe of the navy of Spain, are not the only places where ships of war are built. There are dock yards at the Havanna; and a fund of seven hundred thousand plastres was some time since established to carry on the works. At this

station vessels are built at a more moderate cost also than in Europe.

Spain and her colonies might furnish her navy with all the ship-timber necessary for that service. In 1785 persons, competent to determine, were of opinion that her navy, by means of her colonies alone, might be augmented fifty sail, and at the same time, receive from it materials for the maintenance of the remainder. The resources which it possesses in Europe are as follow.

Andalusia, which formerly produced the best white oak, is now exhausted. Its forests yield not a sufficiency even for the repairs necessary in the department of Cadiz; the wood which they require for that purpose being brought thence from Italy, and some-

times cedar from the Havanna.

The department of Carthagena has no oak within its reach. The nearest to it are the

forests of white oak in Catalonia.

The department of Ferrol is supplied from the mountains of Burgos, Navarre and the Asturias. But the forests of the former are greatly thinned. The two latter countries

are well wooded, but the oak is of a bad quality.

This scarcity of wood in the metropolitan country, is principally owing to the thoughtless conduct of government, who about the year 1756, before roads had been made for the transport of them, caused trees to be felled sufficient for the construction of 122 ships of the line. No more could be brought to service at the time than was enough

^{*} The prince of Castel Franco before mentioned must be excepted, who has lately been deputed ambassador to Vienna; and the marquis de la Grua, a Neapolitan, nephew of the marquis of Branciforte. who after residing at the court of Sweden is at present an envoy at Parma.

for 50 vessels; part of the remainder, through neglect, rotted where they were fallen, and the remainder were stolen.

On the other hand, the colonies possess great resources; Cuba still contains a number of cedars in its interior, notwithstanding many people, judging from its coast, esteem it exhausted. Near the coast of Cumana, as well as there, grows plenty of wood fit for ship building. In 1776 it was in contemplation to fell some of the trees. The death of the minister of the navy, the Bailly d'Arriaga, caused the project to fail. How much are those governments to be pitied whose useful enterprises depend on the life of a single man.

Spain however lies still at the mercy of the powers of the north for her supply of masts. According to the account which the bank of St. Charles gave to the public in 1788, it appears that, from the first of December 1784 to the first of December 1785, upwards of eight millions and a half of rials were paid for masts alone.

Spain is still obliged to employ Dutch vessels. But she will be able to do without them, if the direct commerce she has for some years carried on in the Baltic continues to

She is still nearer to do without depending for her supply of hemp on foreign countries. For a long time the North supplied her with all that her navy required; latterly she has received a quantity furnished by Navarre, Arragon, and particularly by Grenada; so that almost all the navy is fitted out with Spanish hemp; the department of Carthagena alone importing mostly from Italy that of which its cables are made. Our seamen, as well in the American war as in the course of the present year (1802) during their confinement at Cadiz, had sufficient means afforded them of appreciating the goodness of its quality.

Doubtless Spain has yet much to do towards perfecting her navy, but what advance towards it has she not made within this century! Under Philip IV, she purchased from the Dutch, vessels ready built, and the cordage necessary for her fleets and galleons; from the French her sail-cloths; copper from the Germans; tin and lead for the service of the artillery from the English; and galleys from the Genoese. She suffered her timber to rot upon the ground, and neglected the culture of hemp. Attentive to her mines of Mexico and Peru, which promoted her deterioration, she neglected her mines at home, whence she might have drawn her means of defence. The evil became still greater under the reign of Charles II. Spain was then like himself feeble and languishing. When her situation at this period is considered, one is surprised at the different state to which she has been raised by three succeeding sovereigns. Charles V, who left it in such full prosperity, would not know it for the same now, it is true; but his imbecile, his last descendant would still less recollect it again.

She at least possesses a navy which places her on a level with the different maritime powers. In the absence of war in Europe, her continual quarrels with the Barbary powers afford her frequent opportunities of exercising her sailors. But in these short and paltry wars, it is different for her officers to acquire any reputation. Barcelo, who from owner of a bark attained the highest posts in the navy, is almost the only one who has acquired any great reputation for these expeditions.

Of these regencies two in particular continually employ part of the forces of Spain as well naval as military: I mean Algiers and Morocco. Their naval power, it is true, is not very tremendous, and were it not for the supply of ammunition and naval stores afforded them by powers which possess a desire for commerce being respected, they would be almost destitute of the means of equipping their vessels. Among other importations from different states they obtain from Marseilles itself the timber for building their sloops.

Some years back the navy of the emperor of Morocco was reduced to 22 or 23 ships. good and indifferent, the largest of which mounted no more than 22 guns. But its army is respectable, at least as to number, since every subject of 12 years of age and upwards is a soldier. With this army, badly disciplined, and not over courageous, the emperor has several times unsuccessfully attempted to carry the fort of Metille belonging to the

Spaniards, and situated at the eastern extremity of his dominions.

The Algerines are, or at least have been for a long time, an equally inveterate but much more formidable enemy. Five years ago they possessed 5 sacties of from 24 to 34 guns, 3 xebecs of 10, 18, and 20 guns, 4 demi-gallies, and 3 galliots. With this force they were continually tormenting the Spaniards until 1784; when the court of Madrid, losing all patience, and having concluded a peace with England, resolved upon attempting the destruction of this nest of pirates. She destined for this expedition a part of the naval stores and artillery intended for the projected attack, in union with us, upon Jamaica; which preparations were rendered useless by the peace of 1783. Algiers was bombarded by admiral Barcelo for eight successive days. Nearly four hundred houses were damaged; but the buildings belonging to government remained nearly uninjured. The attacking squadron consisted of seventy sail, four of which were of the line, and six frigates. Algiers lost one gun-boat only; but this useless expedition cost the Spaniards 400 men and 1500lb. of gunpowder. The Algerines had to oppose them no more than 2 demi-gallies of 5 guns each, a felucca of 6, two xebecs of 4 guns each, and 6 gun-boats carrying a 12 and a 24 pounder.

The expedition of the succeeding year under the directions of the same admiral Barcelo was still more fruitless, notwithstanding three other powers, Portugal, Naples, and Malta, each joined with part of their forces against the Algerines; the whole armament consisted of 130 sail. The Algerines defended themselves with 46 gun-hoats, 4 bombs, three cariasses armed, and three galliots. They lost three or four of their gun-boats, had 300 men wounded, but satisfied the combined fleet, that a still greater force was requisite to overcome them: and that this nest of thieves, if it merited the indignation of

all commercial powers, did not at the same time deserve their scorn.

In the interval between these two expeditions, the anger of the government had so far cooled as to induce it to enter into negotiations for peace, which, jealous of our connections with Algiers, she took especial care to carry on without our knowledge. The treaty failed, and the second expedition took place. The Spanish minister had resolved upon repeating this attack annually, until the regency of Algiers, harassed and exhausted, should at length be obliged to crouch to Spain. He however suffered himself, at the representations of the officers who had been engaged, to be dissuaded from this project; and negotiations with Algiers were renewed through the means of the count d'Enpilly; they were followed up and concluded by M. de Mazaredo, who was sent to Algiers when the party undesirous of peace saw it about to be effected by a foreigner, and was inclined to ravish that honour from his hands. The Spanish negotiator surpassed the expectations of his party, and little was wanting of his falling into disgrace for his too rapid progress. That these different negotiations were all carried on, unknown to us I will not presume to say, for that would have been difficult, but without any notice thereof to France. The Spanish government was more than suspicious that the trade of Marseilles had furnished the Algerines with their principal succour, and that not without the privity of the court of Versailles. However that may be, the gold of Spain made more impression on the barbarians, than what their bombs had done. Florida Blanca, who some months before had boastingly stated, and caused to be printed in the Madrid gazette, that "Spain would teach the other powers of Europe, by the example she would give, to stoop no longer to be their tributaries;" this minister, following the common routine, thought that he rendered his country a service in purchasing a peace of the regency of Algiers, at the price of 14 millions of rials. Ah, M. de Florida Blanca, you presided over the Spanish monarchy for fifteen years. Your administration was not destitute either of splendour or good fortune; you had an attachment to your country, which was closely allied to an hatred against all others; you rendered it service, if not with a profundity of understanding, yet with loyalty and disinterestedness; the grandeur of your sentiments caused the moroseness and irascibility of your temper to be overlooked; you acquired a title to the esteem of every one by the magnanimity with which you supported disgrace, to which I myself have been witness, and which the cause I served obliged me to approve; but you must allow, that your conduct with respect to Algiers was not among the wise or brilliant atchievements of your administration.

Since the peace concluded in 1785, Spain has had other disputes with Algiers; and, perceiving that the possession of Oran and Mazalquivir, situated on her shores, would ever be an inexhaustible source of quarrel, that as well they were no useful property, and that their position favoured desertion among her troops; Oran as well having experienced two scourges at once, a siege by the bey of Mascara, and an earthquake, which had reduced it to a heap of ruins; Spain, at length, towards the end of 1791, determined on renouncing them both in favour of the dey of Algiers, reserving to herself

some commercial advantages.

Thus did these famous conquests of cardinal Ximenes fall again under the dominion of barbarians. On the 26th of February 1792, six thousand five hundred men, which formed almost all the Spanish population, evacuated Oran, marched round the bay, and proceeded to Malzaquivir, whence they embarked for Carthagena. Every thing was carried away in the sight of the Moors, who shortly after entered the place. Oran could never be defended but at a great expence, and was not of the slightest utility; at least four thousand men were required to man its walls, and they were scarce sufficient; there were four trenches in an amphitheatre, for the purpose of guarding a spring of water, without which the garrison could not subsist, and which the Moors had frequently attempted to cut off from it. Under these circumstances, Spain shewed her wisdom in abandoning both the places: she would have done well if, at the same time, she had given up her other stations on the coast of Africa which nothing but vain glory can induce her to retain, and which are only burthensome to her. She maintains there, particularly at Ceuta, several thousands of galley slaves, called presidarios. Of those who drag their chains after them naked, and covered with rags, there are from four to five thousand; the rest who are not near so numerous, enjoy a degree of liberty, and go in search of labour. Both receive alike a very trifling allowance for their support; and among this refuse of the human race are confounded together, to the disgrape of reason and equity, assassins, criminals of every description, smugglers, deserters, and other unfortunate beings, who expiate in this contagious society crimes of a much less heinous nature.

The navy it is which brought on this digression respecting the Barbary powers, and the presidencies of Africa. It as well naturally leads to commerce; which cannot be maintained without it, and which feeds its protectress. It shall be the subject of the

following chapter.

CHAPTER VI.

ON THE COMMERCE OF SPAIN IN GENERAL. REGULATIONS RESPECTING CORN. INTERIOR TRADE. COMMERCE IN EUROPE.

THE commerce of Spain has more branches possibly than that of any other country on the globe. It has immense regions to supply; possesses a great number, and a large quantity of territorial productions fit for distant exportation, some of which are much sought after, and some cannot be dispensed with. It acted a principal part at the time the Spanish monarchy shone in its splendour, and foreign merchants entered deeply into the interior to exchange their merchandise for the produce and manufactures of the country. Under the successes of Charles V, these golden days had flown, and Spain for a long time carried on no other than a passive and disadvantageous trade. At present, notwithstanding her agriculture and manufactures are far from being at their zenith, it may be safely affirmed, that if she had only herself to supply with such merchandise as she stands in need of, the value of her imports would certainly be at least equalled by that of her exports; so that the disadvantageous balance of trade against her, in her commerce with Europe, is wholly occasioned by her American possessions, and the necessity she lays under of obtaining from other states those articles which her own manufactories do not supply in greater abundance than what her home consumption requires; and such articles, natural or fabricated, as are not produced within herself, to answer the immense demand of her colonies. It is true this is compensated by the produce of her mines, which furnish her with means to answer the balance; whence it must be evident, that these colonies are not altogether so burthensome to Spain as some are apt to imagine; and the less so, from their presenting an incentive to agriculture and industry, in the certainty which they afford of a consumption, and a ready market for the increase of quantity, consequent upon enlarged exertions.

Many readers will possibly look upon this assertion as paradoxical. Fifty years ago it would have been erroneous. It is more than probable now that Spain appears to be awakened from her lethargy; and stands as a fact with those who have made the ex-

tent of her actual resources their study.

In the first place, she possesses all the necessaries of life in abundance. We have spoken of her wools, and her cloths, which, although at present not brought to perfection, are yet sufficient for clothing her population; and, when we treat of Valentia, we shall see what resources she derives from her silk. Her brandies, rich wines, fruits, barilla, soda, and oils, form a considerable branch of exportation from her eastern and southern coasts. She makes all the common wines necessary for the consumption of the kingdom; and agriculture, if more encouraged, would furnish corn sufficient for home consumption, leaving a surplus for exportation. Notwithstanding the present backward state of the country, some of the provinces, Andalusia and Old Castile for example, produce more corn than they can consume; but the difficulty of inland carriage renders this fertility almost useless to the rest of the kingdom. With few roads, not one navigable river, not one canal in full activity, carriage is necessarily very expensive, and very slow. It is well remembered at Madrid, even now, that about twenty-five years ago the capital, from some neglect, being in want of bread, and a sudden supply becoming absolutely requisite, the ministry were obliged to employ 30,000 beasts of burthen, in order to secure a receipt of 2500 fanegas* per day. Spain is therefore at times dependant upon foreigners for a supply of provisions, even when some of its dis-

tricts enjoy a superfluity. But, notwithstanding the cry of scarcity, she never needs more than a thirtieth part above her produce. Of this I subjoin a proof.

Her whole consumption may be computed at 60,000,000 fanegas; at least the fol-

lowing calculation will make this computation plausible.

Sixty million fanegas, if the fanega be esteemed to weigh 90lbs. will give 5,400,000,000 pounds of wheat, which, divided by the population 10,500,000, will give for each individual 520lbs. nearly or less than a pound and a half per day. This statement may be considered as not affording a sufficiency, by nations which, like the French, reckon that each individual will consume two pounds of bread per day, but a different opinion will be formed, if it be considered that, first, the fanega most frequently weighs more than 90lbs.; secondly, that the population is scarcely ten and a half millions; thirdly, that maize is used both mixed with wheat and by itself in many parts of Spain; and, fourthly, that Spaniards are not near so voracious as the French of the article of bread; so that the consumption of the country will be rather overrated than otherwise at 60,000,000 of fanegas.

On the other hand, the forty ship loads at most which she imports can yield no more than 2,000,000 of fanegas; yet this quantity is sufficient for her momentary necessities, which a false panic has exaggerated. Hence Spain, were she left entirely to herself, could not experience a famine. What nation could not upon emergency, without any great effort, diminish her common consumption a thirtieth part? After what occurred in

France in 1794 and 1795 this cannot be doubted.

Nevertheless, upon the most slight appearance of dearth in Spain as well as in other countries, no other remedy is thought of than a prohibition of exportation; a measure at least useless, and frequently disastrous, on account of its depriving fertile provinces of a certain market, which ought rather to meet with encouragement to induce them to

combat successfully the obstacles resulting from peculiar position.

There is yet no permanent law respecting the commerce of grain. Up to the reign of Charles III, its exportation was almost uninterruptedly prohibited, and its price was established at a fixed rate. The inconvenience of this restriction was at length discovered, and M. de Campomanes, who was then fiscal of the council of Castile, caused it to be abrogated. In 1765 it was established by a royal mandate, that the interior commerce of grain should be absolutely free; that it should be permitted to store it in public magazines, whence, to supply pressing necessities, it might be taken at the current price; that leave should be granted to take grain from the magazines, when, after three successive markets, it should have continued at a certain price; that corn from abroad might be introduced and stored in magazines within the country as far as six leagues from the sea, &c. This regulation shortly after experienced some modifications. The exportation of grain was even entirely prohibited in 1769; but the regulation of 1765 was wholly re-established in 1783.

These variations must naturally tend to increase the timidity and indolence of cultivators. To encourage them to derive all possible advantages from their lands, a more permanent law is necessary, one better observed. For that which permits exportation is incessantly eluded by the caprice or avarice of the alcaldes and governors of the frontiers; and when nothing prevents its application there are still many formalities to go through before the exportation can take place. Exportation is therefore rare, and carried on but to a trifling degree in the manner authorised by the law. The slowness and expense of carriage in Spain, is an insurmountable obstacle to the smuggling of that quantity of corn from the kingdom which is supposed to leave it illegally. On the other hand, it is well ascertained, that grain finds its way into Spain by different channels; Gal-

the fol-200,000 each innt may reckon opinion as more thirdly,

cultivaa more ortation e frons to go e, and owness of that e other ; Gallicia and Asturia frequently receive corn from abroad, although the people there consume a great deal of maize; Biscay takes some from the province of Alva, from Navarre and Arragon, and sometimes from foreign nations, by the way of St. Sebastian; all the eastern coast of Spain is in continual want of supply; the kingdom of Valentia receives it from abroad, when La Mancha, in which corn almost constantly abounds, cannot furnish it with a sufficient quantity; and, lastly, Andalusia, notwithstanding its fertility, receives grain from other countries by means of its ports of Cadiz and Malaga.* The exportation of grain cannot take place with advantage, except by the frontiers of Portugal. This kingdom seldom reaps enough for its own consumption, and the neighbouring Spanish provinces have frequently a superabundance.

There is no considerable excess of corn in any province of Spain, except in Old Castile, and this is sent to St. Andero and some neighbouring ports in Gallicia, Asturia, Andalusia, and even to France, as happened in 1782 and 1783. However exportation is greatly in opposition from the rooted prejudices of Old Castile, which however ought not to weigh against experience; since the regulation of 1765 was justified by an increase of almost a third in the produce.

crease of almost a third in the produce. About the same time, a measure was adopted for the encouragement of agriculture, by instituting the Positos. These are magazines of corn established in upwards of five thousand cities, towns, and villages in the kingdom, to insure subsistence to the people against all accidents, and to prevent the alarms which in these delicate matters are often equivalent to real evils. When it is intended to establish one of these positos in any place, the municipal corps (ayuntamiento) obliges every inhabitant who has a field, either in fee or at a quit-rent, to contribute thereto a certain number of fanegas. The year following the inhabitant takes back what he has furnished, and substitutes for it somewhat more; and thus in the following years, until the whole of the different increased quantities deposited, which are called creces, has sufficiently filled the magazine. But this period is retarded at the will of avarice, and there are few positos in Spain, the management of which does not enrich the administrators at the expence of the poorer classes of the people. However, for some years back great pains have been taken to remedy these abuses, and establish the positos according to their original destination, that they may tend to the encouragement of cultivators, and, if possible, a part of the increase be applied to the assistance of those who may be in want of grain for sowing their lands.† Besides these public magazines there are the magazines of corn established in several places, by charitable individuals, for furnishing poor husbandmen with the means of sowing their lands. There are likewise at Valentia and Malaga other beneficent establishments whose object is the encouragement of agriculture. These are named erarios, and consist of funds destined to make advances in money to labourers, for a year only.

These funds were taken from the produce of the spolios y vacantes.‡

But all these aids, all these palliatives, which rather demonstrate good will than intelligence, are insufficient for the vivification of agriculture. Its languor is the result of a ra-

^{*}Valentia imports the grain requisite for its consumption mostly from Italy and Barbary. What it receives from La Mancha is at a higher price, on account of there being no other mode of transporting it but by mules; in peace it is not so dear as in war, on account of the muleteers resorting more to Valentia for salt cod, which is an almost indispensable aliment in their country; in war time they have no back carriage; add to this, it frequently happens that the harvests in La Mancha fail from droughts, on this account Valentia has no safe dependance on this country for its supply.

[†] This resource of poor farmers was dried up during the last war; the king having seized upon the positos to provision the army, promising restoration at a more propitious period of this spoliation, to which he was driven by circumstances.

[†] But they are particularly of late very badly managed. Vol. v. 3 o

dical evil, which will not be exterminated even when all the modes of facilitating communication shall become established. In Spain, individual properties are too considerable, the country too little peopled, and a number of circumstances tend to discourage the cultivators. The mention of one will be sufficient. The privileges of the mesta, which extend to the proprietor whose sheep are fed on his own grounds, obliges him to leave his fields open in all seasons; so that from the instant the grain is sowed to the period of his sowing again, his lands belong less to himself than to the public.**

Were agriculture more encouraged, what a source of wealth would it not be for Spain! Nothing can surpass the natural fertility of many of its provinces. Its grain is of the finest quality. Wheat is reaped among them which, passing through the mill, loses no more than 5 per cent. by conversion into flour, while northern wheats lose 15 per cent. Hence arises a notable difference in the estimation and price of the two descriptions of wheat. The who as of Andalusia have been known to fetch double the

price at Seville which foreign wheats have been sold for at Cadiz.

Waiting until government shall give life to the interior of Spain by establishing roads and canals, its commerce chiefly consists of wine and oil, which are carried in leathern bottles by mules or asses from one province to another; in grain, of which, in like manner by the aid of beasts of burden, the superfluity of one district is transferred to another; and particularly in wool sent from the sheep-folds and washing places of the two Castiles to the ports of the northern coast. Materials for the manufactories and merchandise which pass from the ports or frontiers into the interior parts of the kingdom,

spain is not much farther advanced in the coasting trade. Excepting the vessels of Catalonia and those of Biscay, the carrying trade along the coast is almost wholly in the hands of the French, Dutch, and English; three nations which have the advantage of being more active, and who understand how to navigate their vessels at a less expence and with fewer hands than the Spaniards. What has hitherto obliged Spain to employ a greater number of sailors, is the state of perpetual war she is in against the Moors of Barbary, which has besides the inconvenience of diminishing the confidence in her flag. Its government has however recently felt the necessity of obviating this principal obstacle to the prosperity of her navigation in the Mediterranean Sea.

But it is more particularly in foreign commerce that Spain acts but a passive part. I

shall soon convince my readers of this by taking a view of the coasts.

In the first place, those of Catalonia are an exception. But few of the reproaches alledged against the Spaniards are applicable to the Catalans. The port of Barcelona exports its silks, middling cloths, and cottonades, its indianas, wines, brandies, and other productions; and if we wish to form an opinion of the part the Catalans take in this trade, we must attend to the circumstance, that in 1682, of six hundred and twenty-eight vessels which entered Barcelona, three hundred and seventeen belonged to Spain. It is true, silks from Lyons, stockings from Nimes, several kinds of stuffs and cottons, in spite of the prohibition, and particularly dried cod, an article for which Spain is yet tributary to the English in the sum of 3,000,000 of piastres annually, pass into Catalonia by the same port.

^{*} The impediments to agriculture are exposed in a very luminous manner by Don Gaspard Melepier de Jovellanos, in a piece which forms part of the volume of Memoirs published by the Patriotic Society of Madrid in 1796. The remedies are indicated therein as well as the evils themselves; but the good wishes of a citizen, equally estimable for his zeal as his talents, trench upon the interests of so many as to afford no prospect of any speedy completion.

Remarkable singularity in the history of commerce! that a Protestant nation should furnish a Catholic kingdom with an article, which that nation only can prepare according to the taste of the consumers, by fetching from their own coasts* the salt necessary to cure the fish taken upon the banks of Newfoundland, an island, discovered by the Spaniards; and as if this species of servitude were irrevocably decreed by fate, all the attempts hitherto made to substitute fish taken on the coasts of Biscay and Asturia resembling English cod have been ineffectual; and have proved that laws, policy, and even interest disappear before the caprices of taste.†

The other ports of Catalonia are much in the same situation as that of Barcelona. Tarragona, and the neighbouring ports receive in addition some articles of necessity, and export dry fruits. Tortosa exports or imports wheat, according as the harvests of Arragon and Catalonia are good or bad; but the principal article of exportation from this

port is pot-ash.

A considerable commerce is also carried on in the ports upon the coast of Valentia, and chiefly with France. The French send to Valentia linens, woollens, hardware, spiceries, and grain, to almost as great an amount as the wines, wool, dried fruits, pot-ash, and barilla, which they take from thence. They fetch from Candia the wool used by the manufacturers of Languedoc and Elbeuf, and carry with them French cloths, silks, linens, hardware, &c. The English also carry thither their cloths, and the Dutch ship from thence the brandies of the country. Alicant has been, up to the present time, the most commercial city in Spain, and its port that most frequented by national bottoms. Of nine hundred and sixty-one ships which entered it in 1782, six hundred were Spanish, and most of them Catalans.† The abundant production of its neighbourhood of wines, brandy, almonds, annisced, cordage, salt, saffron, &c. with about five thousand tons of barilla, of which four-fifths is exported by the French, and the remainder by the English; these productions are exported to foreign countries from Alicant in greater abundance than from any other Spanish port. Its port, a large and safe roadsted but not deep, is a depot for all merchandise coming from Mediterranean ports designed for Spain.

Alicant suffered considerably in the last war with England; its port was little frequented unless by neutrals, who came to take in ladings of the productions of the country. In enumerating the objects of exportation from this city, a species of cochineal, known under the name of grana, must not be omitted which is used with nearly the same advantage as that of America, although inferior. It is a mass of small colouring insects sufficiently resembling those of the real cochineal. They are collected upon the oak

tree (roble) which abounds in the neighbourhood of Bussots near to Alicant.

The salt which bears the name of this town is not properly speaking a production of its territory. It is collected from two ponds in the neighbourhood of each other, but which have no communication with the sca; they are called La Mata and Torre Vecchia,

" The salt with which the English salt their cod is brought from St. Ubes and Alicant: whither their ships sometimes come in ballast to load with salt, thence to proceed to Newfoundland.

† The consumption of English cod was greatly diminished during the last war, although neutral vessels brought quantities to Spain under the title of French cod; the 'accalar of Norway has been substituted for English cod in different parts of the kingdom, particularly at Barcelona, where it is preferred, but in almost every other part of Spain, although not so good as the baccalar, there is a marked predilection in favour of English cod.

In the years immediately following this port was not frequented by near so many national ships. The two last wars have every where suspended the activity of the Spanish navy. But in one year as many as eight hundred Swedes had arrived there. The custom-house of Alicant is consequently the

most productive one the monarchy can boast.

and are to be seen half way between Alicant and Carthagena. The simple evaporation excited by a burning sun covers their surface with a foam, which is gathered in the month of August during dry weather; early rains, however, sometimes ruin the harvest. The ponds of La Mata and Torre Vecchia are two sources of salt almost inexhaustible, and sufficient of themselves to furnish the whole of Europe with that commodity. Their annual produce, which is from twenty to forty million pounds, is carried to Alicant, where the nations of the North come to fetch it, particularly the English, to whom it is absolutely necessary for salting their fish, and the Swedes, who annually import 30,000 casks of 3 cwt. each.

The wines of Alicant are of different descriptions. The principal and the only one much known out of Spain is a rich red wine, called Tent. Besides this they have one, but of which very little is made, that is white and of muscaline flavour; and another called d'Aloque, a common wine, some of which is exported to the neighbouring provinces, to Cadiz and to Gibraltar. Their red sweet wines, which, when young, are of a very deep red colour, are sometimes imported into France for Bourdeaux, where they

are employed in giving body and colour to claret.

Almost all the wines called Alicant are made in the neighbourhood of that town. The vineyards begin at about half a league from it, in a canton known by the name of Huerta de Alicant, which owes its surprising fertility to a neighbouring pond, whose water serves for its irrigation. This pond, which belongs to the king, is surrounded with a wall sixty feet high, and wide enough for three carriages to drive abreast upon it, is a remnant of the labours of the Moors, who, in every part of Spain left traces of their industry.

To Carthagena the English, Dutch, and Neapolitans carry merchandisc of all kinds,

and return loaded with silk, wool, cordage, pot-ash, and barilla.

Almeria is a small port, the principal commerce of which is in the hands of the French, whose ships carry thither the productions of their manufactures, and return loaded with lead, pot-ash, &c.

Wine and fruits are exported from Velez Malaga, and Marbella, mostly in foreign

bottoms.

Malaga has a very considerable commerce, the advantage of which is entirely in favour of Spain, but with little profit to its navigation. The English, who are in possession of the greatest part of the trade, carry thither woollens and great quantities of hardware; the Germans linen, the Dutch spice, cutlery, laces, &c. These nations, those of the North, and Italy, export to the amount of two millions and a half of piastres in wines, fruits, sumach, pickled anchovies, oil, &c. and all they carry thither amounts only to about a million and a half. The Spaniards themselves take so little interest in the shipping, which a similar extent of commerce must require, that in 1792, of the crowd of vessels which entered and sailed from Malaga, scarcely sixty were national.

Cadiz, the commerce of which I shall speak of at some length in another place, is a striking proof of the inactivity of Spanish navigation. Scarcely a tenth of the vessels which enter there belong to Spain. Latterly, however, the Spaniards have increased in

activity at this port more than any other of Spain.

The neighbouring little ports of St. Lucar and St. Mary are in miniature what Cadiz

is at length.

If we pass from the coasts of Andalusia to the northern coast of Spain, we shall find the French, English, and Dutch in possession of the trade from Vigo, Ferrol, and particularly from Corunna, which mostly consists in importation; for the pilchards, cattle, and common linens, the only articles Gallicia has to spare, serve to pay the balance due oration in the narvest. ustible, Their Micant, m it is 30,000

nll find particattle, ce due to the neighbouring provinces. Corunna owes to the reign of Charles III, a trifling exportation trade, which it has to America by the packet-boats that sail every month for the Havanna, and every two months for Buenos Ayres. These were eighteen in number, when the war of 1779 began. Several fell into the hands of the enemy, but were afterwards replaced. The conveyance of packets and passengers is the principal object of their institution; but it occasionally furnishes the means of exportation to the productions of Gallicia. They employ about a thousand sailors, and enliven the circumjacent countries. At this instant there is at Corunna for their periodical communication five merchant frigates instead of eight, which there were in 1796; one of three hundred and ninety tons, and four of a hundred and twenty; three brigantines and a corvette. It is as well assisted by four vessels of from eighty to a hundred tons, and two golettas from Porto Rico.

During the war which Spain waged against France in conjunction with the English, she established a provisional courier once a week for Falmouth, by which means she ob-

tained a rapid communication with all the north.

Upon the coast of Asturias there are eighteen ports scarcely known to have a name, the trade of which is almost exclusively in the hands of the Dutch. A little before the American war the English and French, who had been driven from them for some years, appeared there again with linens, woollens, and small ware. Some vessels from the country however sail to France and England in search of what is necessary to supply the wants of the province; and since the establishment of a free commerce with America, the trade of Gijon, the most important of these ports, begins to acquire some activity.

The country adjacent to the Asturias is called the Montanas de Burgos; and is one of the districts of Spain the most unprovided with resources. Government, considering this, permitted that district to receive the necessaries of life duty-free. The treasury was not long before it repented of the concession, under favour of which all sorts of foreign merchandise being introduced by the ports of this coast, administration has recently taken measures to prevent future abuses. Hence acts of rigour, and even ef malevolence have been put in practice against foreigners, particularly the French, of all the people of Europe, that which before the rupture between the two powers seemed to enjoy in respect of this trade the most exclusive privileges.

Saint Andero is the principal of these ports; it receives by about a hundred French vessels from their western ports, every thing which they can furnish for its consumption. These ships return loaded with wool for the manufactures of France, and corn for the other Spanish provinces, and sometimes for those of their own kingdom. The English export from Saint Andero the same articles, in exchange for cod, oil, fish, &c. and employ, in this commerce, about forty vessels. Some Dutch and Hamburgh vessels trade thither also. The establishment of a free commerce has begun there to animate the national navigation. The neighbouring ports, such as those of Suances, Comillas, and St. Vincent de la Barquera carry on a little coasting trade with the barks of the country. Santona, which has an excellent port, sends some vessels loaded with chesnuts to Holland, and a few cargoes of lemons to France.

Their coast, the trade of which, as we have seen, is almost wholly in the hands of foreigners, joins that of Biscay, which carries on the most active commerce in Spain after

that of Catalonia.

The principal ports of Biscay, Bilboa, the Passage, and St. Sebastian, are much frequented by the English, French, and Dutch, who carry thither their manufactures, and return with iron, wool, and anchors. The Biscayners, in their own ships, maintain a regular trade with different ports of Spain, as well as with France, England, and Holland.

A few words upon the trade of the Mediterranean islands, which make a part of the crown of Arragon, will complete this slight sketch of the commerce of Spain.

The island of Majorca, the principal one of the three, although its population be no more than twenty-four thousand four hundred souls, produces wine, and fruit, oranges, almonds, and oil, which are sent to Spain, some brandies, taken by vessels from the north, a little silk which goes to Catalonia, and coarse wools sent to Sardinia and Italy, with inlaid work, for which the Majorcans are famous. It receives corn from the French and Italian ports, cattle from those of Languedoc and Catalonia, and rice and silks from the coasts of the kingdom of Valentia. The English, the Dutch, and particularly the French and Genoese, carry to it all the other articles of which it has need. The people of Majorca, like the inhabitants of most islands, have an inclination and aptitude for navigation. Their dock-yard is at Palma, which is their principal port; they fetch cocoa, sugar, iron, and planks from Marseilles; and their xebecks go to Cadiz, where they take in cargoes. Their spirit of adventure would greatly increase were it not for their apprehension from the Barbary corsairs. It has received a new stimulus, by the establishment of a free trade to America.

Minorca, unfruitful and almost without industry, was furnished with every thing by foreign vessels, and particularly by those of France before it was conquered by Spain. I know not whether the change will be advantageous to the inhabitants with respect to their commerce or not, perhaps they would have been better pleased if the treaty of Amiens had left them subject to their former sovereign.

Iviza, the third of the islands anciently called the Balearic, exports but little, and receives its supplies of necessaries from Majorca and the coasts of Spain. Its principal riches consist in salt, of which foreign ships, particularly Swedish, come thither to take in their cargoes.

These accounts are more than sufficient to prove that the commerce the Spaniards have with foreigners is but passive. The extension of the free commerce with Spanish America however has already had an effect, and will, no doubt, operate advantageously for their shipping interest. This will be sufficiently explained in the following chapter.

CHAPTER VII.

OF THE TRADE BETWEEN SPAIN AND HER COLONIES. THE ESTABLISHMENT OF A FREE COM-MERCE. ADMINISTRATION OF GALVEZ.

AFTER the conquest of Spanish America, the court of Madrid confided the administration of that country to a permanent council, under the name of the council of the Indies, which still subsists, with nearly the same laws and principles, that, according to circumstances, were at first adopted. The organization which it established for its vast possessions forms no part of my subject: I shall say no more of it than what will be necessary to give a proper knowledge of modern Spain, with respect to her connexions with her colonics.

The council of the Indies is, like the council of Castile, composed of several chambers, two of which are especially charged with affairs of administration, and the third with the decision of lawsuits. It has also its camera, which proposes to the king, by means of his minister, such persons as it judges proper to fill places in Spanish America. It is by this council also that the laws and regulations by which that country is governed are framed. This having been the permanent depository of the fundamental laws upon which its constitution was at first erected, it has been a constant enemy to all change.

One of these laws confined the commerce of Spain with her colonies, to a single port: at first that of Seville; but when the Guadalquivir, which in the time of Charles V, was

navigable up to this port, became inaccessible to large vessels, the centre of the Spanish American commerce was removed to Cadiz. The manner in which it was carried on is generally known. It will not be necessary to repeat here what is known to every one, that at stated times a fleet sailed to Mexico to furnish a supply of such articles as it required, and bring back its productions to Cadiz, while, at the same time, galleons sailed for Porto Bello. It will be sufficient to remark, that this method continued to be practised until the war which begun in 1732, when register ships were substituted for galleons, which no longer sailed at any fixed time. But the fleet for Mexico, and the register ships, continued to sail from Cadiz.

In the mean time, the coast of Caraceas received its supply of merchandise from other quarters. The care of furnishing it was deputed by Philip V, to the company of Guipuscoa, which we have noticed before, and which enjoyed the advantage of an exclusive

privilege, without having received it in form.

Bad administration, which, while it enriched the agents, excited complaints from the settlers at Caraccas, occasioned it to decline. The injury it received at the beginning of the American war, and which amounts in loss to 1,500,000 piastres, gave it the finishing stroke; the company then felt the burthen too heavy to be supported, and prayed the king to be dispensed from their obligation of maintaining, with little avail, certain guarda costas, which were an annual expence to them of 200,000 piastres. This prayer was granted, and the company, has preserved the same means for carrying on trade with the Caraccas that its competitors enjoy at present, but with superior facilities.

the Caraccas that its competitors enjoy at present, but with superior facilities.

The experiment made by Philip V, in favour of the settlers of the Caraccas was a step towards new attempts of the same kind. In 1775 Ferdinand VI, permitted a company of merchants at Barcelona to send out ships to St. Domingo, Porto Rico, and Margaretta; but the privilege was clogged with so many restrictions that the company made

no use of it.

In 1763, the dawn of a new day began to illumine Spanish America. Already had certain intelligent persons repeatedly represented to government the inconvenience of confining to a single port, and to periodical voyages, the whole commerce of these extensive colonies. But two unfavourable experiments, made at different periods, had made it timid. Under Charles V, there had been an attempt to establish a free trade, but soon afterwards it was found necessary to restore the former restrictions. From 1748 to 1754, register ships had sailed from different ports of Spain besides Cadiz; and the numerous failures which followed in consequence soon caused the measure to be abandoned. These objections were answered by observing, that precautions and regulations better adapted to the time and the nature of the different expeditions, must prevent the ruinous speculations of new adventurers; that Spanish America, better known by its wants than its resources, no longer presented the same risks to merchants; and that the old plat on one hand exposed the colonists to all the hardships of monopoly, and on the other, left too great an opening to the speculation of smugglers.

A tarif drawn up in 1720, seemed to have been calculated for the advantage of those who pursued this illicit trade. It loaded with export duties the productions of the mother country. It established the ridiculous duty of Palmeo, which was received upon the bales, not according to the quality of the merchandise, but in proportion to their dimensions; a duty which rendered it impossible to take any account of the quantity or quality of foreign stuffs shipped for the colonies. In a word, it prescribed a number of formalities perplexing to legal commerce; and smuggling added to the advantage of eluding them, that of defrauding government of duties on exportation and importation to the amount of 70 per cent. The English profited by this so much, that, according

to calculations which I have reason to believe exact, their contraband trade produced them after the peace of 1763 twenty millions of piastres per annum.

At length the court of Spain opened its eyes; but frequently circumspect even to excess, and prudent even to tardiness, it as yet was satisfied with trying a new regime for a part of its colonies. By a decree of the 16th of October 1783, several European ports were permitted to trade immediately with the Spanish Caribbees, and the provinces of Campeachy, St. Martha, and Rio de la Hacha. The decree diminished the duties of the tarif of 1720, and dispensed with many formalities.

The Spaniards were not at first eager to begin this new traffic; the island of Cuba became the principal object of their timid adventures. Yet in 1770 this island, which, well cultivated, might supply all Europe with sugar, did not furnish enough for the consumption of Spain. Merchants have since become more enterprising. Government has given new encouragement to the trade with the Havanna, especially in facilitating the importation of negroes, by a considerable diminution of the duty on their importation. The company which had the exclusive privilege of furnishing them, had almost ruined itself in the undertaking; but these new measures soon gave it the means of repairing its losses. The island of Cuba began from that moment to prosper visibly. Before the year 1765, searcely six ships in a year arrived at its ports; in 1778, its commerce gave employment to upwards of two hundred, and its crops of sugar were more than sufficient to supply the demands of Spain.

At that time Galvez had enjoyed the post of minister for the Indies scarcely two years; he was of a stern and despotic character, but neither deficient of courage nor intelligence. He had travelled through a great part of Spanish America, was acquainted with the disposition, the wishes, the necessities, and the resources of its inhabitants. He thought this season fit for their liberation from the most galling of their fetters, and for the extension to almost all of them of the advantages of a free trade.

By a decree of the 2d of February 1778, this was extended to the province of Buenos Ayres, and the kingdoms of Chili and Peru; and by another decree, on the 16th of October following, to the vice-royalty of Santa Fe, and the province of Guatimala. It therefore was now permitted to all Spanish America, except Mexico.

The last decree admitted to a participation in a free trade the ports of Seville, Cadiz, Malaga, Almeria, Alicant, Carthagena, Tortosa, Barcelona, St. Andero, Gijon, Corunna, Palma, in the island of Majorca, and St. Croix, in Teneriffe. The Biscayans alone, on account of their aversion to custom-houses, as we have before noticed, were exempted from a direct participation of these advantages.*

The same regulation extended this commerce to four-and-twenty ports in America, and favoured, by an abatement of the duties paid at others, such ports as required this allowance to cause them to be frequented. One of the principal objects of its author, was to encourage the productions of the mother country. In consequence of which, several articles were exempted from duties for ten years from the date of the decree; such as woollens, cotton, and linens of the manufacture of Spain, hats, steel, glass, &c.

With the same view the regulation actually excluded many articles of foreign merchandise, such as cotton stuffs, half beaver hats, silk stockings, and liquors of all kinds, such as wine, oil, brandy, and others, known in Spain by the appellation of caldos. And further to excite the Spaniards to export to the Indies the productions of their own

^{*} During the present war, the prince of the peace, by entirely changing the constitution of Biscay, and assimilating it with that of the other states subject to the crown, at least as far as regards import and export dues, has obviated the motive which caused the restriction to which the Biscayans were subjected. They at present (1807) in common with the rest of Spain, are allowed to traffic with the Spanish colonies direct.

What compensation (if there can be compensation) for some terrible presents she has made us! What number of different woods, minerals, fruits, and nutritive aliments! How many salutary balsams, shrubs, flowers, and medicinal plants! How many articles, in short, calculated to increase our enjoyment, and lessen our ills, and consequently to afford man that small portion of happiness of which he is susceptible on earth! Wherefore do they who possess these treasures retail them with a niggard hand; wherefore load them with form and taxes? as if fate had irrevocably decreed that evil should pour down in torrents, and good but drop by drop.

The precious metals of America, which it might be difficult to class in either rank, made a separate article in the regulation of 1778. Gold, on entering Spain, paid before a duty of five per cent. and silver one of ten per cent. The new regulation fixed these duties at two and a half and five per cent.

Certain articles of merchandise coming from the Indies are necessary to the Spaniards, either for their consumption or for their manufactories. The exportation of these to foreign kingdoms is absolutely prohibited by the regulation: the principal of this description are silver in ingots, gold in every form, spun cotton, ship timber, &c.

America produces many other articles little known in Europe, and of which Spain ought to promote the exportation. And the regulation which exempts them from export duties on leaving the Indies, extends the exemption to their exportation from Spain; such are certain woods, gums, plants, and drugs with which America abounds; and which, placed by nature at a distance from the inhabitants of the old continent, ought long since to have been rendered common in Europe.

All these measures would have been insufficient, if the court of Madrid had suffered the numerous duties established by the tarif of 1720 to remain.

The new regulation abolishes them all, and substitutes in their stead a single duty, which is a certain part of their value. It is accompanied by a tarif, in which the various articles of merchandise are estimated; iron by weight, cloths by measure, stuffs by the piece, and other articles by the dozen. Those which cannot be thus valued, are taken at the current price of the manufactories whence they come, if they be Spanish; or at the invoice price from the port in which they were shipped, if foreign. According to these different valuations, which leave but little room for arbitrary decisions, the tarif subjects all national merchandise to a duty of three per cent. and foreign goods to one of seven per cent. when either are shipped for any one of the great ports of America; that is to say, the Havanna, Carthagena, Buenos Ayres, Montevideo, Callao, Arica, Guyaquil, Valparayso, and Conception; and the duty is but one and a half, or four per cent. when national or foreign merchandise is shipped for any of the lesser Indian ports.

Notwithstanding the wisdom shewn in the construction of the regulation, it excited many complaints. It left, said the complainants, much to be desired with respect to the encouragement meant to be given to national productions. Why were articles of foreign manufacture excluded from the commerce of America, the demand for which the na-

VOL. V.

national manufactories could not for a long time to come sufficiently answer, particularly in the article of silk stockings? Was not this an inducement for the merchants of Spain. convinced of the inability of obtaining enough from their own manufacturers, to engage with foreigners for a supply? And must not this necessary succour, easy to be obtained in spite of prohibitions, cause their manufactories to languish by favouring idleness? The heaviest complaint was against the troublesome formalities to which the regulation subjected the expeditions from the ports of Spain to America. Merchants were exposed to the caprices of favour and the inconvenience of delay, which, added to a duty of seven per cent. to be eluded as well in exports as imports, and to absolute prohibitions of certain articles of merchandise, could not but offer seducing advantages to contraband speculations. Could the name of a free trade, said the complainants, be given to commerce thus shackled, for each operation of which an express permission was necessary from the minister; which intrigue, unwillingness, the slowness of the forms of office and intermediate agents, might delay too long, and consequently render useless? Instead of the advantages of liberty, prohibitions, threats, and punishments, it was added, had been annexed to each article of the regulation.

The merchants of Cadiz were the chief complainants. These only had hitherto had connexions with Spanish America; they were the only persons who had capitals sufficient for such distant expeditions, of which the long delayed returns were exposed to every kind of hazard. The associates given them in thirteen other ports of Spain, would, said they, engage in ruinous speculations, which, without benefiting the colonies, would be a real loss to the commerce of Cadiz.

The voice of self-interest was easily distinguished in these complaints. The experience of a few years has already been sufficient to determine how groundless they were.

The following tables present a view of the effect of the regulation, even in the first year, on seven of the principal ports of Spain, the only ones which at first dared to take part in the trade thrown open to them:

Number of Vessels and Places whence they sailed.		Amount of National Goods.		Amount of Foreign Goo		Amount of Duties there

Ten years afterwards this commerce experienced a prodigious increase. Twelve ports in Spain, instead of seven, engaged in it. The exportation of national merchandise was more than in a quintuple degree; that of foreign more than triple; and the amount of the importations from America more than ten times greater than in 1778.

It is by a comparison between similar tables, better than by any reasoning, that one is led to judge of the progress of prosperity in any nation. The reader himself may compare the year 1778 with that of 1788.

TABLE OF THE TRADE WITH SPANISH AMERICA IN 1788.

Names of	Names of the Ports.		Value of tional Merchandise.	F	Value of oreign Merchandise.		Value of the Returns from America.

		~	157,223,039		142,494,290		804,698,733

From this exposition it appears, that in 1778 goods were shipped for Spanish America to the amount (national and foreign included)	Rials.
And that the returns to Europe amounted to	300,717,529 804,698,733
And thus that the returns exceeded the shipments from Spain by	503,981,204

What better evidence can the Spaniards, can foreigners even require of the advantages of her trade with America? Will it be denied, after inspection of these different tables, that the regulation of 1788, however imperfect it may be, has yet contributed towards the vivification of the Spanish colonies? Even the revenue has been materially benefitted by it.

In 1778, the total amount of	the dutie	es on expor	tation and	impor-	
tation amounted to -	-	•	•	• •	6,761,291
In 1798, they amounted to	-	•	•	•	55,456,949
Leaving a difference of increa	asc of	-	•	•	47,695,658

Notwithstanding this proof of the salutary consequences of the regulation of 1778, even in 1788 it was the object of rather bitter discussion among Spaniards of the best information. They affirmed that it had been enacted with an insufficiency of skill, in as much as it gave too great encouragement to fraudulent interlopers; and they endeavoured to prove it by a statement with which I here present my readers.

Before 1778, they said, almost half the trade of Mexico, and more than half of that of Terra Firma and Buenos Ayres, consisted of smuggling. The consequence was, that a great quantity of piastres, stamped in Spanish America, went directly to foreigners.

For example, it is known as a fact tha	t, from 17	67 to 1778	inclu-	
sive, there were stamped -	•	•	•	187,579,451
That of these there came to Spain	-	-	-	103,889,652

The difference between the two sums was therefore paid to contraband dealers. That if to this be added what was extracted in ingots, in produce, and raw materials, it will be evident that foreigners carried on more than half the commerce of Spanish America.

Moreover they add, since that period smuggling appears to have increased conside-

It had been calculated, that in the six years posterior to the establishment of the free trade, 56,326,029 hard dollars of the whole of those which were stamped, had left America, or annually about 9,400,000; whereas in the ten preceding years no more than 83,689,799 dollars went in that manner, less than 8,400,000 per annum.

Ought one not, said they, to draw from this difference an inference unfavourable to the establishment of a free trade?

And how could the regulation of 1778 be otherwise than advantageous to contraband trade? Spanish America has an immense extent of coast, which, government, in spite of the rigid vigilance of its agents, cannot sufficiently guard; and notwithstanding this regulation has diminished many of the charges of direct trade, it has suffered a sufficient number to remain, for foreigners to be enabled to go themselves and vend their commo-

dities to the colonists, at 20 and 25 per cent. less than the Spaniards. In order to favour national manufactures, it has laid a duty of 14 per cent. on foreign manufactures, which is augmented upon their arrival in some ports in America by an addition of 5, 8, and even 10 per cent. which, if respect be had to the difference of the prices at which they are rated, will make the whole duty from 40 to 50 per cent. on the prime value.

Two new matters posterior to the regulation have tended to favour smuggling still more.

1. A new tarif, published in 1782, increased the charge on foreign merchandise upon its entry into Spain. Spain, however, is obliged to import for her colonies linens, the greater part of the cloth which she ships, thread, a great quantity of silk articles, all her mercery, hard ware, crystals, coarse woollon goods, in short, more than two-thirds of the consumption of the Spanish Indies; all of them articles which, beside the duties to which they are liable on their arrival in America, leave Europe with an impost of 14, 20, and 25 per cent. upon their cost, according to the valuation at which they are rated on their entrance into Spain, being either less or more considerable.

2. The alteration of money has had an influence on the exchanges, which are constantly regulated by its intrinsic value.

Moreover, how can it be expected that the colonists will not prefer bartering their ingots with foreigners for merchandise, to carrying them to the mint, which receives a benefit on the coinage? or, that they should not be induced to export their dollars in contraband, while there exists a duty of 4 per cent. upon their being exported according to law?

An additional circumstance assists smuggling, in the privilege granted to Louisiana of trading with foreigners. This colony receives from Europe direct a much greater number of articles than what it consumes. What becomes of the excess may easily be divined.

Lastly, The inhabitants of the Spanish islands, possessing the liberty of trading with the different parts of the American continent, take advantage of the neighbourhood of the foreign islands, to obtain from them a quantity of merchandise, which is distributed among the Spanish colonies.

To these censors of free trade might be objected, that the greater part of these circumstances existed before its establishment; that it has besides the advantage over the former order of things, in having lessened the duties on a great number of articles; in having relieved from many incumbrances the Spanish merchants of Europe and America; that from this circumstance it must appear strange, nay almost inexplicable, that smuggling should have increased since the regulation of 1778. Doubtless, however, it will be answered, that from having greatly multiplied the places from which expeditions may be dispatched, and those at which they may arrive, the means of cluding the duties imposed on legal commerce have increased, and that in a similar proportion.

After all their inculpations, they yet do not assume that free trade should be abolished, but simply that it has been established in such a manner as to present many temptations to contraband commerce, and that it must excite no wonder if, upon its present

system, it should rather become augmented than reduced.

In fact, it is evident that the Spaniard, if he buys his merchandise at the manufactory, cannot forward it to any of the ports of Spain without being liable to expences which foreigners are not subject to, who ship from their own country. Again, the freight and insurance which he pays, loads him with an addition of three or four per cent. from which the English, the French, and the Dutch are exempt, which is however nearly

compensated by the commission paid on the foreign merchandise which is smuggled. Here then we see goods in the hands of the persons who receive them by contraband, at nearly the same price they cost the Spanish merchant who forwards them in a legal manner. The one has to pay the charges of transports to the American haven, the unloading, and insurance against confiscation; these collective charges are no more than 7 or 8 per cent. But the other must pay at least 14 per cent, duty on entry of his goods in Spain, 7 per cent, on their export, and more than 7 per cent, upon their arrival in an American port, which together make a total charge of 28 per cent. The smuggler thus has an advantage over the Spanish merchant who trades legally of 20 per cent, without reckoning the profit which he draws from the precious articles with which he is furnished for his returns, or the metals which he receives, without paying the export duty.

To place the Spanish merchant, therefore, upon a par with the foreign contraband trader, government should exact no more than 6 per cent, on all merchandise shipped to New Spain. Without this measure, how is it possible that it can compete with the English, who export all their manufactured goods in peace free of duty, and in war time with a convoy duty only of 3 or 4 per cent, a modus not equal to the difference of insurance which vessels navigating under other flags must pay; with the French, who since the revolution pay no duties on exportation; with the Dutch, whose export dues are not more than 1 per cent; or with the Danes, who have a free port in St. Thomas,

Still smaller imposts should be levied on goods shipped for the Spanish islands, and all the immediately contiguous coasts, for the purpose of counterbalancing the facility

for smuggling, which their position affords.

On the other hand, heavier duties might be imposed on merchandise shipped for Buenos Ayres, and somewhat even additional upon those destined for Peru: contraband entries being much less easy at the first of these colonies since the destruction of the colony of San Sagramento, situated opposite to Buenos Ayres, and being almost null in Peru and Chili.

As for Spanish merchandise, perhaps it would be best that the duty on export thereof should at most not exceed 2 per cent. Possibly the diminution of revenue which this would appear to threaten the treasury with, might be objected to by government, not yet persuaded of the truth which in so keen a manner was expressed by Swift; that in the arithmetic of taxes, two and two do not always make four. But if from this reduction, of unpleasant aspect in the first instance, the result should be, that the articles which commerce wafts to the Indies in a contraband manner should take the legal channel, government would not be long in finding that by losing a part of her revenue, she would almost annihilate smuggling, vivify her trade, and of most consequence of all, secure the preservation of her colonies, greatly risked by the clandestine and continual communication which they maintain with foreign nations.

Moreover, the Spanish government should bear in mind, that it has to provide for the military and civil administration of its colonies, for the expence of public works, of charitable institutions, and, in short, for all important charges; that these expences are very far from being covered by the revenue of its mines; that trade is the only profit which Spain draws from her possessions; and that should she be ruined by smuggling, she will be obliged to abandon them for want of means to answer the cost of their dependency. Even this might not eventually be materially injurious to her; but since her glory, whether well or ill understood, prescribes to her the preservation of them, let her study to avoid the rocks against which these possessions, more brilliant than useful, are destined

to strike at some future period.

Even if there should exist a mode of preventing smuggling compatible with the reservation of the duties as they are at present, still ought the government to lessen the impediments to the free course of commerce; as such a measure would increase consumption, and consequently benefit Spain. It already sees that, in spite of prohibition, a manufactory of coarse cloths has been established in the province of Quito, and others of stained cloths, galoons, hats, and different articles besides, in various parts of New Spain. Let European goods arrive there at a moderate price, these would fall of themselves. Allow the colonists a perfect freedom to export their raw articles in return, and they would not suffer by changing the application of their industry. Agriculture of itself is sufficient to employ all their hands, and procure them all the necessaries of life; and, with the superfluity of the varied and valuable productions of their soil, Spain might purchase the produce of the soil and industry of the rest of Europe. Hence would arise a commerce of barter, equally advantageous to both worlds, and the ties between the metropolis and her colonies be drawn more close, by the effectuation of that real happiness which nature appears to have intended. She has bestowed upon Spanish America immense woods, vast countries exceedingly fertile, and a disproportionate population. In such a country manufactories cannot flourish. Every thing which draws its inhabitants from their fields and cultivation, has for a lamentable consequence the effect of

concentrating the population in towns, and leaving the country a prey to wretchedness. These ideas have occurred to me; and whatever may be said of a free commerce, whether its advocates or its opponents be right or wrong in their assumptions, it is incontestible that since its establishment the Spanish Indies have increased in prosperity. It is further more ascertained that smuggling has materially diminished since 1788, the epoch of the outcry that was raised against it. As a proof, the returns of 1791 have been cited. In this year there arrived from Mexico and Peru 22 millions of hard dollars. Now it is known that Mexico yields commonly from 21 to 22 millions annually, and Peru five or six, making together a total of from 26 to 28 millions.* If then from this

capital it be computed that somewhat must remain in the country for its currency, it will be evident that there can be but little left for contraband exportation.

Moreover, it cannot admit a doubt that Spain has lately furnished America with a fat greater quantity of wines, fruits, and other produce, as well as of manufacture d goods, than what it had been used to do, or that productions before unknown have been returned; that those which before came in small portions are furnished plenteously, such as tobacco, sugar and coffee; that Cuba particularly has notably improved notwithstanding at present it be wide of that prosperity which it is capable of attaining; and lastly that communication between the metropolis and her colonies has become infinitely more active: let this single fact suffice; before 1778 the fleet and the galleons used to sail every three years. A merchant then must necessarily have been subjected to considerable expence, and to an infinity of trouble in order to obtain permission for his vessel to form a part of the expedition, which consisted of no more than 14 or 15 ships. In 1791, 89 vessels were dispatched from Spain to the Indies. Does not this at once answer the question of the propriety of a free trade?

At first the minister for the Indies did not deem it proper to extend free commerce to Mexico, which remained for eight years subject to the ancient regulations. When he esteemed himself justified from the numerous data with which he was furnished, and was satisfied that he had nothing to apprehend from extending a species of free trade to this vast colony, with which he was better acquainted than any of the rest, he caused it in 1786 to participate in measure in the regulation of 1778, but confined the annual supply of merchandise to be furnished it, to 6000 tons; whimsical restriction! which evidences the predilection which Galvez had for regulating systems.

I had a close acquaintance with this ambitious minister. He was exceedingly laborious, personally disinterested, and possessed some talent; but with these, his manners were repulsive, and he assumed all the consequence of a vizier. It is true he had all the power, without at the same time running the hazard of an Ottoman minister, and Charles III, had an entire confidence in him. This monarch, truly virtuous, had some peculiarities; he looked upon himself as a great tactician, and in consequence considered and determined every thing that regarded the army, and military plans. As for the other departments, that of his conscience inclusive, he blindly submitted them to the management of those he had charged with them; and none of the ministers profited more by this concession than Galvez, who pretended at all times a difference to the superior intelligence of the sovereign. Marshal Duras became acquainted with him during his embassy in Spain, and appointed him advocate for the French nation; this was not an idle appointment then at Madrid, although it has latterly been suppressed. It closely connected him with the French, and their ambassador. Possibly a near examination into our character may be more prejudicial to the forming a favourable opinion of us, than a slight acquaintance. However that may be, notwithstanding the frequent communications he had with the French, he entertained towards them an aversion, that he but ill disguised beneath the veil of friendly professions. Mr. D'Ossun threw this lean' carp into the fish-pond. He recommended him strongly to the marquis de Grimaldi, who in 1763 took the port folio of foreign affairs, and to Charles III, himself whom he

followed from Naples to Madrid. He greatly contributed towards obtaining for Galve: an important commission to Mexico, where he shewed his domineering and enterpriaing spirit, and where, intoxicated with power and overcome by the fatigue of an extremely laborious mission, he became a prey to a malady, which was accompanied and succeeded by many acts of insanity. On his return he was rewarded for his pains, and revenged for the inculpations on every head which had preceded him in Europe, by an appointment to the office of Minister for India; that is to say by an appointment, which gave him a more extensive and unlimited authority than is possessed by any individual, not himself a sovereign, upon the surface of the globe. In this situation he retained towards Mr. d'Ossun the exterior of gratitude, towards the French nation at least the language of attachment.* Yet of this nation he entertained a jealousy and antipathy which he demonstrated on more than one occasion. His despotic nature was liable to irritation at the slightest contradiction. His administration seemed to be the ark of the covenant with which no one could touch with impunity. Whosoever should presume to reveal or pry into its springs became at the instant a viper in his eyes. He could scarcely ever forgive Robinson for publishing his work on America. He constantly retarded the translation of it, under pretext that he could not have it appear without a correction of certain errors with which it was replete, and which in a supplement to the work, admirable in some respects according to his own allowance, he himself would refute by a statement of facts. Before he had completed this work, perhaps before he had ever seriously thought of it, he died. As for the philosophical history of Raynal, as often as it was mentioned to him, it put him in a rage. I myself have heard him break out into imprecations against certain Frenchmen, who had taken advantage of an allowance granted them for a temporary residence on the coast of Cumana, to introduce some copies of that infernal work.

Galvez displayed the same imperious and violent character in every branch of his vast administration. That he was extremely diligent cannot be denied, nor that he had a resolute inclination to effect the reform of abuses, and oppressive regulations. But among the most enlightened Spaniards it is questionable, whether during his administration he effected most good, or harm, for the Spanish Indies. What however is certain, he created in them, much against his inclinations, a disposition to independence. Too desirous of proving that an able minister might render them productive to the revenue of the metropolis, to which for a long time they had been a burthen; by an increase of taxes, and a bad choice of collectors, he provoked an insurrection in 1781, at Santa Fi; and one shortly after still more serious in Peru. The latter was not terminated but by having recourse to bloody measures, and the condemnation of the intrepid chief of the rioting band Tapacameros. And what instant did he choose for irritating and oppressing the Spanish colonies? The very moment in which, for motives of no greater weight, the colonies of Great Britain rebelled against and deserted her mother country.

[&]quot;Galvez, a man of real talent, and who knew better than M. de Bourgoing the character of the nation with which he had to deal, who from his minute attention to colonial affairs was competent to judge of the remedies for the disorders which existed in the colonies, previous to his administration, and the proper time for application of them; M. Galvez, who was as well a man of sense and keen discrimination, and had a near acquaintance with that nation whose character is more shining than valuable, and truly, and not only probably, better calculated for a slight acquaintance than a near inspection; this M. Galvez had a well founded aversion towards the French. This carp, which the French ambassador threw when lean into the pond, with intention when fatted to serve up at table, although thankful to his benefactor, became soon not only a fat but an old fish; and the French found him continually too cunning to be taken by the nets they cast for him; he was too little of a glutton to seize the tempting baits with which they sought to hook him; and too little sensitive to be tickled out of the water.

For the purpose of establishing and collecting the new taxes he had laid on the people, sixteen thousand officers were employed, whose salaries and misapplications absorbed all their receipts. Notwithstanding this, he boasted with unblushing front, that he had augmented the revenue of Spanish America from five millions of piastres to 18, the while towards the end of his administration, government was obliged to send remittances of money (situados) to the Philippines, to Porto Rico, to Santo Domingo, to Louisiana, and sometimes even to the Havanna.

On the other hand, it must be granted, that he successfully laboured at enlivening commerce and agriculture of the Spanish Indies; that La Trinidad, Louisiana, the Philippines, and particularly Mexico, owe to him the dawn of their prosperity. I shall trace a rapid sketch of what he has effected for these colonies, or at least of the beneficial al-

terations contemporary with his administration.

CHAPTER VIII.

MEASURES ADOPTED WITH REGARD TO LOUISIANA. OF THE CESSION OF SANTA DOMINGO TO FRANCE. RECENT PROSPERITY OF TRINIDAD. TREATY OF SPAIN FOR THE SUPPLY OF NECROES.

From the moment Louisiana was ceded by the French to Spain, the court of Madrid, which to subjugate this colony had employed such vigorous measures as could not fail to render its yoke odious, endeavoured to soften its fate by granting to the inhabitants such privileges as were calculated to insure their prosperity. In 1768, it was enacted, that merchandise going from Spain to Louisiana, and the productions received from that colony, should be exempt from all duties of exportation; and that the produce of the colony should pay a duty of but four per cent. upon entering Spain. But as those in the greatest abundance, such as tobacco, indigo, cotton, and particularly furs, could not find a great sale in Spain, it was agreed that French vessels might load with them at New Orleans, but that they should arrive there in ballast. This ristriction was so frequently eluded, that the Spanish government saw the necessity of taking it off, convinced that the furs, skins, &c. of Louisiana could but be exchanged for goods manufactured in France.

The regulation of 1778, in addition to the other privileges of Louisiana, exempted all furs from duty for the space of ten years. Afterwards in 1782, Pensicola and West Florida being added to the Spanish possessions in the gulf of Mexico, it was established, that for ten years, reckoning from the conclusion of the peace, ships should be permitted to sail from French ports to Louisiana and Pensicola. And bring back returns of all the productions of the two colonies, that the articles, as well exported as imported, should pay a duty of no more than six per cent.; that in case of necessity the inhabitants should be permitted to furnish themselves with provisions from the French American islands; and that the negroes, which they might procure from friendly colonies should enter their ports duty free. The regulation expressly mentioned, that the foreign merchandise received at Louisiana should be for its own consumption only. This restriction was in course evaded; for considering the numerous expeditions made to New Orleans in consequence of the regulation, many speculators would have been ruined, had their cargoes had no other market than that of Louisiana.

This regulation of 1782 soon made some addition to it necessary; the people of Louisiana were to form no commercial connexions but with France. Had the French been able to furnish them with all the articles they required, they would have deprived the contraband traders of any benefit from fraudulent commerce by way of Florida, and

the north of the Mississippi, and would have procured at an easy rate the furs, beaver skins, and other productions of Louisiana. But as the inhabitants of this colony consumed certain foreign merchandise not produced by France, such as Silesian linens, English chintzes, &c. in order to secure the whole profit of this new arrangement to the French, it was necessary to obtain from the French government an allowance for the free importation of these articles, which might afterwards have been shipped from the ports of that kingdom immediately to Louisiana. The Spanish minister confided this negotiation to M. Maxent, father-in-law to general Galvez, a man whom that minister had reason in priding himself at being connected with, a man who in the American war displayed great brilliancy of talent, who had paved the way for the prosperity of Louisiana by the mildness and wisdom of his administration, and who afterwards, promoted to the viceroyalty of Mexico, was by a premature death snatched from his country and a truly interesting family. The French government, fearful of injuring the revenues of the country, declined the proposals of Mr. Maxent; and the court of Madrid was obliged to extend to other ports, such as Ostend, Amsterdam, Genoa, &c. a privilege which at first had been reserved for those of France.

This circumstance however did not hinder the French from enjoying almost the whole of the commerce of Louisiana up to the period of the rupture between the two countries. They even maintained two commissaries in the colony for the purpose of superintending the interests of their merchants.

The state of Louisiana is not materially changed from what it was at the time of its cession to Spain. Its capital at that time contained 5 or 6000 inhabitants. In 1793 it did not contain more than 8000, exclusive of negroes, the number of whom throughout the colony amounted to about 25,000: that of the whole of the colonists might be reckoned about 20,000: the majority of which are French. If the persons employed by government both civil and military be excepted, who are Spanish, few others of that nation are to be met with. The Americans have formed establishments at Natchez, where they have introduced English cultivation with success; and upon the right bank of the Mississippi are some Germans, who next to the Americans are the best farmers in the colony.

The extent of cultivated land in Louisiana is yet very confined; tobacco and indigo are the only articles which have yet attained any high degree of prosperity. Nevertheless before the war with France it had a handsome portion of export trade, the amount may be computed at 8,400,000 leones (350,000l.) annually. But excepting a part which certain avaricious governors are said to take in this trade, the rest is confined to foreign merchants, who only establish themselves at New Orleans for the purpose of acquiring fortunes; and aftewards return to their native country: woeful circumstance, which depriving this colony of capital without which nothing can be undertaken, deprives it of the means of displaying the advantages with which it has been favoured by nature.

These advantages are so numerous and brilliant, that, when known, one is induced to pardon our forefathers for having been led astray by the deceptive illusions of the Mississippi scheme. Let the rapid sketch here adduced serve for framing a judgment of them.

Louisiana is situated in one of the finest climates. It is watered through the whole of its length by a river, which adds to the natural fertility of the soil, and which at its mouth presents an immense outlet for all the productions it nourishes in its course.

At the head of these is to be placed tobacco, which is greatly superior to that of Maryland or Virginia. Of this article 3,000,000lbs. are annually exported on account of the king of Spain; which, at 5d. per lb. amount to 61,250l.

The indigo of Louisiana is equally good with that of St. Domingo, and consequently much superior to that of Carolina. Before the war with France and Spain a great quantity was exported to France; the amount of its annual produce was computed to be

500,000lbs. weight, which at 5s. 6d. per lb. gives for its value 137,500l.

Skins, for a long space of time, formed a principal article of trade from Louisiana. From 1765 to 1778 it was computed that the nature of the annual exportation amounted to 166,600; but this commerce is diminished one half by the cause before noticed; the merchants having no sooner enriched themselves than they withdraw, carrying away with them their capitals, which are absolutely necessary in the fur and skin trade. The savages, with whom this trade is most beneficially carried on, are the Missouries, who bring the produce of their hunting to Saint Louis, a village the inhabitants of which consist principally of Frenchmen, who are well beloved in the adjacent district.

If Louisiuna had more markets to send her productions to, she might reap great benefit from the collection of pitch, and tar, of an excellent quality; which may be obtained

in large quantities, particularly between Mobile and New Orleans.

It produces as well an immense quantity of timber for ship building. The value of its exports of masts, spars, planking, &c. is computed at 35,000l. annually, besides a number of small vessels, and even of as high a burthen as 400 tons, which are built in the Mississippi, and which are equally strong and cheap. Its cedar is of the finest quality; green, white, and red oak are very abundant, and remarkable for the size, height, and toughness of the wood; their cypresses make excellent masts, and to the West Indies they ship prodigious quantities of shingles, staves, and boards. They ship annually for the Havanna 100,000 cases of sugar; and employ near 500 saw mills, of two saws each, which work by the rise and fall of ude.

Immense flocks, and herds, furnish them with a superfluity of meat, and already form a considerable branch of trade, in the exportation of hides and tallow. Finally they could export, if they had a market, a number of horses, vegetable wax, wool, hemp, and even silk. I shall say nothing of rice, peas, maize, &c. of which but small quantities are exported, which however if added to the naval stores may collectively be valued at

17,000l. sterling.

The French trade before the cession of Louisians, to France, employed six vessels, laden with indigo, skins, and dollars for the metropois, more than sixty small vessels between New Orleans, and San Domingo, and some few to Martinico and Guadaloupe, laden with wood, rice, pulse, pitch, tar, tobacco, and particularly piastres, and which car-

ried back all descriptions of European goods, and negroes.

It is at first sight an inexplicable phenomenon, with all these advantages, that a colony so highly favoured by nature, and for which Spain while it was in her power, by lessening the duties so much beneath what her other states were taxed at, and by other privileges granted, so greatly assisted, should have made so little progress. It has now changed its master, and there remains to be seen if in other hands, and with more attention to the advantages to be derived, its race to the jail of prosperity be not as fleet as before it was tardy. The Americans appear destined to force Louisiana at length to fulfil the purpose of nature. Already settled upon the great river Mississippi, and upon the Missouri and the Ohio, whose tributary streams increase its sea of waters, they solicited with threatening impatience a right of passage to the ocean, which the regulating system of the Spanish government refused; and which early or late they must have forced; when Spain in 1795 at length conceded it to them.

This measure, which decided the fate of the western states of America, and secured their success, must naturally tend to augment amazingly the prosperity of Louisiana.

New Orleans must become the depot for the goods which they have to export, as well as juently quanfor those which they may require, and consequently become a place of permanent attraction to speculators; and the example of this fecundating activity cannot fail to enliven to be the whole colony. The English government was greatly pleased with the concession made by Spain. The Mississippi, observed their orators, comes from the north west, risiana. the Ohio which falls into it from the north east. Both traverse countries which are no ounted where surpassed in fertility, countries which produce abundance of wood fit for the cond; the struction of mills, and houses such as oak, fir, elm, and walnut tree. This wood by dely with scending the rivers to their mouth will arrive cheap at the English islands. These islands ic savamoreover may receive by the same channel as far as from Pittsburg in the same latitude o bring consist as New York, wheat, and iron, with which they could not be supplied from New York itself, or Philadelphia, but at a much higher rate. In one word, the opening of the Mississippi insuring sufficient shipments of grain for the consumption of her islands cat bewill dispense England from the necessity of provisioning them, and greatly extend at btained the same time the diffusion of her manufactures. Should experience justify the favourable conjectures of the British ministry, it may be said, that the treaty by which the alue of prince of the peace and Mr. Pinckney terminated a very knotty negetiation in 1795,

> Had Louisiana continued subject to the Spanish, in all human probability it would have reaped advantage from the happy change in its relations, and might by its connections with France have been of more actual benefit than if it formed a part of its colonies; we may at any rate be satisfied with our having abided by the treaty of Basle, and

> after thirteen years discussion, will have possessed the singularity in diplomatic annals,

being content with the cession of the Spanish part of St. Domingo.

of having been directed against no one, and advantageous to all.

Spain, on her side, in yielding it, made no painful sacrifice: to her it was rather burthensome than beneficial. It is well known that within the century preceding 1784, it had been a net expense to her of 17 millions of piastres; and that latterly it cost her 200,000 hard dollars annually. In assuming this sum, which I have especial reasons for deeming correct, it does not appear that I exceed the idea which enlightened people had entertained of its amount, since M. Moreau de St. Mery in his valuable work on this island, rates it at 1,700,000 livres, or upwards of 300,000 dollars. Notwithstanding the Spanish part of the island was double the extent of ours, its population at the period adverted to did not amount to more than 100,000 souls, of which scarcely 3000 negroes followed agriculture; nor did the inhabitants even ten years later, according to St. Mery, surpass 100,000 of free men, and 15,000 slaves. It possessed scarcely any other cultivated lands than such as were tilled by our run-a-way negroes. This colony may on the establishment of power in the West India islands become in our hands of more value than the whole of our Antilles. None of the valuable productions of America are foreign to its soil. It is capable of yielding as much tobacco and sugar as Cuba; as much of coffee and cotton as our former part of St. Domingo was accustomed to do; better cocoa even than that of the Caraccas; but all its productions, although for the most part indigenous, are small in quantity at present in this colony, after having been formerly so plentitul, that in cocoa alone St. Domingo furnished a sufficiency for the entire consumption of Spain. There are two districts on this part of the island well adapted to the rearing of sheep, many suitable to horned cattle, its territory is well watered in every respect, and of an uneven surface. To conclude, four of its ports, San Domingo, Samana, Port de Plata, and Monto Christo, are well adapted for the reception and exportation of its pro-

colony lessenr privihanged n to the efore it he purne Mised with stem of ; when

secured

From the foregoing sketch it will be at once concluded that this new colony acquired by the treaty of Basle is singularly favoured by nature, but at the same time all remains to be done; and consequently, the advantages which the French may reap from it, can be

looked for only at a very distant period.

This at the same time is all that can be granted to those who blame the policy of our making this new acquisition, and among their number it cannot be disputed that there are some who like M. Moreau de St. Mery reason with much plausibility and from incontrovertible facts. With them we are disposed to agree that the French part of St. Domingo will gain by its incorporation with the Spanish part, neither any considerable means of defence, nor perhaps a greater security for its navigation in time of war; but at the same time, we cannot share their apprehensions of seeing the means of subsistence diminish in consequence on the ancient French colony. From the evidence of a century past, of what in this respect has taken place between the French colonists and the Spaniards, it is evident, that the supply of cattle afforded by the Spanish part of the island to the other must necessarily be precarious as long as it is dependant upon foreign governors and administrators, with whom the rulers of the French could make no other than provincial and imperfect stipulations, for the observance of which no guarantee was afforded: whereas in the present state it will be possible to make permanent, and strict re-

gulations, which will secure our ancient colony against this inconvenience.

In vain do they who are of opinion that the acceptance of this colony is impolitic, assume, in opposition, that Africa must be dopopulated to supply it with the million of negroes necessary to open the soil, a difficulty of no less magnitude would remain to be overcome in finding capital for such an immense undertaking; particularly after the horrible commotion which has occurred, and which will leave so much to regenerate in the former French colony. To them may be answered, that the French government lie under no obligation to effect the amelioration of the whole colony at once; and that in fact the means to be employed are not of the description that they appear to indicate; since from the solemn abjuration of the slave trade which has been made in France, it is deprived of the means of consecrating the Spanish part of St. Domingo, to that species of cultivation, which, apparently, cannot be undertaken without the assistance of negroes; that there are other modes of rendering productive a country, which by their own allowance presents so many resources, and that in the interval of the government becoming occupied with its improvement on a more extensive scale, nothing opposes its beginning to populate and clear it, by inviting to it the numerous French families who have been ruined by the revolution, and the numerous wanderers from every country to whom all places are alike, when their distress may find alleviation, or their situation in life be varied for the better. These new colonists, attracted by the beauty of the climate, by the advantages which its incorporation with the French republic holds out to them, and by the cheapness with which they will be enabled to purchase uncleared lands, would thus pave the way for the prosperity of the country, scarcely yet inhabited, without its becoming necessary to depopulate Africa, or empty the national exchequer.

This momentous question of the policy of the acquisition of the former Spanish part of St. Domingo, has been treated by both sides with that exaggeration which disfigures every thing by its attempt at embellishment, and predicts consequences which never happen. On one hand it is affirmed, that this acquisition will ruin the French colony; that the Spanish inhabitants will leave their quarters; the meadows whereon they graze the cattle, without which the French cannot subsist, will be either abandoned or

panish part disfigures hich never ch colony; they graze ndoned or appropriated to cultivation, and the colony will perish for want in the midst of its plantations of sugar and coffee. Again, how can the forces of one single power protect so vast an extent of coast? What a robbery must it not occasion the forces of the metropolis, which so much requires her power at home! What an unwise appropriation of that trease e which she herself is in such need of!

On the other hand, those who are fond of embellishing the future, reckon upon St. Domingo attaining in ten years such a degree of prosperity as is wholly unexampled; increasing the imports of France by 150 millions of livres, and affording a supply for the necessities of all the world. Patriots so easily alarmed, dismiss your sombre fancies; visionaries of optimism, wake from your fairy dreams? Neither of your prognostics bear semblance of a likely feature. You have seen the destined pairs, "hose amiable qualities, whose apparent suitableness for each other, whose mutual and excite such tender interest: their wedding day arrives, how serious the state, how decisive of their future destiny! You exclaim, "on this instant depends their happiness or their misery." The sentence is erroneous: they are deceived as well as those who tell them so. They are about to pass together thirty years of their lives without effecting either the one or the other. Thus will it be with St. Domingo, and with a crowd of similar other cases from which great wonders are expected, or great disasters apprehended.

I now pass on to other colonies which are indebted to the minister Galvez for at least

the dawn of their regeneration.

Trinidad had for a long time been one of the most unprofitable of the Spanish colonies. Its situation at the entrance of the gulf of Mexico, near the coast of Terra Firma, the salubrity of its climate, the fertility of its soil, scarce opened by the husbandman, and the excellence of some of its harbours, on the contrary, ought to make it a valuable possession. Galvez, in order to give new life to this palsied member of the Spanish monarchy, added in 1776 the island of Trinidad to the department of the company of Caraccas. In 1778 it was included in the new regulation. The next year M. d'Avalos, intendant of the province of Caraccas, consulted and encouraged by the minister, took upon himself to people and fertilize Trinidad. A Frenchman, not less active than himself, seconded his intentions: this was M. de Saint Laurent (since known by the name of Roume) who after living several years on an island of Granada, where he has acquired general esteem, went to settle at Trinidad. He was previously acquainted with all the resources of the island, had connections with most of the Caribbe islands, and possessed, in a superior degree, the talent of inspiring confidence and benevolence by his easy manners, and his honest bluntness. M. d'Avalos deputed him to procure settlers for the island of Trinidad. For effecting this purpose he proposed a regulation, which M. d'Avalos published the beginning of 1780, without waiting for the consent of the court, and it produced a speedy effect. In the month of June 1782, there were a hundred and seventy-four families of new colonists, who had brought with them a thousand and eighty-five slaves, and had begun nearly two hundred plantations of sugar, coffee, and cocoa. However the greatest part of the emigrants, upon whom M. d'Avalos reckoned, waited until the court of Spain should make a formal avowal of the promised privileges; and M. de St. Laurent came in 1783 to Europe to solicit it. He was not satisfied with his reception by the jealous minister, who wished every thing should proceed from himself, and could ill brook that any thing beneficial should take effect at the instigation of another. To justify the promises he had made to the emigrants, he demanded privileges which were found incompatible with the laws of the Indies; and the council, the depository of these laws, opposed the ancient inflexibility of its principles. He conceived himself to possess a right to the acknowledgements of Spain, and demanded them with that bluntness which scorns to ask for justice in those accents employed in the solicitations for favours. In short the fate of Trinidad was decided without his occurrence.**

In the month of November 1783, a royal mandate appeared which weakly seconded the advances of the colony to prosperity. It granted to the new colonists, a part only of the privileges which St. Laurent had judged necessary; it allowed them a free trade with the French in Europe as well as in the Caribbees, but stipulated that the commerce

should be carried on in Spanish vessels.

The importation of negroes, which the colony wanted, was permitted but with restrictions, stipulating simply that this island should serve as a depository for all those which foreign nations should bring thither. Spain could not do without these to furnish her colonies. At the expiration of the famous assiento, which the English obtained at the peace of Utretcht, this charge was transferred to a company which had made Porto Rico the depository of all the negroes it bought. The contract of the company expiring in 1780, Spain determined on importing her own slaves. With this www government had acquired from Portugal, by the treaty of peace in 1778, two small islands near the coast of Africa, called Annobon and Fernando del Po. But, besides their being badly situated for the purpose, Spain is in want of funds which are especially necessary for the negro trade; she has neither vessels properly built for the purpose, nor the merchandise suitable to barter for negroes, nor sailors accustomed to the transe, nor surgeons who understand how they should be treated; and until she thus becomes upon an equality with the nations used to this commerce, she will be obliged to have recourse to their assistance. It is however only by degrees that she will be persuaded of this truth. Thus, at first she had recourse to certain foreigners, who within a stated time engaged to furnish her with a limited number of negrees. These partial measures turning out insufficient at the beginning of 1789, she adapted the plan of allowing foreigners as well as Spaniards the liberty of importing negroes into the colonies of St. Domingo, Cuba, Porto Rico, and the Caraccas. In the month of February 1791 she extended this permission to two years longer, and included Santa Fi in the allowance. Towards the close of the same year appeared a proclamation suffering natives as well as foreigners for six years to go to purchase negroes wherever they were to be met with, and disembark them in the colonies previously mentioned, as well as at Buenos Ayres; with this restriction only on foreigners, that their vessels on their arrival on the Spanish coasts should contain no other lading, not even excepting agricultural tools, the introduction of which was exclusively reserved to Spaniards. For all the edicts issued by the Spanish government in modern times are continually shackled with restrictions and exceptions. On this occasion this was particularly experienced by They were entirely excluded from the privilege which the proclamation granted to other foreigners; the motive was clear enough. Even the most pious courts do not oppose the most revolting of all traffics, which is legitimatized in their eyes by the prosperity and profit it brings to their country; but by the importation of French principles they conceived there was nothing to be acquired, and consequently placed every obstacle in its way.

In the mean time we felt offended at the exception. Our traders solicited the revocation of an exclusion which was injurious to them, and in the month of May 1792 I ob-

This estimable man found himself, as the reward of his talents and labours, abandoned to all the anxieties caused by a derangement of property, when marshal de Castries, who had found an opportunity of becoming acquainted with his merit, recompensed him for the injustice and caprice of fortune, by nominating him commissary at Tobago.

II the anxpportunity ortune, by tained their wish. It was at this instant that Spain, acknowledging my character, seemed to be reconciled for a time with the revolution. The French administration, however, at that period did not think it prudent to avail itself of the grant. It was of opinion, that for a trifling pecuniary gain its own islands would be deprived of their regular supply from the proprietors of slave ships, finding it more advantageous to carry their negroes to the Spanish colonies. It was wrong in its computation, for slaves are more dear in the French than in the Spanish settlements, and consequently would secure the former a preference. The English were likely to be most benefited by the edict; their import of negroes amounted to from 40 to 45,000, and was consequently greater than their demand; while the whole importation of the French did not exceed 25,000.

Moreover, the war which shortly after took place between France and Spain made a nullity of the allowance conceded to the former, and the philosophy of our legislators shortly after annihilated the traffic in negroes. The government of Spain has not imitated the generous example. Here, however, it is just that I should observe, that if this horrible practice were tolerable in any part of the globe, it would be under the Spanish dominion; and it is worthy of remark, that the nation which is charged with having used more cruelty than any other in the new world, is that which, with the Portuguese, maintains towards its negroes the most mild and benevolent deportment; as if studious, by its present humane disposition, to expiate, or at least make amends for the cruelties of their forefathers. But let us return to Trinidad.

The court of Madrid at length followed a plan with respect to this island, bold in itself, but with which she has reason to be satisfied. She granted to it a licence, such as perhaps cannot be exampled on the surface of the globe. Before the American war it was almost a desert, in a perfect state of nature. Spain threw open its ports to foreigners of every nation. She invited them to establish themselves there with their capitals and negroes, exempted from duties every thing exported by Spaniards, as well from the colony as from the opposite coast of Terra Firma, and laid but a very moderate duty on whatever was exported by foreigners to alien ports. She did more: she entrusted the government of Trinidad to a person as well informed as he was beneficent, Don Joachim Chacon.*

Hence has arisen a prosperity as brilliant as rapid. The soil of Trinidad is calculated to produce every species of colonial production. Cocoa, indigo, cotton, and coffee have been successively tried; but it has been found impossible to preserve them from the creeping and winged insects with which the colony abounds, and plantations of these descriptions have been abandoned. But the cultivation of sugar is already in the most flourishing state. Less than fifteen years ago there were scarcely twenty sugar plantations, there are now more than three hundred and sixty. From different islands in the West Indies, particularly from the French, the discontented have fled to Trinidad, taking with them all their negroes. It will be no exaggeration to compute its colonists at sixty thousand at this moment; of which but few are Spaniards, many Americans, and many French, as well emigrants as patriots. There, under one of the finest climates in the universe, on a virgin soil, which usuriously repays their labours, they forget their

^{*} Events, however, have proved, or at least have left room for believing, that his courage was not equal to his intelligence. It was he who presided at the defence of Trinidad when the English, with so little difficulty, made themselves the masters of it in 1798. Shortly after, their governor of St. Vincent went to see the actual state of the new conquest, and satisfied himself of its importance, not only with respect to its intrinsic value, but more particularly from its geographical position. The report which he made on his return to London to the British ministry fixed its attention so strongly, that it was easy to perceive, even at that instant, the fixed acquisition of this valuable colony would be made one of the articles sine qua non of the future peace.

former feuds, and live in peace, protected by a wise government, which alike dispenses to every one both happiness and protection. The new comers received advances of agricultural implements, and even capital, the value of which was rigorously reclaimed at the expiration of three years. If they bring capitals, they buy such plantations already begun as are on sale; or grants of lands not then sold are made them from the crown, the price of which is paid after their being brought into a state of production. The rights to which the colonists owed their prosperity were, in 1796, prolonged for eighteen years; in less time than that will Trinidad become as flourishing as any other colony of the new world.*

CHAPTER IX.

WHAT THE SPANISH GOVERNMENT HAS C OR THE PHILIPPINES AND MEXICO. WORKING OF THE MINES.

LOUISIANA and Trinidad are not the only colonies, the regeneration of which has been undertaken by modern Spain; yet is there one at the extremity of Asia which seems to accuse the metropolis of taking too little interest in seconding the bounties of nature. I speak of the Archipelago of the Philippine islands, which, if the Marianas be included, comprise a possession more extensive than France, Spain, and Italy joined together. Not only does every requisite of life abound in them, they at the same time produce abundance of ship timber, woods proper for dyeing, several iron mines, and rivers navigable a long way up the country. Cotton, tobacco, indigo, and sugar thrive in that soil; some gold is also found among the sand of certain rivers. The vegetable kingdom is rich beyond measure. Sonnerat brought away from there in 1781 near six thousand plants before unknown in Europe. The number of subjects who acknowledge the Spanish dominion is upwards of a million, without including the wild natives who live in the woods, and of which the enumeration would be almost impossible.

Convinced of the impossibility of establishing a regular and well supported commerce between them and the mother country, the kings of Spain have confined their efforts to bestowing on them a communication, by the port of Acapulco, with the western coast of Mexico. The famous Nao (Galleon) which every year makes the voyage from Manilla to Acapulco, across the South Sea, is generally known. It was, for the most part, by this route that Spain communicated with the Philippines; a communication without profit for her European subjects, and of which the principal advantage was reaped by the Chinese, the Armenians, and other nations who frequent the eastern ocean. Even the revenue derived no advantage from it; for the moderate produce of the duties was not sufficient to defray the expences incurred in their collection. The civilized inhabitants of the Philippines, without cultivation or industry, had no other resource than in the commissions to which their situation was favourable. Like Spain in Europe, the

^{*} Such was the situation of Trinidad when the English took possession of it; now that is ceded to them by the treaty of Amiens, they will not fail to make their harvest of all the advantages which it holds forth. The principal one for them will be the possession of a colony abutting upon the Spanish coast of Terra Firma, and the being enabled to supply it abundantly with the produce of their manufactories; possibly they may not neglect it in other points of view. Trinidad, to which nature has been prodigal of all descriptions of wealth, contains much treasure worthy of the attention of the naturalist. It was with a view to the discovery thereof that our government, with the consent of the court of Madrid, and provided with a protection from Great Britain, dispatched the frigate La Belle Angelique in 1796, under the command of captain Baudin, for Trinidad, with some of our learned men, skilled in natural history and botany. This object, of which circumstances have permitted no more than the outlines to be sketched, will no doubt be completed by the British government, and leave science nothing to regret from the change of masters which this colony has undergone.

island of Luconia or Manilla, which is the principal of the Philippines, was only a channel through which the piastres of Mexico passed to the Indian nations; so that, notwithstanding the enormous sums of money which commerce has carried to these islands since the time of t' ir conquest, there remains in them but a very moderate quantity.

Their defence was as much neglected as their interior prosperity. It may be recollected with what ease they were taken in the war before the last by the same general Draper who commanded at Minorca under general Murray, when that island was surrendered to the duke de Crillon. Spain has profited by the lesson. The present monarch has ordered the port of Cavite, at the bottom of which Manilla is situated, the capital of the island of Luconia, and the residence of the governor, to be fortified; and in the American war this important place was in a situation to brave the renewed attack of the same enemies.
